Abstract

AIM: To investigate the ability of Lactic acid bacteria (LAB) to modulate inflammatory reaction in human intestinal cell lines (Caco-2, HT-29 and HCT116). Different strains of LAB isolated from new born infants and fermented milk, together with the strains obtained from culture collections were tested.

METHODS: LABs were treated with human intestinal cell lines. ELISA was used to detect IL-8 and TGF-β protein secretion. Cytokines and Toll like receptors (TLRs) gene expression were assessed using RT-PCR. Conditional medium, sonicated bacteria and UV killed bacteria were used to find the effecter molecules on the bacteria. Carbohydrate oxidation and protein digestion were applied to figure out the molecules' residues. Adhesion assays were further carried out.

RESULTS: It was found that *Enterococcus faecalis* is the main immune modulator among the LABs by downregulation of IL-8 secretion and upregulation of TGF-β. Strikingly, the effect was only observed in four strains of *E. faecalis* out of the 27 isolated and tested. This implies strain dependent immunomodulation in the host. In addition, *E. faecalis* may regulate inflammatory responses through TLR3, TLR4, TLR9 and TRAF6. Carbohydrates on the bacterial cell surface are involved in both its adhesion to intestinal cells and regulation of inflammatory responses in the host.

CONCLUSION: These data provide a case for the modulation of intestinal mucosal immunity in which specific strains of *E. faecalis* have uniquely evolved to maintain colonic homeostasis and regulate inflammatory responses.

INTRODUCTION

The role of gastrointestinal microflora, such as several strains of lactic acid bacteria (LAB) in priming the immune system during ontogeny to limit allergy and chronic inflammatory responses has been brought to attention in recent years[1,2]. Clinical and experimental studies have put forward that gastrointestinal microflora is essential for maintenance of intestinal homeostasis, and their influence may extend beyond the gut, modifying systemic immunity. Studies using intestinal epithelial cell (IEC) lines have suggested that commensal bacteria may "program" IECs to prevent or down-modulate pro-inflammatory responses by interfering with Toll like receptors (TLRs) expression[3,4]. At least 13 TLRs have been identified in humans. Among all the 13 members of TLRs, TLR3, TLR5, TLR9 are mainly expressed by epithelial cells. They could be activated by pathogens leading to the initiation of inflammation by secreting pro-inflammatory cytokines such as Interleukin-8 (IL-8) and Tumor necrosis factor (TNF)-α[5].

The population of microbes harbored in the human intestine is dynamic and varies with age. It was reported that infants who developed allergy were often found to possess less enterococci in the intestines than healthy infants during the first month of life[6-8]. *Enterococcus faecalis* is a major commensal gastrointestinal flora in humans[9,10]. So far, it is not clear if the depletion of enterococci in allergic children is a cause or effect of allergy. Although there are some reports that *E. faecalis* caused infections in immune deficient mice[11], many studies also showed that *E. faecalis* could suppress the proliferation of intestinal pathogens and thus may prevent infection and the induction of inflammation[12-15]. Another study showed that *E. faecalis* lysate could relieve the clinical symptoms of Japanese cedar pollinosis[16]. However, the

role and effect of *E. faecalis* in inflammation reactions are not clear. It is the intention of this study to shed light on the role and mechanisms of anti-inflammatory effect of enterococci. This knowledge could provide a therapeutic window and development of treatments or prophylaxis of intestinal infectious, inflammatory and allergic reactions and perhaps carcinogenesis.

In the present study, the anti-inflammatory effect of human intestinal LABs isolated from infants and probiotic bacteria with alleged anti-allergic properties were investigated in human intestinal cell lines (Caco-2, HT-29 and HCT116). It is demonstrated that *E. faecalis* is the main immune modulator among the intestinal LABs. However, the effect is limited to only a few strains of *E. faecalis*. Carbohydrate components on bacterial cell walls were the regulators of the inflammatory responses in the host.

MATERIALS AND METHODS

Cell lines, media, and bacterial strains

Caco-2, HT-29 and HCT116 cells were obtained from American Type Culture Collection (Manassas, VA). Caco-2 and HT-29 are human colonic adenocarcinoma cells. Differentiated Caco-2 are enterocyte-like cells[17] whereas HCT116 are human colon carcinoma cells. All cells were cultured at 37℃ in a 5% CO_2 atmosphere. Caco-2 cells were cultured in MEM (GIBCO, Grand Island, NY) containing 20% fetal bovine serum (Bioclot, Germany) and 1% nonessential amino acids (GIBCO). HT-29 and HCT116 cells were cultured in DMEM (GIBCO) containing 10% fetal bovine serum (Bioclot, Germany). All culture media were supplemented with 100 U/mL penicillin and 100 μg/mL streptomycin (GIBCO).

The origin of the bacterial strains used in the experiment is indicated in Table 1. Lactobacilli were stored in De Man, ROGOSA and SHARPE (MRS) agar (Merck, Darmstadt, Germany) plus 25% glycerol, at -80℃ and grown in MRS broth overnight at 37℃ without shaking. Enterococci were stored in Tryptone Soy broth (TSB) (Oxoid, England) plus 25% glycerol at -80℃ and grown in TSB overnight at 37℃ without shaking. *Streptococcus thermophilus* NCIMB 10387 (10387) was grown on M17 medium (Oxoid, England). *Salmonella typhimurium* 14028 (Salm) was maintained on Luria-Bertani (LB) Agar (BBL, Cockeyville, MD, USA). The freshly cultured bacterial strains were further sub-cultured in a 250 mL conical flask with shaking at 120 r/min overnight. The bacteria were then pelleted by centrifugation, washed using serum-free medium three times and then resuspended in complete medium for use.

Infection of intestinal cells

To obtain a polarized monolayer of intestinal epithelial cells (IECs), 1×10^5 Caco-2 cells were grown in a sterile 24-well plate (Nalge Nunc International, USA) to confluence and then for 2 additional weeks to reach full differentiation and polarization. The culture medium was changed every two days. For HT-29 and HCT116 cell lines, 1×10^5 cells were cultured in sterile 24-well flat-bottom plates (Nalge Nunc International, USA) for 24 h before the infection. For the infection step, Caco-2, HT-29 and HCT116 cells were incubated in fresh medium with bacteria at a multiplicity of infection (MOI) of 100 or 1000 for 6 h. Biological triplicates were done.

RNA extraction and expression analysis by reverse transcription PCR (RT-PCR)

After the infection step, Caco-2, HT-29 and HCT116 cells were washed with cold PBS twice. RNAs were then extracted with a RNA extraction kit (Roche Applied Science, Germany) according to the manufacturer's instruction. Samples were stored at -80℃ before assay. The integrity and quality of RNA were determined by running formaldehyde gel. cDNA were synthesized from a template of 1 μg total RNA using the Superscript Ⅲ (Invitrogen Life Technologies, UK) according to the manufacturer's instruction.

PCR were performed using 2 μL of the cDNA as a template in a final volume of 50 μL. The standard program used was as follows: denaturation for 2 min at 94℃, 35 cycles of 30 s at 94℃, 1 min at 55℃ or 60℃, and 1 min at 72℃, followed by a final elongation for 7 min at 72℃. 0.2 unit of Taq (Invitrogen Life Technologies, UK) was used for one PCR. H_2O was used as a negative control and plasmids containing the specific genes were used as a positive control in the PCR step. After electrophoresis in a 1.2% agarose gel containing Ethidium Bromide, PCR products were quantified using the Gene Tool software (Syngene, UK). The primers used and annealing temperatures are described in Table 2.

In this study, the expression of TLR1, TLR2, TLR3, TLR4, TLR5, TLR9, Tumor necrosis factor (TNF) receptor associated factor 6 (TRAF6) and Toll inhibitory protein (Tollip) were measured using RT-PCR. Cytokine gene expression of IL-8, IL-4, IL-10, TGF-β and TNF-α were also detected using this method.

Determination of effecter molecules

For the tests in this part, we chose only four strains of LAB [*E. faecalis* (EC1, EC3, EC15, EC16)] to infect HCT116 cells with a MOI of 1000. The cells were co-cultured with bacteria at 37℃ with 5% CO_2 for 6 h. The supernatants were then harvested for cytokines assay. Unless indicated otherwise all enzymes and chemicals were from Sigma, USA.

Cell wall component and crude cell extract preparation: Before sonication, a protease inhibitior (2 mmol/L phenylmethylsulfonylfluoride (PMSF), 1 mmol/L dithiothreitol (DTT) and 1 mmol/L sodium metavanadate) was added to bacterial suspensions. The bacterial cells were then disrupted by sonication (MSE Soniprep 150, SANYO, Japan) on ice for 10 cycles with 30 s pulses and 1 min rest[18]. Cell debris was pelleted down by centrifugation at 15000 × *g* for 60 min at 0℃. The bacterial culture supernatant was aseptically kept on ice for use. The remaining pellet was resuspended in an appropriate volume of complete DMEM. One mL of each supernatant and 1 mL of each cell debris suspension were added to the cell culture. Biologically triplicates were done on this experiment.

Conditional medium and cell inserts treatment: In order to test for the location of the active components, the cell culture supernatants obtained from "infection of intestinal cells" were harvested sterilely and were then added to the cell culture prepared as in section "infection of intestinal cells". Supernatants were harvested for further cytokine assay testing. In addition, bacteria themselves were also cultured with the control supernatants obtained from the section "infection of intestinal cells". All the treated cells were then incubated at 37℃ with 5% CO_2 for 6 h. The supernatants were then harvested for cytokines assay.

For the cell insert test, HCT116 cells were plated

in wells of Transwell® (USA) multiple well plate and incubated at 37℃ with 5% CO_2 for 24 h. Accompanying inserts were added 1 h before co-culturing. 100 μL of bacterial suspensions with correct concentration were added to each insert.

Triplicates of each condition were done and supernatants were harvested for the cytokine assay test.

Carbohydrate oxidation and protein digestion of bacterial cell wall test: 4 mL of bacterial cells were pelleted by centrifugation at 15000 g at 0℃ for 10 min. The bacterial cells were washed once in PBS and then suspended in 1.5 mL of one of the following solutions: Solution 1 was 0.05 mol/L sodium m-periodate in buffer A (5 mol/L LiCl in water; 0.1 mol/L citrate-phosphate-0.1 mol/L NaCl) with a final pH 4.5. Solution 2 was 0.05 mol/L sodium iodate in buffer A (pH 4.5). Solution 3 was 5 mg/mL in buffer B (0.05 M Tris-HCl; 0.1 M NaCl) with a final pH 8.0. Solution 4 was 5 mg/mL chymotrypsin in buffer B (pH 8.0).

The bacterial cells were incubated with each of the four solutions (numbered from 1 to 4) for 1 h at 37℃. After that, the bacteria were centrifuged at 15000 g at 0℃ for 10 min, washed twice in 1 mL of PBS and resuspended in 4 mL of complete DMEM. 1 mL of each re-suspension was added to one well containing cell culture. Biological triplicates of each condition were done.

Blocking of specific carbohydrate ligands on cell wall: 3 mL of bacterial cells and broth culture supernatant were separated by centrifugation at 15000 g at 0℃ for 10 min. The bacterial cells were then washed once in PBS and then suspended in 3 mL of one of the following solutions: 15 μg/mL Concanavalin A (ConA) in PBS, 15 μg/mL succinyl Concanavalin A (succinyl-ConA) in PBS and 15 μg/mL *Tetragonolobus purpurea* in PBS. The cells were incubated for 30 min at 37℃, then centrifuged at 15000 *g* at 0℃ for 10 min, washed twice in 1.0 mL of PBS, and resuspended in 3.0 mL of complete DMEM. Treatments were done as described in the section "infection of intestinal cells".

UV killed bacteria: To kill the bacteria, 3 mL of bacterial suspensions were exposed to UV light for 5 min[19] to make sure at least 99% of the bacteria were killed. The killed bacteria were plated on their respective agar plates to ensure cell death. After killing the bacteria, treatments were performed as described in the section "infection of intestinal cells".

Adhesion assay

Monolayers of HCT116 were prepared by inoculating 2-chamber slides (Lab-Tek Chamber Slide, Nunc, Inc., USA) with 1.4×10^5 cells per chamber in 2 mL of complete DMEM 24 h before the adhesion assay. After 24 h, the monolayers were washed twice in 1 mL of sterile PBS. Bacterial strains were prepared and 2 mL of each resuspension was added to a chamber of the slide and incubated at 37℃ with 5% CO_2 for 1 h. After incubation, the monolayers were washed twice with sterile PBS then Gram stained and examined microscopically. The numbers of adherent bacteria per 100 HCT116 cells were counted in 10 random microscope areas.

Cytokine assay

Cytokines in cell culture supernatants were assayed by Enzyme Linked Immunosorbent Assays (ELISAs). After the infection (described in the sections "infection of intestinal cells" and "determination of effecter molecules"), supernatants were harvested and centrifuged for 10 min at 12000 *g* to remove the bacteria. IL-8, IL-4 and IL-10 measurements were performed as the instructions in the ELISAs kits (BD bioscience, San Diego, CA). Individual samples were tested in triplicate and the concentration of cytokines was determined using the standard provided by the manufacture.

For TGF-β assays, 100 μL supernatants were transiently acidified with 2 μL 1 M HCL for 1 h at 4℃, and then neutralized with 2 μL 1 mol/L NaOH. The supernatants were then applied to TGF-β ELISAs (BD bioscience, San Diego, CA) according to the manufacturer's instructions.

Statistical analysis

Data are expressed as means ± SD. Significance of differences was determined using the unpaired Student's *T*-test and analysis of variance. P values < 0.05 were considered to be statistically significant.

RESULTS

A total of 27 strains of LAB were isolated from feces of new born healthy infants aged from 3 d and 1 mo on MRS agar or Slanetz/Bartley media. 29 strains of other LAB were obtained from our collection for the comparison of their modulation of inflammation cytokine (Table 1).

Cytokine secretion in intestinal cell lines after exposure to LAB

To assess the effects of LAB on IL-8 secretion in intestinal cell lines, Caco-2, HT-29 and HCT116 cells were incubated with the respective LAB strains listed in Table 1. The experiments were performed 2-5 times in replicates (Figure 1).

In our study, Caco-2, HT-29 and HCT116 continuously expressed IL-8 at a detectable level. Most of the LAB tested (including strains of *E. faecalis*) showed no significant regulation of IL-8 secretion (data not shown) in these three IECs. *Bifidobacterium*, which was reported to down-regulate TNF-α and IL-8 productions and inhibit NF-κB activation in inflamed mucosa of active ulcerative colitis[20], showed no effect on IL-8 secretion in all the three IECs tested. However, *E. faecalis* (EC1, EC3, EC15, EC16), *L. delbrueckii bulgaricus* D1 (L.bul), *L. rhamnosus* GG (L.GG), *L. paracasei* LP33 (LP33), *L. brevis* T6 (T6) and *Streptococcus thermophilus* NCIMB10387 (10387) downregulated IL-8 secretion in Caco-2 cells (Figure 1). In HT-29 cells, only *E. faecalis* (EC1, EC3, EC15 and EC16) could downregulate IL-8 secretion. Whereas in HCT116, *E. faecalis* (EC1, EC3, EC15, EC16), T6 and LP33 suppressed IL-8 secretion. Strikingly, among the 56 LAB that we have tested, *E. faecalis* (EC1, EC3, EC15 and EC16), which were isolated from new born healthy infants, showed

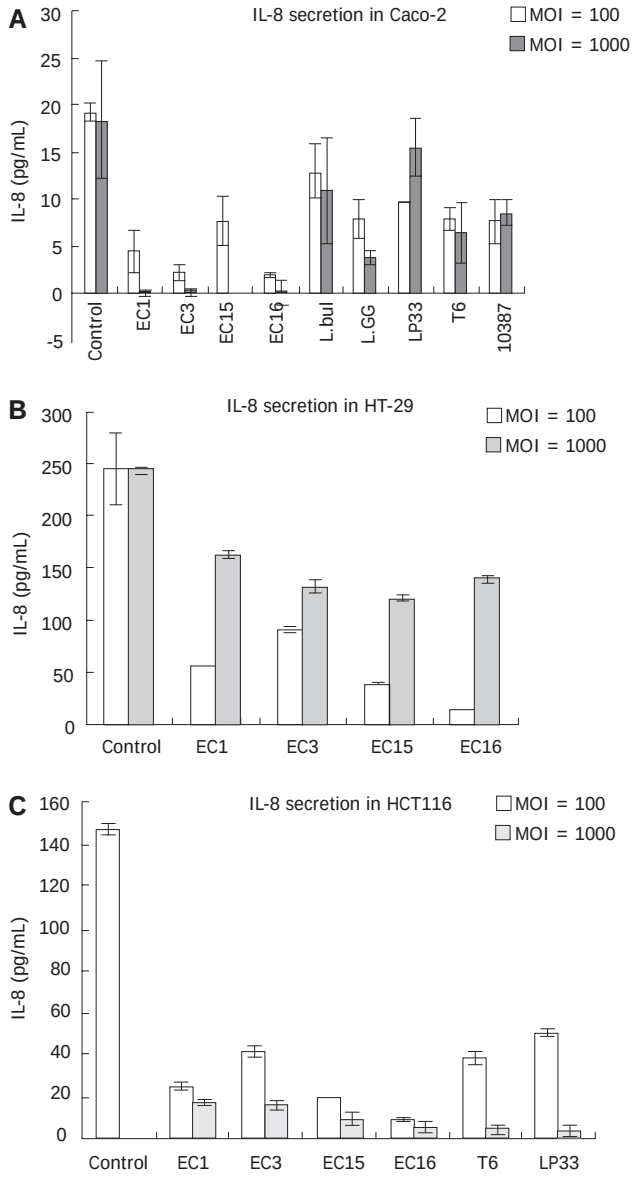

Figure 1 IL-8 production in Caco-2 (**A**), HT-29 (**B**) and HCT116 (**C**) cells treated with LAB for 6 h. Results are shown as mean ± SD of three independent experiments.

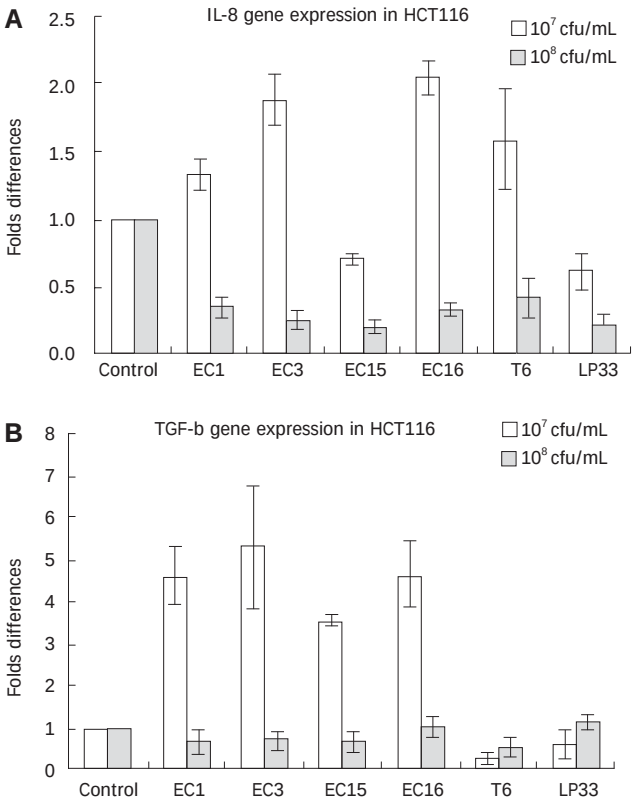

Figure 2 Different cytokines expression in HCT116 cells. RT-PCR analysis was used to determine IL-8 (**A**) and TGF-β (**B**) expression. 10^7 and 10^8 cfu/mL *E. faecalis* (EC1, EC3, EC15, EC16), LP33 and T6 were treated with HCT116, mRNA expression of the cytokines were analyzed as described in Materials and Methods. Quantitative densitometry was carried out on EtBr-stained gels and the results from three independent experiments were compiled to produce the data shown (mean ± SD). The gel densities were normalized against β-actin.

suppression of IL-8 secretion in all the three IECs.

The balance between inflammatory and regulatory cytokines is of crucial importance in the gut immune modulation. TGF-β is an important inflammation regulatory cytokine. In our study, TGF-β cytokine were greatly induced by *E. faecalis* (EC3, EC15) (10^7 cfu/mL) in Caco-2 cells (data not shown). Other LAB, however, could not induce TGF-β cytokine secretion above the detection level (above 62.5 pg/mL) in IECs. IL-4 and IL-10 secretion were not above the detection level in our study (Data not shown).

Immune gene modulation in IECs

Not consistent with IL-8 secretion, addition of *E. faecalis* (EC1, EC3, EC15, EC16) and LP33 (10^7 cfu/mL) to HCT116 cells enhanced IL-8 mRNA expression (Figure 2A). However, 10^8 cfu/mL *E. faecalis* (EC1, EC3, EC16), LP33 and T6 strongly suppressed IL-8 mRNA expression in HCT116 cells (Figure 2A). Interestingly, both concentrations of LAB suppressed IL-8 secretion in HCT116 cells (Figure 1C). Almost the same was observed in Caco-2 cells: IL-8 mRNA was upregulated by 10^7 cfu/mL *E. faecalis* (EC1, EC3, EC15, EC16), L.GG and L.bul. However, there was no significant change in IL-8 mRNA expression with 10^8 cfu/mL LAB stimulation (Data not shown). As shown in Figure 2B, TGF-β gene expression was greatly enhanced by 10^7 cfu/mL *E. faecalis* (EC1, EC3, EC15, EC16) and T6 in HCT116 cells, however, 10^8 cfu/mL of LAB showed no regulation of TGF-β gene expressions.

Activation of signal transduction pathway by TLRs led to the induction of inflammatory cytokine and chemokine genes that function in host defenses and tumor progression. The ability of the intestinal cell lines in response to *E. faecalis* and other LAB at the level of TLRs mRNA expression was therefore assessed using semi-quantitative RT-PCR. Gene encoding TLR1, TLR2, TLR3, TLR4, TLR5, TLR9, TRAF6 and Tollip were analyzed.

Examination of the TLR9 gene expression showed that TLR9 mRNA expression was greatly inhibited by 10^8 cfu/mL *E. faecalis* (EC1, EC3, EC15, EC16), T6 and LP33 treatment in HCT116 cells (Figure 3). As shown in Figure 3, TLR3 mRNA expression was also greatly inhibited by 10^8 cfu/mL *E. faecalis* (EC1, EC15, EC16), T6 and LP33 in HCT116 cells. Most interestingly, TRAF6 gene expression in HCT116 cells was totally inhibited

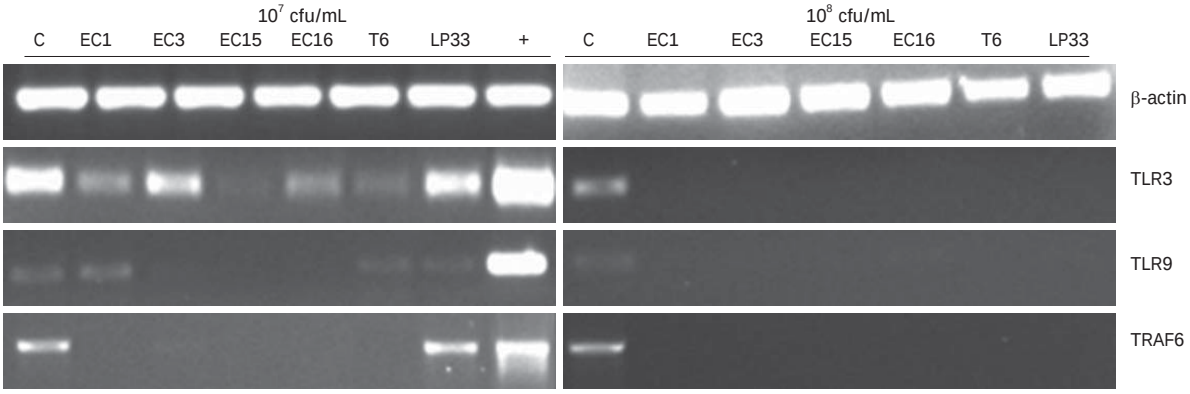

Figure 3 Induction of TLR3, TLR9 and TRAF6 mRNA expression in HCT116 cell line by *E. faecalis* (EC1, EC3, EC15, and EC16), T6, and LP33. The above LAB were added to HCT116 cells as described in Materials and Methods. RT-PCR analysis was used to determine their mRNA expression. "C" represents control using culture medium only. "+" is positive control in PCR reactions using specific plasmid.

Table 3 TLRs regulation in IECs upon the treatment of LAB

	TLR1	TLR3	TLR4	TLR5	TLR9	TRAF6	TOLLIP
HCT116	NE	S	NE	NE	S	S	NC
Caco-2	NE	NC	NC	NE	S	NC	NC
HT-29	NE	NC	S	NE	NC	S	NC

NE: No expression detected in the cells; NC: No significantly change upon the treatments; S: Gene was suppressed upon the treatments.

after treatment with 10^7 cfu/mL (except L.bul) and 10^8 cfu/mL LAB (Figure 3). In HT-29 cells, *E. faecalis* EC1, EC3 and EC15 but not EC16 suppressed TRAF6 mRNA expression (Data not shown). This observation parallels the TLR4 regulation in HT-29 cells. TLR4 is an essential receptor that transduces the signals of bacterial cell wall lipopolysaccharide (LPS). In the TLRs signaling pathways, TLR4 could activate numerous cytokine genes via TRAF6. TLR4 was not regulated significantly by LAB in Caco-2 cells. TLRs expression in these three cell lines were summarized in Table 3.

Possible effecter molecules that might be involved in the anti-inflammation study

Since some LAB tested, especially *E. faecalis*, inhibited IL-8 secretion in colon cancer cell lines, we further explored the possible effecter molecules that may play a role in the anti-inflammatory effects. For simplicity, we chose *E. faecalis* (EC1, EC3, EC15 and EC16), *L. rhamnosus* GG (L.GG) and *S. typhimurium* (Salm) for this study. The components from the bacteria were co-cultured with HCT116 cells. IL-8 level was measured using ELISA method.

First we tested the effects of sonicated bacteria and their cell wall components on IL-8 secretion. Cell wall components from all four *E. faecalis* strains demonstrated similar abilities as whole cells in reducing IL-8 levels (Data not shown). Cell debris of *S. typhimurium*, showed the expected ability in upregulating IL-8 levels. Co-culturing with *L. rhamnosus* GG cell debris caused no change in IL-8 concentration. To study whether attenuation of IL-8 level required bacterial cell contents, crude bacterial cell extract was co-cultured with HCT116 cells. In contrast to the results obtained using the cell debris, the crude cell extract of all four *E. faecalis* strains showed no ability in reducing IL-8 level (Data not shown).

Second, we tested the need for the four *E. faecalis* strains to be viable to attenuate IL-8 levels. The UV killed *E. faecalis* maintained its ability to suppress IL-8 levels (data not shown). The data implies that inhibition of IL-8 secretion from HCT116 cells does not need *E. faecalis* metabolites.

Third, to further confirm whether reduction in IL-8 levels required the direct contact between HCT116 cells and bacteria or could be mediated by a secreted product from either the bacteria or the intestinal epithelial cells, conditional media was made and added to HCT116 cells. In the first treatment (Section "Infection of intestinal cells"), supernatants of the controls containing IL-8 were harvested and used in the subsequent treatment as conditional media. It was shown that *E. faecalis* could not reduce the IL-8 level in the conditional media containing IL-8 (data not shown). Furthermore, intestinal epithelial cell cultures were incubated with bacteria housed in sterile plastic inserts, to ensure physical separation between the HCT116 cells and bacteria while allowing secreted bacterial products to reach the HCT116 cells. The results showed that all the bacterial strains could not suppress IL-8 levels as well (data not shown). Moreover, we investigated the possible ability of the four *E. faecalis* strains to stimulate a release of anti-inflammatory factors by HCT116 cells as described in the section "Conditional medium and cell inserts treatment", it was demonstrated that the supernatant harvested from co-culturing bacterial cells with HCT116 were incapable of reducing IL-8 levels in HCT116 cells.

Combining all the results, there is indication that the presence of bacterial cell wall components and attachment of bacteria to cells are essential in IL-8 attenuation.

To further figure out the possible molecules on the bacterial cell wall that played the key role in the attenuation of IL-8 secretion. The carbohydrates on bacterial cell walls were oxidized using m-periodate and iodate. Results of the four *E. faecalis* strains in buffer A showed an expected large decrease in IL-8 levels as seen in Figure 4A. Interestingly, the Na-iodate and Na-m-periodate treatments of them prevented an appreciable decrease in IL-8 levels (Figure 4A). Results from chymotrypsin and trypsin digested bacterial

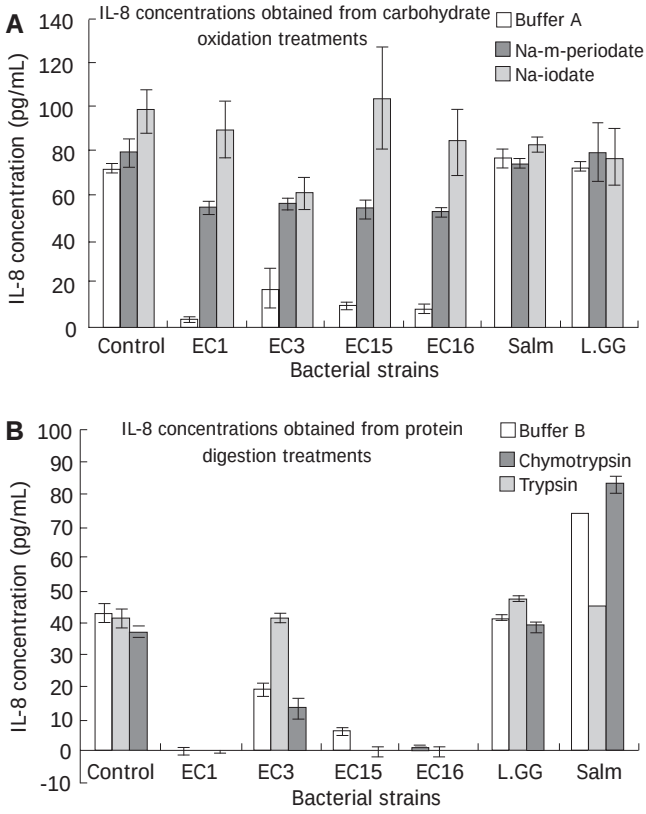

Figure 4 IL-8 secretion in HCT116 upon bacteria with carbohydrates oxidation and protein digestion. **A**: IL-8 concentrations obtained in HCT116 from treatments using bacteria with oxidized cell wall carbohydrates; **B**: IL-8 concentrations obtained in HCT116 from treatments using chymotrypsin- and trypsin-digested bacterial cell wall proteins in buffer B. Experiments were repeated three times independently. Standard deviations were indicated as error bars.

cell wall proteins in buffer B showing that buffer B, chymotrypsin and trypsin did not change the abilities of the *E. faecalis* strains in attenuating IL-8 level (Figure 4B). However, chymotrypsin treated *E. faecalis* EC3 seemed unable to significantly reduce IL-8 levels as seen in Figure 4B. *S. typhimurium* treated with buffer B and with chymotrypsin in buffer B showed no change in its capacity to increase IL-8 levels. Surprisingly, *S. typhimurium* treated with trypsin in buffer B showed a heightened ability in increasing IL-8 concentrations. These results suggest that carbohydrates on the bacterial cell wall are the major effecter molecules in the regulation of IL-8 secretion. However, proteins could also be involved.

In order to test which specific carbohydrates are important in reducing IL-8 levels, bacterial strains were treated with three different lectins. Succinyl-ConA and ConA have affinity for terminal α-D-glucosyl and α-D-mannosyl residues[21]. *Tetragonolobus purpureas* (TPA) on the other hand as an affinity for α-L-fucosyl residues and an especially high affinity for α-L-fucose residues on type Ⅱ chain blood group oligosaccharides[22]. These lectins would bind specifically to these residues and possibly change the overall carbohydrate structures, potentially affecting their role in attenuating IL-8 secretion. Figure 5 showed that the three lectins used also had no effect on depressing IL-8 secretion. Interestingly, with the employment of lectins, the ability to activate IL-8 by *S. typhimurium* was inhibited. This might imply that lectins may act on the carbohydrate in *S. typhimurium* to eliminate its stimulation on IL-8 secretion.

Adhesion assay

In order to study the importance of cell wall carbohydrates in adhering to HCT116 cells, carbohydrates on bacterial cell surfaces were oxidized using m-periodate. Figure 6 demonstrates that m-periodate treatment significantly reduced adhesion of all four *E. faecalis* strains to HCT116 cells (Table 4). Moreover, the secretion of IL-8 in HCT116 was greatly upregulated (Figure 4A). This study implies that carbohydrates on the bacterial cell wall helped bacteria to adhere to cells and the carbohydrate could act as ligands to activate signaling pathways to suppress IL-8 secretion from IECs. The carbohydrate could be structure component since sonicated and UV killed *E. faecalis* strains were able to suppress IL-8 secretion.

DISCUSSION

In the present study, we investigate the immune modulatory effects of infant intestinal *E. faecalis* compared with some other LABs on intestinal cells. Human intestinal cells (Caco-2, HT-29 and HCT116) have been shown to constitutively produce IL-8 in our study. IL-8, which is a potent neutrophil chemo-attractant and plays a key role in allergic inflammation, may be involved in the *E. faecalis* regulation of host immunology. The suppression of IL-8 secretion showed the reduction of inflammation reactions in animal and clinical trials[23]. In this study, most of the LABs tested, including most strains of *E. faecalis* (12 out of 16 strains isolated), did not show any effect on IL-8 production. However, IL-8 secretion was greatly downregulated after exposure to *E. faecalis* strains EC1, EC3, EC15, EC16 and some other LAB in IECs. This suggests that the immune reactions of an individual could be modulated by specific strains of a bacterial species, and his well being is determined by the specific strains of LAB which were established during early childhood. The inhibition of IL-8 protein secretion by *E. faecalis* could explain the increased incidence of allergy in infants deprived of *E. faecalis* in the intestine[6,8]. Although all 4 strains of *E. faecalis* and other LABs could inhibit the secretion of IL-8 (Figure 1), it is interesting to note that the different bacteria were reduced to a different level of IL-8 secretion after their exposure. *E. faecalis* in general suppressed IL-8 production to a higher degree than the other LABs. The downregulation of IL-8 secretion is dose dependent in Caco-2 and HCT116 cells. The higher the concentration of LAB, the less secretion of IL-8. Paradoxically, some of the IL-8 secretion was not parallel with its mRNA expression in the intestinal cell lines in response to the LAB. IL-8 mRNA was enhanced; however, its protein secretion was inhibited in IECs when they were exposed to *E. faecalis* at a concentration of 10^7 cfu/mL. More interestingly, IL-8 protein secretion was enhanced however its mRNA expression remained unchanged after the challenge of *S. typhimurium* at a concentration of 10^7 cfu/mL (data not shown). This implies that *E. faecalis* could boost the immune system to be ready for the challenge of pathogen at a physiological concentration

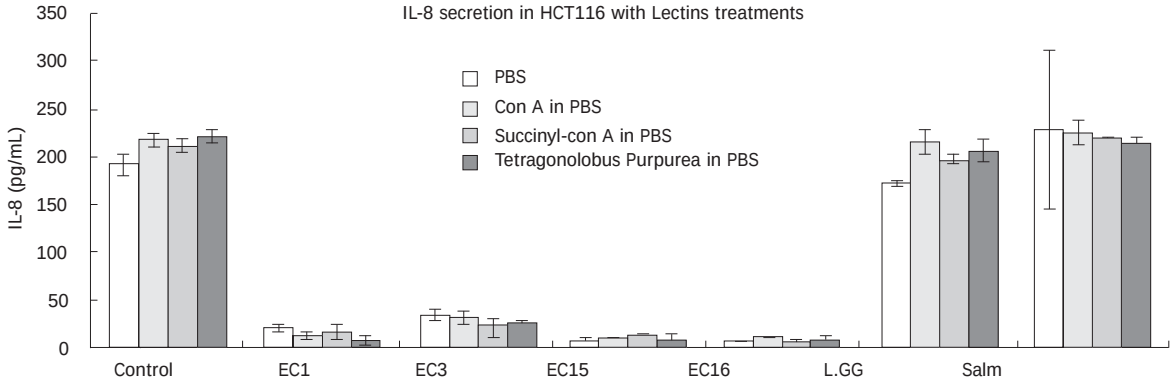

Figure 5 IL-8 secretion in HCT116 cells treated with three Lectins. Three lectins were added to HCT116 cells as described in Material and Methods. Experiments were repeated three times independently. Standard deviations were indicated as error bars.

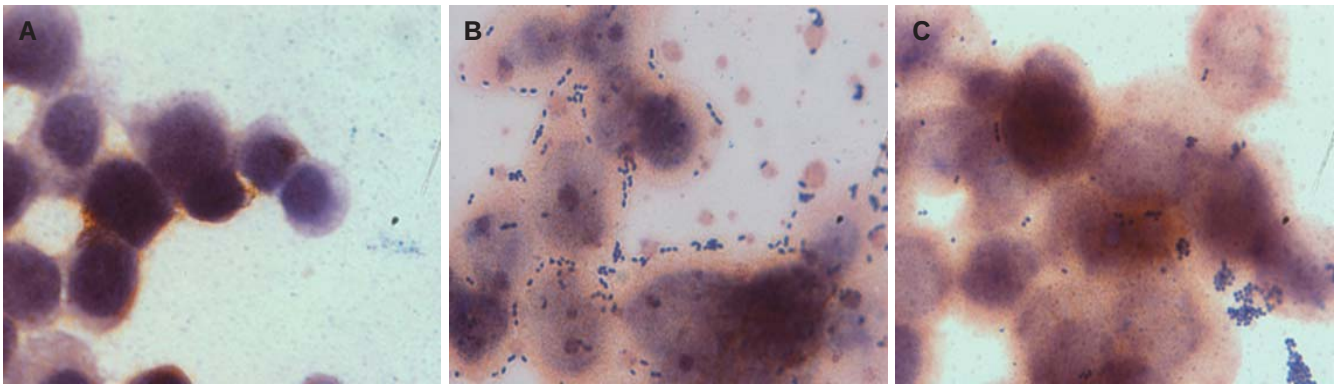

Figure 6 Monolayer of HCT116 cells with or without attached bacteria observed using light microscopy at 1000 ×. EC15 was used as a representation. **A**: Monolayer of HCT116 cells without bacteria treatment observed using light microscopy at 1000 ×; **B**: Monolayer of HCT116 cells with attached *E. faecalis* EC15 observed using light microscopy at 1000 ×; **C**: Monolayer of HCT116 cells with m-periodate treated *E. faecalis* EC15 observed using light microscopy at 1000 ×.

Table 4 Adhesion scores of *E. faecalis* after carbohydrate oxidation

Bacterial Strains	Adhesion score[1]		% change
	Whole cell bacteria	m-periodate treated bacteria	
E. faecalis EC1	1118.1	286	-74.42
E. faecalis EC3	1608	328	-79.6
E. faecalis EC15	1794	442.2	-75.35
E. faecalis EC16	693	282	-59.31
S. typhimurium[2]	49	40	-18.37
L. rhamnosus GG	605	850	40.5

[1]Adhesion is expressed as the number of attached bacteria/100 HCT116 cells, determined in 10 randomized microscope fields in three independent experiments. [2]Differences are not significant due to the small number of observed adherent bacteria.

(10^7 cfu/mL). However, the inflammatory responses were suppressed in the absence of pathogen and the presence of *E. faecalis*. On the contrary, *S. typhimurium* activated inflammatory responses without upregulating the immune gene expression. Thus, the regulation of IL-8 is important in the immune homeostasis. Its modulation by *E. faecalis* could involve post-transcriptional processes in protein synthesis and secretion[24]. The suppression of IL-8 at colon cancer cell lines' basal level could inhibit its inflammatory responses. Furthermore, these data suggests that IECs could differentiate commensal bacteria from pathogenic bacteria and thus lead to different immune responses.

Interestingly, TGF-β, which is important in inflammatory disease recovery, was upregulated significantly by *E. faecalis* EC3 and EC15 in Caco-2 cells at protein level and in HCT116 at the gene level. TGF-β is also a key factor implicated in the regulation of intestinal barrier function and is thought to mediate tolerance to the indigenous microflora. Compared with *Lactobacillus* and *Bifidobacterium*, *E. faecalis* demonstrated stronger effects on TGF-β production. The suppression of IL-8 secretion and activation of TGF-β production in the presence of *E. faecalis* suggested that *E. faecalis* could alter the balance among Th1 and Th2 immunities and leading to prevention of inflammation in intestinal cells.

Toll like receptors (TLRs) are also important in regulating inflammatory responses and Th1/Th2 immunities in the host. In our study, TLR3, TLR4, TLR9 were found to express in some of the colon cancer cell lines and their expression was suppressed by *E. faecalis*. Moreover, we found that TRAF6 mRNA was also suppressed by *E. faecalis* and some of the LABs in IECs. TRAF6 is an adaptor in TLRs signaling pathway. It could bind TAB1, TAK1 and TAB2 to form a complex leading to the activation of NF-κB and MAP kinases[25]. Thus, the suppression of TRAF6 could inhibit the activation of the NF-κB and the

MAPKs families and further the inflammatory responses. The inhibition of TLR3 and TLR9 signaling by LAB may explain the suppression of pro-inflammatory cytokines secretion in the colon cell lines. Hence, the suppression of TLR3 and TLR9 signaling could be used for therapeutic treatment of inflammatory diseases including cancer, asthma and allergy[26,27]. In addition, the low expression of TLR4 in IECs may explain the tolerance of the large quantities of luminal LPS in the intestine[28]. Furthermore, recent studies showed that bacteria-induced experimental colitis involves the activation of TLR[29]. The blocking of TLRs by *E. faecalis* may represent an attractive strategy to treat intestinal inflammation.

Overall, the modulation of intestinal immunity by *E. faecalis* may involve TRAF6, a number of TLRs (TLR3, TLR4, and TLR9) and cytokines (IL-8, TGF-β).

In order to characterize the effecter molecules that modulate inflammatory responses in IECs, studies were further carried out using conditional medium. The use of conditional medium showed that the molecules were not secreted by cells or bacteria or molecules activated after co-culturing the cells and bacteria. This finding was further confirmed using cell inserts. No IL-8 downregulation was observed when the cells and bacteria were separated by cell inserts. However, when bacterial cell wall fragments were applied to the intestinal cells after sonication, there was a dramatic suppression of IL-8 secretion in HCT116. In addition, the remaining supernatant, the crude cell extract containing bacterial cytoplasm, ribosomes, small membrane vesicles, and large membrane structures could not suppress IL-8 secretion. Therefore, the molecules are not inside the bacteria but on the surface of bacterial cell walls. Since only bacterial cell walls could inhibit IL-8 secretion, it implies that the inhibition does not involve bacterial metabolites. Another study using UV killed bacteria confirmed that those killed bacteria retained the ability to suppress IL-8 secretion in HCT116.

Results from oxidation of carbohydrate moieties on the whole cell surfaces of *E. faecalis* showed that the four *E. faecalis* lost their ability to depress IL-8 secretion. Thus, carbohydrates are the main effecter molecules on *E. faecalis*. This mild periodate oxidation at acid pH cleaves carbohydrate vicinal hydroxyl groups without changing polypeptide chain structures[30]. Periodate consumption and iodate formation, give insight to the number of vicinal dihydroxyl groups which possibly play the roles in suppression of inflammation[31]. Chymotrypsin-mediated protein digestion of the effecter molecules, on *E. faecalis* EC3's cell surface, stripped it of its ability to attenuate IL-8 levels. Thus *E. faecalis* EC3's effecter molecule probably has protein structure(s) necessary for depressing IL-8 secretion. Similar chymotrypsin-mediated protein digestion of the three other *E. faecalis* strains and trypsin-mediated protein digestion on all four *E. faecalis* strains failed to alter their ability in reducing IL-8 levels, suggesting that protein might not be the major components from the bacterial cell wall in suppressing IL-8 secretion.

The specific carbohydrate monosaccharides involved in IL-8 level attenuation could not be determined from the lectin study in our experiments. This study suggests that certain monosaccharides that are not part of the inflammation suppressing effecter molecule. α-L-fucosyl, α-L-fucose, D-mannosyl and D-glucosyl residues are probably not vital or possibly absent from the effecter molecule. However they might be important in upregulating IL-8 secretion in *S. typhimurium*.

The adhesion study of *E. faecalis* strains demonstrated that they adhered well to the mucosal layer of epithelial cells. Oxidation of the carbohydrate moieties on the bacterial cell surface caused a decrease in their adhesive abilities as well as a drop in the ability to suppress IL-8 secretion. This suggests that the cell surface carbohydrates are necessary for the adhesion of four *E. faecalis* strains to IECs. This is in congruence with Guzmàn *et al* who previously observed that enterococcal surface carbohydrate adhesins were necessary for binding of *E. faecalis* to Girardi heart human cells and urinary tract epithelial cells[32]. Other studies by Shorrock and Lambert also demonstrated that carbohydrate oxidation reduced the binding abilities of *E. faecalis*, suggesting that surface adhesin with the carbohydrate component is necessary for adhesion[33]. Since the same oxidation of carbohydrate moieties also stripped these enterococci of their IL-8 secretion suppressing abilities, adhesion of these bacteria *via* carbohydrate moieties plays a vital role in suppressing inflammation.

In conclusion, the study has demonstrated that *E. faecalis* is the major human intestinal LAB in modulating expression of host immune genes that participate in inflammation. Moreover, the immune regulatory mechanism may involve the adhesion of *E. faecalis* on intestinal cells and suppression of specific TLRs signaling pathways *via* carbohydrate mediated adhesion-receptor interaction.

ACKNOWLEDGMENTS

The authors gratefully acknowledge the assistance of Mah Ka Weng on isolation of some of the bacteria.

COMMENTS

Background

It has long been assumed that indigenous intestinal microbiotas are involved in the immunomodulation of the host and the effects are strain dependent. However, there are few direct evidences in support of the assumption. In addition, the underlying molecular and cellular mechanisms are unclear.

Research frontiers

Recent studies showed that *Enterococcus faecalis* could suppress the proliferation of intestinal pathogens and thus may prevent infection and induction of inflammation. Studies on *Bacteroides thetaiotaomicron*, a prevalent commensal bacterium of the human intestine showed that it might attenuate inflammation by regulating nuclear-cytoplasmic shuttling of PPAR-γ and Rel A. Toll like receptors (TLRs) and cytokines are involved in the anti-inflammation process.

Innovations and breakthroughs

In our knowledge, this is the first time *E.faecalis* is demonstrated as the main immune modulator in the intestinal Lactic acid bacteria (LAB) of infants, and cell wall carbohydrate is involved in the regulatory effects.

Applications

This finding highlights possible new approaches for therapeutic treatment of inflammatory disease in humans. The study suggests that the immunological status in the gastrointestinal tract of infants may be determined by the presence of specific strains of *E. faecalis*.

Terminology

Probiotics: Live microorganisms which can when administered in adequate amounts confer a health benefit on the host; LAB: Lactic acid bacteria comprise a clade of Gram positive, low-GC, acid tolerant, non-sporulating, non-respiring rod or cocci that are associated by their common metabolic and physiological characteristics. LAB is the most common type of microbe used as a probiotic.

Peer review

Wang *et al* showed that some Enterococcus strains reduced IL-8 secretion from intestinal epithelial cells. Focus of this manuscript is interesting.

Abstract

AIM: To study the origin of calcium necessary for agonist-induced contraction of the distal colon in rats.

METHODS: The change in intracellular calcium concentration ($[Ca^{2+}]_i$) evoked by elevating external Ca^{2+} was detected by fura 2/AM fluorescence. Contractile activity was measured with a force displacement transducer. Tension was continuously monitored and recorded using a Powerlab 4/25T data acquisition system with an ML110 bridge bioelectric physiographic amplifier.

RESULTS: Store depletion induced Ca^{2+} influx had an effect on $[Ca^{2+}]_i$. In nominally Ca^{2+}-free medium, the sarco-endoplasmic reticulum Ca^{2+}-ATPase inhibitor thapsigargin (1 μmol/L) increased $[Ca^{2+}]_i$ from 68 to 241 nmol/L, and to 458 ($P < 0.01$) and 1006 nmol/L ($P < 0.01$), respectively, when 1.5 mmol/L and 3.0 mmol/L extracellular Ca^{2+} was reintroduced. Furthermore, the change in $[Ca^{2+}]_i$ was observed with verapamil (5 μmol/L), La^{3+} (1 mmol/L) or KCl (40 mmol/L) in the bathing solution. These channels were sensitive to La^{3+} ($P < 0.01$), insensitive to verapamil, and voltage independent. In isolated distal colons we found that in normal Krebs solution, contraction induced by acetylcholine (ACh) was partially inhibited by verapamil, and the inhibitory rate was 41% ($P < 0.05$). On the other hand, in Ca^{2+}-free Krebs solution, ACh induced transient contraction due to Ca^{2+} release from the intracellular stores. The transient contraction lasted until the Ca^{2+} store was depleted. Restoration of extracellular Ca^{2+} in the presence of atropine produced contraction, mainly due to Ca^{2+} influx. Such contraction was not inhibited by verapamil, but was decreased by La^{3+} (50 μmol/L) from 0.96 to 0.72 g ($P < 0.01$).

CONCLUSION: The predominant source of activator Ca^{2+} for the contractile response to agonist is extracellular Ca^{2+}, and intracellular Ca^{2+} has little role to play in mediating excitation-contraction coupling by agonists in rat distal colon smooth muscle *in vitro*. The influx of extracellular Ca^{2+} is mainly mediated through voltage-, receptor- and store-operated Ca^{2+} channels, which can be used as an alternative to develop new drugs targeted on the dysfunction of digestive tract motility.

INTRODUCTION

Ca^{2+} is involved in many cellular transduction pathways, and regulation of different cellular phenotypes by $[Ca^{2+}]_i$ has been observed in many cell systems, including smooth muscle cells (SMC). Various agonists induce contraction in a variety of smooth muscle preparations, with a concomitant increase in intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$)[1,2]. The source for this ion is extracellular Ca^{2+} influx and Ca^{2+} release from intracellular stores. The relative contribution of intracellular and extracellular sources of Ca^{2+} depends on the tissue and mode of stimulation[3]. Moreover, agonist-induced increases in the cytosolic Ca^{2+} concentration produce smooth muscle contraction, characterized by a fast initial peak, the phasic component, followed by a decline to a lower maintained tension level, the tonic component[4,5].

In the former, we think two different Ca^{2+} channels participate in extracellular Ca^{2+} influx: voltage-operated Ca^{2+} channels (VOCCs) and receptor-operated Ca^{2+} channels (ROCCs)[6,7]. Participation of these channels in contraction varies among the types of smooth muscle present, the

agonists used, and the experimental conditions planned.

In addition to these influx pathways, there is now significant data from different cell types that demonstrate controlled Ca^{2+} influx also occurs in response to depletion of intracellular Ca^{2+} stores. We call these store-operated Ca^{2+} channels (SOCCs) or capacitative Ca^{2+} entry (CCE) channels. Previous studies have suggested SOCCs are restricted in non-excitable cells[8,9], but they have only recently been investigated in excitable cells , such as smooth muscle cells and neurons, which are involved in smooth muscle tone and regulation of synaptic plasticity. It has been reported there is a relationship between CCE and the regulation of smooth muscle tone with respect to their involvement in pulmonary, stomach, bronchial, vascular, gallbladder, and basilar artery tissue[10-15]. There is thus far no data to show that CCE are necessary as a source of Ca^{2+} in the smooth muscle of the rat distal colon.

The neurotransmitter acetylcholine (ACh) induces smooth muscle contraction *via* activating muscarinic receptors. ACh has been shown to elicit contraction that consists of a rapid phasic phase, followed by a tonic phase, by activation of M_3 muscarinic receptors in the rat and guinea pig gastric fundus and ileum, and the human ileum[16-19]. However, there have been some different results concerning the source of Ca^{2+} for muscarinic receptor-mediated contraction. It has been postulated that the sources of Ca^{2+} for phasic and tonic contraction induced by activation of muscarinic receptors differ among regions of the digestive tract and species of animals used.

It has been suggested that pharmacological manipulation of Ca^{2+} channels may be therapeutically useful in treating colonic motility disorders. Therefore, we tried to clarify the source of Ca^{2+} in the contraction induced by ACh. Sources of activator Ca^{2+} for muscarinic-mediated contraction of proximal colonic smooth muscle in rats have been well documented. With respect to the rat distal colon, the relative importance of the contribution of the different Ca^{2+} influx mechanisms, and the release of Ca^{2+} from the sarcoplasmic reticulum (SR), has not been assessed. The aim of this study was to evaluate the contribution of VOCCs, non-VOCCs and intracellular Ca^{2+} release to ACh-induced contraction in the smooth muscle of rat distal colon *in vitro*.

MATERIALS AND METHODS

Tissue preparation

A segment of distal colon (about 2 cm) was removed from Sprague-Dawley rats (150-250 g, supplied by the animal center of Anhui Medical University, China) killed by cervical dislocation. Pieces of colon were cleaned in a Petri dish, by perfusing with Krebs solution (114.0 mmol/L NaCl, 4.7 mmol/L KCl, 1.2 mmol/L $MgCl_2$, 2.5 mmol/L $CaCl_2$, 1.8 mmol/L NaH_2PO_4, 11.5 mmol/L glucose, 18.0 mmol/L $NaHCO_3$, pH 7.4). The adipose and connective tissues were carefully stripped off with fine forceps. The endothelium of the colon was removed by gently rubbing the inner lumen of the vessels with a rough wooden stick.

Tension measurement

Pieces of distal colon were mounted in 40-mL organ baths containing Krebs solution, maintained at 37℃ and gassed with 95% O_2 and 50% CO_2, pH 7.4. One end of each piece was fixed to a hook on the bottom of the bath and the other attached to a force displacement transducer (Xinhang, Beijing, China). A resting preload of 1 g was applied to each colon, which was then allowed to equilibrate for 1 h. During this time, the Krebs solution was changed every 20 min. Tension was continuously monitored and recorded using a Powerlab 4/25T data acquisition system (Australia AD Instruments) with an ML110 bridge bioelectric physiographic amplifier (Australia AD Instruments). ACh and atropine were dissolved in the perfusate on the day of use.

Cell preparation

A segment of the distal colon was removed and placed in oxygenated HEPES/Ringer buffer solution (126 mmol/L NaCl, 6 mmol/L KCl, 6 mmol/L HEPES, 11 mmol/L $MgCl_2$, 1.5 mmol/L $CaCl_2$), pH 7.4 with 5 mol/L NaOH. The fecal contents were removed by repeated rinsing with HEPES/Ringer solution. After the segment was cut open longitudinally and pinned out in a dissection dish. Under a microscope, longitudinal and circular muscle layers were freed of the mesentery, serosa and mucosa, and cut into small pieces (2 mm^2) and rinsed in HEPES/Ringer solution for 20 min (at 37℃). Dispersion of smooth muscle cells was accomplished by three incubations at 31℃ with agitation in low-Ca^{2+} HEPES/Ringer solution containing collagenase type I (0.6 mg/mL), bovine serum albumin (2 mg/mL) and soybean trypsin inhibitor (0.6 mg/mL). They were then suspended in enzyme-free low-Ca^{2+} HEPES/Ringer solution and gently agitated through the tip of a wide-bore glass pipette to liberate single smooth muscle cells. Isolated cells were collected by low-speed centrifugation and resuspended in HEPES/Ringer solution. Trypan blue exclusion was used to verify cell viability (> 90% of all cells).

Measurement of $[Ca^{2+}]_i$ in distal colon smooth muscle cells

Measurement of $[Ca^{2+}]_i$ in colonic smooth muscle cells using fura-2 was performed using dual excitation wavelength fluorescence microscopy. Aliquots of cell suspension in HEPES/Ringer solution (10^6 cells/mL) were placed in Quartz cuvettes and incubated with 5 μmol/L fura-2/AM at 37℃ for 45 min. After being loaded with fura-2/AM, the cells were rinsed with Ca^{2+}-free solution, centrifuged (1500 r/min) and suspended in Ca^{2+}-free solution for the experiments that were carried out in a 960 MC spectrofluorophotometer (Shanghai Precision & Scientific Instruments, Shanghai, China). Cells were alternately illuminated at 340 and 380 nm and the intensity of fluorescence emission was measured at 500 nm. The $[Ca^{2+}]_i$ was calculated according to Grynkiewicz's equation: $[Ca^{2+}]_i = Kd\ [(F - F_{min})/(F_{max} - F)]$: where the dissociation constant Kd was 224 nmol/L at 37℃; F was fluorescence intensity under different experiment conditions; F_{max} was the maximum fluorescence intensity obtained in the presence of 0.1% Triton ×-100; and the minimum value (F_{min}) was obtained by using 5 mmol/L EGTA in the external medium. Before calculation, the autofluorescence measured from cells that unloaded

Table 1 Measurement of $[Ca^{2+}]_i$ in freshly dispersed suspension of smooth muscle cells from rat distal colon

Group	$[Ca^{2+}]_i$ (nmol/L)		
	Ca^{2+}-free medium	1.5 mmol/L $CaCl_2$ medium	3.0 mmol/L $CaCl_2$ medium
Control	68.32 ± 3.43	104.81 ± 6.37	194.44 ± 3.91
Thapsigargin	240.85 ± 12.65	457.55 ± 19.80[b]	1005.93 ± 54.62[b]

[b]$P < 0.01$ *vs* control.

fura-2/AM should be subtracted. All the measurements were finished in 40 min.

Drugs and solutions

Reagents were procured from the following vendors: thapsigargin, DMSO, ACh, atropine, lanthanum, fura-2/AM, Triton ×-100, EGTA, collagenase type I , bovine serum albumin (BSA) and verapamil were from Sigma (USA), and soybean trypsin inhibitor was from GIBCO (USA). The solutions of thapsigargin and fura-2/AM were prepared by dilution with DMSO. The concentration of DMSO in the final solution was < 0.1% and did not affect $[Ca^{2+}]_i$. In cell experiments, the Ca^{2+}-free HEPES/Ringer solution was prepared without $CaCl_2$ and with addition of EGTA (0.2 mmol/L). The low-Ca^{2+} solution had the same composition, except $CaCl_2$ was 0.03 mmol/L.

Statistical analysis

Biostatistical analysis was performed using the SPSS 11.0 software package. All experiments were repeated at least three times. Results of multiple experiments are given as the mean ± SE. Unpaired Student's *t* test was used for statistical evaluation in two-group comparisons. $P < 0.05$ was accepted as statistically significant.

RESULTS

Establishment of SOCCs

We first established whether SOCCs were present in rat distal colon smooth muscle cells. As shown in Table 1, for the fura-2/AM loaded cells, the incubation in Ca^{2+} free solution lasted 3 min, followed by the addition of two concentrations of Ca^{2+} (1.5, 3.0 mmol/L). It can be seen that cytosolic calcium rose from 68.32 in Ca^{2+}-free solution to 104.81 and 194.44 nmol/L for the two concentrations of 1.5 mmol/L and 3.0 mmol/L, respectively. The incubation of cells in Ca^{2+}-free solution in the presence of thapsigargin (1 μmol/L), followed by the addition of Ca^{2+}, 1.5 and 3.0 mmol/L, increased $[Ca^{2+}]_i$ that was significantly greater (455.77 and 1005.9 nmol/L) than that in the absence of thapsigargin.

Sensitivity to verapamil

To distinguish SOCC-mediated Ca^{2+} influx from that *via* L-type Ca^{2+} channels, we conducted experiments in a separate set of cells using 5 μmol/L verapamil. In these cells pretreated with verapamil, the $[Ca^{2+}]_i$ response to rapid reintroduction of $[Ca^{2+}]_o$ in the presence of thapsigargin ($n = 7$) was determined as above. We found the presence of verapamil during rapid reintroduction of

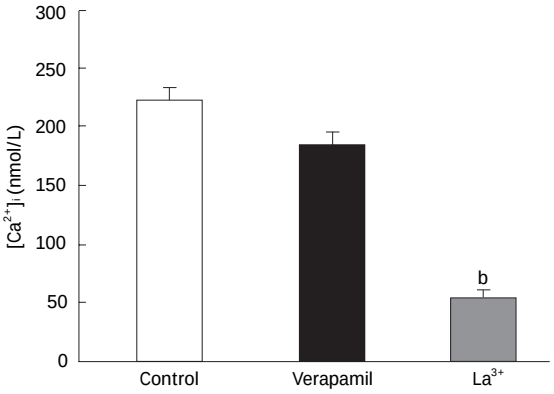

Figure 1 Ca^{2+} influx through SOCCs in enyzmatically dissociated smooth muscle cells of rats distal colon. After depletion of the SR by thapsigargin in the absence of extracellular Ca^{2+}, subsequent rapid reintroduction of extracellular Ca^{2+} resulted in activation of CCE *via* SOCCs. CCE were insensitive to verapamil, but blocked by La^{3+}. [b]$P < 0.01$ *vs* control.

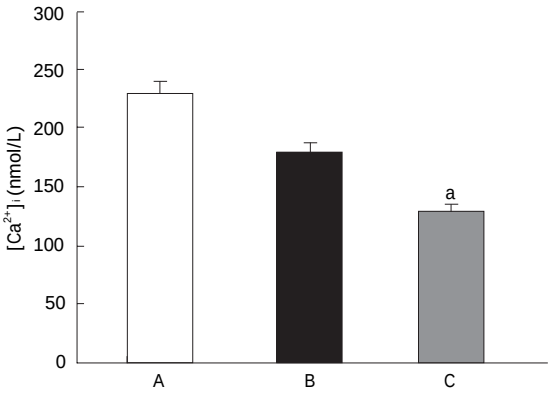

Figure 2 CCE are not mediated *via* L-type Ca^{2+} channels. (A) Controls; (B) 40 mmol/L K^+; (C) 60 mmol/L K^+. Only 60 mmol/L K^+ significantly decreased the Ca^{2+} influx mediated by CCE. [a]$P < 0.05$ *vs* control.

$[Ca^{2+}]_o$ (1.5 mmol/L) did not significantly influence Ca^{2+} influx induced by thapsigargin. Previous studies in other tissues have found that SOCC-mediated Ca^{2+} influx is inhibited by La^{3+}[20,21]. We investigated the sensitivity of multivalent cations to such Ca^{2+} influx. In a separate group of cells, pretreatment with La^{3+} and Ca^{2+} influx to rapid reintroduction in the presence of thapsigargin was greatly changed (Figure 1). Taken together, these results suggest the observed influx of extracellular Ca^{2+} in both instances was not mediated *via* L-type Ca^{2+} channels, but capacitative Ca^{2+} entry through SOCCs.

Role of membrane potential

A potential confounding factor in SOCC-mediated Ca^{2+} influx is the membrane potential, which alters the driving forces for Ca^{2+} entry. Accordingly, separate experiments were performed to determine the role of membrane potential. In the presence of verapamil (5 μmol/L), and pretreatment with high KCl solution (final concentrations of 40, 60 mmol/L), cells were re-exposed to thapsigargin, and $[Ca^{2+}]_o$ was then rapidly reintroduced (final concentration, 1.5 mmol/L). Figure 2 shows the presence of 40 mmol/L KCl did not significantly influence Ca^{2+} influx induced by

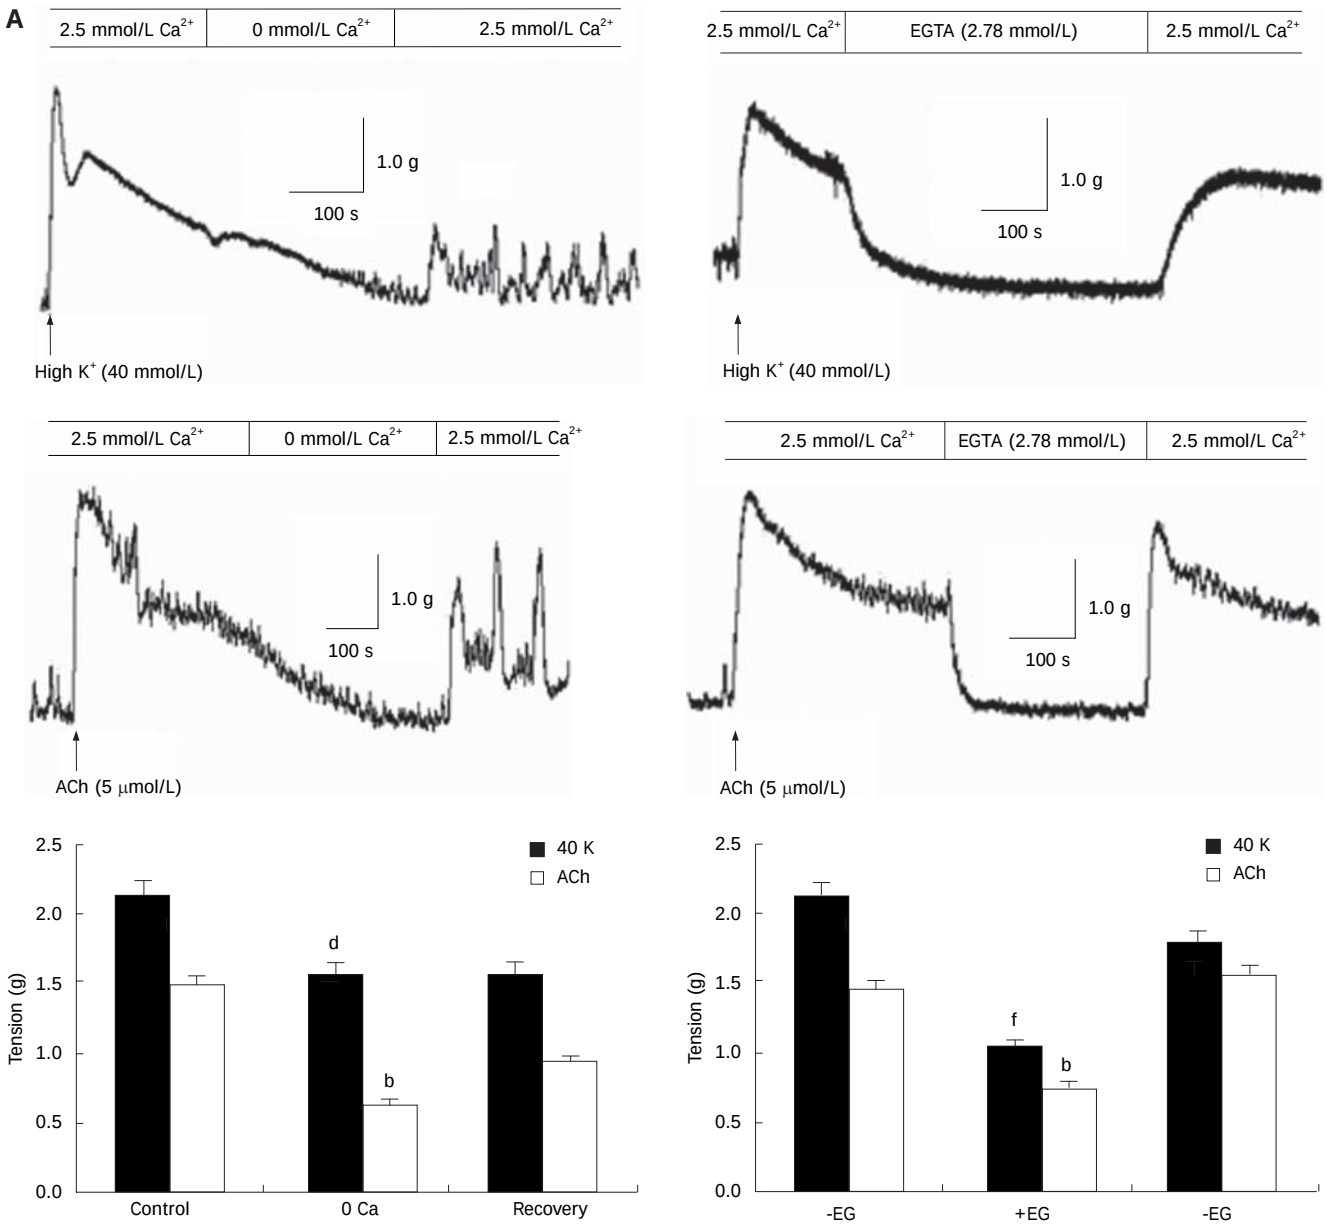

Figure 3 Role of Ca^{2+} in rat distal colon contraction. **A**: Representative results showing that removal of extracellular Ca^{2+} abolished contraction induced by high K^+ and 5 μmol/L ACh. Summarized data showing that tension induced by high K^+ and 5 μmol/L ACh before, during and after application of Ca^{2+}-free Krebs solution. $^bP < 0.01$, $^dP < 0.001$ *vs* Control; **B**: Representative results showing that chelation of extracellular Ca^{2+} with 2.78 mmol/L EGTA abolished contraction induced by high K^+ and 5 μmol/L ACh. Summarized data showing that tension induced by high K^+ and 5 μmol/L ACh in the presence of EGTA $^bP < 0.01$, $^fP < 0.001$ *vs*-EG (before).

thapsigargin. However, in the presence of 60 mmol/L KCl, Ca^{2+} influx was decreased ($P < 0.05$).

Requirement of extracellular Ca^{2+} for distal colon contraction

In isolated rat distal colon, removal of extracellular Ca^{2+} almost abolished the contraction induced by 40 mmol/L KCl or 5 μmol/L ACh, a muscarinic receptor agonist ($n = 11$, Figure 3A). Chelation of extracellular Ca^{2+} with 2.78 mmol/L EGTA, which decreases free Ca^{2+} concentration to 0.5 μmol/L in Krebs solution containing 2.5 mmol/L $CaCl_2$, had the same inhibitory effect on contraction induced by 40 mmol/L K^+ or 5 μmol/L ACh ($n = 7$, Figure 3B). Furthermore, extracellular application of the L-type VOCC blocker verapamil (5 μmol/L) almost abolished the 40 mmol/L K^+-induced tension. The tension decreased from 2.1 to 0.52 g and the inhibitory rate was 74% ($n = 7$, $P < 0.001$). The tension induced by 5 μmol/L ACh was also inhibited, but the inhibitory rate was only 41%. The tension decreased from 1.44 to 0.85 *g* ($n = 7$, $P < 0.05$) (Figure 4). These observations indicated ACh induced rat distal colon contraction by activating multiple Ca^{2+} entry pathways, whereas 40 mmol/L K^+-induced rat distal colon contraction was solely dependent on the membrane-depolarization-mediated opening of VOCCs.

CCE-mediated distal colon contraction

In the absence of extracellular Ca^{2+}, ACh induced a transient contraction that was apparently due to Ca^{2+} release from the SR. The muscarinic receptor blocker atropine (10 μmol/L) was applied to the distal colon when the ACh-induced contraction returned to baseline.

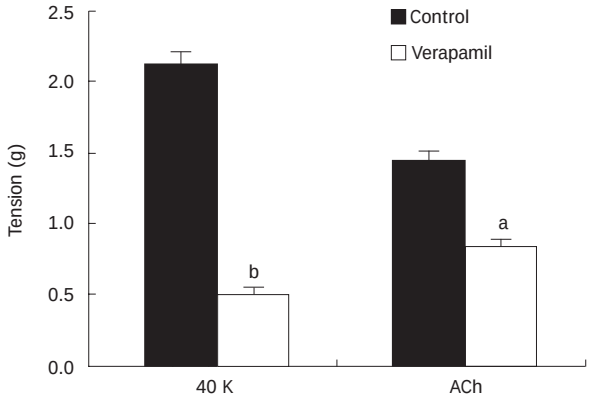

Figure 4 Effects of the VOCC blocker verapamil on distal colon contraction induced by high K^+ and ACh. $^aP < 0.05$, $^bP < 0.001$ *vs* control.

In the presence of atropine, restoration of extracellular Ca^{2+} caused tonic contraction (Figure 5Aa). We further showed tonic contraction was unaffected by verapamil ($n = 5$, Figure 5Ab). The CCE-mediated contraction in the presence of atropine was about 0.46-fold greater than that induced by SR Ca^{2+} release and the total peak contraction induced by ACh in the presence of extracellular Ca^{2+} ($n = 9$, Figure 5B). Taken together, these results showed that Ca^{2+} release from the SR and CCE *via* SOCCs both contribute to agonist-mediated distal colon contraction.

Inhibitory effects of La^{3+} on CCE-mediated distal colon contraction

La^{3+} has been shown to block SOCCs in many cell types[11,31]. La^{3+} (50 μmol/L) was applied to the distal colon when CCE-induced contraction was maximized, and the CCE-mediated contraction was significantly attenuated ($n = 7$, Figure 6A and B). These results indicated the properties of SOCCs in the distal colon are similar to those found in other tissues.

DISCUSSION

The results of this study reveal smooth muscle cells of rat distal colon express functional SOCCs, which play a vital role in agonist-induced contraction.

In many cells, depletion of intracellular Ca^{2+} stores is coupled to activation of CCE. The CCE model has gained support from experiments that used inhibitors of sarcoplasmic endoplasmic reticulum Ca^{2+}-ATPase (SERCA), such as thapsigargin[22,23]. These drugs cause passive store depletion of Ca^{2+} by blocking the reuptake of Ca^{2+} into the SR storage pools[24,25]. Studies in a variety of preparations have demonstrated that SERCA inhibitors increase Ca^{2+} influx and/or smooth muscle tone[26,27]. To investigate the role of CCE in the contractile response in rat distal colon smooth muscle, freshly dissociated cells were incubated with thapsigargin in Ca^{2+}-free HEPES/Ringer solution, followed by reintroduction of extracellular Ca^{2+}, which greatly elevated $[Ca^{2+}]_i$. The lack of effect of thapsigargin resulted in only a slightly elevated $[Ca^{2+}]_i$. Moreover, the properties of the pathway were consistent with the CCE through SOCC found in several types of non-excitable cells. They are insensitive to verapamil

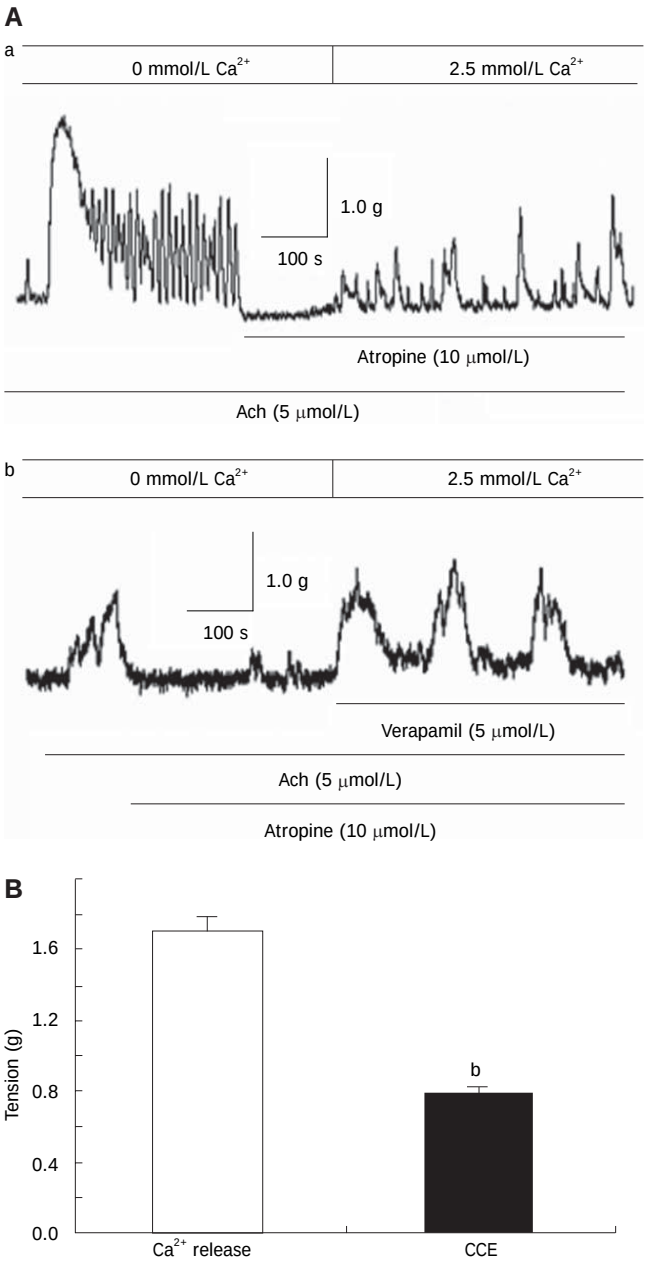

Figure 5 Contribution of Ca^{2+} release from SR stores and Ca^{2+} influx *via* CCE in ACh-induced distal colon contraction. **A**a: In the presence of atropine, restoration of extracellular Ca^{2+} induced contraction, most likely due to Ca^{2+} influx *via* CCE; **A**b: VOCC blocker verapamil (5 μmol/L) negligibly affected CCE-mediated contraction in the presence of atropine; **B**: Summarized data showing that CCE-mediated contraction is about 0.46-fold greater than the contraction induced by SR Ca^{2+} release in ACh-induced rat distal colon contraction. $^bP < 0.001$ *vs* Ca^{2+} release.

(L-type VOCC inhibitor), but sensitive to La^{3+} (SOCC inhibitor). Unlike VOCCs, SOCCs do not appear to be greatly affected by changes in membrane potential. If thapsigargin-induced elevation of $[Ca^{2+}]_i$ in the presence of verapamil is mediated *via* VOCCs, most positive membrane potentials should increase Ca^{2+} influx. However, in this study, such Ca^{2+} influx was not significantly altered by 40 mmol/L K^+. Nevertheless, we do not rule out the role of VOCCs in distal colon smooth muscle cells, because 60 mmol/L K^+ greatly altered elevation of $[Ca^{2+}]_i$. The relative contribution of VOCCs and SOCCs depends on whether a specific agonist causes membrane potential depolarization and/or only intracellular Ca^{2+} release.

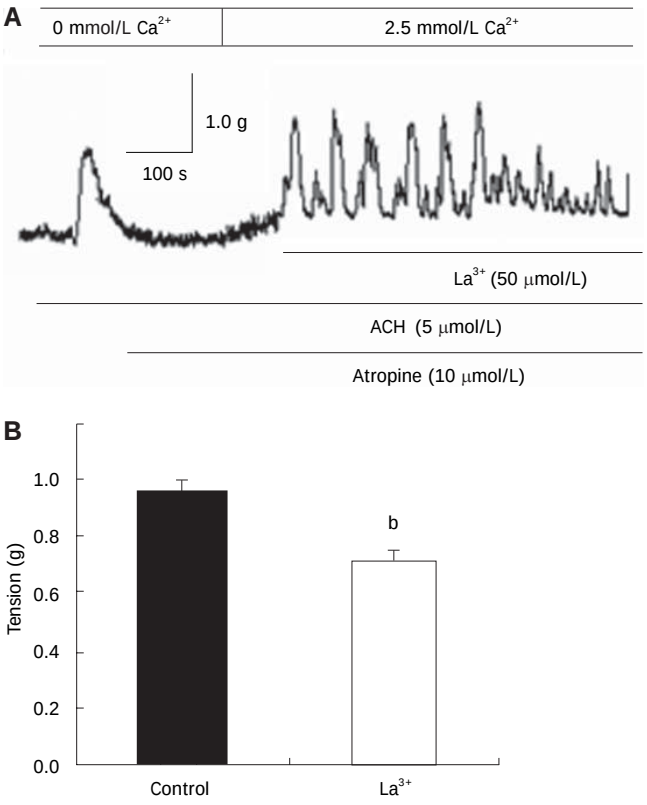

Figure 6 Inhibitory effects of La^{3+} on CCE-mediated distal colon contraction. $^bP < 0.01$ *vs* control. Control: CCE-mediated contraction.

In the rat distal colon, ACh and high K^+ induced the contraction of smooth muscle in a phasic and tonic phase. It has been suggested the phasic contraction is induced by Ca^{2+} released from the SR, whereas the tonic phase is induced by Ca^{2+} that enters from outside the cell[28]. Both pathways for inducing contraction were found in the rat distal colon in the present study. The tonic phase was abolished or significantly inhibited by removal of extracellular Ca^{2+} or chelation of extracellular Ca^{2+} with 2.78 mmol/L EGTA. The present results suggest extracellular Ca^{2+} is necessary for the contraction induced by high K^+ and ACh. ACh studied in the rat distal colon activates Ca^{2+} influx, which may be mediated by different mechanisms, from outside of the smooth muscle cells.

Having established in the present study that the contractile response to ACh in rat distal colon smooth muscle is dependent on extracellular Ca^{2+} influx, we then investigated the contributions of VOCCs and non-VOCCs to this response. Tissue pretreatment with verapamil essentially abolished the 40 mmol/L K^+-induced contraction, but only partially attenuated the response to 5 μmol/L ACh, and the inhibitory rate was 41%. These results indicate the contraction induced by high K^+ is mainly dependent on Ca^{2+} release from SR stores and Ca^{2+} influx mediated by VOCCs. Ca^{2+} influx mediated *via* VOCCs and non-VOCCs is most important for the contraction of rat distal colon smooth muscle induced by ACh.

The muscarinic receptor plays a key role in the parasympathetic nervous control of various peripheral tissues including the gastrointestinal tract[29]. Pharmacological characterization of the contractile response to ACh has suggested the $M_3/G_{q/11}/PLC\beta$ pathway, which acts through the production and release of inositol 1,4,5-trisphosphate (IP_3) to produce mobilization of stored Ca^{2+}, is largely responsible for the contraction[28]. Rather, it is believed the depletion of intracellular Ca^{2+} stores by IP_3 generates an as-yet-uncharacterized signal that activates CCE[30,31]. Because in the present study, ACh induced transient contraction that was apparently due to Ca^{2+} release from the SR in the absence of extracellular Ca^{2+}, the question arises, does CCE has any role in distal colon motility? We found that after the ACh-mediated transient contraction in the absence of extracellular Ca^{2+} and the return to baseline, the subsequent restoration of extracellular Ca^{2+} induced a sustained contraction in the presence of the muscarinic-receptor blocker atropine. Such sustained contraction was not sensitive to verapamil, and was decreased by 50 μmol/L La^{3+}. This contraction was independent of: (1) activation of the muscarinic receptor, (2) intact endothelium, and (3) opening of VOCCs. The result indicated that in the absence of extracellular Ca^{2+}, ACh actively depleted Ca^{2+} from the SR by increasing IP_3 production; therefore, activation of SOCCs and induction of CCE may be the trigger for this contraction. Taken together, the results shows that Ca^{2+} release from the SR is responsible for the phasic contraction, and that CCE *via* SOCC is necessary for the sustained contraction of ACh-induced rat distal colon contraction.

In summary, this study demonstrated the predominant source of activator Ca^{2+} for the contractile response to ACh is extracellular Ca^{2+}, and that intracellular Ca^{2+} has little role to play in mediating excitation-contraction coupling by ACh in rat distal colon smooth muscle *in vitro*. Influx of extracellular Ca^{2+} is mainly mediated by VOCCs, ROCCs and SOCCs. The study of Takeuchi *et al*[32] has shown that the source of Ca^{2+} in smooth muscle cells in the guinea pig proximal colon is mainly dependent on VOCCs. It is postulated that the source of activator Ca^{2+} for the contractile response varies among different regions of the gastrointestinal tract and the animals used. Further studies will hopefully be helpful in developing new drugs with unique properties, such as those that inhibit CCE mediated Ca^{2+} influx.

COMMENTS

Background

Various agonists induce contraction in a variety of smooth muscle preparations, with a concomitant increase in $[Ca^{2+}]_i$. It is suggested the sources of Ca^{2+} for phasic and tonic contraction induced by activation of muscarinic receptors differ among regions of the digestive tract and species of animals used.

Research frontiers

Intracellular Ca^{2+} is a critical second messenger responsible for linking external stimuli to contraction, proliferation and gene expression. It has been suggested some of the motor changes associated with intestinal infection, stress and inflammation are associated with alterations in $[Ca^{2+}]$. Further studies of pharmacological manipulation of Ca^{2+} channels may be therapeutically useful in treating colonic motility disorders.

Innovations and breakthroughs

In this study, we investigated the importance of Ca^{2+} influx in smooth muscle contraction. We also evaluated the contribution of the different Ca^{2+} influx mechanisms and the release of Ca^{2+} from the sarcoplasmic reticulum (SR) to

contraction induced by activation of muscarinic receptors in rat distal colon *in vitro*. The results showed that Ca^{2+} necessary for contractile response in the distal colon of rat was supplied from outside the smooth muscle cells via voltage-operated Ca^{2+} channels (VOCCs), receptor-operated Ca^{2+} channels (ROCCs) and store-operated Ca^{2+} channels (SOCCs), and the SR had a minor role in the contractile response.

Applications

The results provide further evidence for the contraction of the rat distal colon, which hopefully will be of importance in developing new drugs with unique properties, such as those that inhibit capacitative Ca^{2+} entry (CCE)-mediated Ca^{2+} influx.

Terminology

Thapsigargin is a potent skin irritating sesquiterpene lactone isolated from the roots of Thapsia garganica L. It also acts as a non-phorbol-ester-type tumor promoter, which discharges intracellular Ca^{2+} stores by specific inhibition of sarcoplasmic endoplasmic reticulum Ca2+-ATPase (SERCA).

Peer review

This paper examined the relative contributions of internal calcium release and calcium influx to phasic and tonic contraction in the distal colon, and measured calcium concentration and calcium influx in isolated colon smooth muscle cells. The work addressed an old topic but the current discovery of SOCCs in excitable cells such as smooth muscle cell (SMC) is interesting.

Abstract

AIM: To determine patient and process of care factors associated with performance of timely laparoscopic cholecystectomy for acute cholecystitis.

METHODS: A retrospective medical record review of 88 consecutive patients with acute cholecystitis was conducted. Data collected included demographic data, co-morbidities, symptoms and physical findings at presentation, laboratory and radiological investigations, length of stay, complications, and admission service (medical or surgical). Patients not undergoing cholecystectomy during this hospitalization were excluded from analysis. Hierarchical generalized linear models were constructed to assess the association of pre-operative diagnostic procedures, presenting signs, and admitting service with time to surgery.

RESULTS: Seventy cases met inclusion and exclusion criteria, among which 12 were admitted to the medical service and 58 to the surgical service. Mean ± SD time to surgery was 39.3 ± 43 h, with 87% of operations performed within 72 h of hospital arrival. In the adjusted models, longer time to surgery was associated with number of diagnostic studies and endoscopic retrograde cholangio-pancreatography (ERCP, $P = 0.01$) as well with admission to medical service without adjustment for ERCP ($P < 0.05$). Patients undergoing both magnetic resonance cholangiopancreatography (MRCP) and computed tomography (CT) scans experienced the longest waits for surgery. Patients admitted to the surgical versus medical service underwent surgery earlier (30.4 ± 34.9 *vs* 82.7 ± 55.1 h, $P < 0.01$), had less post-operative complications (12% *vs* 58%, $P < 0.01$), and shorter length of stay (4.3 ± 3.4 *vs* 8.1 ± 5.2 d, $P < 0.01$).

CONCLUSION: Admission to the medical service and performance of numerous diagnostic procedures, ERCP, or MRCP combined with CT scan were associated with longer time to surgery. Expeditious performance of ERCP and MRCP and admission of medically stable patients with suspected cholecystitis to the surgical service to speed up time to surgery should be considered.

INTRODUCTION

Nearly 700 000 cholecystectomies are performed in the United States annually, making it the most commonly performed operation on the digestive tract[1,2]. The optimal timing for the performance of laparoscopic cholecystectomy (LC) in the subset of patients with acute cholecystitis has been a point of much discussion. Initially there was concern about potential dangers of performing an operation on an acutely inflamed gallbladder with instruments that lacked the feedback, dexterity, and precision of human hands[3,4]. Studies within the past ten years, however, have determined that laparoscopic cholecystectomy for patients with acute cholecystitis within three days of admission is not only safe but also associated with fewer post-operative complications, decreased morbidity, decreased length of hospital stay, and decreased overall cost when compared to delayed or interval LC[5-9]. Cognizance of the general preferability of prompt surgery, however, may not be uniform among all caretakers. Hence,

we examined the time to laparoscopic cholecystectomy in our institution. In order to help identify potential areas for improvement in current management, we also examined the association of presenting signs, pre-operative imaging studies and procedures, and admitting service (medicine versus surgery) with time to operation.

MATERIALS AND METHODS

We performed a retrospective medical record review of patients identified by a primary or secondary discharge diagnosis of acute cholecystitis (ICD codes 575.0, 575.10, 575.11 and 575.12) at Norwalk Hospital between March 2003 and December 2005. The diagnosis of acute cholecystitis was made at the time of surgery by experienced biliary surgeons and confirmed by acute inflammatory changes being found on pathologic examination[10]. Patients not undergoing cholecystectomy during this hospitalization were excluded from analysis. Data collected included age, sex, symptoms and physical findings, laboratory and radiological investigations performed, co-morbidities, time from arrival to the hospital to operation, admission service, complications, and length of stay (LOS). Patients presenting with discharge diagnosis of acute cholecystitis but not undergoing cholecystectomy during the hospitalization were excluded.

In order to help account for the contributions of pre-operative comorbid illnesses to the measured outcomes, we classified co-morbidities as none, minor (abnormal electrocardiogram (ECG), rhythm other than sinus, low functional capacity, history of stroke, uncontrolled hypertension), intermediate (mild angina, previous myocardial infarction, compensated or prior heart failure, diabetes mellitus, renal insufficiency), or major (unstable coronary syndromes, decompensated heart failure, significant arrhythmias, severe valvular disease) following the criteria by American Heart Association/American College of Cardiology (AHA/ACC) for cardiovascular risk[11]. An abnormal ECG is one indicating left ventricular hypertrophy, left bundle branch block, ST-T abnormalities. Advanced age is also listed in the AHA/ACC criteria as a minor clinical predictor but is undefined. For this study, it was arbitrarily designated as > 75 years old. Liver cirrhosis, which is not included in the AHA/ACC criteria, was added as a major peri-operative risk factor because it is known to increase post-operative mortality[12,13].

Post-operative complications were defined as newly arising occurrences related to the patient's surgical disease or management that prolonged length of stay or required treatment. Complications were categorized as mild (e.g., urinary tract abnormalities, prolonged ileus, prolonged biliary drainage), moderate (e.g., systemic inflammatory response, deep wound infection), and severe (e.g., death, respiratory failure requiring intubation, myocardial infarction)[14].

Statistical analysis

Descriptive analysis was performed for baseline demographic and clinical characteristics. Because of the natural clustering of the observations within physicians/surgeons, we employed a hierarchical generalized linear modeling approach to compare the risk-adjusted mean differences in "time-to-operation" and to obtain the posterior distribution of the true effect size upon change of time by the design variables admission team, pre-operative diagnostic imaging studies, and select physical and laboratory signs indicative of cholecystitis or an inflammatory state (Murphy's sign, temperature > 37.8℃, WBC > 10 200/UL)[15]. Other physical signs indicative of cholecystitis were excluded from the analysis because of infrequency or lack of specificity. This statistical approach accounts for within-physician/surgeon correlation of the observed outcomes and separates within-physician/surgeon variation from between-physician/surgeon variation.

Our aim was not to develop a predictive model but rather to determine the influence of different values of design variables on the change in time-to-surgery with and without controlling for patient characteristics. Thus, the first model was fitted without adjusting for any patient characteristics. The second model adjusted for patient demographics, including age and gender, the third model adjusted for patient demographics, and co-morbidity. The 95% credible interval (CI) was also calculated for each estimate obtained from the models. All of the statistical analyses were conducted using STATA version 8.0 (STATA Corporation, College Station, TX) and SAS version 8.12 (SAS Institute Inc. Cary, NC).

RESULTS

A total of 88 patient charts with the discharge diagnosis of acute cholecystitis were reviewed. In six patients the pathology report did not confirm a diagnosis of acute cholecystitis, and it was concluded that they suffered from biliary colic. An additional 12 patients were discharged without cholecystectomy and were also felt to have had biliary colic rather than acute cholecystitis. These 18 patients were excluded from analysis, yielding a study population of 70 patients. The mean ± SD age was 53 ± 17.3 years. The majority of patients (69%) had no recognized peri-operative co-morbidities (Table 1). Among those with co-morbidities, 16% were classified as minor, 13% were intermediate, and 3% were major. All but one patient presented with abdominal pain and nearly all (89%) had right upper quadrant tenderness on examination. Murphy's sign, considered to be a relatively specific sign in cholecystitis, was present in only one-quarter of the patients. Fever (> 37.8℃ and leukocytosis), which together with Murphy's sign comprise the diagnostic triad for acute cholecystitis, was present in only 23% and 51% of patients, respectively. Guarding was noted in 11% and rebound tenderness was detected in one patient.

Eleven patients presented with aspartate aminotransferase (AST) and alanine aminotransferase (ALT) greater than three times the upper normal limit and 2 (18%) required pre-operative ERCP for stone extraction. Two other patients had pre-operative ERCP performed because of common bile duct dilatation identified on CT scan. All ERCP examinations were therapeutic, removing stones from the common bile duct via sphincterotomy. Three additional patients required post-operative ERCP for retained stones.

The majority of patients were admitted to the surgical

service (83%) (Tables 1 and 2). Patients admitted to the medical service were significantly older (66 years *vs* 52 years, $P < 0.05$), and had more minor and intermediate, but not severe, peri-operative cardiovascular risk factors ($P < 0.05$), including diabetes mellitus, prior heart failure, and age > 75 years. Other non-cardiovascular comorbid conditions among the patients admitted to the medical service included dementia, anxiety, brain tumor, hepatitis B, and chronic Clostridium difficile infection.

Patients admitted to the medical service had significantly more abdominal CT scans done in the evaluation process (Table 2). The distribution of other pre-operative tests was not significantly different between the surgical and medical services. There was a trend toward more medicine patients undergoing pre-operative ERCP, 2 of 12 (17%) patients *vs* 2 of 58 (3%) patients, though this did not reach statistical significance.

The mean time to operation from admission was 39.3 ± 43.1 h (Table 2). Operation within 72 h occurred in 87% of the cases and operation within 24 h occurred in 51% of the cases. Patients admitted to the surgical service compared to the medical service had a significantly decreased mean time to operation, and significantly more surgical patients were operated on within 3 d as well as within 24 h (Table 2).

Post-operative complications occurred in 16 cases (23%). Complications occurred more frequently in medicine patients: 7 of 12 (58%) *versus* 9 of 58 (16%) surgical patients, $P < 0.01$ (Table 2). Complications included prolonged (> 2 d) ileus ($n = 2$), discharge with Jackson-Pratt drain for biliary drainage ($n = 2$), urinary retention requiring discharge with foley catheter ($n = 2$), volume resuscitation for systemic inflammatory response leading to post-operative volume overload requiring diuresis ($n = 1$), penile edema ($n = 1$), gout ($n = 1$), pancreatitis ($n = 2$), delayed operation for gangrenous cholecystitis leading to post-operative deconditioning with inability to walk ($n = 1$), preoperative antibiotics to "cool down" cholecystitis associated with diffuse rash requiring steroids ($n = 1$), hypoxic respiratory failure ($n = 1$), cardiac arrest leading to death ($n = 1$), and multi-organ system failure leading to death ($n = 1$).

Mean ± SD LOS for all patients was 5.0 ± 3.9 d. Patients admitted to the surgical service experienced a shorter LOS compared to patients admitted to the medicine service (Table 2). LOS of 3 d or less was seen more often for surgical patients, while LOS of 6 d or more was observed most often for medicine patients.

Using hierarchical generalized linear models, we evaluated the impact of various factors on time to surgery (Table 3). Adjusting for patient demographics (age and gender), peri-operative co-morbidity level, physical signs, and pre-operative tests, we found that the performance of pre-operative ERCP was associated with increased time to operation. Select physical and laboratory signs (Murphy's sign, temperature > 37.8℃, WBC > 10.2 thousand/UL) had no apparent impact on time to operation in both the unadjusted and adjusted models. Medical admitting team was significantly associated with increased time to operation until ERCP was included in the model (Table 3).

The number of pre-operative diagnostic imaging studies was significantly associated with increased time to operation (Table 3). Time to surgery doubled as the number of diagnostic procedures increased from one to 2 or 3 tests and doubled again when 4 tests were performed. Adjusted models to determine the association between time to surgery and individual studies and combinations of studies revealed that ultrasound alone was associated with the shortest time (mean 23.3, 95% CI 10.7-35.9 h) and the

combination of CT scan and MRCP with longest time (mean 195.4, 95% CI 125.1-256.8 h) to surgery (Table 4). A trend is present toward decreased risk of complication associated with surgery within 24 h of hospital arrival that becomes non-significant after adjustment for diagnostic imaging studies (Table 5).

DISCUSSION

In this study, we find that 87% of cholecystectomies

occurred within 72 h of arrival at the hospital and half of them within 24 h, indicating an overall timely approach. Several studies have shown that performing LC within 72 h of presentation does not increase morbidity and mortality[6,9]. Early LC, furthermore, has been shown to have a lower complication rate, decreased length of stay, decreased cost, and a shorter post-operative recovery period compared to delayed LC[5,7,8,16,17]. The results from a meta-analysis by Papi *et al* of 12 prospective randomized trials from 1970-2000 (9 addressing open cholecystectomy, 3 addressing LC), showed that there was a decrease in conversion to open procedure when LC was done early (17.6% *vs* 25.7%) and there were fewer post-operative complications (10.9% *vs* 15.6%)[17]. Another benefit of early surgery proved to be a shorter length of hospital stay (6.3 d *vs* 9.9 d).

Our analysis suggests a number of potential ways to speed up time to cholecystectomy. The number of pre-operative procedures was significantly associated with adjusted time to surgery, especially when four or more tests were done. Performance of MRCP and CT scan had by far the longest associated adjusted time to surgery. While the need for ERCP and MRCP will always result in some delay in surgery, these studies are routinely available within 24 h at our institution, often on the same day as requested. Efforts to streamline the decision process leading to ERCP and MRCP and then providing these studies promptly when requested may lead to earlier surgery for patients with acute cholecystitis. Additionally, more judicious use of pre-operative diagnostic imaging studies would also reduce delay. Although the sample size was small, not surprisingly, the performance of ERCP was also associated with delayed time to operation.

Also noted was that patients admitted to the medical service experienced over twice the wait for surgery compared to those going to the surgical service. No doubt some of this delay represents treatment of co-morbid illnesses, which were significantly more common in patients admitted to the medical service. However, patients on the medical service also had more imaging procedures performed, mostly abdominal CT scans, indicating confusion over the diagnosis and contributing to delays in definitive surgical therapy. Surgeons directly caring for patients with abdominal pain may be more apt to make the early diagnosis of acute cholecystitis with fewer imaging studies than medical physicians and, thereby, bring those patients to operation earlier. Although admitting patients with abdominal pain suspicious for cholecystitis to the surgical service may reduce time to cholecystectomy, it must be weighed against the advantages of having patients with active co-morbidities managed on the medical service with surgical consultation.

Our findings raise the question whether the benefit seen by early surgery is conferred mainly on those patients operated on within 24 h of arrival. A significant decreased risk of complications was seen in this subset of patients, except in the model including adjustment for diagnostic imaging studies. A reasonable inference is that this subset of patients may be so straight forward that little diagnostic uncertainty exists, fewer tests are required, and admission to the surgical service is favored. Conversely, those patients about whom diagnostic uncertainty is present or who are chosen for "cooling off" with pre-operative antibiotics may be placed at greater risk of complications because of the prolonged inflammatory state. Acute inflammation creating edema in the gallbladder submucosa can mature into a chronic inflammatory response with neovascularization and fibrosis, which can make a delayed procedure potentially more difficult[18]. Often, an operation will be deferred, especially in patients with pre-existing co-morbidities, in an attempt to maximize a patient's medical tolerance of an operative insult. Firm evidence is lacking for whether this delayed approach is truly the best. Indeed, a recent meta-analysis comparing LC within 7 d *versus* longer than 6 wk after index admission showed no clear benefit from waiting[19]. Although the complications observed in the patients in this analysis can be directly or indirectly linked to acute cholecystitis and surgery, no causal connection between them and any delay in operating can be drawn. A prospective trial is likely required to determine the optimal times for LC.

Somewhat surprising was that what many would deem a classic clinical presentation with fever, leukocytosis, and Murphy's sign was not associated with time to surgery. In a retrospective study of patients undergoing nuclear hepatobiliary scans by Singer *et al*[20], fever had a positive predictive value of 100% and a sensitivity of 14.6% for a positive scan. A positive Murphy's sign had 97.2% sensitivity and 93.3% positive predictive value. In their

systematic review of presenting signs and symptoms that may warrant investigation for cholecystitis, Trowbridge *et al*[21] found that no clinical or laboratory finding had a likelihood ratio (LR) sufficient to rule in or out cholecystitis. Murphy's sign, however, appeared the most useful, with a positive LR of 2.8, 95% CI 0.8-8.6. In our study, possibly the variable skill of the clinicians assessing for cholecystitis and the ready availability of imaging studies mitigated any diagnostic benefit from the presence of these findings that would have sped up care.

We chose in this study to use the AHA/ACC risk classification scheme rather than the American Society of Anesthesiologists-Physical Status (ASA-PS) score for risk stratification. While the ASA-PS score's simplicity and widespread use makes it an attractive index of risk, it is subjective and not explicitly intended for estimation of operative risk[22]. Furthermore, we had no measure of inter-anesthesiologist agreement on ASA-PS score and numerous anesthesiologists, so we could not control for variations at the level of the grader. While the AHA/ACC guidelines were derived for cardiovascular risk, it contains a detailed list of factors plausibly conferring risk for non-cardiac complications[23-25].

In summary, our analysis indicates good adherence to the desirable practice of performing cholecystectomies within 3 d of presentation to the hospital and raises the question of whether even prompter surgery may reduce the risk of complications. Efforts to expedite cholecystectomy should consider factors that may contribute to delay in surgery such as ERCP and MRCP, the combination of CT scan and MRCP, and admission to a medical service.

COMMENTS

Background

The optimal timing of surgery for acute cholecystitis (AC) has not been precisely established. We reviewed 70 consecutive cases of AC, confirmed by pathological examination, and identified several factors which led to delay in surgery and which resulted in increased complications because of that delay.

Research frontiers

We used a hierarchical statistical analysis model to identify the relevant factors leading to surgical delay.

Innovations and breakthroughs

While other authors have reviewed the timing of surgery for AC, none have identified specific causes resulting in delay nor reviewed the consequences of delaying surgery.

Applications

We found patients with AC who are admitted to the Medical Service, because of medical co-morbidities, experience significant delays in definitive surgical treatment and have higher post-operative complication rates, even when corrected for the existing co-morbidities. The delay results primarily from an increased number of radiologic imaging studies performed on patients admitted to the Medical Service. Patients with medical co-morbidities in addition to AC require prompt stabilization of their underlying medical illnesses and definitive surgery within 48 to 72 h following admission.

Terminology

The hierarchical statistical analysis used in this article allows multiple variables to be compared, identifying those that impact surgical timing and eliminating individual practice patterns from affecting the analysis.

Peer review

This study by Daniak *et al* is based on a retrospective evaluation of records from patients who underwent cholecystectomy. The authors compared the time of hospital staying between patients admitted in surgery and medical service. Interestingly, they found that admission to the medical service was associated to longer time to surgery compared to admission to surgery service. The study is original, well designed and performed, and results are relevant.

Abstract

AIM: To clarify the usefulness of a new method for performing a pancreaticojejunostomy by using a fast-absorbable suture material irradiated polyglactin 910, and a temporary stent tube for a narrow pancreatic duct with a soft pancreatic texture.

METHODS: Among 63 consecutive patients with soft pancreas undergoing a pancreaticoduodenectomy from 2003 to 2006, 35 patients were treated with a new reconstructive method. Briefly, after the pancreatic transaction, a stent tube was inserted into the lumen of the pancreatic duct and ligated with it by a fast-absorbable suture. Another tip of the stent tube was introduced into the intestinal lumen at the jejunal limb, where a purse-string suture was made by another fast-absorbable suture to roughly fix the tube. The pancreaticojejunostomy was completed by ligating two fast-absorbable sutures to approximate the ductal end and the jejunal mucosa, and by adding a rough anastomosis between the pancreatic parenchyma and the seromuscular layer of the jejunum. The initial surgical results with this method were retrospectively compared with those of the 28 patients treated with conventional duct-to-mucosa anastomosis.

RESULTS: The incidences of postoperative morbidity including pancreatic fistula were comparable between the two groups (new; 3%-17% *vs* conventional; 7%-14% according to the definitions). There was no mortality and re-admission. Late complications were also rarely seen.

CONCLUSION: A pancreaticojejunostomy using an irradiated polyglactin 910 suture material and a temporary stent is easy to perform and is feasible even in cases with a narrow pancreatic duct and a normal soft pancreas.

INTRODUCTION

Leakage of the pancreaticoenterostomy remains a major cause of postoperative morbidity and mortality after pancreaticoduodenectomy[1-7]. Many factors have been identified that are associated with an increased incidence of this complication. Among them, a small pancreatic duct size with a soft pancreas creates one of the technical hurdles to the completion of the anastomosis, and is known to be a risk factor for major leakage[3,8-13]. Several methods have been advocated to reduce the occurrence of leakage[5,14-21], but the best technique is still a subject of debate[22-29].

We established a new anastomotic technique for pancreaticojejunostomy by using a fast-absorbable suture material, irradiated polyglactin 910, and a temporary stent tube.

MATERIALS AND METHODS

One hundred and one consecutive patients underwent an elective pancreaticoduodenectomy for hepato-biliary and pancreatic disease between February 2003 and January 2007 at the Hirosaki University Hospital. Among them, 63 patients, in whom the pancreas was macroscopically normal and soft in texture, and in whom a pathological examination of the pancreatic cut end confirmed the absence of fibrosis or pancreatitis, were included in

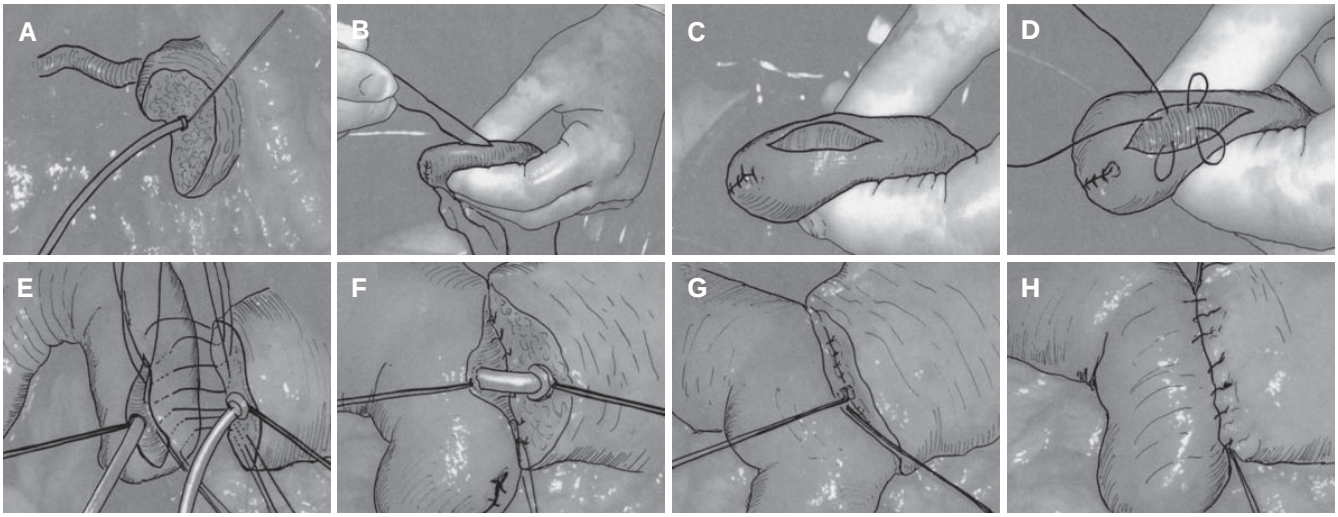

Figure 1 New Duct-to-mucosa contact method. **A**: The stent tube was ligated with the pancreatic duct by an irradiated polyglactin 910 suture; **B**, **C**, **D**: The seromuscular layer of the jejunal wall was cut. The submucosa was exposed and a purse-string suture using an irradiated polyglactin 910 suture was performed at the center, where another tip of the stent tube was introduced and ligated by this suture material; **E**, **F**, **G**: After the posterior side of the pancreatic parenchyma was anastomosed to the seromuscular layer of the jejunal wall, two stay sutures of the stent tube were ligated to approximate the pancreatic ductal cut end and the jejunal mucosa; **H**: The pancreaticojejunostomy was completed by adding an anterior suture to the pancreatic parenchyma and the jejunal wall.

this study. The reconstruction of the pancreatic stump after the pancreaticoduodenectomy was performed by a pancreaticojejunostomy in two fashions, the conventional duct-to-mucosa anastomosis, or a new duct-to-mucosa contact method. Five surgeons performed either of the anastomotic techniques, as was their preference, however, one of the authors, KH, supervised all operations and the procedures were strictly standardized in the institute.

The postoperative management was prescribed according to the clinical pathway. The amylase level in the peripancreatic external drain was measured on postoperative d 1, 3 and 6. In this study, a pancreatic fistula was defined by four internationally well-documented criteria, which are described as follows: (1) drainage of more than 50 mL per day of fluid with an amylase content above three times the serum amylase activity on and after postoperative d 10 as described by Yeo *et al*[30] (Definition A); (2) drainage of more than 50 mL per day of fluid with an amylase content above three times the serum amylase activity on and after postoperative d 7 as described by Park *et al*[31] (Definition B); (3) drainage of more than 10 mL per day of fluid with an amylase content above three times the serum amylase activity on and after postoperative d 4 as described by Buchler *et al*[32] and Pederzoli *et al*[33] (Definition C); (4) drainage of any measurable volume of fluid with an amylase content greater than three times the normal serum value on or after postoperative d 3 according to the International Study Group of Pancreatic Fistula (ISGPF) classification scheme[34,35]. According to the ISGPF definition, outcomes were divided into four grades: (1) no fistula; (2) Grade A: biochemical fistula without clinical sequelae; (3) Grade B: fistula that shows clinical symptoms or requires any therapeutic intervention; (4) Grade C: fistula with severe clinical sequelae. The occurrence of Grade B or C fistulas is included in the postoperative morbidity. A delayed gastric emptying is defined as the need for nasogastric drainage for more than 10 d[2,7,12], or as the delay of the resumption of a regular diet beyond 14 d postoperatively[36]. Computed tomography (CT), either a helical CT or a multidirector row CT, was performed serially before discharge and on the third and sixth postoperative month to rule out cancer recurrence. Based on these findings, the diameter of the main pancreatic duct ventral to the base of the superior mesenteric artery was measured by an enhanced computed tomogram. A progression of pancreatic ductal dilatation was defined by the diameter on the sixth month CT being 130% or greater than that before the hospital discharge. The glucose tolerance was evaluated serially by blood hemoglobin A_1C or a 75-g oral glucose tolerance test at the same intervals as the CT scans. Diabetes mellitus was defined as a fasting glucose level greater than 1.26 g/L or a two-hour glucose level greater than 2 g/L.

The data were collected prospectively for all patients and included the preoperative historical information and laboratory data, the details of the operative procedure, the pathology, and the clinical information regarding the postoperative course, postoperative morbidity and mortality, and the late complications occurring at least 6 mo postoperatively.

The statistical analyses were performed using the SPSS 11.0 statistical software. The comparisons between the two groups were carried out by Chi-square test for the categorical data and Student's *t*-test for the continuous data. The continuous variables were reported as the mean ± SD. *P* values less than 0.05 were thought to be significantly different.

Surgical procedures

New Duct-to-mucosa contact method: The pancreatic transection was performed with an electrocautery or a scalpel. A stent tube (5, 6, or 7.5 Fr, Sumitomo Bakelite, Tokyo, Japan) with a notch near the tip was inserted into the lumen of the main pancreatic duct. The stent tube was ligated with the pancreatic duct near the cut end by a 4-0 fast-absorbable synthetic suture, irradiated polyglactin 910 (vicryl RAPIDE™, Ethicon, Somerville, N.J.) (Figure 1 A),

[1]Carcinomas of the bile duct and the gallbladder; [2]Non-invasive intraductal papillary-mucinous neoplasm, islet cell tumor, and lymphangiohemangioma of the pancreatic head.

The notch functions to prevent the tube from dislodging. The jejunal limb was moved to the pancreatic cut end by a retro-mesenteric route. The seromuscular layer of the jejunum was cut at the anti-mesenteric side, and the serosal side of the mucosa was exposed by the same width as the pancreatic cut surface (Figure 1B and C). A purse-string suture was made by using a 4-0 irradiated polyglactin 910 at the center of the mucosa, where another tip of the stent tube was introduced into the intestinal lumen, and ligated by this fast-absorbable suture (Figure 1D). After the posterior side of the pancreatic parenchyma was anastomosed to the seromuscular layer of the jejunal wall by using 4-0 polydioxanone suture, a long-lasting absorbable synthetic suture (PDS-Ⅱ™, Ethicon) (Figure 1E and F), two stay sutures of irradiated polyglactin 910 were ligated together to approximate the ductal cut end and the jejunal mucosa (Figure 1G). No other suture was added to the duct-to-mucosa contact. Next, the anterior side of the pancreatic parenchyma was anastomosed to the seromuscular layer of the anterior wall of the jejunum by polydioxanone sutures (Figure 1H). The other tip of the tube was introduced extracorporeally through the transhepatic or transintestinal route. The pancreatic juice flowed through the lumen of the stent tube and then drained externally. The whole anastomotic procedure usually required 10 to 15 min at maximum.

After confirmation of a stable anastomosis by the tube pancreatography on postoperative d 14, the tube could be pulled out without any resistance.

Conventional Duct-to-mucosa anastomosis

After the posterior side of the pancreatic parenchyma was anastomosed to the wall of the seromuscular layer of the jejunum by using 4-0 polydioxanone sutures, the pancreatic ductal end was anastomosed to the small hole at the antimesenteric side of the jejunal limb by using 5-0 polydioxanone sutures in an interrupted fashion. Then the anterior side of the pancreatic parenchyma was anastomosed to the wall of the seromuscular layer of the jejunum by using 5-0 polydioxanone sutures. No stent tube was used.

RESULTS

The new duct-to-mucosa contact method was applied to 35 patients, while the conventional duct-to-mucosa anastomosis was performed in 28 patients (Table 1). The male-to-female ratio was the same between the two groups; however the duct-to-mucosa contact method was applied to older patients. There were no differences in the presence of jaundice, diabetes mellitus, or malnutritional status, which was defined as a 10% or greater weight loss.

The operative indications were different between the two groups. The duct-to-mucosa contact method was applied more frequently to biliary cancer, while the conventional duct-to-mucosa anastomosis was preferred in pancreatic cancer. The diameters of the pancreatic duct at the cut surface were significantly smaller in the duct-to-mucosa contact method group (2.4 ± 0.5 *vs* 4.2 ± 1.9 mm, $P < 0.01$). The total operative time, as well as the time after resection, was the same between the two groups. The amount of blood loss and the number of patients transfused were comparable in both groups.

Postoperative complications occurred equally to both groups (Table 2). Pancreatic fistula was noted in 3% of the patients in the duct-to-mucosa contact method group and in 7% in the duct-to-mucosa anastomosis group ($P = 0.43$) according to Definition A. By the more strict definitions of Definition B and C, pancreatic fistula was found in 8% and 17% by the new method, while in 8% and 11% by the conventional method, respectively ($P = 0.77$ and $P = 0.47$). Fistulas of any grade (Grade A-C) by the ISGPF definition occurred in the same degree. Moreover, the incidences of Grade B or C fistulas, which were categorized into clinically relevant fistulas, were also comparable between the two groups (17% *vs* 14%, $P = 0.76$). Intestinal bleeding from the ruptured pseudoaneurysm of the common hepatic artery, which occurred in a patient treated with duct-to-mucosa anastomosis on postoperative d 21, was successfully treated with radiological intervention using a self-expandable metallic stent. Other abdominal and non-abdominal complications, both infectious and non-infectious, were comparable between the two groups. No operative mortality was found in this series. The length of hospital stay and the re-admission rate were equal in both groups.

A late pancreatic ductal dilatation, as determined by a comparison with the ductal diameter before discharge, was noted in one patient in each group. An exacerbation of diabetes mellitus was rarely found in either group, and the recovery of body weight was comparable between the two groups.

DISCUSSION

Pancreatic fistula is the major cause of postoperative

morbidity and mortality after pancreaticoduodenectomy. The incidence is estimated to be 5% to 30%[1,5-7,34,35], which varies according to the definition[34,35]. Many risk factors for pancreatic fistula have been disclosed, among which the most significant factors are thought to be a soft pancreatic texture, a narrow pancreatic duct, and a high output of pancreatic juice[3,8-13].

Pancreaticoenterostomy is the most physiologic method to deal with the remnant pancreatic stump, because the continuity of the pancreatic exocrine and intestinal functions can be restored[37-39]. Indeed, a pancreaticoenterostomy, either *via* a pancreatico-jejunostomy or a pancreaticogastrostomy, is easy to perform in cases of a dilated pancreatic duct with a firm texture of the pancreatic parenchyma, but in cases with a normal pancreas, it is quite hard to anastomose a narrow pancreatic duct and a fragile parenchyma to the jejunal or gastric wall[11,13,40]. To overcome the technical difficulties of performing a pancreaticoenterostomy of a soft pancreas, we have developed a new anastomotic technique of a "duct-to-mucosa contact method" by using a fast absorbable suture material and a temporary stent tube.

In this method, the pancreatic ductal end is approximated to the serosal side of the jejunal mucosa by ligating two stay sutures of the temporary stent tube. This method can be applied easily to a narrow pancreatic duct if the stent tube can be inserted into it. In our series, the mean diameter of the pancreatic duct in the duct-to-mucosa contact method group was significantly smaller than that in the conventional duct-to-mucosa anastomosis group. The surgeons tended to choose this method for the narrow duct because it was a very simple procedure and they did not need to hold a fine needle or use a surgical microscope[21].

The priority of this method is the use of an irradiated polyglactin 910 suture. This synthetic absorbable suture material has an initial strength comparable to that of nylon but it loses its tensile strength rapidly, being 50% at 5 d and almost none at 14 d, according to the commercial information[41]. An added advantage of this material is the very mild inflammatory reaction of the surrounding tissues[42,43]. These characteristics favor its use in the field of oral surgery[44,45] as well as in pediatric[42], gynecological[46,47], and plastic surgery[48,49].

In this duct-to-mucosa contact method, the irradiated polyglactin 910 suture was used to secure the complete external drainage of the pancreatic juice and to approximate the pancreatic duct and the mucosa for about a week. The anastomosis of the pancreatic parenchyma and the intestinal seromuscular wall was secured by the more long-lasting absorbable synthetic sutures comprised of polydioxanone[50]. In most cases, the color of the drained pancreatic juice changes from transparent to bile-staining by POD 14, when the irradiated polyglactin 910 has already been degraded and the stent can be removed without any resistance. These phenomena suggested to us that the exposure of the pancreatic juice to the anastomotic site could be avoided for about 2 wk postoperatively.

It has been suggested that the rate of formation of a pancreatic fistula varies according to the definition. Bassi *et al*[34] summarized the current pancreatic fistula concept by analyzing 26 definitions described in the past 10 year, and applied four definitions to a group of 242 patients undergoing a pancreaticojejunostomy after a pancreatic resection. They found the incidence of pancreatic fistula to range from 9.9% to 28.5% according to the different definitions applied. Pratt *et al*[35] also reported incidences of pancreatic fistula between 9.1% and 19.3% by applying different definitions to 176 patients undergoing a pancreaticoduodenectomy. As a result, it is quite important to use a universally accepted definition of pancreatic fistula to compare the different aspects of the new surgical method with the conventional one. In this study, we applied three well-documented definitions as described by Yeo *et al* (1995)[7], Park (1998)[31], and Buchler (1992)[32] and Pederzoli (1994)[33] to help compare our results with those of previous reports. We examined a high risk group of pancreatic fistula in which the pancreatic texture was soft and the pathology confirmed the absence of fibrosis and pancreatitis change. Nevertheless, the incidences were comparable to the overall incidences of the previous reports using these definitions[1,3,6,7,12,13,22,29], or were even lower than those in cases restricted to the soft pancreas[9,10]. In a current objective definition by the ISGPF classification scheme, Pratt *et al*[35] reported an overall incidence of 11.9% in Grade B fistula and 3.4% in

Grade C fistula, which were comparable with our results of 14.4% in Grade B fistula and 1.6% in Grade C fistula. A subgroup analysis of the incidences of pancreatic fistula limited to the soft pancreas in each Grade according to the ISGPF definition has not yet been reported to date.

Consequently, the total incidence of the postoperative infectious and non-infectious complications was not different from that with conventional duct-to-mucosa anastomosis. The late status of the anastomotic site also seemed to be stable according to the serial measurements of the pancreatic ductal diameter as determined by CT scans. Good recovery of the nutritional status and avoiding worsening of the diabetic symptoms seemed to be primarily due to the uniform preoperative backgrounds of the normally functioning pancreas in this series, but these results may indirectly favor the use of this new method.

The primary aim of this study was to introduce a new method of performing a pancreaticojejunostomy, because this method is quite easy to perform even in a difficult anastomosis of a narrow duct of a normal soft pancreas. Indeed any conclusion for the surgical method needs to await randomization or a good cohort study, but our preliminary results were comparable with those previously reported from mass volume centers. These facts seem to justify the carrying out of a randomized prospective study to compare this new method with appropriate controls.

COMMENTS

Background

A narrow pancreatic duct with a soft pancreatic texture creates a high risk for the development of a pancreatic fistula after pancreaticoduodenectomy. Several methods have been advocated to reduce the occurrence of leakage, but the best technique is still a subject of debate.

Research frontiers

The authors developed a new method for performing a pancreaticojejunostomy with a fast-absorbable suture material, irradiated polyglactin 910, and a temporary stent tube.

Innovation and breakthrough

This easy-to-perform method was feasible in cases with narrow pancreatic duct and a soft pancreas. Both early and late surgical results were comparable to or better than the methods ever reported.

Applications

This method is expected to give a new idea of overcoming the difficulties of pancreaticoenterostomy for a soft pancreatic texture with a narrow pancreatic duct.

Peer review

In this study, 35 consecutive patients with a soft pancreas undergoing a pancreaticoduodenectomy from 2003 to 2006 were treated by a new reconstructive method. This work adds significant information for future development of pancreaticojejunostomy therapy.

Abstract

AIM: To evaluate the sensitivity of brush cytology and forceps biopsy in a homogeneous patient group with hilar cholangiocarcinoma.

METHODS: Brush cytology and forceps biopsy were routinely performed in patients with suspected malignant biliary strictures. Fifty-eight consecutive patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) including forceps biopsy and brush cytology in patients with hilar cholangiocarcinoma between 1995-2005.

RESULTS: Positive results for malignancy were obtained in 24/58 patients (41.4%) by brush cytology and in 31/58 patients (53.4%) by forceps biopsy. The combination of both techniques brush cytology and forceps biopsy resulted only in a minor increase in diagnostic sensitivity to 60.3% (35/58 patients). In 20/58 patients (34.5%), diagnosis were obtained by both positive cytology and positive histology, in 11/58 (19%) by positive histology (negative cytology) and only 4/58 patients (6.9%) were confirmed by positive cytology (negative histology).

CONCLUSION: Brush cytology and forceps biopsy have only limited sensitivity for the diagnosis of malignant hilar tumors. In our eyes, additional diagnostic techniques should be evaluated and should become routine in patients with negative cytological and histological findings.

INTRODUCTION

Current epidemiological data analysis reveals an increasing incidence and mortality from cholangiocarcinoma[1-4]. Cholangiocarcinomas are topographically categorized as intrahepatic or extrahepatic carcinomas. Extrahepatic cholangiocarcinomas are further subdivided into hilar, medial and distal carcinomas. The most common type are hilar cholangiocarcinomas which are classified into 4 stages according to the bismuth classification: stage I or II for tumors expanding up the hilus, type III A/B infiltrating right or left hepatic duct, and stage IV with infiltration of both hepatic ducts and sub segments[5]. Because of late presentation of symptoms and the difficult distinction between benign and malignant strictures the prognosis of patients with hilar cholangiocarcinoma is poor, and survival data for advanced stages reported so far show a very limited life expectancy[6-8]. Surgery is the only curative treatment in patients with cholangiocarcinoma. The results are more favourable for patients with early-stage disease. Therefore, a reliable diagnostic procedure is of great importance for patient's chance for survival. Cholangiocarcinomas are diagnosed by a combination of imaging techniques and endoscopic procedures, including endoscopic retrograde cholangiography and/or percutaneous transhepatic cholangiography[9-13]. Cholangiocarcinomas often grow longitudinally along the bile duct rather than in radial direction

away from the bile duct. Consequently, imaging techniques including ultrasound, computed tomigraphy (CT), and magnetic resonance imaging (MRI) are of limited sensitivity for the detection of the malignant lesion[14-17].

Biliary tissue collection during endoscopic procedures is widely used for distinction between benign and malignant strictures and provides the only definitive diagnosis that can be used for establishing therapeutic strategies. To obtain tissue samples, brush cytology and/or forceps biopsy were routinely performed in patients with suspected malignant biliary strictures. Several studies have evaluated the cancer detection rate of brush cytology since the first description by Osnes *et al*[18] in 1975. Brush cytology is the most common tissue sampling technique and can be performed for most biliary strictures detected by endoscopic retrograde cholangiography. It is generally safe, requires little time, and is technically easier compared to forceps biopsy. The sensitivity of brush cytology for diagnosis of malignant biliary strictures ranges from 30% to 60% in most published series[19-21]. Tissue samples for histological investigation can be obtained from biliary strictures by using forceps. This technique is more time consuming than brushing and is less widely used, but it provides a sample of subepithelial stroma. Consequently, only histological investigation allows diagnosing invasive growth. In patients with malignant biliary stricture the overall cancer detection rate of forceps biopsy is higher compared to brush cytology, ranging form 43% to 81%[22-24].

To date, no study exists investigating the sensitivity of these techniques in patients with hilar cholangiocarcinoma (Klatskin tumors). The present study was designed to address the question of diagnostic sensitivity for endoscopic transpapillary brush cytology and forceps biopsy in a homogeneous group of 58 patients with hilar cholangiocarcinoma.

MATERIALS AND METHODS

The study included 58 consecutive patients (31 male, 27 female, median age 68 ± 10.6 years) with malignant hilar bile duct tumors who were treated from 1995 to 2005 in the Ⅱ. Medizinische Klinik, Klinikum rechts der Isar at the Technical University Munich. The biliary stricture localization was classified in relation to the confluence of the hepatic ducts as described by bismuth[5]. Bismuth stage was classified by endoscopic retrograde cholangiography at the time of primary diagnosis.

Patients included into this study were identified by using an endoscopic database. The analysis of our database was performed as follows: First, all patients with bile duct strictures diagnosed in the period from 1995 to 2005 were identified. Subsequently, cholangiograms of these patients were reviewed and the bile ducts strictures were divided according to its localization. In the next step we tried to clarify the genesis of the hilar stricture by analysing patient records including follow up. In total, 96 patients with hilar cholangiocarcinoma could be identified. In 58 out of 96 patients forceps biopsy and brush cytology was performed.

All of the following inclusion criteria had to be confirmed: (1) Diagnosis of hilar cholangiocarcinoma (histologically/cytologically positive for malignancy or patients for whom the subsequent clinical course confirmed malignancy); (2) Transpapillary brush cytology and forceps biopsy as diagnostic approach. Exclusion criteria were as following: (1) Intrahepatic cholangiocarcinoma; (2) Distal cholangiocarcinoma; (3) Biliary obstruction due to liver metastasis; (4) Hepatocellular carcinoma; (5) No tumor progression in patients with negative histology/cytology; (6) Survival time more than 18 mo in patients with negative histological/cytological investigation. The exclusion criteria were scheduled in order to achieve a homogeneous patients group with hilar cholangiocarcinoma without tumors of different origin.

In all patients, routine diagnostic procedures included abdominal ultrasound, abdominal CT scans and endoscopic retrograde cholangiopancreatography (ERCP) with tissue sampling. After reception of the histology results, patients with strictures were associated with tumors located in the hilar region, respectability was primarily discussed with the abdominal surgeon. In 28 selected patients cholangioscopy was performed. Overall 16 out of 58 patients were transferred to the surgery unit and operation was performed. In patients with negative histology/cytology after first attempt of forceps biopsy/brush cytology another diagnostic approaches including percutaneous ultrasound guided fine needle biopsy, endoscopic ultrasound guided fine needle biopsy, or percutaneous transhepatic cholangioscopic guided biopsy was performed. In patients with furthermore unclear diagnosis, another attempt of transpapillary tissue sampling was performed after 3 mo.

Endoscopic retrograde cholangiography (ERC) was performed with a standard videoduodenoscope Olympus TFJ 160-R (Olympus, Hamburg, Germany). The first ERC comprised an endoscopic sphincterotomy (EPT) which was performed using an Olympus papillotome (Olympus, Hamburg, Germany) introduced over a Terumo guide wire. Under radiographic guidance using contrast fluid bile duct strictures were localized. The forceps was advanced as far as possible into the stricture in the closest position, then forceps was opened and the specimen was obtained. If the forceps could not enter the stricture, the open forceps was gently pushed against the distal end of the bile duct stricture. The specimen was obtained by closing the forceps in this position and fixed in 4% formalin. Bile duct strictures were brushed with multiple, rapid, to and fro movements using a standard 6 French (F) Geenen spring tip sheathed cytology brush inserted over a standard guide wire. The cellular material adherent to the brush was directly transferred to a glass slide in the endoscopy room. The brush was subsequently stored in 50% ethanol and processed at the Institute of Pathology to collect the remaining material. The specimens were evaluated by an experienced cytopathologist. Cytological results were recorded as positive or negative for malignant cells. According to the usual cytologic and histologic classification system, in the current study suspicious and positive specimens were considered as positive, whereas negative specimens and unspecific reactive changes were classified as negative.

In two patients, passage of the Y-shaped stenosis of

Table 1 Patients characteristics, physical and laboratory parameters on admission

	Patient characteristics	Standart values	Scale unit
Number of patients	58	-	-

a complex hilar tumor did not allow a stable passage of a wire guided brush into the periphery after dilatation or use of an internal bougie. Since the tip of the brush runs parallel to the wire although guided by a small plastic shaft, the brush itself is not adherent to the wire (Boston Scientific, Boston, USA). Therefore, brush cytology could only obtained in these two patients by positioning of the brush in the tumor area, moving backward and forward in the tumor area with the tip, although a complete passage with the brush over the tumor area could not be achieved due to a rectangular path of the bile duct within the tumor. Both patients were positive for malignancy. In 4 patients material received by forceps biopsy was not suitable for diagnosis. In these patients another endoscopic procedure was performed.

RESULTS

Patient's characteristics

Patients entered into this study had the following characteristics: mean age 68 ± 10.6 years, bilirubin level 6.9 ± 7.6 mg/dL, alkaline phosphatase 559 ± 270 U/L, γ-GT 404 ± 362 U/L, and leucocytes 8.8 ± 3.8 G/L. At the time of their initial diagnosis 7/58 patients were related to bismuth stage Ⅱ, 25/58 to bismuth stage Ⅲ, and 26/58 to bismuth stage Ⅳ (Table 1). The final diagnosis was made by surgical specimens (n = 3), autopsy (n = 1), percutaneous ultrasound guided fine needle biopsy (n = 3), endoscopic ultrasound guided fine needle biopsy (n = 3), endoscopic transpapillary forceps biopsy and brush cytology (n = 35), and percutaneous transhepatic cholangioscopic guided biopsy (n = 4). In 9 patients, final diagnosis could not be confirmed by histological or cytological diagnostic methods. Therefore, diagnosis was substantiated by clinical course and survival time. Each of these 9 patients has a limited survival time ranging from 4 to 8 mo. Cholangioscopy was performed in 28 out of 58 patients. 10/29 patients had an infiltrative growth and 18/28 patients had a nodular growth.

Table 3 Sensitivity of brush cytology and forceps biopsy in patients with hilar cholangiocarcinoma n (%)

	Positive for malignancy
Brush cytology	24/73[1] (32.9)
	24/58[2] (41.4)

	31/58[2] (53.4)
Combination of cytology and biopsy	35/73[1] (47.9)
	35/58[2] (60.3)

[1]Samples; [2]Patients.

Number of tissue sampling sessions

In case of negative results for malignancy, brush cytology and forceps biopsy was repeated. The mean number of tissue sampling sessions was 1.3 per patient. Table 2 gives an overview of the number of tissue sampling sessions. One patient of our series had 4 histological/cytological investigations. In this patient, all histological/cytological samples were negative and definite diagnosis was obtained by autopsy.

Sensitivity of endoscopic transpapillar brush cytology

Brush cytology was performed in 58 patients. Positive results for malignancy were obtained in 24/58 patients. Overall, brushing was performed 73 times in 58 patients, and malignancy was obtained in 24 of 73 cytological samples. The overall sensitivity of brush cytology for diagnosis of hilar cholangiocarcinoma was 41.4% regarding number of patients, and 32.9% regarding number of samples, respectively (Table 3).

Sensitivity of endoscopic transpapillar forceps biopsy

Forceps biopsy was performed in 58 patients. Malignancy was detected in 31 of 58 patients. If biopsy specimens were diagnosed as non-malignant, forceps biopsy was repeated up to 4 times. Overall forceps biopsy was performed 73 times in 58 patients, and was positive for malignancy in 31 of 73 histological tissue samples. Consequently, the sensitivity of forceps biopsy for the diagnosis of hilar cholangiocarcinoma was 53.4% regarding number of patients, and 42.5% regarding number of tissue samples, respectively (Table 3).

Sensitivity of brush cytology and forceps biopsy in a combined approach

The combination of the results of brush cytology and forceps biopsy resulted in a minor increase in diagnostic sensitivity to 60.3% (35/58 patients). Table 4 shows the distributions of positive and negative results for the 58 patients. 34.4% (20/58 patients) of diagnosis were obtained by both positive cytology and positive histology, 19% (11/58 patients) by positive histology (negative cytology)

Table 4 True positive and false negative results for cytological and histological investigation

	Histology positive		Histology negative		Total	
	Samples	Patients	Samples	Patients	Samples	Patients
Cytology positive	20	20	4	4	24	24
Cytology negative	11	11	38	23	49	34
Total	31	31	42	27	73	58

and only 6.9% (4/58) were confirmed by positive cytology (negative histology). Table 4 illustrates the distribution of positive and negative results of cytological and histological investigations in 73 samples.

DISCUSSION

Suspicious biliary strictures are a diagnostic challenge in endoscopic practice. Tissue collection during endoscopic retrograde cholangiography (ERC) and/or percutaneous transhepatic biliary drainage (PTBD) are the most common techniques for providing a definitive diagnosis[25]. The current study intended to determine the diagnostic value of transpapillary forceps biopsy and brush cytology in patients with hilar cholangiocarcinoma. Pugliese *et al*[25] reported sensitivity of both brush cytology and forceps biopsy in 36 patients with malignant bile duct stricture, but did not focus on hilar lesions. The patients in this study had a wide spectrum of diagnosis including pancreatic cancer (12/36), cholangiocarcinoma (10/36), intraampullary carcinoma (9/36), metastatic cancer (3/36), and malignant islet cell tumor (2/36). Cytological and histological investigation was positive in 19/36 patients. This indicates that the overall sensitivities of both techniques were almost identical (53%). In 6/10 patients (60%) with cholangiocarcinoma histology was positive, whereas cytology was positive in 7/10 patients (70%). Details regarding localization of the cholangiocarcinoma were not given in this paper. Similar to these data, Ponchon *et al*[22] also investigated a heterogeneous patient group with malignant bile duct strictures. In this series, 27/73 patients had cholangiocarcinomas, however also without specification of stricture localization. In 12/25 patients (48%) cytology, in 7/16 patients (44%) biopsy was positive for malignancy. The combination of both cytology and biopsy increased the sensitivity in 14 patients with cholangiocarcinoma to 86%.

Our study comes to the conclusion that diagnostic sensitivity is poor, since only 60.3% of diagnoses were made correctly using brush cytology and forceps biopsy in combined approaches. In our series, sensitivity of transpapillary brush cytology was 32.9% regarding number of cytological samples, and 41.4% regarding number of patients; whereas sensitivity of forceps biopsy was 42.5%, and 53.4%, respectively.

Endoscopic ultrasonography (EUS) complements the role of endoscopic and percutaneous transhepatic approaches and may provide a tissue diagnosis through fine-needle aspiration (FNA). Recently, the yield of EUS-FNA in patients with suspected cholangiocarcinoma was evaluated[26]. The authors reported a diagnostic sensitivity of 86%. However, another group reported lower rates of diagnostic sensitivity (45%) for detection of bile duct lesions by using ultrasound guided fine needle aspiration[27]. Thus, EUS-FNA may represent an alternative approach in the diagnosis of cholangiocarcinoma, especially in patients with negative brush cytology and forceps biopsy findings. One of the major limitations of endoscopic brush cytology from bile duct strictures is the poor quality of cytologic samples.

Recently, investigators have attempted to improve diagnostic assessment with an advanced cytological technique for the detection of malignant pancreaticobiliary strictures[28]. Fluorescence in situ hybridization (FISH) has shown to increase the sensitivity for the diagnosis of malignant pancreaticobiliary strictures compared to conventional cytology. Kipp *et al*[29] used a multitarget FISH probe set which has previously shown high impact in monitoring recurrent urothelial carcinoma[30]. This advanced technique identifies malignant cells by detecting aneusomy and deletion of the locus 9p21. By applying this technique for brush cytology and bile aspirate specimens in 131 patients with bile duct strictures (including 71 with primary sclerosing cholangitis, FISH analysis showed sensitivity of 35% and specificity of 91%. When patients with primary sclerosing cholangitis were excluded, sensitivity for malignancy detection by FISH was 16%[31]. This indicates that probe stets specific for biliary neoplasms will be required for higher sensitivity. However, not all malignant tumors present aneusomy or aneuploidy. In the biliary tract, the percentage of cancers displaying aneuploidy has been estimated to be approximately 80%[32]. Since our current data clearly demonstrate that no improved sensitivity can be obtained by using forceps biopsy and/or brush cytology during endoscopic procedures, we therefore suggest that additional diagnostic techniques such as FISH techniques should be routinely evaluated in patients with negative cytological and histological findings.

COMMENTS

Background

Surgery is the only curative treatment in patients with hilar cholangiocarcinoma. The results are more favourable for patients with early-stage disease. Therefore, a reliable diagnostic procedure is of great importance in these patients. Cholangiocarcinomas often grow longitudinally along the bile duct rather than in radial direction away from the bile duct. Consequently, imaging techniques including ultrasound, computed tomigraphy (CT) and magnetic resonance imaging (MRI) are of limited sensitivity for the detection of cholangiocarcinoma. In patients with suspected malignant biliary stricture brush cytology and/or forceps biopsy were routinely used for distinction between benign and malignant strictures. Biliary tissue collection provides the only definitive diagnosis that can be used for establishing therapeutic strategies.

Research frontiers

To our knowledge, no study exists investigating the sensitivity of brush cytology and forceps biopsy in a homogeneous group of patients with hilar cholangiocarcinoma. The current study was designed to address the question of diagnostic sensitivity for endoscopic transpapillary brush cytology and forceps biopsy in 58 patients with hilar cholangiocarcinoma.

Innovations and breakthroughs

Positive results for malignancy were obtained in 41.4% of patients using brush cytology and in 53.4% of patients using forceps biopsy. The combination of both techniques brush cytology and forceps biopsy resulted only in a minor increase in diagnostic sensitivity to 60.3%. Consequently, in 23 out of 58 patients definitive diagnosis could not achieved using the combination of brush cytology and forceps biopsy.

Applications

Brush cytology and forceps biopsy have only limited sensitivity for the definite diagnosis of hilar cholangiocarcinoma. In our eyes, additional diagnostic techniques such as FISH techniques should be further evaluated and should become routine in patients with negative cytological and histological findings.

Terminology

Cholangiocarcinomas are categorized as intrahepatic and extrahepatic carcinomas. Extrahepatic cholangiocarcinomas are further subdivided into hilar, medial and distal cholangiocarcinomas. The most common type is hilar cholangiocarcinoma which is also called Klatskin tumor. Klatskin tumors are classified into 4 stages according to the bismuth classification: stage Ⅰ or Ⅱ for tumors expanding up the hilus, type Ⅲ infiltrating right (ⅢA) or left (ⅢB) hepatic duct, and stage Ⅳ with infiltration of both hepatic ducts and sub segments.

Peer review

The authors retrospectively analyze the effectiveness of various diagnostic tools to diagnose hilar cholangiocarcinoma. The authors come to the conclusions that brush cytology and forceps biopsy have only limited sensitivity for the definite diagnosis of hilar cholangiocarcinoma. The study suggest that in patients with suspected biliary stricture and negative cytological / histological findings further diagnostic approaches such as cholangioscopy should performed.

Abstract

AIM: To examine if the rate of decrease in serum bilirubin after preoperative biliary drainagecan be used as a predicting factor for surgical complications and postoperative recovery after pancreaticoduodenectomy in patients with distal common bile duct cancer.

METHODS: A retrospective study was performed in 49 consecutive patients who underwent pancreaticoduodenectomy for distal common bile duct cancer. Potential risk factors were compared between the complicated and uncomplicated groups. Also, the rates of decrease in serum bilirubin were compared pre- and postoperatively.

RESULTS: Preoperative biliary drainage (PBD) was performed in 40 patients (81.6%). Postoperative morbidity and mortality rates were 46.9% (23/49) and 6.1% (3/49), respectively. The presence or absence of PBD was not different between the complicated and uncomplicated groups. In patients with PBD, neither the absolute level nor the rate of decrease in serum bilirubin was significantly different. Patients with rapid decrease preoperatively showed faster decrease during the first postoperative week (5.5 ± 4.4 μmol/L *vs* -1.7 ± 9.9 μmol/L, $P = 0.004$).

CONCLUSION: PBD does not affect the surgical outcome of pancreaticoduodenectomy in patients with distal common bile duct cancer. There is a certain group of patients with a compromised hepatic excretory function, which is represented by the slow rate of decrease in serum bilirubin after PBD.

INTRODUCTION

In spite of recent advances in surgical techniques and perioperative management, pancreaticoduodenectomy still carries a significant morbidity and mortality[1,2]. Many studies have been performed to identify the high risk patients for the operation with inconsistent results. The diversity of those study results may be due in part to the heterogeneity of the disease entities included, and also to the patient's conditions which in turn affect the outcome of the complex operative procedures. One of the prime interests has been the effectiveness of preoperative biliary drainage. Many studies favored the usefulness of biliary drainage in improving the surgical outcome[3-7], while others questioned its effectiveness[8-10], and even concluded it provokes more complications[11-15]. The underlying rationale for the preoperative decompression of the bile duct is that obstructive jaundice may interfere with the hepatic function, and relieving the obstruction could improve the recovery of the patients and hence the surgical results[16,17]. It was our impression that there are a certain group of patients whose concentration of total serum bilirubin drops faster after biliary drainage than others. Presumably, the more slowly the concentration of

serum bilirubin drops, the higher the risk of developing complications following pancreaticoduodenectomy might be. If the surgical outcome is complicated by obstructive jaundice, this should be measured by not only the absolute concentration of serum bilirubin but also its rate of decrease after biliary drainage, which is the indicator for hepatic excretory dysfunction and further the presence of liver damage[18-21].

We conducted this study to examine whether the rate of decrease in the concentration of serum bilirubin, as well as its absolute preoperative level per se, are different between the patients with and without major complications after pancreaticoduodenectomy. To avoid skewed results by confounding variables, we included patients with distal common bile duct cancer only.

MATERIALS AND METHODS

Study patients and data collection

A retrospective chart review was done in 49 consecutive patients who received pancreaticoduodenectomy for distal common bile duct cancer from July 1996 to June 2005. Patients were divided into complicated and uncomplicated groups according to whether the complications occurred. We compared the potential risk factors including demographic data, laboratory values, operative data and the history of preoperative biliary drainage between the two groups. Then, the patients with biliary drainage were divided further into two arbitrary subgroups with same sample size according to the rate of decrease in the concentration of serum bilirubin after preoperative biliary drainage, and the incidence of postoperative complications and the postoperative decrease in serum bilirubin were compared between the two subgroups.

Regarding the total serum bilirubin level, we used six parameters defined as follows: (1) the serum bilirubin at presentation as the initial bilirubin (Bi), (2) the preoperative concentration of serum bilirubin (Bo), (3) the ratio of decrease in serum bilirubin [(Bi-Bo)/Bi], (4) the rate of decrease in serum bilirubin per day [(Bi-Bo)/(days of biliary drainage)], (5) the rate of decrease in serum bilirubin during the first week following surgery (Bpod1), (6) the rate of decrease in serum bilirubin during the second week following surgery (Bpod2).

Preoperative biliary drainage

No absolute criterion existed for performing the preoperative biliary drainage. In general, when there were suspicions as to the nature of obstructive jaundice such as benign stricture and choledocholithiasis or malignant obstruction, endoscopic retrograde cholangiography (ERC) was performed for both diagnostic and therapeutic purposes. After the ERC, the patients were usually followed by endoscopic nasobiliary drainage (ENBD) to avoid secondary cholangitis. When malignant jaundice was strongly suspected, magnetic resonance cholangiography (MRC) was performed rather than ERC, in that MRC is a less invasive procedure than ERC. After the presence of malignant biliary obstruction was confirmed, the patients were either followed by percutaneous transhepatic biliary drainage (PTBD) or surgery at surgeon's discretion. The absolute level of serum bilirubin was not regarded as a criterion for the timing of operation. In cases in which the preoperative biliary drainage was considered to be inadequate, in terms of the small daily drainage amount or suspicions for displacement, either the drainage was replaced or the operation schedule was advanced.

Operative procedures

The resection phase of pancreaticoduodenectomy consisted of the standard operative procedures including the regional lymphnode dissection of the porta hepatis, retropancreatic and celiac artery area. When the tumor was suspected to be advanced locally, the distal stomach was resected and the procedure was directed to the standard Whipple's operation. Otherwise, the pylorus was preserved at the pylorus-preserving pancreaticoduodenectomy. The pancreatico-enteric anastomosis was done by either end-to-side pancreaticojejunostomy or duct to mucosa technique. Two active suction drains were applied at the pancreatico-enteric anastomosis site.

Definition of complications

Surgical mortality was defined as the death noted within 30 d postoperatively. Postoperative complications included delayed gastric emptying, pancreatic fistula, intraabdominal abscess and postoperative bleeding. Systemic complications such as pulmonary and cardiac complications were also noted. Delayed gastric emptying was defined as the inability to resume oral intake of food for more than 10 d postoperatively without the evidence of mechanical bowel obstruction. Pancreatic fistula was defined as a drain output more than 10 mL per day of amylase-rich fluid after postoperative day 8 or for more than 8 days postoperatively[22,23]. An intraabdominal abscess was present when there was pus collected intraperitoneally causing symptoms that warranted either surgical or interventional drainage. Postoperative bleeding was defined as a significant drop in hemoglobin concentration with the evidence of intraluminal and/or extraluminal bleeding that required re-exploration or interventional bleeding control. Minor complications such as wound infection that did not affect the overall recovery were not included in the complication.

Statistical analysis

For nominal variables, either χ^2-test or Fisher's exact test was applied where appropriate, and Mann-Whitney *U* test was used for interval variables. Because of the limited number of cases, multivariate analysis was considered inappropriate and not performed. Statistical analysis was done using SPSS for Windows Ver. 12.0.1 (SPSS Inc., Chicago, Illinois). A *P* value less than 0.05 was considered statistically significant.

RESULTS

Demographics of the 49 patients are summarized in Table 1. A total of 26 patients (53.1%) with no major complications were assigned to the uncomplicated group. The remaining 23 patients (46.9%) with major complications were classified as complicated group. In the complicated group, 3 patients

(6.1%) died of complications. A detailed description of the morbidity and mortality is presented in Table 2. On univariate analysis, none of the age, sex, preoperative laboratory values and operative data was statistically different between the two groups.

In our series, 40 patients (81.6%) underwent preoperative biliary drainage. There was no difference in the preoperative bilirubin level whether or not the biliary drainage procedure was performed between the uncomplicated and complicated groups (76.9% *vs* 87.0%, respectively, $P = 0.472$), although the preoperative bilirubin level was significantly lower in those patients without biliary drainage than in those with biliary drainage (41.0 ± 45.8 *vs* 132.2 ± 93.0 μmol/L, respectively, $P = 0.001$). The parameters related to the biliary drainage are shown in Table 3. ENBD was performed in 29 patients (72.5%) and PTBD in 11 patients (27.5%). The method of drainage was not different between the two groups. The initial, preoperative total serum bilirubin level or the duration of drainage was not different between the two groups. Also, neither the ratio nor the rate of decrease in serum bilirubin showed a statistically significant difference ($P = 0.892$ and 0.425, respectively), although there was a tendency for the rate of decrease in serum bilirubin to be higher in the uncomplicated group (Figure 1). The bilirubin drop during the first and second postoperative weeks was not different between the two groups. When the patients were regrouped according to the rate of decrease in serum

bilirubin after biliary drainage, those with a rapid decrease preoperatively showed a significantly faster decrease during the first postoperative week as well, than those with a slower decrease preoperatively ($P = 0.004$). This difference was not seen during the second postoperative week (Table 4, Figure 2).

DISCUSSION

The effect of preoperative biliary drainage in preventing the operative complications after pancreaticoduodenectomy has been addressed in patients with obstructive jaundice due to periampullary tumors. To date, many studies have examined the issue with inconsistent results[10-12]. Periampullary tumors include various benign tumorous conditions such as chronic pancreatitis occurring at the periampullary region, in addition to the malignant lesions developed in the pancreas head, distal common bile duct, ampulla of Vater and duodenum. While the malignant diseases developing at the periampullary region have many characteristics in common, the biologic behavior of each is believed to be different from one another[24], which may in turn affect the surgical results. Also, the standard surgical procedure of pancreaticoduodenectomy is a complicated one with diverse technical variations, and the choice of reconstruction method and the extent of dissection may be dependent on both the operator and the disease entity. In analyzing the effect of preoperative biliary drainage, these factors are intermingled with each other, making the analysis difficult. To minimize the confounding variables, the present study limited the disease entity to the distal common bile duct cancers only. The rationale of selecting distal common bile duct cancers among the other periampullary malignancies is that these cancers are usually fairly confined within the periampullary region compared to the more aggressive diseases such as the pancreas head cancers, while the volume of cases in our database is large enough to make the statistical analysis valid. Nevertheless, it is not so large as to satisfy the requirements for the multivariate analysis, and we performed the univariate analysis only.

Many reports showed that the effectiveness of preoperative biliary drainage is measured by the surgical outcome following pancreaticoduodenectomy according to the specific complication items[8,9,14,15]. The surgical morbidities are commonly classified as bleeding, pancreatic leakage, intraabdominal abscess, delayed gastric emptying and others which include wound infection and systemic complications such as pneumonia or cardiac problems. While the complications are distinct entities clinically, the causes for each complication are either interrelated or obscure, and may be related to the basic fundamental defect, i.e. pancreaticojejunostomy failure[25-27]. Postoperative hemorrhage, when clinically significant, usually originates from the rupture of pseudoaneurysm, which in turn develops most frequently from the inflammatory erosion of arterial wall due to the leaked pancreatic juice[28]. Intraabdominal abscess can be caused by any leakage from the anastomoses, and the pancreaticoenteric anastomosis is the most frequent one to leak[27]. Also, the underlying mechanism of delayed gastric emptying is still unclear, but many authors suggest that the local inflammation induced by the leaked pancreatic enzymes may play an important role[27,29]. Some of the studies performed to date have classified the surgical results as complicated and uncomplicated[7,10-12]. This simple classification of surgical outcome measurement is advantageous in controlling as many confounding variables as possible. Surely, this simplified approach may not identify the risk factors predisposing the specific complications. However, based on the limited number of cases in the current study, it is more plausible to classify the surgical results as complicated and uncomplicated. In essence, this study was designed to investigate if the relief of obstructive jaundice preoperatively can reduce the incidence of the pancreatic anastomosis failure after pancreaticoduodenectomy.

Obstructive jaundice can cause tissue damage by various inflammatory mediators including oxygen free radicals[30]. Animal experiments suggested that the inflammatory mediators have a deleterious effect on not only the hepatic sinusoidal endothelium and then the hepatic function, but also the functions of other remote organs[31,32]. Both clinical and experimental studies have also shown that obstructive jaundice impairs the healing of

abdominal wounds[33], although there is still a controversy in this series[17]. Arnaud *et al*[34] observed that the healing of gastric wounds and abdominal wounds, is delayed in experimentally jaundiced animals. Also, Takahashi[35] showed that the bursting strength of pancreaticojejunostomy is higher and the incidence of anastomotic leakage is lower in dogs with their concentration of serum bilirubin < 5 mg/dL. Considering such evidence, it seems prudent to assume that the high concentration of serum bilirubin is closely associated with the impaired healing of intestinal anastomoses, although the relevant mechanism and the magnitude of such association are still unclear.

Some studies have examined whether the relief of obstructive jaundice could improve the healing of anastomotic wound[36]. Vendemiale *et al*[16] showed that the impairment of hepatic redox status caused by cholestasis in patients with extra-hepatic biliary obstruction could be almost completely resolved by surgical biliary drainage. In addition, Koivukangas *et al*[17] observed that the decreased baseline collagen synthesis in jaundiced patients is partly restored by the resolution of jaundice, although the healing of the blister wound is not affected.

In spite of the scattered evidence that favors the possible positive effect of preoperative biliary drainage on the operative results after pancreaticoduodenectomy, many studies performed so far have failed to show any preferable impact. Povoski *et al*[11] have extensively reviewed the effectiveness of biliary drainage reported in the literature with their own experiences and concluded that the preoperative biliary drainage has no beneficial effect on the surgical results, and rather increases the infectious complications following pancreaticoduodenectomy. In another meta-analysis, Sewnath *et al*[10] also concluded that the preoperative biliary drainage prolongs hospital stay and has its own procedure-related complications without any proven positive effect on immediate postoperative results.

It is our experience that there is a certain group of patients whose serum bilirubin level decrease faster after biliary drainage procedures while there are others in whom the serum bilirubin fails to decrease effectively or even increases despite of good-functioning drainage route. We assume that if the surgical outcome is complicated by obstructive jaundice, this can be measured by not only the absolute serum bilirubin level[18,19], but also its rate of decrease after biliary drainage which is the indicator for hepatic excretory dysfunction and further the presence of liver damage. To date, a few studies have focused on the rate of decrease in the concentration of serum bilirubin[9,20,21]. Even though these studies may have their own limitations, such as the limited number of cases or the inclusion of heterogeneous disease entities, they have shown that the postoperative complications are more prone to develop in patients whose rate of decrease in the level of serum bilirubin is slower after drainage[20,21].

We used two indicators for the changes in the concentration of serum bilirubin: the ratio and rate. None of these indicators showed any statistically significant difference between the complicated and uncomplicated groups, although the serum bilirubin in the uncomplicated group tended to decrease faster than that in the complicated group after biliary drainage. To further investigate the postoperative recovery of hepatic excretory function, we divided the patients into two subgroups according to the rate of decrease in serum bilirubin after drainage. Patients with a higher rate of decrease in the concentration of serum bilirubin did not show a significantly lower rate of postoperative complications. In these patients, however, the rate of decrease in serum bilirubin was also higher during the first postoperative week. These results indicate that the rate of decrease in serum bilirubin after drainage can predict the immediate postoperative hepatic excretory functional recovery, although it cannot select high risk patients. Our results also show that there was a certain group of patients with their hepatic excretory function already compromised by obstructive jaundice before it was relieved by surgical resection of the causative lesion. These findings are in agreement with those presented by Sano *et al*[21], who showed that biliary obstruction causes liver damage represented by the slower rate of serum bilirubin decrease in patients who underwent biliary drainage.

Our study could not disclose the relationship between the compromised hepatic excretory function and surgical morbidity of pancreaticoduodenectomy. We think that the negative results may be due to the limited number of cases. Well-designed, prospective randomized studies in a larger number of cases are warranted to assess the clinical usefulness of the serum bilirubin decrease rate in selecting high risk patients to whom greater attention must be paid during surgery.

COMMENTS

Background

In spite of recent advances in surgical techniques and perioperative management, pancreaticoduodenectomy still carries a significant morbidity and mortality. Many studies have been performed to identify the high risk patients for the operation with inconsistent results. One of the prime interests has been the effectiveness of preoperative biliary drainage, but the issue is under debate.

Research frontiers

Many studies favored the usefulness of preoperative biliary drainage in improving the surgical outcome, while others questioned its effectiveness, and even concluded it provokes more complications. Further studies are warranted on the subject.

Innovations and breakthroughs

If the surgical outcome is complicated by obstructive jaundice, this should be measured by not only the absolute concentration of serum bilirubin but also its rate of decrease after biliary drainage, which is the indicator for hepatic excretory dysfunction and further the presence of liver damage. So far, few studies have focused on the rate of decrease in serum bilirubin.

Applications

We conducted this study to examine whether the rate of decrease in the concentration of serum bilirubin, as well as its absolute preoperative level per se, is different between the patients with and without major complications after pancreaticoduodenectomy. To avoid skewed results by confounding variables, we included patients with distal common bile duct cancer only.

Peer review

The study has certain merits since the authors consider several different variables for each patient. Also, the manuscript is easy to follow and its content is rich.

Abstract

AIM: To examine the ultrastructural changes after ursodeoxycholic acid (UDCA) treatment in hepatocytes from experimentally induced fibrotic livers.

METHODS: Liver fibrosis was induced in male Sprague-Dawley rats with CCl_4 for 12 wk, and the rats were divided into two groups. Group Ⅰ was treated with saline and group Ⅱ with UDCA (25 mg/kg per day) for 4 wk. All the rats were killed at wk 16. Mitochondria, nuclei, rough endoplasmic reticulum (RER) and smooth endoplasmic reticulum (SER) of hepatocytes were evaluated according to a scoring system.

RESULTS: Mitochondria, nuclei, RER and SER injury scores in group Ⅱ were significantly lower than those in group Ⅰ ($P < 0.001$).

CONCLUSION: UDCA alleviates hepatocyte organelle injury in CCl_4-induced liver fibrosis.

INTRODUCTION

Liver fibrosis is characterized by an increase in extracellular matrix (ECM) components and occurs as a common sequel of various chronic inflammatory diseases. Certain collagen types deposit around the sinusoidal cell layer in the space of Disse and a molecular re-organization of various ECM molecules results in alterations in the composition of the fibrotic matrix, with deterioration of hepatic functions[1]. Parenchymal cell damage of varying etiology is central to the initiation of fibrogenesis in the liver. Although experimental and clinical trials to establish effective options for prevention or regression of fibrogenesis in the liver are being conducted, it is still an untreatable condition. Some agents that are currently used for other diseases, and several herbal drugs, have recently been reported to have antifibrotic efficacy with different potency in the liver[2].

Ursodeoxycholic acid (UDCA) is the mainstay of therapy of primary biliary cirrhosis (PBC) in humans. UDCA has been reported to have antifibrotic activity in bile duct ligation and CCl_4-induced experimental liver fibrosis[3,4]. Clinically, long-term UDCA therapy improves liver function tests[5] and delays the development and progression of cirrhosis in PBC[6,7], which leads to prolongation of the time needed for liver transplantation. It has been reported to have antiapoptotic activity on cholangiocytes and hepatocytes[8,9] and an inhibitory effect on generation of reactive oxygen species[10]. In the present study, we examined the ultrastructural changes after UDCA treatment in hepatocytes from experimentally induced liver fibrosis in the rat. This should show us alterations in hepatocyte structure after treatment of established fibrosis and the possibility of regression of organelle injury.

MATERIALS AND METHODS

The Institutional Animal Use and Care Committee of the Gülhane Medical Academy, Ankara, Turkey approved the study, which was also performed in accordance with the National Institute of Health's guidelines for the care and handling of animals. The animals were fed standard rat chow and kept in metabolic cages with controlled temperature and a 12-h light/dark cycle before and during the experiment.

Twenty male Sprague-Dawley rats weighing 250-350 g were injected subcutaneously with 0.2 mL/100 g CCl_4 twice weekly for 12 wk to induce liver fibrosis. Then, the

rats were randomly divided into two groups. Group I ($n = 10$) was treated with saline and group Ⅱ ($n = 10$) with UDCA (25 mg/kg per day) for 4 wk. At the end of wk 16, all the rats were killed under anesthesia and the livers were excised under sterile conditions. The specimens were fixed in 2.5% glutaraldehyde for 24 h and consequently washed in phosphate buffer (pH 7.4), post-fixed in 1% osmium tetroxide in phosphate buffer (pH 7.4), and dehydrated in increasing concentrations of alcohol. The tissues were washed with propylene oxide and embedded in epoxy-resin embedding medium. Semi-thin sections approximately 60-90 nm in thickness were cut with a glass knife on an LKB Nova (Sweden) ultramicrotome. Sections were stained with methylene blue and examined by a Nikon Optiphot (Japan) light microscope. Ultrathin 60-90 nm sections were collected on copper grids, stained with uranyl acetate and lead citrate, and examined with a Jeol JEM 1200 Ex (Japan) transmission electron microscope. Twenty cells from each specimen were examined. Mitochondria, nuclei, rough endoplasmic reticulum (RER) and smooth endoplasmic reticulum (SER) of hepatocytes were examined according to a previously described scoring system[11,12] (Table 1).

Results were expressed as means ± SEM. The significance of differences in histopathological and ultrastructural fibrosis scores and serum amylase activity were assessed by the Kruskal-Wallis test. $P < 0.05$ was considered significant.

RESULTS

After 4 wk UDCA treatment (by the end of wk 16), the most remarkable finding under electron microscopic examination of tissues from saline-treated animals (group Ⅰ) was irregular lamellar organizations of the RER. Large dilatations and focal breaks in the RER were also found in many areas (Figure 1A). Vacuolization in the SER and presence of myelin figures were the other prominent findings in saline-treated animals (Figure 1B). Many of the nuclei had irregular chromatin distribution and margination with clumping. An increase in heterochromatin was seen in some of the nuclei. Almost all of the mitochondria had prominent swelling that was much more severe than that in the UDCA-treated group. Another important finding was the collection of active fibroblasts in some focal areas of the liver.

Ultrastructural findings in the UDCA-treated group (group Ⅱ) were margination and clumping of the chromatin and a marked increase in the amount of heterochromatin (Figure 1C). Mild swelling of mitochondria was observed (Figure 1D). There were mild dilations in the SER and Golgi apparatus. However, vacuole formation in the SER was seen in only a few areas. There were also some breaks in the RER (Figure 1D and E).

When these findings were scored and evaluated according to the system shown in (Table 1), we found that mitochondria (44 ± 0.5 *vs* 61 ± 2, $t = 7.38$, $P < 0.001$), nuclei (29 ± 0.8 *vs* 46 ± 1.5, $t = 9.3$, $P < 0.001$), RER (30 ± 0.7 *vs* 56 ± 1, $t = 21.7$, $P < 0.001$), and SER (22 ± 0.5 *vs* 42 ± 1.2, $t = 15.3$, $P < 0.001$), and injury scores in group Ⅱ were significantly improved. Total electron microscopy score in group Ⅱ was also significantly lower when compared to that in group I (125 ± 2.3 *vs* 205 ± 3.7, $t = 18.2$, $P < 0.001$) (Figure 2).

DISCUSSION

The hepatocytes are the parenchyma cells of the liver, whose main function is synthesis of vital substances and removal of various kinds of molecules from the blood and their excretion into bile. Liver fibrosis is the result of deterioration of function of these cells, which results in initiation of many pathogenic events in the liver. As a result of parenchymal cell damage, activation of hepatic stellate cells occurs, which results in excessive production of collagen, and ultimately pathological and clinical features of cirrhosis develop[13].

UDCA has been shown to reduce hepatocellular damage in PBC. Treatment of patients with PBC with UDCA prevents deposition of perisinusoidal collagen[14]. It prevents hepatocyte apoptosis *in vitro* by inhibiting mitochondrial membrane permeability transition[15]. We performed this work to identify the ultrastructural changes in individual organelles of hepatocytes from UDCA-treated fibrotic livers. Histological changes in hepatic structure after CCl_4 treatment have been well documented. Indeed, most studies addressing antifibrotic efficacy of newly tested agents have been supported by direct evidence of histological changes, despite clear biochemical findings. However, electron microscopically supported morphological results are not frequent. Although there have been some ultrastructural studies of the effects of UDCA on the canalicular system, organelle-based activity of this antifibrotic agent may be helpful.

Although the liver has a high regeneration capacity, which can be linked to the phenomenon of spontaneous recovery, we still found severe hepatocyte organelle injury

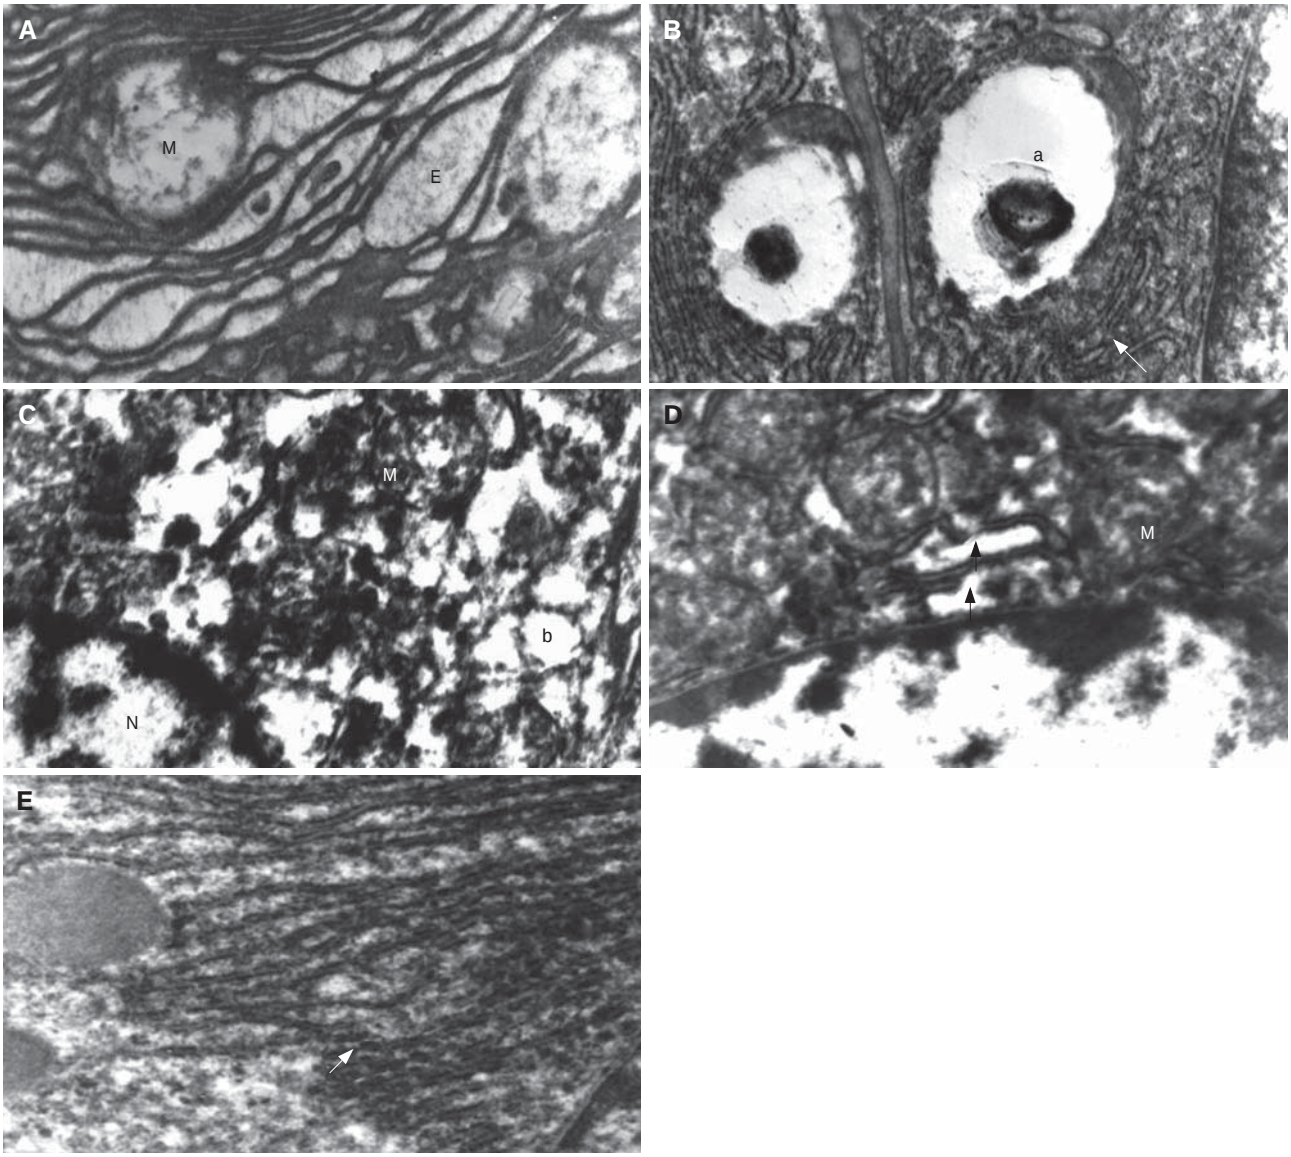

Figure 1 **A**: Electron micrograph showing irregular lamelar organizations and dilation of the RER (E) and swollen mitochondria (M) in the CCl_4 group (× 15 000); **B**: Electron micrograph showing myelin figures in the SER (a) and breaks in the RER (arrow) in group Ⅰ (× 20 000); **C**: Electron micrograph showing the margination and clumping of the chromatin in the nucleus (N), mild swelling in a mitochondrion (M), mild dilation in the SER (b) and breaks in RER in group Ⅱ (× 15 000); **D**: Electron micrograph showing mild swelling in the mitochondria (M) and breaks in the RER (arrow) in group Ⅱ (× 20 000); **E**: Electron micrograph showing normal RER (arrow) in group Ⅱ (× 20 000).

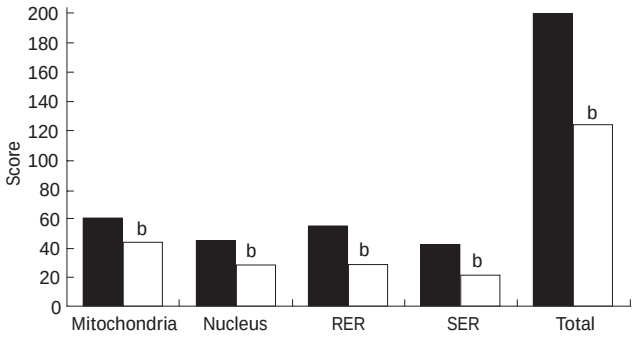

Figure 2 Ultrastructural injury scores in hepatocytes. Individual and total organelle injury scores decreased significantly in UDCA-treated compared with saline-treated animals. $^bP < 0.001$.

after 4 wk of saline administration in CCl_4-treated animals. Disrupted organization of the RER, vacuolization of the SER, and disorganization of nuclear content were indicative of severe organelle damage and established fibrosis. Munoz *et al* have reported a similar organization of ER with CCl_4 treatment in their study which examined the protective effect of adenosine on hepatotoxin-induced liver fibrosis[16]. They have also reported mitochondrial swelling and breaks in the ER after CCl_4 treatment.

Altered chromatin distribution in the nuclei was another noticeable finding in the hepatocytes following hepatotoxin exposure, which is suggestive of nuclear events taking place during necrosis and/or apoptosis. Heterochromatin is the condensed form of chromatin, with specific molecular characteristics and nuclear functions. It occurs around the centromeres and is involved in controlling the transcriptional state of the genome by gene silencing and nuclear organization. It lies next to the inner side of the

nuclear envelope and is broken up at the sites of nuclear pores. Abundant heterochromatin is seen in resting cells, whereas euchromatin is mostly found in transcriptionally active cells. We found a significant decrease in heterochromatin after 4 wk of UDCA treatment. This may be intranuclear morphological evidence of improving regular cell functions. Mitochondrial swelling, which is characteristic of deteriorated function of this organelle, decreased significantly with UDCA. Taken together with parallel changes seen in the nucleus, we could not conclude any association of this finding with apoptosis, although, antiapoptotic activity of UDCA on hepatocytes has previously been demonstrated[9]. Structural reversal of disrupted ER may also result from a beneficial effect of treatment with UDCA.

In conclusion, structural reversal of injured hepatocyte organelles is possible, and administration of UDCA greatly alleviates CCl_4-induced alterations of hepatocyte organelles. Nonetheless, these changes should be inspected at different time points during antifibrotic therapy, to identify the association of such structural recovery of different organelles.

COMMENTS

Background

Liver fibrosis and cirrhosis are mostly the results of chronic hepatocyte injury. A drug approved for the management of PBC (UDCA) is the mainstay of therapy of primary biliary cirrhosis (PBC) and has been reported to have antifibrotic activity in the liver. We investigated the ultrastructural changes after UDCA treatment in hepatocytes from experimentally induced liver fibrosis in rats.

Research frontiers

Understanding the changes in hepatocyte organelles during injury and recovery may be advantageous in developing new diagnostic and therapeutic tools.

Innovations and breakthroughs

An ultrastructural scoring system based on the specific findings of individual organelles is to be used for the first time on animal hepatocytes.

Applications

Transmission electron microscopy may be another tool to follow structural alterations in hepatocytes in the disease state.

Terminology

UDCA: A drug approved for the management of PBC.

Peer review

Significant alterations occur in hepatocyte organelles during CCl_4 administration and UDCA improves those changes to a great extent. Transmission electron microscopy may be used to follow morphological changes in the liver during injury and healing.

Abstract

AIM: To investigate peripheral T-lymphocyte subpopulation profile and its correlation with hepatitis B virus (HBV) replication in patients with chronic hepatitis B (CHB).

METHODS: Distribution of T-lymphocyte subpopulations in peripheral blood was measured by flow cytometry in 206 CHB patients. HBV markers were detected with ELISA. Serum HBV DNA load was assessed with quantitative real-time polymerase chain reaction (PCR). The relationship between HBV replication and variation in peripheral T-cell subsets was analyzed.

RESULTS: CHB patients had significantly decreased $CD3^+$ and $CD4^+$ cells and $CD4^+/CD8^+$ ratio, and increased $CD8^+$ cells compared with uninfected controls (55.44 ± 12.39 *vs* 71.07 ± 4.76, 30.92 ± 7.48 *vs* 38.94 ± 3.39, 1.01 ± 0.49 *vs* 1.67 ± 0.33, and 34.39 ± 9.22 *vs* 24.02 ± 4.35; $P < 0.001$, respectively). Univariate analysis showed a similar pattern of these parameters was significantly associated with high viral load, presence of serum hepatitis B e antigen (HBeAg) expression, liver disease severity, history of maternal HBV infection, and young age at HBV infection, all with $P < 0.01$. There was a significant linear relationship between viral load and these parameters of T-lymphocyte subpopulations (linear trend test $P < 0.001$). There was a negative correlation between the levels of $CD3^+$ and $CD4^+$ cells and $CD4^+/CD8^+$ ratio and serum level of viral load in CHB patients (r = -0.68, -0.65 and -0.75, all $P < 0.0001$), and a positive correlation between $CD8^+$ cells and viral load (r = 0.70, $P < 0.0001$). There was a significant decreasing trend in $CD3^+$ and $CD4^+$ cells and $CD4^+/CD8^+$ ratio with increasing severity of hepatocyte damage and decreasing age at HBV infection (linear trend test $P < 0.01$). In multiple regression (after adjustment for age at HBV infection, maternal HBV infection status and hepatocyte damage severity) log copies of HBV DNA maintained a highly significant predictive coefficient on T-lymphocyte subpopulations, and was the strongest predictor of variation in $CD3^+$, $CD4^+$, $CD8^+$ cells and $CD4^+/CD8^+$ ratio. However, the effect of HBeAg was not significant.

CONCLUSION: T-lymphocyte failure was significantly associated with viral replication level. The substantial linear dose-response relationship and strong independent predictive effect of viral load on T-lymphocyte subpopulations suggests the possibility of a causal relationship between them, and indicates the importance of viral load in the pathogenesis of T cell hyporesponsiveness in these patients.

Effect of viral load on T-lymphocyte failure in patients with chronic hepatitis B. *World J Gastroenterol* 2008; 14(7): 1112-1119 Available from: URL: http://www.wjgnet.com/1007-9327/14/1112.asp DOI: http://dx.doi.org/10.3748/wjg.14.1112

INTRODUCTION

Hepatitis B virus (HBV) is one of the most prevalent

viral pathogens in humans, with almost a third of the world population having evidence of infection, and about 350 million chronically infected patients[1]. Chronic hepatitis B (CHB) is characterized by inflammatory liver disease of variable severity and is associated with a significantly increased risk of cirrhosis, liver failure and hepatocellular carcinoma[1,2]. Seventy-five percent of patients with CHB are Asian[3]. In China, > 120 million people are chronic carriers of HBV, and 40%-60% catch HBV infection from their mothers[1,2]. For neonates and children younger than 1 year who acquire HBV infection perinatally, the risk of the infection becoming chronic is 90%[1,2].

The pathogenesis of persistent viral infection and hepatitis B is very complex. Both viral factors, as well as the host immune response, have been implicated in the pathogenesis and clinical outcome of HBV infection[4,5]. Apart from direct biological effects of viral variants, there is a growing consensus that the host immune response, especially the virus-specific T cell response, is the key determinant influencing the course of disease and the onset of liver disease[5,6]. Many investigators suggest the chronicity of HBV infection is caused by a deficient cellular immune function, but the mechanism has not been defined[7-9]. For a non-cytopathic virus like HBV to persist, it must either overwhelm or not induce an effective antiviral immune response, or it must be able to evade it. Hepatitis B e antigen (HBeAg) may play an important role in the interaction of the virus with the immune system. Data from transgenic mice indicate neonatal tolerance to HBeAg is a crucial mechanism responsible for the lack of an antiviral immune response following mother to infant transmission[10,11]. Milich *et al*[12] have further demonstrated an immunomodulatory role of HBeAg in antigen presentation and recognition by $CD4^+$ cells.

The relationship between HBV specific T-cell response, HBV viral load and HBeAg expression in CHB is complicated by their close correlation and remains unclear. In China, where vertical perinatal transmission is the main route of transmission, most patients with CHB have become infected in the early years of life. The influence of age at infection and maternal HBV infection status on T-cell immune status and HBV replication is still not settled. The aim of the present study was to evaluate the peripheral blood T lymphocyte subpopulation profile and its correlation with HBV replication.

MATERIALS AND METHODS

Enrollment of study subjects

Two hundred and six consecutive patients with CHB who were admitted to the department of Infectious Diseases of the First Affiliated Hospital of Kunming Medical University, the Third Municipal People's Hospital of Kunming and the Yunnan General Hospital of The Chinese People's Armed Police Forces, between January 2006 and May 2007, were prospectively enrolled into the study. The clinical diagnosis was based on liver function tests, hepatitis virus markers, ultrasonography and histopathology. The diagnosis of all the patients was confirmed according to the criteria for viral hepatitis[13,14]. The following criteria were fulfilled by all patients: (1) steady positivity for hepatitis B surface antigen (HBsAg) in the serum for at least 12 mo, to establish CHB; and (2) exclusion of other concomitant causes of liver disease (hepatitis C, D and HIV infection and alcohol consumption > 60 g/d), relatively rare liver disease (autoimmune hepatitis and metabolic liver disease), and treatment with immunosuppressive therapy or antiviral therapy for HBV infection within the past 12 mo before entry. None of the patients was a drug user, or exposed to hepatotoxin. Those who had liver cirrhosis were also excluded since their long history of treatment and terminal disease state may have complicated the interpretation of the results.

One hundred individuals who were free of HBsAg were identified from those attending the outpatient service for a health check-up; 61 of the participants were male, 39 were female; mean age, 33.24 (SD 10.28) year. These served as the control group for comparison of T-lymphocyte subpopulations with those who had HBV infection.

Serological liver function tests and HBV marker evaluation

Serum alanine aminotransferase (ALT), aspartate transaminase (AST) and total bilirubin were tested with routine automated techniques (upper limit of normal; 40 U/L, 40 U/L and 17.1 μmol/mL, respectively) (AU2700, Japan). HBV markers (HBsAg, HBsAb, HBeAg, HBeAb, HBcAb, Anti-HBcAb IgM) were measured at a virological laboratory with the use of ELISA (Anthos 2010, Austria). The experimental methods followed those specified within the reagent kit package insert (Sino-American Biotech Co., Ltd, Shanghai, China).

Quantitative measurement of HBV DNA (viremia)

Serum HBV DNA load in patients was assessed with the real-time fluorescent quantitative polymerase chain reaction method (real-time PCR) using a Lightcycler PCR system (FQD-33A, Bioer, Hongzhou, China) with a lower limit of detection of about 1000 viral genome copies/mL. The handling procedures were performed in strict accordance with the reagent kit package insert (Shenzhen PG Biotech Co., Ltd., Shenzhen, China). The primer was provided in the kit, the reaction volume was 40 μL, and the reaction conditions were 37℃ for 5 min, 94℃ for 1 min, then 40 cycles at 95℃ for 5 s and 60℃ for 30 s. Results were considered abnormal when HBV DNA was > 1000 copies/mL.

Peripheral blood T lymphocyte subsets measurement

Blood samples were collected in heparinized vacutainer tubes. Samples were analyzed with a Muti-Q-Prep processor (Coulter, USA) and thereafter Epics-XL flow cytometry (FCM) (Coulter). Lymphocytes were analyzed using a gate set on forward scatter versus side scatter. Anti-human monoclonal antibodies CD3-PE-CY5/CD4-FITC/CD8-PE were purchased from Immunotech (USA). For each sample, detection was carried out using CELLQuest software (Coulter). The results were expressed as the percentages of $CD3^+$, $CD4^+$ and $CD8^+$ cells found to be positive for the marker antigen in the total T cell

population. The handling procedures were performed in strict accordance with the manufacturer's instructions.

Maternal HBV infection status (MH)

MH was confirmed according to the maternal presence of serum HBV markers and/or HBV DNA, documented on at least two occasions, at least 3 mo apart; or documented maternal death from HBV-related liver diseases such as CHB, HBV-related liver cirrhosis and/or hepatocellular carcinoma.

Age at HBV infection

In the past three decades in China, all children have been obliged to be tested for HBV markers when they first go to kindergarten and elementary school. Subsequent obligatory tests are carried out when they apply for university or a job. The results of these tests were obtained from medical records and interviews. We classified the age of the first positive test as < 8 years, 8-20 years and > 20 years old.

Statistical analysis

Initial sample size calculation came up with 50 subjects positive for HBV DNA positive and the same number negative. This provided the study with a statistical power of 80% at the 0.025 level of significance to detect a difference in T-cell variation values of 33 *versus* 38. However, to cover the problem of being potentially confounded by other variables, and to have enough subjects for stratifying levels of HBV DNA load to examine a dose-response relationship, 206 CHB patients and 100 controls were recruited.

Descriptive statistics were used to examine the age, gender, serum HBV load, HBeAg status, ALT, AST, total bilirubin, age at HBV infection and maternal HBV infection status. The levels of T-lymphocyte subpopulation in normal individuals (HBsAg-negative) were summarized as means ± SD, to serve as a control reference. Effects of various independent demographic, clinical and serological variables on T-cell profile were analyzed only among HBsAg-positive individuals. In univariate analysis, breakdown of these profiles by individual independent variables was carried out. An independent *t* test was done for two-level independent variables and one-way ANOVA for more than two-level variables. The relationship between HBV replication and peripheral T-lymphocyte subpopulation was analyzed by correlation analysis and ANOVA linear trend test. Finally, a multiple linear regression model was employed for multivariate analysis to assess the independent effects of variables on peripheral blood T lymphocytes. Variables yielding $P \leqslant 0.2$ in univariate analysis were included in the multivariate analysis, and the models were refined by backward elimination, guided by a change in log likelihood of successive models. A final $P < 0.05$ was considered statistically significant. Computations were carried out with the aid of R software version 2.5.1[15].

RESULTS

Demographic characteristics and clinical features of CHB patients

The demographic, virological, serological and clinical characteristics of the patients are summarized in Table 1.

Over two-fifths of the CHB patients acquired the infection before the age of 8 year. Almost three-quarters had detectable levels of HBV DNA. Among these, the majority (57.7%) had > 10^7 copies/mL. Around half of the patients' mothers were HBV-positive. A little less than half were HBeAg-positive (46.6%). Among various courses of CHB, all severe-CHB patients had detectable levels of HBV DNA; the majority of severe-CHB patients

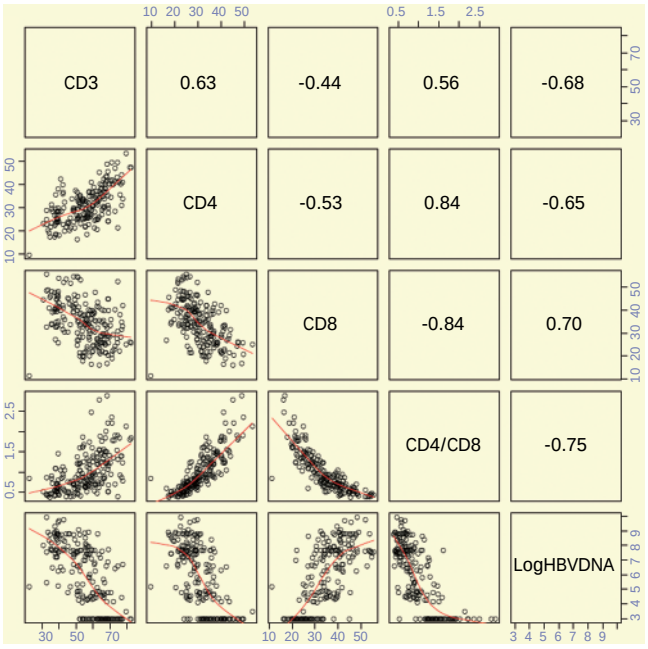

Figure 1 Correlation between peripheral T-cell subsets and serum level of HBV viral load.

had higher viral load (82.4%), higher titer of HBV DNA in serum, higher serum positivity of HBeAg (78.4%), higher maternal HBV infection status (70.6%) and lower age at HBV-infection than mild-CHB and moderate-CHB patients (all $P < 0.01$). The severity of liver diseases was significantly associated with HBV replication status, including higher viral load and HBeAg expression, all with $P < 0.001$ (Table 1).

Over two-thirds of the CHB patients with MH acquired the infection before the age of 8 year (79.8%), whereas age of HBV infection of > 20 years was more common in non-MH patients. Higher positivity of serum HBV DNA and of HBeAg were observed in MH patients than in non-MH individuals (92.3% *vs* 52.0%, OR = 10.96, 95% CI 4.7-28.85; 56.7% *vs* 36.3%, OR = 2.29, 95% CI 1.27-4.19; respectively). The percentage of cases with higher-viral-load viremia (> 10^7 copies/mL) was higher in MH patients than that in the non-MH group (57.7% *vs* 25.5%, OR = 3.96, 95% CI 2.12-7.54). A greater proportion of non-MH individuals had an undetectable-viral-load viremia (< 10^3 copies/mL) compared with MH individuals (48.0% *vs* 7.7%, OR = 10.96, 95% CI 4.7-28.85). A higher double-positivity of serum HBV DNA and HBeAg existed in MH individuals, significantly higher than in non-MH patients (56.7% *vs* 36.3%, OR = 2.29, 95% CI 1.27-4.19).

Peripheral T-lymphocyte subpopulation composition in CHB patients

CHB patients had significantly decreased total CD3$^+$ and CD4$^+$ subpopulations and CD4$^+$/CD8$^+$ ratio, and increased CD8$^+$ subsets compared with uninfected controls, all with $P < 0.001$. Univariate analysis showed that T-cell failure was significantly associated with higher viral load, serum HBeAg expression, severity of liver disease, history of maternal HBV infection, and lower age at HBV infection (Table 2). Linear dose-response relationship between the level of T-lymphocyte subpopulation and copies of HBV DNA was also highly significant (linear trend test $P < 0.001$). A negative correlation existed between the levels of CD3$^+$ and CD4$^+$ cells and CD4$^+$/CD8$^+$ ratio and serum HBV viral load, whereas a positive correlation existed between the level of CD8$^+$ cells and viral load, all with $P < 0.0001$. Correlation between T lymphocytes and viral load is shown in Figures 1 and 2.

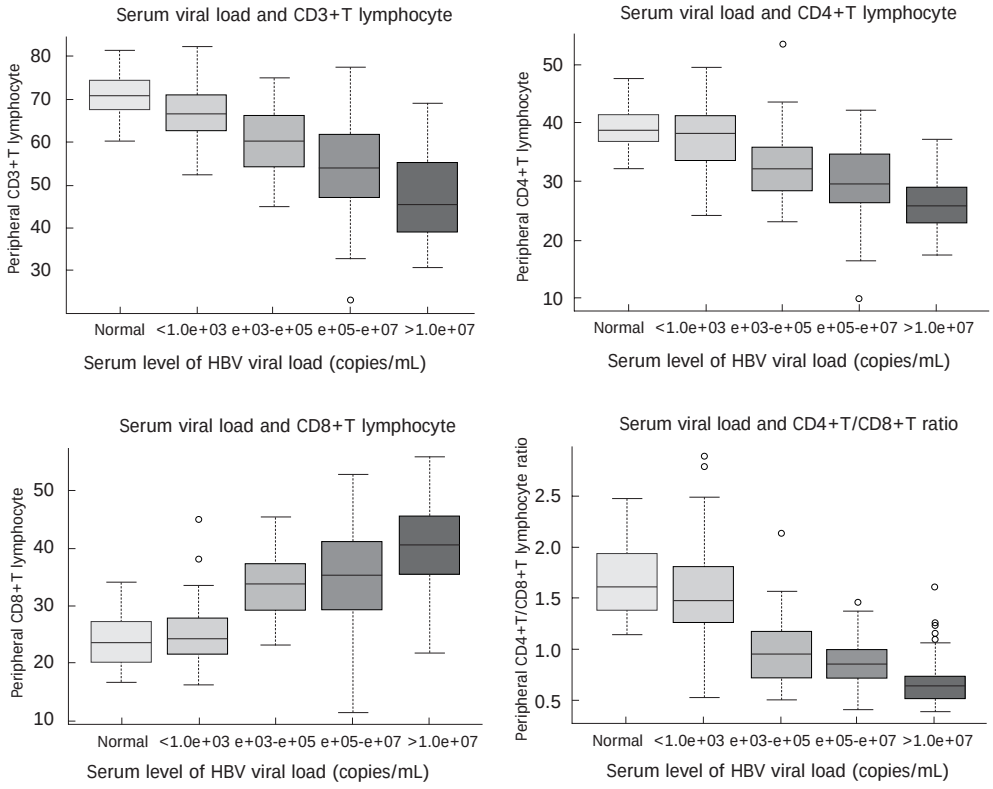

Figure 2 Peripheral T-lymphocyte subpopulations by serum HBV viral load level. On the figure, the marks "<1.0e+03", "e+03-e+05", "e+05-e+07" and ">1.0e+07" denote "< 10^3", "10^3-10^5", "10^5-10^7" and "> 10^7", respectively.

β: Coefficients from the model. [1]Continuous variable; [2]Reference group: HBeAg-negative; [3]Reference group: mild-CHB; [4]Reference group: < 8 yr old age at HBV infection; [5]Reference group: With maternal HBV-infection status.

Furthermore, there was a significant decreasing trend of $CD3^+$ and $CD4^+$ cells and $CD4^+/CD8^+$ ratio with increasing hepatocytic damage; this was inverse for $CD8^+$ cells. A similar pattern was also seen among age at HBV infection, all with a linear trend test *P* value < 0.01.

Linear regression predicting peripheral blood T-lymphocyte subpopulation from relevant parameters

In Table 3, linear regression models are separately summarized for $CD3^+$, $CD4^+$ and $CD8^+$ cells and $CD4^+/CD8^+$ ratio, which are the dependent variables. After adjustment for all independent variables listed in the table, serum HBV viral load was the key predictor for T-cell profile. The severity of liver disease reduced the number of $CD3^+$ T lymphocytes, increased the number of $CD8^+$ T cells, and decreased the $CD4^+/CD8^+$ ratio. Those who had infection at a young age had a lower $CD4^+$ T cell count and $CD4^+/CD8^+$ ratio than those who acquired infection later in life. Maternal infection history and serum HBeAg expression had no independent effect on T-lymphocyte profile.

DISCUSSION

This study demonstrated disorder of cellular immune function in CHB patients. The level of T-cell dysfunction had a linear dose-response relationship with the load of HBV DNA. Furthermore, the study also illustrated that the strong independent effect of HBV viral load seemed to eliminate and/or weaken the effects of liver disease severity, maternal carrier status, early age of infection and HBeAg positivity on the impairment of T-cell function.

Our findings indicate that CHB patients have T-cell failure. The same finding has also been demonstrated previously, namely, that the chronicity of HBV infection is caused by a deficiency in cellular immune function[16-20], and hepatocyte damage is mainly caused by immunological injury[21-29]. However, the mechanism has not been defined[5]. Apart from direct biological effects of viral variants, there is a growing consensus that the host immune response, especially the virus-specific T-cell response, is the key determinant influencing the course of disease and the onset of liver disease[5,6,30]. The significant decrease in total T lymphocyte ($CD3^+$ T) revealed that there is a lack of immunologically competent cells involved in cellular immunoreactivity against HBV infection. A lack of $CD4^+$ T cells can impair $CD8^+$ T-cell activity and antibody production[31], while the inability to mount a virus-specific $CD8^+$ T-cell response results in a level of circulating virus that cannot be cleared by antibodies alone[32-34]. Activation-induced cell death (AICD) is related to a decrease in lymphocytes and functional defects. This phenomenon can cause decreased immune clearance. This may be an important reason for persistent infection with HBV. AICD in peripheral blood T lymphocytes in CHB has been demonstrated previously[35,36]. Thus, AICD is considered an important modulator in down-regulating the "burst" of responding T cells in patients with CHB[36].

Our results revealed T-cell failure was significantly associated with viral replication level. The substantial linear dose-response relationship and strong independent predictive effect of HBV DNA, but not other variables, on T-lymphocyte subpopulations suggests the possibility of a causal relationship between them. However, the cross-sectional nature of our data did not allow us to identify the temporal direction of the causal relationship between these two variables. Mizukoshi *et al*[37] have suggested antiviral therapy of persistently infected patients appears to increase the frequency of HBV-specific $CD4^+$ T-cell responses during the first year of treatment. Boni *et al*[38,39] have reported antiviral treatment can overcome $CD8^+$ T-cell hyporesponsiveness in subjects with CHB, which suggests the T cells are present but suppressed. It has been reported by Pham *et al*[40] in 21 CHB patients that the ratio of $CD4^+/CD8^+$ liver-derived lymphocytes, but not of peripheral blood lymphocytes, appears to be related to the level of HBV replication, which reveals a positive correlation with viral load. The evidence that an efficient antiviral T-cell response can be restored by antiviral monotherapy in CHB, concurrently with reduction of viremia, indicates the importance of viral load in the pathogenesis of T-cell hyporesponsiveness.

The strong independent effect of viral load on T-cell impairment and viral factors (viral variants) might explain the disappearance of the effect of other variables in multivariate analysis. Among our patients, the majority were characterized by young age at first HBV infection, maternal carrier status, and high serum viral load, especially in severe CHB patients. In addition to HBV DNA, HBeAg is also a serological marker for viral replication, which plays a crucial role in chronicity of HBV infection and high viral load, by inducing immunological tolerance to HBV in the fetus. The tolerance-inducing effect of HBeAg has been well characterized in mice[41-43] and likely contributes to the low level of core-specific T-cell responses present in HBeAg-positive CHB patients[4,5]. Clinical evidence supports the tolerogenic effect of HBeAg[5,44]. Also, viral mutations that abrogate or antagonize antigen recognition by virus-specific T cells have been reported in patients with CHB[45,46]. Although the results from univariate analysis in our study showed T-cell dysfunction was significantly related to HBeAg, the association disappeared in multivariate analysis. One possible reason is that some of the subjects were infected with pre-C stop codon mutation virus (pre-C/C mutant), which resulted in a loss of HBeAg. In these patients, therefore, viral replication may have persisted, despite elimination of HBeAg and seroconversion to anti-HBe. While the loss of HBeAg appears irrelevant to the biology of the virus, it may play an important role in the interaction of the virus with the immune system. This may weaken the independent association between HBeAg and T-cell failure, so that the sample size in our study could not detect this magnitude of association. Moreover, those who had a history of maternal carriage usually acquired infection at a younger age, and a higher HBV viral load was detected in the majority of those who had infection at a younger age. In the same way, those who had severe liver damage were usually positive for maternal HBV carrier status and acquired infection in early life, thus a high viral load was measured in these patients. This phenomenon suggests that infection from the mother and/or at younger age predisposes to tolerance to HBV infection and thus, higher viral load.

Our study clearly showed the severity of the liver disease was significantly associated with functional disorder of T-lymphocytes, and the effect was independent of viral load. Hepatocyte damage may also be correlated directly with T-cell failure, rather than through the load copies of viral replication. Previous studies have suggested that hepatocyte damage is mainly caused by immunological injury[9,21-30]. HBV is a typical non-cytopathic virus that can induce tissue damage of variable severity by stimulating a protective immune response that can simultaneously cause damage and protection, by killing an intracellular virus through the destruction of virus-infected cells[5]. Therefore, immune elimination of infected cells can lead to the termination of infection when it is efficient, or to a persistent necroinflammatory disease when it is not[47]. Destruction of infected cells, however, is not the only mechanism implicated in the elimination of intracellular virus, as demonstrated by studies carried out in animal models of HBV infection and in human hepatitis B, which demonstrate the importance of cytokine-mediated, non-cytolytic mechanisms of anti-viral protection[20-31].

The strength of this study lies in the large sample size and the measurements of T-lymphocyte subpopulations using modern advanced FCM technology and viral load with quantitative real-time PCR. A limitation of this study is that the specificity of T-lymphocyte subpopulations and liver-derived T-lymphocytes were not explored concurrently. Although a strong relationship between T-lymphocyte subpopulations and viral load was illustrated, further studies are needed to confirm the causal relationship between them.

Our results, which suggest high viral load contributes to functional impairment of T cells in CHB patients, have practical implications for understanding the pathogenesis and control of persistent viral infection and diseases progression and prognosis. This is because patients with CHB are at risk of persistent viral infection that leads to liver failure, cirrhosis and even hepatocellular carcinoma[1,2]. We should take into account effective intervention strategies such as anti-viral and/or immunotherapy to prevent progression and long-term consequences. Inhibition of viral replication with agents such as lamivudine may enhance the likelihood that therapeutic stimulation of the T-cell response will induce HBV antigen seroconversion, ultimately leading to recovery from disease. Further clinical studies are needed to explore this possibility in persistent HBV-infected patients.

In conclusion, we found a strong, independent predictive effect of viral load on T-lymphocyte subpopulations, which suggests a causal relationship between viral load and T-cell failure. T-cell dysfunction might contribute to viral persistence. HBV establishes persistent infection mainly by vertical transmission from HBV-infected mothers to neonates, and the immunomodulatory effects of HBeAg might play an important role in this setting. High viral load may be one important factor that contributes to T-lymphocyte failure, and is more important than HBeAg in this regard. Clearly, additional studies are required to better understand the complex host-virus interactions that determine the persistence and outcome of HBV infection.

COMMENTS

Background

HBV infection is a global public health problem. Infection with hepatitis B virus (HBV) leads to a wide spectrum of clinical presentations ranging from an asymptomatic carrier state to self-limited acute or fulminant hepatitis to chronic hepatitis with progression to cirrhosis and hepatocellular carcinoma. But the pathogenesis of persistent viral infection and hepatitis B is very complex and has not been clarified until now. Generally, it is not HBV itself that damages hepatocytes directly, but the results of function disorder of cell-mediated immunity. The outcome of HBV infection would depend upon the balance between development of immunity (leading to virus elimination) and tolerance (leading to chronic viral persistence).

Research frontiers

Outcome of infection and the pathogenesis of liver disease are determined by virus and host factors, which have been difficult to fully elucidate because the host range of HBV is limited to man and chimpanzees. The pathogenesis of liver disease and interaction between virus and host remain the research hotspots in this field.

Innovations and breakthroughs

The pathogenesis and correlation of functional disorder of cellular immune and viral replication level remains unknown. In our study, peripheral T-lymphocyte subpopulation of chronic hepatitis B (CHB) patients in large sample size were measured using advanced flow cytometry technology and viral load with quantitative real-time polymerase chain reaction (PCR) method. The results suggest T-lymphocyte failure was significantly associated with viral replication level. The substantial linear dose-response relationship and strong independent predictive effect of viral load on T-lymphocyte subpopulations suggests close proximity of the causal pathway between them, and indicates the importance of viral load in the pathogenesis of T cell hyporesponsiveness in these patients.

Applications

The results, which suggest high viral load contributes to functional impairment of T-cell in CHB patients, have practical implications because the understanding of the immune response upon HBV infection is useful in developing appropriate therapeutic strategies for controlling viral hepatitis and disease progression, as well as for improving current knowledge regarding persistent HBV infection prognosis. In addition, it will be possible to predict the variation of T-lymphocyte subpopulations in peripheral blood in the future by measuring serum viral load level in chronic HBV-infected patients.

Terminology

$CD4^+$ T cells, classically referred to as helper T cells that are required for the efficient development of effector cytotoxic/suppressor $CD8^+$ T-cell and B-cell antibody production, play an important role in HBV infection by secretion of Th1 cytokines that down-regulate HBV replication, and by promoting $CD8^+$ T-cell and B-cell responses. $CD8^+$ T cells go on to clear HBV-infected hepatocytes through cytolytic and non-cytolytic mechanisms, reducing the levels of circulating virus, while B-cell antibody production neutralizes free viral particles and can prevent (re)infection. $CD3^+$, $CD4^+$ and $CD8^+$ cells are major function subgroups of T cells and play an important role in response to HBV infection, which can reflect the situations of cellular immune function and immunoregulation and are usually regarded as a valuable index to forecast the changes of patients' immunity.

Peer review

The authors demonstrated the correlation between T-lymphocyte subpopulation profile and HBV replication level in Chinese patients. Their findings are of some importance.

Abstract

AIM: To analyze the difference of intestinal microbial community diversity between healthy and (*S. enteritidis*) orally infected ducklings.

METHODS: Enterobacterial Repetitive Intergenic Consensus (ERIC)-PCR was applied to analyze the intestinal microbial community diversity and dynamic change including duodenum, jejunum, ileum, cecum and rectum from healthy ducklings and 7-day-old ducklings after oral infection with *S. enteritidis* at different time points.

RESULTS: The intestinal microbial community of the control healthy ducklings was steady and the ERIC-PCR band numbers of the control healthy ducklings were the least with rectum and were the most with caecum. ERIC-PCR bands of orally inoculated ducklings did not obviously change until 24 h after inoculation (p.i.). The numbers of the ERIC-PCR bands gradually decreased from 24 h to 72 h p.i., and then, with the development of disease, the band numbers gradually increased until 6 d p.i. The prominent bacteria changed because of *S. enteritidis* infection and the DNAstar of staple of ERIC-PCR showed that aerobe and facultative aerobe (*Escherichia coli*, *Shigella*, *Salmonella*) became preponderant bacilli in the intestine of orally infected ducklings with SE.

CONCLUSION: This study has provided significant data to clarify the intestinal microbial community diversity and dynamic change of healthy and *S. enteritidis* orally infected ducklings, and valuable insight into the pathogenesis of *S. enteritidis* infection in both human and animals.

INTRODUCTION

Salmonella enteritidis (*S. enteritidis*) remains one of the main causes of food-borne illness and as such is considered to be the most important pandemic zoonosis produced under natural conditions[1-3]. It is estimated that the worldwide incidence is more than a thousand million cases, causing three million deaths each year. *S. enteritidis* can through the food production chain pass to humans, therefore

undercooked or raw eggs and poultry meat are of a high risk for humans[4,5]. Infections caused by Salmonella bacteria belong to the most common zoonotic diseases worldwide[6]. Outbreaks of human salmonellosis caused by *S. enteritidis* have dramatically increased throughout the world since the mid-to-late 1980s and have become an important problem for the poultry industry and public health.

Intestinal microflora plays an important role in digestive function, immunity, and disease resistance. It becomes clear that intestinal resident and in-transit micro-organisms play an essential role in the homeostasis of local and systemic immunity[7,8]. A large number of microbial species exist in gastrointestinal tract. However, traditional culture-based techniques are inappropriate in studying the structure-function relationship of microbial communities due to their highly selective, laborious and time-consuming nature. Only a relatively small fraction of population members in a complex natural community, such as gastrointestinal system, can be recovered with culture-based techniques[9]. ERIC-PCR method developed in recent years can simultaneously compare sequence-based structural features of large numbers of community samples[10-14]. In this study, to understand the changes of intestinal microbial communities of *S. enteritidis*-infected ducklings, ERIC-PCR method was used to fingerprint the kinetics of microbial community of fecal samples of orally infected ducklings with *S. enteritidis*, which will provide valuable insight into the pathogenesis of *S. enteritidis* infection.

MATERIALS AND METHODS

Bacterial strain

S. enteritidis (Duck, No.MY1) was isolated and maintained by Avian Disease Research Center, College of Veterinary Medicine of Sichuan Agricultural University.

Ducklings

The study was conducted with 68 7-day-old white Peking ducklings (the serum and feces samples of all experimental ducklings were tested and found to be *S. enteritidis* negative by PCR methods). All these ducklings were maintained in isolation units in a biosecure animal building and fed a commercial ducklings diet ad libitum. Two groups of ducklings were included in this study. Group 1 was used to test the dynamic change of intestinal microbial community diversity and 48 ducklings in this group were randomly divided into part A (24 orally inoculated ducklings) and part B (24 control healthy ducklings). Ducklings in part A were orally infected with 0.2 mL *S. enteritidis* culture solution (4×10^9 CFU/mL) and ducklings in part B were simultaneously administrated with 0.2 mL isotonic Na chloride. The clinical signs and pathological lesions of infected ducklings were monitored until 21 d after inoculation (p.i.) and the mortality was recorded in Group 2. In this group, 20 ducklings were averagely divided into two parts (C and D) at random. Ten ducklings in part C were orally infected with 0.2 mL *S. enteritidis* culture solution (4×10^9 CFU/mL) and 10 ducklings in part D took simultaneously 0.2 mL isotonic Na chloride.

Collection of samples

Ducklings in Group 1 were killed and sampled at 30 min, 1 h, 2 h, 4 h, 8 h, 12 h, 24 h, 36 h, 48 h, 72 h, 6 d, 9 d p.i.. At each of the 12 sampling time points between 30 min and 9 d p.i., two ducklings of each part in Group 1 were chosen randomly for sampling. Five samples were collected from each duckling, including contents from 3 cm-long duodenum, jejunum, ileum, caecum and rectum tissues. Fresh samples were collected, put into 80% glycerol and stored at -70℃ before DNA extraction.

Total DNA extraction and purification

DNA extraction procedure modified from Wei G *et al*[15] was used to prepare the DNA templates for PCR reactions to ensure that stable, representative and reproducible fingerprints were obtained. The sample above was suspended in 15 mL sterile 0.05 mol/L phosphate buffered saline (PBS) (1 L contained 1.48 g $NaH_2PO_4.2H_2O$, 14.45 g NaH_2PO_4, 4.0 g NaCl; pH 7.4) followed by vortexing for 15 min in an 50-mL tube. The suspension was centrifuged at 600 × *g* for 5 min and transferred to a new tube. This was repeated three times to remove coarse particles. The cells in the supernatant were collected and washed once by centrifuge at 9000 × *g* for 3 min followed by resuspension in 15 mL 0.05 mol/L PBS. The cell pellets were washed three times by centrifuge at 9000 × *g* for 5 min in 5 mL acetone precooling at -20℃. The washed cell pellets were collected in a new 1.5 mL tube and resuspended in 200 μL solution I (50 mmol/L Tris-base, 50 mmol/L Na_2EDTA, pH 7.8), the suspension was mixed with 40 μL lysozyme solution (50 mg/mL), water-bathed for 30 min at 37℃ with gentle mixing by inverting the tube every 10 min, and then was combined with 500 μL solution Ⅱ (200 mmol/L NaCl, 100 mmol/L Tris-base, 50 mmol/L Na_2EDTA, 2.0% SDS, 1.0% Triton X-100) and 12.5 μL Proteinase K, water-bathed for 12 h at 37℃. RNA was digested by adding RNase (0.80 g/L) at 37℃ for 20 min. DNA was then purified by sequential extraction with Tris-equilibrated phenol, phenol and chloroform-isoamyl alcohol (25:24:1), and chloroform-isoamyl alcohol (24:1) followed by precipitation with two volumes of ethanol. DNA was collected by centrifugation, air dried and dissolved in 40 μL sterile TE buffer.

The total DNA samples prepared with the above protocol were characterized with agarose gel electrophoresis for integrity and size. The DNA was adjusted to 40 ng/μL and stored at -20℃ before used as templates for PCR. Two μL DNA sample was added to 23 μL PCR mixtures for each PCR reaction.

DNA fingerprinting

Community fingerprints were obtained for intestinal microflora using total DNA as templates for ERIC-PCR. The sequence of the ERIC primers was based on work by Versalovic *et al*[16], E1 (ERIC1): 5'-ATGTAA GCTCCTGGGGATTCAC-3', E2 (ERIC2): 5'-AAGT AAGTGACTGGGGTGAGCG-3'. Each 23 μL PCR reaction mixture contained 25 pmol of each primer, 5 mmol/L each deoxynucleoside triphosphate (dNTP) and 2.5 U of Taq DNA polymerase (Promega, USA) in the manufacturer's provided buffer. Two microliters of

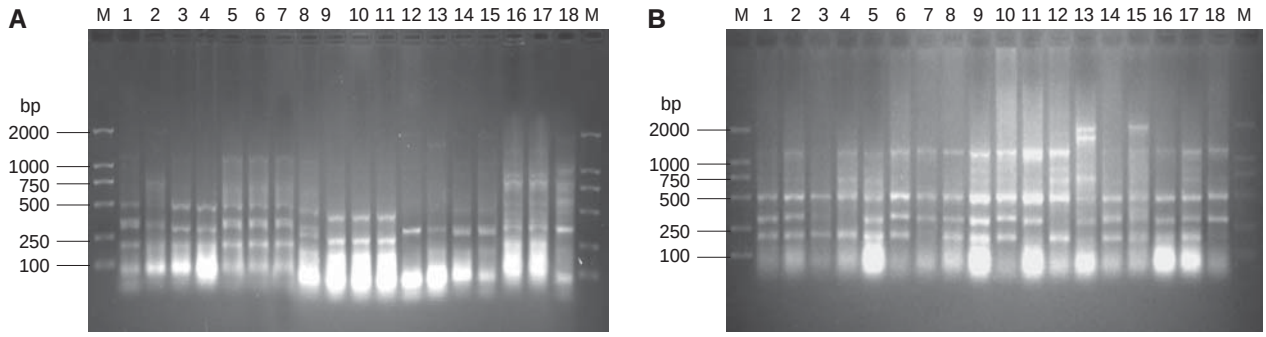

Figure 1 ERIC-PCR results of healthy and orally infected ducklings at different time points. (**A**) M: DL-2000; 1: 6 d duodenum; 2: 72 h duodenum; 3: 24 h duodenum; 4: 1 h duodenum; 5: 6 d ileum; 6: 72 h ileum; 7: 24 h ileum; 8: 1 h ileum; 9: 6 d jejunum; 10: 72 h jejunum; 11: 24 h jejunum; 12: 1 h jejunum; 13: 6 d rectum; 14: 24 h rectum; 15: 1 h rectum; 16: 6 d caecum; 17: 24 h caecum; 18: 1 h caecum. (**B**) M: DL-2000; 1: 1 h duodenum; 2: 24 h duodenum; 3: 72 h duodenum; 4: 6 d duodenum; 5: 1 h jejunum; 6: 24 h jejunum; 7: 72 h jejunum; 8: 6 d jejunum; 9: 1 h ileum; 10: 24 h ileum; 11: 72 h ileum; 12: 6 d ileum; 13: 1 h caecum; 14: 24 h caecum; 15: 6 d caecum; 16: 1 h rectum; 17: 24 h rectum; 18: 6 d rectum.

total fecal DNA (about 80 ng) was added to reach the final 25 μL PCR reaction volume. PCR amplifications were performed in an automated thermocycler (Hybaid, USA) using the following program: 7 min at 95℃; 30 cycles of denaturation at 95℃ for 30 s, annealing at 50℃ for 1 min and extension at 65℃ for 8 min; followed by a final extension at 65℃ for 16 min[14]. The concentrations of the PCR products were determined by DNA Quant 200 fluorometer (Pharmacia, USA) and resolved in 1.5% agarose gel electrophoresis with 300-400 ng total PCR products loaded in each lane. The gels were stained with ethidium bromide and photographed with Bio-Rad, VersaDoc Model 2000.

Cloning and sequencing of DNA fragments from major bands[17]

Gel slices containing individual major DNA bands were excised and transferred into sterile 1.5 mL Eppendorf tubes and purified by UltraClean 15 DNA Purification Kit (MO BIO, USA), according to the manufacturer's instructions. The purified DNA was dissolved in 30 μL sterile water and the concentration was determined by DyNA Quant 200 fluorometer (Pharmacia). The purified fragments were ligated with vector pGEM-T Easy (Promega) and transformed into Escherichia coli DH5α. The transformants were plated on Luria-Bertani (LB) plates containing ampicillin and X-Gal/IPTG. The plasmids were extracted using the alkaline lysis method. For each part of experimental group, two clones were selected for sequencing (TaKaRa, Beijing). The sequences were analyzed with the BLAST program at the NCBI website (http://www.ncbi.nlm.nih.gov/blast).

RESULTS

Clinical observation of ducklings orally infected with SE

Similar clinical signs and gross findings were observed in orally infected ducklings with *S. enteritidis*. Typical clinical signs including inappetence, depression, lameness, fervescence, and white diarrhea were observed in all infected ducklings from around 3 d p.i., and some infected ducklings had nervous symptom and tremor of head-neck. Two inoculated ducklings died as a result of *S. enteritidis* infection between 48 h and 60 h p.i. Necropsy revealed similar lesions in all dead ducklings, including hemorrhages of the heart, hydropericardium, exudative fibrin on the surface of the visceral pericardium, hyperaemia and haemorhage of liver. Hyperaemia and haemorhage of intestinal tract was also observed. As a result of *S. enteritidis* infection, 8 of 10 infected ducklings in part C of Group 2 survived and exhibited no clinical signs except growing slowly and survived throughout the infection, so the mortality of the seven-day-ducklings infected with MY1 strain of *S. enteritidis* was 20%.

The control healthy ducklings in part D of Group 2 had no specific clinical signs and gross findings.

Dynamic monitoring of intestinal microflora in the control healthy ducklings

The ERIC-PCR fingerprints analysis showed that the intestinal microbial community of the control healthy ducklings in part B of Group 1 was steady. The numbers of the band formed by ERIC-PCR with rectum were the least and were the most with caecum. However, the band numbers of duodenum, ileum and jejunum between that of rectum and caecum (Figure 1A) had.

Dynamic monitoring of intestinal microflora in the orally infected ducklings

Obvious changes of ERIC-PCR bands of orally inoculated ducklings were not observed until 24 h p.i. The numbers of the ERIC-PCR bands gradually decreased from 24 h to 72 h p.i. and reached the least at 72 h p.i. Thereafter, with the development of disease, the band numbers gradually increased until 6 d p.i. Two major bands (about 300 bp and 500 bp) were detected in each sample (Figure 1B).

Results of DNA fragments sequencing from major bands

The sequences about 500 bp of jejunum sampled at 72 h p.i., 100 bp of duodenum sampled at 6 d p.i. of healthy ducklings and 500 bp of ileum sampled at 72 h p.i., and 300 bp of duodenum sampled at 24 h p.i. of orally infected ducklings were analyzed with the BLAST program at the NCBI website (http://www.ncbi.nlm.nih.gov/blast) (Table 1).

Table 1 Sequencing results of DNA fragments from major bands

Major bands of health ducklings		Major bands of infected ducklings	
100 bp (6 d duodenum)	**500 bp (72 h jejunum)**	**300 bp (24 h duodenum)**	**500 bp (72 h ileum)**
Sinorhizobium meliloti enterobacterial, Pseudomonas syringae, *Escherichia coli* 536, UTI89, 301. (≥ 95%)	*Sinorhizobium meliloti* enterobacterial, *Xanthomonas campestris* enterobacterial, *Erwinia pyrifoliae* (≥ 90%)	*Yersinia enterocolitica subsp*, enterocolitica 8081 complete genome, *Escherichia coli* W3110 (APECO1, CFT073, L0001, UTI89, 536, K12-MG1655), Shigella dysenteriae Sd197, Shigella flexneri 8401 strain, Salmonella typhimurium LT2, Pseudomonas syringae pv. Phaseolicola, Pseudomonas syringae pv. glycinea, strain CYL325, Salmonella enterica subsp (≥ 90%)	*Sinorhizobium meliloti* enterobacterial, *Xanthomonas campestris* enterobacterial, *Yersinia pestis* (≥ 80%)

DISCUSSION

Methods to analyze intestinal microbial community

The structural dynamics of microbial communities have been monitored using amplified sequences or total genomic DNA and a variety of genetic fingerprinting techniques, such as Terminal Fragment Length Polymorphism (T-RFLP), Amplified Ribosome DNA Restriction Analysis (ARDRA), Denaturing Gradient Gel Electrophoresis/ Temperature Gradient Gel Electrophoresis (DGGE/ TGGE), of amplified partial 16S/18S rDNAs or fragments of conserved functional genes and Random Amplified Polymorphic DNA (RAPD), or Arbitrarily Primed PCR (AP-PCR)[18-21]. These techniques provide genomic patterns or profiles of microbial communities, in which the number of bands reflects the number of predominant community members, while the intensity of bands theoretically reflects population levels. ERIC sequence was first described in Escherichia coli, Salmonella typhimurium and other enterobacteria[22]. Two opposing primers were designed by Versalovic *et al*[16] in 1991 based on the 44-bp entire conserved central core inverted repeat (ERICALL). PCR amplification of bacterial genomic DNA with this primer pair results in highly reproducible and unique banding patterns for different genomes. ERIC-PCR has been widely used for typing of bacterial genomes based on the strain-specific fingerprints. In this study, ERIC-PCR was used to fingerprint the microbial community of fecal samples of research subjects to monitor intestinal microbial community diversity and dynamic change of healthy ducklings and infected ducklings with *S. enteritidis*. The results indicated that intestinal microbial community diversity and dynamic change are closely correlated with the process of infection. The numbers of ERIC-PCR bands of orally inoculated ducklings gradually decreased firstly, and then, with the development of disease, the band numbers gradually increased and recovered.

Distribution and stability of normal flora in intestinal tract

A large number of microbial species exist in gastrointestinal tract. Intestinal microflora plays an important role in digestive function, immunity and disease resistance. In this study, the diversity and dynamics of intestinal microbial community did not change obviously in control healthy ducklings analyzed with ERIC-PCR, which is consistent with the study that the quantity and proportion of each kind of bacteria are steady relatively[23]. The numbers of the bands formed by ERIC-PCR were the largest in healthy caecum that contained a bacterial content of 10^{10} cfu/mL-10^{12} cfu/mL[24]. The reason why the ERIC-PCR band numbers in rectum were the least and its microbial community were not steady is that the quantity and category of microflora were mainly influenced by the proportion of bacterium in ileum and cecum[25]. Duodenum and jejunum are transition zone of intestinal tract, and bacterium would be washed away to ileum[26]. So bands of duodenum and jejunum formed by ERIC-PCR were relatively less compared with that in jejunum and caecum.

Intestinal microbial community diversity and dynamic change of ducklings infected with oral S. enteritidis

The change of intestinal internal environment can result in dysbacteriosis. So-called dysbacteriosis, is that the quantity, category and proportion of each kind of bacteria changed, which will affect the function of host's gastrointestinal tract[27]. In this study, ERIC-PCR bands of orally inoculated ducklings did not change obviously until 24 h p.i. These results may suggest that the infection of *S. enteritidis* did not seriously affect intestinal microbial community of infected ducklings. However, the numbers of the ERIC-PCR bands gradually decreased from 24 h to 72 h p.i. This result may imply that intestinal microbial community diversity was affected by the continuous replication of *S. enteritidis* in the intestine of infected ducklings, which reflect the typical clinical sign of diarrhea and several pathological lesions of hyperaemia and haemorhage of the intestine. However, with the development of disease, the band numbers gradually increased until 6 d p.i., and the typical clinical signs and several pathological lesions also returned to almost normal at this time. Taken together, these data suggest that the stability of intestinal microbial community closely correlated with the progression of *S. enteritidis* infection.

Prominent bacterium in intestinal tract of S. enteritidis infected ducklings

Anaerobic bacterium is prominent in intestinal normal flora. In this study, the sequencing results of DNA fragments from major bands of the control healthy

ducklings indicated that all these bacteria were anaerobe or facultative anaerobe and among these bacteria, *Escherichia coli* and *Erwinia* play an important role in maintaining the balance of intestinal microecology. However, few data are available in the literature showing the other bacteria with ERIC sequence were prominent bacteria in intestinal tract of fowl; further investigations are needed to clarify this. Enteric infection result in the proportion of aerobe and facultative anaerobe increase[28-30]. In this study, sequence analysis showed that the nucleotide sequence homologies of the fragment about 500 bp of infected ileum sampled at 72 h p.i. were above 80% with S*inorhizobium meliloti enterobacterial*, *Xanthomonas campestris enterobacterial*, *Yersinia pestis*, and the nucleotide sequence homologies of the fragment about 300 bp of infected duodenum sampled at 24 h p.i. were more than 90% with *Yersinia enterocolitica subsp*, *enterocolitica* 8081, *Escherichia coli W3110* (*APEC O1, CFT073, L0001, UTI89, 536, K12-MG1655*), *Shigella dysenteriae Sd197*, *Shigella flexneri 8401 strain*, *Salmonella typhimurium LT2*, *Pseudomonas syringae pv. phaseolicola and Pseudomonas syringae pv.glycinea.strain CYL325*, *Salmonella enterica subsp*, *Erwinia amylovora*. However, among these bacteria, they are all pathogenic strains able to make host dysentery except *Escherichia coli K-12*, *MG1655*. These data suggest that the pathogenic bacteria were prominent in intestinal microbial community when orally infected ducklings with *S. enteritidis* developed signs of diarrhea. Moreover, several pathogenic bacterial species including *Yersinia pestis* represent a real secondary infection, which may imply that infected ducklings with *S. enteritidis* were followed by secondary bacterial infection.

The lesions of intestinal mucous membrane caused by *SE* infection result in dysbacteriosis of intestinal normal flora, the increase of native bacterium, and the transformation from beneficial bacterium to pathogenic bacterium. Furthermore, as a result of *SE* infection, depression of immunity, disfunction of intestinal mucous membrane and dysbacteriosis can also raise the pathogenic bacterial levels in the intestine, such as *Escherichia coli*, *Shigella* and *Salmonella*. Therefore, the increased proportion of pathogenic bacteria may be crucial in determination of diarrhea symptoms in *S. enteritidis* infection.

COMMENTS

Background

Salmonella has been a concern of public health for over 100 years and the incidence of Salmonella infections has increased dramatically, especially *S. enteritidis* infection. Knowledge about the Salmonella infection could be an additional means for decreasing the incidence of infection. Infection with Salmonella is usually started by oral ingestion of the pathogen and is followed by dysbacteriosis of the gut and diarrhea. It is therefore, necessary to understand intestinal microbial community diversity.

Research frontiers

Up to date, there has been no report about the intestinal microbial community diversity of animal *S. enteritidis* infected. ERIC-PCR, as a technique used for typing of bacterial genomes based on the strain-specific fingerprints obtained, will be an ideal method to study the intestinal microbial community diversity of *S. enteritidis* infected animals.

Innovations and breakthroughs

Previous studies considered that *S. enteritidis* established itself within the walls of the small intestine before a systemic infection could be demonstrated. However, these works were unable to identify the dynamic change of intestinal microbial community of *S. enteritidis* infected animals. In this study, the authors offered a significant improvement over current studies and suggested that *S. enteritidis* infection can cause dysbacteriosis of gastrointestinal tract.

Applications

This study will provide significant data for clarifing intestinal microbial community diversity of ducklings infected with *S. enteritidis* and new insight into the prevention and treatment of *S. enteritidis* infection.

Terminology

Dysbacteriosis**:** The change in quantity, category and proportion of each kind of bacteria.

Peer review

This study analyzed intestinal microbial community diversity of different segments of the gastrointestinal tract in healthy and orally infected ducklings with Salmonella enteritidis by ERIC-PCR method. The results show that SE infection can result in dysbacteriosis of infected ducklings, and the ERIC-PCR method is a useful tool when applied to pathogenesis and prevention of *S. enteritidis* infection.

Abstract

AIM: To investigate whether KAI1, as a metastasis suppressor gene, is associated with invasive and metastatic ability of pancreatic cancer cells.

METHODS: KAI1 gene was transfected into pancreatic cancer cell line MiaPaCa Ⅱ by liposomes selected with G418. Expression of transfected cells was measured by Western blotting, immunofluorescence and immunocytochemistry. Tumor cell invasion and metastatic ability were detected through gelatinase activity and reconstituted basement membrane (Matrigel) assay. pCMV-KAI1 was directly injected into the heterotopic human pancreatic adenocarcinoma successfully established in the groin of BALB/C nude mice, by subcutaneous injection of MiaPaCa Ⅱ pancreatic cancer cells. The statistical analysis between groups was determined by Student's two tailed *t* test.

RESULTS: By Western blotting, MiaPaCa Ⅱ cells transfected by KAI1 gene indicated KAI1 expression at approximately 29.1 kDa. Cytoplasm staining was positive and uniformly spread in transfected cancer cells, using immunohistochemistry and immunofluorescence. The most obvious difference was present after 30 h (MiaPaca Ⅱ 43.6 ± 9.42, pCMV-MiaPaca Ⅱ 44.8 ± 8.56, pCMV-KAI1-MiaPaca Ⅱ 22.0 ± 4.69, $P < 0.05$). Gelatinolysis revealed a wider and clearer band of gelatinolytic activity in non-transfected than in transfected cells (MiaPaCa Ⅱ cells 30.8 ± 0.57, transfected cells 28.1 ± 0.65, $P < 0.05$). *In vivo* tumor growth rates of KAI1 transfectants with KAI1-Lipofectamine 1.22 ± 0.31 in A group were lower than control 4.61 ± 1.98 and pCMV-KAI 11.67 ± 0.81. Analyses of metastases with and without KAI1 transfection in mice were different in liver and lung between controls 1.62 ± 0.39, 0.45 ± 0.09, pCMV-KAI 1.01 ± 0.27, 0.33 ± 0.09 and KAI1-Lipofectamine 0.99 ± 0.21, 0.30 ± 0.09 respectively ($P < 0.05$).

CONCLUSION: High expression of KAI1 gene was found in transfected MiaPaCa Ⅱ human pancreatic cancer cells with lower metastatic ability. KAI1 gene plays an important role in inhibiting metastasis of pancreatic cancer after direct injection into pancreatic adenocarcinoma. These results show that the suppressed invasion and motor function of pancreatic cancer cells may be a key reason why the KAI1 gene controls pancreatic cancer cell metastasis.

INTRODUCTION

Invasion and metastasis are remarkable characteristics in pancreatic cancer. During invasion and metastasis, primary pancreatic cancer cells have to move out, invade adjacent tissue, and circulate to distant organs where they may form new colonies[1]. Tumor invasion encompasses the process of tumor cell penetration or infiltration into adjacent tissue; therefore, metastasis depends on host immunological ability, local and systemic expansion of the tumor mass, and angiogenesis[2]. Once metastatic cells settle in a distant organ, nutrients and spaces are no longer

limited because newly formed metastases arise as islets of cancer cells surrounded by normal host cells. Invasion and metastasis are complex processes that involve molecular mechanisms, which lead to multiple gene alterations in pancreatic carcinoma, including alterations to KAI1, K-ras, DPC4 and P53[3-6]. KAI1 was originally identified as a metastasis suppressor gene.

KAI1 has been mapped to human chromosome 11p11.2. The expression level of KAI1 mRNA in human cell lines derived from metastatic prostate cancers is undetectable or much lower than that in normal prostate tissue[7]. Moreover, the gene transfer of KAI1 into rat AT6.1 prostate cancer cells results in significant suppression of pulmonary metastases. KAI1, which is identical to CD82, belongs to a structurally distinct family of membrane glycoproteins named transmembrane 4 (TM4). KAI1 is expressed ubiquitously, not only in prostate tissue, but also in a wide variety of other tissues, which suggests that it may play a role in suppressing metastases of other tissue-derived cancers, such as pancreatic, non-small cell lung, bladder, gastric and breast cancer[8-12]. These findings, taken together with the fact that KAI1 protein has a nearly ubiquitous tissue distribution, suggest that KAI1 may function as a metastasis suppressor gene in other types of cancers.

In our previous studies, we have demonstrated that KAI1 expression, at both mRNA and protein levels, is inversely correlated with the metastatic potential of some established human pancreatic cancer cell lines. In addition, we have also assessed KAI1 protein expression in human pancreatic cancer specimens from patients with known clinical outcome. We have found that more malignant tumor types express significantly lower levels of KAI1 protein, and down regulation of KAI1 at the RNA level is correlated with lymph node and distant metastases in patients with advanced pancreatic cancer[12,13]. The function of KAI1 with anti-metastasis has been unclear up till now. The aim of this study was to examine the expression of KAI1 protein in pancreatic cancer cells transfected by the gene, and to determine whether KAI1 transfected into pancreatic cancer cells can suppress invasive and metastatic ability of the cancer cells.

MATERIALS AND METHODS

Cells and cell culture

The human pancreatic cancer cell MiaPaCa Ⅱ was kindly provided by Dr. H. Friess. The cells was cultivated in Dulbecco's Modified Eagle's Medium (DMEM) supplemented with 10% fetal calf serum (FCS), 2 mmol/L L-glutamine, 100 IU/mL penicillin G and 100 μg/mL streptomycin, and passaged with 0.25% trypsin.

Transfection

Expression plasmids encoding KAI1 (pCMV-KAI1 DNA) were obtained from Dr. J. Dong (University of Virginia Health System). The day before transfection, cells were trypsinized and counted, and plated at 1×10^5 cells per well, so that they were 80%-90% confluent on the day of transfection. Cells were plated in 0.5 mL normal growth medium. For each well of cells to be transfected, we diluted 1.0 μg pCMV-KAI1 DNA into 50 μL medium without serum (this can be prepared in bulk for multiple wells). For each well of cells, we diluted 1 μL LF2000 Reagent (GibcoBRL, Maryland, USA) into 50 μL medium without serum and incubated for 5 min at room temperature. The diluted DNA was combined with the diluted LF2000 Reagent, and incubated at room temperature for 20 min. We added 0.5 mL medium without serum, then 100 μL DNA-LF2000 Reagent complexes was added directly to each well and mixed gently by rocking the plate back and forth. The cells were incubated at 37℃ in a CO_2 incubator for 24 h, and passaged at a 1:10 into fresh growth medium. After 24 h, we added 400 μg/mL G418 selection medium for the cells transfected by KAI1. At 4 wk after transfection, stable transfected cells were obtained. MiaPaCa Ⅱ cells transfected with pCMV served as a negative control.

Western blotting analysis

1×10^7 cells for Western blotting were prepared in 0.5 mL Lysis Buffer (10 mmol/L Tris/HCl, 5 mmol/L EDTA, 50 mmol/L NaCl, 30 mmol/L Na_3PO_4, 50 mmol/L NaF, 0.1 mmol/L Na_3VO_4, 1 mmol/L PMSF, 5 mg/mL aprotinin, 0.1% Triton X-100, pH 7.6). Homogenates were centrifuged for 10 min at 10000 rpm at 4℃. The supernatant was collected and maintained at -20℃. After denaturing at 100℃ for 5 min, the supernatant was subjected to SDS-PAGE on 5% concentrated gels and 7.5% segregated gels. Separated proteins were electrophoretically transferred to PVDF membranes for 1.5 h at 4℃. These membrane transfers were dried and incubated over night at 4℃ with 5% defatted milk powder/TBS/0.1% Tween-20. After washing with TBS, the membrane transfers were incubated with purified rabbit polyclonal antibody against KAI1 (CD82) (BD Biosciences, New Jersey, USA) 1:200 in buffer (10 mmol/L Tris/HCl, 100 mmol/L NaCl, 5% BSA, and 0.1% Tween-20, pH 7.4). Following three washes of 20 min in TBS/Tween-20, membrane transfers were incubated with goat anti-rabbit IgG/horseradish peroxidase conjugate for 1 h. Each was removed by three 20 min washes in TBS/Tween-20. Immunoreactive proteins in peroxidase-treated transfers were visualized using an ECL Western blotting detection system (Amersham Life Sciences, Little Chalfont, United Kingdom) with exposure to X-ray film for 30-120 s. Prestained SDS-PAGE standard proteins (Bio-Rad, Richmond, CA, USA) were employed as molecular size markers.

Immunofluorescence

The pancreatic cells before and after transfection were allowed to attach overnight to chambered glass slides. After incubation, cells were rinsed in PBS, fixed in ice-cold methanol, washed, and blocked in a PBS solution containing globulin-free BSA (1%), Triton X-100 (0.3%) and goat serum (3%). The cells were incubated with primary antibodies (CD82, 1:80 dilution) in a humidified

chamber for 1 h at room temperature, washed in PBS, and incubated again for 1 h in the dark with a secondary antibody (1:80 dilution) coupled to the fluorophore. After washing, the cell lines were covered with DAPI solution (Roche, New Jersey USA). Slides were mounted with coverslips and examined by fluorescence microscopy.

Immunocytochemical detection of KAI1 protein

Briefly, cells were washed in PBS, fixed in ice-cold acetone for 20 min at 4℃, soaked in 0.3% H_2O_2 for 30 min, and blocked in a PBS solution containing NP40 and goat serum (10%). The cells were incubated with specific KAI1 antibody, diluted 1:20 in PBS containing 10% goat serum and NP40, at 4℃ overnight. After washing, we added a secondary antibody (1:100 dilution), coupled to biotin for 1 h at room temperature, and the samples were stained with DAB.

Cell invasion assay

In Transwell cell culture chambers (Costar 3422, Cambridge, MA, USA), polycarbonate membranes with 8.0-μm pore size were spread with 40 μL (10 μg) of Matrigel (BD Biosciences) on the upper surface at 37℃. After 1 h, each insert was placed in 500 μL DMEM containing 0.1% BSA, for hydration at 37℃ for 30 min. The membranes were precoated with 40 μL (2 μg) fibronectin (Invitrogen) on the lower surface of the filters. The filters were dried at room temperature for 45 min. MiaPaCa Ⅱ and KAI1-MiaPaCa Ⅱ cells (1×10^5) suspended in 100 μL DMEM containing 0.1% BSA were added to the upper compartment and incubated at 37℃ for 10-60 h. Every 10 h, the filters were fixed with 95% ethanol for 15 min and stained with hematoxylin and eosin. After gently rinsing with water, the cells on the upper surface of the filters were removed by wiping with a cotton swab. The filter containing the stained cells that invaded to the lower surface was manually counted under a microscope at × 400 magnification. Each assay was performed in triplicate.

Gelatin zymography

MiaPaCa Ⅱ and KAI1-MiaPaCa Ⅱ cells (1×10^5) were cultured overnight using ordinary serum-containing DMEM, washed with serum-free DMEM, and further cultured using serum-free DMEM for 24 h. The supernatant was collected, and the cellular fragment was removed by low-speed centrifugation and concentrated 30-fold with a membrane dialysis concentrator. The conditioned medium was used for the detection of gelatinase activity. Gelatin zymograms were obtained according to the method reported by Heussen and Dowdle[18], with some modifications. In brief, the conditioned medium was resolved by SDS-PAGE using 8% separating gel containing 0.1% (w/v) gelatin and 5% stacking gel. The gels were washed twice in 2.5% (w/v) Triton X-100 for 30 min at room temperature to remove SDS, then incubated in reaction buffer containing 50 mmol/L Tris/HCl, pH 7.6, 10 mmol/L $CaCl_2$ and 1 μmol/L $ZnCl_2$ for 12-16 h at 37℃. The gelatin gels were stained with 0.1% (w/v) Coomassie brilliant blue R-250 in 45% (v/v) methanol and 10% (v/v) acetic acid for 4 h. After destaining with 45% methanol and 10% acetic acid, the gelatinolytic activity on the gel was detected as clear bands on a blue background of undigested gelatin, and quantitated using a Master Scan gel analysis system (Scanalytics, Billerica, MA, USA).

In vivo growth and experimental metastasis assay

To investigate the effect of KAI1 on *in vivo* metastasis, 1×10^6 cells in 0.1 mL 0.9% NaCl were injected subcutaneously into the flank region of 36 nu/nu mice (20 g body weight; China Medical University Breeding Laboratories, Shenyang, China). Mice were randomly divided into two groups: group A ($n = 18$) was injected with the KAI1 gene 10 d after injection of pancreatic cancer cells, and group B ($n = 18$) was treated 21 d after injection as our report[14]. The mice in group A were randomly divided into three (six mice per group), including pCMV-KAI1, pCMV-KAI1-Lipofectamine and control. Group B was divided the same as group A. One hundred micrograms of recombinant plasmid pCMV-KAI1, 100 μg pCMV-KAI1-Lipofectamine (1:1) and 100 μL 0.9% NaCl were directly injected into pancreatic adenocarcinoma every 7 d, and repeated three times. Tumor size was monitored 1 wk after inoculation of tumor cells. Tumor volume was determined using the formula $V = A \times B \times 0.4$, where A and B are the larger and smaller diameters of the tumor, respectively. After 50 d, the mice were necropsied, and the lungs were removed. Visible lung metastases were counted in Bouin's fixed tissues, with the aid of a dissecting microscope.

Statistical analysis

The statistical significance of differences between the groups was determined by applying Student's two-tailed *t* test. $P < 0.05$ was considered statistically significant. Values are indicated as the mean ± SD.

RESULTS

Confirmation of KAI1 gene transfection

The pCMV-KAI1 DNA was transformed into CM109 using the Maxi preparation. KAI1 DNA was identified in the correct position. The correct orientation was confirmed by PCR and sequencing analysis. MiaPaCa Ⅱ cells transfected with pCMV-KAI1 DNA retained G418 resistance for 10 generations. The transfection of MiaPaCa Ⅱ cells indicated KAI1 expression.

Expression of KAI1 protein

The stably transfected cells were analyzed by Western blotting to evaluate the intracellular amounts of KAI1 protein. The major specific KAI1 protein was clearly visible at about 29.1 kDa in MiaPaCa Ⅱ pancreatic cells transfected with pCMV-KAI1 DNA, but almost undetectable in cells transfected with pCMV. The most positively staining was found in the cytoplasm in transfected cancer cells. Negative

Table 1 Invasive ability of pancreatic cancer cells (mean ± SD)

Cell type	Number of cells at different times					
	10 h	20 h	30 h	40 h	50 h	60 h
MiaPaca Ⅱ	20.6 ± 6.43	23.6 ± 7.50	43.6 ± 9.42	59.8 ± 6.06	86.8 ± 4.32	117.4 ± 4.88
pCMV-MiaPaca Ⅱ	21.0 ± 7.21	24.8 ± 6.46	44.8 ± 8.56	62.6 ± 3.11	87.4 ± 1.82	115.4 ± 3.58
pCMV-KAI1-MiaPaca Ⅱ	14.8 ± 6.69	16.4 ± 4.51	22.0 ± 4.69	25.6 ± 5.55	29.4 ± 4.93	33.6 ± 6.11
	$P > 0.05$	$P > 0.05$	$P < 0.05$	$P < 0.05$	$P < 0.05$	$P < 0.05$

$P < 0.05$ between KAI1-transfected and non-transfected cells.

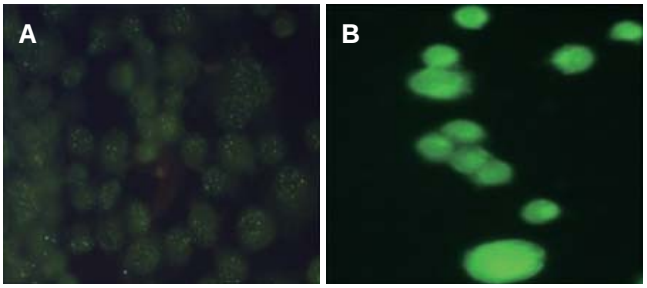

Figure 1 **A**: Very weak immunofluorescence in cells with empty plasmids without KAI1; **B**: Strong green immunofluorescence in cells transfected with KAI1.

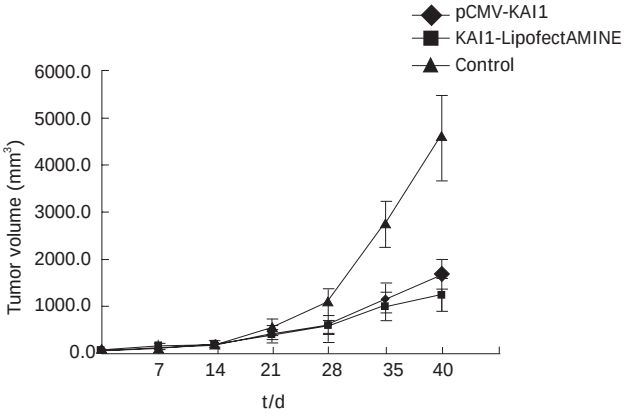

Figure 2 Effect of KAI1 expressions on *in vivo* tumor growth in group A.

staining intensity in non-transfected cells was shown to be comparable with that in transfected cells. Strong green immunofluorescence (Figure 1) was seen in the transfected MiaPaCa Ⅱ pancreatic cancer cells, whereas very weak immunofluorescence was found in cells transfected with pCMV.

Invading ability of cells transfected with KAI1

The transfection of KAI1 cells on tumor invasion of Matrigel was evaluated using a Transwell chamber assay. The data in Table 1 shows that the stained cells invading the lower surface of the filters of pCMV-KAI1-MiaPaca Ⅱ were less than pCMV-MiaPaca Ⅱ and MiaPaca Ⅱ cells without transfection. There was no distinct difference in the number of invasive cells before and 10 and 20 h after transfection, while there was an obvious difference after 30 h ($P < 0.05$). There was no difference in the number of invasive cells observed between cells transfected by pCMV vector control and MiaPaca Ⅱ ($P > 0.05$). The results show that transfection of the KAI1 gene significantly reduced the invasive ability of MiaPaCa Ⅱ cells.

Table 2 Effect of KAI1 expression on *in vivo* tumor growth (mean ± SD)

	Group	*n*	Tumor volume (cm^3)	*t*	*P*
	Control	6	4.61 ± 1.98	-	-
A	KAI1-LipofectAMINE	6	1.22 ± 0.31	2.860	< 0.05
	pCMV-KAI1	6	1.67 ± 0.81	2.414	< 0.05
	Control	6	4.61 ± 1.98	-	-
B	KAI1-LipofectAMINE	6	4.87 ± 1.58	0.199	> 0.05
	pCMV-KAI1	6	4.16 ± 2.81	0.286	> 0.05

$P < 0.05$ between KAI1 transfection and controls.

Gelatinolysis in MiaPaCa Ⅱ pancreatic cells

We investigated the effect of transfection on the gelatinolytic activity of MMP-2 by gelatin zymography. Zymograms from MiaPaCa Ⅱ cells revealed a wider and clearer band of gelatinolytic activity than that from transfected cells. Values of I A were 30.8 ± 0.57 of MiaPaCa Ⅱ cells, moreover 28.1 ± 0.65 of transfected cells ($P < 0.05$).

Tumor growth

Tumor volume was assessed at 7 d after injection of tumor cells and continuously every 3 d until 50 d. Time curves showing the percentage increase in tumor size in saline-treated and KAI1-treated mice are shown in Figure 2. At d 21, the KAI1 transfectants had significantly lower tumor volume compared with the controls ($P < 0.05$). As a result of KAI1 administration, tumor growth was dramatically reduced in pCMV KAI1 in group A.

In group A (Table 2), the tumor volume inhibitory rate of the KAI1 and KAI1-Lipofectamine groups was 63.79% and 73.51%, and the lung metastatic nodule number was 0.5 ± 0.83 and 2.33 ± 1.63, respectively. The tumor volume, lung weight, liver weight and lung metastatic nodule number of the KAI1-treated group were significantly lower than those in the control group ($P < 0.05$; Table 3). These data showed no significant difference between the KAI1 and KAI1-Lipofectamine groups. In group B, there was no significant difference between the gene therapy and saline control groups. There was a significant difference in tumor volume, lung weight, liver weight and lung metastatic nodule number between group A and B ($P < 0.05$).

Table 3 Analyses of liver and lung metastases with and without KAI1 transfaction in mice *in vivo* (mean ± SD)

	Group	*n*	Liver weight (g)	*t*	*P*	Lung weight (g)	*t*	*P*
	Control	6	1.62 ± 0.39			0.45 ± 0.09		
A	KAI1-LipofectAMINE	6	0.99 ± 0.21	2.661	< 0.05	0.30 ± 0.09	3.181	< 0.05
	pCMV-KAI1	6	1.01 ± 0.27	2.295	< 0.05	0.33 ± 0.09	2.291	< 0.05

	pCMV-KAI1	6	1.46 ± 0.28	1.286	> 0.05	0.36 ± 0.04	1.956	> 0.05

$P < 0.05$ between KAI1 transfection and controls.

DISCUSSION

The KAI1 gene as a metastasis suppressor gene may be a useful marker for the metastatic/invasive potential of several human tumor types[9-11,15]. In the case of pancreatic cancer, KAI1 appears to be crucial for the development of distant organ metastasis, since loss of KAI1 expression is found in lymph node and distant metastases[12,13,16], therefore, down-regulation of the KAI1 gene during cancer development may be associated with methylation of the promoter or *p53* regulation, but does not commonly interfere either mutation or allelic loss of the KAI1 gene[17]. Although the mechanisms of invasion and metastasis of the KAI1 gene have not been elucidated in pancreatic and other cancers, a better understanding of these mechanisms that lead to cancer remains a major goal because it may help develop strategies for earlier diagnosis and better treatment.

In the present study, KAI1 expression was examined using immunohistochemistry. Positive staining for the protein in cells transfected with the KAI1 gene should be observed mainly at the cell membrane, because KAI1 is a member of the TM4 superfamily, however protein localization in the transfected cells was mainly found in the cytoplasm, similar to that in previous studies of human pancreatic cancer[18]. We used a rabbit polyclonal antibody and found that KAI1 was expressed abundantly in transfected cells, but there was negative staining in the non-transfected cells. Our data suggests that the protein upregulation in KAI1 transfected cells is the same as the expression in human pancreatic cancer samples. This may suggest that KAI1 inhibits metastasis in pancreatic cancer cells associated with the human samples[12].

Cancer mortality is due largely to distant metastases and subsequent organ failure. Metastasis involves the degradation of the basement membrane and stromal extracellular matrix (ECM) and migration into adjoining blood vessels, which results in tumor growth in distant organs[19,20]. Degradation of the basement membrane and ECM involve the secretion of several proteases, such as one or more members of the MMP family[21-23]. Among more than 20 MMPs that have been identified[24], MMP-2 has been described as a negative prognostic marker of metastasis and disease-free interval[25-27]. We transfected KAI1 cDNA into highly metastatic pancreatic cancer cells, MiaPaCa Ⅱ, and investigated whether KAI1 gene reduced invasive ability of transfected cells and decreased gelatinase activity. In other words, the gelatinolytic activity by gelatin zymography was shown to increase in cells that were not transfected with the KAI1 gene. Our results showed that after KAI1 gene transfection, the activity of gelatinase decreased markedly, which suggests that KAI1 may suppress expression of gelatinase. Through a reconstituted basement membrane (Matrigel) *in vitro*, we found that stained cells invading the lower surface of the filters of pCMV-KAI1-MiaPaca Ⅱ were less than pCMV-MiaPaca Ⅱ and MiaPaca Ⅱ cells without transfection. The number of invasive cells observed did not obviously differ between cells transfected with the pCMV vector and non-transfected cells. This indicates that, as with any malignancy, the propensity for local/regional invasion and distant metastasis of pancreatic cancer may be based on its ability to invade the basement membrane.

The time of gene therapy selected was at 10 d (group A) and 21 d (group B) after injecting pancreatic cells, according to our previous research[14]. In agreement with studies of prostate cancer, colon cancer and melanoma cells[7,28,29], our data also indicated that KAI1 expression suppressed metastasis *in vivo* when transfected into pancreatic cancer cells, and revealed a decrease in tumor volume of KAI1 transfectants 3 wk after inoculation, similar to breast cancer cells[11]. These results showed that KAI1 cDNA may be directly injected into the body of pancreatic adenocarcinoma to inhibit its metastasis and growth, without being mediating by liposomes, but the inhibition distinctly correlated with the time at which KAI1 gene was injected. The present data, along with our previous results[30], showed that the KAI1 gene may have play a key role in inhibiting metastasis of pancreatic cancer, by controlling cancer cell growth at secondary metastatic loci.

KAI1, as a metastasis suppressor gene, has drawn special attention as a new therapeutic target, in the hope that re-activation of the gene reduces the metastatic ability of malignant cells. We found that down-regulation of KAI1 mRNA level was correlated with lymph node and distant metastases in patients with advanced pancreatic cancer[11], whereas the results suggested that the activity of gelatinase, ability to invade the basement membrane, and metastasis of pancreatic cancer in mice, were decreased in the cells transfected with the KAI1 gene. In general, the results demonstrated that a decreased level of KAI1 mRNA expression in advanced pancreatic cancer involves both invasion and metastasis based on principles of cellular and molecular pathology.

ACKNOWLEDGMENTS

We thank Dr. TJ Dong and Dr. H Friess for their generous gifts of the KAI1 plasmid and MinPaCa Ⅱ pancreatic cancer cells, respectively.

COMMENTS

Background

Metastasis is an important feature in pancreatic cancer. However, recently no new breakthroughs have been found. Therefore it is necessary to use new techniques to detect early-stage metastasis in pancreatic cancer.

Research frontiers

This is a frontier of the molecular biology of tumor genetics interfering with up-regulation of the KAI1 gene to inhibit growth and metastasis of primary pancreatic cancer in mice. The propensity for local and regional invasion and distant metastasis of pancreatic cancer may be associated with its ability to invade the basement membrane.

Innovations and breakthroughs

A leading phenomenon on controlling metastasis of pancreatic cancer was found in KAI1 gene regulation. It may suggest mechanisms for inhibiting metastases of other tumors in the human body.

Applications

The findings help to explain some of the mechanisms behind metastasis of cancer. This research may contribute to providing new gene treatment options for pancreatic cancer patients.

Peer review

This is a good study. The authors have shown that there was high expression of the KAI1 gene in transfected MiaPaCa II human pancreatic cancer cells with lower metastatic ability. They conclude that the KAI1 gene plays an important role in inhibiting the metastasis of pancreatic cancer.

Abstract

AIM: To investigate the possibilities and advantages of laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct compaired with traditional open operation.

METHODS: Laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct and traditional open operation were performed in two groups of patients who had gallstones in the left lobe of liver and in the common bile duct. The hospitalization time, hospitalization costs, operation time, operative complications and post-operative liver functions of the two groups of patients were studied.

RESULTS: The operation time and post-operative liver functions of the two groups of patients had no significant differences, while the hospitalization time, hospitalization costs and operative complications of the laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration in the common bile duct group were significantly lower than those in the traditional open operation group.

CONCLUSION: For patients with gallstones in the left lobe of liver and in the common bile duct, laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct can significantly shorten the hospitalization time, reduce the hospitalization costs and the post-operative complications, without prolonging the operation time and bringing about more liver function damages compared with traditional open operation. This kind of operation has more advantages than traditional open operation.

Laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct and traditional open operation. *World J Gastroenterol* 2008; 14(7): 1133-1136 Available from: URL: http://www.wjgnet.com/1007-9327/14/1133.asp DOI: http://dx.doi.org/10.3748/wjg.14.1133

INTRODUCTION

Since the first laparoscopic hepatic lobectomy performed by Reich in 1991, the laparoscopic operation procedure has been practiced in hepatobiliary surgery[1,2]. Because of the abundant blood supply for the liver and pneumoperitoneum, hemorrhage and gas embolism often occur during the operation[3]. Laparoscopic hepatic lobectomy is an operation procedure with high difficulties and risks[4]. However, in recent years, with the development of laparoscopic instruments and operative skills, laparoscopic hepatic lobectomy has gradually become a common operation procedure in clinical practice[5,6]. It has many advantages over the traditional open operation[7]. In traditional open operation, T-pieces should be placed in the common bile duct to drain the bile after exploration of the common bile duct, which provides channels for surgeons to take out the possible remnant gallstones. However, it also brings about heavy burdens on the patients, such as prolonged hospitalization time, unbalance between electrolytes and digestive dysfunction caused by bile drainage, local infection on the abdominal wall caused by the T-piece, complicated care for the T-piece. Researchers have tired to solve these problems for a long

time. In this study, we performed laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct in 10 patients with gallstones in the left lobe of liver and in the common bile from September 2005 to December 2005. At the same time, traditional open hepatic lobecomy and T-piece drainage were performed in 12 patients. The former operation procedure has significant advantages over the latter. The results are reported here.

MATERIALS AND METHODS

Clinical data

Twenty-two patients were definitely diagnosed having gallstones in the left lobe of liver and in the common bile duct by CT and operative exploration from September 2005 to December 2005. Among these patients, 9 were male and 13 were female. Their age ranged from 29 to 58 (average 44) years and their liver functions were normal (Child grade A). Eleven patients had no icterus. The total bilirubin level ranged from 20 to 100 μmol/L in 8 patients, and was higher than 100 μmol/L in 3 patients.

Operation methods

In ten patients, ligments of the liver were dissociated by laparoscopic instruments under pneumoperitoneum condition. The trocar puncture point near the xiphoid was extended to about 5 cm, from which the left lateral lobe of liver was resected and the calculi in the intrahepatic duct were taken out without pneumoperitoneum, the left intrahepatic duct and the common bile duct were examined under a fiber choledochoscope for the possible remnant gallstones. After the remnant gallstones were taken out and the duodenal papillae were validated to be normal. The open part of the left intrahepatic duct and the left liver section were sutured. Traditional open operation was performed in 12 patients. After the left lateral lobe of liver was resected and the remnant gallstones were taken out from the common bile duct, T-pieces were conventionally used to drain the bile.

Statistical analysis

Data were processed with the Systat software (SPSS11.0) for statistical computation and graphing. One-way analysis of variance (ANOVA), independent-sample *t* test and chi square test were used to evaluate the differences between groups. $P < 0.05$ was considered statistically significant.

RESULTS

Operation time and hospitalization time

There were no significant differences in the operation time of laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct and traditional open operation between the two groups. There were no significant differences in the time of hepatic inflow occlusion during the left lateral lobectomy between the two groups. While the hospitalization time and hospitalization costs of the laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration in the common bile duct group were significantly lower than those in the traditional open operation group ($P < 0.05$, Table 1).

Table 1 Operation time, hospitalization time and costs of different groups of patients (mean ± SD)

Comparative aspects	Laparoscopy and choledochoscopy group	Traditional open operation group
Operation time (h)	2.5 ± 0.3	2.0 ± 0.5
Time of hepatic inflow occlusion (min)	15.0 ± 3.0	10 ± 5.0
Hospitalization time (d)	5.0 ± 1.0	13.0 ± 3.0
Hospitalization cost (ten thousand yuan)	1.2 ± 0.3	1.5 ± 0.5

Table 2 Postoperative complications in 22 patients

Postoperative complications	Laparoscopy and choledochoscopy group	Traditional open operation group
Hemorrhage of hepatic incisal margin	0	0
Biliary fistula	0	1
Biliary tract stenosis	0	0
Biliary tract bleeding	0	0
Infection or exudation of abdominal fistulas	0	12

Postoperative complications

The incision in the laparoscopic and choledochoscopic group was much shorter than that in the traditional open operation group. During the operation, the common bile duct needed not to be cut open and T-piece needed not to be used to drain the bile. Postoperative complications such as biliary fistula, biliary tract bleeding and stenosis in the laparoscopic and choledochoscopic group were not as common as in the traditional open operation. Mild biliary fistula only occurred in one patient of the open operation group. A all T-pieces were safely pulled out from all patients of the open operation group one month after operation and the abdominal fistulae healed quite well (Table 2).

Postoperative liver function

There were no significant differences in the postoperative liver function between the two groups three and seven days after operation. However, the liver function in the two groups was better seven days than three days after operation ($P < 0.05$, Table 3).

DISCUSSION

Micro-wound operation is becoming the trend of surgery in the 21st century. Laparoscopic surgery is regarded as an important component part of micro-wound surgery, because of its advantages such as alleviate wound and rapid concrescence. Laparoscopy has been tried in many aspects of abdominal operation[8,9]. Both hepatic artery and portal vein give the blood supply for liver, hepatic inflow

Table 3 Postoperative liver functions in 22 patients (mean ± SD)

Postoperative liver functions	Laparoscopy and choledochoscopy group		Traditional open operation group	
	3 d after operation	7 d after operation	3 d after operation	7 d after operation
Albumin (g/L)	30.2 ± 5.0	40.0 ± 3.5	28.8 ± 4.2	41.0 ± 5.0
Total protein (g/L)	60.0 ± 4.0	75.0 ± 3.0	58.5 ± 5.0	70.5 ± 4.0
AKP (U/L)	90.5 ± 10.0	55.5 ± 7.0	80.0 ± 8.0	50.5 ± 5.0
ALT (U/L)	150.0 ± 32.0	50.0 ± 10.0	180.0 ± 42.0	55.0 ± 8.0

TBIL (μmol/L)	8.0 ± 2.5	5.0 ± 3.2	7.8 ± 3.5	5.2 ± 2.6
SBIL (μmol/L)	16.5 ± 3.0	8.4 ± 1.7	17.5 ± 2.5	9.1 ± 2.0

occlusion and suturing the hepatic incisal margin are usually used to control the bleeding during the open operation[10,11]. However, during laparoscopic hepatoectomy, it would be impossible to use these methods, since they can lead to bleeding more easily[12]. The negative pressure of the hepatic vein and the positive pressure of the abdominal cavity cause CO_2 gas embolism in the blood more easily during laparoscopic hepatoectomy[13,14]. Thus, laparoscopic hepatoectomy is considered a difficult operation with a high risk requiring high techniques[15,16]. In recent years, with the development of laparoscopic appliance and operative skills, laparoscopic operation is wildly performed in hepatobiliary surgery[17,18]. In traditional open common bile duct exploration, T-pieces are used for bile drainage and treatment of possible remnant gallstones[19]. However, it also brings about heavy mental burdens to the patients, such as prolonged hospitalization time, electrolytical and digestive unbalance caused by bile drainage and local infection of the abdiminal wall near the T-piece[20-22]. In our study, laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct was performed in 10 patients with gallstones in the left lobe of liver and in the common bile duct. Ligments of the liver were dissociated with laparoscopic instruments under pneumoperitoneum condition, which avoided the long incision of the ligments, and dissociation in traditional open operation. The trocar puncture point near the xiphoid was extended to about 5 cm, from which we resected the left lateral lobe of liver and took out the calculi in the intrahepatic duct without pneumoperitoneum, thus making it possible to use hepatic inflow occlusion for bleeding control and avoiding CO_2 gas embolism under pneumoperitoneum[23,24]. From the extended trocar incision and the left intrahepatic duct, the common bile duct was examined under fiber choledochoscope for the possible remnant gallstones. After the remnant gallstones were taken out and the duodenal papillae were found to be normal. We sutured the open part of the left intrahepatic duct and the left liver section, thus making the bleeding and biliary fistulae more easily to be controlled. In the laparoscopic operation[25], the wall of the common bile duct needs not to cut open, thus avoiding many common complications of open operation[26], such as biliary fistula, cholangitic stenosis, biliary tract bleeding, electrolytical or digestive unbalance and local infection[27,28]. In our study, the liver function of the two groups was changed. The liver function impairment of the laparoscopic group was milder than that of the traditional open operation group. These finding reflect the advantages of laparoscopic operation. As an importantt component of micro-wound surgery, laparoscopic operation is wildly used in many fields of surgery[29,30]. Because of its micro-wound and safety, it has gradually become the first choice of method for many operations[30]. In laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct, the much shorter insicion lessens the post-operative pain of patients and no T-piece drainage also markedly reduces the post-operative complications.

In conclusion, laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct has more advantages than traditional open operation.

COMMENTS

Background

Since the first laparoscopic hepatic lobectomy performed by Reich in 1991, the laparoscopic operation procedure has been practiced in hepatobiliary surgery. Because of the abundant blood supply for the liver and pneumoperitoneum, hemorrhage and gas embolism often occur during the operation, laparoscopic hepatic lobectomy is considered an operation procedure with high difficulties and risks. However, in recent years, with the development of laparoscopic instruments and operative skills, laparoscopic hepatic lobectomy has gradually become a common operation procedure in clinical practice and has many advantages over the traditional open operation.

Research frontiers

Micro-wound operation is becoming the trend of surgery in the 21st century and laparoscopic surgery is considered an important component part of micro-wound surgery. In this study, we investigated the possibilities and advantages of laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct over the traditional open operation.

Innovations and breakthroughs

In this study, laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct was performed in patients with gallstones in the left lobe of liver and in the common bile duct. Ligments of liver were dissociated with laparoscopic instruments under pneumoperitoneum condition. The trocar puncture point near the xiphoid was extended to about 5 cm, from which we resected the left lateral lobe of liver and took out the calculi in the intrahepatic duct without pneumoperitoneum. From the extended trocar incision and the left intrahepatic duct, the common bile duct was examined by fiber choledochoscopy for the possible remnant gallstones. After the remnant gallstones were taken out and the duodenal papillae were validated to be normal, we sutured the open part of the left intrahepatic duct and the left liver section.

Applications

In the laparoscopic hepatic left lateral lobectomy combined with fiber choledochoscopic exploration of the common bile duct, the much shorter insicion lessened the post-operative pain of patients and no T-piece drainage also markedly reduced the post-operative complications.

Peer review

This clinical study by Zhang *et al* describes a comparison between laparoscopic hepatic left lateral lobectomy *etc vs* traditional open operations. This manuscript is very informative and has impact the the methodology used for common bile duct exploration.

Abstract

A primary clear cell adenocarcinoma of the colon is a rare oncologic entity. We herein report a case of such a tumor of the sigmoid colon in a 71-year-old woman who was successfully treated by an endoscopic polypectomy in our hospital. We also reviewed the published reports regarding cases of primary clear cell tumors in the colon.

INTRODUCTION

The first report of primary clear cell adenocarcinoma of the colon was published in 1964[1]. Even though advances have been made in the techniques regarding pathological examinations and immunohistochemistry over the past years, this tumor has been rarely diagnosed in the colon. We report a rare case of a clear cell adenocarcinoma in the colon which was successfully treated by an endoscopic polypectomy.

CASE REPORT

A 71-year-old Japanese woman presented at our hospital due to symptoms of lower abdominal pain and melena. After further examination, the pain was suspected to be due to ischemic colitis. After the symptoms of the ischemic colitis improved, we performed lower endoscopy to the cecum, which revealed healing ischemic lesions at the descending colon and a 7-mm diameter "berry-like" polyp in the sigmoid colon (Figure 1). The biopsy specimens of the polyp did not disclose a definite adenocarcinoma, but an adenoma instead. Radiologic examinations showed no evidence of a tumor elsewhere in the body, including the kidneys or the gynecologic regions. However, the surface of the polyp had a granular surface pattern and an irregular microcapillary appearance, which seemed to indicate a focal malignancy. Because endoscopic polypectomy alone for early polypoid colonic cancer is highly effective[2], we therefore performed a polypectomy during endoscopy in suspicion of focal malignancy. The resected "berrylike" polyp measured 8 mm × 6 mm in diameter with a granular lesion at the top with a cream colored portion in part.

The microscopic examination showed clear cell adenocarcinoma on the top of the polyp and adenoma at the base and body of the polyp. There was no transition between the areas of the usual adenoma and the clear cell adenocarcinoma. Vascular invasion and lymphatic involvement were not found. The cut margin was negative (Figure 2). As shown in Figure 2, we considered the polypectomy was a curative treatment. In PAS staining, the adenoma portion revealed PAS-positive mucin on the superficial layer, while the clear cell adenocarcinoma portion showed mildly PAS-positive mucin. In the Alcian blue staining, the adenoma took up the blue stain, while the clear cell adenocarcinoma did not (Figure 3). For immunochemical staining, the clear cell adenocarcinoma showed positive staining for p53, negative for CK7, weakly positive for CD10, and positive for CK20 (Figure 4), while the adenoma portion showed slightly less positive staining for p53 than did the clear cell carcinoma, and it was negative for CK7, weakly and focally positive for CD10, and positive for CK20. About 70% of the clear cell adenocarcinoma showed Ki67 positive staining, while the adenoma showed about 45% positive staining.

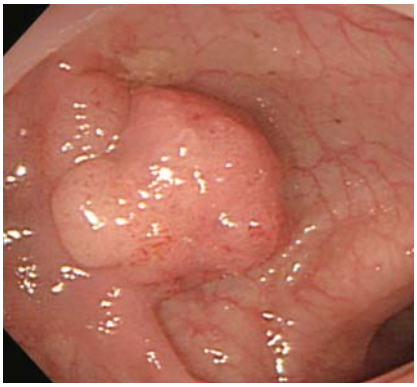

Figure 1 The 7-mm diameter "berrylike" polyp on the sigmoid colon.

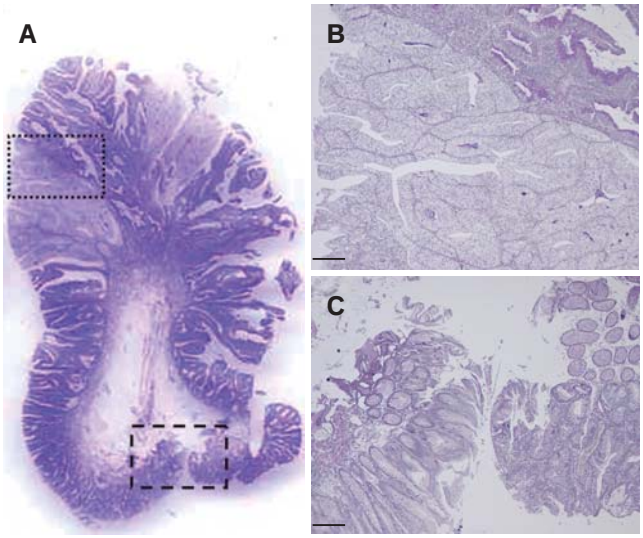

Figure 2 **A**: Polypectomy specimen containing adenoma and partial clear cell carcinoma. The cut margin was showed on the bottom side; **B**: There was no transition between the areas of the usual adenoma on right top of the figure and the clear cell adenocarcinoma on left bottom of the figure; **C**: The cut margin was showed normal colonic mucosa, indicating that this polypectomy was curative treatment. Each bar indicates 200 μm.

DISCUSSION

The presence of clear cell change in colorectal adenoma and adenocarcinoma is extremely unusual. The incidence of a clear cell change in the colorectal adenomas has been reported to be 0.086% out of 3486 cases[3]. In 1964, Hellstrom and Fischer described the first case of adenocarcinoma of the sigmoid colon, composed of neoplastic clear cells which resembled the physaliferous (clear) cells of chordomal tumors[1]. A clear cell adenocarcinoma generally develops in the kidneys[4-6], ovaries[7], extraovarian endometriosis[8,9], uterine cervix[10,11], upper vagina, or lower genital tract[12]. These organs originate from the mullerian system, which may explain the occurrence of clear cell adenocarcinoma in these systems[13]. Therefore, an isolated clear cell adenocarcinoma of the colon is a rare malignancy and its ontogeny remains unclear.

Regarding the clinical characteristics, more male patients with a clear cell adenocarcinoma of the colon have been reported, and the tumor tends to be located on the left side. Almost all cases in Table 1 were reported as an adenoma situated next to a clear cell adenocarcinoma,

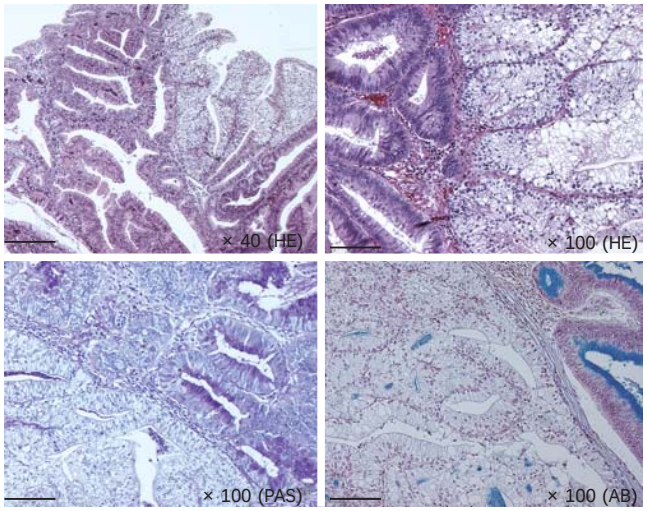

Figure 3 HE staining shows clear cell carcinoma with clear cytoplasm in a normal colonic adenoma (Two top figures). PAS staining shows purple staining on the adenoma on right of the figure, and mild purple staining on the clear cell carcinoma on left of the figure. Alcian blue staining shows granular mucin on the adenoma on right of the figure, and there are no staining on the clear cell carcinoma on left of the figure. Each bar indicates 200 μm.

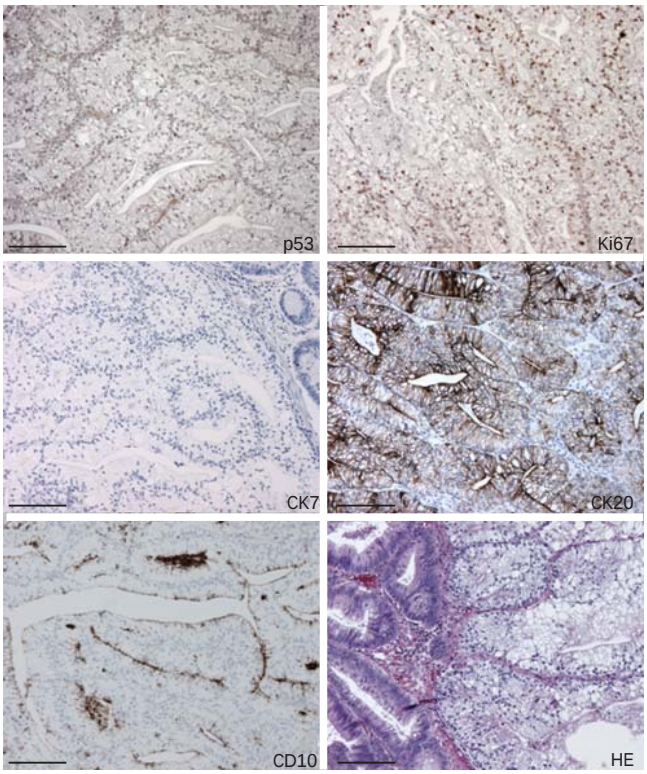

Figure 4 Ki67 is about 70% positive, p53 is positive, CK7 is negative, CK20 is positive, and CD10 is weakly positive on immunochemical staining. Each bar indicates 200 μm.

as well as a clear cell adenocarcinoma situated next to an adenoma. This supports the concept that the adenoma-carcinoma sequence of colorectal carcinogenesis is also valid for the clear cell adenocarcinoma. In our case, a clear cell adenocarcinoma is also presented adjacent to an adenoma.

Most reported cases of clear cell adenocarcinoma

in the colon have been identified as a metastatic focus from other organs, including renal clear cell malignancies or those arising from an ovarian malignancy[14]. A rare combination of primary malignancies in both clear cell renal carcinoma and clear cell carcinoma of the colon has been reported in two patients[4]. In many cases, the differential diagnosis between advanced colonic clear cell adenocarcinoma and metastatic clear cell renal adenocarcinoma seems to be complicated. The similar histologic structure makes it difficult to distinguish between primary colonic clear cell adenocarcinoma and metastases[15]. Our case revealed no other tumors except for the original clear cell adenocarcinoma in the colon. In addition, the clear cell carcinoma occurring next to a normal colonic adenoma also supports the premise that it is the original (primary) tumor. We performed endoscopic polypectomy in this case, and pathological examination showed focal adenocarcinoma with clear cell change on the top of the polyp and common colonic adenoma on the body and base of the polyp. Vascular invasion and lymphatic involvement was not found. The cut margin was negative. As shown in Figure 2, this polypectomy was considered a curative treatment.

Cytokeratins (CK) are a family of at least 20 structural proteins found in the cytoskeletons of epithelial cells. Certain epithelia exhibit characteristic patterns of CK expression depending on the type, location, and differentiation of the epithelium. CK7, essentially, is not expressed in the normal epithelium of the gastrointestinal tract, whereas CK20 is expressed in the intestinal epithelium, the gastric foveolar epithelium, and the endocrine cells in the upper portions of the pyloric glands. On immunochemical staining, it was negative for CK7 and positive for CK20, also indicating that this tumor originated from the colonic mucosa, but not from the mullerian system.

To our knowledge, the proliferative activity among clear cells in adenomas has been rarely discussed. Immunohistochemical staining using antibodies against the Ki67 antigen is recognized to be a useful way to evaluate the proliferative activity of tumors. The increased Ki67 labeling index in the clear cell portion supported a high proliferative activity of the present tumor. The expression of the p53 protein is a well known and frequent abnormality in colorectal cancer, and it is involved in the progression of an adenoma to an adenocarcinoma. In our case, the p53 positivity tended to be higher in the clear cell portion than in the other portions, which supported the high malignant potential of the clear cells. On the other hand, a p53 overexpression has been described in 0%-40% of renal cell carcinomas[16-21] and ovarian clear cell carcinoma, and a p53 overexpression in 7% of other tumors[22]. The p53 immunostaining in this case also supports the evidence for a colonic origin of this colon tumor.

As shown in Table 1, prognosis was not described in most of the cases undergoing polypectomy. One patient was alive for 12 mo without any troubles[24]. This indicates that prognosis of clear cell carcinoma is still unclear. Further reports are necessary for elucidation of this tumor.

In conclusion, we herein reported a rare case of clear cell carcinoma in the colon which was successfully resected by an endoscopic polypectomy.

Abstract

Trichobezoar is a rare intriguing disorder in which swallowed hairs accumulates in the stomach. Being indigestible and slippery, it could not be propulsed and becomes entrapped within the stomach. Large amounts can thus accumulate over the years forming a hair ball. Rapunzel syndrome is a variant where hair accumulation reaches the small gut and beyond in some cases. Although the syndrome has been known for many years, only 24 cases have been reported in the literature and the discovery of a new case is always surprising. In this report, we present two cases discovered within a period of three months. One of them was pregnant and had small bowel intussusception and perforation, a very rare combination. We hereby add two more cases to the literature. To our knowledge, this is the first report on two cases of Rapunzel syndrome, the diagnosis of which demands a high index of suspicion.

INTRODUCTION

Reported in the 18th century[1], trichobezoar is a combination of "trich" meaning hair in Greek and "bezoar" meaning poison antidote in Arabic or Persian[2]. The habitual swallowing of hairs over the years leads to the formation of a hair ball in the stomach. Extension of hairs beyond the stomach into the small bowel in the form of a tail has been termed Rapunzel syndrome[3], after Rapunzel, the heroine of a German fairy tale[4].

CASE REPORT

Case 1

An 11-year-old female, was referred with an abdominal mass associated with epigastric pain, sense of fullness and vomiting after meals, for the previous 15 days. She was a poor school performer and had a history of pica (habitual ingestion of foreign bodies) and habitual thumb sucking. Her siblings, two brothers and two sisters, were all healthy and she had no family or social strains.

On examination, she was uncooperative and mildly dehydrated. Her temperature was 37℃, blood pressure 110/60 mmHg and pulse 90/min. The chest and heart examination were normal. Abdominal examination showed a firm mass about 8 cm × 10 cm in the epigastrium.

Her white blood cell count was 12800/μL (reference range 4000-10000), Hb 12.9 g/dL (reference range 12.1-15.1), platelet count 574000/μL (reference range 190000-405000). The rest of laboratory investigations showed serum proteins of 6.6 g/dL (reference range 6.4-8.2) and serum albumin of 2.7 g/dL (reference range 3.4-5.0). There was no electrolyte disturbance and liver functions, serum amylase and lipase were normal.

Computed axial tomography showed a mass with a hazy outline, filling the stomach. There were air pockets and the mass showed no contrast enhancement. So, the patient was prepared for surgery.

During surgery, a hair ball was found occupying the whole stomach (Figures 1A and 1B) and extending as far down as the jejunum. By gentle manipulation, it was extracted intact (Figure 2), and a gastric ulcer was also found (Figure 3).

After operation, the patient convalesced well, and her hospital stay was uneventful. She was discharged for follow-up in the Paediatric Psychiatry Clinic.

Case 2

A 19-year-old primigravida, at the end of the second trimester, was referred with upper abdominal pain, greenish vomiting, constipation and abdominal distension, for five days. Her history was positive for anorexia and failure to gain weight since childhood. There were no other medical

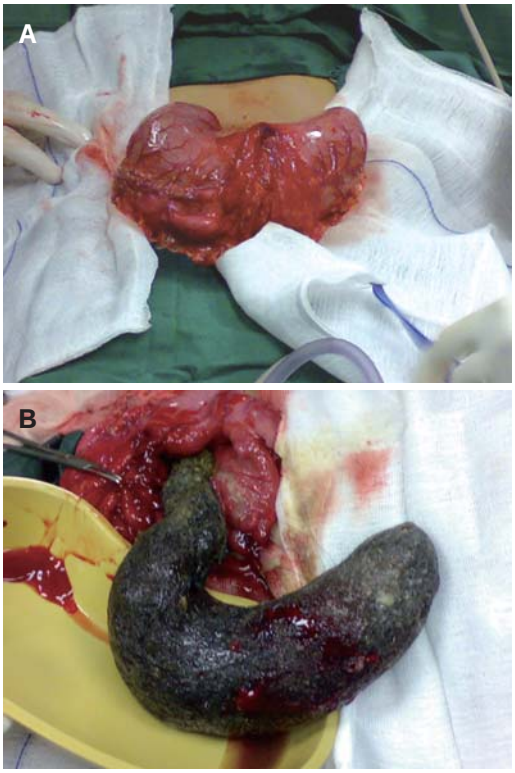

Figure 1 A hair ball occupying the whole stomach (**A**) and extending down into the jejunum (**B**).

Figure 2 Full extent of the hair ball extending into the jejunum.

or psychiatric problems.

On examination, the patient was cachectic and dehydrated, her blood pressure was 120/70 mmHg, pulse 105/min, and temperature 36.8℃. The chest and heart examination were normal.

Abdominal examination revealed a well defined, smooth and firm mass, 18 cm × 20 cm, occupying the epigastrium and almost both hypochondriae. The mass was resonant to percussion and moved freely with breathing.

Her white blood cell count was 5400/μL (reference range 4000-10 000), Hb 9.2 g/dL (reference range 12.1-15.1), platelet count 260 000/μL (reference range 190 000-405 000), Na 138 mEq/L (reference range 135-153), K 2.4 mEq/L (reference range 3.5-5.3). Her random blood sugar, renal values, liver function tests, serum lipase and amylase were within the normal range.

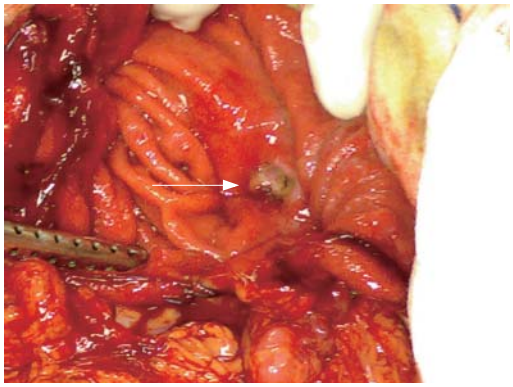

Figure 3 Ulcer in the body of stomach (arrow) caused by hair ball.

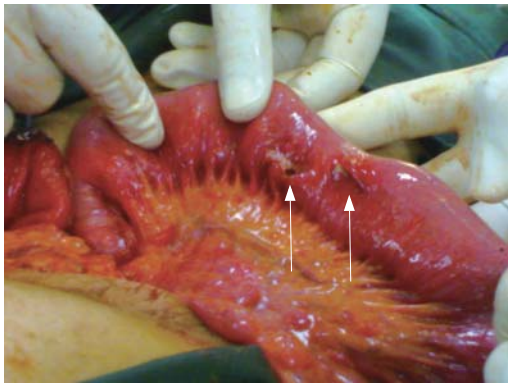

Figure 4 Two perforations at the mesenteric border of the proximal jejunum (arrows).

Abdominal ultrasound showed a large epigastric mass, with acoustic shadow suggestive of a calcified margin. Upper endoscopy disclosed the nature of the mass as a large hair ball occupying the whole stmoch, and the patient was posted for surgery.

At operation, a gastrotomy was done and the hair ball was found extending down to the upper jejunum, causing jejuno-jejunal intussusception. The intussusception was reduced and the hair ball was manipulated out. Two jejunal necrotic perforations were found at the mesenteric border necessitating resection (Figure 4). The gastrotomy was closed in two layers and the abdomen was closed with drainage.

The recovery period was complicated by foetal loss, wound infection and limited ability to receive enough oral feeds. A psychiatric evaluation diagnosed her having an adjustment disorder. The patient finally recovered well and was discharged for psychiatric follow-up.

DISCUSSION

Trichobezoar was first reported in 1779 by Baudamant[1]. The word is a combination of "trich" and "bezoar", with the former meaning hair in Greek, and the later meaning poison antidote in Arabic or Persian[2]. By necessity, trichotilomania (plucking of hairs) and trichophagia (swallowing of hairs) are the leading events.

Rapunzel syndrome, described first by Vaughan

and colleagues in 1968[3], is an extension of the gastric trichobezoar into the small gut in the form of a long tail. It is named after Rapunzel, the heroine of a German fairy tale by the Grimm brothers. She used to let her long golden hair tress down the tower where she was imprisoned, to allow her prince lover to climb up.

The syndrome has been rarely reported. In their report in 1999, Dalshaug and colleagues found only 11 cases[4], whereas in a recent search in 2007, only 24 cases were retrieved from the literature[5].

The reason why hair collects in the stomach is not fully understood. Debakey and Oschner suggested that hair entrapment in the gastric folds is the initiating event[6]. Due to its indigestibility, resilience and slippery nature, it becomes entrapped within the mucosal folds where it gets enmeshed, and acquires more hairs and thus a larger size.

The clinical picture ranges from abdominal pain, nausea, vomiting, early satiety and weight loss, to bleeding ulcer, intestinal obstruction and perforation. Intussusception has also been reported[4].

Although a psychiatric trouble is usually present[7], this is not always the case as the syndrome may affect healthy women[8]. In the first case reported here, the patient had a history of pica, which should be an alarming sign, mandating behavioural or psychiatric intervention. In the second case, although the patient denied any psychiatric troubles or social strains, on careful enquiry, her husband revealed that she had the habit of putting hair in her mouth while thinking.

Anaemia and hypoalbuminaemia associated with chronic gastritis usually go unnoticed until the case is brought to light by the onset of severer complications such as hemorrhage, enteric or pancreatic or biliary obstruction. The onset of perforation and peritonitis is largely responsible for an attendant mortality of about 30%[9]. In the second case, it was evident that intestinal perforation was a very recent onset as the patient showed no relevant signs on initial evaluation.

Trichobezoar affects young females almost exclusively[9] and it has been previously reported during pregnancy[10]. The presence of pregnancy may complicate the management, and foetal loss, as occurred in our second patient, is always a possibility. Provided there is no eminent danger, it might be wise to postpone intervention till the patient delivers.

As mentioned in the classic series of Debakey *et al*[6], an upper abdominal mass remains the commonest presenting sign. In our cases, an upper abdominal mass was easily visible due to its large size and the cachectic habitus of the patients.

Diagnostic modalities include US, CT scan and upper endoscopy. CT scan has a high accuracy rate, but the accuracy of US in such cases is not so high[12]. On CT scan, a well-circumscribed lesion, composed of concentric whorls of different densities with pockets of air enmeshed within it, appears in the region of stomach. Oral contrast fills the more peripheral interstices of the lesion and a thin band of contrast circumscribes it. Absence of significant post intravenous contrast enhancement precludes a neoplastic lesion[13]. In our second case, US failed to give the correct diagnosis, and as CT scan was not an option due to the presence of pregnancy, upper endoscopy was needed to reach the diagnosis. Endoscopy has also been reported to have a therapeutic potential[11]. It is probable that US is not the modality of choice in such conditions[11,12].

Laparoscopy may be successful in extracting the hair ball[10,14]. In our cases, this would not be an easy undertaking due to the young age of the first case and the presence of intussusception and pregnancy in the second. Other minimally invasive modalities like extracorporeal lithotripter, endoscopic lithotripter, and laser fragmentation[9] are emerging. Their role and success rates need to be defined and open surgery remains the gold standard.

In conclusion, surgeons, physicians, and radiologists should consider trichobezoar in the differential diagnosis of gastrointestinal obstruction in young females, especially in the presence of an upper abdominal mass. Timely diagnosis and treatment are of utmost importance to avoid a possible fatal outcome. As recurrences are known, each patient should have a proper psychiatric evaluation and follow-up.

Meetings

Events Calendar 2008-2009

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

18th World Congress of the International Association of Surgeons, Gastroenterologists and Oncologists
8-11 October 2008
Istanbul

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*WJG*, World J Gastroenterol ISSN 1007-9327/ CN 14-1219/R) is a weekly journal with a circulation of more than 15 707, published on the 7th, 14th, 21st and 28th of every month. WJG is a peer-reviewed journal. In 2007 the number of unique overseas visitors to the *WJG* website was 15 600, representing 123 countries worldwide. Original research, reviews, comments, and case reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc*., from all over the world are welcome on the condition that they have not been published previously or submitted elsewhere simultaneously.

Publication model

WJG has a non-profit publication model, which is a combination of an Open Access and commercialized publication model (i.e. payment by a third party). This publication model has proven to be very effective. By 21st December 2007, the number of visitor hits to the *WJG* website reached 21 350 084. *WJG* advocates the tenet that research funding granted to scientists should be used to serve scientists so that high quality scientific articles can be published.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381901-600. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/ analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Patent (list all authors)

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), F test as F (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses, to the reviewers by courier (such as EMS/DHL).

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item for to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Volume 13 Number 8
February 28, 2007

The WJG Press

Contents

EDITORIAL	1149	Practical guidelines for the treatment of inflammatory bowel disease *Kuhbacher T, Fölsch UR*
	1156	New aspects in celiac disease *Torres MI, López Casado MA, Ríos A*
GASTRIC CANCER	1162	(-)-Epigallocatechin-3-gallate inhibits growth of gastric cancer by reducing VEGF production and angiogenesis *Zhu BH, Zhan WH, Li ZR, Wang Z, He YL, Peng JS, Cai SR, Ma JP, Zhang CH*
	1170	Downregulation of survivin by RNAi inhibits growth of human gastric carcinoma cells *Miao GY, Lu QM, Zhang XL*
LIVER CANCER	1175	Selective COX-2 inhibitor, NS-398, suppresses cellular proliferation in human hepatocellular carcinoma cell lines *via* cell cycle arrest *Baek JY, Hur W, Wang JS, Bae SH, Yoon SK*
	1182	Assessment of hemodynamics in precancerous lesion of hepatocellular carcinoma: Evaluation with MR perfusion *Guan S, Zhao WD, Zhou KR, Peng WJ, Tang F, Mao J*
COLORECTAL CANCER	1187	Comethylation of *p16* and *MGMT* genes in colorectal carcinoma: Correlation with clinicopathological features and prognostic value *Krtolica K, Krajnovic M, Usaj-Knezevic S, Babic D, Jovanovic D, Dimitrijevic B*
VIRAL HEPATITIS	1195	Quasispecies evolution in NS5A region of hepatitis C virus genotype 1b during interferon or combined interferon-ribavirin therapy *Veillon P, Payan C, Le Guillou-Guillemette H, Gaudy C, Lunel F*
	1204	Epidemiology and transmission of hepatitis B and C viruses in Kazakhstan *Nurgalieva ZZ, Hollinger FB, Graham DY, Zhangabylova S, Zhangabylov A*
BASIC RESEARCH	1208	Antisense oligonucleotide targeting midkine suppresses *in vivo* angiogenesis *Dai LC, Wang X, Yao X, Lu YL, Ping JL, He JF*
	1214	Tetrandrine stimulates the apoptosis of hepatic stellate cells and ameliorates development of fibrosis in a thioacetamide rat model *Yin MF, Lian LH, Piao DM, Nan JX*
CLINICAL RESEARCH	1221	Role of CARD15, DLG5 and OCTN genes polymorphisms in children with inflammatory bowel diseases *Cucchiara S, Latiano A, Palmieri O, Staiano AM, D'Incà R, Guariso G, Vieni G, Rutigliano V, Borrelli O, Valvano MR, Annese V*
	1230	Molecularly defined adult-type hypolactasia among working age people with reference to milk consumption and gastrointestinal symptoms *Anthoni SR, Rasinperä HA, Kotamies AJ, Komu HA, Pihlajamäk HK, Kolho KL, Järvelä IE*

Abstract

Gastric cancer is one of the most common cancers and the second most common cause of cancer deaths worldwide. Apart from Japan, where screening programmes have resulted in early diagnosis in asymptomatic patients, in most countries the diagnosis of gastric cancers is invariably made on account on dyspeptic and alarm symptoms, which may also be of prognostic significance when reported by the patient at diagnosis. However, their use as selection criteria for endoscopy seems to be inconsistent since alarm symptoms are not sufficiently sensitive to detect malignancies. In fact, the overall prevalence of these symptoms in dyspeptic patients is high, while the prevalence of gastro-intestinal cancer is very low. Moreover, symptoms of early stage cancer may be indistinguishable from those of benign dyspepsia, while the presence of alarm symptoms may imply an advanced and often inoperable disease. The features of dyspeptic and alarm symptoms may reflect the pathology of the tumour and be of prognostic value in suggesting site, stage and aggressiveness of cancer. Alarm symptoms in gastric cancer are independently related to survival and an increased number, as well as specific alarm symptoms, are closely correlated to the risk of death. Dysphagia, weight loss and a palpable abdominal mass appear to be major independent prognostic factors in gastric cancer, while gastro-intestinal bleeding, vomiting and also duration of symptoms, do not seem to have a relevant prognostic impact on survival in gastric cancer.

INTRODUCTION

Although the incidence of gastric cancer is decreasing in many countries, it remains one of the most common cancers and the second most common cause of cancer deaths worldwide[1]. Since the early stage of the disease is often asymptomatic, diagnosis is frequently made at an advanced stage of the disease, characterized by poor prognosis with a reported 5-year survival rate of less than 30% in most series.

Unlike Japan, where the screening programme resulted in a 5-year survival rate of 90%, in Western countries, despite the introduction of open-access gastroscopy, delays in diagnosis still seem to be common and virtually affect the stage of gastric cancer at diagnosis as well as outcome of patients. In fact, in Western countries, where a screening programme is not feasible[2], diagnosis of gastric cancer inevitably relies on symptoms reported by patients. Therefore, the increased awareness of symptoms on the part the patients, as well as correct interpretation of the symptoms and prompt referral for investigation, could reduce the diagnostic delay and, theoretically, improve survival.

To date, perception of symptoms and reasons for seeking, or not, consultation have been more extensively investigated in functional gastro-intestinal disorders than in organic diseases[3,4] and, in several studies, the interpretation and analysis of dyspeptic symptoms seemed to be focused more on reducing the endoscopic workload than on improving the detection of gastro-intestinal malignancy. Finally, the few studies that have analysed the influence of diagnostic delay, namely the symptom-to-diagnosis interval, on survival in gastric cancer have shown disappointing results.

The present review, while focusing attention on an analysis of the literature dealing with the symptoms in diagnosing and suggesting prognosis of gastric cancer, aims to elicit insights into some clinical (unexplored or forgotten) aspects of dyspeptic symptoms and gastric cancer.

IMPORTANCE OF SYMPTOMS IN DIAGNOSIS OF GASTRIC CANCER

Dyspeptic symptoms and also the alarm symptoms that

usually identify dyspeptic patients at higher risk of organic dyspepsia are common not only in patients consulting the general practitioner but also in the general population[5]. Gastro-oesophageal reflux disease, peptic ulcer disease, and functional dyspepsia represent the most frequent causes of dyspeptic symptoms. Only in a few cases are dyspeptic symptoms caused by gastro-oesophageal malignancy[6].

Upper gastro-intestinal endoscopy is usually performed to study patients with dyspeptic symptoms. Endoscopy is, however, expensive, troublesome to the patient, and, in more than 50% of endoscopic examinations, no organic cause can be found[7]. Therefore, non-invasive treatment strategies such as *H pylori* test-and-treat or empirical treatment with acid inhibitory drugs, i.e., proton pump inhibitors and H_2-antagonists, have been proposed and it has become evident that these strategies are at least as effective as upper gastro-intestinal endoscopy followed by targeted treatment[7-10].

However, the main concern, in the application of empirical treatments of dyspepsia are the possibility of missing gastric cancer or of delaying the time to diagnosis. An accurate selection of patients with a higher risk of gastro-oesophageal cancer, to be immediately submitted to endoscopy, is thus very important. Alarm symptoms such as weight loss, dysphagia, signs and symptoms of upper gastro-intestinal bleeding, anaemia, and persistent vomiting, are likely to be more frequently associated with upper gastro-intestinal malignancies, and most guidelines recommend immediate endoscopy in all patients presenting these symptoms[11-13].

The evidence supporting the use of alarm symptoms as selection criteria for endoscopy is, however, inconsistent since, on the one hand, alarm symptoms are not sufficiently sensitive to detect malignancies and, on the other, the overall prevalence of alarm symptoms, in a population of dyspeptic patients is high, while the prevalence of gastro-intestinal cancer is very low.

The studies, so far, reporting a high prevalence of alarm symptoms in gastro-intestinal malignancies are mainly retrospective and, according to these studies, up to 90% of patients with gastro-oesophageal malignancies present alarm symptoms at the time of endoscopy[14-16]. Large prospective cohort studies have achieved less significant results. For example, Meineche-Schmidt[17] showed that, in a large cohort of primary care patients with dyspeptic symptoms, the majority of patients who developed gastric/oesophageal cancer did not present with any alarm symptoms, while Lieberman[18], who studied a large database of endoscopy reports, showed that only 56% of patients with gastric/oesophageal cancer had alarm symptoms.

This discrepancy in results between the different studies may be explained by the fact that, in retrospective studies, patients may have had more advanced cancers which are less often asymptomatic[19] or that the retrospective analysis may have over-estimated the prevalence of alarm symptoms before endoscopy.

Due to the low prevalence of gastric and oesophageal cancer in the population, studies on larger series are needed. A recent investigation by Janssen, which appeared as an abstract[20], combined individual patient data from 7 prospective studies thus referring to more than 13 000 dyspeptic patients undergoing endoscopy. This investigation, which likely offers a more reliable picture of the problem, reported a prevalence of alarm symptoms of 30% (3927/13 377) and of 62% (103/165) in patients with gastro-intestinal cancer. This resulted in a sensitivity of 62.4%, a specificity of 70.5%, a positive predictive value of 2.6%, and a negative predictive value of 99.3% when the parameter "having any alarm symptom" was used to diagnose the presence of cancer. Interestingly, none of each individual alarm symptom was able to identify more than 30% of patients with gastric or oesophageal cancer. Moreover, the prevalence of alarm symptoms did not differ between young (< 50 years) and elderly (> 50 years) patients (11/19, 57.9% *vs* 92/146, 63%).

The role of each individual alarm symptom for predicting cancer in patients referred to a "rapid access upper gastro-intestinal cancer" service was evaluated by Kapoor[21]. In that study, involving, prospectively, 1785 patients referred for urgent endoscopy for suspected organic disease (which derived either from the occurrence of alarm symptoms or the presence of non-responsive, uncomplicated dyspepsia), occurrence of gastro-intestinal malignancies and benign organic disease was 3.8% and 12.8%, respectively. Dysphagia and weight loss were the only symptoms found to represent significant predictive factors for cancer [Odds Ratio (OR) 3.1 and 2.6, respectively]; age > 55 years was also a predictor of cancer (OR 9.5) but, uncomplicated dyspepsia, irrespective of age, was actually found to be a negative predictor of cancer (OR 0.1). From these data the authors developed a model in which, in dyspeptic patients, dysphagia and weight loss would represent criteria to perform endoscopy at any age, while age > 55 years would represent an indication for immediate endoscopy, only in the presence of an alarm symptom.

To improve the diagnosis of gastro-intestinal cancer, age is considered an important factor. There is a gradual increase in the risk of gastric and oesophageal cancer with age, but, unfortunately, a clear cut-off is difficult to define. Although, in the vast majority of the populations studied, almost 90% of patients with cancer are > 50 years, albeit the age distribution of upper gastro-intestinal cancer may vary; indeed, in Poland, Boldys[22] showed that, in a high-risk tertiary care population, as many as 24% of patients with gastric cancer were < 45 years.

Use of the age criteria to select dyspeptic patients to investigate with endoscopy is considered safe by most authors, provided the age cut-off has been determined using data from the local population[23-25]. Male sex is also significantly associated with gastro-intestinal cancer and, according to some authors; the age threshold for endoscopy should be lowered in males to decrease the risk of missing cancer, and could be safely increased in females without affecting outcomes[25].

Approximately 3%-4% of the population, in industrialized countries, consult their general practitioner with upper gastro-intestinal symptoms each year, of which over 10% will have alarm symptoms[26]. The symptoms of early stage cancer may be indistinguishable from those of benign dyspepsia, while the presence of established

alarm symptoms may imply advanced inoperable disease. This represents a dilemma in terms of defining criteria and priorities for investigating upper gastro-intestinal symptoms, particularly in healthcare systems where the potential demand for endoscopy may exceed the level of provision.

Current guidelines, based on the rising incidence of malignancy with age, suggest that patients with uncomplicated dyspepsia be investigated, only if older than a cut-off age[12,13], but the concern of missing cancer in young dyspeptics may be overcome only by investigating every patient with recent-onset dyspeptic symptoms regardless of age. The Canadian (CADET) study, which examined 1021 patients referred from primary care units, without alarm symptoms, identified only 2 cancers[27]. Other studies have demonstrated that the endoscopic yield of cancer, in simple dyspepsia, is low and only very few of the identified cancers are resectable[15,28].

We do not know whether the incidence of malignancy in patients with uncomplicated dyspepsia is different from that in the non-dyspeptic population; but we do know that early gastro-intestinal cancers are asymptomatic and are usually diagnosed by chance in patients undergoing endoscopy for dyspeptic symptoms secondary to benign or functional conditions. The impact of delaying the diagnosis of gastric cancer while giving a short course of empirical treatment is unknown, but, probably, a strategy of initial non-invasive management is unlikely to significantly affect the outcome, in the majority of young patients with benign dyspepsia provided the physician promptly arranges endoscopy where appropriate, i.e., in the event of lack of response to empirical therapy[29].

PROGNOSTIC RELEVANCE OF SYMPTOMS IN GASTRIC CANCER

The prognosis of gastric cancer has improved, in recent years, at least in Eastern countries where the 5-year survival rate is 50%-60%[30-32]. On the contrary, survival rates in Western series are still dismal, ranging between 8% and 26%[33-37]. One of the main reasons for this discrepancy is the efficacy of screening programmes in Japan, where the high incidence and awareness of the condition, and ready access to endoscopy have led to cancers usually being diagnosed in asymptomatic patients or in patients with minor dyspeptic symptoms[38]. In Europe and Western countries, where a screening programme is not feasible, the diagnosis of gastric cancers is invariably made on account of symptoms.

Indeed, the onset, duration and features of dyspeptic and alarm symptoms may suggest the diagnosis of gastric cancer, but they also reflect pathological features of the tumour and, therefore, have some prognostic value.

To date, the survival rates of gastric cancer, as well as the differences in survival rates observed between Eastern and Western case series, have been mainly attributed to the stage of the tumour, namely the depth of gastric wall invasion and status of lymph node and metastasis. Reports in the literature investigating the prognostic factors in gastric cancer, have focused mainly on the relevance of tumour-related features (such as, tumour node metastasis (TNM) classification, histological type, tumour appearance, site and size) or treatment-related factors (extent of gastric resection and lymphadenectomy and post-operative treatment) other than on patient-related clinical features.

However, since the eighties and more consistently in recent years, the prognostic role of symptoms, particularly alarm symptoms, in gastric cancer survival, has been investigated.

Symptoms and cancer stage

The alarm symptoms accompanying dyspeptic symptoms do not only have a diagnostic role in indicating the possible presence of gastric cancer, but when referred to, at diagnosis, in gastric cancer patients, may suggest the site, stage and aggressiveness of cancer and usually indicate poor prognosis.

In a retrospective study on a series of 92 young gastric cancer patients, we have evaluated the relationship of alarm symptoms, such as dysphagia, anorexia, weight loss, gastro-intestinal bleeding and vomiting with pathology (intestinal or diffuse) and site of cancer and stage, according to the TNM classification. Patients presenting with alarm symptoms were comparable to those with uncomplicated dyspepsia as far as concerns age, sex and pathology of gastric cancer, but more frequently showed a proximal site and more advanced TNM stage[19]. These findings have been confirmed by Stephens, who also showed that the number of alarm symptoms, at presentation, correlated with the stage of the tumour, in that patients with the greatest number of alarm symptoms presented with the most advanced disease[39] and by Bowrey, in a more recent study, in which approximately 50% of the patients with alarm symptoms had stage Ⅳ disease[40].

Indeed, the relationship between symptoms and stage of cancer is conceivable if we consider the profile of symptoms in early gastric cancer which are not unlike those of benign gastric ulcer rather than advanced cancer. Epigastric pain and dyspepsia are very frequently present, whilst alarm symptoms occur in only a minority of patients. For instance, weight loss occurs in less than 40% of patients, in early gastric cancer, while it is a common feature of advanced gastric cancer[41]. The reasons triggering benign or malignant symptoms in gastric cancer, and whether benign may convert to malignant symptoms over time, deserve further investigation.

Specific symptoms and outcome of gastric cancer

Since symptoms correlate well with cancer stage at diagnosis, they are likely also of prognostic value. Indeed, several studies have assessed the prognostic value of specific alarm symptoms in gastric cancer, demonstrating that these may be independently related to the survival of patients with gastric cancer and that, an increased number of alarm symptoms and specific symptoms are closely correlated to the risk of death. Studies that evaluated the impact of alarm symptoms on gastric cancer survival showed that the presence of at least one alarm symptom might reduce the 5-year survival rate by an average of 26%[19,39,40]. We have also shown that the

risk of death is nearly threefold in patients with at least one alarm symptom compared with that in patients with uncomplicated dyspepsia[19]. Moreover, Stephens and Bowrey reported that the median survival for patients with alarm symptoms, from presentation to death, ranged from 7 to 11 mo *vs* 24 to 39 mo for patients without alarm symptoms[39,40].

These dismal prognostic data in gastric cancer patients with alarm symptoms are not completely new. Earlier studies and recent confirmation have shown that any symptom may have a significant and independent prognostic role in gastric cancer patients and that specific symptoms may have a particularly greater prognostic impact.

It is difficult to analyse, compare and describe the prognostic role of each alarm symptom reported in the literature on account of the different definition criteria of symptoms, retrospective collection of data in most studies, geographic and time differences in treatment-related prognostic factors, and different age of patients enrolled in the studies. However, of the alarm symptoms most widely considered, namely dysphagia, weight loss, palpable abdominal mass, gastro-intestinal bleeding, anaemia, persistent and continuous vomiting, the data published so far have consistently identified dysphagia, weight loss and palpable abdominal mass as the most relevant and independent prognostic factors in gastric cancer.

Weight loss has been considered among the potential prognostic factors for gastric cancer by at least 13 studies so far, and in 10 of these it resulted significantly and independently related to the fatal outcome[19,39,40,42-51]. It is not possible to calculate life expectancy in gastric cancer patients presenting with weight loss. However, the 5-year survival rate ranged from 13.5% to 31%[39,44] and the mean survival reported was less than 1.2 years[46,40]. Indeed, the prognostic relevance of this symptom is well known. It correlates with malnutrition and impaired immune response. Weight loss does not merely increase post-operative complications, but also reduces the response and increases the toxicity to chemotherapy[45,48,52]. Indeed, it has been shown that 10 d of pre-operative total parenteral nutrition (TPN), which is continued post-operatively, reduces the complication rate and prevents mortality in severely malnourished patients with gastro-intestinal cancer[53].

As far as concerns dysphagia, 5 studies evaluated the prognostic relevance of this symptom in gastric cancer, all of which showed that is was significantly associated with poor outcome[19,39,40,44,46]. Indeed, the prognosis of patients presenting this symptom seems to be even worst than that reported for weight loss, with a 5-year survival rate of 6%-7%[39,44], a mean survival < 10 mo[40,46] and risk of death > 7 times compared to that of patients without alarm symptoms[19]. Dysphagia usually identifies tumours of the cardia and proximal part of the stomach with prognosis being worse than in other locations for gastric cancer. Moreover, it is usually associated also with malnutrition and weight loss.

Another alarm symptom which is invariably associated with poor prognosis is the presence of a palpable abdominal mass. Eight studies have assessed the prognostic value of this sing[39,40,44-47,54] and all but one found a strong association with a very low 5-year survival rate (0%-20%)[39,44,54] and also with a very short life span (< 4 mo)[40,46].

The prognostic role of vomiting and gastro-intestinal bleeding is more controversial. As far as concerns vomiting, as an alarm symptom, 2 out of 4 studies[19,39,40,46] evaluated the prognostic significance of this symptom and showed that is was correlated with brief survival, namely a median survival of 9 mo, in one study[40], and a 5-year survival of 14%, in the other[39]. Indeed, this symptom implies a certain degree of subjective interpretation and it may be difficult to retrospectively consider it as an alarm symptom, if persistent and continuing, or as a 'simple' dyspeptic symptom if occasional or of mild degree.

Gastro-intestinal bleeding has been regarded as a prognostic symptom in 4 studies[19,39,44,47] but in none showed any significant impact on outcome, probably because haemorrhage may appear even in earlier phases of the tumour and may not necessarily be related to the stage. In none of the studies investigating the role of specific dyspeptic symptoms, such as epigastric pain or abdominal discomfort, were these significantly related to survival.

Duration of symptoms and outcome of gastric cancer

The stage of gastric cancer, at diagnosis, has been regarded as the most important prognostic factor for survival. We have shown that it is correlated with the presence of specific symptoms. It has been argued that prolonged duration of symptoms, or - in other words - delay in diagnosis, could result in missing a gastric cancer at a hypothetically curable stage and, therefore, with a negative effect on survival[55].

For this reason, several studies have assessed the impact of dyspeptic versus alarm symptoms on diagnostic delay, and of symptoms-to-diagnosis time interval on survival in gastric cancer. All studies showed, as expected, that delay in diagnosis was longer for patients without alarm symptoms compared to that of patients with alarm symptoms[19,39,40]. However, all these studies also showed that, despite the diagnostic delay, survival rate of patients with gastric cancer who lacked alarm symptoms, at the time of diagnosis, was better than that in patients with alarm symptoms at presentation. Paradoxically and more important, patients with uncomplicated dyspepsia with a delay more than 6 mo showed better survival rates[19,39,55-59].

Indeed, the duration of symptoms has been considered as a relevant prognostic factor in several studies. At least 14 studies have evaluated this prognostic aspect but all showed that duration of symptoms was not related to poor outcome[19,32,43-46,60-67]. It would have seemed obvious that the sooner a patient is treated for cancer, the better the prognosis will be. On the contrary, almost all studies published, so far, have shown that delay in diagnosis is not a relevant prognostic factor and more than one study demonstrated that long duration of symptoms is associated with the earlier the tumours are diagnosed, longer the survival[19,46,59,60].

Other studies have shown that gastric cancer patients with alarm symptoms have a poor prognosis despite a much shorter symptom-to-diagnosis time interval

compared to patients without alarm symptoms, providing indirect evidence that the relationship between duration of symptoms and prognosis is less important than the characteristics of the symptoms at presentation.

One possible explanation for this is that mild or dyspeptic symptoms, that do not alarm the patient or his/her doctor, might be associated with a cancer disease presenting a less aggressive behaviour and slower progress[68]. But this remains to be demonstrated, to date. Another possible explanation is that the delay in diagnosis in patients without alarm symptoms may, instead, be due to the long duration of dyspeptic symptoms, the onset of which had not been related to gastric cancer. In this case, less symptomatic patients tend to have a less severe/advanced disease.

However, it is noteworthy that this inverse relationship between delay in diagnosis and survival has been consistently observed in several studies in various parts of the world. The potential practical implication for this is that a diagnostic delay of 6 mo since presentation of symptoms could be an acceptable time to evaluate the outcome of treatment in patients presenting with uninvestigated, uncomplicated, dyspepsia, without affecting survival if gastric cancer is already present. This has also been demonstrated already in two clinical studies in which anti-secretory drug treatment delayed the diagnosis of upper gastro-intestinal adenocarcinoma without affecting outcome, in most patients[29], and by another where the outcome of patients in whom the cancer was missed, at a previous gastroscopy, showed a similar outcome to that of patients with prompt correct diagnosis[69].

However, it cannot be excluded that improving the diagnosis of gastric cancer, when it presents without alarm or severe symptoms, may result in better prognosis[70]. To date, in fact, the behaviour of symptoms, in gastric cancer, is still poorly understood. Gastric cancer patients with alarm symptoms, at diagnosis, may have complained of uncomplicated dyspepsia at the onset of their symptoms, and developed alarm symptoms later. We do not know whether these patients differ from those presenting with alarm symptoms, as far as concerns delay of diagnosis, features and stage of gastric cancer. Further prospective studies are, therefore, needed not only to evaluate this aspect but would undoubtedly contribute to reaching a more accurate evaluation of symptoms and their impact on prognosis. Symptoms may vary from the onset to the diagnosis and referral of symptoms may depend on social and cultural factors[71]. A supportive study, in this direction carried out by Meineche-Schmidt and Jørgensen[17] in a primary care setting revealed that the majority of patients in whom upper gastro-intestinal cancer developed did not have alarm symptoms at their initial primary care consultation. It thus follows that the diagnosis of upper gastro-intestinal cancer, in most patients, is delayed until alarm symptoms occur, with inevitable consequences in terms of prognosis.

Abstract

Recent reports have suggested that autoimmune enteropathy involving the small bowel may occur in adults as well as in children. Apparently, the endoscopic and histological changes are similar to celiac disease before treatment, but these are not altered by any form of dietary restriction, including a gluten-free diet. As in celiac disease, histologic changes in gastric and colonic biopsies have also been recorded. Anti-enterocyte antibodies detected with immunofluorescent methods have been reported by a few laboratories, but these antibodies appear not to be specific and may simply represent epiphenomena. A widely available, reproducible and quantitative anti-enterocyte antibody assay is needed that could be applied in small bowel disorders that have the histological appearance of celiac disease, but fail to respond to a gluten-free diet.

COMPONENTS OF DIAGNOSIS

A number of reports in adults[1-7], similar to prior publications in children[8-10], have described an entity, termed autoimmune enteropathy (AIE), that appears to involve mainly, but not exclusively, the small intestine[4,7]. Some of the histologic changes, at least in adults, have been reported to permit pathological distinction from other disorders characterized by severe small bowel mucosal architectural abnormalities, specifically untreated celiac disease (Table 1). Specifically, reduced numbers of intra-epithelial lymphocytes, especially in surface epithelium, may be evident in AIE compared to adult celiac disease[7]. In AIE, the diarrhea fails to respond to any form of dietary restriction, including a gluten-free diet[8]. Circulating anti-enterocyte and/or anti-goblet cell antibodies are generally present in diagnosed AIE[7], but their precise significance in the pathogenesis of this disorder is not clear. It has been postulated elsewhere that these antibodies likely only represent epiphenomena since these appear after the onset of mucosal damage and then disappear following treatment, but before return to normal mucosa[11]. In some, pathological changes in gastric and colonic biopsies have also been recorded[7].

The antibodies are reported to appear as a linear pattern along the apex or brush border of the enterocytes, sometimes with an extension along the baso-lateral membrane[10]. Usually, the antibodies are IgG in type, sometimes complement-fixing, while in some, IgM and IgA antibodies occur[7,10]. These anti-enterocyte antibodies do not appear in celiac disease, Crohn's disease or ulcerative colitis[10]. Antibodies may also react with mucus in goblet cells, but these seem to be even less specific than anti-enterocyte antibodies[10]. For example, antibodies to goblet cells have been detected in chronic inflammatory bowel disease patients and their first-degree relatives[12].

Other co-existent autoimmune disorders as well as antibodies of different types have been observed in AIE. Indeed, even antibodies to tissue transglutaminase (tTG) have been described in over 30% of the largest series of reported AIE patients[7]. However, the presence of an associated autoimmune disorder is not a truly distinctive or differentiating clinical feature as autoimmune disorders have been commonly reported in several small bowel disorders, particularly in celiac disease, regardless of duration of gluten exposure[13-16].

DIAGNOSTIC DIFFICULTIES AND THE FUTURE

Most clinicians are likely to encounter significant difficulties in securing a definite diagnosis of AIE, because its precise differentiation from other small bowel disorders may be very difficult, at least based on current suggested criteria for diagnosis of adult AIE[7]. A number of factors have come into play. First, dietary compliance, even in an

Table 1 Comparison of celiac disease and autoimmune enteropathy in adults

	Celiac disease	Autoimmune enteropathy
Diarrhea	Responds to gluten-free diet	No response to diet therapy
Endoscopic and microscopic changes	Not specific, responds to gluten-free diet	Not specific, similar to celiac disease (pre-gluten-free diet)
Gastric and colon microscopic changes	May be abnormal	May be abnormal
Ages reported	All ages	All ages, mainly children
Autoimmune phenomena	Present	Present
TTG antibodies	Usually present	Present in 30% or more
Prognosis	Good with gluten-free diet	Unknown, anecdotal results

adult, may be exceedingly difficult to define. If dietary indiscretion is intentional or unavoidable, it may be very obvious. However, most experienced clinicians know that it may be very difficult to confirm that a specific diet has been continuously followed for prolonged periods (eg., gluten-free diet in celiac disease). Alternative "markers" have been suggested. For example, reduced antibodies to tTG in celiac disease have been suggested by some to provide a marker of compliance to a gluten-free diet, but others dispute this claim[17-19]. Second, failure to resolve symptoms with dietary restriction (eg., gluten) should not necessarily translate into a diagnosis of a persistent or refractory disorder. Other concomitant causes for symptoms, including functional disorders, may co-exist. Third, evidence for persistent histopathological changes in spite of dietary restriction may be more reflective of an inadequate duration of dietary restriction in order to detect a response or an inadequate method of assessment. In celiac disease, for example, histological evidence of normalization of pathological changes may require months or years, and usually occurs first in the most distal sites of involvement. Only later, sometimes much later, can a definite histopathological response to a gluten-free diet be documented in the most proximal small bowel (where endoscopic biopsies are generally taken). Fourth, only a limited number of laboratories claim to be able to detect anti-enterocyte antibodies, even though required methodology is straightforward, i.e., immunofluorescence microscopy. While anti-enterocyte antibodies are apparently not present in celiac disease[10], it appears that some of the histopathologic features of adult AIE may co-exist with those of celiac disease[7], further confusing the clinical picture.

In addition, these anti-enterocyte antibodies are not specific for AIE being reported in HIV-associated immunodeficiency syndromes without intestinal symptoms[20]. As noted earlier, anti-goblet cell antibodies which may be even less specific have been described in inflammatory bowel disease patients and their relatives[12]. Finally, and most importantly, immunofluorescent methods for serum antibody detection are very subjective, and observer-dependent. Use of immunofluorescent methods for screening (eg. anti-endomysial antibodies for celiac disease) are often based on "in-house" assays and may be difficult to reproduce between different laboratories, even if the same sources of sample material are used.

Further studies are needed to determine if AIE in adults is truly a separable clinical entity that may be amenable to other treatments. The most critical element needed is a widely available, reproducible, sensitive and specific assay for anti-enterocyte antibodies that might permit separation of AIE from other small bowel disorders and be an important addition to the investigative methods currently available for persistent diarrhea disorders in adults. To date, different therapeutic options have been used in an anecdotal fashion in adults diagnosed with AIE[7], but a conclusive approach to treatment still requires further evaluation.

Abstract

This article is to offer a concise review on the use of cytoreductive surgery (CRS) plus intraperitoneal hyperthermic chemotherapy (IPHC) for the treatment of peritoneal carcinomatosis (PC). Traditionally, PC was treated with systemic chemotherapy alone with very poor response and a median survival of less than 6 mo. With the establishment of several phase Ⅱ studies, a new trend has been developed toward the use of CRS plus IPHC as a standard method for treating selected patients with PC, in whom sufficient cytoreduction could be achieved. In spite of the need for more high quality phase Ⅲ studies, there is now a consensus among many surgical oncology experts throughout the world about the use of this new treatment strategy as standard care for colorectal cancer patients with PC. This review summarizes the current status and possible progress in future.

INTRODUCTION

The loco-regional progression of gastrointestinal and gynecological cancers usually result in peritoneal carcinomatosis (PC), which is characterized by the presence of tumor nodules of various size, number and distribution on the peritoneal surface, with very poor prognosis and a median survival of less than 6 mo[1-3]. The most widely accepted therapies for such PC are systemic chemotherapy, best support care and palliative treatment, without any hope of cure. Moreover, surgery alone can only remove the bulky visible tumor nodules. For the micrometastases, invisible free cancer cells and those tumor masses not suitable for resection, surgery can not achieve any effect. Therefore, neither surgery nor chemotherapy alone can make obvious positive impact on the survival and quality of life in patients with PC. In order to tackle this difficult problem, a new treatment modality called cytoreductive surgery (CRS) plus intraoperative peritoneal hyperthermic chemotherapy (IPHC) has been developed over the past two decades, which has the advantages of surgery to reduce the visible tumor burden and regional hyperthermic chemotherapy to eradicate micrometastses and free cancer cells[4]. Over the past decade, this treatment modality has gained increasingly wide acceptance in clinical practice and in some cancer centers in Europe, America, Japan and Australia, and has been adopted as the treatment of choice for PC from gastrointestinal tract or pelvic malignancies. This paper summarizes the biological basis, the indications and contraindications, the techniques, the efficacy and safety issues and future directions of this new treatment.

INCIDENCE, MORBIDITY AND MORTALITY OF PC

PC is a direct consequence of loco-regional progression

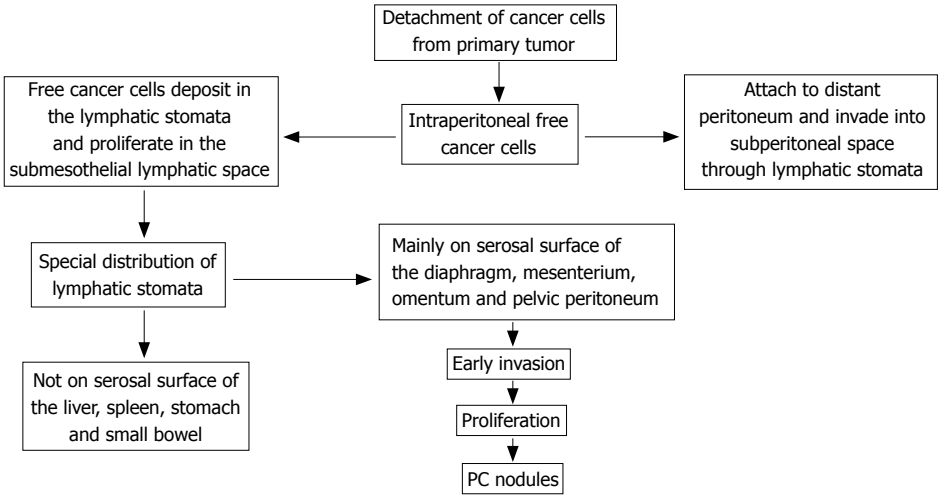

Figure 1 Mechanism of PC development.

of gastrointestinal and gynecological cancers including gastric cancer (GC), colorectal cancer (CRC), ovarian cancer (OC), appendiceal cancer and malignant peritoneal mesothelioma.

For GC, 10%-20% of patients being explored for potentially curative resection are found to have peritoneal seeding at the time of abdominal exploration. This occurs most frequently in patients with signet ring cell type of GC as opposed to intestinal type pathology[5]. Furthermore, peritoneal recurrence develops in 60% of patients with T3 or T4 tumor after curative resection[6]. In T3 or T4 tumor, invisible micrometastases are already present in the peritoneal cavity at the time of curative resection, and peritoneal recurrence is the only site of the first recurrence in 40%-60% of patients[7-9]. Therefore, peritoneal dissemination alone usually results in death of 20%-40% of patients with GC[10].

For CRC, peritoneal seeding of cancer cells leading to PC is rather common. It is estimated that, at the time of diagnosis, the peritoneal surface is already involved in 8%-15% of CRC cases, and that initial recurrence in the peritoneum occurs in up to 50% of patients after curative surgery[11-14]. In approximately 25% of patients with recurrent CRC, the peritoneal cavity seems to be the only metastatic site of the disease, even after a detailed diagnostic workup of the liver and lungs[15].

OC is another malignancy prone to peritoneal metastasis. About 50%-75% of women with OC will develop persistent or recurrent disease with a long survival rate in only 25% patients[16,17]. In about 82% of the cases, the recurrence is within the peritoneal cavity while in 12% it occurs in the retroperitoneal lymph nodes[18-20]. For early stage OC, the median recurrence time ranged between 11 mo and 29 mo with much more involvement of the pelvis or abdomen than retroperitoneal lymph nodes[21-28]. For advanced OC, if the initial treatment achieves meaningful clinical response, the median recurrence time ranges from 18 mo to 24 mo, again with peritoneal metastasis as the most common site[16,19,29-34].

MECHANISMS OF PC DEVELOPMENT

PC is formed through a multi-step process (Figure 1): (1) detachment of cancer cells from primary tumor. The origin of PC in GC, for example, is considered to be the intraperitoneal free cancer cells, which are exfoliated from the serosal surface of the primary tumor; (2) intraperitoneal free cancer cells attach to the distant peritoneum, and invade into the subperitoneal space; (3) invasion into subperitoneal space; and (4) proliferation with vascular neogenesis[35,36].

Recent studies have revealed special anatomical basis for peritoneal metastasis. Yonemura *et al*[9,37] found special peritoneal lymphatic orifices, which are referred to as the lymphatic stomata and connect with subperitoneal lymphatic channel and milky spots. Milky spots are the minute organelles which contain lymphatic vessels, lymphocytes, and peritoneal macrophages. Milky spots distribute mainly on the greater omentum and pelvic peritoneum. Intraperitoneal free cancer cells specifically deposit in the lymphatic stomata and proliferate in the submesothelial lymphatic space. The lymphatic stomata showed special distribution on the peritoneal surface. Numerous stomata are detected on the undersurface of the diaphragm, small bowl mesentery, greater omentum, appendix epiploicae of the large bowel and the pelvic peritoneum. In contrast, there are no lymphatic stomata on the liver capsule, the surface of the spleen and the serosal surface of the small bowel and stomach. Accordingly, the serosal surface of these organs is involved only at the late phase of peritoneal dissemination.

CURRENT TREATMENT STRATEGIES AGAINST PC

For a long time, PC has been considered as a preterminal condition and treated with systemic chemotherapy alone with poor outcome; and the role of surgery is just palliative to relieve intestinal obstruction. But at least 1 phase Ⅲ and many phase Ⅱ studies have shown that the use of CRS with IPHC can improve survival for PC. Currently, such method of treatment has evolved into a novel approach for PC and might represent the standard care in selected patients (Figure 2)[38-40].

Rationale

Intraoperative use of chemotherapeutic agents to maximize

the efficacy of both surgery and chemotherapy has many advantages. First, surgery can separate the adhesions and remove the bulky tumor, leaving microscopic residual tumors much more susceptible to the killing effect of chemotherapeutic drugs. Second, intraperitoneal chemotherapy has distinct pharmaceutical advantages. In a recent phase I study by Morgan *et al*[41], 36 patients with PC of different origin were treated with intraperitoneal gemcitabine chemotherapy. It was found that the median peak peritoneal concentration was 1116 folds (range, 456-1886) higher than the peak plasma level. This could increase the local drug concentration, thus intensifying its direct antitumor effect while reducing the systemic adverse effects. Such preferential high concentration of drugs in the peritoneal cavity also occurs in many other drugs such as doxorubicin, melphalan, mitomycin C, cisplatin, gemcitabine, mitoxantrone, oxaliplatin, etoposide, irinotecan, paclitaxel, docetaxel, 5-fluorouracil, floxuridine and carboplatin[42]. Third, heat itself has direct detrimental effect on the growth of cancer cells. Cell membrane, cytoskeletons, synthesis of macromolecules, and DNA repair mechanisms are all affected by hyperthermia[38]. Temperature over 43℃ has direct cytostatic effect on human breast cancer cell line MCF-7, ovarian SKOV-3 and hepatocarcinoma HEpG2 cells[43]. Fourth, the synergistic effect of hyperthermia and chemotherapy has also been well-documented. It has been shown that hyperthermia increases the cytotoxicity of some chemotherapeutic agents[43-45]. Because of these advantages, CRS plus IPHC has been increasingly used in the treatment of PC from GC[46], malignant mesothelioma[47], appendiceal cancer[48], CRC and OC[49-60].

Indications, contraindications and patient selection

IPHC is commonly indicated for the treatment of PC with GC, CRC, appendiceal cancer, OC, peritoneal mesothelioma, pseudomyxoma peritonei and malignant ascites, if the patients can stand CRS and IPHC[38]. The contraindications are as follows: (1) patients are medically unfit to undergo the rigors of CRS and IPHC e.g. those with renal and myocardial impairments; (2) there is an extra-abdominal disease; (3) parenchymal hepatic metastases; (4) bulk retroperitoneal disease; (5) the peritoneal tumor is incompletely resected or can not be significantly reduced; and (6) patients aged over 70 years[38]. A clear preoperative staging of PC is necessary for such treatment. Preoperative abdominopelvic CT, MRI, positron emission tomography (PET) or PET/CT, or laparoscopy are adequate procedures[39].

Techniques

Complete CRS is vital in improving the survival of patients with PC, although in some patients with limited PC, partial removal of peritoneum is enough to eliminate macroscopic disease[61]. The goal of complete CRS is to remove all macroscopic peritoneal dissemination. Peritonectomy consists of two big surgical components (parietal and visceral peritonectomy). A midline incision extending from xiphoid process to pubis is sometimes necessary, complete parietal peritonectomy can be achieved by stripping off the parietal peritoneum at the abdominal incision, then

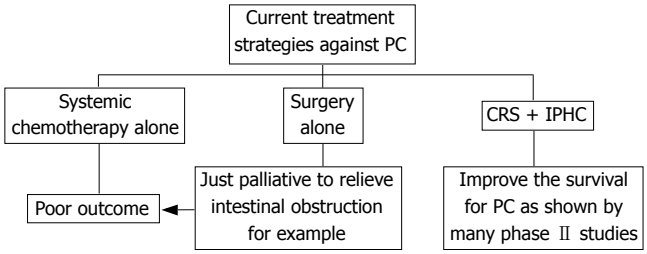

Figure 2 Rationale of CRS plus IPHC in treating PC.

ascending colon, spleen, pancreatic tail, and descending sigmoid colon are mobilized, and all peritoneum lining the lower abdominal wall and pelvis is removed. Visceral peritonectomy includes subtotal colectomy, omentectomy, partial gastrectomy, and resection of mesentery to the extent that they are involved[10].

It is mandatory to examine the greater omentum, undersurface of diaphragm and Douglas pouch as free cancer cells can lodge there due to presence of lymphatic stomata[62]. Micrometastasis on the preserved peritoneum can be managed by intraperitoneal chemotherapy, so complete cytoreduction includes the removal of peritoneum with gross nodules[10,61,62].

After finishing CRS, IPHC is initiated. It has been shown that hyperthermia augments the penetration of anticancer drugs[63], in addition to its synergistic cytotoxicity on cancer cells when combined with some chemotherapeutic drugs such as mitomycin C (MMC) and cisplatin[64]. It is performed either with open or closed techniques, with more advantages of the former due to uniform distribution of the chemotherapeutic agents within peritoneal cavity[10]. In either technique, large volume (5 L-10 L) of saline heated at 42℃-43℃ is introduced into the peritoneal cavity and circulated at a high flow rate of about 10 L/min[10]. The total dose of MMC and CDPP should be 30 mg and 300 mg, respectively with an optimal duration of 60-90 min[10].

ASSESSMENT OF COMPLETENESS OF CRS

There is agreement among many treatment centers that the extent of disease prior to CRS and the completeness of cytoreduction (CCR) score are the principal prognostic indicators for survival[14,38,66-85]. In CCR, the extent of residual disease after CRS is classified into 4 categories: CCR-0 indicating no visible residual tumor; CCR-1, residual tumor $\leqslant$ 2.5 mm in diameter; CCR-2, residual tumor between 2.5 mm and 2.5 cm; and CCR-3, residual tumor > 2.5 cm or confluence of disease present at any site[86]. But those with more diffuse disease (more than 2 quadrants) become worse no matter how good a cytoreduction procedure is. The understanding of a complete cytoreduction may vary according to the disease process, for example, in colorectal PC, complete cytoreduction needs a CCR-0 score[14,66-85] while in pseudomyxoma peritonei, a complete cytoreduction may involve both CCR-0 and CCR-1[39,87].

Table 1 The survival rates of CRS plus IPHC in patients with PC of different malignancies

EFFICACY AND BENEFIT OF CRS PLUS IPHC

It is now clear that CRS plus IPHC improves both the quality of life especially in patients with malignant ascitis[15,103,104], and the survival[15,67]. The results of the most significant studies about the survival rates are summarized in Table 1, which supports the use of this new modality as standard care.

ADVERSE EVENTS OF IPHC

IPHC is associated with a high morbidity rate ranging from 27% to 56%[38]. The adverse events can be classified into CRS-related and chemotherapy-related morbidity[15]. Surgery-related adverse events are abscess, intestinal perforation, fistula, prolonged ileus, bile leakage, pancreatitis, pneumonia, deep vein thrombosis, pulmonary emboli, cardiac insufficiency and cerebral infarcts[11,38].

Multivariate analysis demonstrated that adverse events are related to the stage of PC, the operation duration, the number of anastomoses, and blood loss[38,88].

Main chemotherapy-related side effects are bone marrow suppression and renal insufficiency mostly with use of cisplatin[11]. The mortality rate for IPHC ranges between 0% and 11%, and the most common causes of death are bowel perforation, bone marrow suppression, respiratory failure, methicillin resistant staphylococcus aureus infection, and pulmonary embolism[38].

In spite of the above morbidities, such modality remains the suitable one if not the best at present because the patients with PC might get worse without it as systemic chemotherapy or surgery alone is associated with much poorer outcome. With careful and accurate selection of patients, excluding those who are unfit, it is possible to reduce the morbidities of CRS + IPHC and yield a significantly favorable impact on improving survival of the patients.

FUTURE DIRECTIONS

Recently a panel of 55 experts in PC has reached the consensus, which stated that systemic treatment alone may be no longer appropriate for patients with limited PC from a primary or recurrent colon cancer. CRS plus IPHC as a new treatment strategy have clear advantage in this setting[89]. Such procedure has been approved by the surgical oncology experts on PC from North America, France, Italy, Germany, Holland, Spain and Australia. The consensus also indicated that patients who have isolated PC and are likely to receive a complete cytoreduction, as determined by preoperative CT scans, should undergo CRS; and if complete cytoreduction is achieved, intraperitoneal hyperthermic MMC should be given (at 15-35 mg/m^2, 39℃-42℃, for 60-120 min, either by closed or open instillation), followed by best adjuvant systemic chemotherapy[65].

Several issues have been discussed about the future of this treatment strategy, one of which is how to make such therapy standardized and available to large numbers of patients. The operative procedures required for aggressive cytoreduction are lengthy, challenging and morbid and use a great deal of hospital, blood bank, and operational theater resources[38]. Even though this treatment strategy has been confirmed to be effective in some centers, there is only one randomized clinical trial to definitely establish its efficacy in terms of improving the survival and the quality of life of patients with colorectal PC[39,67]. Currently, a large scale prospective multi-center phase Ⅱ study using CRS and IPHC with MMC followed by modern adjuvant systemic chemotherapy for patients with isolated colorectal PC is in progress. This study involves 66 peritoneal surface malignancy surgeons from 46 institutions in 16 countries. Once completed, this study will provide better evidence as to the efficacy of this treatment modality[89].

It is clear that CRS plus IPHC is not indicated for all patients with PC, and the results achieved by international experts in this field may not be replicated in routine clinical practice. Patients with good performance status, low volume of peritoneal disease, and absence of extra-abdominal metastases are more likely to benefit from the combined treatment. This means early diagnosis, early referral to specialist peritonectomy centers for staging, and prompt intervention are keys to successful management. Only by collaborative efforts from medical oncologists, surgical oncologists, and peritoneal surface malignancy treatment centers can such result be achieved[39].

Abstract

AIM: To develop a fusion vaccine of esophageal carcinoma cells and dendritic cells (DC) and observe its protective and therapeutic effect against esophageal carcinoma cell line 109 (EC109).

METHODS: The fusion vaccine was produced by fusing traditional polyethyleneglycol (PEG), inducing cytokine, sorting CD34+ magnetic microbead marker and magnetic cell system (MACS). The liver, spleen and lung were pathologically tested after injection of the fusion vaccine. To study the therapeutic and protective effect of the fusion vaccine against tumor EC109, mice were divided immune group and therapeutic group. The immune group was divided into P, E, D and ED subgroups, immunized by phosphate buffered solution (PBS), inactivated EC109, DC and the fusion vaccine respectively, and attacked by EC109 cells. The tumor size, weight, latent period and mouse survival period were recorded and statistically analyzed. The therapeutic group was divided into four subgroups: P, inactivated EC109, D and ED subgroups, which were attacked by EC109 and then treated with PBS, inactivated EC109, DC, and EC109-DC respectively. Pathology and flow cytometry were also used to study the therapeutic effect of the fusion vaccine against EC109 cells.

RESULTS: Flow cytometry showed that the expression of folate receptor (FR), EC109 (C), DCs (D) in human nasopharyngeal carcinoma cell line (HNE1) (B) was 78.21%, 89.50%, and 0.18%, respectively. The fusion cells (C) were highly expressed. No tumor was found in the spleen, lung and liver after injection of the fusion vaccine. Human IgG was tested in peripheral blood lymphocytes (PBL). In the immune group, the latent period was longer in EC109-DC subgroup than in other subgroups, while the tumor size and weight were also smaller than those in ED subgroup. In the therapeutic group, the tumor size and weight were smaller in ED subgroup than in P, inactivated EC109 and DC subgroups.

CONCLUSION: Fusion cells are highly expressed not only in FR but also in CD80. The fusion vaccine has a distinctive protective effect against tumor EC109 and can inhibit the growth of tumor in mice, and its immune protection against tumor attack is more significant.

INTRODUCTION

Dendritic cells (DCs) are the most potential and professional antigen presenting cells, which stimulate the native T cells and play an important role in the T lymphocyte-mediated immunoresponse[1]. It was reported that DCs activated by antigen display a good anti-tumor effect both *in vitro* and *in vivo*[2-4]. We have studied the biological characteristics and induced antitumor immunity

of the cancer vaccine prepared by fusing esophageal carcinoma cell line with DCs derived from the cord blood in a previous study[5]. This study was to develop a fusion vaccine and observe its anti-oesophagus cancer effects on EC109 cells in mice with severe combined immune deficiency (SCID). It is expected that this paper may provide some worthy data for the prevention and treatment of oesophageal carcinoma.

MATERIALS AND METHODS

Tumor cells

EC109 cells were obtained from the Pathological Institute of Shantou University Medical College. Human nasopharyngeal carcinoma cell line (HNE1) was obtained from the Tumor Research Laboratory of Tumor Hospital of Shantou University Medical College.

Isolation of DC

CD34+ hematopoietic stem cells were isolated from the cord blood by Ficoll-Hypaque density-gradient centrifugation using the CD34+ progenitor cell isolation kit and the magnetic cell sorting system (MACS). The CD34+ cells were cultured in RPMI 1640 medium supplemented with 10% fetal calf serum containing 300 ng/mL human granulocyte-macrophage colony-stimulating factor (rhGM-CSF), 150 μg/mL human tumor neucrosis factor α (rhTNF-α) and 200 ng/mL human stem cell factor (rhSCF) at 37℃, in an atmosphere containing 5% CO_2 for two weeks and then a large number of DCs were harvested.

Cell fusion

DCs were mixed with EC109 at a 5:1 ratio and incubated in serum free RPMI1640 containing 50% polyethylene glycol and the fusion cells were labeled with HLA-DR MicroBeads for 35 min at 6℃-12℃. The cells were centrifuged at 1000 r/min for 10 min. By using a MiniMACS separation column to enrich the magnetically positive cells, the enriched HLA-DR+ cells were washed, seeded in 12-well plates and cultured overnight. The adherent cells were regarded as fused cells EC109-DC.

Fusion cell verification

Peripheral blood lymphocytes (PBL) were isolated from the peripheral blood of normal donors by Ficoll-Hypaque density-gradient centrifugation. PBL, DC, EC109 and HNE1 were planted in RPMI 1640 medium supplemented with 10% fetal calf serum, washed with PBS and incubated with FA-FITC (which was obtained from Peixuan G, Purdue University, USA) for one hour. PBL were set up for negative cells and HNE1 for masculine cells as previously described[6]. EC109, DCs and EC109-DC were washed with PBS and incubated with FA-FITC and CD80-PE. Fluorescence intensity and positive cell percentage were analyzed by fluorescence-activated cell sorter analysis using FACScan (Beckman Coulter).

Experiment in SCID mice

Preparation of SCID mice: SCID mice, 6-8 wk old, were purchased from the Animal Research Center of Zhongshan University. The animals were kept in micro-isolator cages in a separate barrier facility under a well-controlled pathogen-free environment with ambient temperature monitored and cycles of light and darkness regulated. The mice were fed with laboratory chow and water at the Tumor Research Laboratory of Tumor Hospital of Shantou University Medical College. The guidelines for animal care and use were approved by the experiment animal monitor of Guangdong Province.

Oncogenicity of fusion vaccine: Experiments were divided into sets Ⅰ and Ⅱ. There were 5 mice in set Ⅰ. Live fusion vaccine (0.2 mL) was then injected into vena caudalis of the 5 mice. Twenty-five mice in set Ⅱ were divided into 5 groups (A-E). Group A was injected intraperitoneally with 1×10^6 cells each of EC109-DC. The other 4 groups were injected with the same quantity of cells of EC109 + DC, EC109, DC and PBS. Whether tumor was induced in the mice of set Ⅰ was checked. The development time and size of the tumor, as well as the survival time of the mice were observed every day for 60 d. Organs, such as the spleen, liver and kidney were removed and fixed in neutral formalin, embedded in paraffin and stained with hematoxylin and eosin (HE) for routine light microscopic study. The mice in set Ⅱ were killed on d 28 after inoculation. The removed tumors were weighed and fixed in neutral formalin, embedded in paraffin and stained with HE for routine light microscopic study.

Reconstitution of SCID mice: Human lymphocytes to be transferred in SCID mice were isolated from the whole blood obtained from healthy adult volunteers as previously described[7-11]. Human peripheral blood lymphocytes (PBL) were isolated by Ficoll-Paque gradient centrifugation under sterile conditions. PBL were planted in RPMI 1640 medium supplemented with 10% fetal calf serum. The culture flasks were incubated in a humidified atmosphere containing 5% CO_2 at 37℃. Thirty SCID mice were divided into two groups. Twenty-five mice in PBL group were injected intraperitoneally with 5×10^7 PBL. The other 5 mice in PBS group were injected with the same volume of PBS as a control group. Blood was obtained from the vena caudalis of mice on d 0, 7, 14, 21 and 28, and then centrifuged. The sera were collected for detecting the level of human IgG by avidin-biotin (ABG) ELISA. The successful marking of reconstitution is that the human lymphocytes or human IgG could be found in the peripheral blood of SCID mice.

Induction of anti-tumor immunoprotective effect: Twenty SCID mice with successful immune system reconstruction were divided into P, E, D and ED subgroups. PBS (0.2 mL) was injected into the vena caudalis of mice. EC109, DC and the fusion vaccine were inactivated with 1×10^6 cells each time, twice a day for 3 d. Five days later, all the mice were injected into the right armpit with 5×10^6 of live EC109. The tumor size, weight, latent period and survival period of mice were recorded at the same time point every day for 50 d. Two mice in each group were sacrificed 28 d after tumor attack. Tissues of the spleen, liver and kidney, were fixed in neutral formalin,

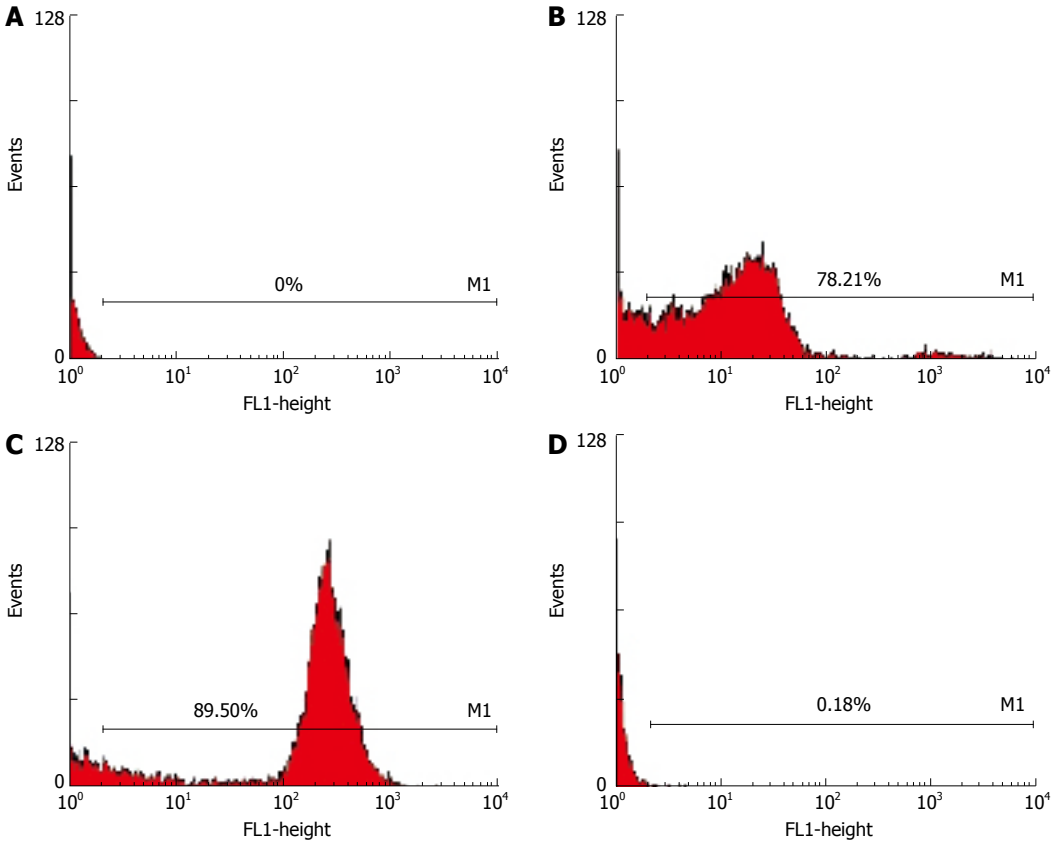

Figure 1 Expression of folate receptor on EC109 and DCs. PBL (**A**) was set up for negative cell and HNE1 for masculine cell. Analyses by flow cytometry, HNE1 (**B**) with expression of FR was 78.21%, EC109 (**C**) was 89.50%, and DCs (**D**) was 0.18%.

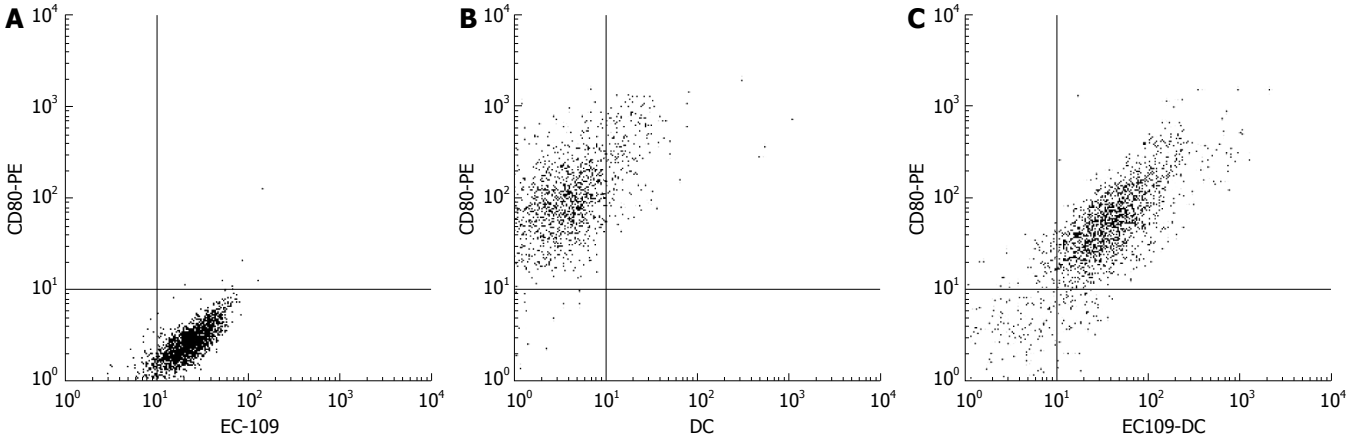

Figure 2 Expression of FR (**A**), CD80 (**B**) and EC109-DC (**C**).

embedded in paraffin and stained with HE for routine light microscopic study.

Anti-tumor therapeutic effect: The EC109 cells at the logarithmic growth phase were collected and washed with PBS. The cell density was adjusted to 5×10^6/mL. Twenty SCID mice with successful immune system reconstruction were injected into the right armpit with 1×10^6 cells of live EC109. The model was successful when the tumor grew as big as a grain. The 20 mice in the model were divided into P, E, D and ED subgroups. PBS (0.2 mL) was injected into the vena caudalis. EC109, DC and the fusion vaccine were inactivated with 1×10^6 cells each time, twice a day for 3 d. Tumor size, weight, latent period and survival period of mice were recorded at the same time point every day. One mouse in each group was sacrificed 28 d after immunity acquirement. Others were observed for an additional 50 d. Organs, such as the spleen, liver and kidney, were fixed in neutral formalin, embedded in paraffin and stained with HE for routine light microscopic study.

Statistical analysis

SPSS10.0 was used for data variation analysis. $P < 0.05$ was considered statistically significant.

RESULTS

Characteristics of EC109-DC fusion cells

After fusion of EC109 and DCs, the resulting heterokaryons showed adherent growth and irregular shape. Flow cytometry displayed that the expression of FR, EC109 and DCs was 78.21%, 89.50% and 0.18%, respectively in HNE1.

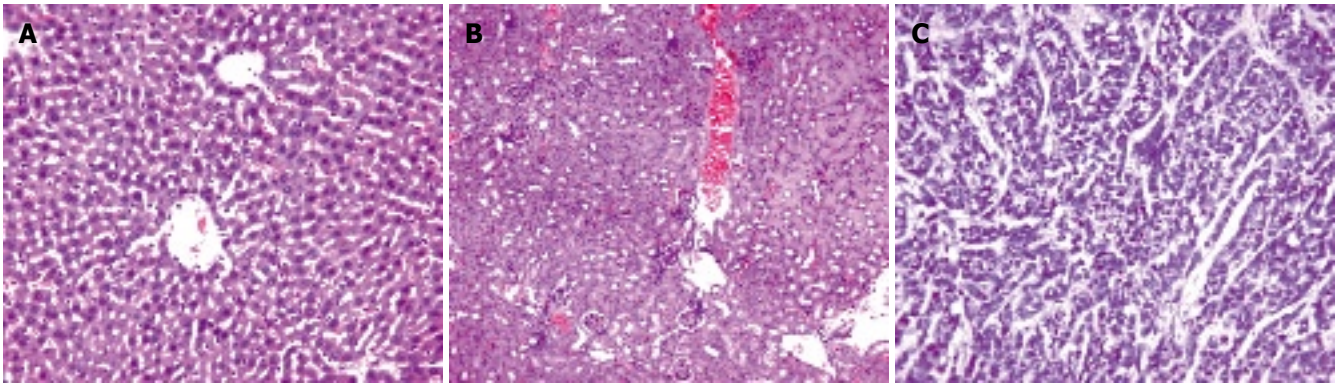

Figure 3 No formation of tumor in the liver (**A**), in the kidney 60 d after injection of EC109-DC into the vena caudalis (**B**) (HE, 20 × 10) and in tumor tissue (**C**) of SCID mice 28 d after injection of EC109 into the abdominal cavity (HE, 10 × 10).

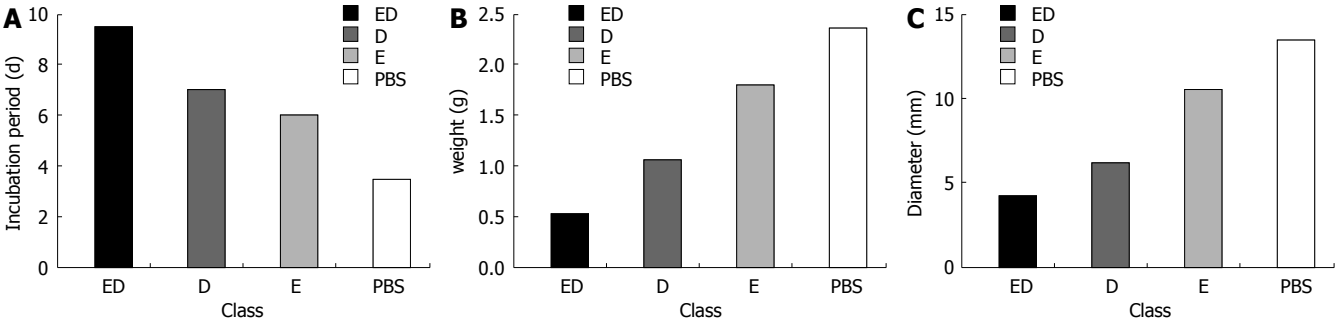

Figure 4 Incubation time (**A**), weight (**B**) and diameter (**C**) of tumors after attacked by EC109.

The fusion cells were highly expressed not only in FR but also in CD80 (Figures 1 and 2).

Oncogenicity

There was no formation of tumor 60 d after injection of EC109-DC in group 1. No formation of tumor tubercles was discovered in the heart, liver, lung, kidney and spleen (Figure 3).

There were no ascites and lump organization 28 d after injection of EC109-DC in group 2. However, hemorrhagic ascites was discovered, grey tumor tissues were generated generally and widely adhered to the ambient organs in groups of EC109 + DC and EC109. The tumor tissues were mostly distributed on the abdominal wall, diaphragmatic muscle, liver and pelvic cavity with a diameter of 1-20 mm. Under light microscope, the size and shape of cancer cells were not extremely consistent, but polygonal and karyolobism lost the characteristics of epithelial cells in normal esophagus (Figure 3).

Examination of reconstitution

During the experiment, human IgG was tested in all the PBL groups and its highest level was 2580 μg/mL, compared with the PBS group ($P < 0.05$, Table 1).

Anti-tumor immunoprotective effect

The incubation period of tumor cells after attacked by EC109 was P < E < D < ED (Figure 4A). The tumor weight and size were ED < D < E < P (Figure 4B and C). Except for 2 mice which were killed on d 28, the other

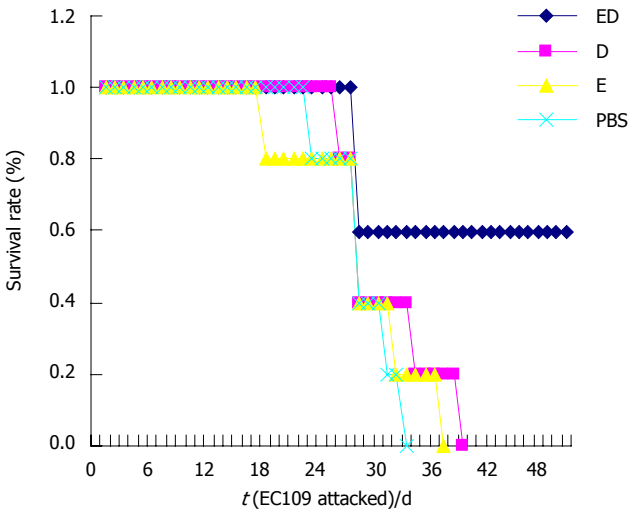

Figure 5 Death and life span in immune, ED and PBS groups.

mice in the ED group survived and their life span was obviously longer ($P < 0.05$). Compared with the PBS group, death occurred in the treatment group and the difference in the life span between the two groups was not significant ($P > 0.05$, Figure 5).

Pathology: Circlar, slippery and pellicular tumors in ED group were distended and movable with neither wide conglutination nor metastasis. Grey and hard tumors with an uneven surface were found in other groups. Some

PBL	25	0.21 ± 0.10	59.28 ± 12.61	260.82 ± 36.16	353.40 ± 69.23	482.7 ± 185.15

$P < 0.05$ *vs* PBS group.

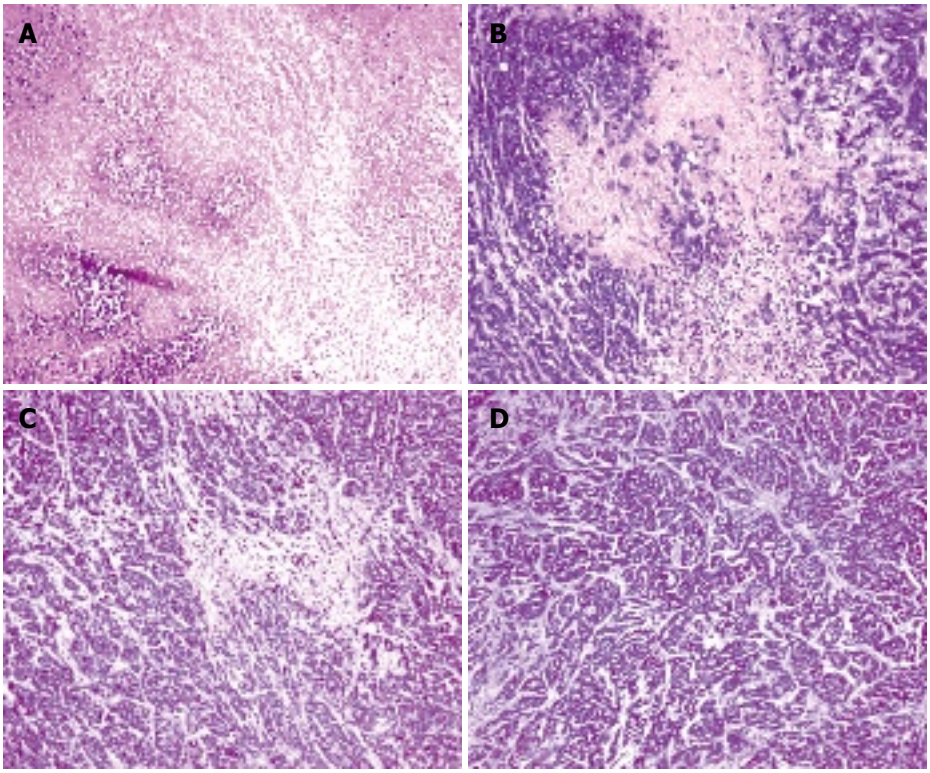

Figure 6 Tumor tissue 28 d after attacked by EC109 showing big necrosis in ED group (**A**), lamella necrosis in D-group (**B**), mottling necrosis in E-group (**C**) and unobvious necrosis in P-group (**D**) (HE, 10 × 10).

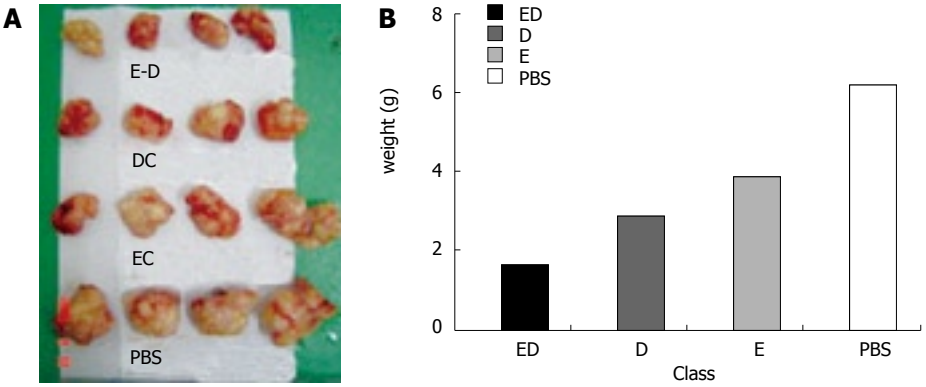

Figure 7 Tumor size (**A**) and weight (**B**) in therapeutic group after treatment of EC109-DC, DC, inactivated EC109 and PBS.

tumors were adhered to the ambient structure, even with distant metastasis. Tumor tissue sections were grey in color with diffuse punctiform necrosis. Under light microscope, tumor tissues from the ED, D and E groups attacked by EC109 for 28 d, except for P group, had different necrosis changes (Figure 6).

Immunotherapy: After treatment of EC109-DC, DC, inactivated EC109 and PBS, the tumor size was DE < D < E < P. On d 50, the growth time of tumors had no remarkable difference but the tumor weight did ($P < 0.05$, Figure 7).

The texture of tumors with a smooth surface was harder, partially adhered to the chest wall and the tumor tissue section was grey in color with diffuse punctiform necrosis. Under light microscope, the tumor tissue had different necrosis changes (Figure 8).

DISCUSSION

In this experiment, the fusion vaccine EC109-DC, was made from amalgamation of DC, which was induced by combining cytokine from CD34+ hematopoietic stem cells isolated from the cord blood, and the EC109 by traditional

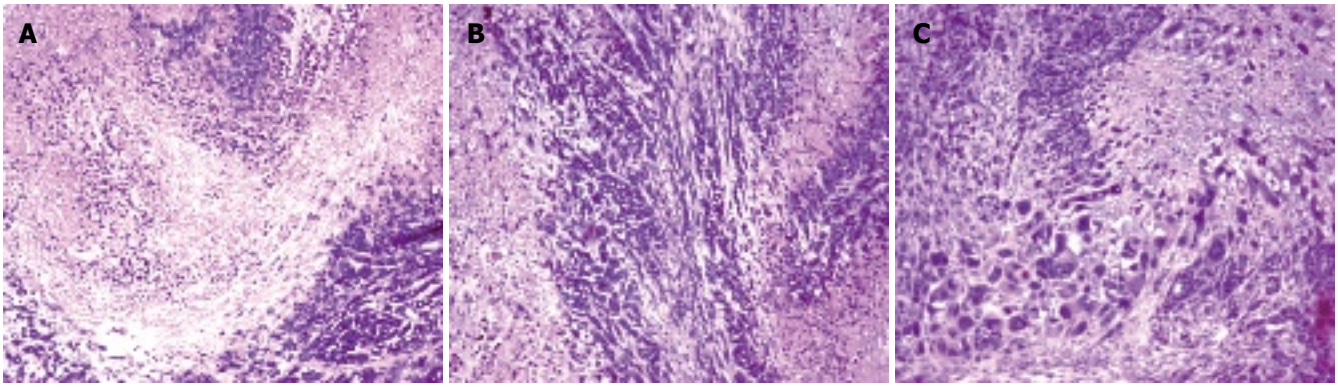

Figure 8 Tumor tissue 28 d after attacked by EC109 showing slight necrosis (**A**), lamella necrosis (**B**) and mottling necrosis (**C**) in therapeutic group (HE, 10 × 10) .

PEG fusing. The fusion vaccine, EC109-DC, integrated the protein, polypeptide and nucleic acid of EC109 and even the whole live cells with the antigen presenting DC, thus it can give immunoreaction to polyvalency tumor antigen, showing all possible antigens to EC109. With no specific antigen to the esophageal carcinoma cell line, it can effectively induce anti-tumor immune response. Consequently, it is more effective and practical to fuse vaccine with DC than a single antigen in theory[12-14]. Some curative effects of fusion vaccine with DC have been seen in clinic experiments[15-25]. However, it cannot be brought into full use due to its lower fusion efficiency, shortage of effective methods of separation and purification as well as the difficulty in obtaining an enough-quantity and high-quality cancer vaccine by fusing cancer cell line with DC.

In this study, we developed the tumor fusion vaccine with HLA-DR mark and Mini MACS sorting method. The tumor fusion vaccine, EC109-DC, was double marked with FA-FITC and CD80-PE. The vaccine's phenotype was accredited by flow cytometry amb-masc mark. After detection, the vaccine highly expressed FR and CD80 simultaneously. The principle of HLA-DR+ cells separated by Mini MACS separation unit is to abrupt the HLA-DR+ cells and the HLA-DR- cells which mark the magnetic by coupling the antibody to the cells, and HLA-DR monoclonal antibody to the HLA-DR+ cell membrane's SA idio-discrimination. The results of our study have not only proved the successful fusion of DC with EC109, but also the separation effect of MACS. This may provide an effective way for the effective purification and separation of the vaccine, as well as for gaining an enough quantity and high-quality of hybrid DC.

Although the fusion vaccine was inoculated in the right abdominal cavity of SCID mice, we could not see hemorrhagic ascites and tumor tubercules in the abdominal cavity. There were hemorrhagic ascites and adhesive tumor organism in the control group. The fusion vaccine was injected into the SCID mice through vena caudalis, no tumor nodus was found in the liver, kidney and spleen of mice, indicating that the fusion vaccine has lost the oncogenicity of parent tumor cells, and is safe and reliable for its application *in vivo*.

In anti-tumor protective immunity *in vivo* experiment, tumor formulation was delayed in the ED and D groups compared with the immunoprotection groups. The time of tumor formulation in P group was the shortest. The tumor was the smallest and lightest in ED group, and the biggest and heaviest in D group, indicating that the fusion vaccine has the best immunity protective function. Our study used the cell-fusion technique to increase the number of cells fused with DC, which highly express MHC, co-stimulate molecules and adhesion molecules and also produce IL-12 and tumor cells which are short of information molecules, form the EC109-DC which change the bionomics of tumor cells. The fusion vaccine was re-infused *in vivo* in which DC carry all esophagus cancer cell antigen information. The fusion cells retain the MHC and co-stimulatory molecules in DC. The EC109-DC activate the CD4+ T and CD8+ T cells as MHC- I and MHC-Ⅱ, secrete homologous cytokines and activate the anti-tumor immune response, thus inducing special anti-tumor immunity reaction more effectively.

Sixty days after treatment of tumor-bearing mice with the fusion vaccine, EC109, the size of tumor in ED group became obviously smaller than that in the control group. The tumor surface in ED group was smooth and divided by circum-tissues and had no conglutination. However, the tumor surface in control group was coarse and adhered to the chest wall and muscle tissues had no clear demarcation. Macro-lamellar necrosis was observed in ED group under light microscope, while punctiform necrosis was found in PBS group, indicating that the fusion vaccine has certain inhibitory effect on the tumor growth, which is in agreement with previous reports[26,27]. At the same time, active immunotherapy for the tumor-bearing mice reduced the growth of the lump body, and the sphacelus became obvious in tumor *in vivo*, demonstrating that such immunity treatment has its certainly value and even cures the tumor-bearing mice if it is used in combination with operation or chemotherapy.

Tumors can escape the host immunity surveillance because tumor cells cannot express the information molecule required by the host immunity system. It was reported that induction of CD8+, CD4+ and B cells is also one of the most effective method to prevent and control chronic infections, diseases, tumors[28]. The immunoreactions in the host are to capture its antigen by APC. After processing, the antigen information is present in T and B lymphocytes, stimulating a series of specific cellular immunologic response and humoral

immunoresponse. It is, therefore, directly related with the induction of immunological activation or immunological tolerance, and the key to the process is APC. DCs are a kind of the strongest APCs in which antigen processes and functions[29,30], and can stimulate the native T cells. DCs are in a unique state of immune response.

This experiment adopted the technology of cell fusion to make DCs, which highly express the major histocompability complex (MHC), co-stimulate adhesion molecule, and produce IL-12, identify cells fused with tumor cells which are short of the information molecule. All these not only change the biological characteristics of tumor cells, but can effectively process presentation antigen and activate the anti-tumor immune response, and the host obtains the immunity protection strength by the resistance to parent tumor attack. During the procedure, it directly fuses the esophageal carcinoma cells (EC109) and DCs, passes the link of DCs insufficient to recognize EC109 which are low in immune function, causes the direct processing and presentation of tumor antigen in DCs.

At the same time, the fusion vaccine excretes corresponding cell factors, possibly combines the cell molecule with the specific acceptor on DCs surface, and increases the stimulation to DC, activates the low function of DCs, and also its function on antigen presentation. On the other hand, the conjugated tumor antigen is stably expressed on the cell surface, which also may be used as the extraneous antigen to the major histocompatibility complex (MHC-Ⅱ), then activates the CD4+ Th, and induces the production of different antibodies. According to the difference in its secretion of Th1 and Th2 cell factors, the activated CD4+ Th can adjust the balance of immunity, enhance the intensity of cellular immunologic response and (or) humoral immunoresponse response. The tumor antigen to EC109 itself just lies in the DCs, which can be effectively captured by DCs, then presented to MHC- Ⅰ, strengthens the reaction of CD8+ CTL, CD4+ Th cells, and the intensity of the cellular immunologic response and (or) humoral immunoresponse response. The fusion vaccine not only remarkably stimulates initial (naive) multiplication of T cells, but also confers upon the activated T cells for certain tumor memory, which may massively activate and expand under the situation of more contacting antigens[31,32].

In addition, the fusion vaccine also participates in the nonspecific immunity. DCs which fuse tumor cells excrete cytokines, such as IL-1, IL-6, IL-8, IL-12, TNF-α, IFN-α and GM-CSF. Among them, IL-6 dissolves tumor cells by activating the complement mannose-binding lectin(MBL) pathway. The other cytokines such as IFN-α, can directly activate NK cells. After activation under the effect of chemotactic factors, the NK cells migrate to the tumor focus and directly kill and wound the responsive tumor cells, with no need to stimulate antigen and other factors. Inactivated macrophages have no lethal effect on tumor cells and can be activated by the stimulus of inflammation or other factors. LK secretes T cells and IFN. The activated macrophages as effector cells have no specificity to kill and inhibit tumors, but may have effect factors killing target cells, including hyperoxide, nitrogen monoxide, TNF and LYS, *etc*. Through the ADCC way, macrophages can also kill and wound target cells. In this experiment, the anti-tumor function of the fusion vaccine is due to the co-effect between specific immunity and non-specific immunity.

In conclusion, the fusion vaccine simultaneously expresses EC109 and DC specific antigen. Meanwhile, the fusion vaccine of DCs and EC109 has no *in vivo* oncogenicity, and has lost its parent characteristics of EC109 cells with malignant growth, becoming safe and reliable. Furthermore, the fusion vaccine has resistant functions against the attack of EC109 cells. Moreover, the fusion vaccine can restrain tumor growth in mice. The fusion vaccine may become a useful tool in preventing malignant tumors.

COMMENTS

Background

The present study demonstrated that immunization strategies for cancer vaccines based on mature dendritic cells (DCs) could present tumor peptide and induce specific anti-cancer immune response. No report is available on the fusion vaccine for human esophageal carcinoma cells fused with DCs derived from the cord blood.

Research frontiers

We have studied the biological characteristics of cancer vaccine and induced its anti-tumor immunity.

Innovations and breakthroughs

The fusion vaccine of esophageal carcinoma cells and DCs was developed. Its protective and therapeutic effect on EC109 cells was studied. The EC109 highly expressed FR and DCs hardly express the FR.

Applications

To summarize the actual application values, the tumor vaccine could become a useful tool for preventing malignant tumors.

Peer review

This manuscript is an original research article on the protective effect of the fusion vaccine. The findings are of great interest and the data are convincing.

Abstract

AIM: To elucidate the localization of RhoA in gastric SGC-7901 cancer cells and its translocation by lysophosphatidic acid (LPA) and/or 8-chlorophenylthio-cAMP (CPT-cAMP).

METHODS: Immunofluorescence microscopy was used to determine the localization of RhoA. Western blotting was used to detect both endogenous and exogenous RhoA in different cellular compartments (membrane, cytosol, nucleus) and the translocation of RhoA following treatment with LPA, CPT-cAMP, or CPT-cAMP + LPA.

RESULTS: Immunofluorescence staining revealed endogenous RhoA to be localized in the membrane, the cytosol, and the nucleus, and its precise localization within the nucleus to be the nucleolus. Western blotting identified both endogenous and exogenous RhoA within different cellular compartments (membrane, cytosol, nucleus, nucleolus). After stimulation with LPA, the amount of RhoA within membrane and nuclear extracts increased, while it decreased in the cytosol fractions. After treatment with CPT-cAMP the amount of RhoA within the membrane and the nuclear extracts decreased, while it increased within the cytosol fraction. Treatment with a combination of both substances led to a decrease in RhoA in the membrane and the nucleus but to an increase in the cytosol.

CONCLUSION: In SGC-7901 cells RhoA was found to be localized within the membrane, the cytosol, and the nucleus. Within the nucleus its precise localization could be demonstrated to be the nucleolus. Stimulation with LPA caused a translocation of RhoA from the cytosol towards the membrane and the nucleus; treatment with CPT-cAMP caused the opposite effect. Furthermore, pre-treatment with CPT-cAMP was found to block the effect of LPA.

INTRODUCTION

RhoA, with molecular mass of 21 kDa, is the most extensively studied member of the Rho GTPase family belonging to the Ras superfamily of small G proteins. The Rho GTPase family consists of at least 11 members sharing more than 50% identity, the best known of them being Cdc42, Rac1, and RhoA. RhoA has been reported to regulate many biological activities including the formation of stress fibers and focal adhesions[1].

Like other small G proteins, RhoA is inactive in its GDP-bound and active in its GTP-bound form, these two forms can be converted by GDP/GTP exchange or GTPase reactions[2-5]. The former and latter reactions are regulated by GDP/GTP exchange protein and GTPase activating protein, respectively. Two types of GDP/GTP exchange proteins are known: one is a stimulatory type named GDS, and the other is an inhibitory type named GDI. GDS stimulates the dissociation of GDP from and the subsequent binding of GTP to each substrate small G protein, whereas GDI inhibits both reactions[6-15]. In addition to the action of GDS and GDI regulating the GDP/GTP exchange reaction, both GDP/GTP exchange proteins regulate the translocation of each substrate small G protein between the cytosol and membranes.

Lysophosphatidic acid (LPA), a commonly used RhoA activator, is a serum-born phospholipid with hormone and growth factor-like properties, which is formed by and released from activated platelets and which can be

generated by the action of secretory phospholipase A2[16,17]. Previous studies showed that it is able to induce the translocation of RhoA from the cytosol to the membrane accompanied with the activation of RhoA[18], probably *via* conversion of the GDP-bound into the GTP-bound form.

cAMP is a well-known classical secondary messenger, and a cAMP-dependent protein kinase A (PKA) phosphorylates RhoA in its C-terminal region on serine residue 188[19]. The cAMP signal mediates down-regulation of RhoA activity[20]. It was reported that cAMP could induce the translocation of RhoA from the membrane to the cytosol accompanied with the inactivation of RhoA[19]. Moreover, translocation of RhoA was shown to be caused by stabilizing the RhoA/Rho GDIs complex by phosphorylating GTP-bound RhoA[21]. Phosphorylation enhances translocation of RhoA to the cytosol through increased interaction of GTP-bound RhoA with Rho-GDI, possibly terminating its activity.

We here describe RhoA to be localized in the nucleus of SGC-7901 cells and a cross talk between LPA/RhoA-mediated and cAMP/PKA mediated signal transduction pathways[22]. Whether there is interaction between LPA induced and cAMP induced RhoA distributions in different cellular compartments deserves further investigation. Our experiments were designed to explore the localization of RhoA and to investigate the effects of a treatment with LPA, cAMP, and cAMP + LPA.

MATERIALS AND METHODS

Cell lines

The human gastric cancer cell line SGC-7901 and human cervix cancer cell line HeLa were provided by the Institute of Cell Biology (Shanghai, China).

Reagents

Dulbecco's Modified Eagle Media (DMEM) was purchased from GIBCO (Grand Island, NY), new-born calf serum (NBCS) from Minhai Bio-engineering C (Lanzhou, China), the antibody against RhoA from Santa Cruz Biotechnology (Santa Cruz, CA), the antibody against GAPDH (glyceraldehyde phosphate dehydrogenase) from Kangcheng (China), the horseradish peroxidase (HRP)-conjugated secondary antibody from Jackson ImmunoResearch Laboratories (West Grove, PA), the cell transfection reagent Lipofectamin 2000, TRIzol reagent, and reverse transcription kit from Invitrogen (Carlsbad, CA), the cellular permeable cAMP analog 8-chlorophenylthio-cAMP (CPT-cAMP) from Calbiochem, LPA and nuclear fluorochrome Hoechst 33342 from Sigma (St. Louis, Missouri), electrochemiluminescence (ECL) reagents from Amersham Biosciences (Buckinghamshire, England), and pGEmol/L vector from Promega (USA). Plasmid DNA constructs of RhoA pcDNAEE-wt (wild type of RhoA), pcDNAEE-63L (a constitutive active form of RhoA), and pcDNAEE-N19 (an inactive mutant of RhoA) were kind gifts from Dr. Renate Pilz, University of California, San Diego.

Cell culture and transfection

SGC-7901 cells were cultured in DMEM supplied with 10% NBCS. The medium was changed every two days and the cells were subcultured at confluence. For transfection, the cells were subcultured the day before the process. The seeding amount of cells was adjusted to attain a density of 80%-90% confluence on the day of transfection. Transfection was performed according to the instruction of the manufacturer.

Immunofluorescence microscopy

The cells grown on cover slips were incubated to reveal nuclei with 0.2 μmol/L Hoechst 33342 for 10 min before fixed with freshly prepared 40 g/L paraformaldehyde in PBS at 4℃ overnight (o/n). After being penetrated with 30 mL/L Triton X-100 and blocked with 30 g/L BSA, the cells were incubated with primary antibodies at 4℃ o/n, and then with FITC- or TRITC-conjugated second antibodies for 1 h at room temperature (RT), with three washes after each incubation. The morphologic changes of the cells were analyzed by fluorescence microscopy.

Membrane, nucleus, and cytosol preparation

According to the method from Jeffrey C. Chen *et al*[23], four 100 mm plates of cells were prepared, one of them considered as control, and the others treated with LPA (1 μmol/L, 15 min), CPT-cAMP (250 μmol/L, 30 min), or CPT-cAMP (250 μmol/L, 30 min) followed by an incubation with LPA (1 μmol/L, 15 min). Cells were extracted by Dounce homogenization in 10 mmol/L Hepes pH 7.5, 2 mmol/L EDTA, 1 mmol/L $MgCl_2$ (HEM buffer). The homogenate was centrifuged at 500 *g* at 4℃ for 5 min to obtain nuclear proteins, and the supernatant was centrifuged at 37000 *g* at 4℃ for 30 min. The supernatant and pellet from the second centrifugation are referred as cytosol and membranes, respectively, with the membrane preparation washed twice in HEM buffer to remove contaminating cytosol. Protein concentrations were determined and equal amounts of protein from each preparation (30 μg) were subjected to SDS-PAGE/Western blotting using mouse monoclonal anti-RhoA (1:200) and GAPDH (1:5000) antibodies.

Purification of nucleoli from SGC-7901

Nucleoli were purified using a procedure adapted from previously published protocols[24]. For a typical experiment, 1×10^8 SGC-7901 cells were plated onto 245 mm Petri dishes in DMEM containing 10% NBCS. Cells were incubated in a humidified atmosphere containing 5% CO_2 at 37℃. At 80% confluence, cells were washed with cold PBS, and scraped off on ice. Cells were collected by centrifugation at 500 *g* at 4℃ for 5 min. Cells were resuspended in 5 mL hypotonic buffer (10 mmol/L Tris-HCl pH 7.4, 10 mmol/L NaCl, and 1 mmol/L $MgCl_2$) and incubated on ice for 30 min. Cell lysis was performed by addition of a final concentration of 0.3% Nonidet P-40 (Roche Applied Science, Mannheim, Germany) and homogenization was performed using a 0.4 mm clearance Dounce homogenizer (Kimblr/Kontes, Owens, IL) for 15 times on ice. Nuclei were collected by centrifugation at 228 *g* at 4℃ for 5 min and resuspended in 3 mL 0.25 mol/L sucrose-containing 10 mmol/L $MgCl_2$. Nuclei were centrifuged at 1430 *g* at 4℃

for 5 min through a 0.35 mol/L sucrose cushion containing 0.5 mmol/L $MgCl_2$ and resuspended in 3 mL 0.35 mol/L sucrose-containing 0.5 mmol/L $MgCl_2$ and then sonicated on ice for ten bursts of 10 s with 1 min intervals between them. Nuclei were then purified by centrifugation at 2800 *g* at 4℃ for 10 min through a 0.88 mol/L sucrose cushion containing 0.5 mmol/L $MgCl_2$. Nuclei were washed with 500 μL 0.35 mol/L sucrose containing 0.05 mmol/L $MgCl_2$ twice, and centrifuged at 2800 *g* at 4℃ for 10 min. Purified nucleoli were resuspended in 50 μL 0.35 mol/L sucrose containing 0.05 mmol/L $MgCl_2$ for further analyses.

Protein extraction from Hela cells in interphase and motosis

Hela cells were seeded on four 100 mm plates and treated with 5 μg/mL Taxol for 12 h. Cells in mitosis phase were collected by "shake off", and the cells left on plates considered in interphase were scraped. Cells were extracted with 500 μL RIPA (50 mmol/L Tris-HCl pH 7.4, 150 mmol/L NaCl, 1 mmol/L PMSF, 1 mmol/L EDTA, 1% Triton X-100, 1% sodium deoxycholate, 0.1% SDS), incubated on ice for 30 min, and then centrifuged at 14000 *g* at 4℃ for 15 min to obtain total protein extracts. Protein concentrations were determined and equal amounts of protein from each preparation (30 μg) were subjected to SDS-PAGE/Western blotting using mouse monoclonal anti-RhoA (1:200) and GAPDH (1:5000) antibodies.

Western blotting

SDS-PAGE gels of different concentrations were cast according to the molecular size of target proteins. Sample proteins were run on 10% SDS-polyacrylamide gels, and were blotted onto polyvinyl difluoride (PVDF) membrane. The PVDF membrane was blocked with 3% (w/v) bovine serum albumin (BSA) in TBS-T for 1 h at room temperature (RT). Membranes were incubated with the primary antibody at 4℃ o/n, and with the secondary antibody for 1 h at RT, with three washes after each incubation. Electrochemiluminescence reagents were used to show the positive bands on the membrane. Briefly, same volumes of solution A and solution B were mixed and added to the protein side of the membrane. The incubation was 5 min at RT. The exposure time of the first film was 15 s. The exposure time of the second film was adjusted according to the intensity of the signal on the first film. The bands on film were analyzed with GeneSnap/ Gene Tool software from Syngene (Cambridge, UK).

RNA isolation, reverse transcription, and real-time quantitative PCR

To detect the difference in expression of RhoA gene between interphase and mitosis phase in HeLa cells, total RNA of interphase and mitosis cells was isolated using TRIzol reagent. cDNA was synthesized in a 20 μL reaction containing 4 μg of total RNA and SuperScript™Ⅱ RT according to the manufacturer's instructions. Primers designed for amplification of the human RhoA gene and GAPDH gene were forward 5'-GGCTGCCATCCGGAA GAAA-3' and reverse 5'-CACAAGACAAGGCACCC AGA-3' and forward 5'-GGATTTGGTCGTATTGG G-3', and reverse 5'-GGAAGATGGTGATGGGAT T-3', respectively. The 25 μL reaction contained 0.5 μL cDNA, 10 pmol/L of each primer, 2 mmol/L $MgCl_2$, 2.5 μL of 200 nmol/L dNTP, and 1 unit of Taq DNA polymerase. The thermal cycle profile for PCR was 94℃ for 5 min followed by 35 cycles of 30 s at 94℃, 30 s at annealing temperature (63.8℃ forRhoA and 55℃ for GAPDH), and 30 s at 72℃ with a final 10 min incubation at 72℃. The amplified fragments of the target genes were cloned into pGEmol/L vector and DNA sequencing was performed by Gene Co. Ltd. (Shanghai, China).

For real-time quantitative PCR, standard curves were prepared by serial dilution of pGEM-RhoA and pGEM-GAPDH vector. Reactions of 25 μL included 1 μL of 1:1500 SYBR Green Ⅰ, 0.5 μL cDNA, 10 pmol of each primer, 2 mmol/L $MgCl_2$, 2.5 μL 200 nmol/L dNTP, and 1 unit of Taq DNA polymerase. To compensate for variations of input RNA amounts and efficiency of reverse transcription, an endogenous 'housekeeping' gene (GAPDH) was also quantified and used to normalize the results. The thermal cycle profile for PCR was 94℃ for 2 min followed by 35 cycles of 30 s at 94℃, 30 s at annealing temperature (63.8℃ for RhoA and 55℃ for GAPDH) and 30 s at 72℃. After the cycling of PCR assay was completed, the samples were subjected to a temperature ramp (from 45℃-95℃ at 0.5℃/2 s) with continuous fluorescence monitoring for melting curve analysis. Analyses were done in triplicates and all reactions were repeated six times independently to ensure the reproducibility of the results. Data were analyzed by Rotor-Gene real-time analysis software (Rotor-Gene 2000, CR, Australia). For each sample the amplification plot and the corresponding dissociation curves were examined. To obtain standardized quantitative results, external controls consisting of cDNA plasmid standards were constructed.

Statistical analysis

Data were expressed as mean ± SE. Statistic significance was examined with Wilcoxon signed-rank test and Student's *t* test, respectively. Probability below 0.05 ($P < 0.05$) was considered as significant.

RESULTS

The subcellular localization of endogenous and exogenous RhoA in SGC-7901 cells

With immunofluorescence staining (Figure 1) and Western blotting (Figure 2) endogenous RhoA was detected in the membrane, the cytosol, and the nucleus of SGC-7901 cells. As shown by Western blotting (Figure 3) exogenous RhoA was also localized in the membrane, the cytosol, and the nucleus of SGC-7901 cells.

The existence of RhoA in nucleoli of SGC-7901 cells

Both immunofluorescence staining (Figure 4) and Western blotting (Figure 5) indicated the nucleolus as the precise localization of RhoA within SGC-7901 interphase nucleus.

The change of RhoA expression during cell cycle

In mitotic active Hela cells, Western blotting indicated that the expression of RhoA protein in interphase (Figure 6A) was higher than that in mitosis phase (Figure 6B).

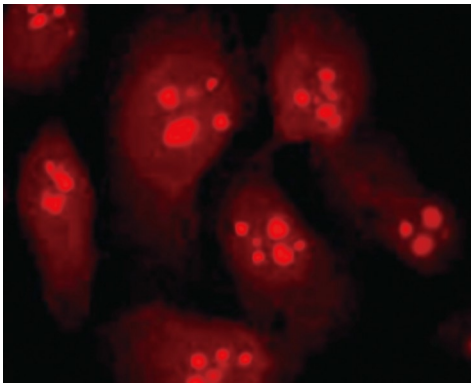

Figure 1 Localization of endogenous RhoA in SGC-7901 cells. RhoA was immunofluorescently stained with a specific mAb and it was localized in the cytoplasm, the membrane, and the nucleus (× 400).

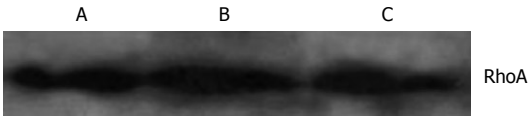

Figure 2 Distribution of RhoA in membrane, cytosol, and nucleus in SGC-7901 cells. SGC-7901 cells were lysed and membrane (A), cytosol (B) and nuclear (C) fractions were obtained. Expression of RhoA in each fraction was detected by Western blotting using a specific anti-RhoA mAb.

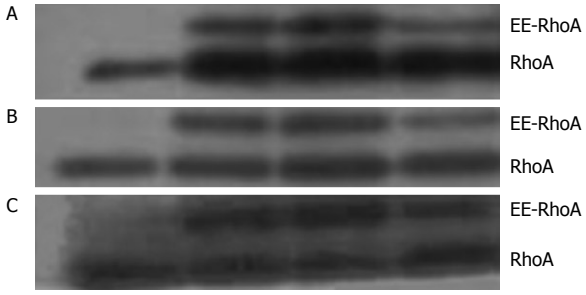

Figure 3 Distribution of endogenous and exogenous RhoA in membrane, cytosol, and nucleus in SGC-7901 cells. SGC-7901 cells were transfected with three types of exogenous EE-tagged RhoA plasmids, and 24 h later, cells were lysed and membrane (A), cytosolic (C) and nuclear (B) fractions were obtained. The expression of different RhoA proteins (lane 1 mock, lane 2 wild type, lane 3 63L, lane 4 N19) in each fraction was detected by Western blotting with mAb against RhoA.

Consistent with this finding, the amounts of RhoA transcripts were also found to be higher in interphase (Figure 7A) than in mitosis phase (Figure 7B).

LPA-induced membrane and nucleus translocation of RhoA in SGC-7901 cells

As shown by Western blotting, a stimulation with 1 μmol/L LPA at 37℃ for 15 min causes an increase in the amount of RhoA in the membrane (Figure 8A) and the nuclear (Figure 8B), but a decrease in the cytosol fraction (Figure 8C).

CPT-cAMP-induced cytosol translocation of RhoA in SGC-7901 cells

An incubation with 100 μmol/L cAMP at 37℃ for 30 min led to a decrease in the amounts of RhoA protein in membrane (Figure 9A) and nuclear (Figure 9B) fractions, but to an increase in cytosol preparations (Figure 9C).

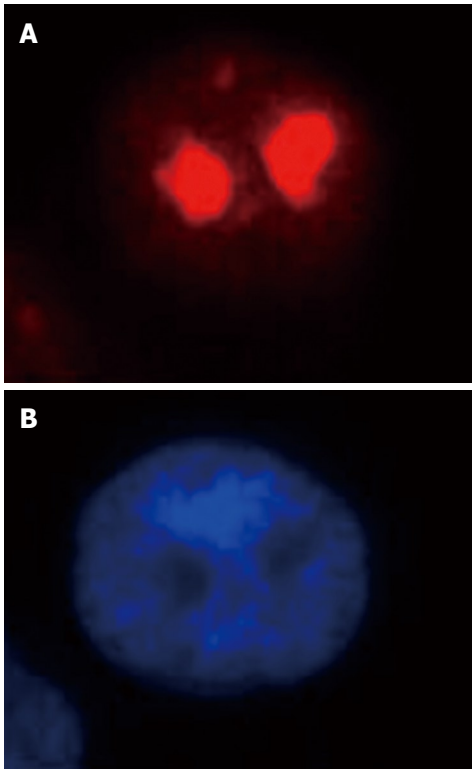

Figure 4 Localization of RhoA in the nucleolus of interphase SGC-7901 cells. RhoA in SGC-7901 cells of interphase was immunofluorescently stained with monoclonal antibody against RhoA (**A**). The chromosomes were stained with Hoechst 33342 (**B**) (× 1000).

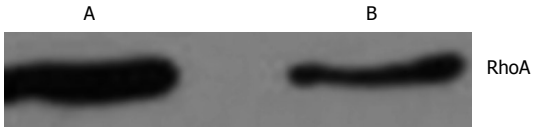

Figure 5 RhoA could be detected in nucleolus in SGC-7901 cells. SGC-7901 cells were lysed and the nucleolus fraction was obtained. Expression of RhoA in the nucleolus fraction (B) was detected by Western blotting with a mAb directed against RhoA, and total protein obtained from SGC-7901 cells (A) served as the positive control.

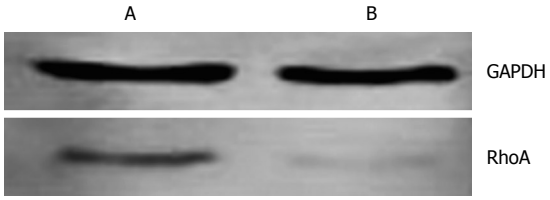

Figure 6 The expression of RhoA protein was higher in interphase than in mitosis phase in HeLa cells. HeLa cells were treated with Taxol (5 μg/mL, 12 h). Control (attached) (A) or mitotic ("shake off") (B) cells were lysed and the expressions of RhoA and GAPDH were detected by Western blotting with mABs directed against RhoA and GAPDH.

CPT-cAMP could block LPA-induced RhoA translocation in SGC-7901 cells

Stimulation with 100 μmol/L cAMP at 37℃ for 30 min

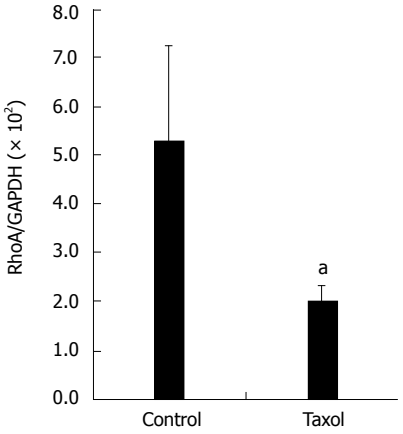

Figure 7 The mRNA expression of RhoA gene was higher in interphase than in mitosis phase in HeLa cells. HeLa cells were treated with Taxol (5 μg/mL, 12 h). Total mRNA was isolated from control (attached) and mitotic ("shake off") cells, and the expression of RhoA gene was detected by real-time quantitative PCR. Each bar represents mean ± SE obtained from five independent experiments. $^aP < 0.05$.

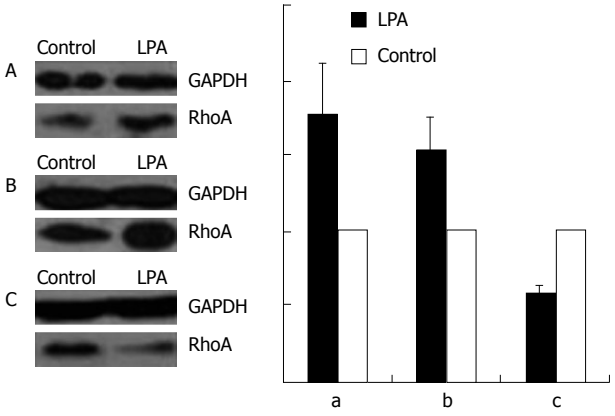

Figure 8 LPA-induced RhoA translocation from cytosol towards membrane and nucleus in SGC-7901 cells. SGC-7901 cells were treated with or without LPA (1 μmol/L, 15 min). Control or LPA -treated cells were lysed and the membrane (A), cytosolic (C), and nuclear (B) fractions were obtained. Expressions of RhoA and GAPDH proteins in each fraction were detected by Western blotting, and the representative band images were shown in the left panels. Densitometric analysis of the bands was shown in the right panels. Each bar represents mean ± SE obtained from five independent experiments. $^aP < 0.05$.

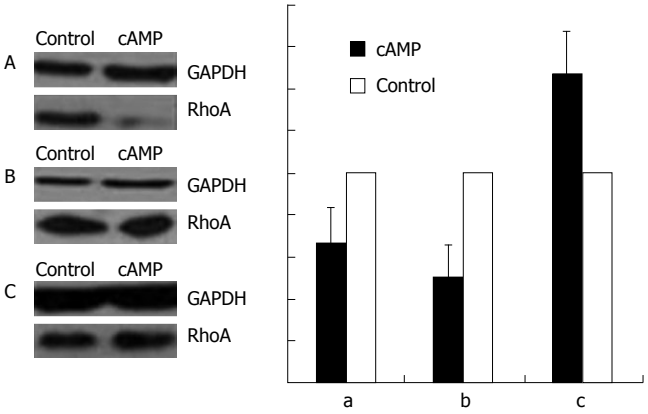

Figure 9 cAMP-induced RhoA translocation from membrane and nucleus towards cytosol in SGC-7901 cells. SGC-7901 cells were treated with or without CPT-cAMP (250 μmol/L, 30 min). Control or CPT-cAMP -treated cells were lysed, and membrane (A), cytosolic (C), and nuclear (B) fractions were obtained. Expressions of RhoA and GAPDH proteins in each fraction were detected by Western blotting, and the representative band images were shown in the left panels. Densitometric analysis of the bands was shown in the right panels. Each bar represents mean ± SE obtained from five independent experiments. $^aP < 0.05$.

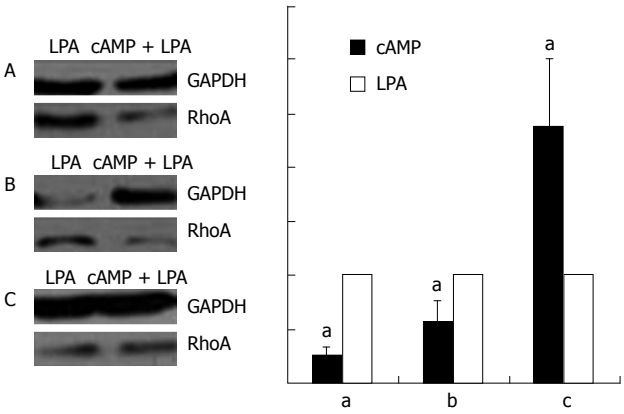

Figure 10 cAMP could block LPA-induced RhoA translocation in SGC-7901 cells. SGC-7901 cells were pretreated with CPT-cAMP (250 μmol/L, 30 min), and then with or without LPA (1 μmol/L, 15 min) treatment. LPA or CPT-cAMP+LPA -treated cells were lysed and membrane (A), cytosolic (C), and nuclear (B) fractions were obtained. Expressions of RhoA and GAPDH proteins in each fraction were detected by Western blotting, and the representative band images were shown in the left panels. Densitometric analysis of the bands was shown in the right panels. Each bar represents mean ± SE obtained from five independent experiments. $^aP < 0.05$.

followed by an incubation with 1 μmol/L LPA at 37℃ for 15 min was found to cause a decrease in the amounts of RhoA protein in the membrane (Figure 10A) and the nuclear (Figure 10B), but an increase in the cytosol (Figure 10C) preparations.

DISCUSSION

RhoA acts as a molecular switch in the cells, regulates signal transduction from cell surface receptors to intracellular target molecules, and is involved in a variety of biological processes, including cell morphology[25], motility[26], cytokinesis[27,28], smooth muscle contraction[29,30], and tumor progression[31,32]. It was widely accepted that the subcellular localization of RhoA was in the membrane and cytosol, and mainly in the latter one[33,34]. Recently, our laboratory reported the existence of RhoA in the nuclei of SGC-7901 cells[22]. In this study, we not only confirm the nuclear localization of RhoA; we were able to localize RhoA proteins more precisely, namely within the nucleolus.

Protein import into the cell nucleus is a typical transport process between the cytosol and the nucleus. It occurs through nuclear pore complexes (NPCs)[35-39]. These elaborate proteinaceous structures act not only as molecular sieves, allowing free diffusion of ions and small molecules, but also mediate the active transport of proteins and ribonucleoprotein particles. In order to enter the nucleus, proteins larger than about 60 kDa generally require a specific nuclear localization signal (NLS). Protein molecules can bind with transporting protein such as

importin *via* NLS and get into the nucleus through ATP dependent process. However, the molecular mass of RhoA is 21 kDa and there is no NLS with its protein structure. Our primary experiment did not detect the combination of RhoA with nuclear transporting proteins such as importin α and importin β (data not shown). So, it was reasonable for us to presume that the molecular mechanism of RhoA protein transportation to the nucleus was not through the classic transportation pathway, but diffusion.

The nucleolus of eukaryotic cells was first described in the early 19th century and was discovered in the 1960s to be the site of ribosome synthesis. It owned a variety of roles of cell activity. rRNA transcription, rRNA processing, and ribosome assembly have been clearly established as major functions of the nucleolus. As research progresses, many other functions of the nucleolus have been recognized, including gene expression, processing of nuclear export of certain mRNAs, processing of U6 RNA, one of the spliceosomal small nuclear RNAs, and processing of tRNA precursors. Recently, the plurifunctional nucleolus concept has been widely accepted.

According to the concept of plurifunctional nucleolus, it is reasonable to speculate that RhoA will share, at least, part of the function of the nucleolus. A previous study suggested a role for major nucleolar proteins in the nucleocytoplasmic transport of ribosomal components, and transient exposure of shuttling proteins to the cytoplasm may provide a mechanism for cytoplasmic regulation of nuclear activities[40]. The expression of some nucleolar proteins, such as B23, changes during cell cycle. In this experiment, the results showed that the amount RhoA protein also changed during cell cycle, exhibiting high amount in S phase, and the change of RhoA mRNA expression was the same as that of the protein. This suggested that RhoA probably played a role in regulation of cell mitogenesis. In this way, our results obviously provide a new insight into investigating some unknown functions of RhoA according to its new distribution.

In our previous study[22], with immunofluorescent microscopy, we did not detect significant translocation of RhoA in SGC-790 treated with RhoA activator LPA or RhoA activation inhibiting reagent cAMP. Since some other studies reported RhoA translocation according to its activity with Western blot assay, in this experiment, we applied different methods to separate cellular components and western blotting to investigate RhoA translocation, especially in nucleus. With these more concise and sensitive methods, we showed that after the treatments with LPA, cAMP, and cAMP + LPA, nucleus translocation of RhoA was the same as its membrane translocation. Furthermore, since it was reported that RhoA in membrane represented its active form[41] and our results showed that RhoA moved into the nucleus and onto the membrane during the stimulation of LPA, we supposed that RhoA in nucleus is also in the active status.

In conclusion, our results indicated that the nucleolus provided a new compartment for RhoA in SGC-7901 cells and that the activation of RhoA had an obvious effect on its translocation, stimulating the distribution of this protein not only in membrane but also in nucleus.

COMMENTS

Background

Until now, more than 100 small G proteins have been found. Among them, only Ran/TC4, Rap1, and H-Ras were found to be located within the nucleus. However, the nuclear localization of these small G proteins was closely related to the proliferation and the malignant change of the cells.

Research frontiers

Both Rap1 and H-Ras are members of Ras family. Active Rap1A and Rap1B were located within the nucleus of epithelium-originated cancer cells, and the distribution was related to the malignancy of the cells. Active H-Ras was found to be located within the nucleus of both transformed cells and NDEA-induced hepatic tumor cells of mice.

Innovations and breakthroughs

Through immunofluorescence microscopy and Western blotting, RhoA has been found to be located in the nucleus of the gastric cancer cell line SGC-7901. The phenomenon was confirmed by confocal microscope observation of vital cells transfected with plasmid encoding GFP-tagged RhoA. However, the concise localization of the protein within the nucleus was not clear. Furthermore, whether the activation of RhoA is related to its nuclear localization or not was not elucidated.

Applications

Since RhoA was found to be located on the nucleolus of the cells and some nucleolar proteins played important role in controlling cell mitosis, it deserves to study the role of nucleolar RhoA in controlling cell mitosis.

Terminology

Small G proteins are GTP/GDP binding proteins with molecular size around 20 kD. Each small G protein has two forms: GTP-binding active form and GDP-binding inactive form. When it changes from GDP-binding form to GTP-binding form, it is activated. Through this change cycle, small G protein performs as molecular switch. RhoA is an important member of Rho small G protein family. It has been found that RhoA played an important role in regulating diverse biological activities of cells.

Peer review

The conclusion of this study was as follows: The localization of RhoA in the SGC-7901 cells was in membrane, cytosol, and nucleus. The novel finding of this study is showing that the precise localization of RhoA protein was in the nucleolus.

LIVER CANCER

Prokineticin 2/Bv8 is expressed in Kupffer cells in liver and is down regulated in human hepatocellular carcinoma

Abstract

AIM: To study the implication of prokineticin 1 (PK1/EG-VEGF) and prokineticin 2 (PK2/Bv8) in hepatocellular carcinoma angiogenesis.

METHODS: The gene induction of PK1/EG-VEGF and PK2/Bv8 was investigated in 10 normal, 28 fibrotic and 28 tumoral livers by using real time PCR. Their expression was compared to the expression of VEGF (an angiogenesis marker), vWF (an endothelial cell marker) and to CD68 (a monocyte/macrophage marker). Furthermore, the mRNA levels of PK1/EG-VEGF, PK2/Bv8, prokineticin receptor 1 and 2 were evaluated by real time PCR in isolated liver cell populations. Finally, PK2/Bv8 protein was detected in normal liver paraffin sections and in isolated liver cells by immunohistochemistry and immunocytochemistry.

RESULTS: PK2/Bv8 mRNA but not PK1/EG-VEGF was expressed in all types of normal liver samples examined. In the context of liver tumor development, we reported that PK2/Bv8 correlates only with CD68 and showed a significant decrease in expression as the pathology evolves towards cancer. Whereas, VEGF and vWF mRNA were significantly upregulated in both fibrosis and HCC, as expected. In addition, out of all isolated liver cells examined, only Kupffer cells (liver resident macrophages) express significant levels of PK2/Bv8 and its receptors, prokineticin receptor 1 and 2.

CONCLUSION: In normal liver PK2/Bv8 and its receptors were specifically expressed by Kupffer cells. PK2/Bv8 expression decreased as the liver evolves towards cancer and did not correlate with HCC angiogenesis.

INTRODUCTION

In vivo, a solid tumor can not progress beyond a few cubic millimeters without oxygen and nutrients supplied by an adequate vascular support[1]. The creation of novel vascular vessels in the tumor microenvironment resulting from an over expression of pro-angiogenic factors plays a central role in tumor invasion and metastasis[2]. Hepatocellular carcinoma (HCC) present typical neo vascularization[3]. Among the soluble factors responsible for the shift towards tumor neo vascularization, vascular endothelial growth factor (VEGF) is thought to play an important role in HCC. This factor is synthesized essentially during hypoxic stress[4] and promotes the growth, migration, morphogenesis of vascular endothelial cells and increases vascular permeability[5,6]. Furthermore, the VEGF/VEGF receptor system is thought to be closely related to the histological grade of hepatocellular carcinoma[7] and strongly expressed in well differentiated HCC[8]. Several other potent angiogenic factors have been reported to be

involved in HCC angiogenesis, notably basic fibroblast growth factor (bFGF)[9,10], angiopoietin 1 (Ang1) and angiopoietin 2 (Ang2)[11]. Interestingly, inflammatory cytokines like Interleukin 8 (IL-8) and tumor necrosis factor-alpha (TNF-α) have also been shown to be implicated in the maintenance of HCC angiogenesis but also in chronic hepatitis[12,13].

Prokineticin 1, also named endocrine gland-vascular endothelial growth factor (PK1/EG-VEGF) and prokineticin 2 also known as Bombina variegata 8 (PK2/Bv8) are widely distributed in mammalian tissue and exhibit diverse biological activities. Prokineticins bioactivities includes, smooth muscle contraction in the gastrointestinal tract[14], supporting neuronal survival, pain sensation and circadian rhythms in the central nervous system[15-17]. Prokineticins display also potent cytokine properties, such as inducing bone marrow leukocyte production, and modulating the growth and function of peripheral leukocytes[18-20]. These peptides were also shown to act as angiogenic mitogens, indeed, PK1/EG-VEGF and PK2/Bv8 induce proliferation, migration and fenestration of endothelial cells from adrenal capillaries[21,22]. In addition, in a mouse model of myocardial infarctions, PK2/Bv8 protected cardiomyocytes by increasing neovascularization[23]. Prokineticins are a family of peptides characterized by a common AVIT motif, and 10 conserved cysteine residues[24-26]. Prokineticins are not structurally related to VEGF and mediate their biological activity by selectively acting on two G protein coupled receptors, prokineticin receptor 1 and 2 (PKR1 and PKR2), for which they have similar affinities[24,26]. Activation of PKRs triggers multiple signaling pathways, such as calcium mobilization, phosphoinositol turnover, and activation of Akt kinase and mitogen-activated protein kinase (MAPK)[27].

Numerous studies have evaluated the implication of prokineticins in tumor development. For example, mice implanted with colorectal cancer cell line SW620 stably expressing PK1/EG-VEGF had an increase of angiogenesis and of colorectal cancer metastasis[28]. In ovarian carcinoma, PK1/EG-VEGF was evenly detected in benign, low malignant potential neoplasms or stage I ovarian cancer[29], and no expression was observed in endometrial carcinoma[30]. However, PK1/EG-VEGF was shown to be associated in Leydig cell tumor growth[31] and in neuroblastoma progression[32]. In prostate cancer, both prokineticin 1 and 2 and their receptors were up regulated[32,33]. Taken altogether, the literature indicates that prokineticins are differentially associated to tumor development. In the present study, we explored the potential implication of both prokineticins in HCC angiogenesis, and identified their cellular origin in liver parenchyma.

MATERIALS AND METHODS

Patients

Liver tissue samples were obtained from 28 patients with HCC undergoing surgical resection of the tumor. Patients with HCC were 25 males and 3 females (59.9 ± 9.0 years). The etiology of fibrosis (n = 8) and cirrhosis (n = 20) included hepatitis C (n = 22), hepatitis B (n = 7) and alcohol abuse (n = 14). All tumor samples were taken within the tumor, and only tissue with anatomic pathology features that allow a matching diagnosis with the pathology report of each patient were used for RNA extraction. Matching non tumor livers (n = 28) were taken distantly from the tumors. Histological evaluation before their inclusion in the study ruled out the presence of tumor tissue in these samples. Controls were 10 histologically normal liver samples obtained from metastatic livers of colorectal cancer[34]. Access to this material was in agreement with French laws and satisfied the requirements of the local Ethics Committee. The histological stage of fibrosis and the intensity of necroinflammatory lesions were graded according to the METAVIR score[35]: A0 = no activity, A1 = mild, A2 = moderate, A3 = severe, F0 = no fibrosis, F1 = portal fibrosis without septa, F2 = portal fibrosis with few septa, F3 = numerous septa without cirrhosis, and F4 = cirrhosis. All tissue sections were routinely analyzed after staining with hematoxylin-eosin-saffran and Sirius red.

Human hepatic cell isolation

Human hepatic cells were isolated from histologically normal specimens of partial hepatectomy from patients undergoing hepatic resection for liver metastases. A2 step perfusion method using collagenase and pronase, followed by differential sedimentation allowed separation and recovery of hepatocytes (HA) from non-parenchymal cells enriched in sinusoidal cells[36]. From the latter fraction, hepatic stellate cells (HSC) were efficiently purified by a density gradient centrifugation with Nycodenz 13% (Sigma-Aldrich, St. Louis, MO) and cultured as previously described[37]. Similarly a population enriched in liver macrophages, also known as Kupffer cells, was obtained from the same non-parenchymal cell population by using a density gradient centrifugation with Nycodenz 17%[38]. The proportion of Kupffer cells present in the Kupffer cell enriched population (KC-Enr) was evaluated by flow cytometry (Becton Dickinson's FACScalibur, Grenoble, France) using an antibody directed against CD14, a typical surface marker of monocyte/macrophage (Immunotech Beckman Coulter, Marseille, France). Kupffer cells were then further enriched from the Kupffer cell enriched population (KC-Enr) by using anti-CD14-Dynabeads according to the manufacturer's indication (Dynal A.S., Oslo, Norway)[38].

Hepatoma cell lines (Hep3B, BC1, B16A2) were cultured in 25% 199, 75% MEM medium (Eurobio, Courtaboeuf, France), supplemented with 1 mg/mL albumin, 5 μg/mL insulin, 50 000 U/L penicillin-streptomycin, 12.5 nmol/L glutamine and 100 ng/mL hydrocortisone. HepG2 cell line was cultivated in MEM α Medium (GIBCO, Paisley, Scotland), to which was added 50 000 U/L penicillin-streptomycin and 12.5 nmol/L glutamine.

RNA isolation and RT-PCR

Total RNA was extracted from isolated human liver cells, liver tissue or directly from Kupffer cells linked to the

CD14 coated beads using the SV Total RNA isolation Kit® (Promega, Charbonnieres-lesbains, France) and 1 μg of total extracted RNA was subjected to a reverse transcription reaction using high capacity cDNA archive kit® (Applied Biosystem, Foster City, CA). A total of 12.5 ng total complementary DNA was used as a template for amplification with primers specific for PK1/EG-VEGF, PK2/Bv8 (PK2β and PK2L) and β-actin (Table 1) used at a 250 nmol/L final concentration. The PCR reaction performed using PCR master mix from Promega for which the final working concentration included 0.5 units of Taq polymerase, 200 μmol/L dNTPs and 1.5 mmol/L $MgCl_2$. The PCR reaction was performed using GeneAMP PCR 9700 (Applied Biosystems), after an initial denaturation step at 94℃ for 2 min, 35 cycles of PCR were programmed for PK1/EG-VEGF and PK2/Bv8, whereas 25 cycles were performed for β-actin. Denaturation step was performed at 94℃ for 30 s, annealing at 60℃ for PK1/EG-VEGF and PK2/Bv8, and 55℃ for β-actin, and extension at 72℃ for 1 min. The last extension was at 72℃ for 7 min.

For real-time quantitative PCR, the mRNA levels of PK1/EG-VEGF, PK2/Bv8 (PK2β and PK2L), VEGF (VEGF A), vWF, CD68, PKR1 and PKR2 were assayed using the 7000 sequence detection system ABI Prism® sequence detector (Applied Biosystems), using the double strand specific dye SYBR® Green system (Applied Biosystems). Primer sequences are summarized in Table 1. The PCR condition and cycle were as follows: initial DNA denaturation 10 min at 95℃, followed by 40 cycles of denaturation at 95℃ for 15 sec, follow by an annealing step, and then extension at 60℃ during 1 min. Each point was performed in triplicate. To ensure that the primers produced a single and specific PCR amplification product, a dissociation curve was performed during the PCR cycle and only primers with a unique dissociation peak were selected, followed by migration on a 2% agarose gel to ensure that the PCR product was unique. The PCR products were then sequenced to confirm that the correct cDNA was amplified (data not shown). The amplification efficiency for each primer pair was calculated and presented in Table 1. The expression level of each gene was adjusted by the level of 18S mRNA and expressed as the ratio to 18S mRNA or as the ratio to the average gene expression level in normal liver.

Immunohistochemical staining

Paraffin embedded liver sections were de-parafinised by 2 changes of xylene for 5 min, and re hydrated, in 2 changes of 100% ethanol for 3 min, 2 changes of 95% and 80% for 1 min, and then washed with distilled water. Antigen retrieval was performed using a citrate pH 6.0 buffer, heated at 95℃-100℃ for 40 min; sections were let to rest at room temperature for 20 min. Endogenous peroxidase activity was inhibited by incubation with 3% hydrogen peroxide (10 min, RT) and the non specific sites were blocked with PBS/BSA 2% (1 h, RT). PK2/Bv8 protein was detected using rabbit polyclonal anti-PK2/Bv8 antibody (gift of Dr. Feige, INSERM U858, Grenoble, France) at a final concentration of 1.44 μg/mL for 1 h at RT or for 24 h at 4℃[39]. CD31, CD34, CD68 and VEGF detection was performed by incubating sections with primary antibodies overnight at 4℃ using mouse monoclonal anti-CD31 IgG1 (clone JC70A, dilution 1:50, Dako, Glostrup, Denmark), mouse monoclonal anti-CD34 IgG1 (clone Qbend10, dilution 1:10 Immunotech, Beckman Coulter), mouse monoclonal anti-CD68 IgG3 (clone PGM1, ready to use, Dako), rabbit polyclonal anti-VEGF (sc-152, dilution 1:100, Santa Cruz Biotechnology, Santa Cruz, CA). Primary antibodies were diluted in Dako's REAL™ Antibody Diluent. Sections were processed with appropriate biotinylated secondary antibody and a streptavidin biotin peroxidase amplification kit (Vectastain, Vector Laboratories, Burlingame, CA). The peroxidase reaction was finally developed with diaminobenzidine (Merck, Whitehouse Station, NJ) and sections were counter stained with Mayer's hematoxylin. Non-immune rabbit serum or control mouse IgG was used instead of primary antibodies as negative controls. In addition, competition experiments were performed by pre-incubating overnight at 4℃ PK2/Bv8 antibodies with the appropriate antigen peptides.

Immunocytochemical staining

Enriched Kupffer cells (10^5 cells) were spotted on slides by cytospin (10 min at 400 rpm) and then fixed using 4% paraformaldehyde at room temperature for 10 min. Permeabilization was achieved by treating cells for 10 min at RT with Triton × 100 0.1% and blocking of non-specific sites by 20min incubation at RT with PBS/BSA 2%. PK2/Bv8 protein was detected with mouse anti-PK2/Bv8 anti-serum (dilution 1:50, Abnova, Tapei City, Taiwan) and revealed by TRITC labeled anti-mouse antibody (dilution 1:150, Merck). CD68 protein was detected directly with FITC labeled mouse monoclonal anti-CD68 IgG1 (clone KP1, dilution 1:10, Dako). Primary and secondary antibodies were diluted in appropriate diluent (Dako's REAL™ Antibody Diluent) and incubated at RT for 2 h and 1 h respectively. The cells were counterstained with nucleus dye DAPI (dilution 1:10000, Dako). Sections processed with one or both of the control primary antibodies (control mouse

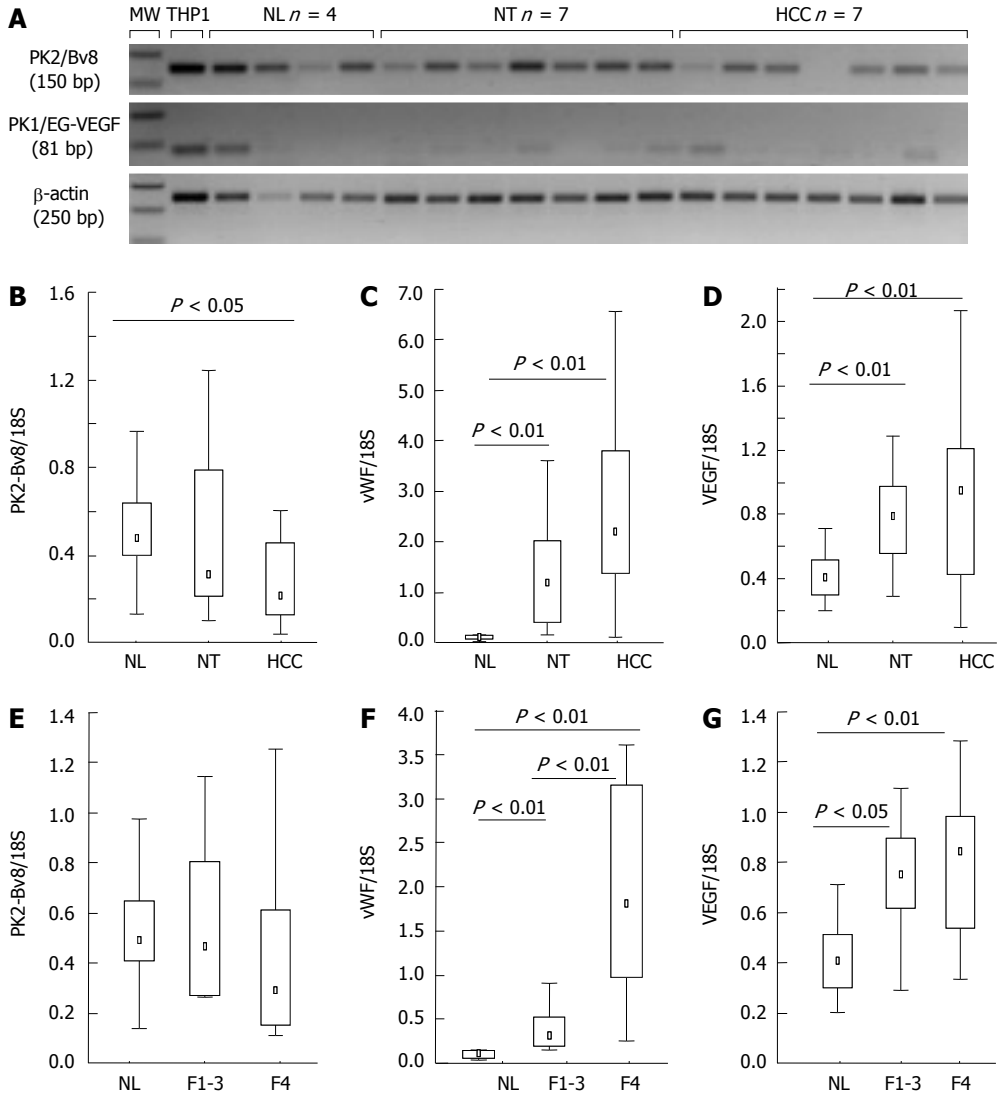

Figure 1 (**A**) RT-PCR analysis of PK1/EG-VEGF and PK2/Bv8, and (**B-G**), real-time PCR analysis of PK2/Bv8, vWF and VEGF in normal liver (NL, $n = 10$), non-tumorous liver (NT, $n = 28$), and in Hepatocellular carcinoma (HCC, $n = 28$).

serum and/or control IgG1) were free of immunostaining in their corresponding color channel. We checked that FITC labeled cells remained negative in TRITC channel.

Statistical analysis

Statistical comparisons for significance were made with Wilcoxon's test for paired samples, and with Mann-Whitney *U* test for un-paired samples. The correlation between continuous variables was examined by means of Spearman's rank-order coefficients. A level of $P < 0.05$ was considered significant. Calculations were made with the commercially available software Statistical.

RESULTS

Expression of PK1/EG-VEGF, PK2/Bv8, vWF and VEGF mRNA in normal and tumoral livers

The mRNA expression of PK1/EG-VEGF and PK2/Bv8 in liver was first evaluated by PCR in 4 normal livers (NL), 7 tumoral livers (HCC) and in their corresponding adjacent non-tumoral tissue (NT) (Figure 1A). THP1, a monocytic cell line which expresses high levels of both PK1/EG-VEGF and PK2/Bv8 transcripts, served as a positive control. Our results show that, in all liver samples analyzed PK2/Bv8 is significantly expressed, whereas PK1/EG-VEGF is barely detectable.

In order to monitor more precisely how PK2/Bv8 varied during HCC progression, we measured the mRNA expression of PK2/Bv8 by real time PCR in a larger cohort of 28 patients (Figure 1B). PK2/Bv8 mRNA is expressed in normal liver ($n = 10$) at significant levels (average cycle threshold is approximately 28). However, a significant decrease in PK2/Bv8 mRNA expression was detected in HCC relative to normal liver tissues ($P < 0.05$), while no significant difference was found between HCC ($n = 28$) and peri-carcinomatous liver tissues (NT, $n = 28$). Such expression of PK2/Bv8 was compared to two angiogenesis markers vWF (Figure 1C) and VEGF (Figure 1D). vWF, an endothelial cell marker, showed remarkable over expression in tumor ($P < 0.01$) and in adjacent liver tissues compared with normal liver ($P < 0.01$). Similarly, VEGF mRNA levels were induced in HCC and the underlying cirrhotic liver (NT) compared with normal liver ($P < 0.01$). By using the spearman's rank order correlation, a significant correlation was observed between VEGF and vWF ($r = 0.6$; $P < 0.001$) but not with PK2/Bv8.

The peri-carcinomatous liver tissues were classified according to the METAVIR score. vWF and VEGF were

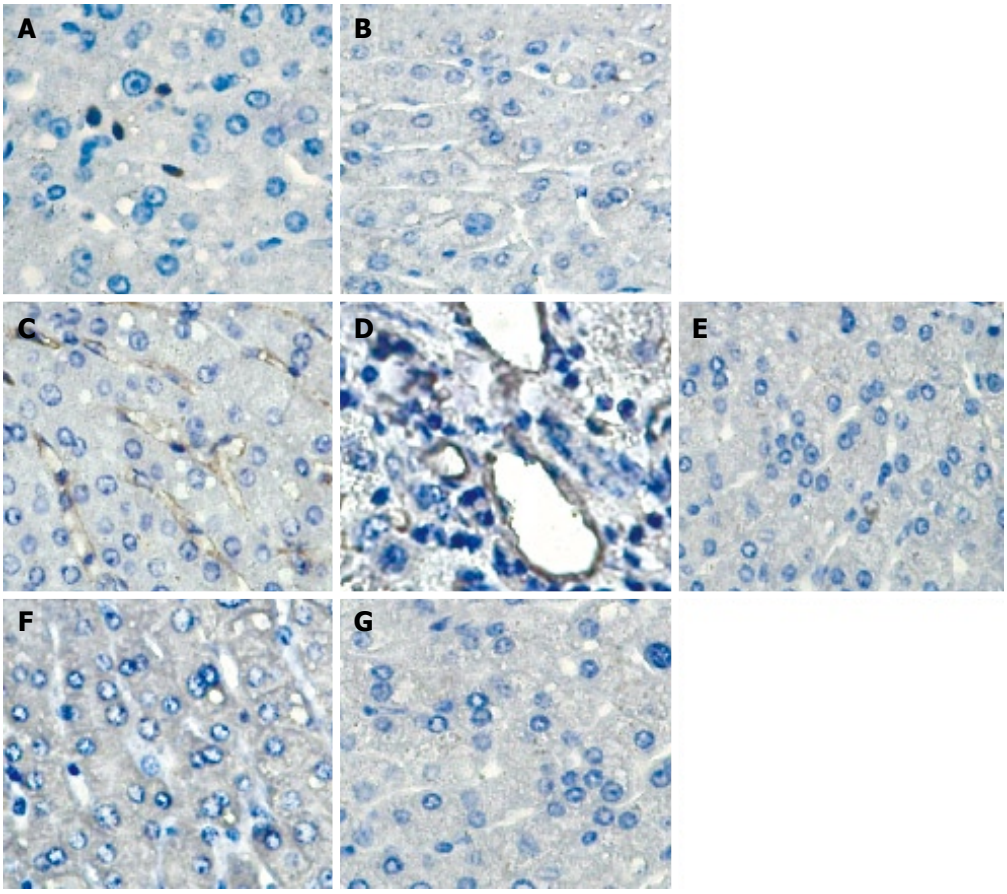

Figure 2 Immunolocalization of PK2/Bv8, CD31, CD34 and VEGF on normal liver sections. **A**: Bv8; **B**: Bv8 + blocking peptide; **C**: CD31; **D**: CD34; **E**: Mouse IgG1; **F**: VEGF; **G**: Rabbit IgG.

significantly up-regulated in fibrosis and cirrhosis ($P < 0.01$) compared with normal liver (Figure 1F and G) whereas no difference was observed with PK2/Bv8 (Figure 1E). Moreover, PK2/Bv8, vWF and VEGF mRNA expression did not show any significant statistical correlation with necro-inflammatory activity (data not shown).

Immunolocalization of PK2/Bv8, CD31, CD34 and VEGF in normal livers

Sections of normal livers from 5 different individuals were immunostained with antibodies against: PK2/Bv8, CD31 (a constitutive marker of endothelial cells), CD34 (a marker of endothelial cell in proliferation), and with an antibody against VEGF A (including 165, 189 and 121 variants). PK2/Bv8 protein expression was detected in cells restricted to the hepatic sinusoids and presenting morphology similar to resident macrophages (Figure 2). The specificity of the staining was demonstrated by the inhibition of PK2/Bv8 labeling after anti-PK2/Bv8 pre-incubation with an excess of recombinant PK2/Bv8 peptide. In normal liver, both large capillary endothelial cells and sinusoidal endothelial cells were positive for CD31, whereas CD34 positive endothelial cells were practically un-detectable in the parenchyma, excepted in large capillaries. VEGF protein was detected at low levels in the hepatic parenchyma.

Expression of CD68 mRNA and protein in normal and tumoral livers

Recent reports have demonstrated that PK2/Bv8 has cytokine properties[20] and is strongly expressed by several types of leukocytes including the monocyte/macrophage lineage[19]. We therefore, hypothesized that the liver resident macrophages might be responsible for the expression of PK2/Bv8. The Kupffer cell population expresses the specific marker CD68, and on this basis we investigated the correlation between CD68 and PK2/Bv8 in term of transcripts and tissue localization. The mRNA expression of CD68 was measured by quantitative PCR in the same cohort of patients. As shown in Figure 3A, there was a significant down expression of CD68 in liver HCCs compared to the expression in normal livers ($P < 0.05$). Thus the expressions of PK2/Bv8 (Figure 1A) and CD68 (Figure 3A) in HCC patients follow a similar down regulation pattern in tumors relative to control livers. Furthermore, using spearman's rank order correlation, CD68 showed a correlation with PK2/Bv8 ($r = 0.45$, $P < 0.01$). Similar to PK2/Bv8, CD68 did not show any correlation of expression with VEGF or vWF. In addition, CD68 and PK2/Bv8 were immunolocalized in normal liver serial sections (Figure 3B). The specificity of PK2/Bv8 staining was evaluated by the disappearance of labeling when anti-PK2/Bv8 antibodies were pre-incubated with antigen peptide. We showed that most CD68 positive cells were not PK2/Bv8 positive. However, all cells showing positive staining for PK2/Bv8 were positive for CD68 staining.

Expression of PK1/EG-VEGF and PK2/Bv8 in Kupffer cell enriched non-parenchymal cells and in isolated hepatic cells

To further investigate the relationship between Kupffer cell population and PK2/Bv8 positive cells in liver, we studied various sequentially purified liver hepatic cells: hepatocytes

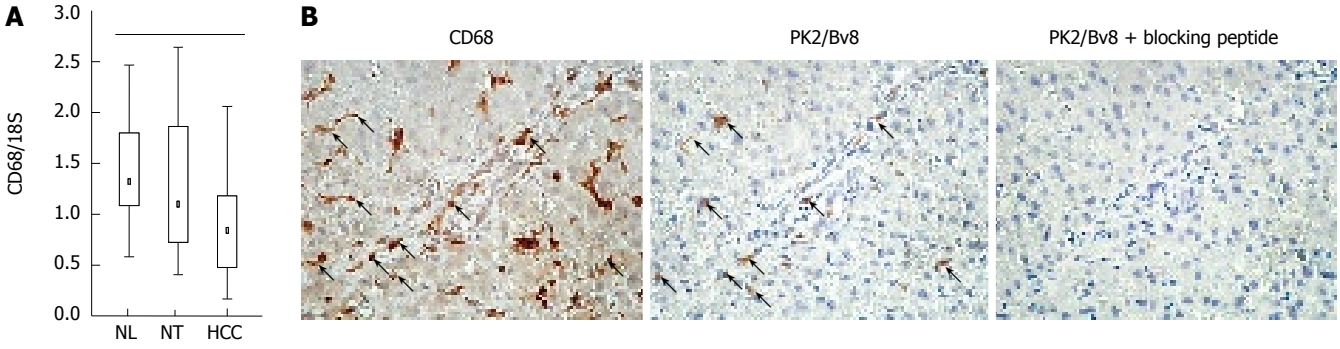

Figure 3 (**A**) Expression of CD68 normal liver (NL, *n* = 10), non-tumorous liver (NT, *n* = 28), and in Hepatocellular carcinoma (HCC, *n* = 28) by real time PCR, and (**B**) immunolocalization of CD68, PK2/Bv8, and PK2/Bv8 with blocking peptide on normal liver paraffin embedded serial sections.

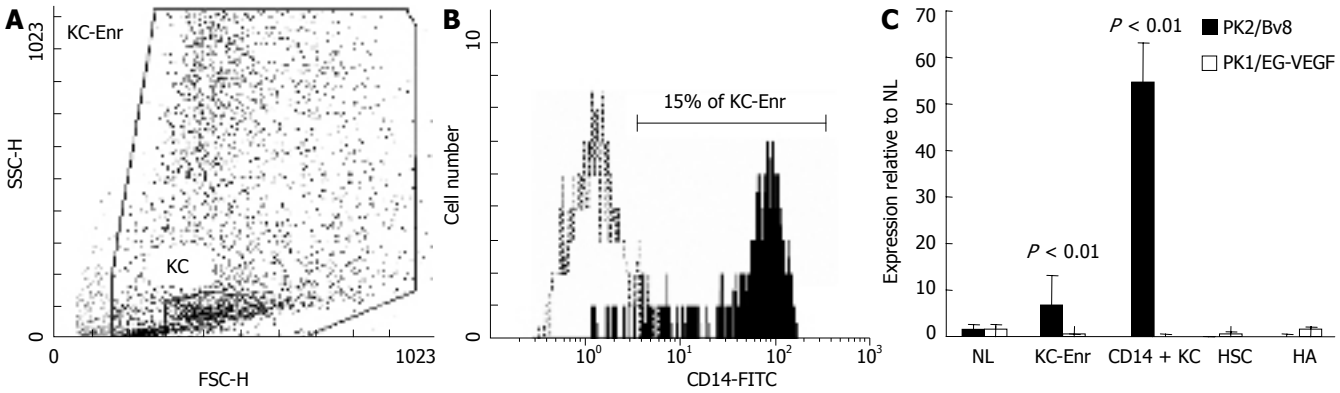

Figure 4 (**A**) Scatter plot and (**B**) histogram plot of CD14+enriched Kupffer cells, and (**C**) expression of PK1/EG-VEGF and PK2/Bv8 mRNA in isolated human liver cells by real time PCR.

(HA), hepatic stellate cells (HSC), and hepatic non parenchymal cell enriched in Kupffer cells (KC-Enr). The proportion of Kupffer cells in the KC-Enr population was evaluated by flow cytometry using an antibody against the cell surface monocyte/macrophage marker, CD14 (Figure 4A and B). This CD14 positive cell fraction represents 15% of the total KC-Enr population (representative of two separate experiments). CD14 positive Kupffer cells (CD14 + KC) were further enriched using anti-CD14 labeled microbeads.

The mRNA expression of PK1/EG-VEGF and PK2/Bv8 was measured by real time PCR on the various isolated liver cell populations, and compared whole liver expression. As shown in Figure 4C, the mRNA expression of PK2/Bv8 increases gradually as the concentration of Kupffer cells increases. Indeed in the KC-Enr cell population, containing 15% of Kupffer cells, the expression of PK2/Bv8 mRNA is 5 fold higher then in normal liver where Kupffer cells compose roughly 2% of the liver mass[40]. In CD14+ Kupffer cells (CD14+KC), expression of PK2/Bv8 is 35 fold higher than in normal liver. Primary hepatocytes, primary hepatic stellate showed no significant PK2/Bv8 expression (Figure 4C), as did several human hepatoma cell lines; BC1, Hep3B, HepG2, B16A2 (data not shown). Concerning PK1/EG-VEGF mRNA expression, it was barely detectable in all liver samples analyzed as shown in Figure 4C (average cycle threshold is about 33). All together these data strongly suggest that PK2/Bv8 transcript production in liver is associated with Kupffer cells.

Immunocytochemical co-localization of CD68 and PK2/Bv8 in isolated human liver cells

The human non-parenchymal liver cell population enriched in Kupffer cells (KC-Enr) was spotted on slides for a double Immunolocalization using FITC directly labeled anti-CD68 and indirectly labeled TRITC anti-PK2/Bv8. Results are presented in Figure 5, CD68 positive cells are shown in green and PK2/Bv8 positive cells appear in red, appropriate negative controls for both of the antibodies showed no specific staining. Co-immunolocalization of PK2/Bv8 and CD68 is shown in orange and demonstrates that all Bv8 positive cells are also CD68 positive.

Expression of PKR1 and PKR2 mRNA in human isolated liver cells and hepatoma cell lines

In order to assess the cellular target of PK2/Bv8 in liver cells, the mRNA level of their receptors, PKR1 and PKR2, was measured by real time PCR in isolated hepatic cells which includes CD14+ KC cells, hepatocytes, stellate cells, and human hepatoma cell lines BC1, Hep3B, HepG2, B16A2. In comparison to normal liver, PKR1 and PKR2 are most strongly expressed by the CD14 positive Kupffer cell population and expression was very weak in cultured stellate cells, in hepatoma cell lines and undetectable in hepatocytes (Figure 6).

DISCUSSION

PK1/EG-VEGF and PK2/Bv8 are two novel peptides with diverse biological functions[27,41] and one of such bioactivities is their ability to act as angiogenic mitogens. Their angiogenic activity was first evaluated in an *in vitro* assay by observing their capacity to induce proliferation, survival and migration of bovine adrenal cortical capillary endothelial cells (ACE)[21,22]. In this report we investigated the angiogenic potential of both PK1/EG-VEGF and PK2/Bv8 in human hepatocellular carcinoma (HCC). Interestingly, the literature shows two reports with divergent results on prokineticin expression in liver. In 2001, Li *et al*[14] showed an equivalent expression of prokineticin 1 and 2 in human liver by northern blot assay, whereas in 2005, Chen and colleagues[42], using RT-PCR observed a strong expression for PK2/Bv8 in human liver and an undetectable expression for PK1/EG-VEGF. Confirming the latter report, our results show a predominant expression of PK2/Bv8 in liver. Thus, we investigated further the expression of PK2/Bv8 in human liver, and its potential role in HCC angiogenesis. Our results show that Bv8/PK2 mRNA levels decrease significantly as the pathology evolves towards cancer.

Most cases of HCC develop on a liver fibrosis/cirrhosis background, which constitutes a very hypoxic environment for liver cells, and drives the production of numerous potent angiogenic factors[43]. In our HCC cohort, we monitored angiogenesis by measuring the expression of the endothelial cell marker; vWF and the angiogenic factor VEGF. Our results show that they are both strongly up-regulated in fibrosis and even more in tumors, confirming that our cohort exhibits a strong angiogenic profile. However, even though our HCC cohort constitutes an angiogenic environment, expression of PK2/Bv8 decreases in fibrosis and even more in tumors, suggesting that in this tissue context PK2/Bv8 is not induced by hypoxia in fibrosis and HCC.

To investigate further why PK2/Bv8, which is expressed at significant levels in normal liver, is down regulated through out the course of HCC development, we identified its cellular origin by several different techniques. Firstly, by immunolocalization on liver paraffin sections, PK2/Bv8 positive cells liver were located in the hepatic sinusoids and showed morphology similar to resident macrophages, otherwise known as Kupffer cells. Secondly, comparison of PK2/Bv8 expression in isolated human primary hepatocytes, hepatic stellate cells, Kupffer cells and hepatoma cell lines, showed that only Kupffer cells express significant levels of PK2/Bv8. Immunostaining on normal liver serial sections of CD68 and PK2/Bv8 showed that all PK2/Bv8 positive cells were equally CD68

positive. Finally, colocalization of PK2/Bv8 with CD68, a Kupffer cell marker, carried out in an isolated Kupffer cell-enriched population showed that all cells positive for PK2/Bv8 were also CD68 positive. Taken all together these data validate the hypothesis that Kupffer cells are the specific source of PK2/Bv8 in liver. Interestingly, it is a well known event that the number of Kupffer cells decreases in cirrhosis and even more in HCC relative to normal liver[44]. In this study, we confirm this previous report and observe that the expression pattern of CD68, a marker for Kupffer cells, decreases in fibrosis and in HCC compared to normal liver. CD68 and PK2/Bv8 follow a similar down-regulation pattern, which is confirmed by a correlation between the two gene expressions. Thus, these results contribute towards a potential explanation that the down regulation of PK2/Bv8 in HCC is due to the gradual decrease in number of Kupffer cells during the progression of the pathology. However, based on our results we can not exclude a possible regulation of PK2/Bv8 in Kupffer cells by the hepatic micro-environment.

Our results showing that PK2/Bv8 producing cells are Kupffer cells; are consistent with the fact that PK2/Bv8 is expressed by several types of leukocytes including the monocyte/macrophage lineage[14,19]. Even though PK1/EG-VEGF was not expressed in Kupffer cells it has also been associated to leukocyte lineage. For instance, PK1/EG-VEGF expression was positively correlated to macrophages in corpus luteum regression and follicular atresia of bovine ovaries[45], and to tumor infiltrating lymphocytes of human ovarian carcinoma[29]. All together, PK1/EG-VEGF and PK2/Bv8 appear to be expressed by immune cells differentially according to the tissue. Furthermore, we characterized the cellular targets of PK2/Bv8 in liver by measuring the expression for PK2/Bv8's receptors, called PKR1 and PKR2, in the same panel of liver cells. Interestingly, PKR1 and PKR2 are most strongly expressed by Kupffer cells. Recent reports have demonstrated that PK2/Bv8 has potent cytokine properties, PK2/Bv8 has the ability to stimulate monocyte production, mobilization and differentiation into macrophage like cells[19,20]. Therefore we can speculate that, in normal liver macrophage physiology, PK2/Bv8 could act by an autocrine manner on the resident macrophage population in the liver sinusoids. PK2/Bv8 might regulate Kupffer cells function and be involved in monocyte recruitment and differentiation of Kupffer cells.

In conclusion, we demonstrate that PK2/Bv8 is expressed in resident Kupffer cells in normal liver and that the expression of PK2/Bv8 decreases significantly as the pathology evolves towards hepatocellular carcinoma.

COMMENTS

Background

Liver cancer is one of the most common types of cancer and is a solid tumor showing important angiogenesis. Angiogenesis is an essential step in tumor progression, where the creation of novel blood vessels allows the growth and dissemination of cancer cells. Disrupting cancer blood vessels by blocking the secreted peptides responsible for endothelial cell proliferation has become a novel axis of anti-cancer treatment. Thus, identifying new secreted molecules involved in liver cancer vascularization could provide novel therapeutic targets.

Research frontiers

The aim of this study was to evaluate if two novel secreted peptides PK1/EG-VEGF and PK2/Bv8, described as having potent angiogenic effects, were involved in the vascularization process of human hepatocellular carcinoma.

Related publications

The present study had for goal to evaluate the angiogenic potential of prokineticins in hepatocellular carcinoma. To this effect we cited several articles from other investigators reporting researches on prokineticin action as an angiogenic factor, their implication in several other types of cancer.

Innovations and breakthroughs

This study clearly shows that PK1/EG-VEGF and PK2/Bv8 are not involved in human hepatocellular carcinoma vascular progression. Furthermore, in liver PK2/Bv8, but not PK1/EG-VEGF, was detected and was specifically expressed only by liver resident macrophages, known as Kupffer cells. Moreover, Kupffer cells express high levels of prokineticin receptor 1 and 2 suggesting paracrine/autocrine regulation by PK2/Bv8.

Applications

Even though our results show that PK2/Bv8 is not associated with hepatocellular carcinoma, it brings novel data on Kupffer cell physiology. All together our findings, corroborate numerous other reports demonstrating that prokineticins are expressed by immune cells, and have potent immunomodulatory activities.

Terminology

Prokineticin 1 (PK1/EG-VEGF) and prokineticin 2 (PK2/Bv8) are small secreted peptides of 8 kDa that signal through two receptors that are members of the G-protein coupled receptors superfamily. In addition to its angiogenic activites, prokineticins have also been shown to be implicated in hematopoiesis, reproductive angiogenesis, neurogenesis, ingestive behaviour and hormone release, gastrointestinal motility, circadian rhythms, and pain sensation. Hepatocellular carcinoma (HCC) is the major type of liver cancer; it develops majoritarily on a cirrhotic background, and is highly angiogenic.

Peer review

This manuscript describes for the first time in detail the expression and localization of PK2/BV8 in human liver, and in general the manuscript is well written.

Abstract

AIM: To investigate the capacity of potentially probiotic strains from six bacterial genera to induce cytokine production alone or in combinations in order to identify potential enhancing or synergistic effects in order to select probiotic bacteria for *in vivo* purposes.

METHODS: Cytokine production in human peripheral blood mononuclear cells (PBMC) in response to stimulation with eleven different potentially probiotic bacterial strains from *Streptococcus*, *Lactobacillus*, *Bifidobacterium*, *Lactococcus*, *Leuconostoc* and *Propionibacterium* genera was analysed. Production and mRNA expression of TNF-α, IL-12, IFN-γ and IL-10 were determined by ELISA and Northern blotting, respectively.

RESULTS: All tested bacteria induced TNF-α production. The best inducers of Th1 type cytokines IL-12 and IFN-γ were *Streptococcus* and *Leuconostoc* strains. All *Bifidobacterium* and *Propionibacterium* strains induced higher IL-10 production than other studied bacteria. Stimulation of PBMC with any bacterial combinations did not result in enhanced cytokine production suggesting that different bacteria whether gram-positive or gram-negative compete with each other during host cell interactions.

CONCLUSION: The probiotic *S. thermophilus* and *Leuconostoc* strains are more potent inducers of Th1 type cytokines IL-12 and IFN-γ than the probiotic *Lactobacillus* strains. Bacterial combinations did not result in enhanced cytokine production.

Probiotic *Leuconostoc mesenteroides* ssp. *cremoris* and *Streptococcus thermophilus* induce IL-12 and IFN-γ production. *World J Gastroenterol* 2008; 14(8): 1192-1203 Available from: URL: http://www.wjgnet.com/1007-9327/14/1192.asp DOI: http://dx.doi.org/10.3748/wjg.14.1192

INTRODUCTION

Probiotics are defined as living microorganisms that have beneficial effects on human health[1]. Documented health effects in human intervention trials include amelioration of acute diarrhoea in children, reduction of the risk of antibiotic-associated gastrointestinal symptoms, relief of milk allergy/atopic dermatitis in infants, reduction in the risk of atopic diseases and respiratory infections, relief of irritable bowel syndrome and rheumatoid arthritis symptoms, suppression of *H pylori* and modulation of the immune response[2-4]. The ways in which probiotic bacteria affect the human immune system *in vivo* and *in vitro* are not fully understood. The immunomodulatory effects of probiotic bacteria could be due to the produced cytokines that further regulate innate and adaptive immune responses.

Different leukocyte types cooperate during the activation of innate and adaptive immune responses. In addition to direct cellular contacts the communication between immune cells depends on secreted mediators including cytokines. Bacteria-induced stress produces inflammatory cytokines promoting the activation of antimicrobial immune responses. TNF-α is a potent

inducer of many inflammatory molecules including other cytokines[5]. IL-12 produced by activated antigen-presenting cells (APC) enhances the development of Th1 type immune responses and stimulates NK and T cell IFN-γ production. All this further enhances cell-mediated Th1 type responses[6]. IL-10 downregulates the inflammatory response and induces an antibody-mediated immune response[7]. In previous studies it has been shown that individual probiotic bacteria can induce the production of TNF-α[8-10], IL-12[11-15], IFN-γ[10,11,13,15] and IL-10[9,15-18] in human peripheral blood mononuclear cells (PBMC) *in vitro*. At present only a limited amount of comparative data is available on the ability of different probiotic strains to induce cytokine production within the same experimental system[9,14-17]. Also, the effect of probiotic bacterial combinations on cytokine production *in vitro* is not well documented.

Understanding of the cytokine patterns that probiotics elicit may help in designing probiotics for specific preventative or therapeutic purposes. Information on the cytokine production induced by different probiotic bacteria and their combinations would enable development and optimal clinical use of these microbes as health promoting substances. In the present study human PBMCs consisting of monocytes, T and B lymphocytes and NK cells, are used for *in vitro* screening for cytokine production. Cytokine production in response to stimulation with different potentially probiotic strains from six bacterial genera *Streptococcus*, *Lactobacillus*, *Bifidobacterium*, *Lactococcus*, *Leuconostoc* and *Propionibacterium* alone or in combinations is analysed in order to identify potential enhancing or synergistic effects.

MATERIALS AND METHODS

Bacterial strains

Streptococcus pyogenes serotype T1M1 (IH32030) and *Escherichia coli* (DH5α) were obtained from the collection of National Public Health Institute (Helsinki, Finland). Eleven potentially probiotic strains; *Streptococcus thermophilus* THS, *Lactobacillus rhamnosus* GG (ATCC 53103), *Lactobacillus rhamnosus* Lc705 (DSM 7061), *Lactobacillus helveticus* 1129, *Lactobacillus helveticus* Lb 161, *Bifidobacterium longum* 1/10, *Bifidobacterium animalis* ssp. *lactis* Bb12, *Bifidobacterium breve* Bb99 (DSM 13692), *Lactococcus lactis* ssp. *cremoris* ARH74 (DSM 18891), *Leuconostoc mesenteroides* ssp. *cremoris* PIA2 (DSM 18892) and *Propionibacterium freudenreichii* ssp. *shermanii* JS (DSM 7067), were obtained from Valio Research Centre (Helsinki, Finland). Bacteria were stored in skimmed milk at -70℃ and passaged three times (except *Bifibobacterium* strains which were passaged four times) before they were used in stimulation experiments. *S. pyogenes* was grown at 37℃ under aerobic conditions in sheep blood agar (Oxoid, Ogdensburg, NY, USA) and tryptone-yeast broth supplemented with 2 g/L glucose[19], *E. coli* at 37℃ under aerobic conditions in Luria-medium (National Public Health Institute, Helsinki, Finland), *Lactobacillus rhamnosus* strains were grown at 37℃ under aerobic conditions in de Man, Rogosa and Sharpe (MRS) medium (Lab M, Topley House, Lancashire, UK), *Lactobacillus helveticus* strains were grown at 42℃ under aerobic conditions in MRS medium (Lab M, Topley House), *L. mesenteroides* was grown at 22℃ under aerobic conditions in MRS medium (Lab M, Topley House), *Bifidobacterium* strains at 37℃ under anaerobic conditions in MRS medium (Lab M, Topley House) with 5 g/L cysteine (Merck, Darmstadt, Germany), *S. thermophilus* at 37℃ under aerobic conditions in M17-agar (Lab M, Topley House) with 20 g/L lactose (J.T. Baker B.V., Deventer, Holland) and M17-broth (Difco, Beckton Dickinson, MD, USA) with 20 g/L lactose (J.T. Baker B.V.), *P. freudenreichii* at 30℃ under aerobic conditions in propioni-medium (Valio Ltd, Helsinki, Finland), *L. lactis* at 22℃ under aerobic conditions in calcium citrate agar (Valio Ltd) and M17-broth (Difco) with 20 g/L lactose (J.T. Baker B.V.). For stimulation experiments bacteria were grown to logarithmic growth phase, and the number of bacteria was determined by counting in a Petroff-Hauser counting chamber.

Cell culture

Human PBMC were purified by density gradient centrifugation over a Ficoll-Paque gradient (Amersham-Pharmacia Biotech, Uppsala, Sweden) from freshly collected, leukocyte-rich buffy coats obtained from healthy blood donors (Finnish Red Cross Blood Transfusion Service, Helsinki, Finland)[20]. After washing, the cells were resuspended in RPMI 1640 medium (Sigma, St. Louis, Mo., USA) containing 10% heat-inactivated fetal calf serum (Integro, Zaandam, Holland) and supplemented with 2 mmol/L L-glutamine (Sigma), 100 U/mL penicillin and 100 mg/mL streptomycin (Gibco BRL, Paisley, Scotland). In stimulation experiments purified leukocytes (2×10^9 cells/mL) were incubated with bacteria in a final volume of 1 mL in 24-well plates (Nunc, Roskilde, Denmark) in 5% CO_2 at 37℃.

Stimulation experiments

All experiments were performed with cells obtained from four different blood donors. During bacterial stimulations PBMCs were maintained in RPMI-1640 medium containing 100 mL/L FCS. Bacteria were added into the cell culture to obtain the required bacteria: host cell ratio. *S. pyogenes* was used as a positive control and RPMI 1640 containing 100 mL/L FCS as a negative control. Bacterial doses and incubation times are as indicated for each experiment. When PBMC were stimulated with a combination of two bacteria or more, equal numbers of different bacteria were used, and the sum bacterial dose of the combinations was 10:1 of a bacteria: host cell ratio. Cell culture supernatants were collected from individual donor cell cultures and stored at -20℃ before analysis. For RNA analysis cells from different donors were pooled.

Cytokine specific ELISA

Cell culture supernatants obtained from individual donors were analyzed for cytokine levels by using enzyme-linked immunosorbent assay (ELISA) essentially as previously described[8]. TNF-α and IL-10 were determined with antibody pairs and standards obtained from BD Pharmingen (San Diego, CA, USA). IFN-γ and IL-12p70 were determined with Eli-pair kits (BioSite, Täby, Sweden).

RNA isolation and Northern blotting

For isolation of total cellular RNA, stimulated cells from different donors were pooled, collected, washed with PBS, and lysed in guanidinium isothiocyanate[21], followed by a centrifugation through a CsCl cushion as previously described[22]. RNA was quantified photometrically and samples containing equal amounts (10 μg) of total cellular RNA were size-fractioned on 1% formaldehyde-agarose gels, transferred to Hybond-N nylon membranes (Amersham-Pharmacia-Biotech) and hybridized. To control equal loading, ethidium bromide staining was used. The cDNA probes were human TNF-α (ATCC), IL-12 p40 and p35[23], IFN-γ[24] and IL-10 (DNAX, Palo Alto, USA). Hybridizations were performed in a solution containing 500 g/L formamide, 5 × Denhardt's solution, 5 × SSPE and 5 g/L SDS at 42℃. After hybridization membranes were washed three times with 1 × saline sodium citrate/g per L SDS at 42℃ for 30 min and once at 65℃ for 30 min. Membranes were exposed to Kodak X-Omat AR films (Eastman Kodak, Rochester, NY, USA) at -70℃ with intensifying screens.

RESULTS

Bacterial dose-dependent induction of cytokine production in human PBMC

To determine the optimal bacterial dose that can induce cytokine production in human PBMC, cells were stimulated with different doses of live probiotic bacteria (2:1, 10:1 and 50:1 bacteria: cell ratio). Cell culture supernatants were collected at 24 h after stimulation and cytokine levels were determined by ELISA. As shown in Figure 1 all bacteria induced TNF-α production and *L. mesenteroides* was the most potent inducer. IL-12 and IFN-γ were best induced by streptococci and *L. mesenteroides*. Bifidobacteria induced IL-10 production in a dose-dependent manner, while other probiotic species were weak inducers of IL-10 production (Figure 1). Bacteria: host cell ratio of 10:1 was chosen for more detailed analyses.

Kinetics of cytokine production in probiotic bacteria-stimulated PBMC

Next the kinetics of cytokine production in PBMC using a 10:1 bacterium: host cell ratio was analysed by ELISA. All probiotic bacteria induced TNF-α production by 6 h after stimulation (Figure 2). With *S. thermophilus*, *Lactobacillus* strains, *B. longum* and *B. breve* maximal TNF-α production levels were reached at 12 h after stimulation (Figure 2). Other measured cytokines were secreted later, and all tested probiotic bacteria induced maximal IL-12, IFN-γ and IL-10 production at 24 h after stimulation (Figure 2). There were considerable differences in the ability of studied bacteria to induce cytokine production in PBMC. *S. thermophilus* and *L. mesenteroides* were the best inducers of proinflammatory cytokines TNF-α, IL-12 and IFN-γ. Anti-inflammatory IL-10 production was induced by all *Bifidobacterium* strains and *P. freudenreichii*. All strains of *Lactobacillus* were weak inducers of IL-10 and Th1 type cytokines.

Probiotic bacteria-induced cytokine mRNA expression

Those bacteria that were the best inducers of cytokines at the protein level (namely *S. thermophilus*, *B. breve*, *L. mesenteroides* and *P. freudenreichii*) were selected for more detailed analysis of cytokine mRNA expression as analyzed by Northern blotting. In addition to our positive control *S. pyogenes*, also *L. rhamnosus* GG that has been extensively studied *in vitro* by our group and in many clinical trials[2-3] was added for the analysis. Consistent with the kinetics of TNF-α protein production, mRNA expression was fast and detectable at 3 h after bacterial stimulation (Figure 3). With all studied bacteria, the kinetics of TNF-α mRNA expression was similar. IL-12 p40, IFN-γ and IL-10 genes were induced later than TNF-α and their expression was detectable starting at 9 h after stimulation (Figure 3). *S. thermophilus*, *B. breve* and *L. mesenteroides* induced IL-12 p40 mRNA expression as well as *S. pyogenes*, a well-known inducer of IL-12 p40 in PBMCs (Figure 3)[11]. *S. thermophilus* and *L. mesenteroides* induced IL-12 p40 mRNA expression at 9 h while *P. freudenreichii* induced the expression only weakly. IL-12 p35 mRNA expression remained under the detection limit (data not shown). The kinetics of IFN-γ mRNA expression differed from that of IL-12 p40. In probiotic bacteria-stimulated PBMCs IFN-γ mRNA expression was observed at 9 h after stimulation, and its expression increased until the 24 h time point. *L. mesenteroides*, *S. thermophilus* and *B. breve*, in this rank order were able to induce IFN-γ mRNA expression (Figure 3). IL-10 mRNA expression was highest at 9 h after bacterial stimulation persisting until the 24 h time point. Interestingly, *B. breve* and *P. freudenreichii* were able to induce IL-10 mRNA expression already at 3 h after stimulation (Figure 3). The kinetics of probiotic bacteria-induced cytokine mRNA expression was in line with the cytokine secretion (Figures 2 and 3).

Combination effect of probiotic bacteria on cytokine production in human PBMC

The probiotic bacteria and their combinations which have been used in clinical trials, namely *L. rhamnosus* strains, *P. freudenreichii* and *B. breve*[25-28], *L. rhamnosus* strains, *P. freudenreichii*, and *B. animalis*[29,30] and *L. rhamnosus* strains and *P. freudenreichii*[31], were used to study whether the effect of probiotic combinations differs from an individual strain. All probiotic combinations induced TNF-α production at the same or lower level as compared to those responses induced by probiotic bacteria alone (Figure 4). IL-12 and IFN-γ production induced by all probiotic bacterial combinations was weak (Figure 4). Also the IL-10 production by the probiotic combinations was lower than by individual *Bifidobacterium* strains (Figure 4) In general; the responses induced by the combinations of probiotic bacteria were an average of responses induced by each bacterium alone (Figure 4). In addition the representatives of the best cytokine inducers in this study, namely *S. thermophilus*, *Bifidobacterium* strains, *L. mesenteroides* and *P. freudenreichii* and our controls *S. pyogenes* and *L. rhamnosus* GG were analysed for their possible additive and synergistic effects on cytokine production in PBMCs. Two different probiotic bacteria were used simultaneously

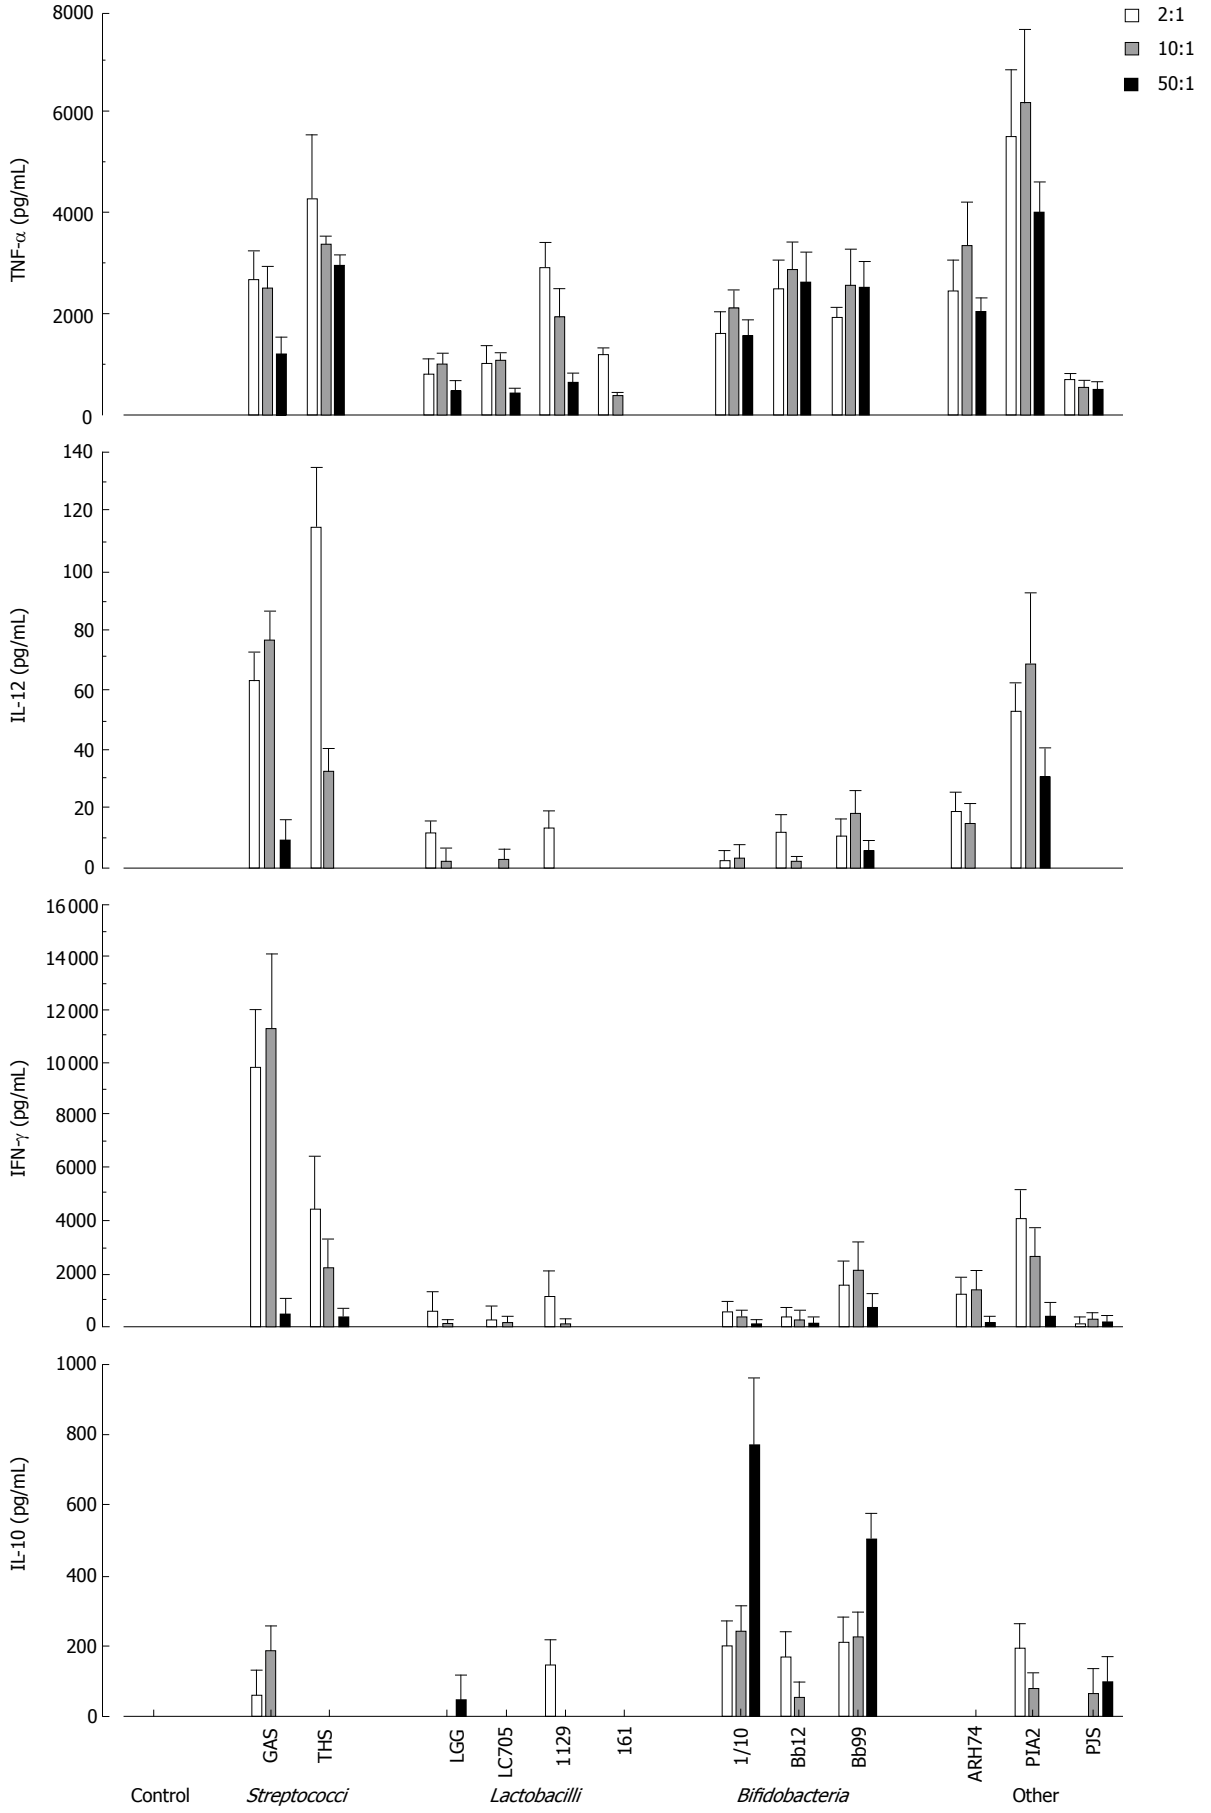

Figure 1 Dose-dependent cytokine production in human PBMC (2×10^6/mL) stimulated with *Streptococcus pyogenes* and 11 probiotic bacteria (2, 10 and 50 bacteria/cell) for 24 h, mean ± SEM, $n = 4$. A representative experiment out of two is shown. GAS: *Streptococcus pyogenes*; THS: *Streptococcus thermophilus* THS; LGG: *Lactobacillus rhamnosus* GG; LC705, *Lactobacillus rhamnosus* LC705; 1129: *Lactobacillus helveticus* 1129; 161: *Lactobacillus helveticus* Lb 161; 1/10: *Bifidobacterium longum* 1/10; Bb12: *Bifidobacterium animalis* ssp. lactis Bb12; Bb99, *Bifidobacterium breve* Bb99; ARH74: *Lactococcus lactis* ssp. *cremoris* ARH74; PIA2, *Leuconostoc mesenteroides* ssp. *cremoris* PIA2; PJS: *Propionibacterium freudenreichii* ssp. *shermanii* JS.

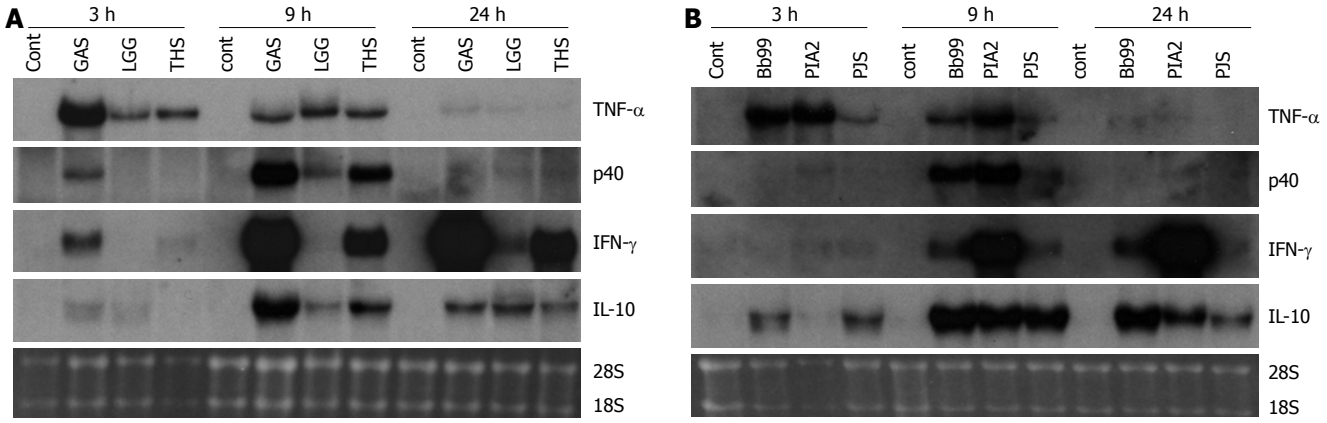

Figure 3 Kinetics of cytokine mRNA expression in probiotic bacteria-induced human PBMC (pooled samples from four donors), 10 bacteria/cell, 10 μg RNA/lane on 10 g/L agarose gel and Northern blot analysis with indicated cDNA probes was carried out. Ethidium bromide staining of gels was used to verify equal loading of RNA. See Figure 1 for abbreviations of bacteria. **A**: *S. pyogenes*, *L. rhamnosus* GG or *S. thermophilus* and **B**: *B. breve*, *L. mesenteroides*, *P. freudenreichii*.

to stimulate PBMCs for 24 h with a bacteria: host cell ratio of 10:1 and cell culture supernatants were collected for ELISA analysis. None of these probiotic bacterial combinations induced additive or synergistic cytokine production in PBMCs. On the contrary, the responses induced by the combinations were closer to an average of responses induced by the individual bacteria (Figure 5).

Effect of probiotic bacteria together with E. coli on cytokine production in human PBMC

All studied probiotic bacteria are gram-positive and thus likely to use Toll-like receptor (TLR)2-mediated signal transduction pathways in host cells while a gram-negative bacterium *E. coli* uses TLR4[32]. We did not observe any additive effects on cytokine production induced by the combinations of our gram-positive probiotic bacteria (Figure 5). Since this could be due to our probiotic bacteria engaging the same receptor, we wanted to analyse whether individual probiotic bacteria combined with *E. coli* would have an effect on cytokine production. Probiotic *S. thermophilus*, *Lactobacillus*, *Bifidobacterium*, *Lactococcus*, *Leuconostoc* or *Propionibacterium* strain and *E. coli* were combined and cell culture supernatants were collected at 24 h after bacterial stimulation followed by determination of cytokine production by ELISA. *E. coli* induced TNF-α, IFN-γ and IL-10 production, but not that of IL-12 (Figure 6). Stimulation of PBMCs with different combinations of probiotic bacteria together with *E. coli* lead to the induction of TNF-α production, but the response was an average of responses with individual bacteria (Figure 6). *E. coli*-induced IFN-γ production was reduced when it was combined with *Lactobacillus* strains, *P. freudenreichii* and *B. longum* (Figure 6). No enhancement of IL-10 production was seen in cells stimulated with the combinations of *E. coli* and probiotic bacteria.

DISCUSSION

In this study we have systematically analysed the ability of potentially probiotic bacterial strains from six different genera; *Streptococcus*, *Lactobacillus*, *Bifidobacterium*, *Lactococcus*, *Leuconostoc* and *Propionibacterium*, to induce cytokine expression *in vitro* in human PBMC. We show that eleven probiotic strains induce cytokine expression differently and the expression pattern seems to be dependent on the bacterial genera. In addition, stimulation of PBMC with any bacterial combinations, whether gram-positive or gram-negative, does not lead to enhanced cytokine production. Also we report for the first time that novel probiotic *S. thermophilus* and *Leuconostoc* strains are more potent inducers of Th1 type cytokines IL-12 and IFN-γ than the probiotic *Lactobacillus* strains presently in clinical use.

Human PBMC offer a model for studying the potential of different probiotic strains to induce cytokine production. *In vivo*, probiotics are not in direct contact with PBMC. Instead, probiotics interact with the epithelial cells of the gut, and probiotics may be taken up by macrophages, dendritic cells or M-cells at Peyer's patches and this can lead to the activation of lymphocytes such as monocytes residing in Peyer's patches[33]. Since PBMC are a source for monocytes among other immune cells, they provide an adequate model to study the immunological properties of probiotic bacteria. Therefore, *in vitro* bacteria-host cell studies aid in selecting novel probiotic strains for clinical trials.

Our data is consistent with previous studies showing that probiotic bacteria are able to induce TNF-α secretion in human PBMC[8,10,11,17]. However, there were considerable differences in the ability of different probiotic bacteria to induce IL-12 and IFN-γ. Interestingly, *Lactobacillus* and *Bifidobacterium* strains which have previously been shown to stimulate IL-12 and IFN-γ production in human PBMC[11-14,17], were in the present study found to be relatively poor inducers of these cytokines. Instead, we found that novel probiotic *S. thermophilus* and *Leuconostoc* strains were extremely good inducers of these Th1 type cytokines. One of the approaches in treating allergy could be tipping the Th1/Th2 balance from Th2 predominance to Th1 type response. In clinical trials *L. rhamnosus* GG[27,34,35] or a combination of two different *L. rhamnosus* strains, *Bifidobacterium* and *Propionibacterium*[28] have been used successfully to prevent atopic diseases. A strong Th1 type cytokine response is also an important factor

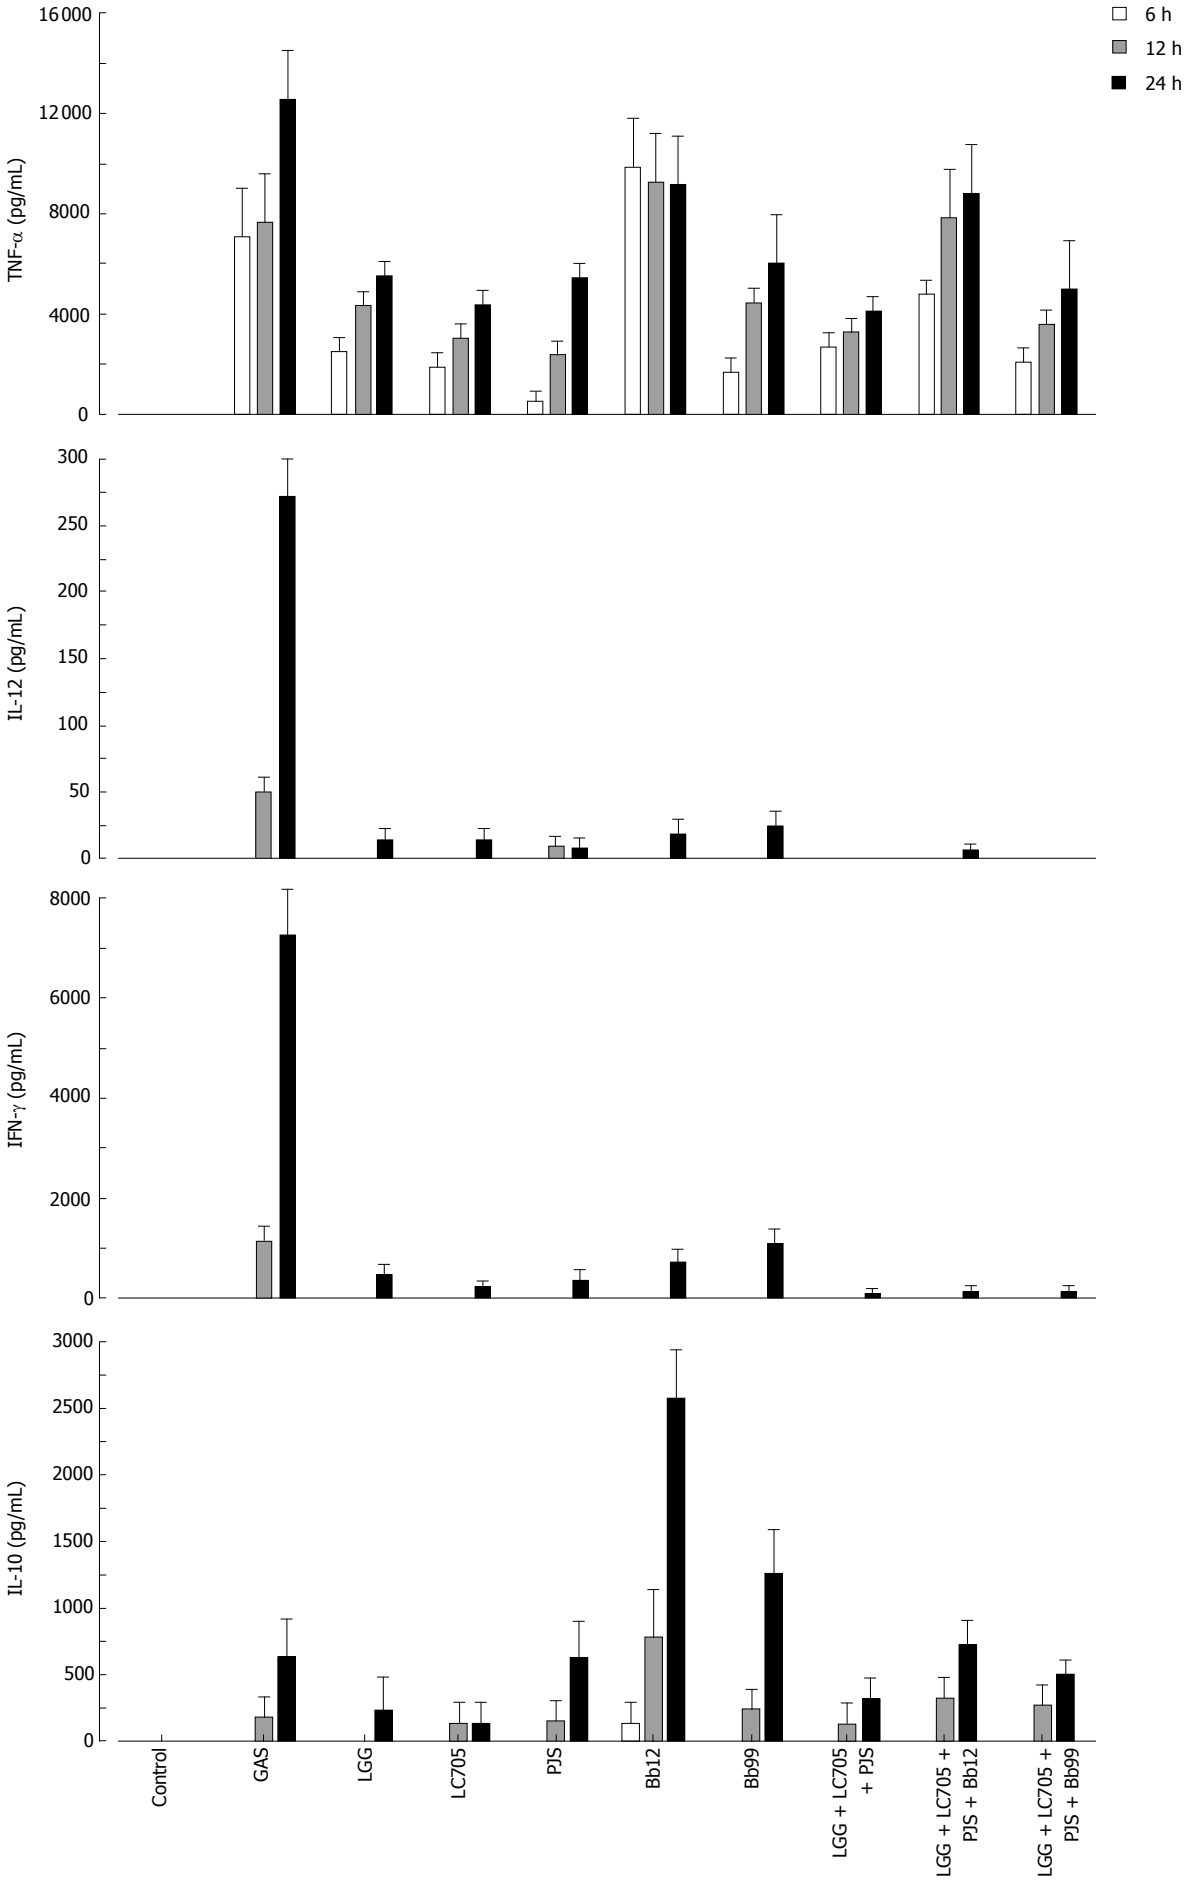

Figure 4 Kinetics of cytokine production in human PBMC stimulated with bacterial combinations. (10 single bacteria/cell, or three bacteria/cell in the combinations, *n* = 4). See Figure 1 for abbreviations of bacteria.

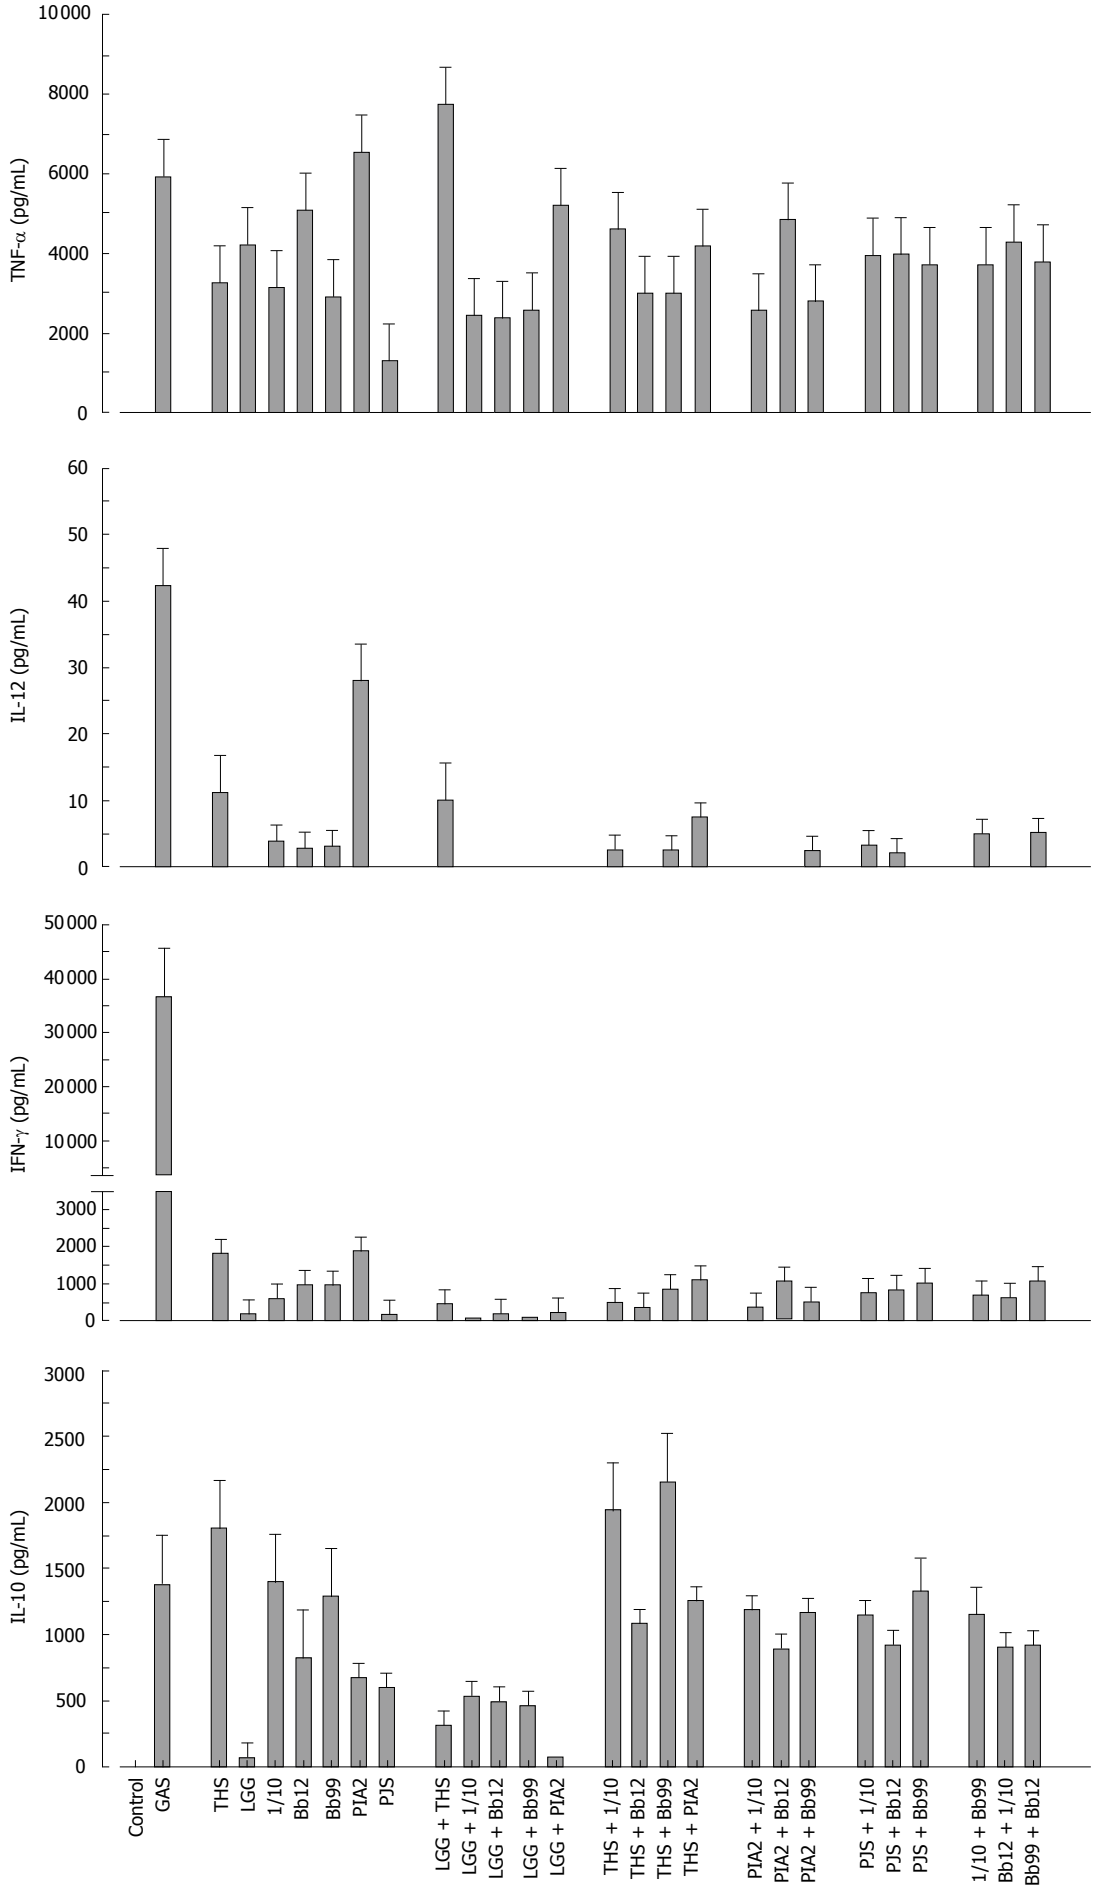

Figure 5 Cytokine production in human PBMC stimulated with probiotic bacterial combinations. (10 single bacteria/cell or their combinations at 5/cell for 24 h, mean ± SEM, *n* = 4). See Figure 1 for abbreviations of bacteria.

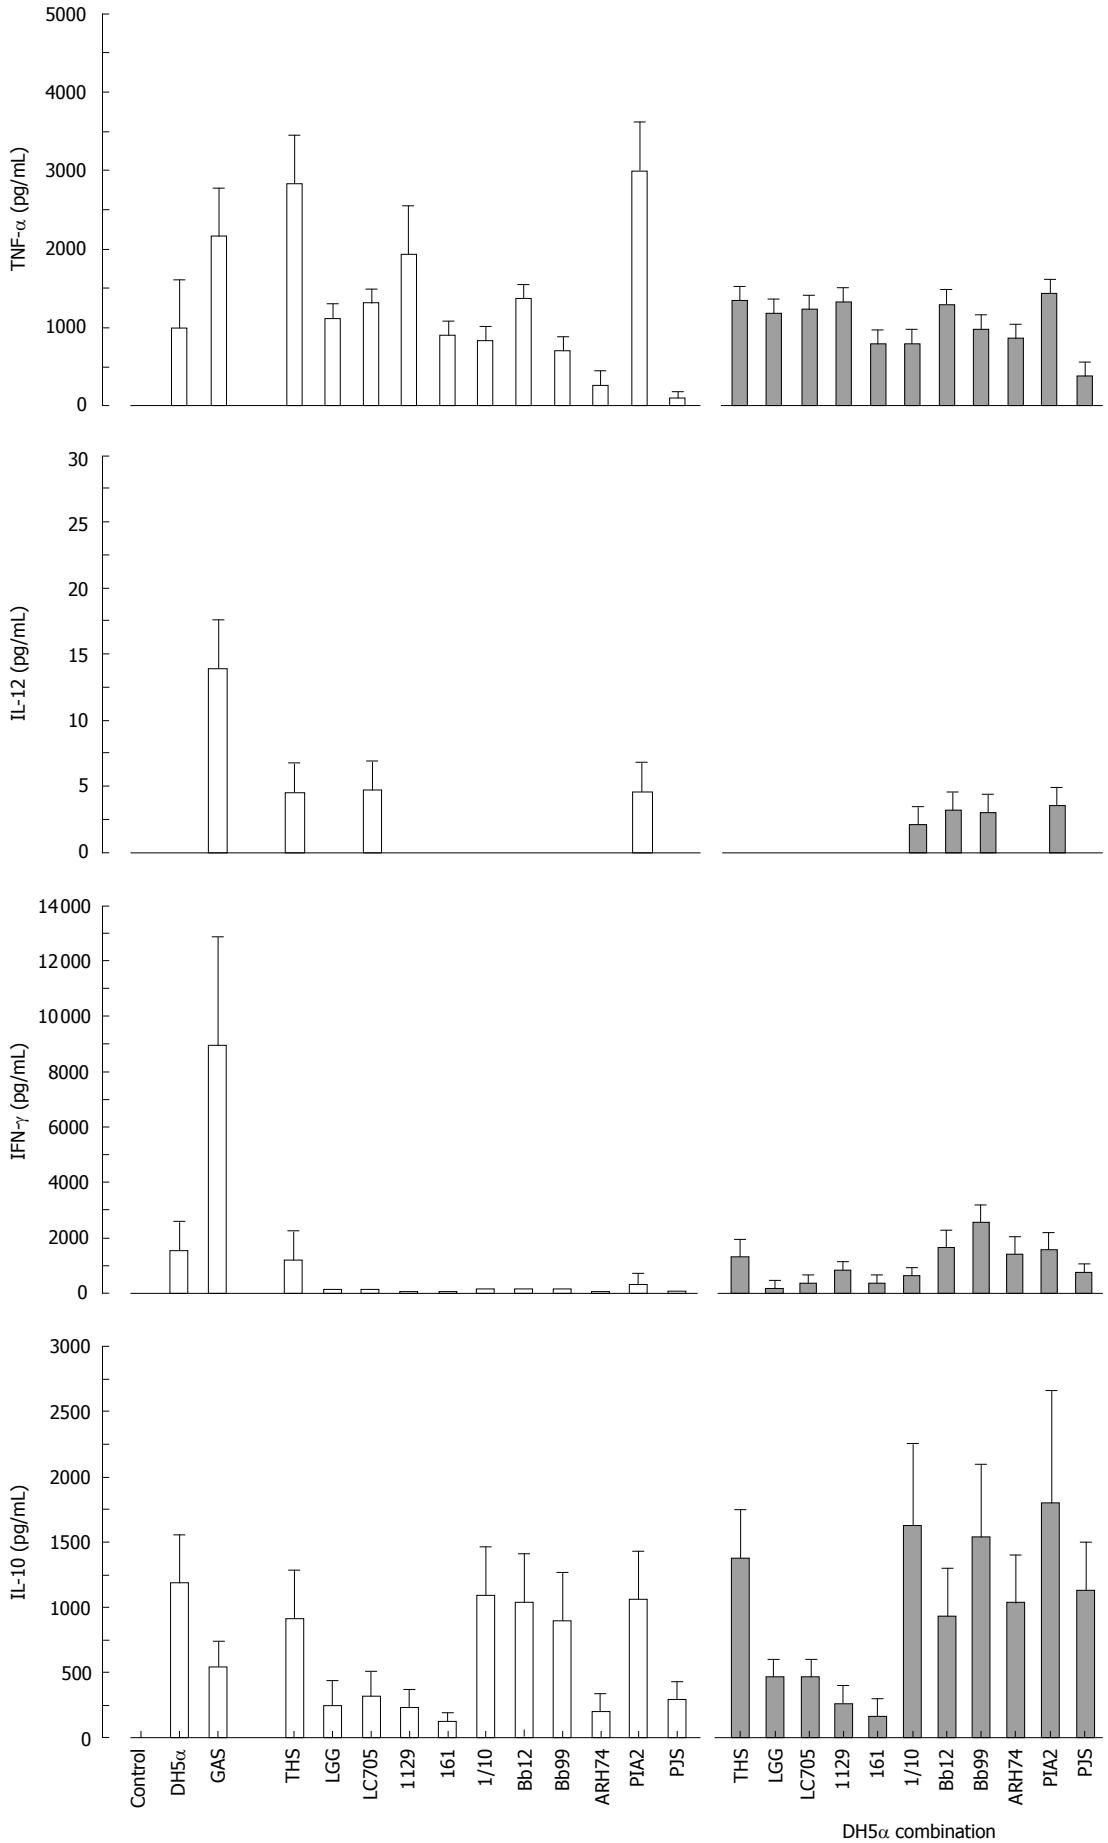

Figure 6 Stimulation of PBMC with a combination of gram-positive probiotic bacteria and a gram-negative bacteria for 24 h. (*E. coli* DH5α or different probiotic bacteria alone at 10 bacteria/cell, or *E. coli* combined with each probiotic bacterium at 5 bacteria/cells means ± SEM, $n = 4$). Abbreviations of bacteria see Figure 1.

in the fight against viral infections such as that caused by influenza A virus. Indeed, *Lactobacillus* strains have been shown to prevent and ameliorate the symptoms of respiratory infections[36-40]. It is of interest that for example *L. rhamnosus* GG has been effective in immune mediated diseases even though in the present study we observed that LGG induced very low cytokine production. This may be due to the fact that cytokine induction is only one of the proposed mechanisms of action for probiotics. Other as important factors may for example be the ability to adhere to the gut epithelium and the promotion of non-immunological gut defence barrier by normalizing permeability and disturbed gut microecology. Since *S. thermophilus* and *Leuconostoc* strains used in the present study were extremely potent inducers of IL-12 and IFN-γ, these strains may show better clinical efficiency in enhancing Th1 response in allergy and in the prevention of respiratory infections than the presently used probiotic *Lactobacillus* strains.

IL-10 was induced by *Bifidobacterium* and *Propionibacterium* strains, whereas IL-10 production induced by *Streptococcus*, *Lactobacillus*, *Lactococcus* and *Leuconostoc* strains remained at a low level. Our data is consistent with previous studies in which bifidobacteria were shown to induce higher IL-10 production as compared to lactobacilli[9,16]. The anti-inflammatory actions of IL-10 could be helpful in the treatment of inflammatory conditions or diseases. There is preliminary evidence that probiotics could be used in the treatment of inflammatory diseases like ulcerative colitis, pouchitis and rheumatoid arthritis[2,41]. The amelioration of these inflammatory diseases could be due to the induction of IL-10. Recent studies indicate a possible role of low-grade mucosal inflammation also in the pathogenesis of irritable bowel syndrome[42,43]. Preliminary evidence exists that a combination of probiotics, which included anti-inflammatory *Bifidobacterium* and *Propionibacterium* strains in addition to two different *L. rhamnosus* strains, relieves the symptoms of irritable bowel syndrome[25]. *Bifidobacterium* and *Propionibacterium* which in this study were able to induce anti-inflammatory IL-10 production could thus be used to treat different types of inflammatory diseases.

The use of probiotic bacterial combinations in clinical trials has shown great promise making it important to understand the immunological properties of a single strain versus different bacterial combinations. However, there is only limited amount of comparative data on the immunomodulatory properties of several different probiotic bacterial strains within the same experimental system. Published data is mainly limited to the analysis of the effects of *Lactobacillus* and *Bifidobacterium* genera[9,11-13,44]. In the present study combinations of different gram-positive probiotic bacteria did not induce any additive or synergistic cytokine production in PBMCs. This could be due to the fact that all gram-positive bacteria are likely to use the same or similar intracellular signal transduction mechanisms to induce cytokine gene expression. Interestingly, no additive or synergistic induction of cytokine production was seen even when gram-positive probiotic bacterial strains were combined with a gram-negative bacteria, *E. coli*. On the contrary, *E. coli*-induced IFN-γ production was reduced when different probiotics were present during the stimulation experiments. Gram-positive and gram-negative bacteria have been shown to induce quite different cytokine production patterns.

In human PBMCs gram-positive bacteria induce TNF-α[8-10], IL-12[11-15] and IFN-γ[10,11,13,15] while gram-negative bacteria have preferentially been suggested to induce IL-10 production[14]. Gram-positive bacteria or their structural components activate cells *via* TLR2, whereas gram-negative bacteria and their major structural component lipopolysaccharide activate host cell *via* TLR4[32]. It is, however, likely that other receptor systems apart from TLRs take part in host cell responses to different microbes[45]. Our data suggests that different bacteria whether they are gram-positive or gram-negative compete with each other during bacteria-host cell interactions. Therefore, combining gram-positive and gram-negative bacteria to activate the respective TLR2 and TLR4-dependent signalling pathways does not further enhance human PBMC responses. Initial analyses with TLR2 and TLR4 ligand combinations also fail to demonstrate any synergistic enhancement in cytokine production (data not shown).

Our results suggest that probiotic bacteria in a genera-specific way direct immune responses to either the Th1 type or the anti-inflammatory side. Besides providing possible explanations for phenomena observed in clinical trials, this finding might enable pinning down the probiotic bacterial (genera) specific factors contributing to the type of immune response elicited. Understanding of the immunological properties of probiotic bacteria is needed in the development of probiotic bacteria for targeted treatment of different disease conditions.

COMMENTS

Background and research frontiers

Probiotic bacteria have been used for the prevention and treatment of a diverse range of disorders. However, the ways in which probiotic bacteria elicit their health effects are not fully understood. One of the action mechanisms could be the ability to induce cytokines that further regulate innate and adaptive immune responses.

Innovations and breakthroughs

At present there is only a limited amount of comparative data available on the ability of different probiotic strains to induce cytokine responses within the same experimental system. Also, the effect of probiotic bacterial combinations on cytokine production *in vitro* is not well documented although bacterial combinations have been used in many clinical trials. In the present study we have analysed the cytokine production of eleven different potentially probiotic strains from six bacterial genera alone or in combinations in human peripheral blood mononuclear cells in order to indentify potential enhancing or synergistic effects.

Applications

We found that probiotic bacteria direct immune responses to either Th1 type or anti-inflammatory way in a bacterial genera-specific manner. The probiotic *S. thermophilus* and *Leuconostoc* strains are more potent inducers of Th1 type

cytokines IL-12 and IFN-γ than the probiotic *Lactobacillus* strains. Bacterial combinations did not result in enhanced cytokine production. More detailed information on the cytokine patterns that probiotic bacteria elicit may help in designing probiotics for specific preventative or therapeutic purposes.

Terminology

Probiotic bacteria are defined as living microorganisms that have beneficial effects on human health.

Peer review

This paper explores a mechanism of action of probiotics, namely the induction of cytokines by different strains of probiotics. The authors have designed a clear, logical study of different strains, dose-response, time of response and interactions of different probiotic strains. The paper includes an excellent exploration of probiotic mixtures.

Abstract

AIM: To study the molecular mechanism of laterally spreading tumor (LST), a cell line [Laterally Spreading Tumor-Rectum 1 (LST-R1)] was derived and the characteristics of this cell line were investigated.

METHODS: A new cell line (LST-R1) originated from laterally spreading tumor was established. Properties of the cell line were characterized using scanning and transmission electron microscopy, immunohistochemistry method, cytogenetic analysis and nude mice xenograft experiments. *In vitro* invasion assay, cDNA microarray and Western blotting were used to compare the difference between the LST-R1 and other colorectal cancer cell lines derived from prudent colon cancer.

RESULTS: Our study demonstrated that both epithelial special antigen (ESA) and cytokeratin-20 (CK20) were expressed in LST-R1. The cells presented microvilli and tight junction with large nuclei. The karyotypic analysis showed hyperdiploid features with structural chromosome aberrations. The *in vivo* tumorigenicity was also demonstrated in nude mice xenograft experiments. The invasion assay suggested this cell line has a higher invasive ability. cDNA microarray and Western blotting show the loss of the expression of E-cadherin in LST-R1 cells.

CONCLUSION: We established and characterized a colorectal cancer cell line, LST-R1 and LST-R1 has an obvious malignant tendency, which maybe partially attributed to the changes of the expression of some adhesion molecules, such as E-cadherin. It is also a versatile tool for exploring the original and progressive mechanisms of laterally spreading tumor and the early colon cancer genesis.

INTRODUCTION

Two routes have been described that can lead to colon carcinogenesis: one is the adenoma-carcinoma model, which is the main carcinogenetic pathway of prudent colorectal tumor and has been widely accepted in the west. However, an increasing number of superficial or flat colorectal tumors have been reported, particular in Japan[1,2]. The superficial tumors are considered to have a distinct clinicopathologic, genetic feature and behave a different carcinogenetic pathway, called de novo pathway[3-6]. Laterally spreading tumor (LST) is a unique subtype of superficial colorectal tumor, which was first reported by Kudo S in 1993[7,8] and many names such as granular cluster type, nodule-aggregating tumor, creeping tumor, superficial spreading (epithelial) tumor, flower-bed-like lesion had been used. In 1998, it was defined as tumors originated from the colorectal mucous membranes and mainly extends laterally rather than vertically with its diameter greater than 1 cm (Figure 1A)[9-12]. It has a tendency to affect the rectum, sigmoid colon, and caecum. In some studies, it has been reported that the carcinogenesis rate of LST is 8.64%-52.5%[13-15].

Moreover, our previous study has also shown that the incidence of LST is not low in China[16]. Flat appearance makes it difficult to detect it and previous study has shown that laterally spreading tumors have a higher malignant potential than conventional adenomas[2,17,18]. To study the distinctive biological behavior and the underlying biological mechanisms responsible for LST cancer progression will certainly help improving the detection rate of LST and eventually lead to the decreasing morbidity of colon cancer.

Invasion is an important step in the intricate process leading to the formation of cancer and has close relationship with the adhesion ability of the cancer cells. To investigate the higher malignant tendency of colorectal superficial tumor, we established a stable cell line derived from LST and assessed its invasion ability by *in vitro* invasion assay. Here we show that the invasion ability of LST is higher than SW480 and lovo cells, which is originated from prudent colon cancer. To elucidate the reason for this difference, we have developed a cDNA microarray, representing 18000 cDNA clusters to profile the gene expression patterns in Laterally Spreading Tumor-Rectum 1 (LST-R1), SW480, lovo cell lines and found that many genes associated with adhesion showed a different expression profile. Our data suggest that LST-R1cells have some distinct characteristics comparing with SW480 and lovo cells. Further investigations on the cells should enhance our understanding on the distinct biology of LST.

MATERIALS AND METHODS

Tumor origin

Laterally spreading tumor cells were derived from a rectal LST of 59-year-old Chinese woman. Magnifying endoscope showed a flat granular tumor with nodus (about 70 mm × 60 mm) in rectum, 3 cm far from anus. Examination of the biopsy specimen revealed that it has the characteristic morphology of a villous adenoma accompanied by moderate sever atypical hyperplasia (Figure 1B).

Tissue and cell culture

Tissue specimens were obtained by endoscopic partial mucosal resection (EPMR), and were transferred to a transport medium containing five folds penicillin, streptomycin (Invitrogen, Carlsbad, CA) and amphotercin B. The specimens were vibrated for about ten minutes to get rid of filth and washed five times with transport medium. They were then trimmed to remove fat and connective tissue, minced into pieces in a sterile culture dish, and subsequently plated in a 25 cm^2 flask. Cells were incubated in a 37℃ incubator with 5% CO_2. RPMI1640 medium (Invitrogen, Carlsbad, CA) containing 10% fetal bovine serum (FBS, Invitrogen, Carlsbad, CA)was added to the cells four hours later and media was changed every 2-3 d. Clonal growth was observed after 27 d of culture, and colonies were identified and subcultured. After 2 passages, the cells grew rapidly and were polymorphic with a few fibroblasts. To purify the cells, they were inoculated in 96-well plates and were cultured separately to get rid of fibroblasts. Finally, the polymorphic cells (more than 90%) were designated as LST-R1.

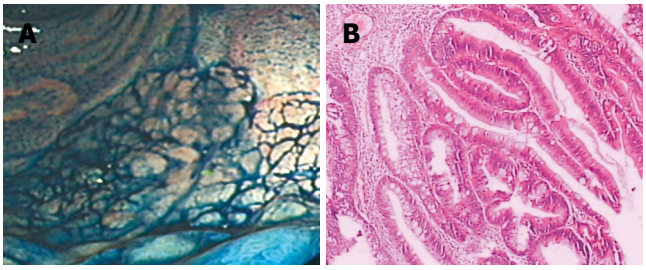

Figure 1 Endoscope and the histopathology of LST. **A**: LST under endoscope which grows laterally in the rectum, 3 cm far from the anus and has a diameter of 60 mm × 70 mm; **B**: The histopathology of the tissue: a villous adenoma accompanied by moderate severe atypical hyperplasia.

HCT116, lovo, SW480 and colo205 colon tumor cell lines were commercially obtained from the American Type Culture Collection and maintained in RPMI 1640 medium supplemented with 100 U/mL penicillin,100 μg/mL streptomycin, 10% fetal bovine serum in 75 cm^2 tissue culture flasks at 37℃ in a 5% CO_2 environment.

Confirmation of epithelial origin

Cells were grown on chamber slides and stained for CK20 and ESA expression with a specific antibody (Beijing ZhongShan Biology technology Ltd, Beijing, China).

Scanning and transmission electron microscopy

LST cells grown on slides were trypsinized and centrifuged. After fixed in 2.5% glutaraldehyde and postfixed in 1% osmium, they were dehydrated with acetone. The sample was divided into two parts: one half was added with acetas, dried on critical point of CO_2 and observed under scanning electron microscope, another half was embedded in paraffin and cut into thin pieces with a thickness of about 700 mm, stained with uranyl acetate and citrate, and observed under transmission electron microscope.

Metaphase chromosome preparation and spectral karyotyping (SKY)

Metaphase cells were obtained by treatment of the cultured cells with Colcemid (Gibco, Grand Island, NY, USA) at a final concentration of 0.03 μg/mL for 3 h. The harvested cells were treated with 0.8% sodium citrate for 15 min at 37℃ and fixed in 3:1 methanol/acetic acid. Metaphase chromosome spreading was performed as previously described[19]. The slide with metaphase cells was aged at room temperature (R.T.) for 5-7 s prior to SKY. The slide was treated with DNase-free RNase solution (0.1 g/L) at 37℃ for 1 h, and briefly rinsed in distilled water. After washing in 2 × SSC for 10 min at R.T, the slide was treated with proteinase K (0.5 μg/mL) solution for 10 min at 37℃ and washed in 2 × SSC at R.T. for 10 min. The slide was then fixed in 1% paraformaldehyde and washed in 2 × SSC at R.T. for 10 min each, followed by dehydration in 70%, 85%, and 95% ethanol at R.T. for 2 min. The slide was placed in 70% formamide/2 × SSC at 70℃ for 4 min and dehydrated in 70%, 85%, and 95% ethanol for 2 min

each. Other protocols including SKY probe (Applied Spectral Imaging, Migdal Ha'Emek, Israel) denaturation, hybridization and detection were done according to the recommendations of SKY probe manufacturer. SKY image capturing and karyotyping were performed using the SkyVision Imaging System equipped with a Zeiss Axioplan 2 fluorescence microscope. Recommendations were followed in karyotyping descriptions[20].

In vitro and in vivo growth properties of the cells

To determine the population doubling time and mitotic index of LST-R1 cells, the cells were suspended at a concentration of 1×10^5 per mL and 100 μL suspension was cultured in each well of 96 well plates. The cell growth was monitored after 12 h, 24 h, 36 h and 48 h by 3-(4, 5-dimethylthiazol- 2-yl)-2, 5-diphenyltetrazolium bromide (MTT, the final concentration = 0.5 g/L) assay. The value indicated the mean of three independent experiments.

In vivo tumorigenicity studies were performed using 5-wk-old athymic nude mice obtained from the Animal Center of the First Military Medical University (Guangzhou, China). LST-R1 cells at passage 51 were trypsinized, washed twice with serum-free RPIM1640 medium, and resuspended in serum-free RPMI-1640 (1×10^6 per mL). A final volume of 0.2 mL was injected per site on the back of 8 athymic nude mice. Tumor growth was measured weekly using calipers. The tumor area was calculated according to the following formula: tumor area = $\pi \times$ (width/2 × length/2). When the tumors grew to a certain extent (about 6 mm × 4 mm), tissue was removed and fixed in neutral buffered formalin for histological examination. Some cells from the xenografts were re-established *in vitro* to compare their morphology with that of the original cell line.

In vitro invasion assay

The invasion assay was performed by using 24-well BD BioCoat™ Matrigel™ Invasion Chamber with 8-μm polycarbonated filters (Becton Dickinson, Bedford, MA), as described by Albini *et al*[21]. 1×10^4 cells were seeded on Matrigel invasion chamber plates and cultured in routine medium. Cells were incubated for 22 h at 37℃ in a humidified incubator with 5% CO_2. Nonmigratory cells on the upper surface of the filter were removed by wiping with a cotton swab. Invasive cells that penetrated through pores and migrated to the underside of the membrane were stained with Giemsa solution after fixation with 4% formaldehyde in PBS. The cell number was counted under microscopic vision.

Screening of differentially expressed genes

Total RNA was extracted using standard Trizol RNA isolation protocol (Life Technologies, Inc., Grand Island, NY). The poly (A) mRNA was isolated from the total RNA using a poly (dT) resin (Qiagen, Hilden, Germany). Nylon membrane-based cDNA microarrays were prepared by using Spotter (BioRobotics, Cambridge, U.K.) containing clones from the present work and other tissue resources and the internal controls. The procedures for probe preparation, hybridization, washing, scanning, and signal intensity normalization of the spots were performed also using a previously described method[22]. The differential expression was considered as significant between LST and SW480, lovo cell lines when the ratio of signals between the same spots on different membranes was greater than 2.

Western blotting analysis

Western blotting analysis was assessed according to the protocol described before[23]. In brief, cells were washed with ice-cold PBS twice and lysed with ice-cold lysis buffer. Protein samples (15 μg) were separated by SDS/PAGE (12% acrylamide gel) using a Bio-Rad Mini-Protean Ⅲ system (45 mA for about 2 h). Proteins were transferred to PVDF membranes and the membranes were blocked for 1 h at room temperature with TBST. Blots were then incubated at room temperature with primary antibodies (1:500 dilution) and then primary antibodies were removed and the blots were extensively washed with TBS/Tween 20 min for three times. Blots were then incubated for 1 h at room temperature with the secondary antibodies (1:2000 dilution). Then blots were extensively washed as above for 1 h and developed using the Enhanced Chemiluminescence detection system and quantified using the GeneTools systems.

RESULTS

Origin and morphology of LST-R1

When established *in vitro*, LST-R1 cells grew as attached cells with spindle or polygonal morphology. 90% of the individual cells have 1 or 2 heterogenous nuclei with 1 or 2 prominent nucleoli (Figure 2A). To confirm the epithelial origin of this cell line, expression of ESA and CK20 were determined by immunocytochemistry. The positive expression of ESA and CK20 staining revealed that the cells are of epithelial origin (Figure 2 B and C). Under the scanning electron microscope, microvilli and tight junction were observed. There are fewer organelles (such as Golgi apparatus and endoplasmic reticulum) and more secretory granules were observed (Figure 2 D and E).

Cytogenetic analysis

Karyotypic analysis was performed on the LST-R1 cell line at passage 111 by spectral karyotypic technique. The composite karyotypes were summarized in Table 1. Basically, two subclones were identified. Although there were some karyotypic differences between the two subclones, the majority of chromosome aberrations existed in all 30 metaphases analyzed, indicating that the cells were derived from a single progenitor aberrant cell. Chromosome numbers differed in a narrow range (from 64 to 66). A representative karyotype of LST-R1 cells with 66 chromosomes is shown in Figure 2 F.

Origin and morphology of LST-R1

Generally, the cells were triploid with complex structural chromosome aberrations and a number of numerical abnormalities.

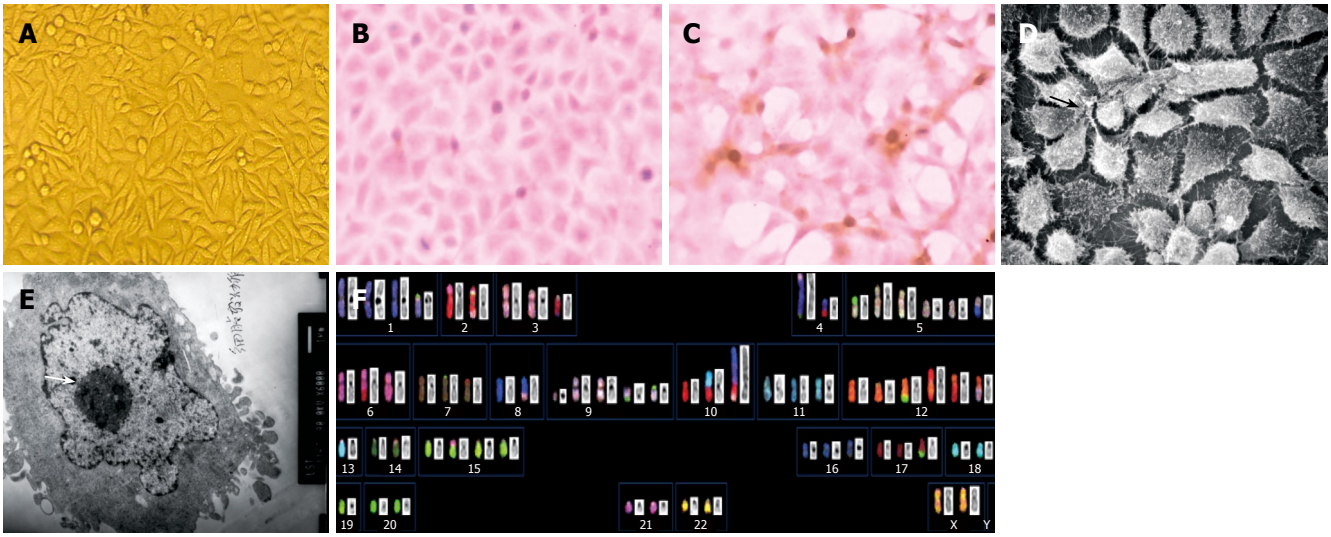

Figure 2 Origin and morphology of LST-R1. **A**: The morphology of cultured cells under microscope at passage 5. The cells are polymorphic and the percentage of epithelial cells is more than 90% (× 10); **B**, **C**: Immunostaining for the epithelial markers ESA and CK20 in LST-R1 cells at passage 5. Cells were grown on chamber slides and stained for ESA (**B**) and CK20 (**C**) expression with a specific antibody; **D**: Under scanning electron microscope (× 1000), dense microvilli and tight junction were observed. Arrow indicates tight junction; **E**: cell observed under transmission electron microscope (× 6000). Arrow indicates nucleus; **F**: Representative karyotype of LST-R1 cell line. Aberrations were observed in the majority of LST-R1 cells. The karyotypic description is listed in Table 1.

The growth properties of LST-R1 in vitro and in vivo

LST-R1 cells were passaged for more than 110 times. In medium containing 10% FBS, the cells grew as monolayers with varying degrees of attachment. They grew rapidly with large nuclei. The population doubling time was 36 h, and the mitotic index arrived at the peak value at the fourth day in a 25-cm^2 flask (Figure 3A).

The *in vivo* tumorigenicity of LST-R1 cells was studied using athymic nude mice xenograft. Tumor formation was observed 15 s after inoculation, and tumors grew in all of the 8 mice. Tumor area progressively increased and reached an average of 3 cm^2 in size 28 s after inoculation. The histopathology of the xenograft tumor showed that it was a poorly differentiated adenocarcinoma (Figure 3B). Cells cultured from the xenograft tumor (using the same protocol as previously described) had the same properties as the original cell line.

The invasion ability of LST-R1 in vitro

In vitro invasion assay revealed that invasive activity increased significantly in LST-R1 comparing with the other two cell lines. Twenty-four hours later, the numbers of LST-R1 cells invading the membrane were significantly higher (179.3 ± 40 cells/well) than those of lovo (139.3 ±

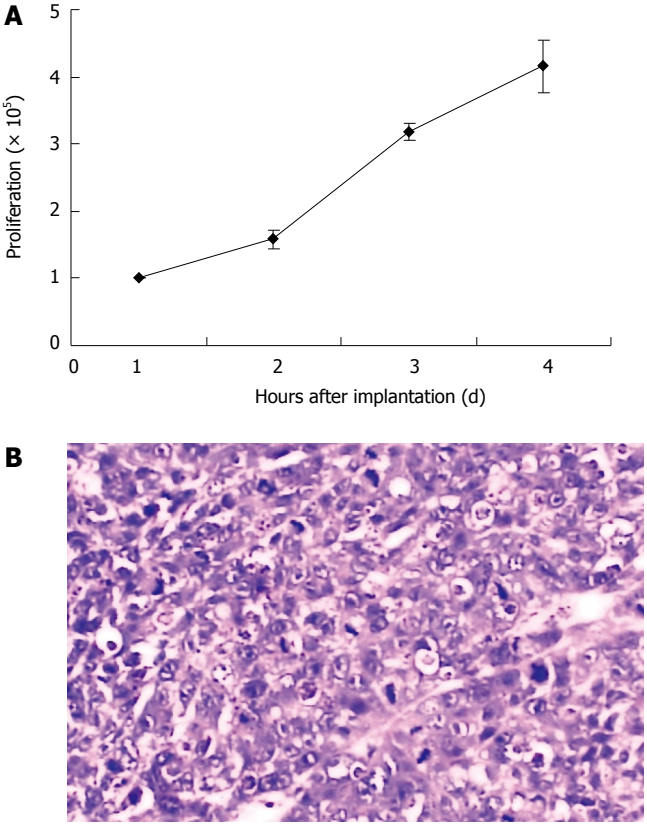

Figure 3 The growth properties of LST-R1 *in vitro* and *in vivo*. **A**: The growth curve of LSR-R1 cell line. Data points are the means of three independent experiments; **B**: Tumorigenicity *in vivo*. The nude mice were sacrificed when the tumor reached 60 mm × 40 mm in size. The histopathology shows a poor differentiated adenocarcinoma.

Table 2 Genes differentially expressed in LST cells when compared with SW480 cells are functionally categorized based on the Gene Ontology terms available from the online batch extract interface for SOURCE. (http://smd.stanford.edu/cgi-bin/source/sourceBatchSearch). This table shows the genes categorized in cell adhesion

Accession	Gene name	Gene symbol	Fold change
Z24725	Mitogen inducible 2	MIG2	3.21
Z22555	CD36 antigen (collagen type I receptor, thrombospondin receptor)-like 1	CD36L1	3.10

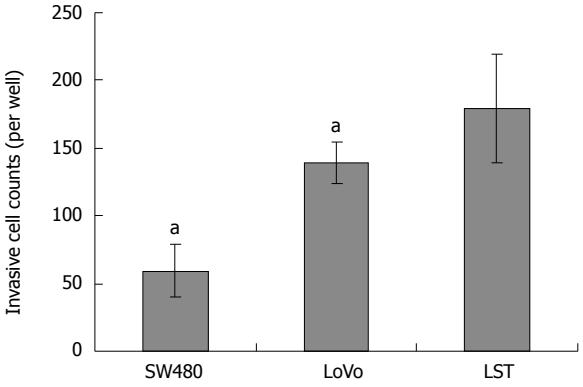

Figure 4 The invasion abilities of various cancer cell lines. The Matrigel invasion chamber was used to measure the LST cells invading through a matrix of reconstituted basement membrane compared to the other two cell lines SW480 and lovo. $^{a}P < 0.05$, significant difference between LST and other two cell lines, paired *t*-test.

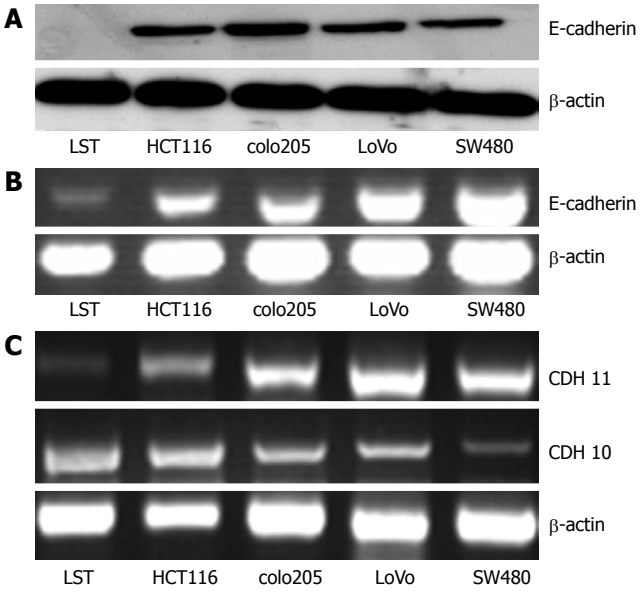

Figure 5 Detection of E-cadherin, CDH10 and CDH11 expression in various colorectal cancer cell lines by Western blotting analysis (**A**) and RT-PCR (**B** and **C**). The experiment was repeated for three times with similar result as shown here.

15.1 cells/well) and SW480 (59.3 ± 19.1 cells/well) cells (Figure 4).

cDNA microarray analysis

As shown in Tables 2 and 3, the cDNA microarray was applied to analyse the expression patterns of the three cell lines: SW480, lovo, LST. Expression of the cell adhesion molecule E-cadherin in different colon cancer cell lines was confirmed by Western blotting. As shown in Figure 5, the expression of E-cadherin in LST cell line was at a very low level comparing with the other four colon cancer cell lines.

DISCUSSION

Recent molecular studies have demonstrated a different histogenesis of flat and depressed tumor in comparison with polypoid adenomas. Flat and depressed tumor has a more malignant tendency and LST is an important subtype of it[24-27]. In the study of disease genesis, cell line and animal model are useful tools to understanding the biological characteristics. However, until now, there is no report on LST cell line and/or animal model. So there is an absolute need to establish *in vitro* model systems to study the distinctive behavior of LST and the potential mechanism of colon carcinogenesis.

In the present study, we report the characterization of LST-R1 from a fresh laterally spreading tumor specimen. Although the tissue, which the cell line derived from, is villous adenoma accompanied by severe atypical hyperplasia, our data showed it has an obvious malignant tendency. First, LST-R1 cells were passaged more than 110 times without the use of any immortalizing agent;

Table 3 Genes differentially expressed in LST cells when compared with LoVo cells are functionally categorized based on the Gene Ontology terms available from the online batch extract interface for SOURCE. (http://smd.stanford.edu/cgi-bin/source/sourceBatchSearch). This table shows the genes categorized in cell adhesion

Accession	Gene name	Gene symbol	Fold change

second, the karyotypic analysis showed the cells were triploid with structural chromosome aberrations and a number of numerical abnormalities; third, the tissue from the inoculated nude mice are poorly differentiated adenocarcinoma, which suggests the cell line is originated from malignant clones. The most possible reason for this difference could be that the pathologic type of the tissue (60 mm × 70 mm) was large and uneven, and only a little part of it has been taken for histopathological study while most of the tissue was taken for cell culture. Analysis from only a small number of serial sections might lead to the missed diagnosis of the cancer. Normal cells proliferate at a slower rate than the malignant cells, therefore only the malignant cells left after several passages.

The epithelial and colorectal origin of these cells were confirmed by positive ESA and CK20 staining, miniville and tight junction observed under the electron microscope, as well as morphological observation. After 15 d of inoculation in nude mice, the tumors occurred and grew vertically rather than laterally spreading. The reason

we proposed is associated with the different circumstances between hypodermic and colon lumen mucosa. Although the lack of lateral growth in nude mice limits its utility as an *in vivo* model, it may prove otherwise as an *in vitro* model system to investigate biological behaviors and malignancy-associated phenotypes of the disease at its onset.

The superficial colon tumor is more likely to invade the mucous membranes and developed cancer[2]. So we compared invasion ability between LST-R1 and other two colorectal cancer cell lines derived from prudent colon cancer with the Matrigel invasion chamber. SW480 is human colorectal adenocarcinoma (Duke' type B). Lovo is human colorectal adenocarcinoma derived from a fragment of a metastatic tumor nodule in the left supraclavicular region (Duke' type C, grade Ⅳ). Our results demonstrated that the number of LST cells invading through the membrane was more than the other two cell lines and showed that the LST-R1 cells had a high ability of invasion, which was in consistent with the high malignancy of LST.

It is well known that the low expression of the adhesion function contributes to the increasing invasive ability of colon cancer. To explore the reason of higher invasion of LST-R1 cell line, we compared the gene expression profile of LST-R1 cells with SW480 and lovo cells by cDNA microarray. According to cDNA microarray data, a number of genes associated with cell adhesion changed, such as E-cadherin. E-cadherin is a 120-kDa transmembrane glycoprotein that belongs to a large superfamily of calcium-dependent cadherin adhesion molecules[27] and plays an important role in embryogenesis and in mature epithelia. Abnormalities of E-cadherin expression have been described in colorectal carcinoma[28] and have been correlated with increased invasiveness, metastatic potential and poor patient prognosis in this tumor type[29]. Recent research showed that E-cadherin expression was significantly lower in the de novo group tissue than that in the prudent group[30,31]. In the present study, by Western blotting analysis, we also confirmed that LST-R1 cells have a prominent lower expression of E-cadherin than that in several other cell lines. Our data therefore suggest that the high invasive ability of LST-R1 cell line has a close relationship with the low expression of adhesion molecule. Further investigations should be taken to study the role of the adhesion molecules (such as E-cadherin) in determining the malignancy of LST.

In conclusion, we established a stable cell line (LST-R1) derived from an early colon cancer-LST and this cell line has an obvious malignant tendency. LST-R1 is also characterized with high invasive ability, and this property may result from the loss of adhesion molecules such as E-cadherin.

COMMENTS

Background

Invasion is an important characteristic of malignant tumor and the mechanism of invasion is not very clear. Many genes had been verified to be involved in invasion of cancer including E-cadherin. Cell lines are useful tools for molecular level study and many cell lines have been established for various studies.

Research frontiers

Laterally spreading tumor (LST) is a unique subtype of superficial colorectal tumor and in some studies, it has been reported that it had a higher carcinogenesis rate. Invasion is a pivotal step of colorectal cancer carcinogenesis progression and E-cadherin is an important invasion-associated gene. We established a colorectal cell line with high invasion ability and a low expression of E-cadherin.

Innovations and breakthroughs

In this study, we establish a cell line derived from a laterally spreading tumor tissue. Our data suggested that this cell line is a colorectal cell line and has high invasion ability compared with SW480 and Lovo cell lines. There is a loss of E-cadherin expression in Laterally Spreading Tumor-Rectum 1 (LST-R1) cells. This cell line will be a useful tool for the study of colorectal cancer invasion mechanism.

Applications

This cell line is a useful tool for colorectal cancer invasion mechanism study. We will investigate the role of E-cadherin in LST-R1 cells and the relationship between low expression of E-cadherin and high invasion ability.

Terminology

SKY in this study means metaphase chromosome preparation and spectral karyotyping.

Peer review

This article is interesting. In this article, the authors characterized a laterally spreading tumor cell line and compare it to several typical colorectal cancer cell lines. Since these tumors progress in a different fashion than typical adenoma to carcinoma colorectal tumors that protrude into the gut lumen, the isolation and comparison of expression of growth patterns of these cells is important.

Abstract

AIM: To assess the ability of ^{18}F-fluorodeoxyglucose positron emission tomography/computer tomography (^{18}F-FDG PET/CT) to differentiate between benign and malignant portal vein thrombosis in hepatocellular carcinoma (HCC) patients.

METHODS: Five consecutive patients who had HBV cirrhosis, biopsy-proven HCC, and thrombosis of the main portal vein and/or left/right portal vein on ultrasound (US), computer tomography (CT) or magnetic resonance imaging (MRI) were studied with ^{18}F-FDG PET/CT. The presence or absence of a highly metabolic thrombus on ^{18}F-FDG PET/CT was considered diagnostic for malignant or benign portal vein thrombosis, respectively. All patients were followed-up monthly with US, CT or MRI. Shrinkage of the thrombus or recanalization of the vessels on US, CT or MRI during follow-up was considered to be definitive evidence of the benign nature of the thrombosis, whereas enlargement of the thrombus, disruption of the vessel wall, and parenchymal infiltration over follow-up were considered to be consistent with malignancy. ^{18}F-FDG PET/CT, and US, CT or MRI results were compared.

RESULTS: Follow-up (1 to 10 mo) showed signs of malignant thrombosis in 4 of the 5 patients. US, CT or MRI produced a true-positive result for malignancy in 4 of the patients, and a false-positive result in 1. ^{18}F-FDG PET/CT showed a highly metabolic thrombus in 4 of the 5 patients. ^{18}F-FDG PET/CT achieved a true-positive result in all 4 of these patients, and a true-negative result in the other patient. No false-positive result was observed using ^{18}F-FDG PET/CT.

CONCLUSION: ^{18}F-FDG PET/CT may be helpful in discriminating between benign and malignant portal vein thrombi. Patients may benefit from ^{18}F-FDG PET/CT when portal vein thrombi can not be diagnosed exactly by US, CT or MRI.

Highly metabolic thrombus of the portal vein: ^{18}F fluorodeoxyglucose positron emission tomography/computer tomography demonstration and clinical significance in hepatocellular carcinoma. *World J Gastroenterol* 2008; 14(8): 1212-1217 Available from: URL: http://www.wjgnet.com/1007-9327/14/1212.asp DOI: http://dx.doi.org/10.3748/wjg.14.1212

INTRODUCTION

Hepatocellular carcinoma (HCC) carries a high risk of invasion of the portal vein. The detection and etiologic characterization of these thrombi are essential for treatment planning, particularly in patients with hepatic tumors, because malignant thrombosis is a negative factor in terms of prognosis[1,2]. Macroscopic tumor thrombi in the portal vein appear to occur during the terminal stage of HCC. The management of HCC with portal vein tumor thrombosis is complicated and controversial[3,4]. However, benign portal vein thrombi can usually be successfully

managed with early identification[5]. Portal vein thrombosis (PVT) can be diagnosed noninvasively by using either real-time or duplex Doppler sonography, contrast-enhanced sonography, computer tomography (CT) or magnetic resonance imaging (MRI). Typical appearances of venous thrombosis include an intraluminal filling defect, peripheral ring-like enhancement and collateral venous channels[6,7]. Micro-invasive fine-needle aspiration (FNA) of a portal vein thrombus under ultrasound guidance also is an effective, well-tolerated method for the diagnosis of HCC patients with PVT[8,9].

This pattern of ^{18}F-FDG PET/CT has been reported in cases with different kinds of malignant tumor[10], while portal tumor growth and portal vein thrombosis identified by PET/CT in HCC patients have rarely been reported to date. We found highly metabolic thrombi of the portal vein on ^{18}F-FDG PET/CT scans in four patients with HCC. ^{18}F-FDG -avid lesions may represent malignant portal vein thrombosis. The importance of this finding for the diagnosis of and prognosis in HCC and the role of ^{18}F-FDG PET/CT in the diagnosis of PVT are discussed.

MATERIALS AND METHODS

Patients

Between January 2007 and October 2007, five HCC patients with suspected portal vein tumor thrombus (PVTT) were assigned to PET/CT evaluation. Five consecutive patients who had HBV cirrhosis, biopsy-proven HCC, and thrombosis of the main portal vein and/or left/right portal vein on US, CT or MRI, were also studied by ^{18}F-FDG PET/CT. PET/CT. US, CT or MRI results were compared with those at follow-up.

FDG PET/CT technique

The patients were asked to fast for at least 4 h before undergoing PET/CT. The blood glucose levels of these patients should have been within the normal range (0.7-1.2 g/L) prior to intravenous injection of ^{18}F-FDG. The patients received an intravenous injection of 370-666 MBq (10-18 mCi) of ^{18}F-FDG. Data acquisitions by an integrated PET/CT system (Discovery STE; GE Medical Systems, Milwaukee, WI, USA) were performed within 60 min after the injection. Data acquisition was performed as follows: CT scanning was performed first, from the head to the pelvic floor, with 110 kV, 110 mA, a tube rotation time of 0.5 s and a 3.3 mm section thickness, which was matched to the PET section thickness. Immediately after CT scanning, a PET emission scan that covered an identical transverse field of view was obtained. Acquisition time was 3 min per table position. PET image data sets were reconstructed iteratively by applying the CT data for attenuation correction, and co-registered images were displayed on a workstation.

Definitive diagnoses of thrombosis and thrombus malignancy

On integrated PET/CT images, thrombi were considered malignant if the maximum standardized uptake value (SUV) was greater than those of normal liver structures with a discrete margin and/or the ^{18}F-FDG uptake was greater than that of the lumen of the descending aorta in the same axial slice. Thrombi were considered benign if the maximum SUV was lower than those of normal liver structures and/or the ^{18}F-FDG uptake was lower than that of the lumen of the descending aorta in the same slice.

All patients were followed-up monthly by US, CT or MRI. Shrinkage of the thrombus and/or recanalization of the vessels on US, CT or MRI during follow-up was considered to be definitive evidence of the benign nature of the thrombosis, whereas enlargement of the thrombus, disruption of the vessel wall, and parenchymal infiltration over follow-up were considered to be consistent with malignancy.

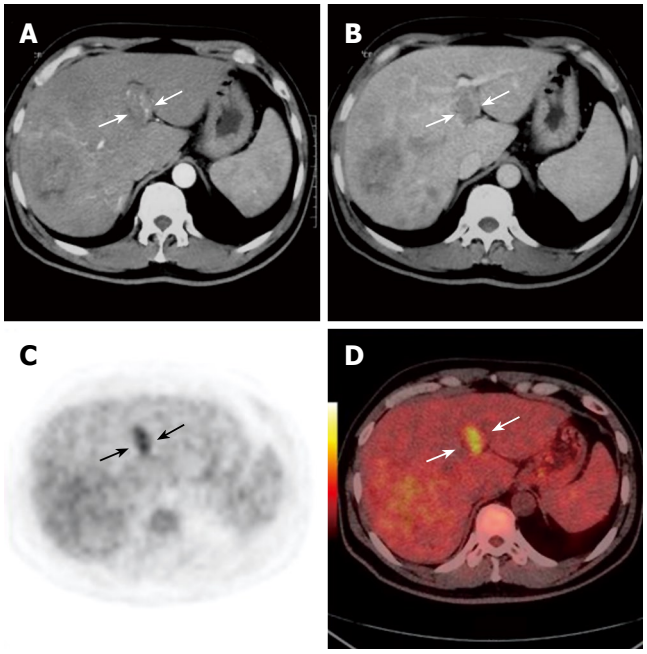

Figure 1 Contrast CT scan showing right lobe and caudate lobe mass and portal vein thrombus in a 55-year-old man. During the arterial phase, the thrombus appears as an iso- to hypodense intraluminal area with dense linear enhancement (white arrows, **A**). A filling defect was detected in the left branch during the portal phases (white arrows, **B**). PET (black arrows, **C**) and PET/CT fused images (white arrows, **D**) reveal a highly metabolic thrombus in the left branch.

RESULTS

Follow-up (1 to 10 mo) showed signs of malignant thrombosis in 4 out of 5 patients. US, CT or MRI produced a true-positive result for malignancy in 4 out of 5 patients, and a false-positive result in 1. ^{18}F-FDG PET/CT was positive in four patients with malignant thrombi, and revealed a true-negative result in the remaining patient. ^{18}F-FDG PET/CT showed highly metabolic thrombi in 4 of the 5 patients. No false-positive result was obtained using ^{18}F-FDG PET/CT.

As shown in Figures 1-5, the four malignant thrombi had SUVs of 3.0-11.5, which were higher than those of the normal liver parenchyma and the lumen of the descending aorta in the same axial slice. The SUVs of these malignant thrombi were lower than those of the HCC mass in the same axial slice. Thrombosis was significantly more common in patients with highly metabolic tumor lesions

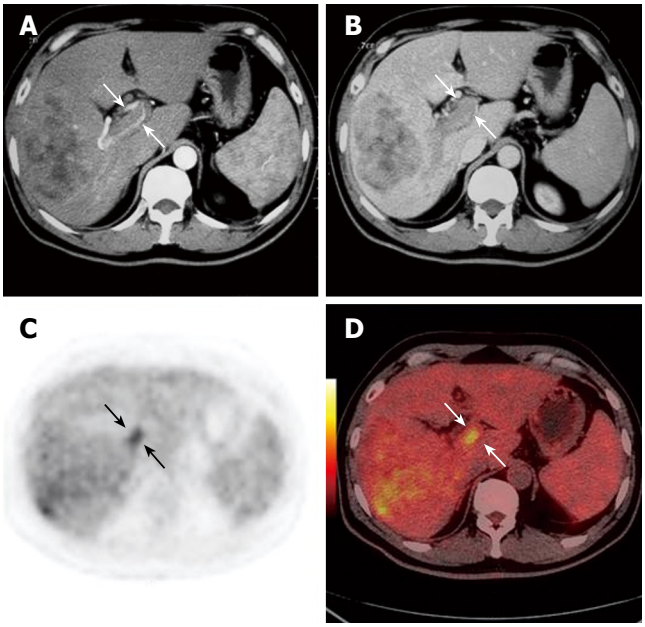

Figure 2 Contrast CT scan showing right lobe and caudate lobe mass and portal vein thrombus of the right branch in the same patient. During the arterial phase, the thrombus appears as an iso- to hypodense intraluminal area with dense linear enhancement (white arrows, **A**). A filling defect was detected in the right branch during the portal phases (white arrows, **B**). PET (black arrows, **C**) and PET/CT fused images (white arrows, **D**) reveal a highly metabolic thrombus in the left branch.

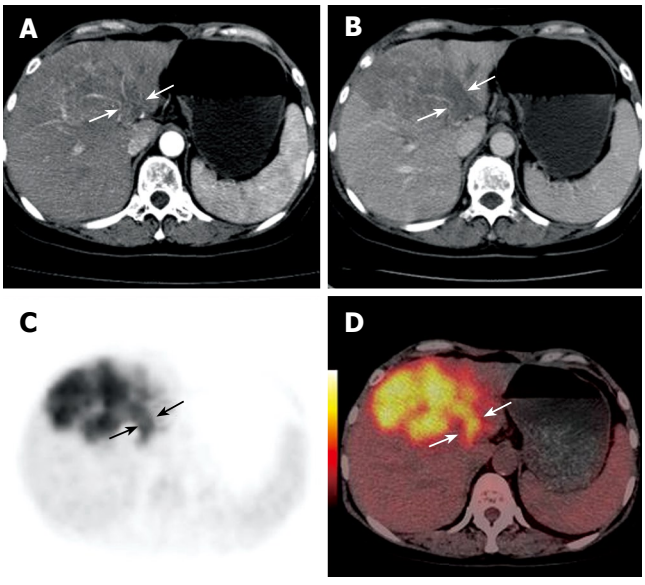

Figure 3 Contrast CT scan demonstrating a left lobe mass and portal vein thrombus in a 60-year-old woman. During the arterial phase, the thrombus appears as a hypodense intraluminal area with dense linear enhancement (white arrows, **A**). A filling defect was detected in the left branch during the portal phases (white arrows, **B**). PET (black arrows, **C**) and PET/CT fused images (white arrows, **D**) reveal a highly metabolic thrombus in the left branch.

than in those with weakly metabolic tumor lesions. All four patients with malignant thrombi had advanced HCC. All of the malignant high metabolism thrombi had discrete margins in PET and PET/CT images.

The remaining patient was shown by ultrasound to have a portal thrombus in the left portal vein 6 mo after HCC

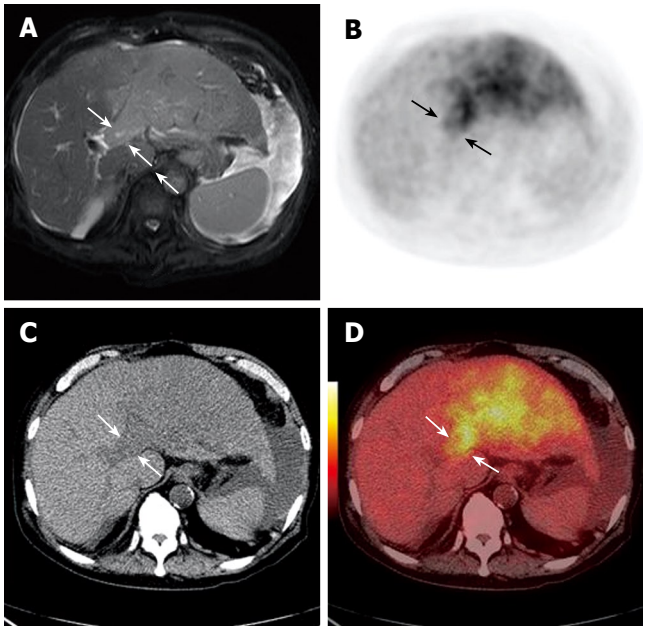

Figure 4 MRI scan showing a left lobe mass and portal vein thrombus in an 80-year-old man (white arrows, **A**). CT detected a low-density lesion in the left branch (white arrows, **C**). PET (black arrows, **B**) and PET/CT fused images (white arrows, **D**) reveal a highly metabolic thrombus in the left branch.

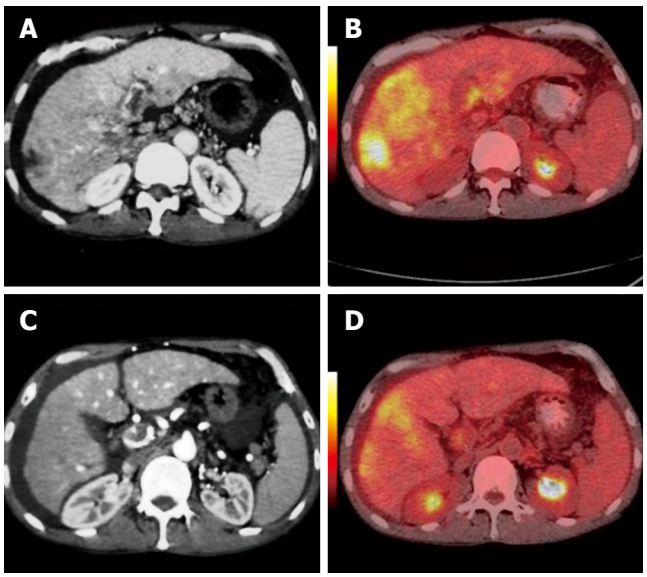

Figure 5 Contrast CT scan showing a diffuse tumor and portal vein thrombus in a 44-year-old man. During the arterial phase, the thrombus appears as a hypodense intraluminal area with mild enhancement at the LV (white arrows, **A**) and PV (white arrows, **C**). PET/CT fused images reveal a highly metabolic mass and a highly metabolic thrombus at the LV and PV, respectively (white arrows, **B**, **D**).

resection. Malignant thrombus was suspected on contrast CT. Contrast-enhanced MRI demonstrated a thrombus in the left portal vein. In the PET/CT examination, the thrombus of the left portal vein had an SUV of 3.0, which was lower than those of the normal liver parenchyma and lumen of descending aorta. ^{18}F-FDG PET/CT found no high ^{18}F-FDG uptake in the left portal vein. The left portal vein was recanalized in the contrast MRI 10-mo follow-up (Figure 6). Finally, diagnosis of the left portal vein blood

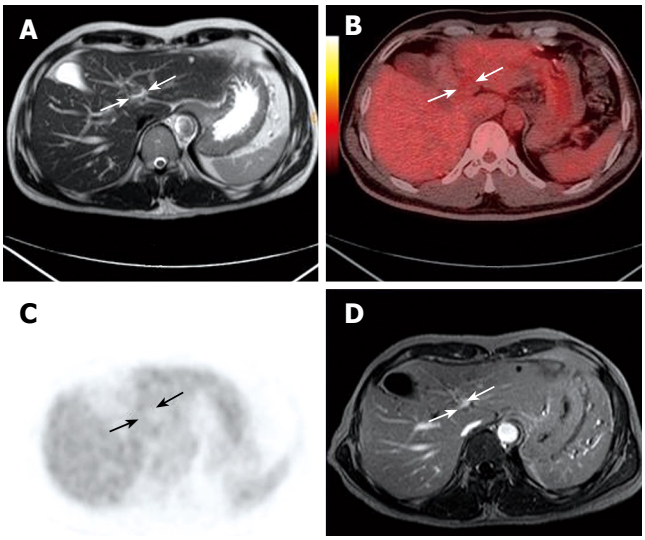

Figure 6 MRI showing a portal vein thrombus in a 44-year-old man six months after HCC resection (white arrows, **A**). PET/CT fused images (white arrows, **B**) and PET (black arrows, **C**) reveal no highly metabolic thrombus in the left branch. LP was recanalized in the contrast MRI at 10 mo follow-up (white arrows, **D**).

thrombus was established. Tables 1 and 2 summarize the clinical and image characteristics of the five patients.

DISCUSSION

HCC tends to invade the intrahepatic vasculature, especially the portal vein. In clinically treated series, the rate of portal invasion is 34%-40%[11-13]. The natural history of untreated HCC is still poor, especially in patients with PVTT; the median survival of such patients was reported to be 2.7 mo, whereas survival in those without PVTT was 24.4 mo. PVTT causes acute portal hypertension, acute upper gastrointestinal hemorrhage, refractory ascites, and finally, acute liver function failure[14-16]. Our findings in the present study confirm portal vein thrombosis is a frequent complication of primary liver tumors, especially those with diameters larger than 3.0 cm, and diffuse tumors.

The reported increased sensitivity of PET/CT over CT has been attributed to the ability of FDG-PET to detect metabolic abnormalities that precede the morphologic changes seen by CT. The global (skull base to proximal thighs) nature of PET/CT study also contributes to increased sensitivity through the detection of distant metastases[17]. ^{18}F-FDG PET/CT has become one of the standard imaging modalities in diagnosing and staging of tumors, and monitoring therapeutic efficacy in hepatic malignancies[18-19]. In this initial clinical experience, ^{18}F-FDG PET/CT appears to be a reliable technique for evaluating the veins of the portal system thrombus. The main advantage of ^{18}F-FDG PET/CT over conventional sonography techniques is its ability to assess the ^{18}F-FDG metabolism activity of portal vein thrombi. Compared with US, the main limitations of no contrast ^{18}F-FDG PET/CT is the absence of ability to observe the portal vein blood stream clearly along the main portal vein and its branch[20,21]. In the fourth patient, arterioportal shunt was confirmed by contrast CT. Thus, when ^{18}F-FDG PET/CT-suspected PVTT is considered, a whole body ^{18}F-FDG PET/CT examination combined with a contrast three-phase liver CT scan in the same PET/CT system is recommended.

Table 1 Clinical data on patients with high and low-metabolism thrombi of the portal vein

Patient	Age (yr)/ sex	Symptoms and signs	Laboratory data	Outcome
1	55/M	No	AFP 5 ng/mL; abnormal HFT	Died of liver failure 2 mo after EPI
2	60/F	Pain in right hypochondriac region	AFP > 1000 ng/mL; abnormal HFT	Died of hepatic failure 3 mo after TACE
3	80/M	Cough	AFP 30 ng/mL; abnormal HFT	Died of renal failure 1 mo after admission
4	65/M	Ascites	AFP > 1000 ng/mL; abnormal HFT	Died of liver failure 1 mo after admission
5	44/M	Six mo after HCC resection	AFP normal; normal HFT	Recanalization

AFP: Alpha-fetoprotein level; HFT: Hepatic function test.

Table 2 Imaging data on patients with high and low-metabolism thrombi of the portal vein

Patient	US, CT, MRI findings		FDG PET/CT SUV ratio		
	Liver tumor location and size	Location of PV tumor thrombus	T/NT	Th/NT	Th/DAo
1	Right and caudate lobe 11 cm × 13 cm	RPV LPV	4.8/3.0 4.8/5.9	5.2/3.0 5.9/3.0	5.2/2.1 5.9/2.1
2	Right lobe 8.4 cm × 9.6 cm	LPV	15.5/2.8	11.5/2.8	11.5/2.7
3	Left lobe diffuse tumor	LPV	9.0/3.6	7.9/3.6	7.9/2.4
4	Both lobes diffuse tumor	LPV PV	5.3/2.7 5.3/2.7	4.9/2.7 3.4/2.7	4.9/2.2 3.4/2.2
5	Six mo after right lobe lesion resection	LPV	-	3. 0/3.0	3.0/2.0

SUV: Standardized uptake value; T: Tumor target; NT: Non tumor target; Th: Thrombi; Dao: Descending aorta; RPV: Right portal vein; LPV: Left portal vein; PV: Portal vein.

Preliminary studies have already highlighted the potential value of ^{18}F-FDG PET/CT in HCC staging and restaging for the TNM stage. It is helpful in early diagnosis and proper treatment, which are very important for patients with PVTT to prolong their lives[22-24]. The reported increased sensitivity of PET/CT over CT has been attributed to the ability of ^{18}F-FDG PET to detect metabolic abnormalities that precede the morphologic changes seen by CT. The global (skull base to proximal thighs) nature of PET/CT study also contributes to increased sensitivity through the detection of distant metastases in HCC patients[25,26].

Dodd *et al*[27] reported that emboli might develop in the portal veins of hepatocirrhosis patients, and that these are mostly portal vein blood thrombi (PVBT), benign hepatic cells, or even bile duct epithelial cells. In recent years, some scholars have found that, during percutaneous ethanol injection, the alcohol that leaks out of the tumor and

flows into the portal vein may cause a benign thrombus. ^{18}F-FDG is not only uptaken by tumor cells, but also by normal cells[28-31] because benign hepatic cells and even bile duct epithelial cells in PVBT can uptake ^{18}F-FDG, which may also have active metabolism in PET/CT images. Thus, further studies are needed to confirm the ability of ^{18}F-FDG PET to discriminate PVTT and PVBT. The potential of this novel approach to characterize the veins of a portal system thrombus should be elucidated in large, ongoing clinical trials.

In conclusion, ^{18}F-FDG PET/CT can be helpful in discriminating between benign and malignant portal vein thrombi. Patients may benefit from ^{18}F-FDG PET/CT when portal vein thrombi can not be diagnosed exactly by US, CT or MRI.

COMMENTS

Background

To select an appropriate treatment regimen, it is essential to accurately characterize the nature of a thrombus in hepatocellular carcinoma (HCC) patients. This study investigated the ability of ^{18}F-fluorodeoxyglucose positron emission tomography/computer tomography (^{18}F-FDG PET/CT) to differentiate between benign and malignant portal vein thrombosis in HCC patients.

Research frontiers

PET and CT are becoming more and more widely available, and their application with ^{18}F-FDG in oncology is beginning to be realized. However, the potential for ^{18}F-FDG PET/CT in the diagnosis of benign and malignant portal vein thrombosis in HCC patients is undefined.

Innovations and breakthroughs

Thrombi with maximum standardized uptake values (SUVs) greater than those of normal liver structures with a discrete margin and/or an ^{18}F-FDG uptake greater than that of the lumen of the descending aorta in the same axial slice were considered malignant. Thrombi with maximum SUVs lower than those of normal liver structures and/or an ^{18}F-FDG uptake lower than that of the lumen of the descending aorta in the same slice were considered benign.

Applications

Our findings can be helpful in discriminating between benign and malignant portal vein thrombi, and can be used to select an appropriate treatment for HCC patients, especially when portal vein thrombi can not be diagnosed exactly by US, CT or MRI.

Peer review

In this study, the authors reported the clinical significance of ^{18}F-FDG PET/CT for the discrimination between benign and malignant thrombi in advanced HCC. This manuscript arouses interest for readers and provides an important clue to diagnose or differentiate portal thrombus characteristics.

Abstract

AIM: To investigate the usefulness of secretin injection-MRCP for the diagnosis of mild chronic pancreatitis.

METHODS: Sixteen patients having mild chronic pancreatitis according to the Cambridge classification and 12 control subjects with no abnormal findings on the pancreatogram were examined for the diagnostic accuracy of secretin injection-MRCP regarding abnormal branch pancreatic ducts associated with mild chronic pancreatitis (Cambridge Classification), using endoscopic retrograde cholangiopancreatography (ERCP) for comparison.

RESULTS: The sensitivity and specificity for abnormal branch pancreatic ducts determined by two reviewers were respectively 55%-63% and 75%-83% in the head, 57%-64% and 82%-83% in the body, and 44%-44% and 72%-76% in the tail of the pancreas. The sensitivity and specificity for mild chronic pancreatitis were 56%-63% and 92%-92%, respectively. Interobserver agreement (κ statistics) concerning the diagnosis of an abnormal branch pancreatic duct and of mild chronic pancreatitis was good to excellent.

CONCLUSION: Secretin injection-MRCP might be useful for the diagnosis of mild chronic pancreatitis.

INTRODUCTION

Chronic pancreatitis is morphologically characterized by irregular sclerosis associated with destruction and permanent loss of the exocrine parenchyma which may be either, focal, segmental or diffuse. These changes may present together with varying degrees of dilatation of the duct system at different segments[1]. Chronic pancreatitis is classified according to morphologic changes of the pancreatic ducts, as defined in the 1983 Cambridge Symposium[2].

MR cholangiopancreatography (MRCP) is a useful non-invasive technique to depict the projection images of the pancreatico-biliary tree, and is expected to become a valuable alternative to endoscopic retrograde cholangiopancreatography (ERCP)[3-8]. However, visualization of the branch pancreatic ducts by MRCP is not good[9-11], and there are few reports about the diagnostic value of MRCP in mild chronic pancreatitis (Cambridge classification). On the other hand, secretin injection-MRCP might allow better visualization of the pancreatic ductal system[12-16].

The purpose of this study was to evaluate the usefulness of secretin injection-MRCP for the diagnosis of abnormal branch pancreatic duct in patients with mild chronic pancreatitis.

MATERIALS AND METHODS

Patients

The MRCP image obtained after secretin injection was examined in 16 patients (32-39 y.o.; mean 36 y.o.) having

mild chronic pancreatitis according to the Cambridge classification, and in 12 control subjects (31-37 y.o.; mean 35 y.o.) showing no abnormal findings on the pancreatogram, who had already undergone ERCP. In the Cambridge classification mild chronic pancreatitis is defined as "more than 3 abnormal side branches with a normal main pancreatic duct". In the present study, we selected patients in their 30's, because we wanted to exclude those with ductal changes associated with aging. In all the patients the maximum diameter of the main pancreatic duct was within 2 mm and the ultrasonogram and CT revealed no findings suggestive of chronic pancreatitis, such as atrophy, calcification, dilatation or stenosis of the pancreatic duct. The control subjects had no pancreatic diseases and were selected from a population that had undergone ERCP for a suspected biliary disease. Patients with mild chronic pancreatitis were selected from a population that had been subjected to ERCP for recurrent attacks of abdominal pain associated with increased serum levels of amylase and lipase in the absence of conclusive US or CT findings of chronic pancreatitis. The symptomatic period was between 15 and 54 mo. Secretin injection-MRCP was performed within 4 wk after ERCP. Informed consent was obtained from all patients after explanation of the examination process. The study protocol was approved by the ethical committee of our institution.

MRCP

After a 6-h fast, MR studies were performed on a 1.5 T scanner using a phased-array multi-coil. With the patients in the supine position, 100 U of secretin (Eisai Corporation, Tokyo, Japan) was injected intravenously. Half-Fourier fast echo sequences with the single slice method were obtained in the coronal plane and left and right oblique planes to emphasize the pancreatic body, head and tail, respectively. MRCP images of axial planes were also added on demand. The sequence parameters were: effective echo time, 250 ms; echo train length, 212; matrix, 384 × 384; FOV, 25 to 35 cm. A thin slice, thickness of 10-30 mm, was adopted to delineate the fine structure of the minimally dilated branches. The acquisition time for an image was 3 s with complete breath-holding. Acquisition was repeated every 30 s during 10 min.

Image analysis

Only clear MRCP images of the pancreatic ducts were regarded as acceptable. MRCP images were reviewed using ERCP as the gold standard. Two sets of MRCP films and one set of ERCP films were prepared so that each reviewer could work separately on the films. MRCP images were interpreted independently by two reviewers (Sai J and Takayashi Y) and ERCP images by another reviewer (Kubokawa Y); all of them were experienced in pancreaticobiliary imaging. Each MRCP and ERCP film was randomly numbered, and reviewers were blinded to the clinical information associated with each film. Abnormal branches of the pancreatic ducts were documented with markings on the duplicate films of ERCP and MRCP by each reviewer, who did not participate in the examination; visible branch pancreatic ducts were regarded as abnormal branch pancreatic ducts on MRCP images because they are not detectable on MRCP except in pathologic cases[10]. Then MRCP images were compared with the ERCP images for the number and location of the abnormal branch pancreatic ducts, lesion by lesion under consensus.

Statistical analysis

The sensitivity and specificity for the diagnosis of abnormal branch pancreatic ducts and mild chronic pancreatitis (Cambridge classification) determined by each reviewer was examined. Regarding the diagnosis of ectatic branch pancreatic duct and mild chronic pancreatitis on MRCP images, the interobserver agreement was analyzed with κstatistics: values were classified as excellent (above 0.75), fair to good (0.40 to 0.75), or poor (below 0.40).

RESULTS

Successful MRCP images were obtained after secretin injection in patients with mild chronic pancreatitis and control subjects. The rates for visualization of the main pancreatic duct on MRCP were 100%.

Abnormal branch ducts delineated on MRCP images correlated with ERCP images, lesion by lesion. The sensitivity and specificity for the diagnosis of abnormal branch pancreatic ducts determined by the two reviewers were 55%-63% and 75%-83% in the head, 57%-64% and 82%-83% in the body, and 44%-44% and 72%-76% in the tail of the pancreas, respectively (Table 1a, b). The sensitivity and specificity for the diagnosis of mild chronic pancreatitis (Cambridge classification) was 56%-63% and 92%-92%, respectively (Table 2). Interobserver agreement (κ statistics) for identifying abnormal branch pancreatic ducts and for diagnosing mild chronic pancreatitis was good to excellent (Table 3).

DISCUSSION

Early-stage chronic pancreatitis is difficult to diagnose because less obvious changes occur over time, before the development of overt exocrine or endocrine insufficiency and visible structural abnormalities[17]. Therefore, a major diagnostic challenge occurs when patients have clinical signs suggestive of chronic pancreatitis, in the absence of demonstrable pancreatic abnormalities on ultrasonography and CT. Reversely, in patients with advanced disease, findings such as atrophy, calcification, dilatation and stenosis of the pancreatic duct are obvious[18]. One of the earliest findings of chronic pancreatitis is an abnormal branch of the pancreatic duct detected by ERCP[2,18]. ERCP is the sensitive method for the diagnosis of early-stage chronic pancreatitis[19-21]; however, it is invasive and associated with complications[22,23], because sufficient contrast medium must be injected to the peripheral branches of the pancreatic ducts when mild changes of chronic pancreatitis are sought[24].

Today, diagnostic ERP is challenged by MRCP, which is a noninvasive alternative to diagnostic ERP for the evaluation of normal and diseased pancreatic ducts[5-9]. However, it is difficult to delineate minimally dilated

Table 1a Sensitivity and specificity of MRCP for abnormal branch pancreatic ducts as compared with ERCP by Reviewer 1. Result of the assessment of images

Location of abnormal branch pancreatic ducts	Number of lesions				Sensitivity (%)	Specificity (%)
	TP	TN	FP	FN		
Head	25	40	13	15	25/40 (63)	40/53 (75)
Body	16	88	18	12	16/28 (57)	88/106 (83)
Tail	4	19	6	5	4/9 (44)	19/25 (76)

TP: True positive; TN: True negative; FP: False positive; FN: False negative; Numbers are numbers of patients (numbers in parentheses are percentages).

Table 1b Sensitivity and specificity of MRCP for abnormal branch pancreatic ducts as compared with ERCP findings by Reviewer 2. Results of the assessment of images

Location of abnormal branch pancreatic ducts	Number of Lesions				Sensitivity (%)	Specificity (%)
	TP	TN	FP	FN		
Head	22	44	9	18	22/40 (55)	44/53 (83)
Body	18	87	19	10	18/28 (64)	87/106 (82)
Tail	4	18	7	5	4/9 (44)	18/25 (72)

branch pancreatic ducts on MRCP despite its improved resolution because while on ERCP images the collapsed branches and main pancreatic duct are distended by the contrast medium, MRCP reflects the physiologic state of the pancreatic duct.

Since Takehara *et al*[10] first reported the MRCP images of moderate to severe chronic pancreatitis obtained after the injection of secretin; several authors have reported the usefulness of secretin injection-MRCP in the diagnosis of chronic pancreatitis[12-15]. Secretin stimulates fluid secretion in the ductal system; and increases the tonus of the sphincter of Oddi during the first 5 min, inhibiting the release of fluid through the papilla of Vater[9]. Therefore, secretin increases the absolute volume of intraductal free water and fills the collapsed branches with fluid[10], facilitating the detection of mild ductal changes in patients with mild chronic pancreatitis, even when no abnormalities can be demonstrated by MRCP under physiologic conditions. According to Mansfredi *et al*[25], visualization of the pancreatic duct branches improved from 71% to 100% in 93 patients with severe chronic pancreatitis and from 4% to 63% in 84 patients suspected of having pancreatic disease. Since the pancreatic juice secretion decreases in patients with advanced chronic pancreatitis, secretin injection-MRCP could be of diagnostic value for those with early-stage chronic pancreatitis, although the occurrence of mild chronic pancreatitis was underestimated by secretin injection-MRCP compared with ERCP in the present study.

There were some limitations to the present study. MRCP should be interpreted by someone blinded to the clinical information to avoid biases. Furthermore, although ERCP was chosen as the gold standard, it is well known that chronic pancreatitis may exist in the presence of a normal pancreatogram. Besides, parenchymal abnormalities may precede ductal and functional changes, and EUS is considered a more sensitive test for parenchymal abnormalities[26-30]. Therefore, the diagnostic value of secretin injection-MRCP for mild chronic pancreatitis might be limited.

Table 2 Sensitivity and specificity of MRCP for mild chronic pancreatitis (Cambridge Classification)

	Sensitivity (%)	Specificity (%)
Reviewer 1	10/16 (63)	9/12 (75)
Reviewer 2	9/16 (56)	10/12 (83)

Table 3 Interobserver agreement regarding the identification of abnormal branch pancreatic ducts (κ statics)

Location of abnormal branch pancreatic ducts	κ value
Abnormal branch, head	0.67
Abnormal branch, body	0.68
Abnormal branch, tail	0.86
Diagnosis of mild chronic pancreatitis	0.79

In conclusion, secretin injection-MRCP might allow an earlier diagnosis of chronic pancreatitis and reduce the rate of false-negative cases detected with MRCP.

COMMENTS

Background

Early-stage chronic pancreatitis is difficult to diagnose because less obvious changes occur over time. One of the earliest findings of chronic pancreatitis is an abnormal branch of the pancreatic duct detected by endoscopic retrograde cholangiopancreatography (ERCP). On the other hand, MR cholangiopancreatography (MRCP) is expected to become valuable alternative to ERCP. However, diagnosis of mild ductal changes of chronic pancreatitis using magnetic resonance cholangiopancreatography (MRCP) is quite challenging, because visualization of the branch pancreatic ducts is not good.

Research frontiers

We examined the diagnostic accuracy of secretin injection-MRCP regarding abnormal branch pancreatic ducts associated with mild chronic pancreatitis (Cambridge classification) using ERCP for comparison, and there were no other related or similar studies.

Innovation and breakthrough

The sensitivity and specificity for the diagnosis of mild chronic pancreatitis (Cambridge classification) was 56%-63% and 92%-92%, respectively. Secretin injection-MRCP might allow an early diagnosis of chronic pancreatitis.

Application

The application of this study could be expanded to diagnose early chronic pancreatitis in larger series.

Terminology

Secretin injection-MRCP was acquired as follows: with the patients in the supine position, 100 U of secretin was injected intravenously. MRCP was repeated every 30 s during 10 min.

Peer review

Secretin injection-MRCP could be a useful method for the diagnosis of mild chronic pancreatitis (Cambridge Classification), although the occurrence was underestimated compared with ERCP.

Abstract

AIM: To investigate the effects of bombesin (BBS) and neurotensin (NTS) on apoptosis and colitis in an ulcerative colitis model.

METHODS: In this study, a total of 50 rats were divided equally into 5 groups. In the control group, no colitis induction or drug administration was performed. Colitis was induced in all other groups. Following the induction of colitis, BBS, NTS or both were applied to three groups of rats. The remaining group (colitis group) received no treatment. On the 11th d after induction of colitis and drug treatment, blood samples were collected for TNF-α and IL-6 level studies. Malondialdehyde (MDA), carbonyl, myeloperoxidase (MPO) and caspase-3 activities, as well as histopathological findings, evaluated in colonic tissues.

RESULTS: According to the macroscopic and microscopic findings, the study groups treated with BBS, NTS and BBS + NTS showed significantly lower damage and inflammation compared with the colitis group (macroscopic score, 2.1 ± 0.87, 3.7 ± 0.94 and 2.1 ± 0.87 *vs* 7.3 ± 0.94; microscopic score, 2.0 ± 0.66, 3.3 ± 0.82 and 1.8 ± 0.63 *vs* 5.2 ± 0.78, $P < 0.01$). TNF-α and IL-6 levels were increased significantly in all groups compared with the control group. These increases were significantly smaller in the BBS, NTS and BBS + NTS groups compared with the colitis group (TNF-α levels, 169.69 ± 53.56, 245.86 ± 64.85 and 175.54 ± 42.19 *vs* 556.44 ± 49.82; IL-6 levels, 443.30 ± 53.99, 612.80 ± 70.39 and 396.80 ± 78.43 *vs* 1505.90 ± 222.23, $P < 0.05$). The colonic MPO and MDA levels were significantly lower in control, BBS, NTS and BBS + NTS groups than in the colitis group (MPO levels, 24.36 ± 8.10, 40.51 ± 8.67 and 25.83 ± 6.43 *vs* 161.47 ± 38.24; MDA levels, 4.70 ± 1.41, 6.55 ± 1.12 and 4.51 ± 0.54 *vs* 15.60 ± 1.88, $P < 0.05$). Carbonyl content and caspase-3 levels were higher in the colitis and NTS groups than in control, BBS and BBS + NTS groups (carbonyl levels, 553.99 ± 59.58 and 336.26 ± 35.72 *vs* 209.76 ± 30.92, 219.76 ± 25.77 and 220.34 ± 36.95; caspase-3 levels, 451.70 ± 68.27 and 216.20 ± 28.17 *vs* 28.60 ± 6.46, 170.50 ± 32.37 and 166.50 ± 30.95, $P < 0.05$).

CONCLUSION: The results of this study suggest BBS and NTS, through their anti-inflammatory actions, support the maintenance of colonic integrity and merit consideration as potential agents for ameliorating colonic inflammation.

INTRODUCTION

Inflammatory bowel diseases (IBDs), including Crohn's

disease (CD) and ulcerative colitis (UC), are chronic relapsing inflammatory conditions of unknown etiology. The most common symptoms of both UC and CD are diarrhea, which may be profuse and bloody, and abdominal pain[1].

The exact pathogenesis in IBD is poorly understood, but evidence suggests IBD involves interactions between the immune system, genetic susceptibility and the environment[1]. Some studies have analyzed the role of a variety of soluble peptides and other mediators that, once secreted in a co-ordinated fashion in the injured area, are able to restore mucosal integrity[2].

CD affects the full thickness of the wall of the colon or the small intestine, whereas UC primarily affects the mucosa of the colon. Histologically, the affected tissue shows ulceration and the infiltration of inflammatory cells from the circulation[3].

Neuropeptides are small molecules that, in the intestine, modulate several biological processes and modify the activities of cells responsible either for triggering tissue damage or promoting healing[4,5]. The tetradecapeptide bombesin (BBS) was originally isolated from the skin of the amphibian *Bombina bombina*, and is analogous to mammalian gastrin-releasing peptide[6]. In the gastrointestinal tract, BBS stimulates the secretion of various gut hormones and peptides (for example, gastrin, somatostatin, cholecystokinine, insulin, glucagon, motilin, pancreatic polypeptide and neurotensin), exerts trophic effects on intestinal mucosa and pancreas, and stimulates intestinal motility[7,8]. It has been shown BBS improves intestinal integrity in experimental models of gut barrier dysfunction, like administration of methotrexate and elemental diets[9,10], and that it also has mitogenic effects[11]. Neurotensin (NTS) is a tridecapeptide, found mainly in the brain and gut. Intestinal NTS is produced by a discrete population of endocrine cells scattered throughout the jejeuno-ileal mucosa[12]. The peptide is released into the circulation after food ingestion. Its digestive functions include stimulation of pancreaticobiliary secretions, intestinal blood flow, inhibition of gastric acid secretion and motility, stimulation of colon motility and inhibition of jejuno-ileum motility. It is a potent trophic agent for the small and large intestines[13,14]. NTS has been shown to prevent intestinal atrophy induced by feeding rats an elemental diet, and to enhance intestinal mucosal restoration after small bowel resection[15]; it also has immunoregulatory functions[16].

The intact mucosa and an indigenous intestinal flora are important components of body defenses against luminal pathogenic bacteria. The epithelia of the colon are dynamic and rapidly proliferating tissues that are profoundly affected by changes in luminal contents and injury. The aim of this study was to determine the effects of BBS and NTS on an experimental colitis model, because of their potent trophic, metabolic and mitogenic effects.

MATERIALS AND METHODS

Animals

Male Wistar-albino rats (Erciyes University Hakan Cetinsaya Experimental and Clinical Research Center, Kayseri, Turkey) weighing 225-290 g were fed ad libitum a nutritionally balanced rodent diet and water. They were kept under constant environmental conditions. Water only was provided during the 12 h preceding the experiments. Our institutional ethical committee approved the experimental procedures of this study.

Experimental design

Fifty Wistar-albino rats (28-32 wk) were used in the study. The rats were divided into 5 groups containing 10 rats each: Group I (Control) = normal animals; Group Ⅱ (Colitis) = induction of experimental colitis without further treatment; Group Ⅲ (BBS) = induction of experimental colitis plus administration of bombesin; Group Ⅳ (NTS) = induction of experimental colitis plus administration of neurotensin; and Group Ⅴ (BBS + NTS) = induction of experimental colitis plus administration of bombesin and neurotensin together.

Experimental procedures

Colitis was induced as previously described[17]. Briefly, rats were lightly anesthetized with halothane, and an infant feeding tube (Unoplast A/S DK 330; Hundested, Denmark) fitted onto a blunt 18-gauge needle was inserted rectally. The tip of the tube was placed nearly 8 cm into the colon and 25 mg 2,4,6- trinitrobenzene sulphonic acid (Sigma, St. Louis, Missouri) mixed with 0.25 mL 30% ethanol (TNBS-E) was intracolonically instilled. After instillation, the rats were supported in the supine position until recovery from anesthesia to prevent immediate anal leakage of the instillate. The control group rats received intracolonic saline. For the 10 subsequent days, the animals in groups 3 and 5 were treated daily with BBS (10 μg/kg, subcutaneously, 3 times a day), and those in groups 4 and 5 were treated daily with NTS (300 μg/kg, intraperitoneally, once a day). Rats in control and colitis groups received sterile saline at the same volumes and same times. All injections were given after topical application of an antiseptic solution of povidone iodine 10%.

All rats were fed standard rat chow for 10 d. On the 11th d, all animals were operated on. Rats were anesthetized by intraperitoneal injection of ketamine-HCl (10 mg/kg; Ketalar®, Eczacibasi, Istanbul, Turkey) and xylazin (3 mg/kg; Rompun® 2%, Bayer, Germany). The abdominal skin was cleansed with povidone-iodine after shaving. All procedures were performed under sterile conditions by one surgeon. The abdomen was opened by a midline incision, and a 2-mL blood sample was collected from the portal vein to measure the levels of TNF-α and IL-6. The distal colon was removed for analysis of myeloperoxidase (MPO) activity, carbonyl content (protein oxidation), lipid peroxidation (malondialdehyde [MDA]), caspase-3 activity and histologic examination. At the end of surgical procedure, all rats were sacrificed by overdose ether inhalation.

Peptides preparation

Stock solutions of BBS (Sigma Chemical Co) and NTS (Sigma Chemical Co) were prepared by first dissolving the amount of peptide needed for the study in 1 mL of sterile

Table 1 Colon macroscopic scoring system

Score	Criteria
0	No damage
1	Hyperemia
2	Hyperemia and thickening without ulceration
3	Ulceration at a single site
4	Two or more sites of ulceration or inflammation
5	Ulceration or inflammation extending > 1 cm along the length of colon
6-10	Damage covering > 2 cm along the lenght of colon, with the score being increased by 1 for each additional centimeter of involvement

water containing 0.1% (weight/volume) bovine serum albumin, and then diluted with normal saline containing 1% bovine serum albumin, so that the amounts of BBS and NTS needed for each injection were contained in a volume of 0.1 mL. Aliquots of 1% bovine serum albumin and BBS were stored in plastic tubes at -20℃. To prolong the rate of absorption after each injection, BBS in saline was mixed 1:4 (volume/volume ratio) with 8% (weight/volume) hydrolyzed gelatin (Sigma Chemical Co) before administration. A final volume of 0.5 mL containing 10 μg BBS/kg body weight, was injected subcutaneously 3 times daily[7]. The NTS solution was divided into equal aliquots of 0.1 mL that were stored in glass vials at -20℃. At the time of administration, each aliquot was further diluted with 0.4 mL of sterile saline to a final volume of 0.5 mL, which was given intraperitoneally as a bolus injection containing 300 μg NTS/kg body weight[18].

Determination of serum tumor necrosis factor-alpha and interleukin-6 levels

The levels of serum tumor necrosis factor-alpha (TNF-α) and interleukin-6 (IL-6) were determined using specific enzyme-linked immunosorbent assay kits (BioSource Rat TNF-α ELISA and BioSource Rat IL-6 ELISA). The results were expressed as pg/mL.

Assessment of colonic damage

The distal colon was removed, opened longitudinally and fecal material was rinsed with a gentle spray of 0.9% saline. The freshly opened colonic segments were pinned out on a wax block and examined by a pathologist who was blinded to the treatment.

Colon macroscopic score

The extent of mucosal damage was assessed using the colon macroscopic scoring system of Wallace *et al* (Table 1)[19].

Colon microscopic score

Tissue samles were fixed with 10% formaldehyde solution for 24 h and transferred to 70% ethanol solution. The tissues were embedded in parafin; 4-μm thick sections were made, and histologic examination was performed under a light microscope after hematoxylin and eosin staining. A pathologist who was unaware of the animals' groupings evaluated the specimens. Tissues were assessed for the presence and activity of colitis as well as the extent of tissue damage using a large number of serial sections. Colonic inflammation was assessed using a modification of the histopathologic grading system of MacPherson and Pfeifer (Table 2)[20].

Table 2 Histopathologic grading scale of TNBS-E-induced colitis

Grade of colitis	Microscopic findings
0	No damage
Ⅰ	Mild mocosal and/or submucosal inflammatory infiltrate and edema: punctuate mucosal erosions often associated with capillary proliferation, muscularis mucosa intact
Ⅱ	Grade Ⅰ changes involving 50% of the specimen
Ⅲ	Prominent inflammatory infiltrate and edema frequently with deeper areas of ulceration extending through the muscularis mucosa into the submucosa, rare inflammatory cells invading the muscularis propria but without muscle necrosis
Ⅳ	Grade Ⅲ changes involving 50% of the specimen
Ⅴ	Extensive ulceration with coagulative necrosis bordered inferiorly by numerous neutrophils and fewer mononuclear cells, necrosis extends deeply into the muscularis propria
Ⅵ	Grade Ⅴ changes involving 50% of the specimen

Myeloperoxidase measurement in colon tissue

After being scored, a sample of distal colon was frozen for subsequent measurement of MPO activity as an index of granulocyte infiltration[19]. The method described by Bradley *et al* was used to measure MPO activity in colon homogenates[21]. The previously frozen colon tissues were homogenized for 30 s in 4 mL of 20 mmol/L potassium phosphate buffer, pH 7.4, and centrifuged for 30 min at 40 000 × *g* at 4℃. The pellet was resuspended in 4 mL of 50-mmol/L potassium phosphate buffer, pH 6.0, containing 0.5 g/dL hexadecyltrimethyl ammonium bromide. Samples were sonicated for 90 s at full power, incubated in a 60℃ water bath for 2 h and centrifuged. The supernatant (0.1 mL) was added to 2.9 mL of 50-mmol/L potassium phosphate buffer, pH 6.0, containing 0.167 mg/mL dianisidine and 0.0005% hydrogen peroxide. Absorbance of 460 nm visible light (A460) was measured for 3 min. The results were expressed as units of enzyme activity per gram of wet tissue weight (U/g tissue).

Malondialdehyde measurement in colon tissue

One part of the tissue was homogenized in 10 parts of 15 mmol/L KCl for the MDA assay. MDA, which is the end product of fatty acid peroxidation, reacts with thiobarbituric acid (TBA) to form a colored complex. Measurement of MDA content by TBA reactivity is the most widely used methods to assess lipid peroxidation[22]. The principle of the method is based on measurement of the absorbance of the pink color produced by the interaction of TBA with MDA at 530 nm. Values were expressed as nmol/g wet tissue weight.

Determination of carbonyl content

Tissue carbonyl molecule formation was determined to reflect protein oxidation as a biochemical marker of oxidative damage owing to colitis. Protein oxidation

Table 3 Comparison of macroscopic and microscopic colonic damage scores

Colonic damage score		Group Ⅰ Control	Group Ⅱ Colitis	Group Ⅲ BBS	Group Ⅳ NTS	Group Ⅴ BBS and NTS	*P*
Macroscopic score	mean ± SD	0.3 ± 0.48	7.3 ± 0.94	2.1 ± 0.87	3.7 ± 0.94	2.1 ± 0.87	< 0.01
	Median (Min-Max)	0 (0.0-1.0)[b]	7 (6.0-9.0)[d]	2 (1.0-3.0)[b]	4 (2.0-5.0)[f]	2 (1.0-3.0)[b]	
Microscopic score	mean ± SD	0.4 ± 0.69	5.2 ± 0.78	2.0 ± 0.66	3.3 ± 0.82	1.8 ± 0.63	< 0.01
	Median (Min-Max)	0 (0.0-2.0)[b]	5 (4.0-6.0)[d]	2 (1.0-3.0)[b]	3.5 (2.0-4.0)[f]	2 (1.0-3.0)[b]	

Data are expressed as means ± SD and median (min-max). [b]$P < 0.01$ *vs* colitis and NTS; [d]$P < 0.01$ *vs* BBS, NTS and BBS and NTS; [f]$P < 0.01$ *vs* colitis, control, BBS and BBS and NTS. BBS: Bombesin; NTS: Neurotensin.

was assayed by a modified streptomycin sulfate, 2,4-dinitrophenylhydrazine-based method, and expressed in nmol total carbonyl groups/mg total protein[23].

Caspase-3 proteolytic activity

The caspase-3 activity ratio was calculated using a colorimetric assay (Chemicon International, Temecula, CA). Cells harvested from the different treatment groups were lysed and 200 μg of protein was tested for protease activity by the addition of a caspase-specific substrate peptide, DVED-pnitroaniline. Caspase-3 cleavage of the peptide releases the chromophore p-nitroaniline (p-NA), which was quantitated spectro-photometrically at 405 nm. The level of caspase-3 enzymatic activity in the cell lysate was directly proportional to the extent of the color reaction. The results are expressed as the fold increase of caspase activity in apoptotic cells relative to their respective controls. In background reactions, no DVED-p-NA substrate was added, and the values obtained were subtracted from experimental results before calculating the fold increase[24].

Statistical analysis

The data are presented as means ± SD. One-way analysis of variance (ANOVA) was used to compare the levels of serum TNF-α, IL-6, colon MDA and MPO, and caspase-3, as well as carbonyl content, among the 5 groups. The Tamhane test was used as a post hoc test for multiple comparisons between groups. Non-parametric Kruskal-Wallis tests were used to compare macroscopic and microscopic damage scores. Dunn's test was used for multiple comparisons between groups. Data were analyzed using Statistical Package for the Social Sciences (SPSS) for Windows (version 13.0). Significance was set at $P < 0.05$.

RESULTS

Macroscopic colonic damage

Table 3 shows the results of assessment of gross colonic injury. In rats treated with BBS in which a macroscopic response was evident, there was minimal damage to the surface epithelium, and there was mild inflammation of the mucosa, but no transmural inflammation. In the colitis group, the damage comprised broad mucosal ulcers with a surface layer of necrotic slough, accumulation of mesenteric fat and fibrinous adhesions to the bowel. Macroscopic colonic damage score was highest in the colitis group (median; 7.0). This score was significantly lower in BBS and BBS + NTS groups, but higher than that in control rats ($P < 0.01$). Although the score in rats in NTS group was higher than those in rats in the BBS and BBS + NTS, and lower than that in the colitis group, there was no significant difference ($P > 0.05$) (Table 3).

Microscopic colonic damage

Histopathologic evaluation of the control group was within normal limits. Microscopic examination showed low levels of damage or inflammation in rats treated with BBS (groups Ⅲ and Ⅴ), whereas in rats with colitis, there was widespread destruction of the mucosa with transmural infiltration of neutrophils, monocytes and lymphocytes ($P < 0.01$) (Table 3).

Serum tumor necrosis factor-alpha and interleukin-6 levels

Serum TNF-α and IL-6 levels in the colitis and study groups were significantly increased at d 11 compared with the control group ($P < 0.05$). This increase was significantly smaller in the BBS, NTS and BBS + NTS groups than in the colitis group ($P < 0.05$) (Figures 1 and 2).

Myeloperoxidase levels

The colonic tissue MPO levels were higher in the colitis group than in the control, BBS, NTS and BBS + NTS groups ($P < 0.001$). There were no significant differences between the control and BBS groups ($P = 0.27$), or between the BBS and BBS + NTS groups ($P = 1.00$), whereas the MPO levels in the control and BBS + NTS groups were statistically significant different ($P = 0.001$). The increase in the NTS group was significantly high than the increase in the BBS ($P = 0.004$) and BBS + NTS groups ($P = 0.005$) (Figure 3).

Malondialdehyde levels

MDA levels were highest in the colitis group, and were significantly higher in the BBS, NTS and BBS + NTS groups compared with the control group ($P < 0.01$). There was no statistically significant difference between BBS and BBS + NTS groups ($P = 1.00$), but the MDA levels in these two groups were significantly higher than those in the NTS group ($P = 0.047$ and $P = 0.002$) (Figure 4).

Carbonyl contents

Carbonyl contents were higher in the colitis and NTS groups compared with the control, BBS and BBS + NTS groups ($P < 0.001$). The carbonyl contents of the control, BBS and BBS + NTS groups were not significantly different ($P > 0.05$, range; 0.997-1.00). The carbonyl content of the NTS group was significantly higher than

that of the control, BBS and BBS + NTS groups, but lower than that in the colitis group ($P < 0.001$) (Figure 5).

Caspase-3 levels

Colon caspase levels were higher in the colitis and NTS groups than in the control, BBS and BBS + NTS groups ($P < 0.05$, range; 0.001-0.034). There was no statistically significant difference between the BBS and BBS + NTS groups ($P = 1.00$), but the increases in caspase-3 levels in these two groups were significantly smaller than those in the control, colitis and NTS groups ($P < 0.05$, range; 0.001-0.034) (Figure 6).

DISCUSSION

IBDs are chronic intestinal inflammatory disorders that are considered to be the result of an inappropriate response of the immune system to luminal antigens[25]. Studies over the past several years have shown a variety of soluble peptides, prostaglandins, growth factors, cytokines and chemokines are secreted in a coordinated fashion in the injured area to restore mucosal integrity[26-28]. Although experimental animal models of colitis are of value in eliciting some of the mechanisms underlying IBDs, different models

differ in their relative use. Most animal models lack certain characteristics of IBDs and model acute events rather than the chronic features typical of IBDs. TNBS colitis has been well characterized and has clinical, biochemical and pathologic similarities to colonic CD. Animals with TNBS model colitis respond to drugs that have proven useful in IBDs[19]. Therefore, we used TNBS-induced colitis, which has the dual advantage of chronicity and acuteness so often seen in patients with IBD. Some other advantages of this model of colitis are its reasonable reproducibility and its value in assessing the efficacy of therapeutic agents commonly used for the treatment of colitis[19].

BBS and NTS are biologically active neuropeptides that are widely distributed in the central and peripheral nervous systems as well as in the endocrine systems. They have multiple biological effects, such as gastrointestinal motility, mucosal blood flow, cell growth and immunoregulation[29]. Their biological effects may result from direct actions of BBS and NTS, as neurotransmitters, on the target organ, or indirectly through the action of gastrointestinal hormones released in response to these neuropeptides. Furthermore, the nature and amplitude of neuropeptide-mediated effects may be different in normal tissue and in inflammatory disorders, because the levels of receptors and cell populations expressing neuropeptide receptors may be strikingly different[30]. In this study, we aimed to assess the role of BBS and NTS in a model of colitis using TNBS, a well-accepted model for IBD.

Although BBS and NTS improve intestinal barrier function in an experimental colitis model[7,14,18], we don't know the precise mechanisms underlying these effects. Therefore, we aimed to evaluate the effects of BBS and NTS on lipid peroxidation, protein oxidation and apoptosis in a colitis model. We also aimed to analyse the molecular mechanisms of these effects.

In the colitis group, increased macroscopic and microscopic damage scores revealed severe inflammatory changes. BBS and NTS treatment attenuated the colonic damage, suggesting these agents may have an additional protective role supporting colonic integrity. Although both agents significantly reduced macroscopic and microscopic colonic damage scores, we don't know if the effects of these two agents are additive or synergistic, and whether these effects are dose-dependent or not. There is no report in the literature about the therapeutic doses of BBS and NTS in experimental colitis models. However, in most studies, both agents were administered at the same doses[7,31]. Brun *et al* reported the mucosal level of NTS showed a 5.8-fold increase in an experimental colitis model compared with normal mice[4]. On the contrary, in patients with chronic inflammatory disorders, neuropeptide levels have been reported to be low[32]. All of these observations suggest the neuropeptide response depends on the severity of the inflammatory process and the site of the event. Receptor changes may cause these effects. Of the three mammalian bombesin-like receptors, only the type-2 receptor is present in the human intestine. The receptor types present and their localization were not altered in patients with IBD, although there was an obvious decrease in the number of binding sites in the smooth muscle of patients with IBD compared with normal control patients. In the mucosa of patients with IBD, very few binding sites for BBS were seen[33]. This suggests that if the administration of BBS has any effect, it will be observed in the human mucosa, acting via indirect mechanisms such as release of other trophic agents, for example, cholecystokinin, neurotensin.

TNF-α and IL-6 are multifunctional cytokines produced primarily by activated monocytes and macrophages; they play a crucial role in the initiation and continuation of mucosal inflammation and immunity[34,35]. These cytokines are involved in many cell processes including apoptotic cell death, metabolism, inflammation, thrombosis and fibrinolysis[36]. TNF-α and IL-6 induce the production of other cytokines including adhesion molecules and arachidonic acid metabolites, and activation of immune and non-immune cells[37]. Systemic inhibition of soluble TNF-α by infliximab (chimeric anti- TNF-α mAbs) has been reported to induce remission in up to 50% of patients with CD and to significantly improve clinical symptoms in most patients[38]. Worledge *et al* reported that the administration of TNF-α antibodies effectively treated experimental colitis in rats[39]. Analysis of endoscopic biopsy samples from IBD patients revealed the involved colonic mucosa from patients with active disease contains larger amounts of IL-6 than colonic mucosa from patients in remission[40]. In another study, the administration of anti-IL-6 antibody was shown to ameliorate disease[41]. In our study, TNF-α and IL-6 levels were correlated with the increased level of inflammation in the colitis group. By contrast, TNF-α and IL-6 levels decreased in all study groups, this decrease was more significant in the BBS and BBS + NTS groups. At this point, TNF-α and IL-6 may be promising markers in monitoring the progress of IBD and the response to treatment. Such findings indicate blockade of TNF-α and IL-6 signaling are clinically advantageous in the treatment of IBDs. The results of our study suggest the therapeutic potential of BBS and NTS in human IBDs with decreases TNF-α and IL-6 levels. Assimakopoulos *et al* reported experimental obstructive jaundice induces regional loss of occludin expression in the intestinal epithelium, which may be a key contributing factor to the disruption of the mucosal barrier. The gut regulatory peptides BBS and NTS prevent this alteration leading to lower portal and systemic endotoxemia and inflammation[31]. These inflammatory responses are characterized by the release of cytokines and other proinflammatory mediators, such as TNF-α, IL-6 and oxygen-free radicals. These agents may produce injurious effects on the structure and function of tight junctions, compromising intestinal epithelial barrier function[35,37,42]. Specifically, it has been demonstrated TNF-α downregulates the human occludin promoter[43]. In addition, endotoxemia and inflammation reduce splanchnic blood flow and disrupt intestinal microcirculation, resulting in hypoxia of enterocytes and energy depletion[44]. Studies in epithelial cells have shown that adenosine triphosphate (ATP) depletion induces the structural perturbation of the tight junction[45]. Increased ATP levels in treatment groups may affect energy balance positively, with improved functional and morphological restoration.

Cell death by apoptosis plays an important role

in the regulation of intestinal epithelial homeostasis. Administration of anti-IL-6 and TNF-α antibodies to rats with different forms of experimental colitis leads to decreases in the severity of colitis and the occurrence of apoptotic cells in the inflammed tissues[46]. However, Atreya *et al* have reported the mechanisms underlying the therapeutic effects of anti-IL-6 antibodies are more profound; they affect the survival of $CD4^+$ T cells mediating inflammation such that the main action of the antibodies is on the cells inducing or producing the cytokines[47]. The potential relevance of modulating T-cell resistance against apoptosis as a therapeutic target in IBD is underlined by Zhou *et al*, who showed drugs that facilitate apoptosis can be used for the supression of T-cell mediated autoimmune disease[48]. Control animals showed basal levels of apoptotic activity, known as spontaneous apoptosis. TNBS-E-induced colitis resulted in a significant increase in the levels of proinflammatory cytokines and apoptosis, while BBS and NTS reduced the levels of proinflammatory cytokines and the rate of apoptotic death. Potential mechanism for increased apoptosis after TNBS-E induced colitis may implicate the excessive release of IL-6 and TNF-α, activation of cytotoxic T cells. Activated cytotoxic T cells induce death of inflammatory $CD4^+$ T cells via independent and possibly synergistic mechanisms. Assimakopoulos *et al* reported BBS and NTS signficantly decreased apoptosis in obstructed jaundiced rats, and they speculated this effect occurred by decreasing intestinal oxidative stress, which is an important apoptosis inducer[49]. In addition, it should be taken into consideration that neuropeptide-mediated effects may be modulated by complex interactions with other mediators involved in tissue restitution, such as chemokines[28]. An indirect mechanism may be related to a further reduction of intestinal lipid peroxidation, because oxidative state is involved in the modulation of cell proliferation and death[50]. The anti-apoptotic effect of BBS and NTS may be mediated by a reduction in endotoxemia and amelioration of the subsequent systemic inflammation, which may activate the apoptotic process. Another explanation of their anti-apoptotic action may be through induction of vasodilation[51], which improves intestinal microcirculation, thus preventing hypoxia, energy depletion and activation of apoptotic pathways. The anti-apoptotic effects of BBS and NTS may be mediated by acting on one or more factors. For this reason, the future of therapy for many types of IBDs might lie in combined anti-cytokine, anti-oxidant and anti-apoptotic therapies, rather than treatment with a single agent alone.

It has been proposed that oxygen-derived free radicals are implicated in the pathogenesis of IBDs[52]. Numerous studies showed MDA is formed in increased amounts in intestinal tissue[52,53]. MDA (lipid peroxidation) and carbonyls in cellular proteins (protein oxidation), generated by oxygen free radicals, is believed to be an important cause of damage to cell membranes[23,54]. Previous experimental studies had shown BBS and NTS improved gut barrier functions after chemically induced colitis[13,15]. Similarly, in our study, TNBS-E-induced colitis resulted in increased MDA and carbonyl production in colonic tissue. Additionally, BBS and NTS administration significantly reduced intestinal MDA and carbonyl content in rats with TNBS-E-induced colitis. These results provide evidence of an antioxidant action of BBS and NTS in the intestine in an experimental colitis model. These effects might be related to a reduction in endotoxemia or improvement in intestinal microcirculation induced by BBS and NTS, leading to oxidative metabolism. This antioxidant effect may be attributed to a direct receptor-mediated mechanism. Binding of neuropeptides to their specific receptors is followed by activation of protein kinase[55], which is known to activate intracellular antioxidant enzyme systems. An alternative explanation might be the reduction of endotoxemia, which is associated with the generation of oxygen free radicals *via* xanthine oxidase-dependent pathways. Moreover, improvement in intestinal microcirculation induced by regulatory neuropeptides prevents hypoxia and energy depletion, leading to oxidative metabolism. Since structural and functional integrity of mitochondria is crucial for the maintenance of cell metabolic homeostasis, this mechanism enhances cellular defenses against oxidant injury.

In our experiments, the inflammatory response caused by TNBS-E is described by an important increase in neutrophil infiltration into the colonic tissue, and the subsequent augmentation of MPO levels. This increase in MPO activity was substantially reduced in rats treated with BBS and NTS. Neutrophils play a crucial role in this regard by producing superoxide anions and a cascade of various reactive species. Activated neutrophils pass out of the circulation and enter the inflammed mucosa and submucosa of the colon during acute inflammation, leading to a large amount of production of reactive oxygen and nitrogen species that can contribute to intestinal injury[56]. MPO catalyzes the formation of such potent cytotoxic oxidants. The reduction in colonic MPO activity, as well as the histological findings of the absence of cellular infiltration following treatment with BBS and NTS, may indicate their antioxidant and anti-inflammatory effects.

The present study has shown TNBS-E-induced ulcerative colitis was associated with macroscopic, microscopic and biochemical changes. Medical treatment of IBDs is principally aimed at inhibiting the production of inflammatory mediators and at modulating the immune system. Treatment with BBS and NTS attenuated colitis as shown by the lower serum levels of TNF-α and IL-6, and the reduced colonic tissue levels of MPO, MDA, carbonyls and caspases. Additionally, these neuropeptides stimulate growth and regeneration of the intestinal mucosa. For these reasons, they have been implicated in the treatment of IBDs. However, further studies are needed to explain the cellular mechanism underlying the trophic and regenerative effects of BBS and NTS.

COMMENTS

Background

The exact pathogenesis in inflammatory bowel diseases is poorly understood, but some studies have analyzed the role of a variety of soluble peptides and other mediators that, once secreted in a co-ordinated fashion in the injured area, are able to restore mucosal integrity.

Research frontiers

The epithelium of the colon consists of dynamic and rapidly proliferating cells that are profoundly affected by changes in luminal contents and injury. Previous experimental studies have shown intrarectal instillation of 2,4,6- trinitrobenzene sulphonic acid (Sigma, St. Louis, Missouri) mixed with 30% ethanol (TNBS-E) promotes morphologic alterations in the colonic mucosa indicative of atrophy, increases apoptosis and induces intestinal oxidative stress. Treatment with bombesin and neurotensin attenuated colitis, as shown by the lower serum levels of tumor necrosis factor-alpha and interleukin-6, and the reduced colonic tissue levels of myeloperoxidase, malondialdehyde, carbonyls and caspases.

Innovations and breakthroughs

This study demonstrates the gut trophic peptides bombesin and neurotensin improve TNBS-E-induced ulcerative colitis. This effect related to a regulatory effect of peptides on epithelial cell production and apoptosis, and reduction of intestinal oxidative stress. Although the results of laboratory experiments are not readily applicable to the clinical situation, these findings offer further insight into the pathophysiology of gut barrier functions and suggest an important biologic effect of regulatory peptides.

Applications

The results from this experimental study confirm the protective effect of bombesin and neurotensine on TNBS-E-induced colitis and apoptosis. This encourages us to apply these agents in treating inflammatory bowel diseases in the future clinical trials.

Terminology

Bombesin and neurotensin exert a wide spectrum of biologic actions on gastrointestinal tissues, influencing intestinal motility, blood flow, secretion, absorption and immune responses. These agents are small molecules that, in the intestine, modulate several biological processes and modify the activity of cells responsible for promoting healing.

Peer review

This is a well-written manuscript. The authors describe the effect of ameliorative effects of bombesin (BBS) and neurotensin (NTS) on trinitrobenzene sulphonic acid-induced colitis.

Abstract

AIM: To evaluate the performance of commercially available immunochromatographic (ICT) and immunoblot tests covering the current infection marker CIM and conventional ELISA for the diagnosis of *H pylori* infection in adult dyspeptic patients.

METHODS: Consecutive non-treated dyspeptic patients undergoing diagnostic endoscopy were tested for *H pylori* infection by culture, rapid urease test, and histology of gastric biopsy specimens. Serum from 61 *H pylori* infected and 21 non-infected patients were tested for anti-*H pylori* IgG antibodies by commercial ELISA (AccuBind™ ELISA, Monobind, USA), ICT (Assure® *H pylori* Rapid Test, Genelabs Diagnostics, Singapore), and immunoblot (Helico Blot 2.1, Genelabs Diagnostics, Singapore) assays. ICT and immunoblot kits cover CIM among other parameters and their performance with and without CIM was evaluated separately.

RESULTS: Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of ELISA were 96.7%, 42.8%, 83.1%, 81.8%, and 82.9%, of ICT were 90.1%, 80.9%, 93.2%, 73.9%, and 87.8%, of ICT with CIM were 88.5%, 90.4%, 96.4%, 73.0%, and 89.0%, of immunoblot were 98.3%, 80.9%, 93.7%, 94.4%, and 93.9%, and of immunoblot with CIM were 98.3%, 90.4%, 96.7%, 95.0%, and 96.3%, respectively.

CONCLUSION: Immunoblot with CIM had the best performance. ICT with CIM was found to be more specific and accurate than the conventional ELISA and may be useful for non-invasive diagnosis of *H pylori* infection.

INTRODUCTION

H pylori causes peptic ulcer disease[1,2] that can be cured by antimicrobial treatment[3-5]. 'Test and treat' strategy that involves non-invasive testing without endoscopy and eradication therapy in young patients[6] is effective in management of dyspepsia[7-9]. This calls for a simple, reliable and non-invasive diagnostic test for *H pylori* infection in clinical practice. At present there is no single test for *H pylori* that can be used as the 'gold standard'[10].

Culture, rapid urease test, and histology require endoscopic biopsy of gastric mucosal tissue that is expensive, inconvenient for the patient and available only at specialized centers. Moreover, because of a patchy distribution of *H pylori* in the gastric mucosa, biopsy tissue examination may yield false negative results[11]. Serological tests that detect anti-*H pylori* IgG antibodies are non-invasive, less expensive, not influenced by sampling error, and less likely to be confounded by suppression of *H pylori* infection by colloidal bismuth, proton pump inhibitors, or antibiotics[12]. Serological tests are widely used[13] but they cannot differentiate a current infection from a past exposure[10]. Performance of serological tests depends on the antigen preparation used[12,14], and as *H pylori* strains differ among geographic locations, local validation of the test is necessary[13,14]. A recent development in *H pylori* diagnosis is a commercial immunochromatographic test (ICT) and an immunoblot test covering the current infection marker CIM. CIM is an antigenic protein synthesized by recombinant DNA technology. It is homologous to a conserved secreted protein of *H pylori*. According to its manufacturer (Genelabs Diagnostics, Singapore), presence of anti-CIM IgG antibody is highly predictive for active *H pylori* infection. If so, it should be helpful for diagnosis of *H pylori* infection where facility for endoscopy is not available. Several studies have found the immunoblot test Helico Blot 2.0, its newer version Helico Blot 2.1, and ICT kit Assure® *H pylori* Rapid Test, all of which are able to detect anti-CIM antibodies, effective for diagnosis of *H pylori* infection in adults and children[15-20]. Bangladesh is a developing country with a high prevalence of *H pylori* infection and peptic ulcer[21,22]. Different tests have been evaluated for diagnosis of *H pylori* infection in Bangladesh[23-26]. Two studies involved in-house immunoblot assays[25,26]. To the best of our knowledge standardized commercial immunoblot or ICT tests with CIM have not been evaluated in Bangladesh. The aim of this study was to evaluate the performance of three commercially available serological tests based on three methods to find a reliable serological test for non-invasive diagnosis of *H pylori* infection in adult dyspeptic patients: ELISA (AccuBind™, ELISA, Monobind, USA), ICT (Assure®, *H pylori* Rapid Test, Genelabs Diagnostics, Singapore), and immunoblot (Helico Blot 2.1, Genelabs Diagnostics, Singapore). ICT and immunoblot assays cover CIM. The performance of ICT and immunoblot tests was evaluated separately with and without CIM to see whether CIM improves performance of these tests.

MATERIALS AND METHODS

Patient selection

Consecutive adult dyspeptic patients attending the Department of Gastrointestinal, Hepatobiliary and Pancreatic Diseases (GHPD) of Bangladesh Institute of Research and Rehabilitation in Diabetes, Endocrine and Metabolic Disorders (BIRDEM) for diagnostic endoscopy during June 2004 to January 2005 were selected. Informed consent was obtained from each patient before endoscopy, and sample collection and approval of the Ethical Review Committee of BIRDEM was taken prior to initiation of the project work. Patients who underwent partial or complete gastrectomy, or those with a prior *H pylori* eradication therapy, or those who were treated with any antibiotics, colloidal bismuth compounds, proton pump inhibitors, or H2 receptor blocker within the last four weeks were excluded.

Endoscopy and gastric biopsy

Endoscopy was done with an Olympus EVIS 160 video endoscope (Olympus Optical Company, Japan) after an overnight fast. Six gastric biopsies (three from antrum and three from corpus) were taken from each patient.

Collection of serum

After endoscopy 3 mL of venous blood was collected from each patient. Serum was separated after 1 h and kept at -70℃ until serological tests were performed.

Culture

Two gastric biopsy specimens, one from the antrum and one from the corpus, were taken up into Stuart's transport media. Cooled samples were transported to the *H pylori* Laboratory of Laboratory Sciences Division of International Centre for Diarrhoeal Diseases Research, Bangladesh (ICDDR,B) within 3-4 h where culture was done as described previously[27]. Positive cultures were identified by colony and Gram stain morphology and positive catalase, oxidase, and urease tests.

Rapid urease test (RUT)

Two gastric biopsy specimens, one from the antrum and one from the corpus, were taken up in Christensen's urea agar media (pH adjusted at 7.0) in screw-capped bottles. A change of color from yellow to pink by any specimen within 2 h was considered as positive.

Histology

Two gastric biopsy specimens, one from the antrum and one from the corpus, were fixed in 10% formalin in separate containers and were sent to the Histopathology Laboratory of Ibrahim Medical College. Samples were embedded in paraffin wax, cut at 5 μm thickness and were stained by modified Giemsa and hematoxylin & eosin (HE) dye. *H pylori* was identified from its characteristic appearance and distribution. The histopathologist (Nasim Ahmed) was unaware of patients' clinical conditions and other test results.

'Gold standard' definition of H pylori infection

As there is no single 'gold standard' test for *H pylori*, an operational 'gold standard' definition of *H pylori* infection was used. The definition was as follows: Patients with positive culture result were considered as infected. In the case of a negative culture, patients positive by both RUT and histology were considered as infected. Patients negative by all three gastric biopsy specimen based tests were considered as non-infected. Patients negative by culture and positive by either RUT or histology were considered as indeterminate[16,17].

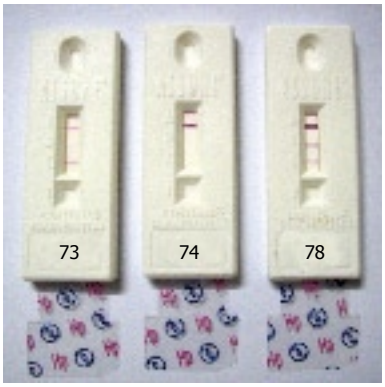

Figure 1 Photograph of serum ICT by Assure® *H pylori* Rapid Test. Left: ICT positive; Middle: Negative; Right: ICT with CIM positive (73, 74, and 78: Patients' identification numbers).

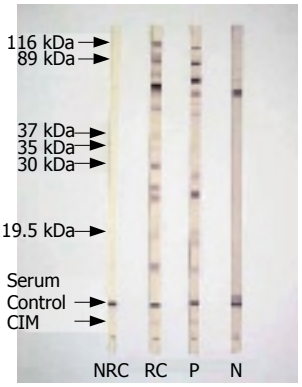

Figure 2 Photograph of serum Immunoblot test by Helico Blot 2.1. kDa: kilo Dalton; CIM: Current infection marker; NRC: Non-reactive control; RC: Reactive control; P: Positive Immunoblot with CIM; N: Negative.

ELISA

ELISA test for anti-*H pylori* IgG antibody was performed using a commercial test kit, AccuBind™ ELISA (Monobind, USA), according to instructions of the manufacturer.

ICT

ICT test was performed by the commercial test kit Assure® *H pylori* Rapid Test (Genelabs Diagnostics, Singapore) according to the instructions of the manufacturer. When control (A) and test line (C) were visible the ICT test was regarded positive, when control (A), test (C), and CIM line (B) were visible it was regarded ICT with CIM positive. When only control line (A) was visible, the test was regarded negative (Figure 1). When control line (A) was absent or control line (A) and CIM line (B) present but test line (C) absent the test was regarded to be invalid.

Immunoblot

Immunoblot test was done using the commercial kit Helico Blot 2.1 (Genelabs Diagnostics, Singapore). Helico Blot 2.1 consists of a Western Blot made from bacterial lysate of *H pylori* strain ATCC 49503 and a recombinant antigen called CIM[18]. The test strip contains *H pylori* antigens with molecular weights of 116 kDa (CagA), 89 kDa (VacA), 37 kDa, 35 kDa, 30 kDa (Urease A), and 19.5 kDa as separate lines. CIM is located at the bottom of the strip as an independent band. The test was done and interpreted according to instructions of the manufacturer (Figure 2). The manufacturer's recommended criteria for determining *H pylori* positivity by Helico Blot 2.1 was as follows: (1) 116 kDa (CagA) positive, where CagA has to be present with at least one of the following bands - 89 kDa (VacA), 37 kDa, 35 kDa, 30 kDa (UreA), or 19.5 kDa, or with CIM, (2) presence of any one band at 89 kDa, 37 kDa, or 35 kDa, with or without CIM, (3) presence of both 30 kDa and 19.5 kDa band with or without CIM.

ELISA, ICT, and immunoblot tests were carried out at the Immunology Laboratory of the Department of Immunology of BIRDEM.

Calculation of performance

Samples from 62 patients who were infected and 21 patients who were non-infected according to 'gold standard' definition were subjected to serological testing. Eight patients were indeterminate and excluded. Results of serological tests were plotted against *H pylori* infection status, and sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy with 95% confidence interval were calculated using standard formula.

RESULTS

Patients' characteristics

A total of 82 patients were included in the study. They were aged between 18 to 75 years with a mean age of 47.6 years and standard deviation 14.0 years. Patients' characteristics are shown in Table 1.

H pylori positivity by different tests

Of the 82 patients, 53 (64.6%) were culture positive, 40 (48.8%) were rapid urease test positive, 31 (37.8%) were histology positive, 71 (86.5%) were ELISA positive, 59 (71.9%) were ICT positive, 56 (68.2%) were ICT with CIM positive, 64 (78.0%) were immunoblot positive, and 62 (75.6%) were immunoblot with CIM positive.

Performance of serological tests

Sensitivity, specificity, PPV, NPV, and accuracy of serological tests were calculated from data presented in Table 2, and the calculated performance is shown in Table 3. ELISA was very sensitive but its specificity was low. Sensitivity and NPV of ICT were lower but specificity, PPV, and accuracy were much higher than ELISA. CIM decreased sensitivity of ICT slightly but increased its specificity, PPV, and accuracy. Sensitivity of immunoblot was higher than ELISA or ICT. Its specificity was higher than ELISA and same as ICT. Its PPV, NPV, and accuracy were much higher than ELISA and ICT. CIM increased specificity, PPV, NPV, and accuracy of immunoblot without altering its sensitivity (Table 3).

DISCUSSION

Since its discovery many tests have been designed for diagnosis of *H pylori*[12]. But no test is accurate enough to be the 'gold standard'[10]. Serological tests are widely used for non-invasive diagnosis[13] but a positive serological test does not mean active infection[10]. To find a reliable non-invasive test for *H pylori*, we evaluated commercially available conventional ELISA, and new ICT and immunoblot assays covering the recombinant CIM.

Table 1 Characteristics of selected patients (n = 82)

Characteristics	n	Percentage
Age group (yr)		
≤ 30	11	13.4
31-40	15	18.3

Duodenitis	8	9.8
Peptic ulcer	25	30.5
Gastric carcinoma	4	4.8
Reflux esophagitis	1	1.2

Table 2 Comparison of serological tests with *H pylori* infection (n = 82)

Test	*H pylori* infection[1]	
	Infected (n = 61) n (%)[2]	Non-infected (n = 21) n (%)[2]
ELISA		
Positive (n = 71)	59 (83.0)	12 (17.0)
Negative (n = 11)	2 (18.2)	9 (81.8)
ICT		
Positive (n = 59)	55 (93.2)	4 (6.8)
Negative (n = 23)	6 (26.1)	17 (73.9)
ICT with CIM		
Positive (n = 56)	54 (96.4)	2 (3.6)
Negative (n = 26)	7 (26.9)	19 (73.1)
Immunoblot		
Positive (n = 64)	60 (93.8)	4 (6.2)
Negative (n = 18)	1 (5.6)	17 (94.4)
Immunoblot with CIM		
Positive (n = 62)	60 (96.8)	2 (3.2)
Negative (n = 20)	1 (5.0)	19 (95.0)

[1]Infected: Culture positive or culture negative but both RUT and histology positive; non-infected: All three tests negative; [2]Percentages are over row total.

The commercial ELISA that we evaluated was very sensitive but less specific (Table 3). Performance of the ELISA kit varies in different populations. Laheij *et al* reviewed a range of sensitivity of 57%-100% and a range of specificity of 31%-100% for different commercial kits in different populations[28]. A study in the Netherlands evaluated eight commercial ELISA tests and found sensitivities of 93%-98% and specificities of 95%-98%[29]. Using a further commercial kit, a study from Bangladesh found sensitivity, specificity, PPV, and NPV of 100%, 13.6%, 54.8%, and 100%, respectively[24].

Performance of ICT with CIM evaluated in this study was better than two other commercial ICT kits evaluated in Chinese patients[30] and similar to another commercial ICT kit evaluated in African-American, Caucasian, and Asian population with ^{13}C urea breath test as the 'gold standard'[31]. Its performance in our study was lower than a study that evaluated this kit in Thai children[19] and similar to a study that evaluated this kit in Portuguese children[20].

Performance of immunoblot with CIM in our study was similar to reports that evaluated the same kit in adult French population[16] and Portuguese children of different age groups[17]. Its specificity was lower in our study than a study in Japanese and American population[18]. Lepper *et al* compared different immunoblot kits and found sensitivity, specificity, PPV, and NPV 62.8%-95.9%, 85.7%-100.0%, 97.2%-100.0%, and 37.7%-82.4%, respectively[32].

Among the serological tests evaluated, immunoblot with CIM had the highest sensitivity, specificity, PPV, NPV, and accuracy (Table 3). It thus may be useful for non-invasive diagnosis of *H pylori* infection. Though conventional ELISA was highly sensitive it may not be reliable for diagnostic purpose in these patients due to its low specificity. Immunoblot is costly, takes longer time, and requires laboratory set-up and a trained staff. Though ELISA is cheaper than immunoblot, it also requires laboratory set-up and a trained staff. ICT with CIM had sensitivity and NPV lower than immunoblot or ELISA, but its specificity, PPV, and accuracy were higher than ELISA. Considering sensitivity, specificity, PPV, and accuracy, ICT with CIM yielded good performance (Table 3). ICT is a rapid test, easy to carry out, and can be done at the physician's chamber or in the field level where well-equipped laboratory and trained staff is not available.

In conclusion, immunoblot with CIM had the best performance. Though the sensitivity of ICT with CIM was slightly lower, due to its high specificity and accuracy it would be a more reliable diagnostic tool than conventional ELISA. As ICT with CIM has good performance and it is cheap, easy and rapid, it may be useful for non-invasive diagnosis of *H pylori* infection in adult dyspeptic patients of Bangladesh.

We wish to thank Genelabs Diagnostics, Singapore, for kindly providing Assure® *H pylori* Rapid test and Helico Blot 2.1 test kits free of cost.

COMMENTS

Background

A reliable non-invasive test for *H pylori* is essential in clinical practice. Commercial serological tests based on enzyme linked immunosorbent assay (ELISA), immunochromatographic test (ICT) and immunoblot are widely used. But they are unable to distinguish between active infection and a previous contact. Gastric biopsy based tests can indicate active infection but they are inconvenient for the patients and not available everywhere. A recent development is commercial ICT and immunoblot tests with CIM that may indicate active *H pylori* infection. In this study we evaluated performance of commercial ELISA without CIM and ICT and immunoblot with CIM for pre-treatment diagnosis of *H pylori* infection.

Research frontiers

CIM is an antigenic protein synthesized by recombinant DNA technology.

Table 3 Performance of serological tests

Test	Performance (95% Confidence interval) in percentage				
	Sensitivity	Specificity	PPV[1]	NPV[2]	Accuracy
ELISA	96.7 (88.6-99.4)	42.8 (21.8-65.9)	83.1 (72.3-90.9)	81.8 (48.2-97.7)	82.9 (73.0-90.3)
ICT	90.1 (79.8-96.3)	80.9 (58.0-94.5)	93.2 (83.5-98.1)	73.9 (51.5-89.7)	87.8 (78.7-93.9)
ICT with CIM	88.5 (77.7-95.2)	90.4 (69.6-98.8)	96.4 (87.6-99.5)	73.0 (52.2-88.4)	89.0 (80.1-94.8)
Immunoblot	98.3 (91.2-99.9)	80.9 (58.0-94.5)	93.7 (84.7-98.2)	94.4 (72.7-99.8)	93.9 (86.3-97.9)
Immunoblot with CIM	98.3 (91.2-99.9)	90.4 (69.6-98.8)	96.7 (88.8-99.6)	95.0 (75.1-99.8)	96.3 (89.6-99.2)

[1]PPV: Positive predictive value; [2]NPV: Negative predictive value.

According to its manufacturer, presence of anti-CIM IgG antibodies indicates active *H pylori* infection. It is interesting because usually active infection cannot be diagnosed from serum IgG response to an organism.

Innovations and breakthroughs

Though the commercial kits used in this study may not represent the methods, from this study we can see both ICT and immunoblot with CIM have better performance than conventional ELISA evaluated, and CIM improves performance of both ICT and immunoblot kits. We can also see that performance of CIM varies depending on the method in which it is used. It performed better in immunoblot than in ICT.

Applications

This study will facilitate diagnosis of *H pylori* infection.

Peer review

In this clinical report, Dr. Rahman *et al* evaluated the performance of serological tests with current infection marker and ELISA for the non-invasive diagnosis of *H pylori* infection. Informative results were obtained from their study which could benefit other physicians. Therefore, this study is of importance.

Abstract

AIM: To analyze the Hepatitis C virus (HCV) genotype distribution and transmission risk factors in a population of unselected patients in Luxembourg.

METHODS: Epidemiological information (gender, age and transmission risks) were collected from 802 patients newly diagnosed for hepatitis C and living in Luxembourg, among whom 228 patients referred from prison. Genotyping using 5'noncoding (5'NC) sequencing was performed. We compared categorical data using the Fisher's exact *F*-test and odds ratios (OR) were calculated for evaluating association of HCV genotype and risk factors.

RESULTS: The sex ratio was predominantly male (2.2) and individuals aged less than 40 years represented 49.6% of the population. Genotype 1 was predominant (53.4%) followed by genotype 3 (33%). Among risk factors, intravenous drug usage (IVDU) was the most frequently reported (71.4%) followed by medical-related transmission (17.6%) including haemophilia, transfusion recipients and other nosocomial reasons. Genotype 3 was significantly associated to IVDU (OR = 4.84, $P < 0.0001$) whereas genotype 1 was significantly associated with a medical procedure (OR = 2.42, $P < 0.001$). The HCV genotype distribution from inmate patients differed significantly from the rest of the population (Chi-square test with four degrees of freedom, $P < 0.0001$) with a higher frequency of genotype 3 (46.5% *vs* 27.5%) and a lower frequency of genotype 1 and 4 (44.7% *vs* 56.8% and 5.3% *vs* 9.6%, respectively). IVDU was nearly exclusively reported as a risk factor in prison.

CONCLUSION: We report the first description of the HCV genotype distribution in Luxembourg. The repartition is similar to other European countries, with one of the highest European prevalence rates of genotype 3 (33%). Since serology screening became available in 1991, IVDU remains the most common way of HCV transmission in Luxembourg.

INTRODUCTION

Hepatitis C virus (HCV) is a major cause of chronic liver disease and hepatocellular carcinoma worldwide. The most recent WHO estimate of the prevalence of HCV infection is 2%, ranging from 0.6% to 2.3% in North America, Northern and Western Europe and Australia[1]. HCV has a high molecular diversity worldwide. A recent international standardization of the nomenclature proposed a classification into 6 genotypes (1 to 6) and more than 70 subtypes (termed a, b, c, d,…)[2].

Although genotypes 1, 2 and 3 are responsible for more than 90% of the infections in North and South America, Europe and Japan[3], prevalence and distribution peculiarities of HCV genotypes are linked to geographical location and mode of transmission[4]. Three broad patterns

of genotype distribution have been identified to date[4]. One pattern, characterized by high genetic diversity, involves geographically discrete areas where HCV has been endemic for a long time such as West Africa with types 1 and 2, Central Africa with type 4, and Asia with types 3 and 6. Another pattern involves areas with a few subtypes circulating in specific risk groups, e.g. subtype 3a in drug addicts. The third pattern involves areas where a single subtype is present, such as in Egypt with subtype 4a and South Africa with subtype 5a.

Beside epidemiological considerations, HCV genotyping also has a clinical impact. Treatment for chronic hepatitis C includes standard or pegylated (PEG) interferon-α (IFN-α) in combination with ribavirin[5,6]. HCV genotype is a strong independent predictor of sustained virological response, which is defined by an undetectable HCV RNA level 24 wk after the end of treatment[7]. Genotypes 2 and 3 are significantly associated with a better therapeutic response, and knowledge on the HCV genotype is now used for tailoring therapeutic modalities: the duration of treatment is longer (48 wk) for genotype 1, 4, 5 and 6 than for genotype 2 and 3 (24 wk).

Up to now, no population-based study has been undertaken in Luxembourg and the precise prevalence rate of HCV infected people is not known. The National Council of Communicable Diseases in 2006 estimated the prevalence of HCV infection to be between 0.5% and 1%. Therefore, between 2250 and 4500 individuals might be infected in Luxembourg. Identifying risk factors is important to plan preventive activities and is necessary to target the higher risk population. HCV spreads in humans mainly through parenteral transmission. While uncontrolled medical procedures or transfusion were major causes of HCV transmission before serology screening was available, intravenous drug use (IVDU) has now become the predominant source of infections in developed countries[8]. Transmission of HCV also occurs through occupational, perinatal or sexual exposures, albeit with much less efficiency. Practices such as non-injection drug use (particularly via sharing of non-injecting drug equipment), tattooing or body piercing have also emerged as additional causes of HCV transmission[9].

The relation between incarceration and the high transmission of blood-borne viruses has been known for several years[10-12]. The HCV prevalence rate in prison is higher than in the general population because of the concentration of injecting drug users. HCV screening and genotyping was introduced in prisons of Luxembourg in 2002. These patients are usually referred to the Centre Hospitalier of Luxembourg (CHL) for medical treatment.

Because of its impact on patient management and treatment, we made a retrospective analysis of the HCV genotype distribution in a population of 802 unselected patients living in Luxembourg using 5'noncoding (5' NC) sequencing. We also analysed transmission risks related to infection. As almost 30% of the patients live in prison, we distinguished this population in our analysis. Our survey gives the first estimation of the distribution of HCV genotypes amongst unselected HCV patients in Luxembourg.

MATERIALS AND METHODS

Patients

Genotype and epidemiological information (gender and age) was collected from 802 patients newly diagnosed for hepatitis C and referred to the Centre Hospitalier of Luxembourg from 1991 to 2006. Among the overall population of 802 patients, a subset of 228 (28.4%) referred from prison (Centre Pénitentiaire of Luxembourg or CPL) has been distinguished from the remaining 574 patients, the latter being considered as general population. Among the 802 patients, 60 (7.6%) were also chronically co-infected with HIV-1 and 7 (0.9%) with HBV. Information regarding risk factors [intravenous drug usage (IVDU), medical reason (including transfusion and haemophilia or other nosocomial reasons), sexual transmission, mother-to-child transmission, occupational exposure, tattooing and body piercing] was available for 437 of the 802 patients (54.5%), and for 103 of the 228 patients (45.2%) of the CPL.

Methods

Detection of sera specific antibodies to HCV (ABBOTT Axsym HCV v3.0, Abbott, Louvain-la-Neuve, Belgium), antigen/antibodies to HIV (HIV Combo v4.0, Abbott) and surface HBV antigens (Ag HBs v2.0, Abbott) was performed with commercial kits. HCV viral load was determined with the quantitative COBAS AMPLICOR® HCV test v2.0 (Roche Diagnostics, Mannheim, Germany). Only samples with a viral load superior to 20 000 IU/mL were considered for genotyping. PCR products generated with the COBAS AMPLICOR® HCV test were collected for subsequent genotyping using the TRUGENE® HCV 5' NC methodology (Bayer s.a., Brussels, Belgium).

HCV genotype incidence

The incidence of HCV genotypes in our cohort has been calculated, per year, as the proportion of the number of new included genotypes divided by the total number of new included genotypes. Results are expressed as percentages. Patient inclusion in our cohort is based on the date of the first viral load analysis. Determination of the incidence has been performed from 1999 to 2006.

Statistical analysis

The Fisher's exact test was used to compare categorical data such as genotype, age and gender. Odds ratios were calculated for evaluating association of HCV genotype with risk factor. Stratified analyses were conducted using the Mantel-Haenszel estimator for adjusting odds ratios with age and gender.

RESULTS

Gender and age

The sex ratio (SR) of the 802 investigated patients was predominantly male (2.2) (Table 1). Individuals aged less than 40 years, for whom a more recent time point of infection could be assumed, represented 49.6% of all patients. The population of HCV-infected patients at CPL was almost exclusively male (94.7%, SR = 17.8), with a

significantly larger proportion of younger patients (77.6% patients aged less than 40 years, compared to 38.5% in the rest of the population, $P < 0.0001$).

Genotype distribution

Genotype 1 was predominant, with 428 patients (53.4%), followed by genotype 3 (33%), 4 (8.3%), 2 (4.6%) and 5 (0.6%) (Table 1). Among patients co-infected with HIV or HBV, the genotype distribution was similar to the overall population (data not shown). Regarding prison inmates (Table 1), genotypes 1 and 3 were predominant (44.7% and 46.5%, respectively), followed by genotype 4 (5.3%) and 2 (3.5%). The HCV genotype distribution in patients from CPL differed significantly (Chi-square test with four degrees of freedom, $P < 0.0001$), with a higher frequency of genotype 3 (46.5% *vs* 27.7%) and a lower frequency of genotype 1 and 4 (44.7% *vs* 56.8% and 5.7% *vs* 9.58%, respectively).

As shown in Figure 1, the analysis of HCV genotype incidence has been performed from 1999 to 2006. The rate of genotypes 1, 2, 3 and 4 was relatively constant over time, only isolated cases of genotype 5 were observed during this 7 years period.

Distribution of genotypes according to gender and age

As described in Figure 2A, genotype 3 was significantly more frequent in males (69.1% *vs* 30.9%, $P < 0.0001$), while genotypes 2 and 5 were more frequent in females ($P = 0.047$ and $P = 0.0027$, respectively). The frequency of genotypes 1 and 4 were independent of gender and age (Figure 2A and B).

Genotype 3 was associated significantly with patients aged less than 40 years (60% *vs* 44.5% for patients aged more than 40 years, $P < 0.0001$) (Figure 2B). Conversely, Genotype 2 was significantly associated with patients aged more than 40 years (73% *vs* 49.3%, $P = 0.0064$).

Transmission risk factors

Among risk factors (Table 2), IVDU was the most frequently reported (71.4%), followed by medical-related transmission such as transfusion, haemophilia or other nosocomial reasons (17.6%, 77/437, of whom 68 cases through transfusion). 35 patients (4.7%) reported infection through sexual contact (homosexual, bisexual and heterosexual transmission). Other routes of transmission were also reported such as non-injection drug use (5 cases), occupational exposure (3 cases), tattooing (3 cases), mother-to-child transmission (1 case) and body piercing (1 case). IVDU was nearly exclusively reported as a risk factor for CPL (94.2% of the reported cases) (Table 2). Four inmate patients reported infection through medical procedure, one after sniffing and another one after tattooing. In the general population, the predominant source of infection remained IVDU (64.3%).

Association of the genotypes and transmission risk factors

Odds ratios were determined for evaluating association of HCV genotype with risk factor in the overall population (Table 3). The odds ratio for association of IVDU and HCV genotype 3 was 4.84 (95% confidence intervals, 2.86 to 8.25; $P < 0.0001$). When adjusted for age and gender, IVDU patients were still significantly more likely than other patients to be infected with HCV genotype 3 (Mantel-Haenszel adjusted odds ratio = 4.54, 95% confidence intervals, 1.60 to 12.7; $P = 0.0043$). Conversely, IVDUs were at lower risk of being infected with HCV genotype 1 whether or not they were adjusted for age and gender.

The odds ratio for association of medical procedure and HCV genotype 1 was 2.42 (95% confidence intervals, 1.43 to 4.05; $P = 0.0008$). When adjusted for age and gender, patients reporting infection through a medical procedure were still 2.34 as likely as other patients for contracting HCV genotype 1 (Mantel-Haenszel adjusted odds ratio = 2.34, 95% confidence intervals, 1.35 to 4.06; $P = 0.0025$).

Finally, when adjusted for population type, IVDU patients were still significantly more likely than other patients to be infected with HCV genotype 3 (Table 3).

Table 1 Patient details and HCV genotype distribution in the overall population, in the Centre Pénitentiaire of Luxembourg (CPL) and in the general population

Variable	Overall	CPL	General
n (%)	802 (100)	228 (28.4)	574 (71.6)
Sex ratio	2.2	17.8	1.44
Age (% less than 40 yr)	49.6	77.6	38.5
Genotype			
1	428 (53.4)	102 (44.7)	326 (56.8)
2	38 (4.7)	8 (3.5)	30 (5.2)
3	264 (33)	106 (46.5)	158 (27.5)
4	67 (8.3)	12 (5.3)	55 (9.6)
5	5 (0.6)	0	5 (0.9)

DISCUSSION

We report here the first description of HCV molecular epidemiology in Luxembourg. This survey has been realized with a relatively confident case number of 802 unselected patients seen in routine practice, irrespective of their clinical background. The genotype distribution is similar to other European countries with yet one of the highest European prevalence of genotype 3 (33%). Injecting drug use has currently become the principal cause of HCV transmission.

HCV genotypes 1 and 3 were the most prevalent in our patients. In Europe, there have been dynamic changes over time in the prevalence of the different HCV subtypes. The prevalence of HCV 1b and 2 have decreased, while HCV 1a , 3a and 4 have increased[13-15]. Regarding incidence of genotypes in Luxembourg, we did not notice significant changes in the emergence of genotype 3 from 1999 to 2006. The genotype proportion, as observed in our cohort, has been relatively constant overtime. No new genotype has been massively introduced in Luxembourg despite strong progression of the immigration flow from 1985 to 2001. One reason might be that the majority of immigrants are coming from the European Union. Because of the few data available, we were not able to find

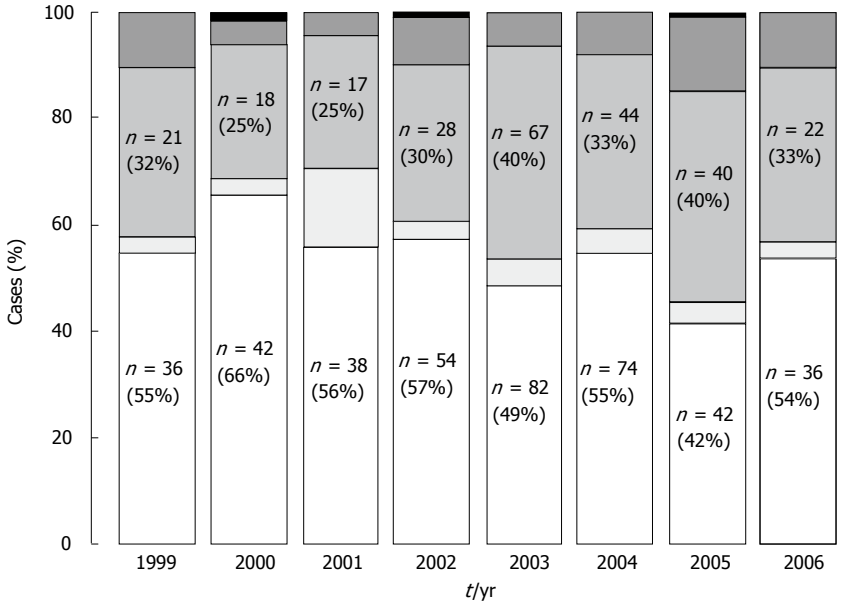

Figure 1 HCV genotype incidence from 1999 to 2006. The genotypes are indicated in the bars by different shades of grey, representing from bottom to top, genotypes 1, 2, 3, 4 and 5. Number of cases and percentages are mentioned for genotype 1 and 3. No significant changes in genotype distribution over time have been observed during this 7 years period.

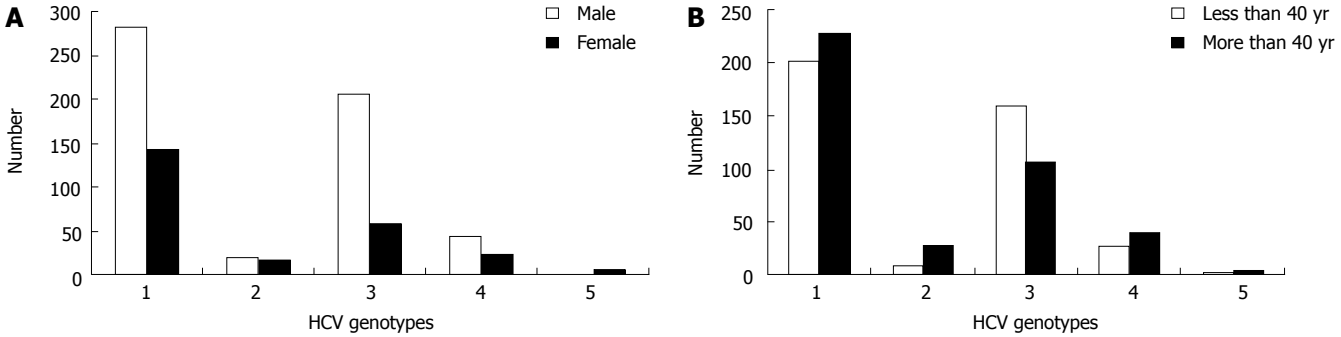

Figure 2 Distribution of HCV genotypes. **A**: Distribution of HCV genotypes in patients according to gender. Genotype 3 is more frequent in male ($P < 0.0001$), genotype 2 and genotype 5 are more frequent in female ($P = 0.047$ and $P = 0.0027$ respectively); **B**: Distribution of HCV genotypes in patients according to age. Genotype 3 is associated to patients < 40 yr ($P < 0.0001$). Genotype 2 is associated to patients > 40 yr ($P = 0.0064$).

any association of genotypes and demographic data for the patients. As for the several genotype 4 viruses identified in our cohort, we can assume that their introduction could be related to African immigration[16]. One limitation of our study is the methodology used for genotyping: the TRUGENE® HCV 5'NC method indeed does not allow for easy discrimination between HCV subtypes. Therefore, the apparent invariability of HCV molecular epidemiology may mask significant variability in terms of subtypes.

The high prevalence of HCV genotype 3 in our population is attributed to IVDU in the overall population and in particular in the incarcerated population. In similar studies from neighbouring countries, distribution rate of genotype 3 varied from 13.42% in Germany[14], 22%-26.3% in France[13,17] to 29.3% in the Netherlands[18]. In prison, injecting drug use is the most commonly reported risk factor[19-21]. In the rest of the population, the prevalence of genotype 3 is 27.5%. This rate is comparable with other studies[13,14,17,18] in which inclusion of prisoners was not specified. Other molecular epidemiology studies have shown that HCV subtype 3a is significantly associated with transmission through injecting drug use in industrialized countries[22-24] and explain the prevalence of subtype 3a in many North and South American and European countries. HCV subtype 3a originates from Asia and has spread widely among injecting drug users[25,26]. Mechanisms of subtype 3a transmission remain poorly defined. Genotype 3 was not associated with a high level of HCV RNA as compared to the others genotypes in our cohort. Nevertheless, the relative homogeneity of NS5B sequences of injecting drug users from France, South America, Australia and California have indicated that HCV subtype 3a has been transmitted from a common origin through a unique worldwide epidemic among the drug user communities[27]. In this study, the authors reported region-specific HCV 3a variants suggesting local transmission among intravenous drug users from the same geographical area. Therefore, the intrinsic characteristics of the transmission network of IVDU (unsafe injecting practices, drug preparation materials, needle or syringe exchange) together with the importance of the social context of drug injections may explain the efficiency of HCV genotype 3 transmission in Luxembourg.

Our study shows that the main risk factor for infection by genotype 3 is IVDU whereas the main risk factor for infection by genotype 1 is medical-related transmission.

Table 2 Transmission risk factors in the overall population, in the Centre Pénitentiaire of Luxembourg (CPL) and in the general population

Risk factor	Overall	CPL	General
n (%)	437 (100)	104 (23.8)	333 (76.2)
IVDU	312 (71.4)	98 (94.2)	214 (64.3)
Medical-related	77 (17.6)	4 (3.8)	73 (21.9)
Sexual	35 (8)	0	35 (10.5)
Other	13 (3)	2 (2)	11 (3.3)

Table 3 Associations between genotype and transmission risk factors for the overall population

Risk factor	IVDU	Medical-related
Odds ratios (OR)		
Genotype 1	0.50 (0.33 to 0.77, $P = 0.0016$)	2.42 (1.43 to 4.05, $P = 0.0008$)
Genotype 3	4.84 (2.86 to 8.25, $P < 0.0001$)	0.17 (0.09 to 0.35, $P < 0.0001$)
MH adjusted OR[1]		
Genotype 1	0.49 (0.30 to 0.84, $P = 0.0084$)	2.34 (1.35 to 4.06, $P = 0.0025$)
Genotype 3	4.54 (1.60 to 12.70, $P = 0.0043$)	0.21 (0.07 to 0.64, $P = 0.0064$)
MH adjusted OR[2]		
Genotype 1	0.55 (0.35 to 0.85, $P = 0.0081$)	2.24 (1.31 to 3.84, $P = 0.0033$)
Genotype 3	4.28 (2.42 to 7.57, $P < 0.0001$)	0.20 (0.09 to 0.42, $P < 0.0001$)

Odds ratio with confidence intervals 95%. [1]Mantel-Haenszel odds ratio adjusted for age and gender; [2]Mantel-Haenszel odds ratio adjusted for population type.

These data are in agreement with other studies in Europe[15,28-30]. Serology screening is routinely performed since the early 1990s and recent infections are more likely attributable to other risk factors rather than medical-related transmission (blood, blood transfusion or surgery). Interestingly, 4 patients from the general population reported infections through tattooing and body piercing. This finding reemphasizes the fact that practices using sharps in personal services are potential sources of spread of infection.

The age of infected individuals may be a direct variable for the genotype distribution. Nevertheless, our data did not show that patients infected by genotype 1 were older than 40 years. This would mean other routes of infection by genotype 1 such as IVDU. Since serology screening is available, IVDU remains the more common route of HCV transmission in Luxembourg. Genotype 3 is significantly associated with males aged less than 40 years which is consistent with the profile of drug injecting users. The male/female ratio of the IVDU population is 3:1 and the mean age of indexed intravenous drug users is about 30 years in Luxembourg. We found that genotype 2 is significantly associated with patients aged more than 40 years. These results may indicate that the type 2 infections were not recent but probably linked to some distant event like blood transfusion. Unfortunately, we could not find any correlation of this genotype with a route of transmission. In addition, we have also shown that genotype 2 and 5 are more frequent in female. To our knowledge, this association has never been reported and merits further investigation.

Incarcerated individuals have high rates of infectious diseases. The concentration of a marginal population in prison has necessitated systematic and rigorous screening for hepatitis B and hepatitis C. Consistent with similar studies worldwide, the prevalence of HCV in prison inmates in CPL (23.7% in 2006) is higher than in the general population suggesting probable transmission in prisons through intravenous drug use and unsafe sexual behaviour[12,21,31,32]. In CPL, the prevalence rate of HCV has increased from 19.7 % in 2001 to 23.7% in 2006. This increase is consistent with the continuous increase of infection rate in the IVDU population observed in Luxembourg as well as other European countries[33]. HCV among injecting drug users is one of the European Union's major public health problems. In 2004, statistics from our laboratory provided the proportion of 74% reported HCV infections with acute and chronic HCV infections in the IVDU population. Therefore, prisons provide a good location to offer HCV screening and treatment and to prevent future transmission. Sharing injection equipment as well as tattooing and piercing during incarceration among intravenous drug users are more frequent than in the community[34]. In this respect, a syringe/needle exchange program was implemented in CPL in 2005. Exchange is conducted through the medical unit and requires an initial evaluation by the prison doctors.

In conclusion, our study gives the first estimation of the genotype distribution in Luxembourg. Like in other countries from the European Union, IVDU is the driving force for HCV transmission in Luxembourg. Therefore, increased prevention efforts targeted to drug injection are urgently needed to curb the epidemic. HCV genotype distribution has to be followed in the future in order to improve the biological tests for diagnosis and the development of preventive procedures among IVDU or the prison population. As the genotype distribution has a direct impact on medical practice and treatment, it may require new therapeutic strategies in particular with regards to vaccine development.

COMMENTS

Background

Hepatitis C virus (HCV) has a high molecular diversity worldwide and is classified into 6 genotypes. Prevalence and distribution peculiarities of HCV genotypes are linked to geographical location and mode of transmission.

Research frontiers

Data on genotypic distribution from various areas are crucial to understand the spreading mode of HCV. Identifying risk factors is important to plan preventive activities and is necessary to target the higher risk population.

Innovations and breakthroughs

This report describes for the first time the HCV genotype distribution in Luxembourg. The repartition is similar to other European countries, with one of the highest European prevalence rates of genotype 3 (33%) which is associated to intravenous drug usage.

Applications

HCV among injecting drug users is one of the European Union's major public health problems. Mechanisms of genotype 3 transmission remain poorly defined and need to be investigated to explain the efficiency of HCV genotype 3 transmission in Luxembourg.

Peer review

This article is interesting. The authors have provided valuable information about epidemiological aspects of HCV genotype distribution in Luxembourg with nice connections to the similar studies worldwide.

Abstract

AIM: To compare the effects of treatment of *H pylori*-infected individuals with the effects of treatment of individuals as well as all *H pylori*-infected family members.

METHODS: *H pylori*-positive patients with similar demographic specifications were prospectively randomized with respect to treatment, with a triple regimen of either patients and all *H pylori*-positive family members living together (group Ⅰ) or patients only (group Ⅱ). Nine months after treatment, all patients were assessed for *H pylori* positivity.

RESULTS: There were 70 *H pylori*-positive patients in each group; patients in groups Ⅰ and Ⅱ lived with 175 and 190 *H pylori*-positive relatives, respectively. Age, sex and *H pylori* positivity rate were similar in both groups of relatives. Nine months after 14 d standard triple therapy, *H pylori* positivity was 7.1% in group Ⅰ patients and 38.6% in group Ⅱ patients [$P < 0.01$, OR = 8.61 95% confidence interval (CI): 2.91-22.84].

CONCLUSION: The present results indicate bad environmental hygienic conditions and close intra-familial relationships are important in *H pylori* contamination. These findings indicate all family members of *H pylori*-positive individuals should be assessed for *H pylori* positivity, particularly in developing countries where *H pylori* prevalence is high; they also suggest patients, their spouses and all *H pylori*-positive family members of *H pylori*-positive individuals should be treated for *H pylori* infection.

Key words: *H pylori*; Gastric adenocarcinoma; Intra-familial infections; Gastric lymphoma; Peptic ulcer disease; Non-ulcer dyspepsia

INTRODUCTION

Almost half of the world's population is infected with *H pylori*[1-3]. The incidence of infection has been reported to be as high as 80% in less developed countries and as low as 20% in Western countries[3]. *H pylori* is involved in the etiology of gastric mucosa-associated lymphoid tissue (MALT)[4] lymphoma and gastric adenocarcinoma, leading the World Health Organization to declare *H pylori* a first degree carcinogen[5-9]. Less invasive diagnostic methods have enabled easier and earlier diagnosis and more widespread use of treatments.

Although *H pylori* infection is thought to occur in childhood, its method of transmission is not known[2,10-13]. Research in highly infected populations has shown the importance of intra-familial infections, bad hygiene and lower socio-economical status in the spread of *H pylori*[2,3,12,14]. However, these routes suggest infection is preventable.

The total time to exposure to *H pylori* has been found to correlate with the development of gastric adenocarcinoma[5-7,15], making diagnosis and eradication of the bacteria crucial. Furthermore, re-infection with *H pylori* may occur after eradication, owing to exposure to untreated individuals, indicating treatment focused on the patient alone will not result in total eradication. We sought to determine whether treatment of *H pylori* should be extended to *H pylori*-positive family members dwelling with the patient, or whether treatment of the patient alone would be sufficient. Treatment extended to the family would theoretically decrease the risk of re-infection.

MATERIALS AND METHODS

A two-armed prospective, randomized study group was composed of *H pylori*-positive patients in our gastroscopy unit with similar socio-economic status and family backgrounds. The sampling number was calculated based on a 20% statistically significant difference (lower limit

Table 1 Relationship of family members to patients

	Sex	Group 1 *n* (%)	Group 2 *n* (%)	*P* value
Spouse	Male	31 (51.7)	31 (51.7)	0.92[2]
	Female	29 (48.3)	30 (49.2)	
1. Child	Male	20 (42.6)	26 (45.6)	0.87[2]
	Female	27 (57.5)	33 (54.4)	
2. Child	Male	18 (66.7)	13 (50.0)	0.29[2]
	Female	9 (33.3)	13 (50.0)	
Mother	Female	16 (59.3)	18 (60.0)	0.99[1]
Father	Male	11 (40.8)	12 (40.0)	
Siblings	Male	3 (50.0)	3 (42.9)	0.99[1]
	Female	3 (50.0)	4 (57.2)	
Grandchild	Male	3 (60.0)	3 (42.9)	0.99[1]
	Female	5 (40.0)	4 (57.1)	

[1]Fisher's absolute χ^2; [2]Yates corrected χ^2.

8%) with type I error = 0.05, type Ⅱ error = 0.02 and power 0.80. The minimum sample size was 67 subjects. Due to possible dropouts, 70 *H pylori*-positive subjects who lived with family members were included in each arm of the study. All patients and family members provided written informed consent. Using a random number table subjects were divided into two equal groups. All family members dwelling with each subject (namely, spouses, children, brothers, sisters, fathers and mothers) were screened for *H pylori* positivity. *H pylori* antigen testing of stools was used to screen children under the age of 14 years and endoscopic biopsy and/or stool test was used to screen all other subjects. In both groups, the ages of the patients as well as their family, sex, relationship to the patient, endoscopic findings, type of *H pylori* screening and positivity were recorded.

Patients randomized to Group I and all *H pylori*-positive family members were treated for *H pylori* infection; patients randomized to Group Ⅱ only were treated, but their family members were not. Patients and their adult relatives received standard triple therapy of clarithromycin, amoxicillin and proton pump inhibitors. Treatment of children and infants was individually handled by pediatric gastroenterologists. Nine months after treatment, all patients in both groups and treated family members in group I were assessed for *H pylori*-positivity using stool antigen tests.

Statistical analysis

A Student's *t* was used for continuous and normative variables, the χ^2 test was used for categorical variables and the McNemar test was used to assess before and after *H pylori* positivity rates. Statistical significance was defined as $P < 0.05$, both directions.

RESULTS

Each group consisted of 70 patients, and there were no drop-outs. The two groups were similar in age and sex ratio ($P = 0.86$, $\chi^2 = 0.02$). The 70 patients in Group I lived with 175 relatives, whereas the 70 patients in Group Ⅱ lived with 190 relatives, all of whom were screened for *H pylori* (Table 1). The number of family members, relationship to each patient, age and sex distribution did not differ significantly between the two groups ($P > 0.05$).

Table 2 Pre-treatment *H pylori* positivity rates in relatives of both groups

[1]Fisher's exact test.

The most common endoscopic findings in both groups of patients were pan-gastritis and antral gastritis. Diagnostic variables did not differ significantly between the two groups ($P > 0.05$).

Ninety-five family members underwent gastroscopy and biopsy, whereas the remaining family members were assayed for *H pylori* by the stool *H pylori* antigen test. Family members in the two groups who underwent gastroscopy did not differ in number, relationship to patient, gender, age and pathological findings ($P > 0.05$). Of the 95 family members who underwent endoscopy, 75 (78.9%) were spouses. Sixty-three (66.3%) family members presented with various pathologies on gastroscopy, the most common pathologies being antral gastritis (40.9%), pan-gastritis (26.4%) and hiatal hernia (17.7%). The remaining 32 family members had normal gastroscopic findings.

The highest prevalence of *H pylori* positivity was among the spouses of *H pylori*-positive individuals, followed by parents and siblings. Children and grandchildren were among the least likely to be infected. Pretreatment *H pylori* positivity was statistically similar in both groups ($P > 0.05$, Table 2).

All *H pylori*-positive patients in both groups, and *H pylori*-positive family members in Group I, were treated with standard triple therapy for 14 d. Nine months later, 7.1% of Group I patients were *H pylori*-positive, compared with 38.6% of Group Ⅱ patients [$P < 0.001$, OR = 8.61, confidence interval (CI): 2.91-22.84; Table 3].

Table 3 ***H pylori*** **positivity rates after 9 mo in relatives of both groups**

Group 1		Group 2	
	n **(%)**		***n*** **(%)**
Positive	5 (7.2)	Positive	27 (38.6)
Negative	65 (92.8)	Negative	43 (61.4)
Total	70 (100)	Total	70 (100)

$P < 0.001$, OR = 8.61, 95% CI: 2.91-22.84.

Four of the 5 Group I patients (80%) and 24 of the 27 Group Ⅱ patients (88.9%) who remained *H pylori* positive 9 months after initial therapy had *H pylori*-positive spouses at follow-up. The rate of spousal infection in Group Ⅱ was higher at follow-up than before treatment (78.7% *vs* 88.9%). The 65 initially *H pylori*-positive relatives in Group Ⅰ were all *H pylori*-negative at follow-up.

A total of 15 children aged 5 years or less (8 in Group Ⅰ and 7 in Group Ⅱ) were included in the study. Four infants, 2 in each group (26.7%), were initially *H pylori* positive; all in group Ⅰ were *H pylori* negative 9 months after treatment.

DISCUSSION

Although the exact environmental factors contributing to *H pylori* infection are unclear, bodily fluids and personal contact may be key factors in the spread of disease among family members[10-12,14,16]. Due to improved hygiene and environmental conditions, *H pylori* prevalence has decreased significantly in Western countries, but it remains high in developing countries such as Turkey[2,7,17,18]. Lower socio-economic status resulting in more personal contact (for example, sharing sleeping facilities), crowded families and sharing of common living areas with compromised hygiene can also lead to increased dissemination of *H pylori*[2,12,19,20].

Patients who are diagnosed *H pylori* positive should be unquestionably treated. The recommended treatment regimen for *H pylori* eradication consists of 7 to 14 d of triple therapy with clarithromycin, amoxicillin and a proton pump inhibitor[21-24]. Theoretically, in areas and socio-economic groups where intra-familial infection is highly probable, treatment of the patient only may not prevent re-infection over the long term. The present study was designed to investigate this hypothesis.

The most important finding from this study was that statistically significant *H pylori* eradication was achieved in patients whose *H pylori*-positive family members were also treated, compared with those whose *H pylori*-positive family members were not treated, in long-term follow-up (7.1% *vs* 38.6%, group Ⅰ and Ⅱ, respectively). The rate of resistant *H pylori* infection (7.1%) was higher than expected, possibly due to other environmental, life style and hygiene issues outside the family.

H pylori is highly prevalent in the healthy partners of patients with *H pylori* infection. To decrease long-term re-infection rates, family members of *H pylori*-positive patients should be tested and, if positive, treated for *H pylori* infection. Since spouses had the highest *H pylori* positivity rates, our findings suggest that at least the spouse of an *H pylori*-positive patient should be screened and treated if positive. The prevalence of *H pylori* in children aged 5 years or less (6.7%) was also alarming, considering the long-term health problems associated with this infection.

Among the possible routes of *H pylori* infection, the fecal-oral, oro-oral and gastro-oral routes are the most probable. *H pylori* has been cultured in vomit, feces and sputum[2,3,11,12,16,25]. Although intra-familial transmission is a major factor contributing to *H pylori* infection, the relative contributions of close interpersonal contact and genetic similarity are not known[10,26-28]. Spouse-spouse transmission would appear to be an obvious source of infection in adulthood[16,29].

In areas where the risk of contamination is high, re-infection can be prevented by eradication programs[30,31]. Lifestyle changes are recommended, but they are unlikely to occur in the short term. Thus, in such areas, the re-infection rate is high due to contact with the source of *H pylori* infections. Our findings clearly show the necessity of screening and treating all *H pylori*-positive family members to eradicate the source of infection. Larger scale studies, in Turkey and in other developing countries with high *H pylori* infection rates, may determine the routes of infection and other possible methods of prevention.

COMMENTS

Background

The prevalence of *H pylori* infection is higher in developing countries due to higher rates of intra-familial transmission. *H pylori* infection is the causative factor of some gastrointestinal symptoms, such as non-ulcer dyspepsia, peptic ulcer and gastric adenocarcinoma. The whole family besides the *H pylori* positive patient should be given medical treatment.

Research frontiers

Our findings show that new research performed in different population groups are needed to support a new approach to family members in the case of positivity in one family member.

Innovations and breakthroughs

The necessity of medical treatment aiming to eradicate *H pylori* infection in all siblings, especially the spouse, as well as the patient.

Applications

Routine eradication of *H pylori* infection in the whole family and decreasing the prevalence of peptic ulcer disease, mucosa-associated lymphoid tissue lymphoma and gastric cancer.

Peer review

The paper is interesting and the design is correct.

Abstract

AIM: To determine the relationship between pre-operative hypoalbuminemia and the development of complications following rectal cancer surgery, as well as postoperative bowel function and hospital stay.

METHODS: The medical records of 244 patients undergoing elective oncological resection for rectal adenocarcinoma at Siriraj Hospital during 2003 and 2006 were reviewed. The patients had pre-operative serum albumin assessment. Albumin less than 35 g/L was recognized as hypoalbuminemia. Postoperative outcomes, including mortality, complications, time to first bowel movement, time to first defecation, time to resumption of normal diet and length of hospital stay, were analyzed.

RESULTS: The patients were 139 males (57%) and 105 females (43%) with mean age of 62 years. Fifty-six patients (23%) had hypoalbuminemia. Hypoalbuminemic patients had a significantly larger tumor size and lower body mass index compared with non-hypoalbuminemic patients (5.5 *vs* 4.3 cm; $P < 0.001$ and 21.9 *vs* 23.2 kg/m^2; $P = 0.02$, respectively). Thirty day postoperative mortality was 1.2%. Overall complication rate was 25%. Hypoalbuminemic patients had a significantly higher rate of postoperative complications (37.5% *vs* 21.3%; $P = 0.014$). In univariate analysis, hypoalbuminemia and ASA status were two risk factors for postoperative complications. In multivariate analysis, hypoalbuminemia was the only significant risk factor (odds ratio 2.22, 95% CI 1.17-4.23; $P < 0.015$). Hospitalization in hypoalbuminemic patients was significantly longer than that in non-hypoalbuminemic patients (13 *vs* 10 d, $P = 0.034$), but the parameters of postoperative bowel function were not significantly different between the two groups.

CONCLUSION: Pre-operative hypoalbuminemia is an independent risk factor for postoperative complications following rectal cancer surgery.

INTRODUCTION

Malnutrition is a common problem in gastrointestinal cancer patients that adversely affects surgical outcomes[1-3]. There are many tools to assess patients' nutritional status. Serum albumin is a good and simple predictor of surgical risk and has a close correlation with the degree of malnutrition[4]. Hypoalbuminemia is a predictor of delayed recovery of bowel function and is strongly associated with postoperative complications after right hemicolectomy for right-sided colon cancer[5], or following other major gastrointestinal surgery[6-8]. However, there is little information regarding the effect of hypoalbuminemia on the development of postoperative complications after rectal cancer surgery, and the results remain controversial[9-11].

The aims of this study were to determine the relationship between pre-operative hypoalbuminemia and the development of complications following rectal cancer surgery, and to evaluate the effect of hypoalbuminemia on postoperative bowel function and hospital stay.

MATERIALS AND METHODS

Patients and data collection

After obtaining approval from the Institutional Ethics Committee, we carried out a retrospective analysis of patients undergoing elective oncological resection for rectal adenocarcinoma between January 2003 and December 2006 at the Department of Surgery, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand. Rectal cancer was defined as a tumor with the lower edge located within 15 cm of the anal verge, as measured by rigid sigmoidoscopy. Patients were excluded if they had pelvic exenteration, or had had operations for recurrent tumors or acute complicated conditions such as colonic obstruction.

Each patient had a pre-operative serum albumin assessment. Serum albumin less than 35 g/L was recognized as hypoalbuminemia. Every patient underwent pre-operative mechanical bowel preparation. Standard oncological resection of the rectum was performed by either a laparoscopic or open approach. In case of sphincter-saving operation, colorectal anastomosis was performed without colonic pouch formation or protective stoma. In the case of abdominoperineal resection, primary closure of the perineal wound was performed after a pelvic drain had been placed. A nasogastric tube was inserted at the surgeon's discretion.

Routine postoperative care was provided to each patient. Time to first bowel movement (passing flatus) was recorded by nursing staffs. The patients were allowed to have oral fluid if passing flatus. Resumption of a normal diet was decided by surgeons with patients' compliance. Patients were discharged from the hospital if the drain was removed and they had no fever, good appetite and good ambulation. All patients were scheduled for follow-up at 30 d postoperatively.

Data recorded included patient demographic, tumor characteristics, operative details and postoperative outcomes. Patient-related factors included age, gender, American Society of Anesthesiologist (ASA) status, obesity (body mass index over 30 kg/m^2), anemia (pre-operative hematocrit less than 30%), hypoalbuminemia and neoadjuvant chemoradiation. Tumor-related factors included location, size and TNM stage. Operation-related factors included the type of operation and requirement of blood transfusion. Postoperative outcomes, including mortality, complications, time to first bowel movement, time to first defecation, time to resumption of normal diet and length of hospital stay, were analyzed.

Statistical analysis

All data were prepared and analyzed using Statistical Package for the Social Sciences program version 11.0 for Windows (SPSS®, SPSS Inc., Chicago, IL). The Kolmogorov-Smirnov test was used to test for a normal pattern of data distribution. Unpaired *t*-tests were used to compare data between the two groups when they showed a normal distribution pattern. The Mann-Whitney *U* test was used when this was not the case. Pearson's Chi-square test and Fisher's exact test were used when the data were quantitative. Stepwise regression analysis was used for multivariate analysis in order to determine any confounding factors. A *P*-value of less than 0.05 was considered statistically significant.

Table 1 Demographic data on non-hypoalbuminemic and hypoalbuminemic patients

	Non-hypoalbuminemic (*n* = 188)	Hypoalbuminemic (*n* = 56)	*P* value
Age (yr)	61.4 ± 11.9	64.5 ± 13.5	0.100
Male	111 (59)	28 (50)	0.230
BMI (kg/m^2)	23.2 ± 3.8	21.9 ± 3.4[a]	0.021
Tumor size (cm)	4.3 ± 1.7	5.5 ± 2.3[b]	< 0.001
TNM stage			0.310
Ⅰ	48 (26)	8 (14)	
Ⅱ	43 (23)	14 (25)	
Ⅲ	94 (50)	34 (61)	
Ⅳ	3 (1)	0 (0)	
Type of anesthesia			0.860
GA alone	73 (39)	21 (38)	
GA + EB	115 (61)	35 (62)	

GA: General anesthesia; EB: Epidural block. Values were given as number (percentage) or mean ± SD. [a]$P \leqslant 0.05$, [b]$P \leqslant 0.01$ *vs* Non-hypoalbuminemic.

RESULTS

Two hundred and forty four patients were studied. There were 139 males (57%) and 105 females (43%) with a mean age of 62 years (range 23-87). Fifty-six patients (23%) had hypoalbuminemia. Patients with hypoalbuminemia had a significantly larger size of the tumors and lower body mass index (BMI), compared with those without hypoalbuminemia (5.5 *vs* 4.3 cm; $P < 0.001$ and 21.9 *vs* 23.2 kg/m^2; $P = 0.02$, respectively). Gender and tumor staging were not statistically different between the two groups (Table 1).

Thirty day postoperative mortality was 1.2% (3 patients died; one massive pelvic hemorrhage, one perioperative myocardial infarction, and one anastomotic leakage with respiratory failure). Overall complication rate was 25%. Infectious complications were diagnosed in 59 patients (24%); 42 surgical site infections, 13 anastomotic leakage, 2 urinary tract infection and 2 pneumonia. Two patients (1%) developed noninfectious complications during hospitalization (one acute respiratory failure and one perioperative myocardial infarction). Hypoalbuminemic patients had a significantly higher rate of postoperative complication (37.5% *vs* 21.3%, $P = 0.014$).

Univariate analysis revealed hypoalbuminemia and ASA status as two risk factors for the development of postoperative complications (Table 2). In multivariate analysis, hypoalbuminemia was the only significant risk factor for postoperative complications (odds ratio 2.22, 95% CI 1.17-4.23; $P < 0.015$). Length of hospital stay in hypoalbuminemic patients was significantly longer than that in non-hypoalbuminemic patients (13.0 *vs* 10.4 d, $P = 0.034$), but time to first bowel movement, time to first defecation and time to resumption of normal diet were not significantly different between the two groups (Table 3).

DISCUSSION

Patients with rectal cancer are at risk of malnutrition due to cancer-induced higher metabolism, dietary intake reduction, and cancer cachexia[12-14]. Tumor necrosis factor-alpha is considered to be the main mediator of cancer cachexia

Table 2 The relationship between the clinical characteristics of the patients and the development of postoperative complications analyzed using a univariate model

Variables	Category	*n*	Complication rate, *n* (%)	*P* value

[a]$P \leqslant 0.05$.

as it is responsible for different metabolic alterations and leads to impairment of hepatic protein synthesis[15]. Cancer patients also have increased whole protein turnover and subsequent body nitrogen loss[16]. Albumin has a long half-life of 20 d, so that metabolic effects on its concentration reflect prolonged malnourishment, as in cancer patients. Hypoalbuminemia is widely accepted to be a good indicator for malnutrition in many national cancer studies[7,11,17]. It is remarkable that tumor size, but not the stage, is relevant to hypoalbuminemia. The clear explanation of this association remains unknown. It is possible that large tumors cause more gastrointestinal symptoms, leading to poor intake and partial gut obstruction.

In this present study, univariate analysis showed that hypoalbuminemia and ASA status were significant risk factors for postoperative complications following rectal cancer surgery. However, hypoalbuminemia was the only independent factor for postoperative morbidity after multivariate analysis. Our finding is consistent with those of two large population-based prospective studies in France[7] and the United States[11]. Gibbs *et al*[11] reported that a decrease in serum albumin from concentrations greater than 46 g/L to less than 21 g/L was associated with an exponential increase in mortality rates from less than 1% to 29% and in morbidity rates from 10% to 65% following non-cardiac surgery. Moreover, hypoalbuminemia was a better predictor of some types of morbidity, especially sepsis and major infections. Ryan *et al*[18] showed decreased serum albumin concentration on the first postoperative day was also an independent predictor of poor surgical outcome following gastrointestinal cancer surgery.

Table 3 Univariate analysis of clinical outcomes (mean ± SD)

	Non-hypoalbuminemic (*n* = 188)	Hypoalbuminemic (*n* = 56)	*P* value
Postoperative complication (%)	21.3	37.5[a]	0.014
Time to first bowel movement (h)	2.3 ± 1.4	2.7 ± 1.6	0.090
Time to first defecation (d)	4.5 ± 1.7	4.6 ± 2.5	0.730
Time to resumption of normal diet (d)	4.8 ± 2.7	5.4 ± 2.9	0.180
Length of hospital stay (d)	10.4 ± 8.0	13.0 ± 8.9[a]	0.034

[a]$P \leqslant 0.05$.

Hypoalbuminemia was associated with poor tissue healing, decreased collagen synthesis in the surgical wounds or at the anastomosis[19-21], and impairment of immune responses, such as macrophage activation and granuloma formation[22,23]. Therefore, in hypoalbuminemic patients, wound infection, remote infections such as pneumonia, and anastomotic leakage, were commonly found.

According to the present study, a tendency towards delayed recovery of postoperative bowel function has also been found in hypoalbuminemic patients, although this effect did not reach statistical significance. This may be because such patients develop more complications, including intra-abdominal sepsis, and because lower serum albumin causes swelling and edema of the intestine[24], resulting in paralytic ileus. Clearly, there would be other factors contributing to postoperative bowel function, such as narcotics administration and electrolyte status[25-27]. Prolonged hospitalization in hypoalbuminemic patients may be the result of higher rates of postoperative complication and delayed bowel recovery.

With regard to the treatment of pre-existing hypoalbuminemia, no published studies have been able to demonstrate any advantage of albumin infusion on morbidity and mortality[28,29]. This may be because of insufficient albumin replacement or increased leakage of synthetic albumin into the extravascular spaces. However, a recent prospective randomized study reported the administration of a supplemented diet before and after surgery was beneficial to outcomes in malnourished patients with gastrointestinal cancer[30].

In conclusion, pre-operative hypoalbuminemia is an independent risk factor for postoperative complications following rectal cancer surgery. Hypoalbuminemic patients also have a nonstatistically significant tendency to delayed recovery of postoperative bowel function. Low serum albumin may be used as a simple and low-cost prognostic tool to predict the risk of adverse surgical outcomes.

ACKNOWLEDGMENTS

The authors are grateful to Mr. Suthipol Udompunturak (Clinical Epidemiology Unit, Office for Research and Development, Faculty of Medicine Siriraj Hospital, Mahidol University) for his excellent support in statistical analysis.

COMMENTS

Background

Malnutrition is a common problem in gastrointestinal cancer patients that adversely affects surgical outcomes. There are many tools to assess patients' nutritional status. Serum albumin is a good and simple predictor of surgical risk and has a close correlation with the degree of malnutrition. Hypoalbuminemia is a predictor of delayed recovery of bowel function and is strongly associated with postoperative complications in colon cancer surgery.

Research frontiers

There is little information regarding the effect of hypoalbuminemia on the development of postoperative complications after rectal cancer surgery, and the results remain controversial.

Innovations and breakthroughs

The present study clearly demonstrates hypoalbuminemia is associated with an increased rate of complications, and has a negative impact on postoperative recovery following rectal cancer surgery.

Applications

Pre-operative assessment of patients with rectal cancer may routinely include serum albumin levels. Patients with pre-operative hypoalbuminemia should be informed about the higher rate of complications after rectal cancer surgery. Every effort to improve patients' pre-operative malnourishment without delayed surgical treatment should be encouraged. Further research might focus on the effect of hypoalbuminemia on long-term surgical outcomes and cancer survival.

Terminology

Pre-operative hypoalbuminemia is an independent risk factor for postoperative complications following rectal cancer surgery.

Peer review

This is an interesting paper showing that hypoalbuminemia will have an impact on postoperative recovery and complication. It is well known that malnourished patients do worse than those with a good nutrition status in the postoperative course. It is well written, the data is excellent and references timely.

Abstract

AIM: To investigate the P wave dispersion as a non-invasive marker of intra-atrial conduction disturbances in patients with Wilson's disease.

METHODS: We compared Wilson's disease patients (n = 18) with age matched healthy subjects (n = 15) as controls. The diagnosis was based on clinical symptoms, laboratory tests (ceruloplasmin, urinary and hepatic copper concentrations). P wave dispersion, a measurement of the heterogeneity of atrial depolarization, was measured as the difference between the duration of the longest and the shortest P-waves in 12 lead electrocardiography.

RESULTS: All the patients were asymptomatic on cardiological examination and have sinusal rhythm in electrocardiography. Left ventricular and left atrial diameters, left ventricular ejection fraction and left ventricular mass index were similar in both groups. The Wilson's disease patients had a significantly higher P wave dispersion compared with the controls (44.7 ± 5.8 *vs* 25.7 ± 2.5, P < 0.01).

CONCLUSION: There was an increase in P wave dispersion in cardiologically asymptomatic Wilson's disease patients which probably represents an early stage of cardiac involvement.

INTRODUCTION

The persistence of P-wave duration is an accepted indicator of a disturbance in the interatrial conduction[1,2]. P wave dispersion (PWD) constitutes an important contribution to the field of noninvasive electrocardiology and is defined as the difference between the longest and shortest P wave duration recorded from surface electrocardiogram (ECG) leads. PWD has been thoroughly examined in a number of diseases including hypertension, coronary artery disease, coronary artery bypass surgery, and paroxysmal atrial fibrillation (AF)[3-7]. Therefore, it has been suggested that PWD can be used to diagnose patients with a high risk of AF[8-13]. Wilson's disease is a severe genetic metabolic disorder, which is associated with intracellular copper overload and multiple organ involvement. Cardiac manifestations in Wilson's disease include arrhythmias, cardiomyopathy, cardiac death, and autonomic dysfunction[14]. To our knowledge, no previous studies have compared P wave duration and PWD of Wilson's disease patients to healthy controls. The aim of this study was to investigate the PWD as a non-invasive marker of intra-atrial conduction disturbance in patients with Wilson's disease.

MATERIALS AND METHODS

Subjects

Eighteen cardiologically asymptomatic patients with Wilson's disease and 15 healthy subjects were included in the study. We excluded patients with previous acute myocardial infarction, thyroid dysfunction, uncontrolled diabetes mellitus, chronic renal disease, valvular heart disease, cardiomyopathy, chronic obstructive pulmonary disease, systemic

or pulmonary hypertension and alcohol abuse. All of the patients were in sinus rhythm and none were taking medications like antiarrhythmics, tricyclic antidepressants, antihistaminic and antipsychotics. The diagnosis of Wilson's disease was established based on the clinical manifestations, family history of neuropsychiatric manifestations, jaundice, and premature death attributable to Wilson's disease, evidence of Kayser-Fleischer rings on slit lamp examination, low serum copper and ceruloplasmin assay, and increased 24-h urinary excretion of copper. Radiologic investigations included a cranial computed tomography (CT) scan with or without iodinated contrast and/or magnetic resonance imaging (MRI) and X-rays of long bones, pelvis, and chest to evaluate for skeletal abnormalities[15]. The diagnosis is confirmed by the liver biopsy and quantitative liver copper assay[16].

Echocardiographic measurements

In all subjects, two-dimensional, M-mode pulsed and color flow Doppler echocardiographic examinations (Vivid 7 Dimension, GE, Horten, Norway) were performed by the same examiner. Internal left ventricular (LV) end-diastolic and end-systolic diameters and interventricular septal and posterior wall thickness at end-diastole, and left atrial dimension were measured from parasternal long axis window in M-mode echocardiography[17]. The ejection fraction of the left ventricle was obtained using modified Simpson's method[18].

Conventional Doppler echocardiography

Early diastolic wave peak velocity (E), late diastolic wave peak velocity (A), early to late velocities (E/A) ratio and E wave deceleration time of left ventricular inflow velocities were measured by pulse wave Doppler placing the sample volume in-between the tips of the mitral valve leaflets in apical four-chamber window. Isovolumic relaxation time (IVRT) was obtained from the apical-five-chamber view by placing the sample volume between the tip of the mitral anterior leaflet and left ventricle outflow tract.

Electrocardiography

Twelve-lead ECGs of all patients at rest, with 1 mV/cm amplitude and 50 mm/s rate, were obtained. The P-wave onset was defined as the first atrial deflection from the isoelectric line and the offset was the return of the atrial signal to baseline. Patients whose measurements could be performed in at least 8 derivations were included in the study. In all patients, derivations were excluded if the beginning or the ending of the P wave could not be clearly identified.

Maximum P wave duration (P_{max}) is defined as the longest and minimum P wave duration (P_{min}) is defined as the shortest P wave duration. PWD defined as difference between P_{max} and P_{min}. All the measurements were repeated three times and average values were calculated for each of electrocardiographic parameter. All of the measurements were performed using the same experienced investigators blind to the subject's clinical status. Intra-observer and inter-observer variability was assessed in a random sample of 15 ECG (10 from patients who have Wilson's disease and 5 from control subjects) by a second investigator. The study was approved by the local ethics committee of our institution, and all patients gave written informed consent.

Table 1 The demographic and clinical characteristics of the study population

	Wilson's patients (n = 18)	Control group (n = 15)	P
Age (yr)	49 ± 26	44 ± 11	0.424
Left atrium (cm)	3.1 ± 0.4	3.2 ± 0.6	0.240
Left ventricular end diastolic diameter (cm)	4.5 ± 0.3	4.7 ± 0.4	0.316
Left ventricular end systolic diameter (cm)	2.8 ± 0.3	3.0 ± 0.3	0.320
Interventricular septum thickness (cm)	0.8 ± 0.1	0.9 ± 0.1	0.435
Posterior wall thickness (cm)	0.9 ± 0.1	0.8 ± 0.1	0.349
Ejection fraction (%)	66.6 ± 6.6	64.6 ± 6.1	0.335
E (cm/s)	93.7 ± 14.3	88.2 ± 12.5	0.323
A (cm/s)	68.8 ± 14.6	75.2 ± 25.1	0.303
E/A	1.3 ± 0.4	0.8 ± 0.2	0.090
EDT (ms)	177 ± 53.2	167 ± 34.2	0.213
IVRT (ms)	68.4 ± 12.0	72.2 ± 22.4	0.275
P wave dispersion (ms)	44.7 ± 5.8	25.7 ± 2.5	0.007
Minimum P wave duration (ms)	65 ± 12	74 ± 10	0.239
Maximum P wave duration (ms)	109 ± 8	102 ± 10	0.031

Statistical analysis

The SPSS statistical software package (11.0) was used to perform all statistical calculations. Number of sample is expressed as n, continuous variables were expressed as mean ± SD, and categorical variables as percentages. Pearson correlations were used to compare the association between indexes. Categorical variables were compared by Pearson Chi-square test. Comparisons of continuous variables between two groups have been performed by means of unpaired Student's t test. For all tests, $P < 0.05$ was considered statistically significant.

RESULTS

The study included 18 patients (age: 49 ± 26 years, range 10-49 years) with Wilson's disease and 15 healthy controls (age: 44 ± 11 years, range 25-50 years). In Wilson's disease patients, the patients' age at the diagnosis was 42 ± 18 years (range, 2.5-42 years), the mean disease duration was 9.6 ± 7 years (range, 1-29 years). Serum copper, ceruloplasmin and urinary copper excretion were 1670 ± 800 μg/L, 300 ± 120 mg/L, 167 ± 80 μg/dL, respectively. Aspartate aminotransferase (AST), alanine aminotransferase (ALT), hemoglobin, total cholesterol, low density lipoprotein, high density lipoprotein, and triglyceride levels were 53.2 ± 42 IU/L, 45.6 ± 35 IU/L, 138 ± 18 mg/L, 131 ± 37 mg/dL, 50 ± 31 mg/dL, 66 ± 23 mg/dL, and 95 ± 16 mg/dL respectively.

The demographic and clinical characteristics of the Wilson's patients and the controls were shown in Table 1. There was no significant difference between the two groups in regard to gender, age, body mass index (BMI), heart rate or blood pressure. All Wilson's patients were treated with copper chelation therapy. Seventeen of the

Wilson's patients have been treated with D -penisillamine (0.75-1 g p.o., t.i.d.) and one patient was switched to trientine (750 mg, p.o. t.i.d.) of because drug related thrombocytopenia.

P_{max} and PWD were significantly higher in Wilson's patients than controls. However, there was no significant difference in P_{min} between the two groups (Table 1; A = Transmitral late diastolic peak velocity, E = Transmitral early diastolic peak velocity, EDT = E wave deceleration time, IVRT = Isovolumic relaxation time).

PWD was considerably correlated only with the age at diagnosis (r = -0.606, P = 0.048), serum copper level (r = -0.801, P = 0.009) and mitral E wave velocity (r = -0.724, P = 0.027) in patients with Wilson's disease. We were not able to find any statistically significant correlation between PWD and other clinical and echocardiographic parameters.

The intra-observer standard deviation for P_{max}, P_{min} and PWD were 10.3, 6.5, and 11 ms, respectively, and the corresponding intra-observer variability was 0.05%, 0.06%, and 0.2%, respectively. The inter-observer standard deviation for P_{max}, P_{min} and PWD were 10.5, 11.0, and 13.9 ms, respectively, and the corresponding inter-observer variability was 0.04%, 0.2%, and 0.5%, respectively. The percentage difference in P_{max}, P_{min} and PWD were 2.4%, 3.5%, and 6% within observers and 3%, 5.2%, and 5.9% between observers.

DISCUSSION

Wilson's disease is a severe genetic multisystem disorder associated with intracellular copper storage. Wilson's disease is characterized by an inadequate excretion of absorbed dietary copper *via* bile resulting in the accumulation of toxic amounts of copper in the liver and other organs. It is inherited as a rare autosomal recessive condition with an incidence of one in 40 000 live births in most populations, and with a calculated carrier frequency in the general population of one in 90[19,20]. Copper is an essential micronutrient but ionic copper is toxic. The toxic effects are thought to be mediated by the generation of reactive oxygen free radical species in Wilson's patients[19]. Cardiac involvement in Wilson's disease has rarely been recognized. Cardiac manifestations in Wilson's disease include arrhythmias, cardiomyopathy, cardiac death, and autonomic dysfunction[14,19]. Electrocardiographic abnormalities occurred in 34 percent, including left ventricular hypertrophy, biventricular hypertrophy, early re-polarization, ST depression and T inversion, premature atrial or ventricular contractions, atrial fibrillation, sino-atrial block and Mobitz type 1 atrio-ventricular block. Asymptomatic orthostatic hypotension, an abnormal response to the Valsalva maneuver, ventricular fibrillation, and dilated cardiomyopathy can be occurred in Wilson's disease[14].

The major pathological findings of the myocardium in Wilson's disease included the presence of interstitial and replacement myocardial fibrosis, intra-myocardial small vessel disease, focal myocarditis and cardiac hypertrophy, AV nodal degeneration and occlusive atherosclerosis in early ages[21]. These alterations are non-specific, but they are similar to those observed in other cardiomyopathies[21,22]. Their existence in a relatively young group of patients without other significant etiology for the development of heart disease, suggests the possibility of a direct relationship between Wilson's disease and cardiac degeneration[20].

Therefore, we investigated PWD in patients with Wilson's disease patients. PWD is a new electrocardiographic marker that has been associated with the heterogeneous and discontinuous propagation of sinus impulses. Furthermore, the correlation between the presence of intra-atrial conduction abnormalities and the induction of paroxysmal AF has been well documented[8-10,23,24]. Prolonged P wave duration and increased PWD have been reported to carry an increased risk for atrial fibrillation[5-7,17]. Therefore, it has been suggested that PWD can be used to diagnose patients with a high risk for developing AF[8-10]. To our knowledge, this is the first study that has investigated the P wave duration and PWD changes in Wilson's disease patients. This study shows that P_{max} and PWD are higher in Wilson's disease patients than control subjects. These results suggest that Wilson's disease patients may be under the risk for atrial fibrillation. This study also shows that PWD was correlated with mitral E wave velocity which is a parameter of left ventricular diastolic function and the serum copper level. Previously, it has been reported that PWD was associated with diastolic dysfunction and coronary artery disease[3,25,26].

The precise mechanism of arrhythmias seen in Wilson's disease patients is not clear. A recent report Kaduk *et al*[27] describing cardiomyopathy in Wilson's disease, suggested that mitochondrial alterations were the consequence of the accumulation of myocardial copper These alterations are non-specific, and in some cases of limited severity; however, in previous study it was concluded that cardiac degeneration might have contributed to the death of Wilson's patients[27]. PWD may well be associated with autonomic dysfunction in patients with Wilson's disease[27]. Dysautonomia, often subclinical, is only one of the many features of Wilson's disease[28]. A central, rather than peripheral mechanism is hypothesized. Sympathetic and parasympathetic arms are affected equally. The abnormality is independent of involvement of the liver and the duration and severity of Wilson's disease[29].

Previous experiments showed that electrical remodeling of atrial myocardium could be induced by autonomic nervous transmitters and suggested that autonomic nerve activity was an important factor to promote AF episodes[30]. This study population is relatively small and therefore our results should not be extrapolated to all Wilson's patients. Further studies are necessary to investigate the frequency of atrial arrhythmias by rhythm holter in patients with Wilson's disease, who have or do not have high PWD.

Furthermore, one of the relative limitations of our study was that we could not use the method of digital recording and storing of 12-lead electrocardiograms with onscreen measurement of P waves duration which provides the most accurate method for PWD calculation[31]. Secondly, the ability of P wave duration and PWD to predict future atrial fibrillation episodes was not checked in present study, since the patients included in this work were not followed-up. But, it has been well documented previously that prolonged P wave duration and increased PWD carry

an increased risk for atrial fibrillation[8-10,23,24] and therefore, it has been suggested that PWD can be used to diagnose patients with a high risk for developing AF[8-10].

Consequently, involvement of the heart may be seen in patients with Wilson's disease even in the absence of clinical cardiac manifestations. In this study, P_{max} and PWD were found to be higher in patients with Wilson's disease than healthy control subjects. Therefore, the patients with Wilson's disease who have increased PWD should be closely followed for atrial arrhythmias.

COMMENTS

Background

Wilson's disease is a rare severe genetic metabolic disorder associated with intracellular copper overload and related complications. Cardiac manifestations in Wilson's disease include arrhythmias, cardiomyopathy, cardiac death, and autonomic dysfunction. P wave dispersion, a measurement of the heterogeneity of atrial depolarization.

Research frontiers

No previous studies have compared P wave duration and P wave dispersion (PWD) of Wilson's disease patients to healthy controls. The aim of this study was to investigate the PWD as a non-invasive marker of intra-atrial conduction disturbance in patients with Wilson's disease.

Innovations and breakthroughs

Prolonged P wave duration and increased PWD have been reported to carry an increased risk for atrial fibrillation. Therefore, it has been suggested that PWD can be used to diagnose patients with a high risk for developing AF. In previous reports researchers showed that electrical remodeling of atrial myocardium could be induced by autonomic nervous transmitters and suggested that autonomic nerve activity was an important factor to promote AF episodes. This study also shows that PWD was correlated with mitral E wave velocity which is a parameter of left ventricular diastolic function and the serum copper level. Previously, it has been reported that PWD was associated with diastolic dysfunction and coronary artery disease.

Applications

Prolonged P wave duration and increased PWD carry an increased risk for AF. Therefore, it has been suggested that PWD can be used to diagnose patients with a high risk for developing AF. This study shows that Pmax and PWD are higher in Wilson's disease patients than control subjects. These results suggest that Wilson's disease patients may be under the risk for atrial fibrillation.

Terminology

Wilson's disease is a severe genetic metabolic disorder associated with intracellular copper overload and multiple organ involvement. P wave dispersion was measured as the difference between the duration of the longest and the shortest P-waves in 12 lead electrocardiography.

Peer review

This report is original and has to be considered interesting. The authors aimed to investigate the P wave dispersion as a non-invasive marker of intra-atrial conduction disturbances in patients with Wilson's disease. This rather small but homogenous patient population showed promising results with the application of PWD at such a rare genetic disorder.

Abstract

AIM: To find out potential serum hepatocellular carcinoma (HCC)-associated proteins with low molecular weight and low abundance by SELDI-based serum protein spectra analysis, that will have much application in the diagnosis or differentiated diagnosis of HCC, as well as giving a better understanding of the mechanism of hepato-carcinogenesis.

METHODS: Total serum samples were collected with informed consent from 81 HCC patients with HBV(+)/cirrhosis(+), 36 cirrhosis patients and 43 chronic hepatitis B patients. Serum protein fingerprint profiles were first generated by selected WCX2 protein chip capture integrating with SELDI-TOF-MS, then normalized and aligned by Ciphergen SELDI Software 3.1.1 with Biomarker Wizard. Comparative analysis of the intensity of corresponding protein fingerprint peaks in normalized protein spectra, some protein peaks with significant difference between HCC and cirrhosis or chronic hepatitis B were found.

RESULTS: One hundred and twenty-eight serum protein peaks between 2000 and 30 000Da were identified under the condition of signal-to-noise > 5 and minimum threshold for cluster > 20%. Eighty-seven of these proteins were showed significant differences in intensity between HCC and cirrhosis ($P < 0.05$). Of the above differential proteins, 45 proteins had changes greater than two-fold, including 15 upregulated proteins and 30 downregulated proteins in HCC serum. Between HCC and chronic hepatitis B, 9 of 52 differential proteins ($P < 0.05$) had intensities of more than two-fold, including 2 upregulated proteins and 7 downregulated proteins in HCC serum. Between cirrhosis and chronic hepatitis B, 28 of 79 significant differential proteins ($P < 0.05$) changes greater than two-fold in intensity, including 17 upregulated proteins and 11 downregulated proteins in cirrhosis serum. For the analysis of these leading differential proteins in subtraction difference mode among three diseases, the five common downregulated proteins in HCC serum (M/Z 2870, 3941, 2688, 3165, 5483) and two common upregulated proteins (M/Z 3588, 2017) in HCC and cirrhosis serum were screened.

CONCLUSION: Because the interference of unspecific secreted proteins from hepatitis B and cirrhosis could be eliminated partly in HCC serum under subtraction difference analysis, these seven common differential proteins have the obvious advantage of specificity for evaluating the pathological state of HCC and might become novel candidate biomarkers in the diagnosis of HCC.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the third leading cause of cancer death worldwide, with the highest incidence being in east and southeast Asia and sub-Saharan Africa, and the estimated annual number of cases is > 500 000[1,2]. In recent years, an increasing incidence and mortality rate of HCC have also been observed in western industrialized countries[3,4]. Most studies on the etiology of HCC suggest that risk factors such as HBV/HCV, cirrhosis, dietary aflatoxin B1 (AFB1) intake, and alcohol abuse are responsible for almost all HCC development. Both HBV

and HCV are attributed to > 80% of HCC development worldwide[5]. In high incidence areas of China, > 90% of HCC cases are reported to have an HBV background[6]. Liver cirrhosis, regardless of its etiology, is recognized as the most powerful independent risk factor for HCC, and about 55%-85% of cases finally develop into HCC with poor prognosis[7,8]. On the other hand, the other two known risk factors (AFB1 and alcohol) only appear as synergistic factors with pre-existing chronic hepatitis or cirrhosis during liver carcinogenesis[9,10]. Although much is known about the effects of the above etiological agents on HCC development, the detailed pathological mechanisms of HCC remain to be unequivocally defined, mainly due to its complex multigene and multifactorial involvement, as well as strong associations with hepatitis or cirrhosis.

Presently, early surgical interventions, including hepatectomy or percutaneous radio frequency ablation, are still the best hope for a clinical cure of HCC. Unfortunately, many cases of HCC exhibit intrahepatic and distant metastasis at the time of diagnosis, which miss the optimal opportunity for surgical resection. This indirectly indicates no ideal tumor markers can be recommended for early detection or differential diagnosis of HCC. Thus, discovering more HCC-associated proteins and identifying a single or a set of reliable, non-invasive new biomarkers is one of the best options for improving the diagnostic efficiency of HCC.

Alteration of serum protein profiles can effectively reflect the pathological states of liver injury. It seem much more challengeable to screen specific HCC-associated proteins in serum of HCC patients with the background of HBV/HCV or cirrhosis because hepatitis and cirrhosis can also cause great changes in the serum protein profile. Moreover, separation and identification of disease-associated proteins is laborious and difficult, relying on low-technology approaches and screening strategies. While some serum tumor markers, including enzymes (GGT (gamma-glutamyl transferase), AFU (alpha-1-fucosidase), DCP (des-gamma-carboxyprothrombin), and oncofetal and glycoprotein antigens [AFP (alpha fetoprotein), AFP-L3 (alpha fetoprotein-L3), GPC3 (glypican-3)], have been widely applied to the detection of HCC, the diagnostic accuracy for HCC is still unsatisfactory, especially in early and differential diagnosis. Even though AFP is a well-known biomarker for HCC, its sensitivity has been reported at 39%-64% and its specificity as 76%-91%, it has been shown to be particularly useful in detecting HCC with non-viral etiology[11,12]. Unlike conventional serological biomarkers with high molecular weight (MW) and high abundance, a lot of uncharacterized serum proteins with low MW and low abundance, which promise to contain important disease information, have attracted much attention in the diagnosis of HCC[13,14]. A promising high-throughput proteomics approach, on-chip protein fractionation coupled to SELDI-TOF-MS (surface enhanced laser desorption ionization-time of flight-mass spectrometry), provides a novel pathway for rapid screening and identification of specific tumor markers with low MW in the proteomes of body fluids. To date, a number of single or combined SELDI spectra peaks have been successfully identified by means of this technology and used to discriminate differential diseases as disease related biomarkers[11,15,16].

In the present study, by comparative analysis of SELDI serum spectra between HCC with HBV(+)/cirrhosis(+) and cirrhosis or HBV, using Ciphergen SELDI Software 3.1.1 with Biomarker Wizard and subtraction difference analysis, some potential serum common HCC-associated proteins with low MW were discovered, which might be new candidate biomarkers for HCC diagnosis.

MATERIALS AND METHODS

Study population and sample preparation

With patient consent, serum samples were obtained from 81 HCC patients with HBV/cirrhosis from the Liver Cancer Institute of Zhongshan Hospital, Fudan University, China. All HCC patients were diagnosed according to combined clinical criteria, including imaging data and serum tumor markers, and further confirmed by histopathological analysis. Samples from 36 patients with liver cirrhosis were kindly provided by the Department of Infection of Shanghai East Hospital, Shanghai, China. Diagnosis of liver cirrhosis was mainly dependent on clinical history, physical examination, laboratory findings, ultrasonography and/or computed tomography, with or without liver biopsy. Serum samples of 43 HBV-infected patients were collected based on the presence of HBsAg (hepatitis B surface antigen), HBeAg (hepatitis B e antigen) and HBV DNA, from Shandong Provincial Hospital, China. All serum samples were separated and divided into 10-μL aliquots, then stored at -80℃ until assayed.

Ciphergen protein chip SELDI-TOF-MS analysis

Compared with other protein chips (anionic, copper mental binding and hydrophobic), the WCX2 protein chip (Ciphergen Biosystems, Fremont, CA, USA) was selected for further serum differential protein spectrum analysis because it generates the best serum profile with the largest number and resolution of protein fingerprint peaks. Serum samples were first diluted 1:2 with U9 sample buffer containing 9 mol/L urea, 2% CHAPS, 50mmol/L Tris/HCl and 1% DTT (pH 9.0, Sigma, USA). Subsequently, 108 μL WCX2 binding buffer (50 mmol/L sodium acetate, pH 4.0; Sigma) was mixed with the above samples homogeneously. One hundred microliters of diluted serum samples was then applied to each spot on pre-equilibrated WCX2 protein chips, packed in a processor for 60 min incubation with shaking. After two washes with WCX2 binding buffer and one quick rinse with HPLC grade water, 1 μL of a saturated solution of EAM sinapinic acid (Ciphergen Biosystems) in 50% acetonitrile and 0.5% trifluoroacetic acid (Sigma) was loaded on each spot and air-dried for MS detection. Mass accuracy was calibrated externally through the use of the All-In-One peptide molecular mass standard (Ciphergen Biosystems). The protein chips were read using the PBSII MS system (Ciphergen Biosystems). Each spot on protein chips was scanned with a laser intensity of 185 and a detector sensitivity of 8, and data acquisition parameters were set as 22. delta to 4. transients per to 7 ending position to 82 by SELDI Quantitation. Assessment of the reproducibility

of the SELDI system was the same as in our previous study[17]. The intra- and inter-assay CV for intensity and m/z in this SELDI system were 17.46% and 0.024%, and 17.74% and 0.0237%, respectively.

Bioinformatics and subtraction difference analysis

Protein spectra were automatically generated after all raw data were collected. All spectra were first normalized to a total ion current with an m/z of 2000 and 30 000 and then aligned by baseline subtraction, mass accuracy calibration using Ciphergen SELDI Software 3.1.1 with Biomarker Wizard. Protein peaks ranging from 2 to 30 kDa were autodetected in term of an S/N > 5 and a minimum threshold for cluster > 20%, and were further checked and labeled to minimize mismatched peaks. The m/z value within the 0.3% mass accuracy windows was defined to be identical between replicates. By comparative analysis of the intensity of corresponding protein fingerprint peaks in normalized protein profiles with Biomarker Wizard analysis, some protein fingerprint peaks between HCC and hepatitis or cirrhosis were found to be significantly different ($P < 0.05$). The *P* value represented the power of each peak in discriminating HCC from hepatitis or cirrhosis. From these, some leading differential proteins between HCC and cirrhosis or chronic hepatitis B (average intensity ration > 2 or < 0.5) can be selected for future identification. Analysis of these leading differential proteins in subtraction difference mode, common differential proteins among three diseases, which showed potential specificity and clinical significance in dictator for HCC, can be determined successfully.

RESULTS

All protein spectra were normalized and aligned under the same parameters using Ciphergen SELDI Software 3.1.1 with Biomarker Wizard, and then auto-identified protein peaks were visually examined to minimize mismatched peaks between HCC and hepatitis or cirrhosis. Under the condition of signal-to-noise > 5 and minimum threshold for cluster > 20%, the sum of 128 serum protein peaks between 2 and 30 kDa were identified.

Comparison of serum protein spectra between HCC with HBV/cirrhosis and cirrhosis

Eighty-seven of 128 protein peaks were shown to be significantly different in intensity between HCC and cirrhosis after Biomarker Wizard software analysis ($P < 0.05$). Of the above differential proteins, forty-five differential proteins had over two-fold changes, which were defined as leading differential proteins, including 15 up-regulated proteins (m/z 8696, 13 769, 13969, 28060, 8772, 23 415, 22 857, 9354, 9730, 11 702, 9422, 9406, 2143, 9195, 5058) and 30 down-regulated proteins (m/z 2688, 2870, 3246, 3450, 3493, 3654, 4178, 4965, 2546, 4160, 3165, 2530, 2026, 2361, 3378, 3941, 5483, 2892, 3063, 3714, 2513, 2904, 2615, 2674, 2590, 3513, 3091, 5341, 3356, 8143) in HCC serum. However, the expression of eight up-regulated proteins (m/z 13 769, 13 969, 28 060, 9354, 9422, 9406, 2143, 9195, 5058) also increased in serum of HBV patients in this study, which suggested up-regulation of these eight common differential proteins might have reflected the pathological changes of hepatitis B, but were non-specific for HCC development.

Comparison of serum protein spectra between HCC with HBV/cirrhosis and chronic hepatitis B

Using Biomarker Wizard software analysis, nine of 52 differential proteins ($P < 0.05$), including two up-regulated proteins (m/z 3588, 2017) and seven down-regulated proteins (m/z 2870, 3654, 3941, 2688, 3450, 3165, 5483) in HCC serum, were found to be over twofold different in intensity between HCC and chronic hepatitis B. Compared with hepatitis patients, the expression of m/z 3588 and 2017 was also up-regulated in the serum of cirrhosis patients (Figure 1, Table 1). Therefore, these two common leading differential proteins may play a role in the progress of HBV-induced or cirrhosis-induced HCC, which merits further investigation. The other seven downregulated proteins in HCC serum were all detected to be downregulated in HCC serum as compared with serum protein spectra of cirrhosis (Figure 1, Table 1). This demonstrated that these common differential proteins possessed potential specificity and clinical significance in HCC diagnosis because they eliminate the influence of hepatitis and cirrhosis under subtraction difference analysis. However, expression of the two other leading differential proteins (m/z 3654, 3450) was higher in cirrhosis than in HCC and hepatitis, which indicated they were more specifically associated with cirrhosis.

Comparison of serum protein spectra between cirrhosis and chronic hepatitis B

Between cirrhosis and chronic hepatitis B, 28 of 79 significant differential proteins ($P < 0.05$) were found to have a greater than twofold change in intensity, including

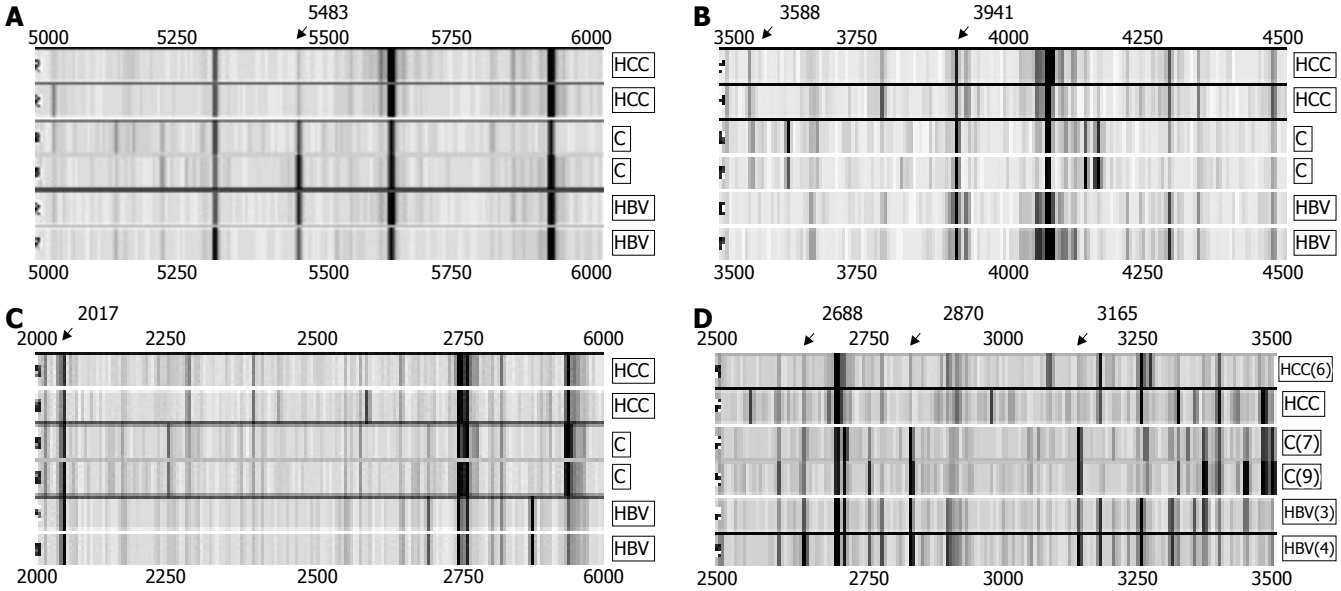

Figure 1 SELDI spectra of serum samples from patients with HCC with HBV/cirrhosis, cirrhosis and chronic hepatitis B. Arrows represent seven common leading differential proteins with low MW, including five common down-regulated proteins in HCC serum (m/z 2870, 3941, 2688, 3165, 5483) and two common up-regulated proteins (m/z 3588, 2017) in HCC and cirrhosis, using Ciphergen SELDI Software 3.1.1 with Biomarker Wizard and subtraction difference analysis. The intensity of each band in the gel view reflects the peak area in the original spectrum. HCC, HCC with HBV/cirrhosis; C, cirrhosis; HBV, hepatitis B virus.

17 up-regulated proteins (m/z 4178, 4965, 3493, 2892, 3476, 3246, 2017, 3714, 3279, 3450, 5003, 3588, 3513, 2513, 2904, 5810, 3654) and 11 down-regulated proteins (m/z 13769, 4075, 13969, 7772, 9291, 9422, 9354, 9406, 28060, 5058, 9195) in cirrhosis. Among 17 up-regulated differential proteins, expression of 11 (m/z 4178, 4965, 3493, 2892, 3246, 3714, 3450, 3513, 2513, 2904, 3654) also increased in cirrhosis, as compared to HCC, which indicated these proteins might have been specifically related to cirrhosis.

DISCUSSION

Several lines of evidence have shown that disease-related proteins or peptide fragments, produced by the tumor or tumor-host microenvironment, either at tumor onset or later, are readily released into the blood as it bathes or circulates through diseased tissue[13,18,19]. Therefore, blood can be used as a rich source of tumor biomarkers for the clinical diagnosis of many tumors. Over the years, many clinical blood tests based on serum markers have been developed for the detection of cancer[20-22]. For example, increased serum levels of CA125 (carbohydrate antigen 125), CA153 (carbohydrate antigen 153) and PSA (prostate specific antigen) are routinely used in clinics for detection of cancer in the ovary, breast and prostate, respectively. AFP, AFP-L3 and DCP are the most useful serum tumor markers for the diagnosis of HCC[23-25], and combination of these three tumor markers can improve the diagnostic accuracy, especially in differentiating HCC from non-malignant liver disease[12]. However, none of these biomarkers meets the goal of early diagnosis of HCC, or has satisfactory accuracy in detecting HCC and predicting prognosis when used alone. Recently, Wright[26] *et al* have summarized traditional and novel serum markers for HCC by review of the latest literature (2001-206). They predicted that in the near future a new generation of HCC serum markers, including complex proteomics features and tumor specific autoantibodies, will have the potential to replace its flawed leader, AFP, after strict validation in properly controlled clinical studies.

In the past, 2DE coupled with MS was the major technology in biomarker screening of serum proteomes. Following this classic screening pathway, 11 serum proteins with differential expression that is increased or decreased in response to HCC treatment have been identified. These proteins might be involved in liver carcinogenesis or become candidate biomarkers for the development of diagnostic and therapeutic tools[27]. In another recent study, two different screening strategies (2-DE combined with nano-HPLC-ESI-MS/MS or nano-HPLC-ESI-MS/MS) were simultaneously applied to discover more HCC-related proteins. This work means that scientists are beginning to address the shortcomings of 2DE in clinical proteomic studies of serum tumor marker screening[28]. 2DE technology is labor intensive, time-consuming, and requires a large amount of sample, therefore, it is not suitable for large-scale serum screening programs and clinical testing[29]. Furthermore, proteins with a low MW and abundance, and extreme pIs exceed the analytical capability of 2DE, although such proteins convey valuable information for disease assessment. As a result of its pre-fractionation, high resolution and powerful spectrum analysis software, application of SELDI-based systems can remedy some of the drawbacks of 2DE. They also have significant advantages over other proteomics technology for serum biomarkers screening.

For specific biomarkers discovery of HCC with HBV(+)/cirrhosis(+) in serum, two challenging aspects should be addressed (1) to eliminate the interference of most unspecific abundant proteins secreted by liver damage such as hepatitis, cirrhosis, etc., which were also 'reasonable'

differential proteins as compared with health controls (2) to reduce the complexity of serum proteome as more as possible so that most uncharacterized proteins with low abundance and low MW can be detected in serum. Serum proteins have a range of concentrations and are dominated by a handful of high-abundance proteins such as albumin, transferrin, haptoglobulin, immunoglobulins and lipoproteins[13]. Therefore, identification of low-abundance biomarkers is generally hampered by the presence of a few more abundant proteins. Pre-fractionation with simple chemical affinity beads or surface is an effective method to decrease the sample complexities. In this study, chip protein fractionation coupled to high resolution SELDI-TOF-MS not only reduced the complexity of serum proteomes prior to MS analysis, but also improved detection of uncharacterized proteins with low abundance and MW. On the other hand, subtraction difference analysis attenuated the influence of non-specific abundant proteins secreted by patients with hepatitis B or cirrhosis, and guaranteed that candidate tumor biomarkers screened were more specifically for HCC. Through mutually comparative analysis of serum SELDI spectra among three disease groups, the five common down-regulated proteins in HCC serum (m/z 2870, 3941, 2688, 3165, 5483) and another two common up-regulated proteins (m/z 3588, 2017) in HCC and cirrhosis serum were screened, and showed potential clinical significance for diagnosis of HCC (Figure 1, Table 1). Because most studies for HCC biomarker discovery mainly focused on the changes of its serum SELDI spectra in comparison with that of hepatitis B/C or cirrhosis alone, or between non-HCC and HCC patients[16,17,30], some identified differential proteins probably reflect the pathological alteration of hepatitis or cirrhosis only, but unspecific for HCC development[16,26]. Therefore, the above seven common differentially expressed proteins, screened in HCC serum, undoubtedly possessed an advantage in specificity for evaluating the pathological stage of HCC. More recently, applying combination technology of enrichment, SELDI and LC-MS/MS or SELDI, 2-DE as well as LC-MS/MS, some candidate biomarkers for HCV-related HCC such as complement C3a[16], κ and λ immunoglobulin light chains[30], *etc*. were identified in succession. These identification studies will offer a valuable reference to characterize these seven common differential proteins for HCC diagnosis in our proceeding study.

In summary, common differential candidate proteins screened here among three disease groups under SELDI system and subtract difference analysis not only show potential clinical significance in HCC indicator, but also provide a novel option to discover specific biomarkers in serum of HCC.

COMMENTS

Background

Although some serum tumor markers including enzymes (GGT, AFU, DCP), and oncofetal and glycoprotein antigens (AFP, AFP-L3, GPC3) have been widely used in the detection of HCC, the diagnostic accuracy for HCC is still unsatisfactory, especially for early and differential diagnosis. There is an urgent need to discover new specific HCC-associated proteins, using novel technology and screening strategies. For biomarkers for diagnosis of HCC with HBV/cirrhosis, two challenging questions remain: (1) how to eliminate the interference of most non-specific abundant secreted proteins from hepatitis and cirrhosis; and (2) how to reduce the complexity of serum proteome, which hinders the discovery of specific HCC-associated serological proteins.

Research frontiers

A promising high throughput proteomics approach, on-chip protein fractionation coupled to SELDI-TOF-MS, provides a novel pathway for rapid screening and identification of specific tumor markers with low MW in the proteomes of body fluids.

Innovations and breakthroughs

Applying SELDI and subtraction difference analysis, we successfully discovered seven common differential candidate proteins with potential clinical significance for HCC indicator. This screening strategy provides a novel method for discovering specific biomarkers with low MW and low abundance in the serum of patients with HCC.

Applications

These seven common differential proteins with potential clinical significance for HCC diagnosis merit being further identified and validated in large numbers of HCC samples.

Terminology

SELDI-TOF-MS detects proteins affinity-bound to a protein chip array. This system is a novel, sensitive, rapid detection system for analyzing complex mixtures of proteins and peptides.

Peer review

This study investigated serum HCC-associated proteins with low MW and low abundance in patients with HCC with HBV/cirrhosis by SELDI-based serum protein spectrum analysis. Seven common differential candidate proteins with potential clinical significance in diagnosis of HCC were discovered by subtraction difference analysis. These preliminary results and subtraction screening strategy will provide a useful reference for the discovery of biomarkers for HCC.

Abstract

AIM: To investigate the antiviral effect of beta-L-enantiomer of 2′,3′-didehydro-2′,3′-dideoxyadenosine (β-L-D4A) on 2.2.15 cells transfected with the hepatitis B virus (HBV) genome.

METHODS: Lamivudine (3TC) as a positive control. Then, HBV DNA in treated 2.2.15 cells and the Hepatitis B surface antigen (HBsAg) in the culture supernatants were detected to determine the inhibitory effect of β-L-D4A. At the same time, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) was used to detect the survival ratio of 2.2.15 cells.

RESULTS: β-L-D4A has a dose-dependent inhibitory effect on HBV DNA replication; this effect was apparent when the concentration was above 1 mol/L. When β-L-D4A was at the highest concentration, 100 mol/L, the HBsAg inhibition ratio was above 50%. The Therapeutic index (TI) of β-L-D4A was above 2.1.

CONCLUSION: β-L-D4A has a dose-dependent inhibitory effect on the replication of HBV DNA and the secretion of HBsAg at low toxicity.

INTRODUCTION

Hepatitis B virus (HBV) is a partially double-stranded DNA virus, which is able to induce acute or chronic infection in humans[1]. Chronic HBV infection can last a lifetime, causing persistent hepatitis that frequently progresses to more-severe liver diseases[2], including cirrhosis and hepatocellular carcinoma[3-5]. Chronically infected patients also serve as sources of HBV transmission.

Traditionally approved therapies against HBV include treatment with alpha interferon and lamivudine (3TC). However, the efficacy of alpha interferon is limited by undesirable side effects, low sustained response rate and high cost[6-7]. While lamivudine (3TC) is well-tolerated and less costly, resistance emerges in approximately 20% of patients receiving monotherapy per year[8].

Adefovir-dipivoxil prodrug (ADV) and entecavir (ETV) are recently approved anti-HBV therapeutics. While these two agents produce multilog suppression of serum HBV DNA, they cause only modest rates of HBV surface antigen seroconversion and, thus, require long-term administration to control disease in most patients[9]. ADV retains clinical efficacy against lamivudine-resistant mutants[10], but selects the mutations rtN236T and rtA181V[11]. In addition, treatment with ADV is reported to be associated with dose-limiting nephrotoxicity[12]. Entecavir shows reduced susceptibility to lamivudine-resistant mutants *in vitro* and clinically, and an accelerated development of entecavir resistance mutations (rtI169T, rtM250V, rtS202I and rtT184S/G) in lamivudine-resistant patients[12,13]. Therefore, more effective and safer therapies are needed for the treatment of chronic HBV infections.

β-L-D4A is an L-enantiomer of the natural nucleoside deoxyadenosine. The structure of β-L-D4A is shown in Figure 1. In this report, we detected the efficacy of β-L-D4A against HBV replication *in vitro*.

MATERIALS AND METHODS

Materials

2.2.15 cells and 3TC were kindly provided by Professor Yung-Chi Cheng (Yale University) and plasmid P3.6 was offered by Professor Wang Yuan (Shanghai Institute of

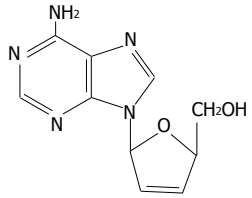

Figure 1 Chemical structure of β-L-D4A.

Biochemistry, Chinese Academy of Sciences). β-L-D4A was synthesized by the Department of Pharmacology of Wuhan University. G418 and MTT were purchased from Sigma (USA) and DMEM was from Gibco (USA). Fetal bovine serum was purchased from Hyclone (USA), random primers were purchased from Takara (Japan) and DIG-labeled dUTP was purchased from Roche (Germany). An EIA Kit for the detection of HBsAg was purchased from Kehua (Shanghai). HBV DNA fluorescent quantified PCR (FQ-PCR) Kit was purchased from Biotronics (USA).

Methods

Cell culture: 2.2.15 cells were maintained in DMEM (supplemented with 10% fetal bovine serum, 200 g/mL G418, 2 mmol/L glutamine, 50 U of penicillin per milliliter and 50 μg of streptomycin per milliliter) at 37℃ and 5% CO_2. The medium was changed every three days.

Intracellular HBV DNA analysis: 2.2.15 cells were digested by parenzyme, seeded at a density of 1×10^5 cells per well on 24-well plates and maintained in 1.5 mL DMEM at 37℃ and 5% CO_2 for 48 h. Then, 2.2.15 cells were treated with freshly prepared medium containing β-L-D4A or 3TC. The following concentrations were used: 0.0001, 0.001, 0.01, 0.1, 1, 10, 100 mol/L. Negative control cells were treated with DMEM only. Media were changed every three days; on day 8, both the supernatants and cells were collected and stored at -20℃.

Then, the cells were lysed at room temperature with 1 mL of lysis buffer [50 mmol/L Tris-HCl (pH 7.4), 150 mmol/L NaCl, 5 mmol/L $MgCl_2$, 0.2% Nonidet P-40]. Removal of cellular debris was accomplished by a 5-min microcentrifuge spin at 16 000 r/min. Lysates were then incubated with 20% PEG 8000 and 1 mol/L NaCl at room temperature for 2 h, followed by a 1-min microcentrifuge spin at 16 000 r/min. The resulting pellets containing HBV core particles were resuspended in solution added with proteinase K [10 mmol/L Tris (pH 7.6), 10 mmol/L EDTA, 0.25% SDS, 1 mg/mL proteinase K] at 56℃ for 2 h, followed by extraction with phenol-chloroform and ethanol precipitation. Nucleic acids were dissolved in ddH_2O, electrophoresed through 1% agarose, transferred to a positively charged nylon membrane and hybridized to a probe, which was prepared from a full-length HBV DNA genome template excised from plasmid P3.6 and DIG-labeled using a random primer. Then, the membrane was incubated with anti-DIG and developed with NBP/ BCIP.

The concentration of extracted HBV DNA was also determined by real-time fluorescent quantitative Polymerase Chain Reaction(FQ-PCR). The inhibition ratio was calculated according to the following formula: inhibition ratio = (HBV DNA concentration of negative control - HBV DNA concentration of experimental group)/HBV DNA concentration of negative control × 100%. Then, the 50% inhibition concentration (IC_{50}) was calculated according to the Reed-Muench method[14].

Detection of HBsAg: 2.2.15 cells were treated with antiviral compounds and lysed as described above. The collected supernatants were detected using an EIA Kit for the detection of HBsAg according to the manufacturer's instructions, and A_{450} was observed. Inhibition ratio to HBsAg (%) = (A_{450} of negative control -A_{450} of experimental group) / (A_{450} of negative control -A_{450} of blank control) × 100%.

Analysis of cellular toxicity: MTT assays were used to detect the survival rates of 2.2.15 cells[15]. Briefly, 2.2.15 cells were seeded at a density of 1×10^5 cells per well on 24-well plates and treated with media containing β-L-D4A or 3TC of different concentrations. The following concentrations were used: 1000, 500, 250, 125, 62.5 and 31.25 mol/L. Three days later, the supernatants were discarded and 2 mL of MTT (1 mg/mL) was added per well. After incubation at 37℃ and 5% CO_2 for 4 h, the supernatants were discarded and 2 mL of acidified isopropanol (isopropanol:HCl = 500:1.68) was added per well. The survival ratio of 2.2.15 cells (%) = (A_{570} of experimental group/A_{570} of negative control) × 100%. Then, the 50% toxicity dose (TD_{50}) was calculated according to the Reed-Muench method.

Evaluation of treatment: Therapeutic index (TI) = TD_{50}/IC_{50}. If the TI is above 2.1, the compound is high in efficacy and low in cellular toxicity. If TI is between 2 and 1, the compound is both considerably effective and toxic. If TI is below 1, the compound is low in efficacy, but high in cellular toxicity.

Statistics analysis

All statistics were analyzed using SPSS10.0, and differences were considered significant when the P value was < 0.05.

RESULTS

β-L-D4A inhibits the replication of HBV DNA

To investigate the potential of β-L-D4A to inhibit HBV viral replication, HBV DNA was isolated from treated 2.2.15 cells and detected by Southern hybridization. Figure 2 shows that the production of HBV DNA lessened following treatment of cells with β-L-D4A; this effect became more notable as the dose of β-L-D4A increased. A similar phenomenon was observed in cells treated with 3TC.

The concentration of HBV DNA in 2.2.15 cells was determined by real-time fluorescent quantitative PCR. As shown in Figure 3, β-L-D4A had an apparent inhibitory effect on the concentration of HBV DNA ($P > 0.05$ when compared to that of 3TC). Calculated according to the Reed-Muench method, the IC_{50} values of β-L-D4A and 3TC were 0.61 mol/L and 0.30 mol/L, respectively.

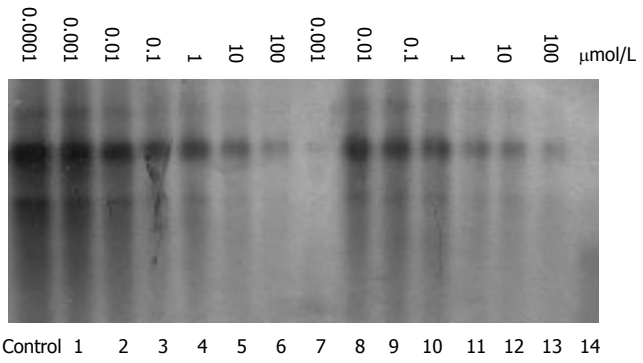

Figure 2 Southern analysis of the HBV DNA extracted from 2.2.15 cells. Lane control: HBV DNA extracted from untreated 2.2.15 cells; Lane 1-7: HBV DNA extracted from 2.2.15 cells treated with β-L-D4A; Lane 8-14: HBV DNA extracted from 2.2.15 cells treated with 3TC.

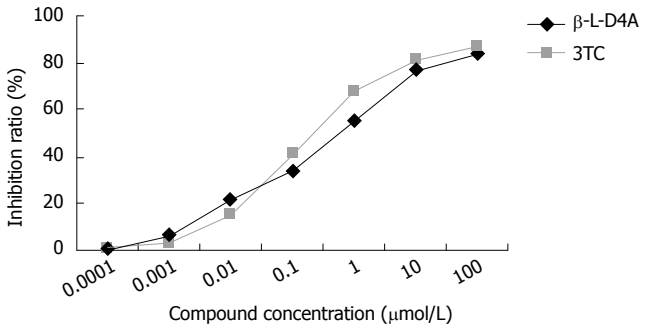

Figure 3 The inhibition ratio to HBV DNA.

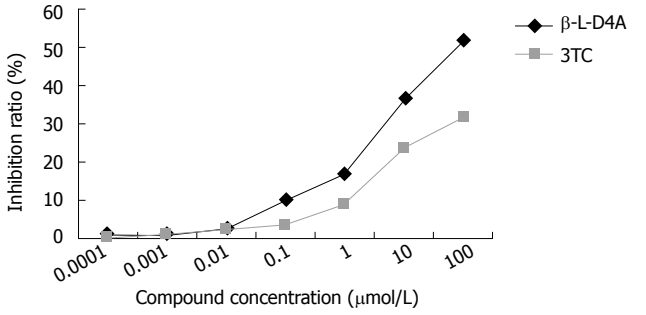

Figure 4 The inhibition ratio to HBsAg.

β-L-D4A inhibits the secretion of HBsAg

Following treatment of 2.2.15 cells with antiviral compounds for eight days, HBsAg was detected in the medium. As shown in Figure 4, when the concentration of β-L-D4A was 100 mol/L, the HBsAg inhibition ratio was above 50%. However, the HBsAg inhibition ratio with 3TC was less than 40% even at the highest concentration.

Cellular toxicity of β-L-D4A

The cellular toxicity of both compounds was not evident at drug concentrations below 125 mol/L. The survival ratios were less than 50% when the drug concentrations were as high as 1000 mol/L, with both compounds. Calculated according to the Reed-Muench method, the TD_{50} values of β-L-D4A and 3TC were 417 mol/L and 243 mol/L, respectively.

Table 1 TIs of β-L-D4A and 3TC

Group	IC_{50} (μmol/L)	TD_{50} (μmol/L)	TI
β-L-D4A	0.61	417	683
3TC	0.30	243	810

TI: Therapeutic index.

Evaluation of treatment

Table 1 shows the TIs for both β-L-D4A and 3TC were above 2.1. This means that these two compounds are high in efficacy and low in cellular toxicity.

DISCUSSION

HBV infection is one of the most prevalent viral diseases in the world and more than 350 million people are chronically infected[16,17], with about 1 million deaths annually[18]. In order to screen anti-HBV compounds, researchers often purify HBV DNA polymerase. However, the purification procedure is very complicated and the quantity of polymerase is not satisfying[19,20]. 2.2.15 cells can stably replicate HBV DNA and express HBsAg; thus, they can be used as an ideal cell model to screen the *in vitro* antiviral efficacy of medicines[21,22].

In this study, we found that β-L-D4A has a dose-dependent inhibitory effect on HBV DNA replication that is apparent when the concentration is above 1 mol/L. However, the inhibition of the secretion of HBsAg was not as pronounced as that of HBV DNA replication. When β-L-D4A was at the highest concentration, 100 mol/L, the HBsAg inhibition ratio was slightly above 50%. The TI of β-L-D4A shows that it is high in efficacy and low in toxicity, which indicates that β-L-D4A is a promising anti-HBV compound.

β-L-D4A is a new type of L-nucleoside for which the natural counterpart is deoxyadenosine. Although there have been reports about L-nucleosides since 1960s, it was only after about 30 years that the merits of L-nucleoside became widely recognized[23-24]. Previous studies revealed the bioactivities and securities of L-nucleoside analogues were superior to their counterpart enantiomers[25-27]. β-L 3/(2R, 5S)-1,3-oxathiolane-cytidine (lamivudine, 3TC), a typical L-nucleoside, was reported to be about 50 times more effective than its D-enantiomer[28-30].

The mechanism of action of β-L-D4A is speculated to be inhibition of HBV DNA polymerase and termination of DNA replication. In order to confirm this speculation, further study is necessary. It also remains to be seen whether β-L-D4A is effective against lamivudine-resistant HBV mutants and whether it will lead to HBV mutants resistant to β-L-D4A. Besides, much work remains to be done to gain a better understanding of the metabolism, toxicology and pharmacokinetic parameters of this compound. Our studies to date suggest β-L-D4A deserves further development as a potential treatment for chronic HBV infection.

ACKNOWLEDGMENTS

We thank Professor Yung-Chi Cheng for the kind gift of

2.2.15 cells and 3TC. We also thank Professor Wang Yuan for the plasmid P3.6.

COMMENTS

Background

Hepatitis B virus (HBV) is one of the causative agents of acute or chronic hepatitis in humans, and there are an estimated 350 million persistently HBV-infected carriers worldwide. Such prevalence of HBV demands the discovery of new effective therapeutics for the treatment of acute and chronic infections.

Research frontiers

There have been articles studying the antiviral effects of Entecavir and Adefovir, which are analogs of deoxyguanosine and deoxyadenosine, respectively. While these two agents produce pronounced suppression of serum HBV DNA, they cause only modest rates of HBV surface antigen seroconversion and even induce resistant mutants. Thus, there is an urgent need to develop a new potent anti-HBV drug.

Innovations and breakthroughs

In this study, we find that β-L-D4A has a dose-dependent inhibitory effect on the replication of HBV DNA and the secretion of HBsAg at low toxicity.

Applications

The results of this study confirm the *in vitro* antiviral effect of β-L-D4A, which indicates it is a promising new drug against HBV infection.

Terminology

β-L-D4A is an L-enantiomer of its natural nucleoside-deoxyadenosine.

Peer review

This study aimed to investigate the antiviral effect of β-L-D4A on 2.2.15 cell line by comparing with 3TC. They found β-L-D4A has concentration-relative inhibitory effect to HBV DNA replication and the therapeutic index of β-L-D4A was above 2.1. It's an interesting subject.

Abstract

AIM: To evaluate the effects of antiviral agents and HBV genotypes on intrahepatic covalently closed circular DNA (ccc DNA) in HBeAg-positive chronic hepatitis B patients.

METHODS: Seventy-one patients received lamivudine (n = 35), or sequential therapy with lamivudine- interferon alpha 2b (IFN-α 2b, n = 24) for 48 wk, or IFN-α 2b (n = 12) for 24 wk. All subjects were followed up for 24 wk. Intrahepatic ccc DNA was measured quantitatively by PCR. HBV genotypes were analyzed by PCR-RFLP.

RESULTS: Sequential lamivudine- INF-α therapy, lamivudine and INF-α monotherapy reduced ccc DNA of 1.7 log, 1.4 log and 0.8 log, respectively (P < 0.05). Seventeen out of the 71 patients developed HBeAg seroconversion, the reduction of ccc DNA in the HBeAg seroconversion patients was more significant than that in the HBeAg positive patients (3.0 log *vs* 1.6 log, P = 0.0407). Twenty-four weeks after antiviral therapy withdrawal, 16 patients had a sustained virological response, the baseline intrahepatic ccc DNA in the patients with a sustained virological response was significantly lower than that in the patients with virological rebound (4.6 log *vs* 5.4 log, P = 0.0472). HBV genotype C accounted for 85.9% (n = 61), and genotype B for 14.1% (n = 10), respectively, in the 71 patients. There was no significant difference in the change of ccc DNA level between HBV genotypes C and B (2.1 log *vs* 1.9 log).

CONCLUSION: Forty-eight week sequential lamivudine-INF-α therapy and lamivudine monotherapy reduce ccc DNA more significantly than 24-wk INF-α monotherapy. Low baseline intrahepatic ccc DNA level may predict the long-term efficacy of antiviral treatment. HBV genotypes C and B have no obvious influence on ccc DNA load.

INTRODUCTION

Hepatitis B virus (HBV) is one of the major causes for liver disease, more than 350 million people are infected with HBV, and eventually 15% to 25% of these individuals will progress to liver cirrhosis and hepatocellular carcinoma[1]. Interferon-alpha (IFN-α)[2-4] and nucleoside analogue agents[5-8] are the currently available antiviral drugs for the treatment of patients with chronic hepatitis B. Long-term anti-viral treatment can decrease the occurrence rate of hepatocellular carcinoma in patients with chronic hepatitis B, thus improving their survival. Nonetheless, after withdrawal of treatment, relapse occurs in the great majority of patients. Furthermore, relapse may lead to severe exacerbation of the disease, causing hepatic failure and even death. The main reason for the rebound of HBV DNA to its pretreatment level after antiviral

treatment withdrawal is that these agents have a profound effect on relaxed circular DNA (rc DNA) and almost no effect on covalently closed circular DNA (ccc DNA)[9-11]. ccc DNA provides the template for the transcription of all viral genes. After hepatocytes are infected with HBV, covalently closed circular DNA is formed through DNA repair of the relaxed circular replicative HBV DNA inside the nuclei of hepatocytes[12]. DNA-containing nucleocapsids can either recycle back to the nuclei to amplify and maintain the pool of ccc DNA or become enveloped and are secreted into the blood[13]. Since ccc DNA is required for the maintenance of HBV infection, it must be eliminated for viral clearance to present. Currently, ccc DNA in human peripheral blood mononuclear cells and liver biopsies can be quantitated [14-16]. Thus, it is possible to measure the intrahepatic ccc DNA level for monitoring antiviral treatment.

The aim of the present study was to analyze the effects of sequential lamivudine-INF-α therapy, lamivudine monotherapy and INF-α monotherapy on intrahepatic ccc DNA. The relationship between intrahepatic ccc DNA and HBV genotypes was also observed.

MATERIALS AND METHODS

Subjects

Between March 2003 and March 2005, seventy-one patients with HBeAg -positive chronic hepatitis B were recruited, including 59 males and 12 females aged 19-47 (mean 32 ± 9) years. Informed consent was obtained from all involved patients. The inclusion criteria for the patients were as follows: positive for HBsAg and HBeAg, serum HBV DNA $\geqslant 1 \times 10^5$ copies/L, serum alanine aminotransferase (ALT) levels at least two-fold higher than the normal range (normal range = 0-667 nkat/L) for more than 6 mo. Exclusion criteria were as follows: patients with alcoholism, pregnancy, cirrhosis, chronic renal failure, concurrent autoimmune disease, severe neurological disorders, human immunodeficiency virus (HIV) infection and viral hepatitis A, C, delta or E. Patients treated with interferon or other antiviral therapies for 6 mo prior to enrollment in this study were also excluded. Patients were randomized (at the ratio 3:2:1) to receive 48 wk of 100 mg lamivudine once daily (n = 35), or lamivudine from the first to the 8th mo and IFN-α from the 7th to the 12th mo (n = 24), or 24 wk of 5 million units of interferon-alpha (IFN-α) three times per week (n = 12). All subjects were followed up for 24 wk after antiviral therapy. Presence of serum HBV DNA levels $\leqslant 1 \times 10^3$ and normalization of serum ALT levels were assessed as treatment response.

Measurement of HBV markers and genotypes and biochemical tests

Blood samples were obtained before, immediately after treatment and at wk 24 of follow-up. Liver biochemistry and HBV marker test (using commercial assays, Abbott Laboratories, USA) were performed on these samples.

Liver biopsy specimens were collected by needle liver biopsies (0.5-1.5 cm) before and immediately after treatment. The tissue was washed several times in cold phosphate-buffered saline (PBS) and stored at -70℃. Total DNA was extracted from liver tissue with the Qiaamp DNA tissue Mini DNA kit (Qiagen, Germany). Serum and intrahepatic HBV DNA were measured quantitatively by real-time polymerase chain reaction (PCR) (Model 5700, ABI Company, USA) with a lower limit of detection of 1×10^3 HBV DNA copies/mL and 1×10^3 copies/μg total DNA, respectively. HBV genotypes were determined by PCR restriction fragment length polymorphism (PCR-RFLP) analysis as previously described[17].

PCR amplification for CCC DNA

The primers were synthesized for amplifying ccc DNA according to the published consensus sequence. Sequences of the primers and the probe are as follows: 5'-ATACGGGTCAATGTCCATGC-3' (nt 1551, sense), 5'-CCGTCTGTGCCTTCTCATCT-3' (nt 1991, antisense), and 5'-CCAAAGCCACCCAAGGCACA-3' (nt 1880, probe).

PCR was performed at 94℃ for 2 min, followed by 45 cycles at 94℃ for 20 s, at 60℃ for 1 min.

Histology measurement

Histologic inflammation was scored with a modified Knodell scoring system[18]. Histologic response was defined as a decrease by at least two points in the Knodell scoring system.

Statistical analysis

Data were analyzed with the Statistical Program for Social Sciences (SPSS 13.0 for Windows). Categorical variables were tested using chi-square test or Fisher's exact test. Normally distributed variables were tested using t-test or ANOVA, whereas continuous variables with skewed distributions were tested using the Kruskal Wallis test. Correlation between two variables was tested using Pearson's correlation analysis after logarithmic transformation of data with skewed distributions. $P < 0.05$ was considered statistically significant.

RESULTS

There was no significant difference in all the parameters among the three groups before treatment. The antiviral outcome of 48-wk sequential lamivudine - INF-α therapy was similar to that of 48-wk lamivudine monotherapy, but slightly better than that of 24-wk INF-α monotherapy. The reduction in serum HBV DNA, intrahepatic HBV DNA and ccc DNA after sequential lamivudine - INF-α therapy and lamivudine monotherapy was greater than that after INF-α monotherapy ($P < 0.05$) (Table 1).

Data on histology, biochemistry and virology in HBeAg seroconversion patients and HBeAg positive patients

After antiviral treatment, the means of Knodell score, serum HBV DNA levels, intrahepatic HBV DNA levels, intrahepatic ccc DNA and serum ALT levels in all the 71 patients were significantly decreased ($P < 0.05$). Of the 71 patients, 17 developed HBeAg seroconversion. There was no significant difference in the parameters mentioned

[a]$P < 0.05$ *vs* post-treatment, [c]$P < 0.05$ *vs* HBeAg positive, [e]$P < 0.05$ *vs* sustained virological response. ALT: Alanine aminotransferase; ccc DNA: Covalently closed circular DNA.

above between the HBeAg seroconversion patients and HBeAg positive patients before treatment, except for the baseline intrahepatic HBV DNA levels (5.6 log *vs* 6.3 log, $P = 0.02$). The HBeAg seroconversion group had greater improvements than the HBeAg positive group. The mean of intrahepatic HBV DNA decreased to (4.1 ± 0.8) log10 in the seroconversion group ($P = 0.0124$) and to (5.1 ± 1.5) log10 ($P = 0.0872$) in the HBeAg positive group. The mean of intrahepatic ccc DNA decreased from (5.8 ± 0.6) log10 to (2.8 ± 1.3) log10 in the HBeAg seroconversion group, and from (5.5 ± 1.1) log10 to (3.9 ± 1.1) log10 in the HBeAg positive group ($P = 0.0407$, Table 2).

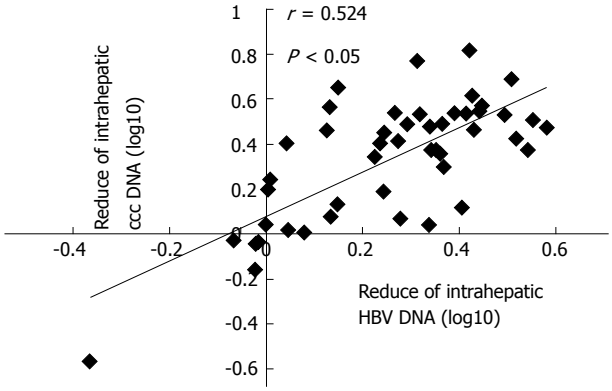

Figure 1 Correlation between the reduction in intrahepatic ccc DNA and a similar reduction in intrahepatic HBV DNA.

Data on histology, biochemistry and virology in patients with different long-term responses

In the 24-wk follow-up period, of the 48 patients with virological response at the end of therapy, 18 achieved a sustained virological response, and 30 presented virological rebound. The means of intrahepatic and serum HBV DNA loads, histology and serum ALT level in the patients with a sustained virological response were similar to those in the patients with virological rebound before and after treatment. The baseline intrahepatic ccc DNA level in the patients with a sustained virological response was, however, significantly lower than that in the patients with virological rebound ($P = 0.0472$), but no significant difference was found at the end of treatment between the two groups (Table 2).

The mean of HBV ccc DNA in the 71 patients before and after treatment was (6.83 ± 0.37) log and (5.72 ± 0.23) log, respectively ($P > 0.05$). The change in intrahepatic ccc DNA had a positive correlation with a similar reduction in intrahepatic HBV DNA ($r = 0.525$, $P < 0.05$, Figure 1). The ccc DNA level was correlated with the serum HBeAg titer at the end of treatment ($r = 0.432$, $P = 0.002$, Figure 2).

Intrahepatic ccc DNA level and HBV genotype

HBV genotype C accounted for 85.9% ($n = 61$), and genotype B for 14.1% ($n = 10$) in the 71 patients. The mean of intrahepatic HBV DNA loads was (6.1 ± 0.9) log10 and (4.9 ± 1.4) log10, respectively ($P < 0.05$), and that of intrahepatic ccc DNA loads was (5.6 ± 1.1) log10 and (3.5 ± 1.5) log10, respectively, in the genotype C patients before and after treatment ($P < 0.05$). The baseline and post-treatment intrahepatic HBV DNA level was (5.6 ± 1.5) log10 and (4.7 ± 1.2) log10, respectively

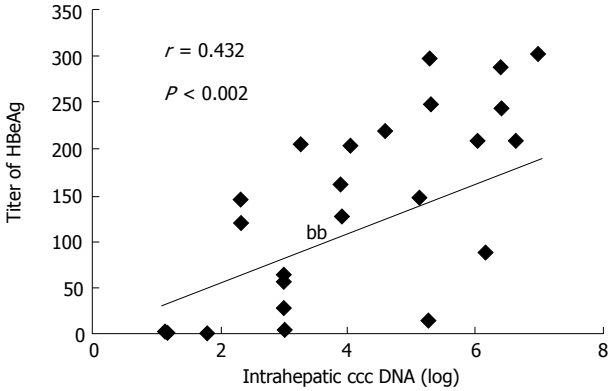

Figure 2 Relationship between intrahepatic ccc DNA level and HBeAg titer at the end of treatment.

($P > 0.05$), and that of intrahepatic ccc DNA loads was (5.8 ± 0.6) log10 and (3.9 ± 1.9) log10, respectively, in the genotype B patients ($P = 0.064$). No statistically significant difference was found in serum intrahepatic HBV DNA loads and ALT levels between the two groups after treatment. There was no significant difference in serum HBV DNA and alanine aminotransferase levels at 24 wk after treatment withdrawal, the sustained virological response rate and ALT normalization rate were also similar (Table 3).

Table 3 Histological, biochemical and virological data on HBV genotypes C and B (mean ± SD)

DISCUSSION

It was reported that lamivudine reduces serum ccc DNA levels by magnitude of 2 log[19]. Forty-eight weeks after adefovir dipivoxil therapy resulted in a significant decrease of 0.8 log in ccc DNA copies/cell and changes in ccc DNA are correlated with a similar reduction in serum HBsAg titer[20]. A clinical study from Hong Kong reported that 48 wk treatment with entecavir ($n = 21$) and lamivudine ($n = 19$) can reduce serum viral load, intrahepatic total HBV DNA, and ccc DNA of about 4.8 logs, 2 logs, and 1 log, respectively[21]. In our study, 48 wk after sequential lamivudine - INF-α therapy ($n = 24$) and lamivudine monotherapy ($n = 35$), and 24 wk after INF-α monotherapy ($n = 12$) reduced serum HBV DNA of about 3.7 logs, 4 logs, and 2.8 log, intrahepatic total HBV DNA of about 1.1 logs, 1.6 logs and 0.7 log, ccc DNA of about 1.7 logs, 1.4 logs and 0.8 log, respectively ($P < 0.05$), indicating that either sequential lamivudine - INF-α therapy or lamivudine therapy significantly reduces HBV DNA and ccc DNA than INF-α monotherapy, and the relatively short duration of INF-α therapy may be responsible for such a difference.

Since serum HBV DNA and alanine aminotransferase levels often flare up after antiviral therapy even if the patients develop HBeAg seroconversion, it is important to determine what the parameters help assess the success of treatment and decide how long the therapy should be. The present data indicate that 17 out of the 71 patients developed HBeAg seroconversion after antiviral therapy, the change of ccc DNA in the HBeAg seroconversion patients was more significant than that in the HBeAg positive patients (3.0 log *vs* 1.6 log, $P = 0.0407$), suggesting that reduction in ccc DNA is crucial for chronic hepatitis patients to achieve better antiviral efficacy. Twenty-four weeks after antiviral therapy withdrawal, 18 patients achieved a sustained virological response. The baseline and post-treatment intrahepatic HBV DNA and serum HBV DNA levels in these patients were similar to those in the patients with virological rebound, except for the baseline level of intrahepatic ccc DNA (4.6 log *vs* 5.4 log, $P = 0.0472$), showing that a lower baseline intrahepatic ccc DNA helps chronic hepatitis patients to maintain a sustained virological response.

As previously reported[15,20], the data obtained from our study show that the reduction in intrahepatic ccc DNA was positively correlated with the change in intrahepatic HBV DNA ($r = 0.525$, $P < 0.05$), and the ccc DNA level was correlated with the serum HBeAg titer at 48 wk after treatment ($r = 0.432$, $P = 0.002$). Since liver tissue is not accessible to obtain for measuring intrahepatic ccc DNA, serum HBeAg titer may be used for assessing the intrahepatic ccc DNA load.

Eight genotypes (A-H) have been found in HBV, each showing a distinct geographical distribution and disease progression. HBV genotype C is believed to be associated with a higher risk of reactivation and progression to cirrhosis compared to HBV genotype B[22,23]. Whether hepatitis B virus (HBV) genotypes influence the response to antiviral treatment remains controversial, and the relationship between HBV genotypes and ccc DNA is still unknown. It was reported that HBV genotypes do not influence the development of resistance to lamivudine, but the severity of liver disease[24]. In the present study, 85.9%

of patients were infected with HBV genotype C and 14.1% with HBV genotype B. There was no significant difference in serum HBV DNA level, intrahepatic HBV DNA and ccc DNA load, as well as in biochemical and histological findings before and after treatment between the two groups. Twenty-four weeks after treatment withdrawal, sustained virological response rate and ALT normalization rate were very similar ($P > 0.05$), indicating that HBV genotypes (B and C) have almost no effect on intrahepatic HBV DNA, ccc DNA load and the long-term efficacy of antiviral therapy.

In conclusion, 48-wk sequential lamivudine - INF-α therapy and lamivudine therapy can significantly reduce HBV DNA and ccc DNA compared to 24-wk INF-α monotherapy. Low baseline intrahepatic ccc DNA level may predict the long-term efficacy of antiviral treatment. Reduction in intrahepatic ccc DNA is positively correlated with the change in intrahepatic HBV DNA, and the ccc DNA level is correlated with the serum HBeAg titer. Intrahepatic ccc DNA level is not significantly affected by the HBV genotype. Since the sample was not large enough, well-designed and placebo-controlled studies are needed.

COMMENTS

Background

Little effect of antiviral agents on ccc DNA is the main reason for the rebound of HBV DNA after antiviral treatment. It is, therefore, important to measure intrahepatic ccc DNA for monitoring antiviral treatment. The aim of this study was to evaluate the effects of antiviral agents and HBV genotypes on intrahepatic ccc DNA in HBeAg-positive chronic hepatitis B patients.

Research frontiers

After antiviral treatment, relapse occurs in the great majority of chronic hepatitis B patients, and the main reason for the rebound of HBV DNA to its pretreatment level is that the currently available antiviral agents have little effect on ccc DNA (covalently closed circular DNA). Since ccc DNA has been found mainly in liver tissues, how it works or changes due to the action of antiviral agents remains unclear. If it could be taken as a parameter for monitoring antivirus treatment need further study.

Innovations and breakthroughs

It was a first-hand report about the effect of INF-α monotherapy and HBV genotypes on intrahepatic ccc DNA, the relationship between baseline intrahepatic ccc DNA level and the long-efficacy of antiviral treatment.

Applications

Antiviral agents can significantly reduce intrahepatic ccc DNA load, but the duration of treatment should be long enough. Low baseline intrahepatic ccc DNA level may predict the long-term efficacy of antiviral treatment, and can be used as an optimal parameter for monitoring antiviral treatment.

Terminology

ccc DNA (covalently closed circular DNA): After virion enters a susceptible hepatocyte, HBV DNA is then enters the nuclei where it forms a convalently closed circular DNA called ccc DNA. The (-) strand of such a ccc DNA is the template for transcription by cellular RNA polymerase Ⅱ of a longer-than-genome-length RNA called pregenome and a shorter subgenomic transcript, all of which serve as mRNAs.

Peer review

Effects of the currently available antiviral drugs for chronic hepatitis B are not satisfactory. The main reason for the rebound of HBV DNA after therapy is the sustained existence of ccc DNA pool. The aim of this study was to evaluate the effects of antiviral agents and HBV genotypes on intrahepatic ccc DNA in HBeAg-positive chronic hepatitis B patients. The authors found that 48-wk sequential lamivudine - INF-α therapy and lamivudine monotherapy could significantly reduce ccc DNA compared to 24-wk INF-α monotherapy. Low baseline intrahepatic ccc DNA level may predict the long-term efficacy of antiviral treatment and HBV genotypes (C and B).

Abstract

AIM: To evaluate the therapeutic efficiency of replicative adenovirus CNHK300 targeted in telomerase-positive hepatocellular carcinoma.

METHODS: CNHK300, ONYX-015 (55 kDa protein deleted adenovirus) and wtAd5 (wild type adenovirus 5) were compared, and virus proliferation assay, cell viability assay, Western blot and fluorescence microscopy were used to evaluate the proliferation and cytolysis selectivity of CNHK300.

RESULTS: The replicative multiples in Hep3B and HepG Ⅱ after 48 h of CNHK300 proliferation were 40625 and 65326 fold, respectively, similar to that of wtAd5.. However, CNHK300 exhibited attenuated replicative ability in normal fibroblast cell line BJ. CNHK300 could lyse hepatocellular carcinoma cells at a low multiplicity of infection (MOI), but could not affect growth of normal cells even at a high MOI.

CONCLUSION: CNHK300 is a cancer-selective replication-competent adenovirus which can cause oncolysis of liver cancer cells as well as wtAd5 (wild type adenovirus 5), but had severely attenuated replicative and cytolytic ability in normal cells. This novel strategy of cancer treatment offers a promising treatment platform.

INTRODUCTION

Replication-defective adenoviruses have been successfully established to deliver genes for cancer gene therapy. But, progress in clinical practice has been hampered by lack of cell specific infectivity and poor viral distribution within the tumor mass[1,2]. To confer specificity of infection and increase viral spread in the tumor mass, replication-competent adenovirus is being developed as an promising cancer therapeutic agent. These replication-competent adenoviruses can cause oncolysis of tumor cells as part of the virus life cycle, the new virus progeny released from the dead cells infects the neighboring cells and continues to replicate and spread until the tumor is eradicated. Furthermore, tumor antigens released from the dead cells can enhance antitumor immunity[3]. Until now, more than 10 kinds of replication-competent oncolytic viruses have been evaluated in different phases of clinical trials. This novel strategy of cancer treatment offers a promising treatment platform[4-6].

The key of replication-competent oncolytic adenovirus modification is to constrict viral replication to tumor cells. One approach is to regulate expression of viral genes essential for replication with tumor-specific promoters that are highly active in tumor cells, but inactive in normal cells. For example, human breast cancer has been targeted with the adenovirus Ad. DF3-E1 in which the E1A gene is under the control of the DF3/MUC1 gene promoter/enhancer[7]. Several other tumor-specific promoters are also being evaluated to restrict viral replication to their cognate tumors, such as prostate-specific antigen enhancer element for prostate carcinoma and α-fetoprotein for

hepatocellular carcinoma[8-10]. Although these results demonstrated that these reconstructed adenovirus had high selectivity, their major drawback was that they were only available for treatment of a narrow range of tumors, because only a limited number of tumors could express the targeted tumor markers. Telomerase is the broadest spectrum molecular marker of malignancies, which is highly activated in immortalized cell lines and most of the malignant tumors, but is inactive in normal comatic cells. Human telomerase reverse transcriptase (hTERT) is the major determinant of human telomerase activity[11]. HTERT promoter is highly active in tumor cells but inactive in normal cells, and utilizing hTERT promoter to drive antitumoral genes in cancer gene therapy can target to and selectively kill the cancer cells with positive telomerase activity[12-14].

In this study, we report a strategy for the development of a novel replication-competent oncolytic adenovirus. In this virus, the E1A gene was placed under the control of the human hTERT promoter to allow us to target a wide range of telomerase-positive tumors with little influence on the growth of normal cells.

MATERIALS AND METHODS

Virus

CNHK300 is a tumor-specific replication competent adenovirus variant that was reconstructed at our lab. hTERT gene promoter was inserted at the upstream of the E1A encoding region of the viral genome. Because different cell lines may show various levels of susceptibility to adenovirus infection and virus production, non-selectively replicating wild type 5 adenovirus (wtAd5) was compared with the tested conditionally replicating adenovirus CNHK300. CNHK300-GFP virus carried green fluorescent protein (GFP) as reporter gene which inserted the upstream of hTERT promoter of CNHK300. ONYX-015 is an E1B 55 kDa deleted adenovirus kindly presented by Professor Berk AJ (University of California, USA)[15-17]. All adenoviruses were grown on the human embryonic kidney cell line HEK293. Virus titers were determined by plaque assay. Ratios of virus particle and plaque were between 20:1 and 100:1 normally. CNHK300 and ONYX-015 virus preparation were free of the wtAd5 and endotoxin contamination.

Cells and cell cultures

The human hepatocellular carcinoma cell lines HepG Ⅱ (wild-type p53), Hep3B (mutated p53) and human normal fibroblast cell line BJ were purchased from the American Type Culture Collection (Manassas, VA). Transformed human embryonal kidney HEK293 cell line was obtained from Microbix Biosystem Inc. (Toronto, Ontario, Canada). HEK293, HepG Ⅱ and Hep3B were cultured in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% fetal bovine serum (Hyclone). BJ was maintained in Minimum Eagle Medium (MEM) with 10% fetal bovine serum (FBS), 2 mmol/L L-glutamine. All the media were supplemented with 100 U/mL penicillin and 100 μg/mL streptomycin and maintained at 37℃ in 5% CO_2.

Detection of hTERT mRNA in various cell lines

RT-PCR amplification method was used to detect the hTERT mRNA. Total RNA was extracted from cell lines by the Trizol Reagent (Invitrogen Corp., San Diego, CA). First strand cDNAs synthesis and PCR reaction were performed using the SuperScript one-step RT-PCR with Platinum Taq Kit (Invitrogen Corp.) according to the manufacturer's protocol. The reaction mixture was heated at 50℃ for 30 min, and then 30 cycles of PCR were performed, including denaturation at 94℃ for 30 s, annealing at 60℃ for 30 s and extension at 72℃ for 60 s, and then 72℃ for 2 min. For PCR reaction, sense and antisense oligonucleotide primers (5'-CGGAAGAGT GTCTGGAGCAA-3'; 5'-GGATGAAGCGGAGTC TGGA-3') were designed. The PCR products (150 bp in length) were electrophoresed on 10% agarose gel.

Detection of E1A expression by Western blotting

HepG Ⅱ, Hep3B and BJ cells were plated at a density of 5×10^5 in 6-well plates (Falcon) and 24 h later infected with CNHK300, ONYX-015 or wtAd5 at a MOI corresponding to IC_{50}. After a 2 h incubation at 37℃ in 5% CO_2, culture medium were removed, the cells were then washed twice with serum-free medium and incubated at 37℃ in 5% CO_2. Forty-eight hours later, culture medium were removed, total cell lysates were prepared using 150 μL/well of Mammalian Protein Extraction Reagent (M-PER, PIERCE, Rockford, IL). Twenty μL of aliquots were subjected to detection on 10% SDS-PAGE and E1A protein was detected with M73 antibody against adenovirus E1A (Santa Cruz Biotechnology, Santa Cruz, CA). The signals were visualized with LumiGLO chemiluminescent reagent and peroxide (Cell Signaling Technology, Bevery, MA).

Proliferation of CNHK300-GFP and GFP expression

Hep3B and BJ cells were plated at a density of 2×10^5 in 6-well plates (Falcon). When the cells reached 80% confluence 2-4 d later, the cells were infected with CNHK300-GFP at a MOI of 0.01, 1, 10 plaque forming unit (pfu)/cell, respectively. The cells were observed and photographed at 3, 7 and 10 d after infection.

In vitro viral replication assay in different cell types

HepG Ⅱ, Hep3B and BJ cells were plated at a density of 5×10^5 in 6-well plates (Falcon) and 24 h later infected with CNHK300, ONYX-015 or wtAd5 at MOI of 5 pfu/cell. After a 2 h incubation at 37℃ in 5% CO_2, culture medium were removed, the cells were then washed twice with serum-free medium and incubated at 37℃ in 5% CO_2 for varying periods of time (0 h, 12 h, 24 h, 48 h, 96 h), the cultures at each time point were harvested and lysed by three cycles of freeze and thaw. The supernatant of each time point was tested for virus production on 293 cells for 10 d with plaque assay. The relative ability of the viruses to amplify in these cells after infection was calculated by comparing the ratio of viral yields to initial virus input.

In vitro cell viability assay

MTT assay was performed to determine cell viability at

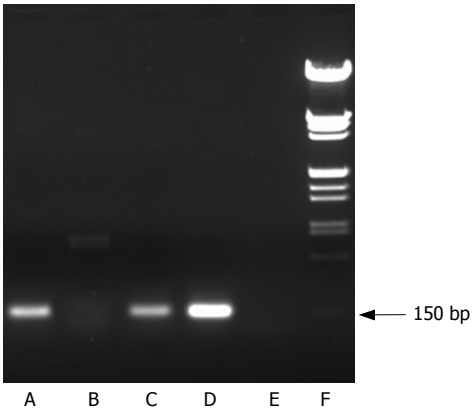

Figure 1 CNHK300 hTERT mRNA expression in various cell lines. Telomerase hTERT mRNA expression was positive in cancer cell lines HepG Ⅱ (A) and Hep3B (C), but not in the normal fibroblast cell line BJ (B) CNHK300 hTERT mRNA expression was detected in E1 transformed human embryonal kidney cell line HEK293 (D) as a positve control. E: Negative control, F: DNA marker.

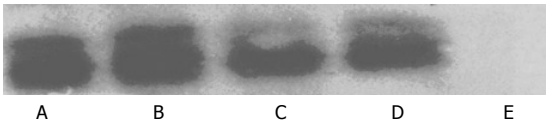

Figure 2 Detection of E1A expression by Western blotting. CNHK300 could express E1A in HepG Ⅱ (A) and Hep3B (C) cells but not in the BJ human normal fibroblast cells (E), whereas wtAd5 did not show any selectivity in E1A expression, wtAd5 E1A expression was positive in Hep3B cells (D). E1A expression was detected in E1 transformed human embryonic kidney cell line HEK293 (B) as a positive control.

various viral MOIs. HepG Ⅱ, Hep3B and BJ cells were plated at a density of 1×10^4 in 96-well plates (Falcon) and 24 h later, the cells were infected with CNHK300 at increasing MOIs. After 7 d of incubation, cell viability was measured by the MTT assay using the non-radioactive cell proliferation kit (Roche Molecular Biochemicals) according to the kit protocol and the spectrophotometrical absorbance of the samples using a microtiter plate (ELISA) reader at 570 nm (the reference wavelength was 650 nm). The percentage of cell survival was calculated using the formula: Cell survival (%) = (A value of infected cells/A value of uninfected control cell) × 100%. Eight replicate samples were taken at each MOIs, and each experiment was performed at least three times.

RESULTS

Detection of hTERT mRNA in various cell lines

RT-PCR was performed to detect the hTERT mRNA expression in HepG Ⅱ, Hep3B cells and normal cells. As shown in Figure 1, telomerase hTERT mRNA expression was demonstrated in both cancer cells tested. In contrast, BJ fibroblast cells did not express hTERT mRNA.

Detection of E1A expression by Western blotting

The Western blotting revealed that CNHK300 could express E1A in the HepG Ⅱ and Hep3B cells but not in the BJ human normal fibroblast cells. As controls, BJ cells were also infected with wtAd5, and the results indicated that wtAd5 could effectively express E1A in BJ cells. These findings demonstrated that CNHK300 selectively expressed E1A in telomerase positive hepatocellular cancer cells, whereas wtAd5 did not show any selectivity in E1A expression (Figure 2).

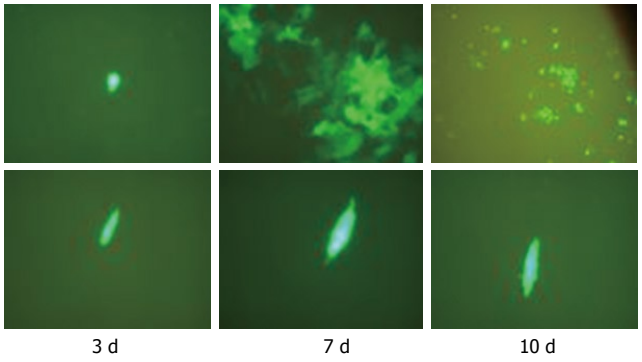

Figure 3 Proliferation selectivity of CNHK300-GFP in Hep3B (upper) and BJ (lower) under fluorescence microscope. CNHK300-GFP could infect both BJ cells and Hep3B cells. But after days of infection, CNHK300-GFP virus could proliferate effectively in cancer cells and induced cytopathologic effect (CPE) at d 7, whereas in normal cell lines, CNHK300-GFP proliferation was attenuated, and BJ cells did not show CPE after days of infection.

Proliferative selectivity of CNHK300-GFP

As shown in Figure 3, CNHK300-GFP could infect both BJ and Hep3B cells and expressed GFP within 3 d. But after 7 d of infection, CNHK300-GFP virus could proliferate effectively and express GFP protein. When the CNHK300-GFP was released from the infected cancer cells, it could infect the adjacent cells and enter into new life cycles. Therefore, the cancer cells showed obvious proliferation and cytopathologic effect (CPE) at the 7th day. Because many cancer cells died from virus infection after 10 d of infection, the GFP protein was degraded and extincted gradually. Whereas in normal cell lines, CNHK300-GFP proliferation was attenuated, and BJ cells did not show CPE after days of infection (Figure 3).

Replication of CNHK300 attenuated in normal cells but not in tumor cells

To determine whether the CNHK300 viruses we reconstructed replicate preferentially in tumor cells and replicatively attenuated in normal cells, we performed virus yield assay in HepG Ⅱ and Hep3B tumor cell lines and BJ normal cell lines, and because different cell lines may show different susceptibility to adenovirus infection and replication ability to correct the difference in infectivity and virus production between various tumor cell lines and normal cell lines, wtAd5 served as a control. As shown in Figure 4, CNHK300 replicated by 40 625 and 65 326 folds on tumor cell HepG Ⅱ and Hep3B, respectively, similar to those of wtAd5. However, the CNHK300 replication (180-folds) was attenuated significantly as compared with wtAd5 (4000-folds) in BJ normal cell lines.

Specificity of cytotoxicity of CNHK300 by MTT assay

MTT assay was performed to characterize the specificity

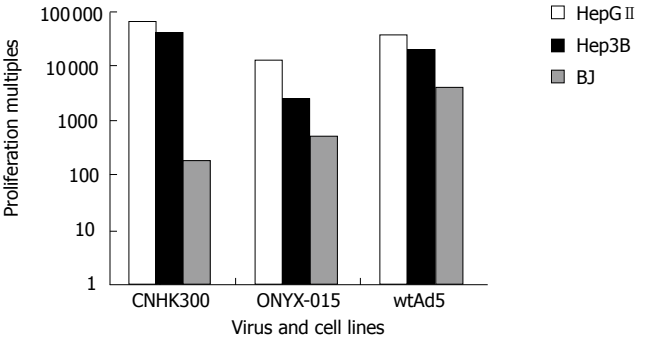

Figure 4 CNHK300, ONYX-015 and wtAd5 proliferation multiples in hepatocellular cancer cells HepG Ⅱ, Hep3B and normal fibroblast cells BJ after 48 h virus infection. CNHK300 replicated by 40 625 and 65 326 folds on tumor cell HepGII and Hep3B, similar to those of wtAd5. The CNHK300 replication (180-folds) was attenuated significantly as compared with wtAd5 (4000-folds) in BJ normal cell lines.

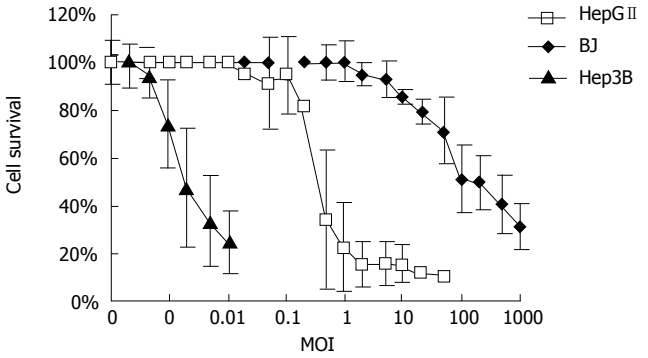

Figure 5 Hepatocellular cancer cells HepGII, Hep3B and normal fibroblast cells BJ survival curves after the cells were infected with CNHK300 at increasing MOIs. CNHK300 caused significant cytolysis in HepGII and Hep3B tumor cell lines with a MOI of 0.5 pfu/cell and 0.0002 pfu/cell. For normal fibroblast cell lines BJ in contrast, cells infected with CNHK300 showed over 50% cell viability rate at the same time points with MOI of 100 pfu/cell.

of CNHK300 on tumor cells with no or less toxicity than normal cells. As shown in Figure 5, CNHK300 could cause significant cytolysis in HepG Ⅱ and Hep3B tumor cell lines with a MOI of 0.5 pfu/cell and 0.0002 pfu/cell, respectively. However, cells infected with CNHK300 showed an over 50% cell viability rate at the same time points with MOI of 100 pfu/cell, suggesting that more than 200-500 000 folds of CNHK300 were needed to kill half of normal fibroblast cells compared with HepG Ⅱ and Hep3B tumor cells.

DISCUSSION

Many independent studies indicated that telomerase was active in over 85% malignant cancers, but not in normal tissues except hematopoietic stem cells and germ cells in the ovary and testis. Telomerase activation has been regarded as the critical characteristic of malignant tumors[18]. hTERT is the major determinant of human telomerase activity, and hTERT promoter has been successfully used to drive antitumoral genes in cancer gene therapy to target to and selectively kill the cancer cells with positive telomerase activity[19-21]. In our study, we constructed a replicative adenovirus CNHK300, in which, the E1A gene was placed under the control of the human hTERT promoter to allow us to target a wide range of telomerase-positive tumors[22]. A key requirement for clinical application of tumor-specific oncolytic virus is their attenuation in non-target tissues. So, *in vitro* viral replication assay and *in vitro* cell viability MTT assay were used to test the replicative specificity and cytotoxicity of CNHK300 in cancer cell lines and attenuated cytolysis in normal cells. Our experiments achieved similar results with some foreign studies[23-25]. As shown in our results, CNHK300 showed strong differences in replication and cytotoxicity in different hepatocellular cell lines. Though we tested higher titers of CNHK300 in HepG Ⅱ cells than in Hep3B cells after 48 h of virus exposure, CNHK300 did not show stonger cytotoxicity on HepG Ⅱ cells. There might be some other cell-killing mechanisms besides oncolytic effect due to virus replication.

Hematopoietic stem cells and germ cells in the ovary and testis are all telomerase-positive cells. Therefore, CNHK300 may replicate in above normal cells if it infects these cells. Fortunately, CNHK300 can not get into these cells because they lack adenovirus-specific CAR receptor on their cell surface[26].

Adenovirus is widely used in generating replication-selective viruses. In recent years, two major strategies have come into force. In the first one, viral genes that become dispensable in tumor cells, such as the genes responsible for activating the cell cycle through p53 or Rb binding, have been completely or partially deleted[15-17]. E1b 55 kDa deleted adenovirus Onyx-015 was proposed to replicate selectively in p53-deficient cells. Yet, several studies indicated that Onyx-015 was independent of the p53 status[15-17]. In the second strategy, transcription of viral genes has been controlled by replacing the native viral promoters with tumor-specific promoters[8-10,22-25]. In contrast, great progress has been made in the study of tumor-specific promoter regulated replication-selective adenovirus, Paul Hallenbeck (Genetic Therapy-Novartis, Gaithersburg, MD) and Daniel R. Henderson (Calydon, Sunnyvale, CA) have initiated the efforts in this direction using the α-fetoprotein (AFP) and prostate specific antigen (PSA) promoters to drive the adenovirus E1A gene. It has been proved that modified adenovirus using this strategy has some advantages compared with Onyx-015[27-30].

COMMENTS

Background

Viruses can infect, replicate in and kill human cells through diverse mechanisms. Clinicians have treated hundreds of cancer patients with a wide variety of wild-type viruses over the last century, but the approach was abandoned due to toxicity. However, with the advance of recombinant DNA technology, it became possible to genetically engineer viruses to enhance their safety and antitumoral potency. Conditionally replicating adenoviruses (CRAds) represent a promising new platform for the treatment of malignant tumors. Recently, the promoter of human telomerase reverse transcriptase (hTERT) was used to restrict adenoviral replication to telomerase-positive cancer cells through controlling the adenoviral E1a gene. Compared with other promoters, the hTERT promoter is highly active in more than 85% of different human cancers, but inactive in most normal somatic cells, therefore. this mechanism can be applied to a wide range of cancers. In this study, the authors tested the antitumor activity of the hTERT promoter regulated tumor-selective RCAd CNHK300, and confirmed its highly efficient antitumor activity *in vitro* in HCC cell lines.

Research frontiers

In recent years, two major strategies have come into force. In the first one, viral genes that become dispensable in tumor cells, such as the genes responsible for activating the cell cycle through p53 or Rb binding, have been completely or partially deleted. In the second strategy, transcription of viral genes has been controlled by replacing the native viral promoters with tumor-specific promoters. McCormick's group at Onyx proposed that an E1b 55 kDa deleted adenovirus Onyx-015 would replicate selectively in p53-deficient cells. Recently, the progress made in the study of tumor-specific promoter regulated replication-selective adenovirus has proved that modified adenovirus using this strategy has some advantages compared with Onyx-015.

Innovations and breakthroughs

Tumor specificity is a major challenge in viral therapy. For adenovirus, one strategy is the development of promoter-driven replicative adenovirus to achieve selective-replication adenovirus. The promoters of AFP, MUC-1 and PSA have been studied to control the adenovirus E1A expression targeting hepatocellular, breast and prostate carcinomas, respectively. In CNHK300, the E1A gene was placed under the control of the human hTERT promoter to allow us to target a wide range of telomerase-positive tumors with little influence on the growth of normal cells.

Applications

The results demonstrated CNHK300 could replicate in liver cancer cells efficiently as well as wtAd5 and kill heptocellular carcinoma, but had severely attenuated proliferation and cytolysis in normal cells. It may has a strong potential for targeting therapy of a wide range of cancers including hepatocellular carcinoma.

Peer review

This is a paper worthy of publishing. The design of the study in all aspects is methodologically sound. hTERT promoter-regulated replicative adenovirus CNHK300 can specifically kill a wide range of cancer cells including HCC. This new cancer therapy strategy may be proven to be very promising in clinical practice.

Abstract

AIM: To develop a model using easily obtainable, objective, verifiable preoperative parameters, to help evaluate post transplant survival probability for hepatocellular carcinoma (HCC) patients with hepatitis B.

METHODS: We retrospectively examined a cohort of 150 consecutive primary cadaveric liver transplants with HCC in our center over 6 years. Thirteen preoperative biochemical parameters and six tumor-related factors were analyzed to identify their correlation with post transplant survival using the Cox proportional-hazards regression model. The predictive power of a new model and the model for end stage liver disease was compared by the receiver operating characteristic curve.

RESULTS: In univariate analysis, the factors significantly associated with post transplant survival were serum concentrations of albumin, total bilirubin, alkaline phosphatase, alpha-fetoprotein, γ-glutamyltransferase, aspartate aminotransferase, sodium, tumor diameter and the number of tumor nodules. Multivariate analysis showed alpha-fetoprotein, serum sodium, alkaline phosphatase and the number of tumor nodules were significantly associated with the post transplant outcome. Based on the four variables, we established a new model with a c-statistic of 0.72 which was significantly greater than 0.50 (P = 0.001), and the c-statistic of MELD was 0.59 (P = 0.146).

CONCLUSION: The new model based on four objective tumor-related parameters has the capacity to evaluate the risk of post transplant mortality for HCC patients with hepatitis B.

INTRODUCTION

As a high hepatitis risk region, hepatocellular carcinoma (HCC) patients in China account for approximately 55% of HCC over the world, and more than 90% HCC in China are related to hepatitis B and accompanied by cirrhosis[1]. Liver transplantation (LT) has become accepted as an effective therapeutic modality for these patients[2,3], but the discrepancy between the livers available and patients in need of transplantation is outstanding. In 2002, the new MELD-based allocation policy was implemented by the United Network of Organ Sharing (UNOS) as the criteria for liver allocation[4]. Although the model for end stage liver disease (MELD) has been validated to predict disease severity and ranking in LT candidates on the waiting list[5-7], its capacity to predict post-LT outcome remains controversial. Heretofore, the relationship between severity of illness at LT and outcome after LT is still a major area of debate[8], especially for HCC candidates.

MELD was developed based on benign liver diseases and many aspects of malignant tumor were not taken into

account[9], therefore, the proposal to use the MELD system for post transplant evaluation lacks predictive power. Some studies supported that HCC-related parameters should be added into MELD to improve its assessing capacity for the HCC patients[10]. The aim of our study, therefore, is to find some risk factors associated with post transplant outcome of HCC recipients and attempt to develop a new model using some easily obtainable, objective, verifiable preoperative parameters, to help assess post-LT survival probability.

MATERIALS AND METHODS

Subjects

We followed 161 consecutive HCC patients aged 18 years or older who underwent primary cadaveric LT at West China Liver Transplantation Center between February 1999 and June 2006. All of the diagnoses of HCC were confirmed by pathology. Among these 161 recipients, eight were eliminated because of failure in follow-up; three, for death within 10 d after transplantation due to some perioperative factors. The remaining 150 transplants were under analysis. All included recipients' demographic characteristics, pre-LT laboratory data and HCC-related parameters were abstracted from our liver transplant database (Tables 1, 2 and 3), and all data were from the latest examination before LT. Just as the radiological Milan criteria, the tumor features in our study were also obtained by CT or MRI, and all last images were within 3 d before transplantation. The same surgical team performed all LTs using standard techniques, and all recipients were followed up by June 30, 2007.

MELD calculation

The MELD scores were calculated according to the following model[5]: MELD = 3.78 × $\log_e$TB (mg/dL) + 11.20 × $\log_e$INR + 9.57 × $\log_e$Crea (mg/dL) + 6.4. In this formula, values for creatinine, INR and TB less than 1.0 were reset to equal 1, and values for creatinine were capped at 4. In patients with creatinine value less than 4 who were on dialysis at the time of transplantation, the creatinine should be increased to equal 4.

Statistical analysis

Cox proportional-hazards regression was the main statistical tool for survival modeling. Recipients' survival was estimated by the Kaplan-Meier method, and comparison of survival differences performed by the log-rank test. To decrease the influence of extreme laboratory values, all quantitative variables were transformed to their natural logarithms ($\log_e$ value)[5]. We first performed univariate Cox regression analysis of all parameters shown in Tables 2 and 3, and those found to be significant at the 0.10 level were selected for the multivariate analysis. The final multivariate model was obtained by a backward elimination stepwise selection method with the criteria for factor removal being $P \geqslant 0.05$. Based on the selected variables, prognostic index (PI) and survival function could be constructed.

To assess the validity in predicting the risk of post transplant death, we performed ROC curves for the two models and measured their concordance statistic (c-statistic), the mathematical measure to determine the validity of a model[11,12]. Comparison of the c-statistic was done using the method of Hanley[13]. All analyses were performed using SPSS13.0 statistical software.

Table 1 Demographic characteristics of recipients

Gender	*n* (%)
Male	129 (86.0)
Female	21 (14.0)
Median age (range)	51 (28-68)
Hepatitis B	150 (100)
Child's score	
A (5-6)	89 (59.3)
B (7-9)	46 (30.7)
C (10-15)	15 (10.0)
MELD score	
⩽ 18	132 (88.0)
> 18	18 (12.0)

Table 2 Pretransplant biochemical features of recipients

Variables	mean ± SD	Min value	Max value
Hb (g/dL)	12.23 ± 2.62	4.3	18.7
PLT (× 10^9)	131.4 ± 86.0	17	569
Urea (mmol/L)	4.90 ± 2.01	2.4	16.2
Crea (mg/dL)	1.06 ± 0.10	1	1.44
ALB (g/dL)	3.79 ± 0.68	2.01	5.28
TB (mg/dL)	26.8 ± 37.4	10	260.2
AKP (u/L)	160.51 ± 130.97	18	779
GGT (u/L)	215.34 ± 255.40	24	1630
AST (u/L)	89.83 ± 76.23	19	421
ALT (u/L)	101.49 ± 99.19	12	486
INR for PT	1.25 ± 0.24	1	2.16
AFP (μg/L)	426.65 ± 393.91	1.97	3000
Na^+ (mEq/L)	137.12 ± 5.33	114.2	150.3

RESULTS

Univariate analysis

Table 4 shows the results of the univariate analyses: serum concentration of ALB, TB, AKP, GGT, AST, AFP, Na^+, tumor diameter and the number of tumor nodules were significantly associated with survival after transplantation. The positive regression coefficient implies that the risk of death would increase with increasing values of a risk factor.

Multivariate analysis

Of the candidate variables derived from univariate analyses, serum concentration of AKP, AFP, Na^+ and the number of tumor nodules were significant predictors of survival after transplantation (Table 5). The negative regression coefficients of "Na^+" and "single tumor nodule" imply that the risk of death would decrease with their increasing values.

Calculating the prognostic index and predicted survival probabilities

The prognostic index for individual patients can be

Table 3 HCC-related features of recipients

Variable		Code	Frequency	Proportion (%)
History of hepatectomy for HCC	Present	1	15	10
	Absent	0	135	90
Tumor diameter	1: < 5 cm	1	65	43.3
	2: 5 cm-	2	58	38.7
	Reference: > 10 cm	3	27	18
Tumor nodule	Nodule 1: one	1	93	62
	Nodule 2: two	2	31	20.7
	Reference: > two	3	26	17.3
Vascular invasion	Present	1	20	13.3
	Absent	0	130	86.7
Intrahepatic tumor dissemination	Present	1	33	22
	Absent	0	117	78
Perihepatic lymphadenectasis	Present	1	10	6.7
	Absent	0	140	93.3

calculated by combining their four prognostic values with the regression coefficients reported in Table 5. The formula for PI as well as the MELD is given as follow:

PI = 0.663 × $\log_e$ (AKP u/L) + 0.122 × $\log_e$ (AFP μg/L) - 8.755 × $\log_e$ (Na^+ mEq/L) - 0.631 × the number of tumor nodules (single nodule coded 1, multinodular tumor coded 0).

To assess the probability of survival at a certain time after LT, we constructed the survival function of the new model[9,14]: $S(t) = [S_0(t)]^P$ P = expPI. $S(t)$ was the survival function, and $S_0(t)$ was the individual baseline survival function which could be calculated using the linear interpolation method in baseline survival rate series. Finally, the survival probability $S(t = \chi)$ of time point χ could be computed by putting both the PI value and the $S_0(t = \chi)$ into the above formula. The larger the $S(t)$ is, the higher probability of death of the patient would be after time point χ.

Validation of the new model and comparison with MELD

The recipients' post transplant survival was compared based on this new model. Because their PI values did not follow the normal distribution (*Shapiro-Wilk* test, $W = 0.949$, $P = 0.001$), recipients were stratified into two risk groups according to the median of PI values, namely a high PI value (high risk) group and a low PI value (low risk) group. The low risk group had a better prognosis than the high risk group, and the survival difference between them was statistically significant (*log-rank* test, $\chi^2 = 10.71$, $P = 0.001$ Figure 1A).

According to ROC analysis (Figure 1B), the c-statistic of the new model was 0.72 (95% CI = 0.609-0.824) which was significantly greater than 0.50 ($P = 0.001$), and the c-statistic of MELD was only 0.59 (95% CI = 0.470-0.711) which did not have significantly predictive value ($P = 0.146$). The c-statistic may range from 0 to 1, with 1 indicating perfect discrimination and 0.5 (the area under the chance line) indicating what is expected by chance only[15]. When a c-statistic above 0.50 has statistical significance compared with 0.50, it means the model is valid[9]. Meanwhile, for the prognostic model, with a c-statistic above 0.7 is generally considered as a useful model[5], and a c-statistic below 0.7 suggests poorly predictive ability[16]. So the new model was valuable in assessing the post transplant outcome.

Table 4 Univariate Cox analysis of parameters

Variable	Regression coefficient	Regression coefficient SE	Wald	*P*-value	Exp$^\beta$

DISCUSSION

The MELD has been validated to predict the pretransplant mortality risk in patients with many types of end-stage liver disease and to determine the medical urgency for transplantation[5,7,8], but abundant further investigations indicate it's not adequate for HCC candidates[4,17]. We hold that the main reason could be attributed to the fact that the development of MELD was based on benign liver diseases and did not incorporate aspects of malignant tumors[9]. Therefore, modifications were made in the MELD/HCC allocation system in April 2003[18]. Meanwhile, although the value of MELD for assessing disease severity and predicting pretransplant survival has been convincingly established, its ability to evaluate post transplant outcome is still under controversy. To date, many studies have proved the poor capacity of MELD in predicting post

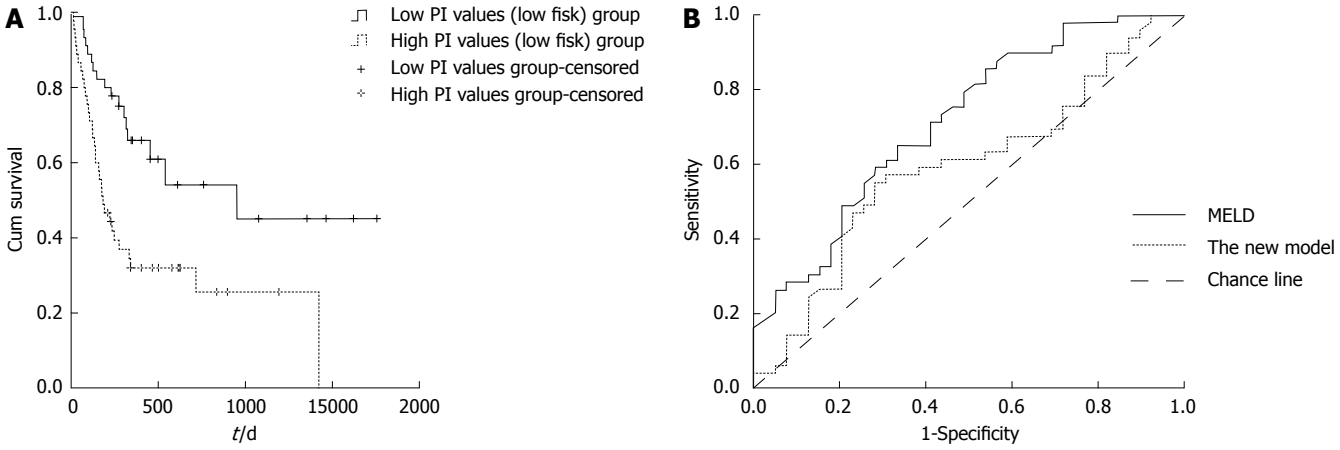

Figure 1 **A**: Comparison of posttransplant survival (Kaplan-Meier) for two groups of recipients according to the median of their PI values; **B**: Receiver operating characteristic curve (ROC) for MELD and the new model.

transplant survival[19-22]. We also confirmed the MELD scores were poorly correlated with the post transplant prognosis of HCC recipients, its c-statistic was only 0.59.

A model like the MELD which can stratify disease severity may optimize the timing of LT, and a prognostic model which can predict the post transplant survival probability may screen the appropriate candidates who can benefit mostly from the transplantation. The importance of understanding predictors of post-LT outcome before surgery was first recognized in 1987 by Malatack[23], who identified several pretransplant parameters associated with post transplant prognosis in pediatric recipients. Similarly, we also identified four variables correlated with post transplant outcome of HCC/LT recipients in our study: the serum concentration of AKP, AFP, Na^+ and the number of tumor nodules, which were easily available, objective and reproducible biochemical tests and tumor-related factors before operation. Further analyses confirmed this newly derived model based on these four variables resulting in a c-statistic of 0.72, which indicates its validity in post transplant outcome evaluation. We consider that the inclusion of these tumor-related parameters may contribute to the validity of our model because of the close correlativity between cancer biological features and patients' prognosis.

The serum concentration of AFP, combining with specific imaging techniques, has been one of the diagnostic criteria for HCC on account of its satisfactory sensitivity and specificity[24]. Also, AFP level is an important predictor of HCC prognosis[25]. The pretransplant AFP level was proved to associate with tumor recurrence and prognosis[26], and the adjuvant treatments often fail to prevent tumor progression in patients with high AFP level[27]. Ochiai *et al*[28] investigated 95 HCC patients undergoing hepatectomy and found that the serum AFP concentration above 400 μg/L was one of the preoperative risk factors associated with postoperative prognosis. Furthermore, studies from Carlis *et al*[29] and Del Gaudio *et al*[30], who retrospectively analyzed 121 and 87 HCC patients who received LT, verified serum AFP level was not only significantly related to the development of tumor recurrence, but also a significant independent risk factor of patient overall-survival after transplantation. Our finding was consistent with these studies which all identified AFP level did associate with the postoperative outcome.

Liver is a main organ to synthesize and secrete AKP in adults. Pathological changes of the hepatocytes, therefore, will cause certain changes of AKP, so it is a parameter to indicate the hepatic function. Meanwhile, since the elevated serum concentration of AKP can be observed in several liver malignant tumors such as intrahepatic cholangiocellular carcinoma and HCC, it has also been accepted as a kind of tumor marker even though its specificity is not so satisfactory yet. Screening by mathematical statistics in our study revealed that combination of AFP and AKP could have predictive value for HCC recipients in post-LT survival evaluation. If the serum concentration of AFP and AKP stay at a high level continuously or increase again after transplantation, it is usually parallel to the presence of residual tumor cells or the probability of cancer recurrence. That is consistent with what we observed clinically.

MELD does not encompass complications of portal hypertension, but many studies suggest some complications, especially the refractory ascites and serum sodium are predictors of mortality for patients with liver diseases[31-34]. In 2004, a preliminary report from Argentina first documented that addition of serum sodium to the MELD as either a dichotomous or a continuous variable could improve its predictive power[35]. Further, studies from Heuman *et al*[31] and Biggins *et al*[32] confirmed serum sodium could enhance MELD and help risk-stratify patients more accurately. The correlation between ascites and hyponatremia had been already documented by several reports[6,31]. Compared to the serum sodium, ascites is not consistently quantified, and standardization of ascites measurement among centers cannot be easily accomplished because it's a subjective and ambiguous variable. According to abundant evidence-based proofs, a conference in 2004 recognized this fact and recommended collection of serum sodium for all liver registrants to ascertain the value of adding this parameter into MELD[36]. The UNOS/OPTN Board also approved inclusion of serum sodium, either as

a dichotomous or as a continuous variable, to the list of laboratory tests collected in liver transplant recipients[36].

In our study, serum sodium showed significant association with post transplant prognosis. Its prognostic value may be reflected by the way that serum sodium can characterize patients with the hemodynamic or internal environmental derangement and the poor general conditions. Its negative regression coefficient indicates that the effect of serum sodium in whole model is protective, which means the higher the serum sodium concentration is, the lower risk of mortality the patient would be.

The number of tumor nodules is a specific character for tumor patients and a well-recognized predictor of prognosis in patients with HCC. Various clinical and pathologic factors related to the cancer recurrence and recipients' outcome have been validated in many studies, including the tumor size, the presence of satellite nodules, multilobarly distributed tumors, intrahepatic or extrahepatic dissemination, vascular invasion (microscopic and macroscopic), histological degree of differentiation[10,30,37,38]. Our results identified the number of tumor nodule as an independently predictive variable associated with post transplant survival, which was consistent with the findings from Bismuth[37]. Not surprisingly, either the tumor development from multicenter or the presence of intrahepatic metastasis will apparently parallel the poor prognosis in HCC recipients. That's why the selection guidelines for HCC candidates which have been generally acknowledged and widely used, such as the Milan criteria and the UCSF criteria, not only pay attention to the tumor size, but have severe restrictions to the number of tumor nodules.

The results of our study showed the new model, which employs four objective and widely reproducible variables, were more useful in assessing the prognosis of HCC recipients than MELD. Our study supported that incorporation of related biochemical parameters and tumor-specific variables would be a feasible way to develop a model for post transplant outcome assessment in HCC recipients. This kind of prognostic model, we believe, should play an important role in the selection of the best appropriate HCC candidates into liver allocation schemes. Whether the new model is widely useful or not, still needs to be validated by further investigation. We hope there would be continued improvement of the model, and we are looking forward to the confirmation of our findings in larger-volume patients' series.

COMMENTS

Background

Liver transplantation has been accepted as an effective therapeutic modality for HCC patients, but the relationship between severity of illness at LT and outcome after LT is still a major area of debate. Although the MELD has been proved to accurately predict pretransplant mortality, it's still controversial whether the MELD can evaluate post transplant outcome for HCC recipients.

Research frontiers

Although the value of MELD for assessing disease severity and predicting pretransplant survival has been convincingly established, abundant further investigations proved its poor capacity in predicting post transplant survival. Many studies have supported the HCC-related parameters should be added into MELD to improve its assessing capacity for the HCC patients.

Innovations and breakthroughs

In this study, we developed a new model to evaluate the risk of post transplant mortality in recipient of liver transplantation for HCC with hepatitis B. Our results also confirmed that this new model based on the four objective tumor-related parameters is more useful than MELD in assessing the prognosis of HCC recipients.

Applications

A prognostic model which can evaluate the risk of post transplant mortality may screen the appropriate candidates who can benefit mostly from the transplantation. So the new model, we believe, could play some role in selection of the best appropriate HCC candidates into liver allocation schemes.

Peer review

This paper is of some interest, its results support that incorporation of related biochemical parameters and tumor-specific variables would be a feasible way to develop prognostic model for post transplant outcome assessment in HCC recipients. This idea is deserved to explore.

Abstract

AIM: To study the relationship between the cytotoxin-associated gene-A (CagA) status of *H pylori* strains and cerebral infarction among European Caucasians and Chinese Han by conducting a meta-analysis.

METHODS: Ten case-control studies, with data on a total of 907 cases and 966 controls, were retrieved and considered; disqualified studies were excluded. The included studies were then tested for heterogeneity, and a meta-analysis was performed.

RESULTS: The combined data revealed CagA-bearing strains of *H pylori* which cause chronic infection are associated with an increased risk of cerebral infarction (OR = 2.66, 95% CI: 2.17-3.26), but no such relationship was found with CagA-negative strains (OR = 0.74, 95% CI: 0.49-1.10) in the overall population. We performed subgroup analyses, dividing the overall population into European Caucasians and Chinese Han subgroups, and analyzed the studies according to their subgroup classification. Through the subgroup analysis, an association between cerebral infarction and CagA-bearing strains was found in both subgroups (OR = 2.60, 95% CI: 1.93-3.49 in Chinese Han; OR = 2.71, 95% CI: 2.05-3.59 in European Caucasians), but no significant association was found between cerebral infarction and CagA-negative strains (OR = 0.81, 95% CI: 0.45-1.48 in Chinese Han; OR = 0.64, 95% CI: 0.37-1.09 in European Caucasians).

CONCLUSION: These results suggest CagA-bearing strains of *H pylori* are significantly associated with susceptibility to cerebral infarction in Chinese Han and European Caucasians, but that CagA-negative strains are not a definite predisposing factor in either subgroup. The magnitude of this association with cerebral infarction needs to be confirmed by prospective studies and combined studies of *H pylori* eradication.

INTRODUCTION

There is increasing evidence, from both clinical and experimental observations, that chronic inflammation (including that caused by Chlamydia pneumoniae, Cytomegalovirus and *H pylori*) plays an important role in the development of atherosclerotic lesions in patients with coronary artery disease and ischemic stroke. The role of chronic inflammation in atherogenesis has been studied extensively over the past decade. Conceiving atherosclerosis as an inflammatory condition has given rise to a series of hypotheses aimed at finding determinants for the occurrence of cardiovascular and cerebrovascular diseases beyond the traditional risk factors[1]. Among these hypotheses, the contributions of chronic infections to the development of atherothrombosis have been investigated in many cross-sectional and prospective studies, and are currently regarded as co-operating factors in maintaining a chronic inflammatory status[2]. Clinical trials have also addressed the question of a possible

positive impact of antibiotic therapy on the clinical burden from cardiovascular disease[3]. *H pylori* is the most common gastrointestinal agent worldwide. *H pylori* infection has been linked to other non-classical markers of atherosclerotic diseases, such as heat shock proteins[4], and the relationships between infection and these markers have been largely unexplored.

There is now clear evidence that cytotoxic strains of *H pylori* bearing the cytotoxin-associated gene A (CagA) have greater potential for eliciting systemic immune responses. Several subsequent case-control and cohort studies have assessed the association between CagA status and atherosclerotic diseases. Patients with atherothrombotic disease seem more likely to be infected by CagA-bearing strains of *H pylori* than healthy subjects[5]. As a consequence, these studies have assessed a wide variety of *H pylori* CagA-bearing strains, with inconsistent results worldwide, possibly because of the lack of adequate statistical power, selection bias or population diversity. A meta-analysis may avoid some of these methodological difficulties. In this article, we have performed for the first time a meta-analysis of population-based studies, and examined the evidence on the relationship between CagA status of *H pylori* strains and the risk of cerebral infarction (not including cerebral embolism) in European Caucasian and Chinese Han populations.

The aims of the present meta-analysis were: (1) To examine if there is an association between cerebral infarction and more virulent, CagA-bearing strains *H pylori*; (2) to confirm if there is an association between cerebral infarction and CagA-negative strains of *H pylori*; and (3) to confirm if there exists a difference between European Caucasians and Chinese Han.

MATERIALS AND METHODS

Data sources

The present meta-analysis follows the MOOSE statement guidelines[6]. We performed an electronic search of the MEDLINE (1966 to May 2007), Cochrane library (issue 2, 2007) EMBASE (1966 to May 2007), CBMdisc (Chinese Biomedical Literature analysis and retrieval system for compact disc, 1978 to May 2007) and CNKI (China National Knowledge Infrastructure, 1994 to May 2007) databases. In order to reduce publication bias, we collected data by contacting investigators to request unpublished data. Although it was virtually impossible to obtain all unpublished data, we conducted a manual search from the references of the papers retrieved, important academic conference articles and important Masters and Doctoral dissertations. We searched for the following key words from the MeSH index: "*Helicobacter Pylori*", "cytotoxin-associated gene-A", "atherosclerosis", "cerebral infarction", "cerebral ischemia", "stroke", "vascular", "ischemic cerebrovascular disease" and "atherosclerotic cerebral infarction". The languages were restricted to Chinese and English.

Selection criteria

We restricted our review to case-control studies and prospective studies on CagA-bearing strains of *H pylori* and the risk of cerebral infarction; the individuals in case and control groups were all European Caucasians or Chinese Han. We excluded abstracts, review articles, editorials, commentaries and book chapters. Thus, inclusion criteria for the studies were: (1) The demographic characteristics of cases and controls are similar; (2) a confirmed diagnosis of cerebral infarction, and the diagnosis was valid and specified (that is, CT or MRI scan, or a diagnosis of carotid atherosclerosis according to transcranial Doppler ultrasound); (3) cases and controls are similar in terms of all important features except for the disease in question, or they are matched, or adjustment is performed in the calculation of odds ratios; (4) information about exposure was gathered in the same way from cases and controls; (5) validated testing tool(s) for detecting the CagA status of *H pylori* and *H pylori* strains were used; and (6) detection of CagA status was performed blindly.

Studies were excluded when raw data had been duplicately published or the principal investigator was not contacted and couldn't provide the raw data. All identified publications were independently evaluated and selected by two investigators (Zhang S. and Guo Y.) based on their compliance with these criteria. The results were compared and disagreements were resolved by consensus.

Statistical analysis

The aim of this meta-analysis was to assess the relationship between the CagA-bearing strains of *H pylori* and cerebral infarction. To have an internal control, valid in all studies, for this association, valid in all studies, we also assessed the relationship between CagA-negative strains of *H pylori* and cerebral infarction. Because there are no specific tests for detecting CagA-negative strains, for the purposes of the present analysis, we calculated the prevalence of CagA-negative strains of *H pylori* by subtracting the number of CagA-seropositive subjects from the total number of individuals with *H pylori* infection reported in each study.

Data analysis was performed using Review Manager 4.2.10 software (available from the Cochrane Collaboration at http://www.cochrane.org, accessed on June 12, 2007). The studies were pooled by averaging the ORs and 95% CIs with 2-tailed *P* values through a fixed-effects model, using the Mantel-Haenszel approach when no heterogeneity was observed among studies. When evidence of heterogeneity among studies was detected, a random-effects model was adopted for a combination of all studies. Heterogeneity among studies was tested by the Chi-square statistic, obtained by summing up the weighted squares of the deviations of each estimate from the pooled estimate ($P < 0.05$ was considered evidence of heterogeneity).

Lack of adjustment for potential confounders and classic cardiovascular risk factors may inflate estimates of any association of novel candidate risk factors with atherosclerotic cerebral infarction. We performed a sensitivity analysis, with the same statistical methods used for the main analysis, excluding studies that did not provide an adjusted odds ratio.

Publication bias was examined by plotting a funnel plot of the reported effect and fail-safe number (Nfs) methods[7]. We plotted the studies' log odds ratio versus the sample sizes to detect asymmetry in the distribution

of trials. A gap in the funnel plot indicates potential for publication bias.

RESULTS

Study retrieval and inclusion

We found a total of 10 retrospective case-control studies on CagA-bearing strains of *H pylori* and cerebral infarction that were eligible for inclusion; these included 6 studies[8-13] of Chinese Han and 4 studies[14-17] of European Caucasians. We performed a meta-analysis of these studies, dividing the overall population into Chinese Han and European Caucasian subgroups, yielding a total of 907 "cases" and 966 "controls". The study parameters are summarized in Table 1.

All of the included studies adjusted data for important confounding factors, the important confounding factors (for example, age, gender, diabetes, hypertension, smoking, social class, BMI, hyperlipidemia, peptic diseases and other pathogenic micro-organism infection) between groups were comparable, and 6 studies[8,11,12,14-16] performed multivariate analysis. All studies used enzyme-linked immunosorbent assay (ELISA) to detect seropositivity for the CagA antigen.

Result of meta-analysis on the relationship between CagA-bearing strains of H pylori and cerebral infarction

The results of tests for heterogeneity in the overall population and its subgroups revealed homogeneity in these studies ($P = 0.29$ in Chinese Han; $P = 0.77$ in European Caucasian and $P = 0.61$ in overall population); therefore, we adopted a fixed effect model to perform combined analysis. The results of combined analysis were statistically significant (OR = 2.60, 95% CI: 1.93-3.49, $P < 0.00001$ in Chinese Han; OR = 2.71, 95% CI: 2.05-3.59, $P < 0.00001$ in European Caucasians; OR = 2.66, 95% CI: 2.17-3.26, $P < 0.00001$ in the overall population), suggesting CagA-bearing strains may be a determinate predisposing factor for the risk of cerebral infarction in the overall population. Moreover, it is also suggested there is no significant difference between Chinese Han and European Caucasians. The results of meta-analysis are shown in Figure 1.

Result of meta-analysis on the relationship between CagA-negative strains of H pylori and cerebral infarction

The test for heterogeneity suggested there was significant in these studies ($P = 0.001$ in Chinese Han; $P = 0.009$ in European Caucasian and $P < 0.0001$ in overall population). We performed combined analysis with a random effect model, yielding ORs of 0.81 (95% CI: 0.45-1.48, $P = 0.50$) in Chinese Han; 0.64 (95% CI: 0.37-1.09, $P = 0.10$) in European Caucasians and 0.74 (95% CI: 0.49-1.10, $P = 0.14$) in the overall population, indicating there was no apparent association between CagA-negative strains of *H pylori* and cerebral infarction. The results were similar in both the Chinese Han and European Caucasian cohorts. The results of meta-analysis are shown in Figure 2.

Publication bias

The publication bias of the meta-analysis on the relationship between the CagA status of *H pylori* strains and cerebral infarction was detected by the Funnel Plot and fail-safe number methods. Although no major asymmetries were detectable in the plot (see Figures 3 and 4), the small number of studies retrieved did not allow publication bias to be excluded. Applying fail-safe number methods (with $P = 0.05$ and $P = 0.01$) to evaluate publication bias suggested there was no potential for lack of published data for the negative outcomes. (Nfs0.05 = 81.70, Nfs0.01 = 37.45 in Chinese Han; Nfs0.05 = 169.96, Nfs0.01 = 82.18 in European Caucasians and Nfs0.05 = 498.68, Nfs0.01 = 242.01 in the overall population).

Sensitivity analysis

All of the studies retrieved considered important and

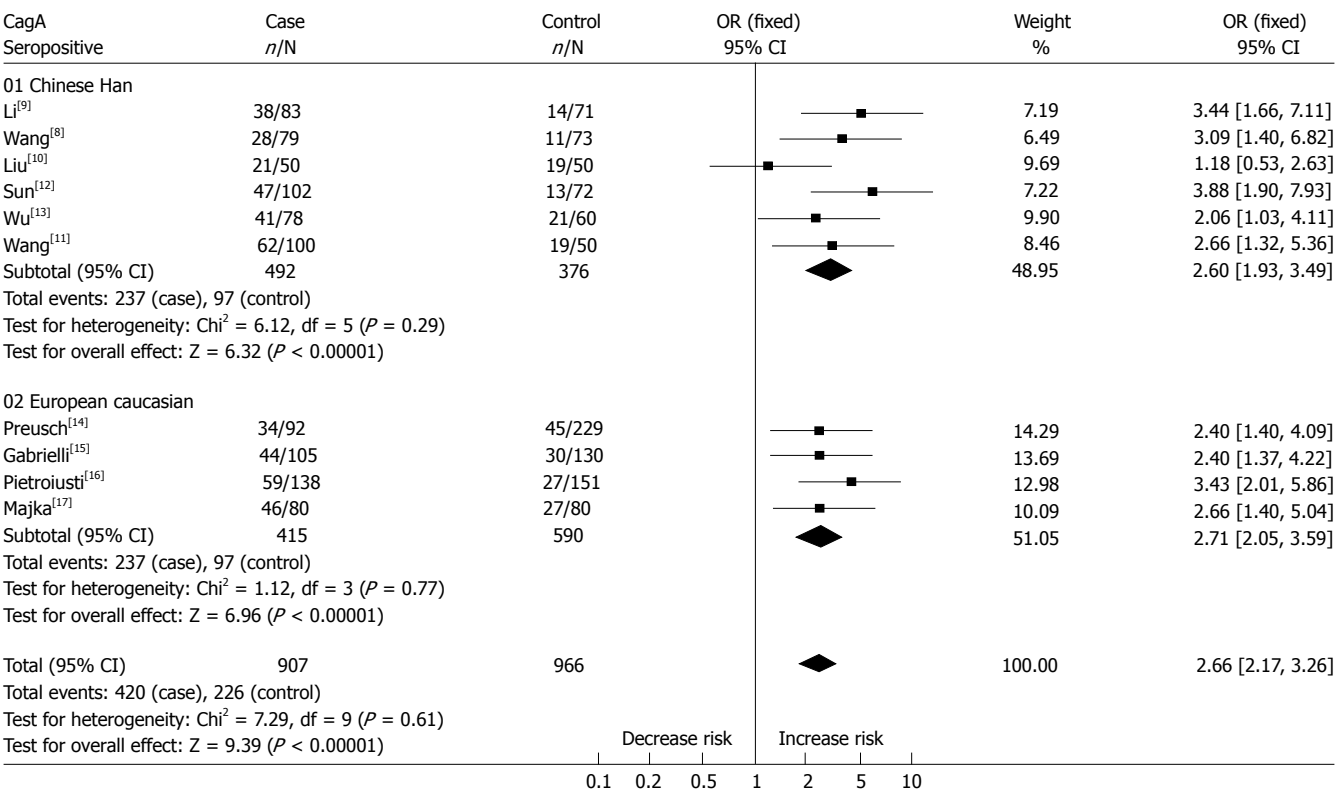

Figure 1 Relationship between CagA-seropositive strains and cerebral infarction.

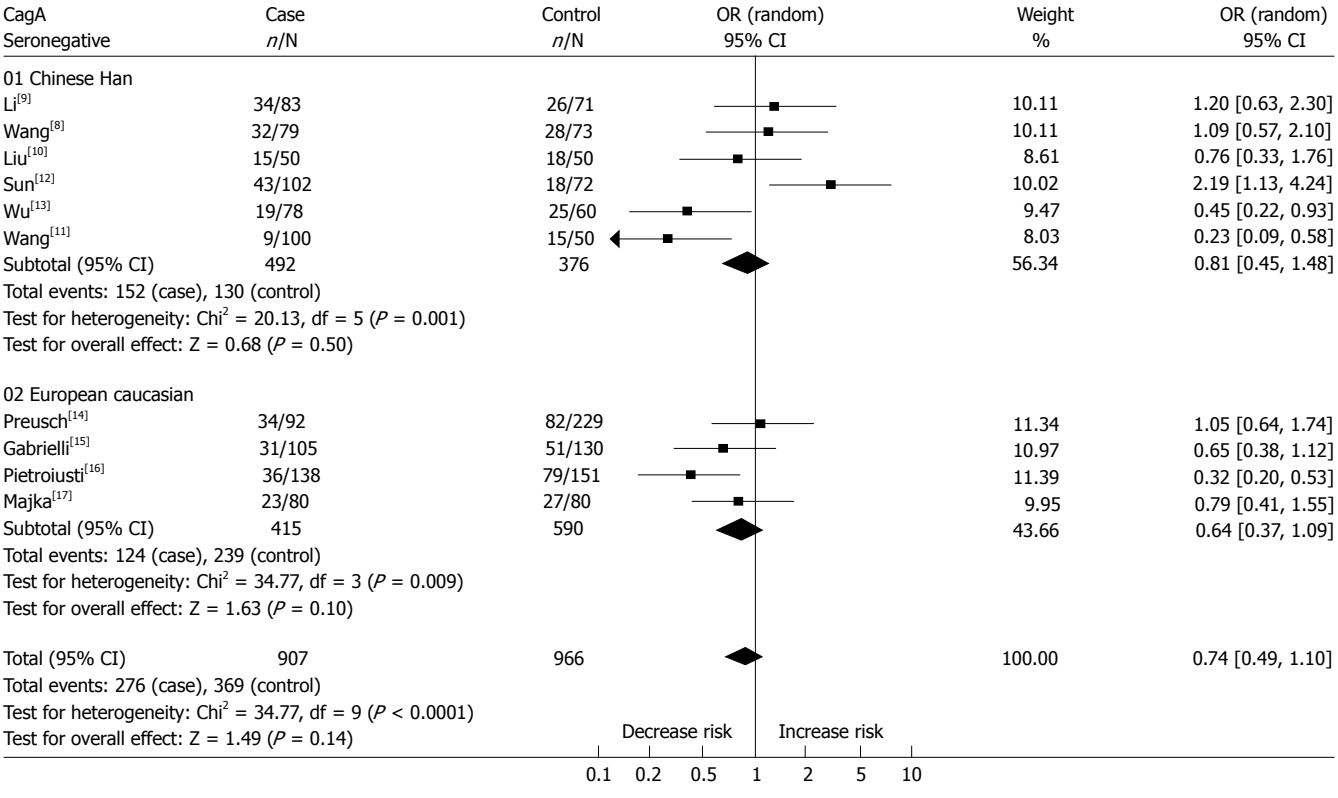

Figure 2 Relationship between CagA-seronegative strains and cerebral infarction.

potential confounders and classical cardiovascular disease risk factors. However, there were four studies, three[9,10,13] in the Chinese Han subgroup and one[17] in the European Caucasian subgroup that did not provide adjusted odds ratios for the relationship between cerebral infarction and CagA-bearing strains. The sensitivity analysis performed after excluding studies without adjusted odds ratios gave a pooled odds ratio of 2.89 (95% CI: 2.25, 3.71, $P < 0.0001$)

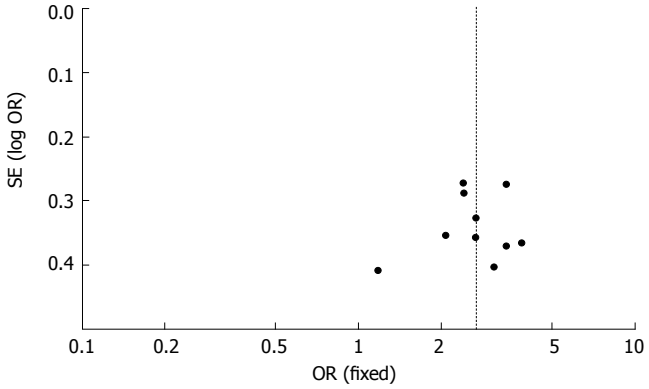

Figure 3 Funnel plot for CagA-seropositive strains.

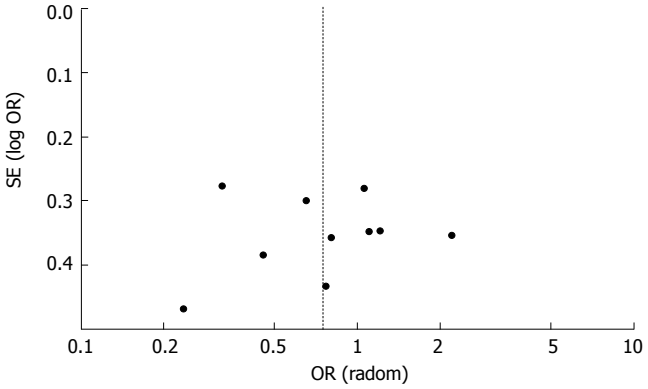

Figure 4 Funnel plot for CagA-seronegative strains.

in the overall population. These results were similar to the results of the meta-analysis before the sensitivity analysis, suggesting the combined results of meta-analysis were reliable.

DISCUSSION

Infection by *H pylori* is one of the most common chronic infections, occurring in approximately half of the world's population. It commonly affects the gastric mucosa[18,19]. Recent studies have found evidence that has resulted in *H pylori* strains being approximately classified into three types; type I includes highly virulent strains expressing CagA toxin and VacA toxin, which is strongly related to CagA. Recent studies have found evidence of *H pylori*, especially CagA-bearing strains, in atherosclerotic plaques[20,21] and an association with atherosclerotic diseases.

Using meta-analysis, we found a significant association between cerebral infarction, particularly that caused by atherothrombosis of large vessels, and CagA-bearing strains of *H pylori*, but not CagA-negative strains. In addition, no difference was found between Chinese Han and European Caucasian populations. By applying sensitivity analysis, we excluded articles that did not provide an adjusted odds ratio, and no difference was found in the conclusion. This indicated the conclusion was reliable and credible. Conducting chronic infected by CagA seronegative strain as the risk factor to combine analysis, we found no statistical significance between CagA-negative strains of *H pylori* and cerebral infarction in both subgroups and the overall population. Thus, it was uncertain whether CagA-negative strains of *H pylori* increase the risk of cerebral infarction.

Several mechanistic models may be invoked to explain the association we identified in our meta-analysis. First, it is well known CagA-bearing strains are able to induce enhanced inflammation in the gastric mucosa[22]. Since inflammation plays a major role in atherosclerosis and complicated lesions are associated with an increased inflammatory response[23], the strong inflammatory response related to infection by CagA-bearing strains may influence process of atherosclerosis through an immune-mediated release of cytokines and other substances endowed with pro-inflammatory properties[16,17]. Second, it has been suggested *H pylori*, as well as Chlamydia pneumoniae, could directly provoke inflammation within atherosclerotic plaques. *H pylori* DNA has been found in carotid atherosclerotic lesions and is associated with features of inflammatory responses[20]. Third, an auto-immune reaction could be postulated. Cross-reactivity between anti-CagA antibodies and vascular wall antigens has been recently demonstrated, suggesting these antibodies may contribute to the activation of inflammatory cells within atherosclerotic lesions[24]. This activation might eventually lead to plaque destabilization.

Although the results of the meta-analysis were positive, it is important to note there were no prospective studies on CagA status and risk of ischemic cerebral diseases. The prospective data available on the topic come from four studies that gave contrasting results on the association between *H pylori* infection and stroke[25-28]. Regrettably, these studies were heterogeneous in design and provided no raw data to calculate a pooled odds ratio. Only one of these studies[25] reported a large prospective study that compared CagA-seropositive and *H pylori*-seronegative subjects with regard to the relationship between CagA status and progression of carotid atherosclerosis, during a 5-year follow-up; and the authors showed that infection by CagA-bearing strains of Helicobacter is associated with a larger increase in carotid intimal-medial thickness (IMT) and concluded that infection with CagA-bearing strains could contribute to the pathogenesis of early atherosclerosis. However, no data are available for clinical end points. One study[28] also found that CagA-positive atherosclerotic stroke patients had poorer initial outcomes based on serial measurements of NIHSS scores. No significant differences in IMTs and NIHSS scores were found between *H pylori*-positive and *H pylori*-negative patients. Ischemic cerebrovascular diseases, especially cerebral infarction, is likely to be multifactorial[29], involving both polygenic and environmental influences. This article has provided evidence of an association between CagA status and the risk of cerebral infarction in Chinese Han and European Caucasians. It is important to bear in mind the observation nature of meta-analysis, so the standard of quality control could not be completely identical[30]. However, the majority of studies included performed multivariate adjustment in order to minimize bias. Moreover, the sensitive analysis, funnel plot and fail-

safe number analysis performed in this article could avoid and evaluate the bias to some extent. More efforts are still needed to perform an accumulated meta-analysis by conducting a high-quality prospective study with expanded sample size, so as to lay a solid foundation for further combined research. Prospective evidence will also clarify the impact of *H pylori* eradication on the risk of cerebral infarction, and may clarify the relationship between them.

ACKNOWLEDGMENTS

We are grateful to Wei Dong (Department of Clinical Epidemiology, First Affiliated Hospital, China Medical University) for her valuable contribution and kindly revising the manuscript.

COMMENTS

Background

Accumulated evidence indicates a variety of infections contribute to the pathogenesis of atherosclerosis and cerebral infarction, but conflicting results have emerged from the literature. To assess the association between the cytotoxin-associated gene-A (CagA) status of *H pylori* strains and the risk of cerebral infarction, we carried out a meta-analysis of all related studies.

Research frontiers

There have been many clinical and experimental observations highlighting the important role of chronic CagA-bearing strains of *H pylori* in the development of cerebral infarction. Our study provides evidence for the possible involvement of CagA-bearing strains in cerebral infarction by enhancing some risk factors of atherogenesis. Moreover, the investigation into two genetically distinct populations is of interest.

Innovations and breakthroughs

The most interesting result of this study is we have performed a systematic meta-analysis of population-based studies investigating CagA-bearing and CagA-negative strains of *H pylori* and their association with the risk of cerebral infarction. The association between *H pylori* and acute cerebrovascular disease seems to be due to a higher prevalence of more virulent *H pylori* strains in patients with atherosclerotic stroke.

Applications

The meta-analysis suggests *H pylori* is associated with other markers of atherosclerosis ischemic stroke. The presence of CagA-bearing strains of *H pylori* causing chronic inflammation is a statistically significant risk factor for cerebral infarction. this article is valuable for the prevention and prediction of cerebral infarction in high-risk populations.

Terminology

Meta-analysis is a statistical tool for combining results across studies; it is becoming popular as a method for resolving discrepancies in association studies of risk factors.

Peer review

This is a well-conducted meta-analysis.

Abstract

We report a case of a 32-year-old woman with episodic right lower quadrant abdominal pain. With the diagnosis of either acute appendicitis or tubo-ovarian abscess, she was treated with antibiotics, which successfully relieved the pain and the inflammatory findings. She repeated the clinical condition a few times and antibiotics worked each time. In a year, her subjective symptoms became milder, however, a giant pelvic cyst appeared. She had an exploratory laparotomy to confirm this diagnosis. Histopathological studies revealed herniated appendiceal mucosa through the muscular layer associated with chronic inflammation and marked fibrosis. Gynecological disorders such as endometriosis or lutein cyst rupture was denied. These findings represent appendiceal diverticulitis. We discuss the clinical features of the disease and its relation with the pelvic pseudocyst.

CASE REPORT

A 32-year-old woman visited our hospital with diarrhea, abdominal pain and fever. With the diagnosis of acute enteritis, an oral antibiotic was given, which resolved her symptoms. Eight months later, pain in the upper abdomen, then in the lower, appeared. Inflammatory markers such as WBC and CRP arose up to 13.0 × 10^9/L and 57 mg/L respectively. Ultrasonography detected no more than the wall thickening of the small intestine. Enteritis was the diagnosis and antibiotics worked again. Two months later, upper stomachache relapsed, which afterwards moved to the right lower quadrant. At this time, the pain was accompanied by remittent fever up to 39 centigrade. Pelvic CT scan showed a whip-shaped low-density structure with a high-density spot at its caudal end extending downwards along the bulging right pelvic wall which was then assumed to be the effect of inflammation (Figure 1). The lesion was thought to be either the swollen appendix with a fecal stone or tubo-ovarian abscess with calcification. In order to be effective in either case, an intravenous antibiotics, flomoxef sodium, was infused for a week, which successfully subsided the inflammatory symptoms but occasional abdominal pain. In four months, lower abdominal pain, neither accompanied by high fever nor related with gynecological episodes such as ovulation or menstruation, gradually became worse. The laboratory data suggested the presence of inflammation again, with WBC 11.7 × 10^9/L and CRP 45 mg/L. The outstanding finding of CT scan was a cyst in cyst structure in the pelvis, with the diameter of 3 cm and 8 cm respectively. The high density spot, without low density lesion nearby at this time, relocated cranially into the right iliac fossa and the bulging of the right pelvis disappeared (Figure 2A and B).

Though our initial diagnosis was the pelvic abscess caused by appendiceal perforation, the abscess of tubo-ovarian origin was still possible. So, laparotomy was chosen to confirm the diagnosis and the treatment.

At laparotomy, peritoneal cavity was free of ascites. The terminal ileum and the top of the uterus adhered to each other to block the exploration down the pelvic cavity. While dissecting the conglomerated organs, the dark brown serous fluid without pus-like odor or feel came out. Then, the ruptured cyst with the right ovary appeared. The atrophic appendix adhered to the back of the cecum, being entirely wrapped by dense fibrous tissue.

Though other cysts were not elsewhere as far as we explored, we tentatively made the diagnosis of ovarian endometriosis. That was because the inner wall of the cystic lesion was chocolate brown and bumpy, and in addition, the appendix lacked acute inflammatory findings. We first resected the right ovary and tube together and scraped the ruptured cystic wall as much as possible. Then appendectomy was added. She recovered well except the

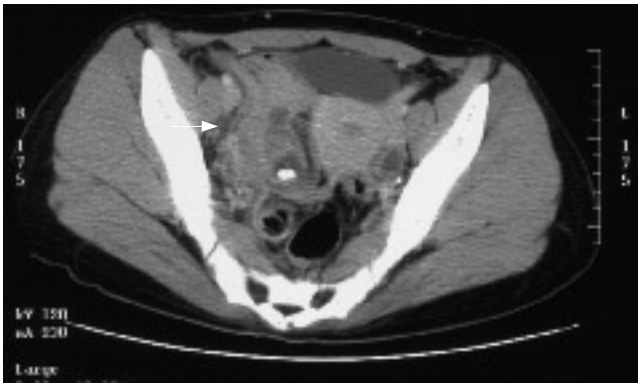

Figure 1 Pelvic CT shows a whip-shaped low density structure with a high density spot along the bulging right pelvic wall.

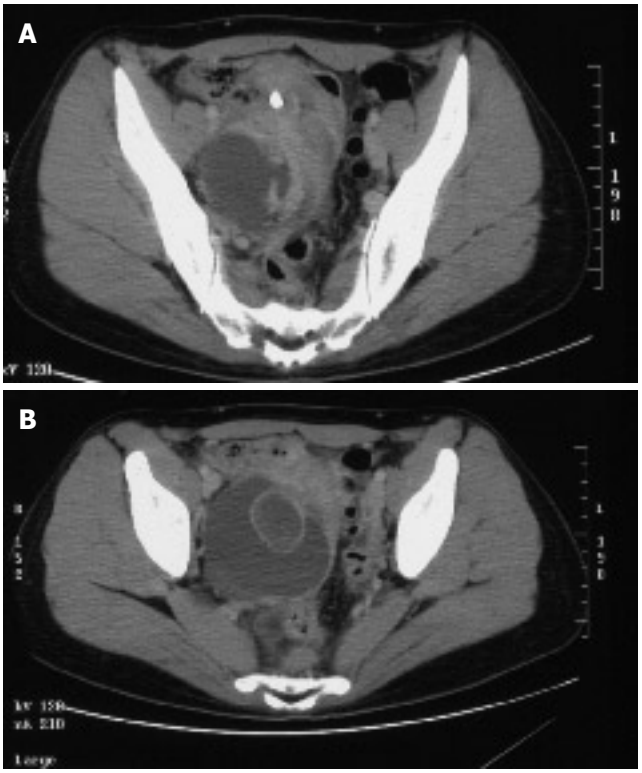

Figure 2 Pelvic CT in 4 mo. A cyst in cyst structure and the high density spot in the right iliac fossa were revealed.

wound infection at the subdermal level and was discharged on the postoperative d 14. The abdominal annoyances have not recurred since then.

The pathologic examination was as follows. The cystic wall did not have any endometrial components, but had hemosiderin deposits, which suggests a pseudocyst with old bleeding. The ovarian cyst was composed of luteal body and follicles. The appendix had a mucosal protrusion in the subserosal layer near its orifice, which is thought to be a diverticulum. Only chronic inflammation was found both along the peridiverticulum and in the whole appendix.

DISCUSSION

Appendiceal diverticulum is classified as either congenital or acquired form like other intestinal diverticulum[1]. The congenital diverticulum has full layers, that is, mucosa, submucosa, muscle, and serosa, and therefore it hardly perforates. The congenital form is exceedingly rare and was found in 0.0014% in the study of a series of 50 000 appendices[2]. The acquired form lacks muscular layer, which explains its mechanical weakness and inclination to perforation[1]. The acquired one is more common and its incidence ranges from 0.004% to 2.1%[1]. Diverticula are usually located in the distal one third of the appendix[2]. A high proportion of diverticula occurs along the mesenteric border, which is structurally weak because of the existence of vascular hiatuses[3]. Although appendiceal diverticulitis presents with similar signs and symptoms to appendicitis, its clinical features are different in some ways. Appendiceal diverticulitis is seen mainly after the third decade of life while the average age of appendicitis patient is 19 years[1,4,5]. The disease is more common in men, is usually accompanied by previous attacks of pain, and presents fewer gastrointestinal symptoms[1,4].

Those with appendiceal diverticulitis are four times more likely to have a perforation compared with simple appendicitis, which is thought to be responsible for a longer convalescence and 30-fold more mortality[1,4,6,7]. Importantly, the incidence of perforation in cases of diverticulitis was 66%[6]. However, the way of perforation, whether to free peritoneal cavity or into retroperitoneal space is not well documented. Simpson *et al* reported a case of diverticular abscess of the appendix in the right iliac fossa[4]. According to their CT figures, the abscess extends over to the preperitoneal space anteromedial to the right iliac crest, which implies retroperitoneal perforation of the diverticulum. Place *et al* reported a case of chronic appendicitis with diverticular formation of which CT finding suggested extensive inflammation in the right retroperitoneum and pericecal area[1].

Since most acquired appendiceal diverticula are on the mesoappendix, the inflammatory process may well be contained within the mesentery after perforation and cellulitis may develop in the nearby retroperitoneum. That may be one of the reasons why generalized peritonitis is uncommon in the appendiceal diverticulitis[7].

In acute appendicitis, on the contrary, perforation usually heads for the free peritoneal cavity followed by diffuse peritonitis.

In our case, we speculate that the appendiceal diverticulum also perforated into the retroperitoneal space and made phlegmon beneath the right pelvic peritoneum. Considering the above-mentioned case reports, we assume that inflamed diverticula may be apt to perforate into a less symptom presenting space, that is, retroperitoneum, at an earlier inflammatory stage. Moreover, unless appendicitis is accompanied, significant findings are hard to get by imaging tests. Prescribing antibiotics without keeping in mind the possibility of diverticulitis might just complicate the symptoms and make it insidious. Complication of a large pelvic cyst with appendiceal diverticulitis like our case has not been reported as far as we searched. Since the large cyst was not present 4 mo before and gynecological disorder such as endometriosis is pathologically unlikely, it should be related to diverticulitis. It is possible that

the permeated appendiceal fluid brought about cellulites underneath the right pelvic retroperitoneum, which eventually developed the pooling of infectious exudates. We speculate that during the course of treatment, it may have re-perforated into the free pelvic cavity to form a large pseudocyst, while appendiceal diverticulitis became chronic and almost healed. The treatment strategy of appendiceal diverticulitis should depend on its degree and spread of inflammation. Because its direct diagnosis is not easy, in the patients with repeating lower abdominal pain with inflammatory findings, we should take this clinical entity into account.

We experienced a case of appendiceal diverticulitis associated with a large pelvic pseudocyst. We speculate that the appendiceal diverticulum perforated into the retroperitoneal space and made phlegmon beneath the right pelvic peritoneum, which eventually developed the pooling of infectious exudates. Then, during the course of treatment, it may have re-perforated into the free pelvic cavity to form a large pseudocyst. Since appendiceal diverticulitis has 30 times mortality compared with simple appendicitis, to recognize this disease is clinically most important.

Abstract

An 81-year-old man presented with epigastric pain and weight loss for one month. He had a past history of pulmonary tuberculosis, 10 years ago. We performed a gastroscopy, which showed a linear depressed whitish gastric ulcer scar (0.8 cm in length) in the posterior wall of the prepyloric antrum. The result of biopsy was reported as squamous epithelium. Immunohistochemical staining using an antibody to high molecular weight cytokeratin (HMC) revealed positive staining in the squamous epithelium. Two years later, the lesion was followed up. The lesion remained at same site endoscopically, but no squamous epithelium could be seen microscopically.

INTRODUCTION

Squamous metaplasia of the stomach is not a rare clinical entity associated with gastroesophageal reflux disease and Barrett's esophagus at the cardia of the stomach[1-3]. It has been rarely described with other associated diseases, such as peptic ulcers[4], tuberculosis[5], syphilis[6], corrosive gastritis[7], extreme cachexia[8], pernicious anemia[9] and aberrant pancreatic tissue[10]. It may coexist with neoplasms[11,12].

However, there has been no report of squamous metaplasia occurring at an old ulcer scar site in the distal antrum with none of the associated diseases described above. We confirmed squamous metaplasia by a forcep biopsy with immunohistochemistry; it had disappeared spontaneously, microscopically, by the time of follow-up gastroscopy biopsy two years later.

CASE REPORT

The patient was an 81-year-old Korean man who was admitted to the authors' institution because of general weakness and loss of weight of 1 mo duration. He had pulmonary tuberculosis 10 years before admission. The patient was found to be thin, weighing only 36 kg. Breathing sound was decreased on the left lung field. Physical examination revealed no abnormal findings in the abdomen or elsewhere. The hematology values were more or less normal. Stool was negative for occult blood. Urinalysis and ECG were normal. Endoscopy revealed a linear depressed whitish old gastric ulcer scar of about 0.8 cm in length in the posterior wall of the prepyloric antrum (Figure 1). The lesion was slightly depressed. There was no evidence of malignancy in the biopsy, and squamous epithelium was obtained from the area (Figure 2). Immunohistochemical staining using an antibody against high molecular weight cytokeratin (HMC) (Moll's No 1, 5, 10, 14) from Dako (Carpinteria, California, USA) revealed positive staining in the squamous epithelium (Figure 3). Two years later, follow-up gastroscopy was performed, and the lesion was still present (Figure 4). A biopsy showed no evidence of malignancy, and no squamous epithelium was found. The patient is continuing to receive follow-up examinations in our hospital.

DISCUSSION

Squamous cell metaplasia of the stomach is not rarely reported in association with gastroesophageal reflux and distal esophageal inflammation. Takeda *et al* described

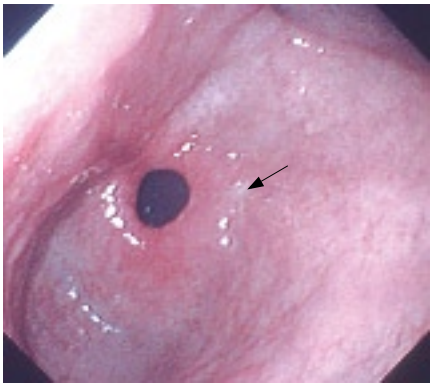

Figure 1 EGD showing a linear depressed whitish mucosal lesion of about 0.8 cm in length (arrow).

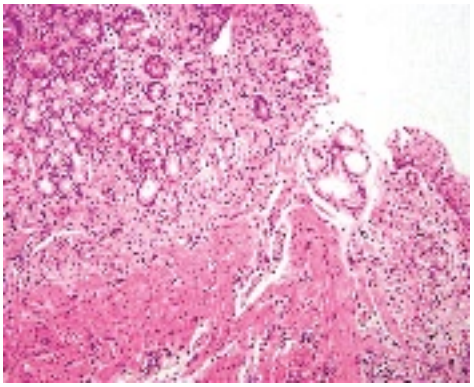

Figure 2 Photomicrograph showing squamous metaplasia (HE; original magnification, × 100).

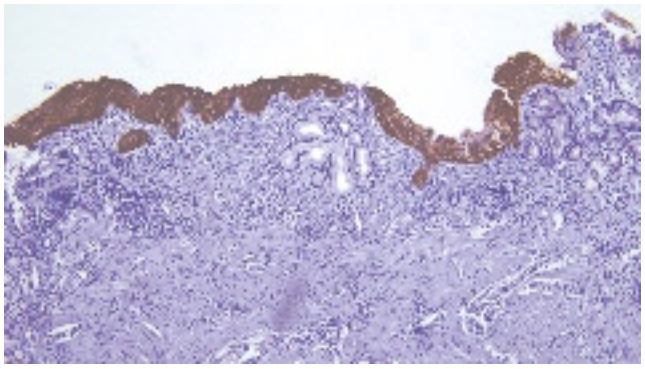

Figure 3 Photomicrograph showing an immunohistochemical demonstration of high molecular weight cytokeratin (original magnification, × 40).

Figure 4 Follow-up EGD showing a linear depressed whitish mucosal lesion without interval change (arrow).

two cases of squamous metaplasia in the lesser curvature of the cardiac region, which were recognized as white or pale mucosal areas, and the lesions were slightly depressed when sprayed with indigo carmine[1]. It has been known squamous cell metaplasia may affect the lesser curvature of the stomach preferentially, if it does not spread into the entire stomach[4]. In our case, squamous metaplasia developed at an old gastric ulcer scar site in the prepyloric antrum; this is the first reported case of squamous metaplasia in such a location and without associated disease. We confirmed the squamous metaplasia by forcep biopsy combined with immunohistochemistry (for HMC). To our knowledge, the present case is the first to describe positive immunohistochemical staining using an antibody against HMC. The distinctive staining pattern by HMC antibodies may help in the identification of squamous metaplasia. In animal studies, gastric squamous metaplasia has been experimentally induced in by the injection of pyrogallic acid[13] and methylcholanthrene[14].

It has been postulated the squamous epithelial cells develop as a progeny of a multipotent stem cells[15]. However, the pathogenesis of squamous metaplasia in the stomach remains speculative. Also, in these cases, the underlying pathogenesis of metaplasia is unknown, but it is thought to occur transiently, induced by gastric stem cells during the healing of gastric ulcers. This transient phenomenon of metaplasia was confirmed by comparing the results of the initial biopsy with those of a follow-up biopsy performed two years later. Whether squamous metaplasia of the stomach represents a premalignant change is not known. However, some reports have shown squamous cell carcinoma of the stomach sometimes develops from squamous metaplasia[4,6,7,11]. It is thought this case could have developed from gastric stem cells ontogenically, like a gastric squamous cell carcinoma. In our case, no tumorous change occurred at the metaplasia site during a two year follow-up period. Based on this evidence, close endoscopic follow-up is necessary for patients with squamous metaplasia in whom the pathogenesis of metaplasia remains to be elucidated.

In conclusion, we report a case of squamous metaplasia on the posterior wall side of the prepyloric antrum of the stomach, in an elderly male patient. Squamous metaplasia should be considered in patients with a white or pale depressed mucosal area by endoscopic examination. Careful and close endoscopic follow-up is warranted for patients with squamous metaplasia.

Abstract

Von Hippel-Lindau syndrome (VHL) is a rare autosomal-dominant, inherited familial cancer syndrome. Hemangioblastomas, pheochromocytomas and renal carcinoma are the frequent reported VHL tumors. Neuroendocrine tumors have also been described, mostly in the pancreas and rarely in the biliary trees. We report the second case of bile duct carcinoid in a 31-year-old VHL woman. She underwent right adrenalectomy for a pheochromocytoma in the past. She also had a positive family history of phenotypic expression of VHL syndrome. The patient presented with biliary colic. Endoscopic retrograde cholangio-pancreatography showed intra-luminal bile duct mass. Surgical exploration identified a beige nodular lesion that was a carcinoid tumor on histology. This new association should be clarified by further genetic investigations.

INTRODUCTION

Von Hippel-Lindau syndrome (VHL) syndrome is a rare autosomal-dominant, inherited familial cancer syndrome. It is caused by germline alterations in the VHL tumor suppressor gene (3p25)[1]. It has a reported incidence of 1/36 000 births. Twenty percent of patients have no familial history[1]. This germline mutation is associated with a significant variability in the expression of the different tumor associated with the syndrome[1]. The VHL gene codes a protein whose physiological function is the down-regulation of transcription activity of cell growth and cell cycle[2]. VHL gene inactivation may contribute to VHL tumorigenesis[2]. Most frequent VHL tumors include hemangioblastomas of the central nervous system and/or retina, pheochromocytomas (often bilateral), renal carcinoma and pancreatic cystic tumors[1]. Neuroendocrine tumors (NETs) have been reported in VHL patients, mostly of the pancreas[3]. In the bile duct, only one case of NET has been described in VHL patients[4]; we report the third case over the last 16 years.

CASE REPORT

A 31-year-old woman was routinely screened for von Hippel-Lindau (VHL) syndrome since 1998 after undergoing partial right adrenalectomy for a pheochromocytoma. She had a positive family history of phenotypic expression of VHL syndrome. Her mother was asymptomatic, but her brother was submitted to bilateral adrenalectomy for pheochromocytoma. In 2005, she underwent right adrenalectomy for recurrent pheochromocytoma. A few months later, she also underwent cholecystectomy for symptomatic cholelithiasis.

Six months post cholecystectomy, she presented with biliary colic. Abdominal ultrasound showed normal liver architecture and non dilated bile ducts. Endoscopic retrograde cholangio-pancreatography (ERCP) showed a distal partial filling defect compatible with an intra-luminal bile duct mass (Figure 1). No evidence of recurrence of pheochromocytoma was identified on abdominal CT scan.

The patient was then referred for complementary management. At the time of assessment, she was totally asymptomatic. Her weight was stable. Physical examination was unremarkable. The liver function tests as well as the CA19-9 level were completely normal. Urinary catecholamine level was normal. Endoscopic ultrasound revealed an intra-luminal bile duct polypoid solid mass of

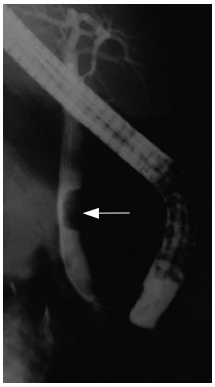

Figure 1 ERCP showing intra-luminal bile duct lesion.

16 mm in diameter. Fine needle aspiration biopsy as well as brush cytology were negative twice.

Based on these findings, surgical exploration was considered. At laparotomy, an intra-luminal bile duct lesion was palpated. Bile duct resection, hilar node dissection and hepatico-jejunostomy bile duct reconstruction was performed. The post operative course was uneventful. Macroscopically, the lesion was a beige nodular lesion measuring 1.2 cm × 1 cm. Pathological analysis reported a well-differentiated carcinoid tumour of the common bile duct. It is considered to be a complication of VHL syndrome (Figure 2).

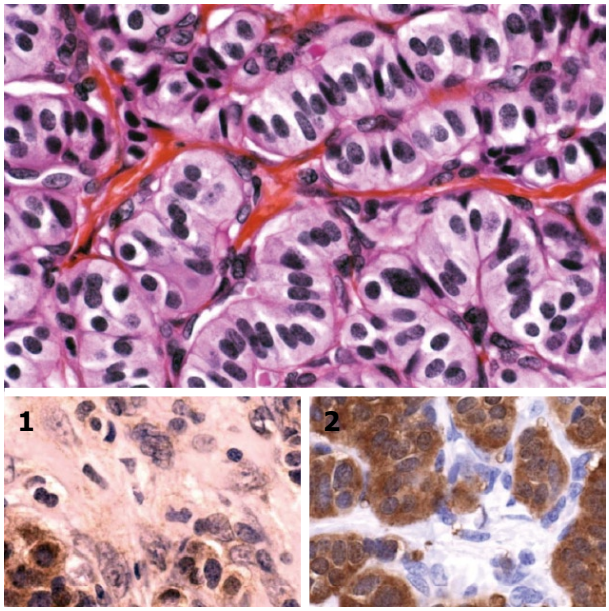

Figure 2 Trabecular pattern of neuroendocrine cell proliferation (HPS, × 200). Insert: (1) Strong staining of all tumor cells (NSE, × 200). (2) S-100 nuclear staining of 20% of tumor cells which also co-expressed NSE (× 400). No sustentacular staining pattern. NSE: neuron-specific enolase; HPS: Hematoxyline-phloxine-safran.

DISCUSSION

VHL syndrome is a rare autosomal-dominant, inherited familial cancer syndrome. It is caused by germline alterations in the VHL tumor suppressor gene (3p25). It has a reported incidence of 1/36 000 births. Twenty percent of patients have no familial history[1]. This germline mutation is associated with a significant variability in the expression of the different tumors associated with the syndrome[1]. The VHL gene codes a protein whose physiological function is the down-regulation of transcription activity of cell growth and cell cycle[2]. VHL gene inactivation may contribute to VHL tumorigenesis[2]. Most frequent VHL tumors include hemangioblastomas of the central nervous system and/or retina, pheochromocytomas (often bilateral), renal carcinoma and pancreatic cystic tumors[1]. The lifetime risk for developing these tumors is about 70%. It varies according to the nature of the germline mutation[1]. Globally, tumors in VHL syndrome occur at an earlier age than usual and are often multifocal[2]. Neuroendocrine tumors (NETs) have been reported in VHL patients, mostly of the pancreas[3]. NETs are derived embryologically from enterochromaffin cells. Hammel found hormonally non-functional pancreatic NETs in 12.3% of VHL patients[3]. Lubensky associated NETs with VHL syndrome on the basis of an allelic deletion of the VHL gene[5]. NETs in the bile duct and gallbladder have been described in only two patients with VHL syndrome[4,6]. The rarity of enterochromaffin cells in the biliary tree could explain this observation. Their number increases with intestinal metaplasia of the biliary mucosa consequent to chronic inflammation[7]. In VHL syndrome, the biliary complications are usually associated with pancreatic cystic lesions[8].

Only 49 cases of extrahepatic biliary carcinoid have been reported so far. These tumors occurred mostly in the common bile duct, were non-functional in the majority of cases and affected mostly women in their fifth decade of life. Jaundice was the predominant symptom. Less than one-third of patients present with metastases. Most of them are suitable for curative resection with prolonged disease-free survival[9-11].

Biliary NETs in VHL patients could be an independent tumor type of the syndrome or may only be related by chance. This relationship has been clearly established by genetic investigations for pancreatic NETs. Therefore, the next step in the determination of VHL biliary NET pathogenesis should be the identification of genetic changes at this level.

Abstract

Gastrointestinal stromal tumour (GIST) is a rare tumour of the gastrointestinal tract which does not generally originate in the rectum. The authors describe a case of a 70-year-old man who underwent an anterior resection of the rectum for a low-risk GIST. The patient was not given adjuvant chemotherapy with imatinib and is still disease-free 30 mo after surgery. The authors conclude that although rectal GIST is extremely uncommon, it should be included in differential diagnosis when a tumour in the rectum is detected. Biopsy of the tumour is essential, since this makes it possible to reach a sure preoperative diagnosis based on the immunohistological features of the CD117 and CD34. Although complete surgical resection with negative tumour margins is the principal curative procedure for primary and non-metastatic tumours, further studies are still needed for the determination of the most effective treatment strategy for patients with rectal GIST.

INTRODUCTION

Gastrointestinal stromal tumour (GIST) is a rare tumour involving the gastrointestinal tract and expresses CD117, a c-kit proto-oncogene, which can be detected immunohistochemically[1,2]. The most common GIST sites are the stomach (60%-70%) followed by the small intestine (20%-25%), whereas only about 5% of all GISTs start in the rectum[3,4]. Rectal GISTs make up 0.1% of all tumours originating in the rectum. According to a recent epidemiological investigation conducted in the USA, their incidence is 6.8 per million people annually[3,5]. In this report, the authors describe a rare case of GIST of the rectum.

CASE REPORT

A 70-year-old man was referred to our hospital complaining of a dragging sensation in the rectum and several episodes of rectal pain, without any problems of the alvus. A clinical examination did not detect any palpable abdominal mass. Digital investigation of the rectum revealed a mass of approximately 4 cm in diameter on the left lateral rectal wall at about 2 cm above the dentate line. The mass was hard, elastic and immobile, with an irregular surface. No blood was found on the exploratory finger. A provisional diagnosis of rectal carcinoma was made and a colonoscopy was programmed. This examination confirmed the presence of a mass, probably of submucous origin, measuring about 4 cm in its maximum diameter, attached to the lateral left rectal wall and at 2 cm above the dentate line. The surrounding mucosa proved to be healthy. Endoscopic observation suggested that the lesion probably originated in the connective tissue, transrectal ultrasound was therefore performed, together with an echo-guided needle-biopsy for the histological examination and a computed tomography (CT) with contrast medium of the abdomen and the chest and an assay of the carcinoembryonic antigen (CEA) and Ca19.9 tumoral markers.

Laboratory investigations revealed microcytic hypochromic anaemia, with haemoglobin of 11.9 g/dL, while CEA and Ca19.9 values were normal.

Transrectal ultrasound confirmed a predominantly exophytic, heterogenous, hypoechoic submucosal mass (measuring 35 mm × 26 mm) on the lateral left rectal wall (Figure 1). The histological examination of the biopsy samples led to a diagnosis of GIST due to the

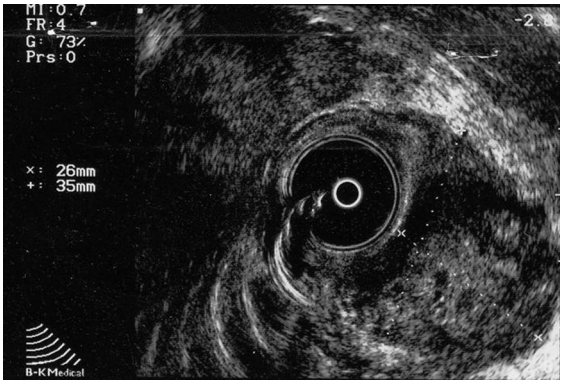

Figure 1 Transrectal ultrasound confirming a predominantly exophytic, heterogenous, hypoechoic submucosal mass (measuring 35 mm × 26 mm) on the lateral left rectal wall.

Figure 2 TC confirming the sonographic findings of the presence of a mass with a marked, irregular, eccentric thickening of the lateral left wall of the lower third of the rectum, but providing no evidence for either pelvic lymphadenopathy or distant metastasis.

immunohistochemical positivity for CD117 and CD34. Furthermore, there was also a mitotic activity of a 3 × 50 high power field (HPF), together with moderate cytological atypia and absence of necrosis.

TC confirmed the sonographic findings of the presence of a mass with a marked, irregular, eccentric thickening of the lateral left wall of the lower third of the rectum, but there was no evidence for either pelvic lymphadenopathy or distant metastasis (Figure 2).

The patient underwent nerve-sparing, anterior surgical resection of the rectum, with removal of the mesorectum, followed by colo-anal anastomosis and the formation of a protective colostomy. The post-operative period was perfectly normal, with no complications, and the patient was sent home on d 10. The colostomy was closed up two months after surgery.

Histological examination showed a submucous, intraparietal mass measuring 4 cm × 3 cm × 2 cm, with a central necrotic area and a completely healthy mucosa. The morphological aspect suggested a spindle-cell GIST, a diagnosis confirmed by the immunohistochemical investigation. Both CD117 and CD34 were, in fact, extremely positive (+++), and the mitotic index was < 5 × 10 HPF. The neoplasia was 5 cm away from the margin of the distal resection.

The patient did not undergo adjuvant therapy with imatinib. After 30 mo of follow-up, he showed no signs of either local regression or distant metastases.

DISCUSSION

GIST is an uncommon mesenchymal tumour located throughout the gastrointestinal tract and expresses CD117, a tyrosine-kinase growth factor receptor and the most important GIST marker[1]. CD117 also serves as the target for drug therapy with imatinib, a selective tyrosine-kinase receptor inhibitor that is at present the only promising chemotherapeutic drug for the treatment of patients with advanced GIST, although complete surgical resection remains the most effective treatment for such a tumour[6].

GISTs are most commonly found in the stomach (60%-70%), followed by the small intestine (20%-25%), only about 5% of all GISTs originate in the rectum[3,4].

The symptoms of GIST in the rectum do not generally differ from those of other rectal tumours and diagnostic work-up is also similar to that for any other rectal mass. Digital examination of the rectum, colonoscopy and transrectal ultrasound are essential for its diagnosis, together with preoperative biopsy, which plays a key role in the diagnosis of GIST, since it provides information on the immunohistochemical features and mitotic count. GIST typically expresses CD117, often CD34 and sometimes SMA and S-100, but its expressions vary depending on different sites. Miettinen *et al*[7] found that CD34 expression in rectal GIST is 92%, but only 50% in small intestinal GIST. Smooth muscle antigen (SMA) is most frequently seen in the small intestinal GISTs (47%), whereas it has been observed in only 14% of rectal GISTs. The reason for these variations has not yet been explained. Perhaps the differences in origin and their correlation with prognosis will be explained in the future.

Although endoscopy provides the diagnosis and biopsy material, a definite diagnosis is difficult if there is no mucosal invasion or extrinsic deformity. Most GISTs originate within the muscularis propria and most commonly have an exophytic growth pattern[8-10], seen on CT and MRI images. A focal, well-circumscribed mural mass is the most common finding and an infiltrated layer can be clearly assessed[11]. Furthermore, CT or MRI scanning is needed for the definition of local invasion level and for the detection of the presence of possible metastases.

Since the incidence of rectal GIST is much lower than that of GIST in the stomach or small intestine, the clinicopathological profiles of rectal GIST have not yet been accurately characterised, and there is therefore the tendency to validate the same prognostic factors for the latter as for such tumours at other sites, particularly gastric GIST. The most important and easily applicable histological criteria for prediction of GIST are its size and mitotic rate[12-15]. A rate of ⩽ 5 mitoses per 50 HPF is commonly used as a limit for a tumour with expected benign behaviour, and according to a large study, this can discriminate between benign and malignant tumours, especially gastric GISTs[12]. Tumours of 2 cm in diameter

are generally expected to behave in a benign fashion. Tumours of < 5 cm in diameter are associated with a better survival rate than those of 5 cm-10 cm in diameter, which in turn have a better prognosis than those of > 10 cm in diameter. Degrees of cellularity and atypia have also been suggested as useful criteria, but their reproducibility is more problematic. The epithelioid phenotype, which seems to lead to a worse outcome, together with symptoms lasting for at least a year, might be considered as further prognostic factors.

It is generally agreed that complete surgical resection with negative tumour margins is the principal curative procedure for primary and non-metastatic tumours, particularly for those at a low risk[8,16-18]. For rectal GIST, various surgical procedures may be considered, including local excision, anterior resection of the rectum and abdomino-perineal resection. The choice of procedure depends on tumour size and location[4,19]. Although not essential for the purpose of oncological radicality, we ourselves prefer to remove the mesorectum, which makes it much easier to spare the nerves of the lower hypogastric plexus, reduces intraoperative bleeding and guarantees more locoregional radicality, and this, in our opinion, also reduces the rate of local relapse. Neoadjuvant imatinib may enhance the resectability of inoperable malignant GIST and may allow for optimal surgical timing. Therapy with imatinib is also used in the adjuvant post-operative treatment of tumours at a high risk or in cases of incomplete surgical resection. It has now been more or less accepted that imatinib is a valid treatment for advanced or metastatic tumours, but further evidence for the efficiency of this drug is needed in the case of high risk tumours and for the neoadjuvant therapy.

In conclusion, rectal GIST should be included in differential diagnosis when a tumour in the rectum is detected although it is extremely rare. The diagnostic work-up of rectal GIST is exactly the same as that advised for any other type of rectal neoplasia. There is no doubt that biopsy of the tumour is an essential diagnostic instrument, since it can reach a certain preoperative diagnosis by means of the immunohistochemical characterisation of CD117 and CD34. Finally, the lack of a large series of patients under long-term follow-up observations makes it difficult to assess the necessary extent of surgical resection for rectal GIST and the indication for treatment with imatinib. Further studies are necessary to establish the most effective treatment strategy for patients with rectal GIST.

CASE REPORT

Two cases of duodenal obstruction due to a congenital web

Abstract

We present two cases of windsock deformity; both were rare in location and one had a rare associated anomaly. In the first case, the windsock was observed in the fourth part of duodenum, causing partial intestinal obstruction. In the second case, the windsock was located in the third part of the duodenum.

INTRODUCTION

Windsock deformity (WD) is a rare anomaly. Fewer than 100 cases of WD have been reported[1-3]. The second part of the duodenum is the most common site of WD[1]. Associated anomalies, such as intestinal malrotation and a preduodenal portal vein, are well known. Presentation of a fenestrated duodenal web with acute pancreatitis has also been reported[4]. We report two cases of windsock deformity; both were rare in location and one had a rare associated anomaly.

CASE REPORT

Case 1

A 19 mo-old boy was admitted to the Clinic of Pediatric Surgery at the University of Yuzuncu Yil, Van, Turkey, with abdominal distention and vomiting. He had tolerated only milk and fluids since birth. The parents were children of first-degree relatives and had six living children. Two brothers of the case died immediately after birth and one sister died at an age of eight months, of unknown causes.

On physical examination, epigastric distention was present, but no mass or organomegaly was palpated. Abdominal X-ray on admission showed a dilated stomach (Figure 1). An upper gastrointestinal contrast study demonstrated an axial rotation appearance of the stomach. The transition time of small intestine content was evaluated as normal.

At laparotomy, the stomach was significantly dilated and the pylorus seemed to be completely erased at the junction. The wall thicknesses of the duodenum at the first and second parts were increased and similar to the thickness of the antral wall. The jejunoileal walls were thinner than normal and were empty at the distal end. Attempts were made to pass a nasogastric catheter to the jejunum, but the catheter could not go beyond the fourth part of the duodenum. Normal saline, given from the nasogastric catheter, could not pass freely to the distal end, and caused distention of the proximal duodenum. A longitudinal incision was made from the antimesenteric border at the transitional zone. A web, which caused an obstruction just before the Treitz ligament, was observed. In the centre of the web was a hole with a diameter of about 3-4 mm. The web was excised circumferentially. The vertical incision was closed. The nasogastric catheter was taken out on the seventh postoperative day. Abdominal X-rays at early and late postoperative days were normal. A contrast study in the fourth week after the operation revealed a normal duodenal appearance.

Case 2

A 5 mo-old girl presented to the same institution with abdominal distention and bilious vomiting, mostly seen after meals, for three months. At physical examination, she had mild epigastric distention. There was no mass or organomegaly in the abdomen on palpation. Hematologic parameters and biochemical laboratory findings were normal.

An upper gastrointestinal contrast study pre-operatively showed a dilated stomach. The duodenum was dilated in the first and second parts, but the third part was narrow (Figure 2). Abdominal ultrasonography revealed a normal liver size with a hyperechogenic lesion of 30 mm × 25 mm × 20 mm in size, compatible with hemangioma at the caudate lobe.

At laparotomy the duodenum was dilated and the wall

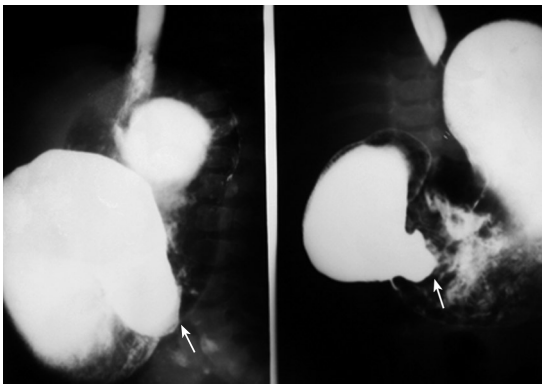

Figure 2 Pre-operative contrast study of case two showing a distended duodenum with contrast medium. Obstruction due to the web can be seen (arrow).

thickness was increased. Duodenotomy was performed longitudinally on the antimesenteric side after palpation of a membranous structure in the lumen. A web was seen and a windsock deformity was diagnosed. The opening in the middle of the web was catheterized with a 12 CH catheter (Figure 3). The web was excised circumferentially and the enterotomy was closed.

During exploration, a lesion localized in the caudate lobe of the liver 25 mm × 30 mm in size, elastic in nature and compatible with hemangioma was detected. Neither biopsy, nor excision was performed. The nasogastric catheter was pulled out postoperatively at sixth day. Oral feeding was tolerated well and she was discharged from the hospital on the 12th postoperative day.

DISCUSSION

Only 100 cases of WD have been reported in the literature[1-3]. The second part of the duodenum is the most common site, representing 85% to 90% of all WD cases. The third and fourth parts of the duodenum represent 20% and 10% of WD cases, respectively[1,5].

The WD in our first case was in the fourth part of the duodenum, which is a very rare location. The duodenum undergoes a solid phase; between the eighth and tenth week of gestation, the duodenal lumen is re-established by the gathering of vacuoles, and re-canalization occurs. Insults

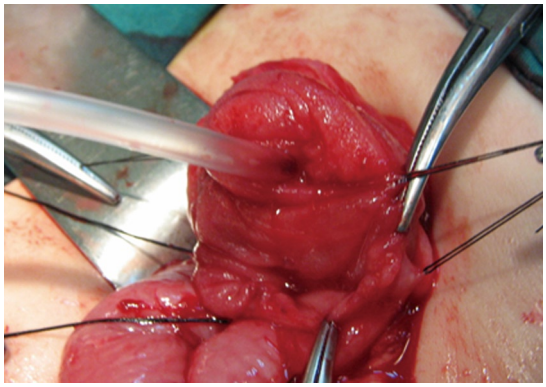

Figure 3 Duodenotomy revealing catheterized windsock deformity in the distal position. The web and its opening can be seen.

during this crucial period of development are believed to result in a failure of re-canalization and consequent atresia, stenosis and webs[5,6]. The resultant obstruction causes dilatation in the proximal duodenum and stomach, as well as hypertrophy and distention of pylorus[5].

Abdominal distention and vomiting were common complaints in each of our cases. Our first case was followed up by a pediatrician with diagnoses of constipation and growth failure. The great majority of individuals with WD are asymptomatic. A significant proportion of patients have a later onset of symptoms, and in some, the diagnosis is delayed until adulthood[7]. Clinical presentation may be characterized by nonspecific abdominal symptoms. Abdominal discomfort is usually located in the epigastria, right upper abdomen or umbilical area, and is made worse or brought on by eating and relieved by vomiting, belching or assuming a certain posture[1,5].

WD can be an incidental finding of upper gastrointestinal barium examination. In the second case, a pre-operative upper gastrointestinal study revealed the intraduodenal web. One of the most important features of duodenal diverticulum is the retention of barium in the sac. Barium retention for 6 or more hours is diagnostic[1,3].

Associated anomalies, such as intestinal malrotation and a preduodenal portal vein, are well recognized. Pancreatitis has also been reported in individuals with intraluminal duodenal diverticula[4,5]. Superior mesenteric artery syndrome is a very rare condition in childhood, most frequently resulting in duodenal obstruction in the adult population[12]. Bleeding from ulcers at the diverticulum[8], obstruction from gallstones[9] and marbles[3], as well as cholangitis[10] have been described. Hepatic hemangioma is an unusual finding in the pediatric population and is more common in older children and adolescents than in neonates and infants[1,11]. We discovered, incidentally, the hemangioma during US for the diagnosis of intestinal pathology.

Duodenotomy with web excision was performed in both of our cases. Two basic options for the repair of duodenal obstruction secondary to a web or atresia are presented: duodenoduodenostomy and duodenotomy with excision of the web. The web should be defined with the aid of a tube trough in the stomach, and the ampulla of Vater should be carefully identified prior to excision.

The advent of improved pediatric flexible fiberoptic endoscopes and fiberoptic laser technology makes endoscopic ablation of duodenal webs and windsocks in the newborn possible[5,9].

We aimed to present two cases of WD showing rare locations in the fourth and third part of the duodenum from the same institution.

Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*WJG*, World J Gastroenterol ISSN 1007-9327/ CN 14-1219/R) is a weekly journal with a circulation of more than 15 707, published on the 7th, 14th, 21st and 28th of every month. WJG is a peer-reviewed journal. In 2007 the number of unique overseas visitors to the *WJG* website was 15 600, representing 123 countries worldwide. Original research, reviews, comments, and case reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc*., from all over the world are welcome on the condition that they have not been published previously or submitted elsewhere simultaneously.

Publication model

WJG has a non-profit publication model, which is a combination of an Open Access and commercialized publication model (i.e. payment by a third party). This publication model has proven to be very effective. By 21st December 2007, the number of visitor hits to the *WJG* website reached 21 350 084. *WJG* advocates the tenet that research funding granted to scientists should be used to serve scientists so that high quality scientific articles can be published.

Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/ Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology* and *Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

Published by

The WJG Press

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://wjg.wjgnet.com. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to submission@wjgnet.com, or by telephone: +86-10-85381901-600. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

Author controbutions: The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/ analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, etc. should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: http://www.wjgnet.com/wjg/help/11.doc.

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: http://www.wjgnet.com/wjg/help/instructions.jsp.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID requirement

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation(doi:10.3748/wjg.13.6458). This link (http://www.crossref.org/SimpleTextQuery/) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Inappropriate references
Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data
Write as mean ± SD or mean ± SE.

Statistical expression
Express *t* test as *t* (in italics), F test as F (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as γ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units
Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/wjg/help/15.doc.

Abbreviations
Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics
Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori*, *E coli*, *etc.*

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

Editorial Office
World Journal of Gastroenterology
Editorial Department: Room 903
Ocean International Center, Building D
No. 62 Dongsihuan Zhonglu
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-59080039
Fax: +86-10-85381893

Language evaluation
The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form
Please download a Copyright assignment form from http://www.wjgnet.com/wjg/help/9.doc.

Responses to reviewers
Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/wjg/help/10.doc.

Proof of financial support
For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript
WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases
Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee
Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
