This study was designed to assess the optimal surgical procedure for duodenal GIST, and to compare segmental resection with more extensive pancreaticoduodenectomy (PD).

Innovations and breakthroughs

The authors reported good oncological outcomes with long-term disease-free survival (DFS) in the segmental duodenectomy (SD) group. Thus, whenever associated with clear surgical margins, SD is a reliable and curative option for most duodenal GISTs. However, PD remains a good alternative for tumors in the vicinity of the ampulla of Vater.

Applications

Segmental resection should be preferred, when possible, to more extensive procedures for duodenal GIST. However, for tumors located in the vicinity of the ampulla of Vater, PD remains a good option.

Peer review

The authors evaluated the results of SD (five cases) and PD (two cases) for duodenal GIST. The very low number of patients is certainly a weakness of this study; on the other hand, duodenal GIST is very rare. The authors obtained good DFS following limited resection (SD) with clear margins.

Abstract

AIM: To assess whether the use of fibrin sealant shortens the closure time of postoperative enterocutaneous fistulas (ECFs).

METHODS: The prospective case-control study included 70 patients with postoperative ECFs with an output of < 500 mL/d, a fistulous tract of > 2 cm and without any local complication. They were divided into study (n = 23) and control groups (n = 47). Esophageal, gastric and colocutaneous fistulas were monitored under endoscopic visualization, which also allowed fibrin glue application directly through the external hole. Outcome variables included closure time, time to resume oral feeding and morbidity related to nutritional support.

RESULTS: There were no differences in mean age, fistula output, and follow-up. Closure-time for all patients of the study group was 12.5 ± 14.2 d and 32.5 ± 17.9 d for the control group (P < 0.001), and morbidity related to nutritional support was 8.6% and 42.5%, respectively (P < 0.01). In patients with colonic fistulas, complete closure occurred 23.5 ± 19.5 d after the first application of fibrin glue, and spontaneous closure was observed after 36.2 ± 22.8 d in the control group (P = 0.36). Recurrences were observed in 2 patients because of residual disease. One patient of each group died during follow-up as a consequence of septic complications related to parenteral nutrition.

CONCLUSION: Closure time was significantly reduced with the use of fibrin sealant, and oral feeding was resumed faster. We suggest the use of fibrin sealant for the management of stable enterocutaneous fistulas.

INTRODUCTION

The formation of enterocutaneous fistulas (ECFs) can be either spontaneous or as a consequence of intra-abdominal surgery. The incidence of spontaneous fistulas is around 15%-25%[1,2]. These can be secondary to Crohn's disease, malignancy, infectious diseases such as tuberculosis and deep mycosis, diverticulitis, vascular failure, radiation exposure and ischemia of the mesentery[3]. Postoperative fistulas account for 75%-85% out of all fistulas in the digestive tract and they arise from unintentional enterotomy, dehiscence of an anastomosis because of tension in the suture line, a foreign body located close to the anastomosis, inadequate suture techniques, distal obstructions, hematomas, abscess formation at the site of the anastomosis, or tumors[3-5]. Morbidity and mortality associated with postoperative fistulas are substantial as they are highly associated with nutritional deficits, septic complications and concomitant diseases that may appear during prolonged hospital stays[5-7]. The conventional treatment for postoperative fistulas includes intestinal rest, correction of electrolytic disturbances, parenteral nutrition, protection of the skin surrounding the fistula, and treatment and prophylaxis of any related local or systemic septic complications[5,6]. Spontaneous closure of ECFs occurs after 6-8 wk in 60%-70% of the cases after specific medical management[8]. Fistulas that do not close with conservative medical treatment require surgery[2,7].

Biological fibrin glues have long been used extensively in many surgical and speciality fields[9,10]. Fibrin glue contains high concentrations of human fibrinogen and thrombin and it has been widely applied clinically as a biological adhesive system for tissue adhesion or hemostasis[11-13]. Additionally, in comparison with other adhesives, this compound has several advantages in terms of biocompatibility, biodegradation and hemostasis[14-16]. Its use has also been extended for the management of untreatable fistulas that have not responded to conservative treatment[11,12]. The efficacy of fibrin varies depending on a number of features, such as the output volume of the fistula, the location of the fistula, and the presence of a fistulous tract long enough (greater than 2 cm) to allow fixation of the patch[17]. Following the placement of the fibrin patch, it is replaced by collagen after about 4 wk, leading to cessation of drainage and promotion of closure of the fistula[9,16] with avoidance of inflammatory processes, finally resulting in improved healing[18].

The aim of this study was to determine the outcomes and advantages of treating low-output-volume ECFs with the addition of fibrin glue and compare them with conservative management without the use of adjuvant application of fibrin glue into the fistulous tract.

MATERIALS AND METHODS

Over an 8-year period, 70 male and female adults with stable, non-complicated, low-output ECFs were included in this non-randomized prospective case-control study. During the same period, a total of 218 patients were evaluated for postoperative enterocutaneous fistulas. One hundred and forty-eight patients were not considered for the study because of high output volume (> 500 mL/24 h), abdominal infection, fistulous tract < 2 cm, entero-atmospheric fistulas and residual intestinal or peritoneal disease. Patients were divided into 2 groups, a study group (n = 23) in which patients received variable doses of fibrin glue through the external opening of the ECFs, and a control group (n = 47) of patients treated without fibrin glue. Both groups were assessed to compare endpoint variables. Patients belonging to the control group were selected according to the origin of the fistula, using 1 case per 2 controls. Both groups were treated with the same conservative management, known to promote spontaneous closure. Patients with any concomitant condition that impeded spontaneous closure were excluded from the study.

Evaluation of the external fistula and medical treatment

Patients with a fistula output volume of less than 500 mL/24 h for at least 3 consecutive days were chosen to participate in the study. We evaluated the characteristics of the fistulas with contrast fistulography, computed tomography (CT) scans and proximal or distal endoscopy to confirm the absence of any condition that might impede spontaneous closure of the fistula, such as complex tracts, associated abscesses, intra-abdominal sepsis, residual disease, foreign bodies or distal obstruction, and to determine the length of the fistulous tract. Those cases with purulent collections were treated with percutaneous drainage before the application of the fibrin glue. Fistulous tracts measuring less than 2 cm were not included in the study because it was not possible to produce an adequate adhesion area for the patch into the fistulous tract. Pure pancreatic fistulas were not included.

Conservative treatment consisted of fasting, suppression of gastric secretion with oral or intravenous omeprazole or ranitidine, subcutaneous octreotide and nutritional support, either parenteral or enteral according to the anatomic location of the fistula. All patients received skin protection with barriers to prevent burns. The most important endpoint variables were the changes in the output volume, the time required to reduce the output of the fistula to zero for 2 consecutive days, the time re-

quired to resume normal oral intake, and fistula reopening. In addition, we studied complications related to the use of nutritional support.

Fibrin glue application

To allow the adhesion of the fibrin glue patch, all fistulous tracts were debrided with an endoscopic brush to produce a smooth surface. The adhesive was composed of fibrinogen at a concentration of 80 mg/mL and 1000 IU/mL of thrombin (both of human extraction) combined with tranexamic acid and calcium chloride (Quixil®; Omrix Biopharmaceuticals Ltd., Tel-Hashomer, Israel). Prior to application, the adhesive was defrosted and components were placed separately in a double-syringe system with distal mixing device. The application of the glue through the external opening of the fistula was controlled endoscopically to assure total occlusion of the internal hole, in those patients with esophageal, gastric and colocutaneous fistulas. Patients with fistulas arising from the duodenum (after gastrectomy and gastrojejunostomy), jejunum and ileum, the control of the glue application was performed with fistulography to establish the distance between the internal and external holes, fistulous tract diameter and estimated volume of fibrin glue to administrate into the fistulous tract. We considered therapeutic failure when the fistula output persisted after the third application of the adhesive without a limit time.

Ethical considerations

This study was conducted according to the declaration of Helsinki of 1989 and Mexican Health Guidelines. The protocol was approved by the Ethical Committee of the Western National Medical Center at the Mexican Institute of Social Security. Full written informed consent was obtained from all patients before their inclusion to this study.

Statistical analysis

Results are described as percentages and central tendency and dispersion measures. Qualitative variables were analyzed using χ^2 or Fisher's exact test, and for quantitative variables the Mann Whitney U test or Student's t test was used according to the resulting distribution. All P values less than 0.05 were considered statistically significant.

RESULTS

Between January of 2000 and December of 2007, 70 patients were included. The study group consisted of 23 patients (14 male, 9 female) with a mean age of 51.95 ± 11.67 years, and a control group of 47 patients (30 male, 17 female) with a mean age of 51.17 ± 13.78 years. In both groups, all external fistulas were classified according to the anatomical origin (Table 1).

Esophago-gastrocutaneous fistulas

We included 10 patients with esophago-gastrocutaneous fistulas secondary to esophageal resection of distal carcinoma, caustic burns or high-grade dysplasia associated with Barrett's metaplasia. In all cases, the esophagus was replaced by gastric transposition through the posterior mediastinum. There were 3 cases in the study group and 7 in the control group. There was no difference in mean

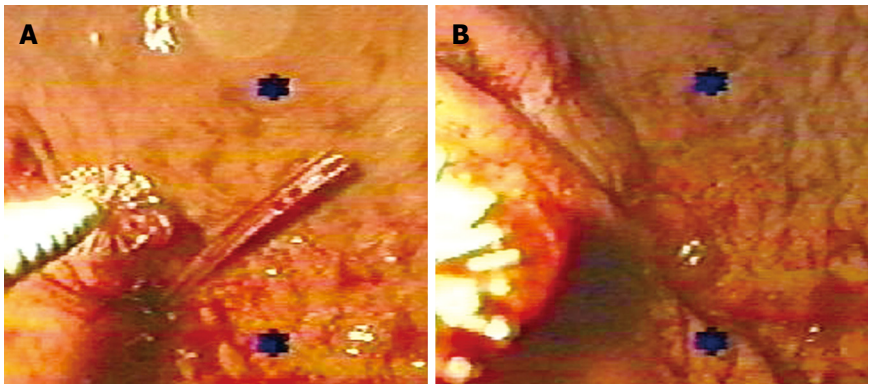

Figure 1 Endoscopic control of the application of fibrin glue in a patient with a gastrocutaneous fistula. A: The sealant was instilled externally; B: For better results, a complete occlusion of the internal hole of the fistulous tract is required.

age between groups (P = 0.85). The average output of the fistulas was 70 ± 42.7 mL and 88.1 ± 19 mL, respectively (P = 0.15). The fistulous tract measured 3.6 ± 0.36 cm and 3.65 ± 0.48 cm, respectively (P = 0.86). The mean quantity of fibrin glue applied into the external opening was 9 mL (range 7-11 mL). The time to obtain complete closure following the initial application was 8 ± 4 d in the study group. Spontaneous closure was observed after 19.1 ± 6 d of medical treatment in the control group (P < 0.05).

Gastrocutaneous fistulas

Five patients with gastrocutaneous fistulas were included in the study group and 10 in the control group. Gender distribution was similar in both groups and there were no differences in age (P = 0.19). Average fistula output was 151.4 ± 146.1 mL and 131.4 ± 28.8 mL (P = 0.67). The majority originated from endoscopic or surgical gastrostomies. One case in the control group had a fistula that originated from a partial dehiscence of a gastrojejunostomy. The fistulous tract measured 4.3 ± 0.77 cm and 4.1 ± 0.61 cm (P = 0.76) in study and control groups, respectively. The adhesive application was performed under endoscopic visual control to ensure complete occlusion of the internal hole (Figure 1). The mean quantity of fibrin glue was 18 mL (range 6-30 mL). In the study group, complete closure was observed 7.0 ± 3.1 d after the application. In the control group, spontaneous closure occurred after 35.2 ± 18.7 d (P < 0.01).

Duodenum and jejunocutaneous fistulas

Fifteen patients, 8 male and 7 female, were included in this group. One patient in the study group and 2 patients in the control group had pure duodenal fistulas after total or partial gastric resections. The remaining 12 cases had external jejunocutaneous fistulas, 4 in the study group and 8 in the control group, all of which resulted from partial dehiscence of jejunorrhaphy or anastomoses after resection. There were no differences in age between groups (P = 0.34). The mean fistula output was 111.6 ± 75.9 mL in the study group and 123.6 ± 19.9 mL in the control group (P = 0.63). The fistulous tract measured 6.5 ± 0.56 cm and 6.9 ± 0.68 cm (P = 0.26), respectively. The mean quantity of the fibrin glue applied into the external opening was 12.5 mL (range 10-15 mL). Complete closure was observed 7.6 ± 2.6 d after the application of the adhesive in the study group and at 30.0 ± 17.1 d in the control group (P < 0.01).

Ileocutaneous fistulas

Eighteen patients, 8 male and 10 female were included in this group, 6 in the study group and 12 in the control group. All fistulas were secondary to partial dehiscence of end-to-end anastomoses or enterorrhaphy. There was no age difference between the groups (P = 0.69). The average fistula output was 132.8 ± 47.6 mL *vs* 143.0 ± 36.6 mL in study and control groups, respectively (P = 0.61). The fistulous tract measured 10.4 ± 1.8 cm and 10.6 ± 1.9 cm, respectively (P = 0.85). The mean quantity of fibrin glue applied into the external opening was 14.5 mL (range, 10-19 mL). For the study group, complete closure was observed 16.1 ± 21.6 d after the first application and 37.8 ± 17.2 d in the control group (P < 0.05). In one of the patients the fibrin glue was applied endoscopically because the fistula originated from dehiscence of an ileocolic anastomosis 70 cm from the anal margin.

Colocutaneous fistulas

This group had 12 patients, 8 male and 4 female, 4 in the study group and 8 in the control group. There was no age difference between groups (P = 0.84). The average of the fistula output was 87.7 ± 40.8 mL in the study group and 106.1 ± 16.5 mL in the control group (P = 0.28). The fistulous tract measured 15.4 ± 2.1 cm and 14.1 ± 1.5 cm (P = 0.24). All fistulas were secondary to left colon resection, with manually constructed end-to-end anastomosis or primary closure after trauma. Diagnoses made before the resection were diverticular disease, sigmoid or proximal rectal cancer, and trauma with incidental perforation. The mean quantity of fibrin glue applied into the external opening was 14.5 mL (range 12-26 mL). In the study group, complete closure occurred 23.5 ± 19.5 d after the first application, and spontaneous closure was observed after 36.2 ± 22.8 d in the control group (P = 0.36).

Fistula recurrence, complications related to nutritional support and mortality

During an 18-mo follow-up period, reopening of fistulous tracts was observed in 2 patients with colocutaneous fistulas. Both patients belonged to the study group. One

patient suffered incidental perforation of the left colon during a necrosectomy with primary closure. After the reopening of the fistulous tract, endoscopic evaluation showed sigmoid stenosis, and a CT scan demonstrated a retroperitoneal inflammatory process probably related to a previous episode of acute pancreatitis, and after 8 mo he experienced spontaneous closure. The second case was a patient with residual diverticular disease of the left colon that was not identified during the initial evaluation before fibrin glue application. This patient underwent a segmental colon resection with subsequent resolution of the complication.

Morbidity related to nutritional support was significantly different between groups. In the study group, there was one minor and one major complication (8.6%). One patient required a change of jejunostomy tube because of obstruction, and the other patient, who had short bowel syndrome and was receiving long-term total parenteral nutrition, developed septic shock secondary to *Candida albicans* infection 11 mo after the resolution of the fistulous complication. This patient eventually died of multiple organ failure. In the control group, morbidity was observed in 20 patients (42.5%). This difference was statistically significant ($P < 0.01$). Minor complications such as tube obstruction, enteral nutrition-associated diarrhea, and central venous catheter obstruction were observed in 8 cases (17%). The remaining 12 patients developed major complications, such as fever related to a central venous catheter in 11 cases: 4 with negative cultures which were resolved with a new access; 7 patients with positive cultures, 6 with Gram-positive cocci (*Staphylococcus aureus* and *Streptococcus epidermidis*); and the remaining patient died of septic complications caused by a systemic *C. albicans* infection. There were 2 additional deaths during the follow-up from non-related causes, including one patient from each group (acute myocardial infarction and diffuse abdominal carcinomatosis). There were no complications related to the application of the fibrin glue. Finally, when we considered all patients stratified only by the interventional maneuver, we observed highly significant results. The time to achieve total fistula closure was 12.5 ± 14.2 d in the study group (fibrin glue) and 32.5 ± 17.9 d in the control group ($P < 0.001$).

DISCUSSION

Fibrin sealant, also referred to as fibrin glue or fibrin tissue adhesive, is a surgical hemostatic agent derived from plasma coagulation proteins[19]. Fibrin sealants are widely used for many surgical procedures in all fields of surgery[20]. They can be used for hemostasis, wound closure, and tissue sealing, and in contrast to synthetic adhesives, they have the advantage of being biocompatible and biodegradable, and they are not associated with inflammatory processes, foreign body reactions, tissue necrosis, or extensive fibrosis. With normal wound healing, fibrin absorption occurs within days to weeks of application, depending on the type of surgery, the proteolytic activity at the treated site, and the amount of sealant used[21].

Commercial concentrates containing human fibrinogen, factor XIII and bovine thrombin became available in Europe in the late 1970s and have been extensively used since then for hemostasis and other indications[22]. All these products contained antifibrinolytic agents. However, when first introduced, fibrin sealants were excluded from use in the United States based on the risk of transmission of infection[21,22]. The risk of viral transmission was reduced through careful donor selection followed by heat treatment of the human fibrinogen component. Virally inactivated human thrombin has replaced bovine thrombin in most European products[23]. A number of researchers have described the postoperative development of antibodies to bovine thrombin in some patients[24].

The first new generation fibrin sealants used in the United States, with removed or inactivated viruses, was Tisseel (Baxter Healthcare), which was approved by the US Food and Drug Administration (FDA) in 1998[25]. Tisseel was used in the majority of the studies performed to assess the use of this adhesive. In the present study, we used a fibrin sealant known as a second-generation sealant, which received FDA approval in March 2003 and is known as Crosseal (American Red Cross)[26]. Both Tisseel and Quixil are composed of human fibrinogen and human thrombin, which are combined at the time of use. The respective formula differs from each other because Tisseel contains bovine aprotinin (BA), while Quixil contains tranexamic acid, both known as antifibrinolytic agents[26].

Adverse events associated with the use of fibrin sealant over the least 25 years have been inflammatory processes, allergic reactions and viral infections secondary to the bovine component[27].

Hino *et al*[28] recently reported 3 cases of iatrogenic parvovirus B19 infection after the use of a fibrin sealant. This viral transmission was attributed to the use of dry-heat viral inactivation, which is not effective against non-enveloped viruses. Thus far, there are no reports of human immunodeficiency virus seroconversion or hepatitis B or C infection after the use of fibrin sealant[29]. However, the risk of virus transmission by fibrin sealants is still a subject of debate[19]. Three cases of anaphylaxis have been reported in Japanese patients, one of which was linked to the bovine aprotinin component of the sealant[30].

Fibrin adhesives have been used for several decades to close or obliterate fistulous tracts[31] and their effectiveness varies depending on the output volume of the fistula, its location, and the presence of a sufficiently long fistulous tract (greater than 2 cm) to allow fixation of the patch[32]. Postoperative fistulas of the digestive tract are relatively frequent in surgical practice. Serious technical difficulties such as variability in the location of the fistulas, quantification of drainage, time of evolution of the fistula, patient status and underlying pathology, have hindered scientific research comparing various therapeutic options and treatments[32]. This is one of the reasons why there are just a few randomized controlled clinical trials with the use of fibrin sealants[19].

In 1996, Hwang *et al*[32], published a small randomized clinical trial in patients with very low-output enterocutaneous fistulas (less than 20 mL). They used fibrin glue extracted from a blood bank and activated with bovine thrombin. The anatomic origin of the fistulas was varied and included upper and lower digestive tract fistulas. In 6 patients treated with external application of the adhesive, the time needed to close the fistulous tract was reduced significantly (2 ± 0.4 d), as was the hospital stay. Control patients (n = 7) received conventional treatment with total parenteral nutrition. In this group, spontaneous closure was observed after 13 ± 2 d ($P < 0.01$). The authors concluded that the use of fibrin glue is safe and effective for patients with stable and low-output enterocutaneous fistulas.

Waag *et al*[33] performed the first endoscopic application of an adhesive in 1979, for the treatment of a tracheo-esophageal fistula. Subsequently, with the introduction of different types of biological tissue adhesives and the development of dual and triple lumen catheters in 1984, fibrin glues have been used in the endoscopic treatment of fistulas of the digestive tract[34]. However, only proximal and distal digestive tract fistulas are accessible for endoscopic evaluation and management. In 1990, Nakagawa *et al*[35] reported the use of a small-diameter endoscope for the evaluation and treatment of fistulous tracts with fibrin glue. Fifteen patients were included in this study, and they were submitted to endoscopic examination, the clinical significance of which was assessed, and it was concluded that fistuloscopy is a safe and easy technique that results in less stress for the patients and is considered to be effective for the examination and treatment of fistulas[35].

Lange *et al*[36] investigated whether the endoscopic procedure could be used as an adjuvant technique for the sealing of gastrointestinal fistulas in 17 enterocutaneous fistulas. The success rate was 64.5%, and they described complementary treatment for abscesses associated with the fistulous tract. Some patients developed complications because of the high pressure of the fibrin glue application, and one patient died of pulmonary air embolism[36].

As reported by Shand *et al*[37] in 1997, some adjuvants have been purported to favor the early closure of fistulous tracts. They described a case of a patient with a non-healing low-output gastrocutaneous fistula closed by endoscopic means with fibrin glue and surgical packs. The fistula reopened 3 d after the procedure, and closure of the fistula was reattempted by direct endoscopic application of surgical packs and adhesive. Complete closure was obtained 11 d after direct endoscopic application of the fibrin glue[37].

Recently, Lomis *et al*[38] performed a study in which they evaluated 7 patients with persistent fistula, treating them with collagen plugs. Under fluoroscopic guidance and using direct-catheter techniques, collagen plugs were applied into the fistulas. The success rate was 85.7%; 6 of the 7 patients had resolution of the fistula with no evidence of fistula recurrence 30-180 d after the closure.

In 1990, Eleftheriadis *et al*[39] reported 7 cases of proximal digestive fistulas with high-volume output (700 mL in 24 h minimum) that were closed with fibrin gel by endoscopic means, with a 100% success rate. In 2002, the same authors reported a study in 14 patients; 7 with low-volume-output fistulas (discharging 20-50 mL/d) and 7 with high-volume-output fistulas (200-1000 mL/d), using fistuloscopy to evaluate the fistulous tracts and to measure the length of the fistula, with removal of necrotic material and non-absorbable sutures. Fibrin sealant was applied under direct observation. The fistulas healed within 2-17 d (mean 9.2 ± 5.1 d) in all patients except one with peritoneal carcinomatosis. The authors concluded that fistuloscopy could be used as both a diagnostic and a therapeutic tool in low- and high-output postoperative fistulas resistant to conservative treatment[40]. More recently, in 2004, the same author reported the endoscopic application of fibrin sealant for the treatment of gastrocutaneous fistula after bariatric surgery in three morbidly obese patients[41].

Kurokawa *et al*[42], reported an 85% success rate after the selective occlusion of complex digestive fistulas with fibrin glue application under fistuloscopy in patients in whom fistula closure had not occurred after 3 wk of conservative postoperative treatment.

Ramón Rábago *et al*[43], recently reported the largest series of postoperative digestive fistulas treated with transendoscopic application of fibrin glue. They included 30 patients with proximal, distal and internal fistulas of low- and high-output. The medium time of conservative treatment was 95 ± 199 d for all types of digestive fistulas. The success rate was 80% and 25% respectively and 55% for internal fistulas. They recommended that conservative treatment should not be prolonged beyond 2-4 wk, since most postoperative fistulas required 14 d to stabilize, and that endoscopic treatment should be performed at that stage. After follow-up periods ranging from 6 mo to more than 6 years, only one of the sealed fistulas reopened requiring a new endoscopic resealing. Rabago and his colleagues concluded that endoscopic treatment achieves a very high success rate, without complications and at a lower cost[43].

The first Mexican experience with fibrin sealants was published in 1997 by Justo-Janeiro *et al*[44]. They evaluated the application of concentrated human fibrinogen activated with bovine thrombin, fundamentally for hemostatic purposes, protection of high-risk anastomosis, seroma prevention and closure of enterocutaneous fistulas (4 patients). The success rate in the early closure of fistulous tracts was limited (50%), and failures were a consequence of distal obstruction to the fistula origin and intense inflammatory reactions[44].

Since 1998 commercially-prepared fibrin glue became available in our country and in 1999 our group designed protocols to evaluate the efficacy of the fibrin sealant in different surgical indications, including general surgery. In this study, we used human fibrin glue exclusively in low-output digestive fistulas, and we made comparisons with patients who received the same medical treatment but without the use of the adhesive. Our results are relevant

as the closure times achieved were significantly reduced, and the time needed to resume oral intake was also decreased. Application through the external opening is very useful when the characteristics of the fistulous tract are well known. Recently, Murakami *et al*[45], demonstrated adequate closure of complex postoperative digestive fistulas identifying the characteristics of the fistulous tract with an injection of contrast medium through the drainage tube. Eighteen patients were included in the study, with an 88% success rate (16 patients) with the applications of 1 to 9 treatment sessions of diluted solution of thrombin and fibrinogen 80 mg/mL. They studied the effect of thrombin dilution in saline solution and found the optimal concentration at 8 mg/mL of thrombin with a coagulation time of 45 ± 5 s. The delayed coagulation time permitted injection of the glue through all the complex fistulous tracts reaching a high success rate despite 60% of patients having abscesses associated with the fistulous tracts. The treatment was offered between 31 and 168 (66 ± 40.4) d after the surgical procedures.

In the series presented here, endoscopic control of the applications was performed in 13 cases with proximal or distal fistulas. The persistence of inflammation and inadvertent diverticular disease induced the recurrence of 2 colonic fistulas which eventually resolved with medical and surgical treatment. We attribute the success rate, even without performing a fistuloscopy or transendoscopic application, to the meticulous instillation of the fibrin glue, the low-volume output of the enterocutaneous fistulas, and the absence of complex fistulous tracts or any other condition that impeded spontaneous closure of the fistulas, such as associated abscesses, intra-abdominal sepsis, residual disease and foreign bodies or distal obstruction. Morbidity related to nutritional support was higher in the control group due to the prolonged time to feeding, and mortality was secondary to catheter-related sepsis in chronic parenteral nutrition. Since accelerated closure was not the purpose of this study, we proposed to treat patients as soon as the fistulas became stable and low-output without any associated obstruction, infection or residual disease, as other authors suggested in treatment of this complication[32,43,45].

In summary, we recommend the use of fibrin glue in those patients who do not experience spontaneous closure, to reduce the time needed to complete the resolution of the fistula and to minimize the rate of complications related to the secretions of the fistulas. The sealant should be applied as soon as the fistula becomes stable with the lowest output to assure closure after one or more applications of the glue.

Endoscopic control of the fibrin glue application should be performed whenever possible to ensure complete occlusion of the internal hole. The technique employed in this study has the advantage of allowing the removal of necrotic tissue and non-absorbable sutures from the fistulous tracts. Radiological visualization of the fistulous tracts, as studied here, requires less technological support, and we successfully treated digestive fistulas originating from the small bowel, including the duodenum, with external application of the adhesive. Patients did not present any adverse reactions, and recurrences were attributed to residual or untreated disease, particularly in those patients with colonic fistulas.

COMMENTS

Background

The formation of enterocutaneous fistulas can be either spontaneous or as a consequence of intra-abdominal surgery. The incidence of spontaneous fistulas is around 15%-25%, and postoperative fistulas account for 75%-85% of all fistulas of the digestive tract. Morbidity and mortality associated with postoperative fistulas are substantial as they are highly associated with nutritional deficits, septic complications and concomitant diseases that may appear during prolonged hospital stays. The conventional treatment for postoperative fistulas includes intestinal rest, correction of electrolytic disturbances, parenteral nutrition, and protection of the skin surrounding the fistula, and treatment and prophylaxis of any related local or systemic septic complications. Spontaneous closure occurs after 6-8 wk in 60%-70% of cases after specific medical management.

Research frontiers

Biological fibrin glues have long been used extensively in many surgical and specialty fields. Its use has also been extended for the management of untreatable fistulas that have not responded to conservative therapy. The efficacy of fibrin varies depending on the features of the fistula, such as output volume, location, and the presence of a fistulous tract long enough (> 2 cm) to allow fixation of the patch. Following the placement of the fibrin patch, it is replaced by collagen, leading to cessation of drainage and closure of the fistula with avoidance of inflammatory processes, finally resulting in improved healing.

Innovations and breakthroughs

This study determined that the application of fibrin glue through the external opening of stable enterocutaneous fistula reduced the closure time and the morbidity associated with nutritional support.

Applications

Instillation of variable quantities of fibrin glue (6 to 30 mL) according to the fistulous tract in one to 3 treatment sessions. The application of the glue was controlled endoscopically to assure total occlusion of the internal hole in proximal and distal fistulas.

Peer review

This is a good paper which targets a difficult and important topic.

Abstract

AIM: To study the relationship between platelet count-to-spleen diameter ratio and post-gastrectomy esophageal varices (EVs) development in patients without liver cirrhosis or hepatitis.

METHODS: We retrospectively studied 92 patients who underwent gastrectomy. They were divided into 2 groups on the basis of the surgical treatment: the distal gastrectomy (DG) group and total gastrectomy (TG) group. The incidence of EVs was determined and postoperative platelet counts, spleen diameters, and platelet count-to-spleen diameter ratios were compared between the 2 groups.

RESULTS: EVs were not detected during the first 6 mo after surgery in either group; however, at 12 mo after surgery, EVs were detected in 2 patients (3%) in the DG group and in 1 patient (3.6%) in the TG group; their mean platelet count-to-spleen diameter ratio was 2628 ± 409, and 2604 ± 360, respectively.

CONCLUSION: Endoscopy should be performed to detect EVs when the platelet count-to-spleen diameter ratio is < 2600.

Post-gastrectomy spleen enlargement and esophageal varices: Distal *vs* total gastrectomy. *World J Gastroenterol* 2010; 16(22): 2801-2805 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i22/2801.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i22.2801

INTRODUCTION

Esophageal varices (EVs) are one of the major life-threatening complications of liver cirrhosis[1], and its prevalence is approximately 40% at the time of diagnosis, and 60% in those with decompensated disease[2,3]. When EVs rupture, the mortality rate ranges from 17% to 57%[4-7]. Therefore, screening of all patients diagnosed with liver cirrhosis for the presence of EVs is recommended[8,9]. Giannini *et al*[10] performed a study to identify parameters that could aid noninvasive prediction of EVs, and reported that the platelet count-to-spleen diameter ratio was the best noninvasive predictor of EVs. However, spleen enlargement is frequently observed during follow-up of noncirrhotic patients who have

undergone gastrectomy, and, in addition, some of these patients developed EVs. Thus, we studied the relationship between the platelet count-to-spleen diameter ratio and the development of EVs, and compared distal and total gastrectomy (TG) with regard to these variables in patients without liver cirrhosis or hepatitis.

MATERIALS AND METHODS

Patients

We retrospectively studied 92 patients (66 men and 26 women; age range, 30-80 years; mean age, 68 ± 10 years) who underwent gastrectomy between May 2002 and April 2006 at the Department of Surgery, Social Insurance Yokohama Central Hospital, Yokohama, Japan. The following patients were excluded from our study: those who had undergone abdominal operation in the past, those with hepatitis, and those in whom disease recurrence was observed. Preoperative upper gastrointestinal endoscopy was performed in all the patients, further, EVs were not confirmed in any of the patients. These patients were divided into the following 2 groups on the basis of the surgical treatment they received: patients who underwent distal gastrectomy (DG), and patients who underwent TG. The maximum bipolar diameter of the spleen was measured by ultrasound scanning. The platelet count, spleen diameter, and platelet count-to-spleen diameter ratio were measured after surgery, and their relationship with the occurrence of EVs was studied.

Endoscopic classification of esophageal varices

On the basis of the endoscopic findings, the EVs were classified into 3 grades: grade 1, varices could be compressed with the endoscope; grade 2, varices could not be compressed with the endoscope; and grade 3, varices were confluent around the esophagus[11].

Statistical analysis

Univariate analysis was performed using the Student *t* test for continuous variables and Fisher's exact test and the χ^2 test for categorical variables. A *P*-value of less than 0.05 was considered to be significant.

RESULTS

Table 1 shows the patient characteristics and preoperative variables. No differences were observed between the 2 groups with respect to mean age, sex ratio, and preoperative clinical data. The gastric cancers were staged according to the Japanese Classification of Gastric Carcinoma[12], and their stages were found to be similar.

Table 2 shows the variables 3 mo after the operation. The mean platelet count, mean spleen diameter, and mean platelet count-to-spleen diameter ratio were 25.8 × 10^4 ± 4.2 × 10^4/μL, 93.9 ± 7.6 mm, and 2769 ± 453, respectively, in the DG group, and 25.1 × 10^4 ± 3.9 × 10^4/μL, 96.8 ± 9.5 mm, and 2593 ± 328, respectively, in the TG group. No differences were observed between the 2 groups, and no EVs developed in either group.

ly, in the TG group. No differences were observed between the 2 groups. However, 2 patients (3%) in the DG group and 1 patient (3.6%) in the TG group had grade 1 EVs. There was no significant difference between the 2 groups with respect to the occurrence of EVs.

Table 5 shows the variables 24 mo after the operation. The mean platelet count, mean spleen diameter, and mean platelet count-to-spleen diameter ratio were 26.4 × 10^4 ± 3.7 × 10^4/μL, 104.4 ± 9.8 mm, and 2546 ± 380, respectively, in the DG group, and the corresponding values were 25.8 × 10^4 ± 4.0 × 10^4/μL, 109.9 ± 10.1 mm, and 2357 ± 365, respectively, in the TG group. No differences were observed between the 2 groups with respect to the platelet count; however, the mean spleen diameter in the TG group was significantly greater than that in the DG group ($P < 0.0164$), and the mean platelet count-to-spleen diameter ratio in the TG group was significantly lower than that in the DG group ($P < 0.00287$). Two patients (3%) in the DG group and 2 patients (7.1%) in the TG group had grade-1 EVs, and 1 patient (3.6%) in the TG group had grade 2 EVs; however, there was no significant difference between the 2 groups with respect to the occurrence of EVs.

Table 6 shows the variables 36 mo after the operation. The mean platelet count, mean spleen diameter, and mean platelet count-to-spleen diameter ratio were 26.3 × 10^4 ± 3.8 × 10^4/μL, 105.6 ± 9.8 mm, and 2515 ± 386, respectively, in the DG group, and 25.5 × 10^4 ± 4.3 × 10^4/μL, 110 ± 9.6 mm, and 2317 ± 381, respectively, in the TG group. No differences were observed between the 2 groups with respect to the platelet count; however, the mean spleen diameter in the TG group was significantly greater than that in the DG group ($P < 0.0147$), and the mean platelet count-to-spleen diameter ratio in the TG group was significantly lower than that in the DG group ($P < 0.0256$). However, 3 patients (4.7%) in the DG group and 3 patients (10.7%) in the TG group had grade 1 EVs, and 1 patient (1.6%) in the DG group and 1 patient (3.6%) in the TG group had grade 2 EVs. There was no significant difference between the 2 groups with respect to the occurrence of EVs.

DISCUSSION

Bleeding from ruptured EVs is the leading cause of death among patients with liver cirrhosis[1], and the mortality rate from this complication varies between 17% and 57%[4-7]. Thus, cirrhotic patients should be screened for the presence of EVs. Some authors suggested that repeated endoscopy at intervals of 2-3 years should be performed in patients without varices, and that it should be performed at intervals of 2 years in patients with small varices in order to evaluate the development or progression of EVs[13,14]. However, in order to develop less invasive and cost-effective screening procedures for EVs, several studies have attempted to validate parameters that could be used for noninvasive screening[15-21], and have found that platelet count and spleen diameter showed a good correlation with the presence of EVs. In addition, Giannini *et al*[10] and Baig *et al*[22] reported that

the platelet count-to-spleen diameter ratio has the highest accuracy for noninvasive prediction of EVs in cirrhotic patients. However, spleen enlargement is frequently observed after patients have undergone gastrectomy. Thus, we studied the relationship between the platelet count-to-spleen diameter ratio and the presence of EVs after gastrectomy, and compared distal and TG with regard to these parameters in patients without liver cirrhosis or hepatitis. In addition, in order to avoid surgical influence, patients who had undergone abdominal operation in the past were excluded from this study. All our patients were healthy and did not exhibit any recurrence during their follow-up. In patients who did not have liver cirrhosis or hepatitis, the occurrence rate of EVs was thought to be low; however, splenic arterial flow was thought to increase after but not before the surgery. In general, blood flow in the celiac artery (CA) is diverted into 3 arteries: the common hepatic artery (CHA), left gastric artery (LGA), and splenic artery (SA). During gastrectomy (distal and total), the LGA and left gastric vein are ligated and cut, and blood flow from the CA is diverted into 2 arteries - the CHA and SA. Thus, blood flow in the CHA and SA increases after surgery. Moreover, during lymph node dissection around the celiac axis, collateral veins from the splenic vein are ligated and cut; thus, in our patients, blood outflow from the spleen was thought to decrease after the surgery as compared to that before the surgery. Also, in the TG group, short gastric veins were ligated and cut, and blood outflow from the spleen was thought to be lower than that in the GD group patients. This may be one of the main reasons why spleen enlargement was greater in the TG group than in the DG group.

Giannini *et al*[10] reported that the prevalence-adjusted positive and negative predictive values for a platelet count-to-spleen diameter ratio of 909 were 96% and 100%, respectively, and Baig *et al*[22] reported that the prevalence-adjusted positive and negative predictive values for a platelet count-to-spleen diameter ratio of 1014 were 9.4% and 95.1%, respectively. In our study, grade 1 EVs were detected in 2 patients (3%) in the DG group, and in 1 patient (3.6%) in the TG group at 12 mo after surgery, and the mean platelet count-to-spleen diameter ratio of the patients was found to be 2628 ± 409 in the DG group, and 2604 ± 360 in the TG group. At 24 mo after surgery, grade 2 EVs were detected in 1 patient (3.6%) in the TG group, and the mean platelet count-to-spleen diameter ratio of these patients was found to be 2357 ± 365. In the DG group, grade 2 EVs were detected 36 mo after the surgery, and the mean platelet count-to-spleen diameter ratio of the patients was found to be 2515 ± 386. In our study, EVs developed in 4 patients each in the DG group (6.3%) and the TG group (14.3%) after the surgery; however, no patient exhibited grade 3 EVs. In addition, none of our patients had liver cirrhosis or hepatitis; this contributed to the higher platelet count-to-spleen diameter ratio than that reported by Giannini *et al*[10] and Baig *et al*[22]. To the best of our knowledge, studies on the relationship between the platelet count-to-spleen diameter ratio and the presence of EVs have not been conducted in patients who underwent gastrectomy. Thus, on the basis of the results of our study, we suggest that the occurrence rate of EVs may increase after 6 mo post DG and when the platelet count-to-spleen diameter ratio is less than 2600. Thus, in the case of patients who have undergone gastrectomy for gastric cancer, the development of EVs after surgery is a strong possibility.

In conclusion, spleen enlargement after gastrectomy is greater in the case of TG than DG, and the platelet count-to-spleen diameter ratio is a useful parameter for the noninvasive prediction of EVs after gastrectomy. In addition, we think that the occurrence rate of EVs increases after 6 mo post gastrectomy, and therefore, when the platelet count-to-spleen diameter ratio is less than 2600, endoscopy should be performed to determine the presence of EVs.

COMMENTS

Background

Esophageal varices (EVs) are one of the major life-threatening complications of liver cirrhosis, and its prevalence rate is approximately 40% at the time of diagnosis, and 60% in those with decompensated disease. Therefore, screening of all patients diagnosed with liver cirrhosis for the presence of EVs is recommended.

Research frontiers

Spleen enlargement is frequently observed during follow-up of noncirrhotic patients who have undergone gastrectomy. The authors studied the relationship between the platelet count-to-spleen diameter ratio and the development of EVs, and compared distal and total gastrectomy (TG) with regard to these variables in patients without liver cirrhosis or hepatitis.

Innovations and breakthroughs

The authors retrospectively studied 92 patients who underwent gastrectomy. They were divided into 2 groups on the basis of the surgical treatment: the distal gastrectomy (DG) group and TG group. The incidence of esophageal varices was determined and postoperative platelet counts, spleen diameters, and platelet count-to-spleen diameter ratios were compared between the 2 groups.

Applications

Spleen enlargement after gastrectomy is greater in the case of TG than DG, and the platelet count-to-spleen diameter ratio is a useful parameter for the noninvasive prediction of EVs after gastrectomy.

Peer review

It is an interesting manuscript, though the background did not identify the real reason why the authors were embarking on their endeavor. The results were well presented and the discussion would be improved. It is a nice experiment.

Abstract

AIM: To evaluate the safety and outcomes of endoscopic piecemeal mucosal resection (EPMR) for large sessile colorectal polyps.

METHODS: The patients enrolled in this study were 47 patients with 50 large sessile polyps (diameter, 2 cm or greater) who underwent EPMR using a submucosal saline injection technique between December 2002 and October 2005. All medical records, including characteristics of the patients and polyps, complications, and recurrences, were retrospectively reviewed. The first follow-up endoscopic examination was performed at 3-6 mo after initial endoscopic resection, and the second at 12 mo post-EPMR. Subsequent surveillance colonoscopic examinations were individualized, taking risk factors into account.

RESULTS: The patients were 23 men and 24 women, with a mean age of 60 years. Mean polyp size was 30.1 mm. Of 50 polyps identified, 34 (68%) were benign and 16 (32%) were malignant. There were 6 (12%) cases with EPMR-related bleeding: 5 intra-procedural and 1 early post-procedural bleeding. All bleeding episodes were managed by endoscopic clipping or argon beam coagulation. There were no perforations. Recurrence was identified in 5 cases (12.2%): 4 local recurrences detected at 3 mo post-EPMR and 1 local recurrence detected at 14 mo post-EPMR. The recurrence rate after EPMR was 3.1% for benign polyps and 33.3% for malignant polyps ($P < 0.05$). Median follow-up time was 37 mo.

CONCLUSION: EPMR is safe, but should be applied carefully in malignant polyps. Close follow-up endoscopic examinations are necessary for early detection of recurrence.

Recurrence after endoscopic piecemeal mucosal resection for large sessile colorectal polyps. *World J Gastroenterol* 2010; 16(22): 2806-2811 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i22/2806.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i22.2806

INTRODUCTION

Endoscopic resection of large sessile colorectal polyps

remains challenging because of its technical difficulty and high complication rate[1]; even so, the endoscopic removal of colonic adenomatous polyps is a commonly used technique that reduces the incidence of colorectal cancer. Some investigators have reported that endoscopic piecemeal mucosal resection (EPMR) is a safe and effective procedure for large sessile colorectal polyps[2-4]; however, this approach remains controversial because of the high possibility of coexisting malignancy and a high recurrence rate associated with large sessile polyps. Endoscopic submucosal dissection (ESD) has recently been attempted by expert endoscopists for *en bloc* resection of large sessile polyps[5,6]; however, this procedure has a long procedure time and high complication rate, and is not currently widely used due to its technical difficulty[7].

Several studies have shown that the incomplete removal of large sessile colorectal polyps, particularly by piecemeal resection, can contribute to a higher subsequent incidence of colorectal cancers[8,9]. Thus, recent guidelines recommend that when large sessile polyps are removed by piecemeal resection, a repeat examination should be performed at a short interval (2-6 mo) to verify complete removal[10]. However, few studies report the recurrence rate after EPMR, and the long-term outcomes of EPMR have yet to be established. This study was designed to evaluate the safety, efficacy, and long-term outcomes of EPMR of large sessile colorectal polyps.

MATERIALS AND METHODS

We retrospectively reviewed and identified 77 patients with 80 large sessile colorectal polyps (2 cm or greater) detected by colonoscopy at the National Cancer Center, Korea, between December 2002 and October 2005. Among these patients, 30 were excluded for the following reasons: co-existence of synchronous advanced colorectal cancer (n = 15), non-lifting tumor (n = 4), encircling lesion > 70% (n = 4), transfer to other institution (n = 4), suspicion of muscle invasion by endoscopic ultrasound (n = 1), and recurrent tumor (n = 2). A final total of 47 patients with 50 large sessile polyps who underwent EPMR using submucosal saline injection technique were enrolled in this study. We reviewed medical records, including patient demographics, endoscopic findings, histopathological reports, and follow-up data. The study was performed in accordance with the Declaration of Helsinki and informed consent was obtained from all patients.

Colonoscopy

Patients were prepared with mechanical bowel preparation. The patients received either two 45 mL doses of sodium phosphate (Fleet®; C.B. Fleet Co. Inc., Lynchburg, VA, USA) or 4 L of polyethylene glycol solution (Colyte-F®; Taejoon Pharm, Seoul, Korea) and underwent colonoscopy under conscious sedation with midazolam. Colonoscopy was performed to the cecum or terminal ileum with white light colonoscopic examination. Polyps suspicious of invasive cancer (the presence of ulceration, induration, friable mucosa, or non-lifting sign[11]) were referred for surgical resection. Polyp size (measured in comparison with open biopsy forceps) and morphology were generally estimated and recorded by the endoscopist.

EPMR technique

Endoscopic resection was performed using a snare piecemeal method with submucosal saline injection technique (Figure 1) according to the strip biopsy method described by Karita *et al*[12] Colonoscopy was performed with a standard video colonoscope (CF Q260L; Olympus Optical Co., Ltd., Tokyo, Japan). Briefly, the injection catheter was passed through the channel, and saline solution mixed with diluted epinephrine (1:100 000) was injected into the submucosal layer near the sessile polyp until the entire polyp was elevated. If the polyp was not elevated after one injection, additional injections were made around the polyp. The injection catheter was removed and a snare device was inserted through the channel. The surrounding normal mucosa, along with the lesion, was encircled by the snare. After the snare device was positioned, resection was performed using electrosurgical coagulation current, a combination of coagulation and blended currents in sequence. If necessary, argon plasma coagulation (APC) was used to treat the polyp base in an attempt to destroy any residual polyp.

Complications

EPMR-induced bleeding was defined as intraprocedural (occurring during EMR), early (within 24 h after EPMR), or delayed (≥ 24 h after EPMR), as described previously[13]. The diagnosis of early or delayed bleeding was based on the passage of blood per rectum. Bleeding was controlled by endoscopic clip (HX-600-135, Olympus) placement and/or APC. Perforation was defined as the presence of free air on plain abdominal film or computed tomography (CT).

Histopathology

All resected material was retrieved for histopathologic evaluation. Specimens were collected using a basket or by aspiration into the suction channel. For entire retrieval of sessile polyps located in the right colon, the colonoscope was withdrawn and reinserted as many times as necessary. A single pathologist assessed all histopathologic specimens and was not blinded to the endoscopic findings. Malignant polyps with unfavorable histology, such as poor differentiation, angiolymphatic invasion, and deep submucosal invasion (≥ 1000 μm), or having a positive deep resection margin, were referred for surgical treatment after polypectomy.

Follow-up

Patients who had undergone endoscopic treatment alone were followed up with colonoscopy to evaluate whether endoscopic resection of the sessile polyps had been complete. Endoscopic examinations were scheduled as follows: the first follow-up endoscopic examination was

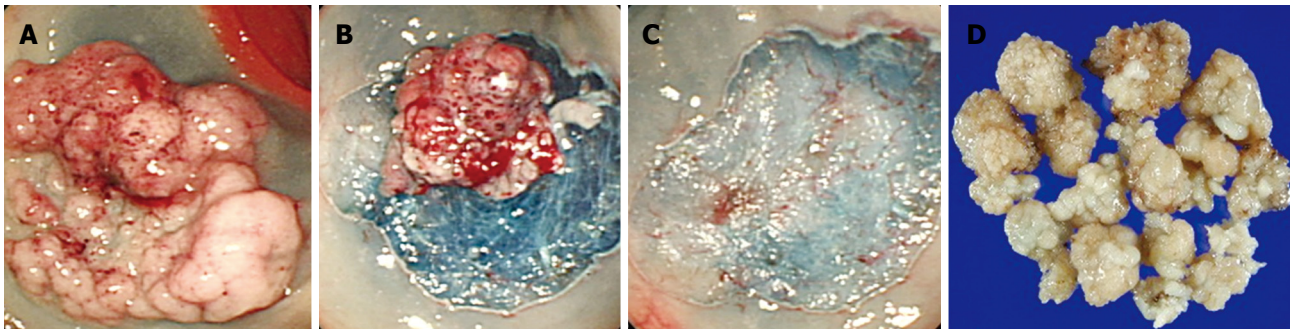

Figure 1 Endoscopic piecemeal mucosal resection of a large sessile polyp. A: Endoscopic view of the rectum showing a large sessile polyp (40 mm in diameter) after submucosal injection; B, C: Piecemeal polypectomy was performed; D: Retrieved specimens after resection of small pieces.

performed at 3-6 mo after the initial endoscopic resection, and the second was performed at 12 mo post-EPMR. Subsequent surveillance colonoscopic examinations were individualized with consideration of risk factors. If a polyp was detected on follow-up examinations, it was resected if possible. Residual polypoid tissue with the appearance of granulation tissue was biopsied, but not counted as residual adenoma. Recurrence or residual polyp was defined as the presence of any amount of adenomatous or carcinomatous tissue on follow-up, even as small as 1 mm, confirmed by histology at the site of prior piecemeal polypectomy[14]. All recurrences were demonstrated by pathology to contain dysplastic (adenoma) or carcinomatous tissue. The difference in recurrence between EPMR for benign polyps and EPMR for malignant polyps was determined by the log-rank test using SPSS 14.0 for Windows (SPSS Inc., Chicago, IL, USA). P values of < 0.05 were considered statistically significant.

RESULTS

The clinicopathologic characteristics of the 47 patients with 50 polyps are listed in Table 1. Among the patients, 5 had a history of non-steroidal anti-inflammatory drugs (NSAIDs) administration that was stopped at least 7 d before endoscopy. The mean size of resected polyps was 30.1 ± 10.9 mm (range, 20-60 mm). Locations of the large sessile polyps were as follows: cecum in 2 polyps, ascending in 7, hepatic flexure in 6, transverse in 4, splenic flexure in 1, descending in 5, sigmoid in 6, and rectum in 19. Of the 50 polyps, 34 (68%) were benign and 16 (32%) were malignant. Histological examination revealed tubular adenoma in 20 polyps, tubulovillous adenoma in 7, villous adenoma in 1, serrated adenoma in 4, hyperplastic polyp in 2, and carcinoma in 16 (Tis, 11; T1, 4; T2, 1).

The outcomes of EPMR for large sessile polyps are listed in Table 2. After EPMR, there were 6 (12%) cases of procedural bleeding: 5 intraprocedural and 1 early after initial endoscopic resection, which were managed by endoscopic means with the application of hemoclips alone in 4 cases, APC alone in 1 case, and hemoclips with APC plus fibrin glue in 1 case. There was no significant bleeding requiring blood transfusion or surgical intervention, and no delayed bleeding following polypectomy. No patient suffered colonic perforation as a result of endoscopic resection. Bleeding prophylaxis was performed in 6 cases (12%) by applying a hemoclip. The median hospital stay (from procedure to discharge) was 3 d (range, 1-5 d), with the exception of 4 patients: 3 who were not admitted and 1 who underwent consecutive colonic resection.

Of the 47 patients, follow-up data were available for 45 patients (95.7%); the exceptions were 2 without follow-up endoscopy. The median follow-up time was 37 mo (range, 3-72 mo). Recurrence was identified in 5 patients (12.2%): including 4 cases of local recurrence detected at 3 mo post-EPMR and 1 local recurrence detected at 14 mo post-EPMR (Table 3).

Of the 32 patients with benign polyps, there was 1 (3.1%) case of recurrence: a patient with benign recurrent adenoma who was successfully treated by endoscopic resection. Other follow-up endoscopy showed no recurrence. Of the 16 patients with malignant polyps, 4 polyps

HGD: High grade dysplasia; EMR: Endoscopic mucosal resection; LAR: Low anterior resection; AR: Anterior resection.

with unfavorable histology underwent surgery. Among the remaining 12 patients with malignant polyps, 4 (33.3%) had recurrence: 1 patient with benign recurrent adenoma was treated by endoscopic resection and 3 patients underwent surgery because their recurrent lesions could not be removed by endoscopic resection (Table 3).

The difference in recurrence between EPMR for benign polyps and that for malignant polyps was statistically significant (3.1% *vs* 33.3%, $P < 0.05$).

The follow-up results of the 50 large sessile polyps are shown in Figure 2.

DISCUSSION

Endoscopic resection of large sessile colorectal polyps (2 cm or greater) is increasingly used as an alternative to surgery, but remains challenging because of its technical difficulty, the high risk of complications such as bleeding or perforation, and the possibility of coexisting malignancy. Recent advances in endoscopic technique and equipment have enabled the development of techniques such as EPMR and ESD to remove large sessile colorectal polyps[1-6]. Comparing these two techniques, the mean procedure times for EPMR[4,6] and ESD[6,15] ranged from 29 to 55 min and from 70.5 to 108 min, respectively. Regarding complications, the perforation rates for EPMR[6,8,14] and ESD[4,6,15] ranged from 0.8% to 1.3% and 6.2% to 10.0%, respectively. Because EPMR has a shorter procedure time and lower perforation rate than ESD, EPMR appears to be an easy and safe procedure; however, Saito *et al*[6] demonstrated that EPMR resulted in a higher recurrence rate compared with ESD (14% *vs* 2%). The rate of recurrence at the polypectomy site after EPMR was reported to be 20%-55% in several other studies[8,14,16]. The recurrence rate after EPMR of 12.2% in the present study (11.36% in 44 polyps) is relatively low for the 44 large sessile polyps that had follow-up endoscopy. Several investigators have reported that additional techniques (e.g. APC) may further improve the success of polypectomy, and hence lower the recurrence rate[3,14,17]. In the present study, 91% of cases were treated with APC. Our low recurrence rate was probably influenced by the high application rate of APC to the tumor bed following EPMR. With regard to histopathology of the polyps, the recurrence rate was 3.1% for benign polyps and 33.3% for malignant polyps; in other words, EPMR of malignant polyps resulted in a higher recurrence rate than that of benign polyps. In contrast, Conio *et al*[13] reported similar recurrence rates for benign and malignant polyps. The recurrence rate of malignant colorectal polyps after EPMR varies among studies; however, it is difficult to compare the results of different series because there are wide variations in polyp size and the length of follow-up[13]. In addition, it is difficult to explain the reason why the incidence of recurrence after EPMR in malignant lesions is higher than that in benign lesions. However, we should try to remove all cancer cells completely because microscopic residual cancer cells after EPMR can cause recurrences. Further studies are needed to confirm the usefulness of EPMR for malignant colorectal polyps.

The most common complication after polypectomy is bleeding; the risk of post-polypectomy bleeding ranges from 0.3% to 6.1%[18,19]. The risk factors for bleeding include large polyp size and location in the proximal colon[19,20]. In large sessile polyps (2 cm or greater), the incidence of bleeding during and after polypectomy has been reported to be as high as 13.5%[2,3,8,14,16]. In the present study, bleeding occurred in 5 cases (12.2%), and all patients with bleeding were treated by endoscopic management, without surgery or blood transfusion. Thus, we can consider these cases as having "minor complications," as described in a previous report[3]. In the present study, none of the patients with bleeding were taking NSAIDs (aspirin) or had known coagulopathy at the time of the EPMR procedure. In our endoscopic database, any procedural bleeding requiring additional endoscopic treatment was described, and we classified EPMR-induced bleeding as intraprocedural, early, or delayed. Doniec *et al*[21] suggested that it is doubtful whether hemorrhage should be classified as a complication during endoscopic treatment when it can be managed endoscopically; no surgeon would regard bleeding as a complication during an operation such as mucosectomy. We used submucosal injection of epinephrine-saline mixture 1:100 000 in all EPMR cases, not only for submucosal elevation but also to prevent procedure-related bleeding. Iishi *et al*[2] injected only 0.9% saline solution alone to elevate sessile polyps, and reported bleeding in 7% of cases; however, no study has definitely proved the superiority of submucosal solution. In the present study, there was no delayed bleeding or perforations. Taking our experience into consideration, it is clear that the risk of perforation increases with increased width of the polypectomized colonic wall during snaring, rather than with increasing polyp size.

Rectal polyps are considered easy to remove due to the relatively low rate of perforation. In our study, 19 (40.4%) out of 47 polyps were located in the rectum. However, the recurrence rate after EPMR was not different between rectal polyps and colonic polyps (17.6% *vs* 7.4%, $P = 0.359$).

Previous studies have reported the risk of malignancy in large sessile colorectal polyps (2 cm or larger) as being up to 29%[22,23]. In the present study, 16 polyps (32%) were found to be adenomas containing an area of carcinoma; of these, 5 (10%) were invasive cancer. We evaluated the lifting sign of the tumor using saline injection to the submucosal layer before EPMR in all cases. This technique may have caused the relatively low incidence of invasive cancer in the large sessile colorectal polyps in the present study.

It is well known that initial colonoscopy has a significant miss rate of 24% for all types of adenomas[24]. Yamaji *et al*[25] reported recurrence rates for small adenomas and advanced lesions of 19.3% and 22.9%, respectively. In the present study, 80% of recurrences were identified at 3 mo post-EPMR, and the other recurrences were detected at 14 mo post-EPMR. Missed or metachronous adenomas detected at 3-6 mo, 1-3 years, and 3 years post-EPMR were detected in 32%, 46%, and 32% of cases, respectively. The higher rate of metachronous adenomas may have been influenced by the fact that our patients had more advanced lesions (i.e. all had large sessile polyps), including invasive cancers. The present results support current guidelines which recommend that patients who undergo piecemeal resection of large sessile adenomas should have an initial follow-up colonoscopy within 3-6 mo, followed by an additional colonoscopy 1 year later[10].

In conclusion, EPMR is a safe procedure for large sessile colorectal polyps, but should be applied carefully in malignant polyps because of high recurrence rate. Close follow-up endoscopic examinations are necessary for early detection of recurrence.

COMMENTS

Background

Endoscopic removal of colonic adenomatous polyps is a commonly used technique that reduces the incidence of colorectal cancer. However, endoscopic resection of large sessile colorectal polyps is still challenging because of its technical difficulty.

Research frontiers

Endoscopic piecemeal mucosal resection (EPMR) can be used for large sessile colorectal polyps. However, this approach remains controversial because of the high possibility of coexisting malignancy and the high recurrence rate associated with large sessile polyps. Few studies report the recurrence rate after EPMR, and the long-term outcomes of EPMR have yet to be established.

Innovations and breakthroughs

Several studies have shown that the incomplete removal of large sessile colorectal polyps, particularly by piecemeal resection, can contribute to a higher subsequent incidence of colorectal cancers. This study shows that EPMR is safe for benign colorectal polyps, but should be applied carefully in malignant polyps due to high recurrence rate.

Applications

By identifying the recurrence rate and long term follow-up results after EPMR, this study may contribute to the development of a therapeutic guideline for patients with large sessile colorectal polyps.

Terminology

EPMR, which is used to increase safety, is a technique for removing large sessile polyps. During EPMR, the polyp can be broken down into multiple pieces. However, this makes it difficult to evaluate the resection margin pathologically.

Peer review

This paper is devoted to obtaining knowledge on the outcome of piecemeal mucosal and large sessile polyps. The authors have concluded that EPMR should be carefully applied in malignant polyps.

Abstract

AIM: To investigate gastrointestinal (GI) symptoms in peritoneal dialysis (PD) patients and to explore related factors contributing to GI symptoms.

METHODS: One hundred and twelve patients undergoing PD participated in the study. The gastrointestinal symptom rating scale was used for measuring GI symptoms. Information on age, height, weight, body mass index, disease leading to chronic renal failure, history of corticosteroid therapy, presence of predialytic GI symptoms, daily dosage of pills, and duration, type and daily dialysate volume of PD was obtained by interviewing patients and/or reviewing the medical records. Hemoglobin, albumin and Kt/V data were obtained from follow-up database. We used multiple regression analysis with stepwise backward variable selection to test for factors predicting GSRS scores with significance level of selection entry at 0.05 and selection of stay at 0.10.

RESULTS: The prevalence of eating dysfunction, reflux and indigestion in the PD patients was 44.2%, 32.7%, 32.7%, respectively. A history of corticosteroid therapy (b = 8.93, $P < 0.001$) and all pills daily intake (b = 0.16, $P = 0.007$) were positively correlated to GI symptoms, while residual renal Kt/V (b = -3.47, $P = 0.009$) was negatively correlated to GI symptoms. Other factors were proven to be not associated with GI symptoms, with $P > 0.05$.

CONCLUSION: Eating dysfunction, reflux and indigestion were common in PD patients. Daily dosage of pills and corticosteroid history predicted GI symptoms, while residual renal function prevented them.

INTRODUCTION

Gastrointestinal (GI) symptoms are common in patients with chronic renal failure (CRF)[1-3], especially in patients having continuous ambulatory peritoneal dialysis (CAPD)[4]. A variety of GI symptoms in CAPD patients have been reported[4,5], of which, gastroesophageal reflux symptoms (GERS), dyspepsia and eating dysfunction seem to be the most common ones[4,5].

Anderson *et al*[6] reported that 44.7% of PD patients

had frequent gastroesophageal reflux disease (GERD) and that age < 60 years, smoking, and body mass index (BMI) ⩾ 27 predicted GERD; in contrast, sex, race, diabetes, PD, non steroidal anti-inflammatory drugs (NSAIDs), calcium channel blockers (CCBs), and coffee and alcohol use did not. Stojakowska *et al*[7] have proven a negative correlation between GERD symptom score index and normalized protein catabolic rate (nPCR), and a positive correlation between GERD symptom score and the time from onset of CAPD, through observation in 43 patients. It is not clear whether PD *per se* is a risk factor for GERD[6].

It is the high prevalence of GI symptoms in PD patients that raises questions about contributing factors and other possible factors, but previous studies obtained controversial results with a relatively small sample size. Whether the onset of these GI symptoms is related to the chronic renal failure itself, its treatment, or, alternatively, other factors, is still unknown.

The aim of this study was to investigate GI symptoms in CAPD patients and to explore the possible correlated factors contributing to these symptoms.

MATERIALS AND METHODS

Ethics

Patients gave informed consent and the study was approved by the Ethics Committee of Changhai Hospital, Shanghai, China.

Participants

The patients on active PD were recruited from the PD unit in Changhai Hospital. They consisted of in-patients and out-patients who maintained PD for at least three months. Patients with dementia, severe infectious illness, hepatocholecystopathy, peritonitis in the last three months, unstable blood pressure or glucose levels, and unwillingness to participate in the study were excluded.

Subjective gastrointestinal symptoms: the gastrointestinal symptom rating scale

To evaluate the presence of GI symptoms in PD patients, they were asked to complete the gastrointestinal symptom rating scale (GSRS) measuring GI symptoms in general.

The GSRS, a self-administered questionnaire, includes 15 items and uses a 7-grade Likert scale defined by descriptive anchors such that 1 = none, 2 = minor, 3 = mild, 4 = moderate, 5 = moderately severe, 6 = severe, and 7 = very severe discomfort. The questionnaire was originally constructed as an interview-based rating scale designed to evaluate a wide range of GI symptoms[8] and was later modified to become a self-administered questionnaire[9]. The items can be grouped into five dimensions: abdominal pain syndrome (three items), reflux syndrome (two items), indigestion syndrome (four items), diarrhea syndrome (three items), and constipation syndrome (three items). One dimension, eating dysfunction, which was developed in a manner analogous to the GSRS[10], was also considered relevant for the study and added to the original GSRS. Eating dysfunction dimension includes questions concerning early satiety, difficulties in eating normal portions, and postprandial pain. The questions concern symptom severity during the previous two weeks. A dimension score was calculated as the mean value of the items belonging to the specific syndrome with a minimum value of 1 and a maximum value of 7.

Patient information

By interviewing patients and/or reviewing the medical records we obtained information on age, height, weight, BMI, disease leading to CRF, history of corticosteroid therapy, presence of predialytic GI symptoms, daily dosage of pills and duration, type and daily dialysate volume of PD. The latest serum hemoglobin (HGB), albumin (ALB), and Kt/V urea, as an index of dialysis adequacy, were obtained from the follow-up database. Kt/V were calculated by Daugirdas Formula[11].

Statistical analysis

Data were presented as mean (SD) for continuous variables that were approximately normally distributed, as median and interquartile range for skewed continuous variables, and as percentage for categorical variables. We used multiple regression analysis with stepwise variable selection to test for factors that predicted the GSRS scores with significance level of selection entry at 0.05 and selection of stay at 0.10. Results were considered significant when $P < 0.05$. All analyses were performed with SPSS for Windows, version 16.0.

RESULTS

Patient characteristics

In total, one hundred and twelve PD patients were approached to participate in the study and completed the questionnaires. Table 1 presents characteristics of the included PD patients. The sex distribution among PD patients was 61 men and 51 women. The mean age among PD patients was 59.67 (14.18) years and the mean BMI was 23.26 (4.27) kg/m^2. Patients with diabetes mellitus (DM) made up 24.1% of the study population in total and a majority (87.5%) of PD patients had no GI symptoms before the start of PD. The median duration of PD was 15.00 (8.00-33.00) mo and 53.6% of the patients underwent CAPD.

The gastrointestinal symptom rating scale scores

The prevalence of troublesome GI symptoms (GSRS > 1) was 61.6% for any dimension, 44.2% for eating dysfunction, 32.7% for reflux, 32.7% for indigestion, 18.6% for constipation, 6.2% for abdominal pain, and 5.3% for diarrhea (Figure 1). The mean GSRS scores for eating dysfunction were 1.57 (0.84), for reflux 1.71 (1.15), for indigestion 1.32 (0.56), for constipation 1.23 (0.58), for diarrhea 1.07 (0.35), for abdominal pain 1.04 (0.19).

GSRS scores and patient variables

There was no significant relationship between the GSRS scores and age, BMI, hemoglobin, albumin, presence of

Peritoneal Kt/V	-0.21	0.84
Total Kt/V	-0.24	0.81

[1]Restricted to the 81 patients (72.32% of the overall sample) for whom complete information on age, diabetes status, weight, height, serum hemoglobin, albumin levels, presence of predialytic gastrointestinal symptom, peritoneal dialysis type, duration of peritoneal dialysis, daily dialysate volume, history of corticosteroid use, daily dosage of pills, residual renal Kt/V, peritoneal Kt/V, total Kt/V were available. Adjusted for diabetic status (yes = 1, no = 0), presence of predialytic GI symptoms (yes = 1, no = 0), PD type (CAPD = 1, IPD = 0). GSRS: Gastrointestinal symptom rating scale.

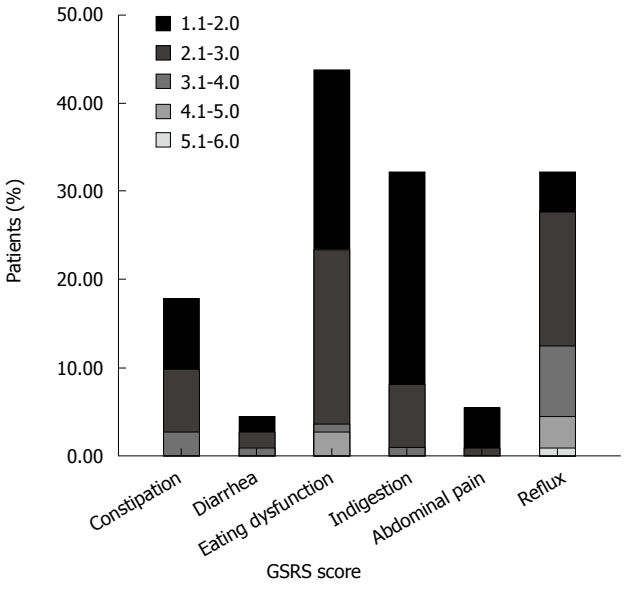

Figure 1 Prevalence and grading of gastrointestinal symptoms in peritoneal dialysis patients according to the gastrointestinal symptom rating scale.

daily intake (b = 0.16, $P = 0.007$) was significant and its coefficient was also positive, indicating that the more pills patients took daily, the higher the GSRS scores. Finally, the residual renal Kt/V (b = -3.47, $P = 0.009$) was significant and its coefficient was negative which would indicate that higher residual renal Kt/V was related to lower GSRS scores (Table 3).

DISCUSSION

The present study shows that gastrointestinal symptoms are common in PD patients, especially eating dysfunction (44.2%), reflux and indigestion (both 32.7%). A history of

Table 3 Coefficients of multiple stepwise regression model of the variables associated with GSRS scores[1]

Variables	Unstandardized coefficients		Standardized coefficients	*t*	*P* value
	B	SD	β		
Constant	21.89	1.25	-	17.58	< 0.001
History of corticosteroids	8.93	2.13	0.39	4.20	< 0.001
Daily dosage of pills	0.16	0.06	0.26	2.80	0.007
Residual renal Kt/V	-3.47	1.30	-0.25	-2.68	0.009

[1]Restricted to the 81 patients (72.32% of the overall sample) for whom complete information on age, diabetes status, weight, height, serum hemoglobin, albumin levels, presence of predialytic gastrointestinal symptoms, peritoneal dialysis type, duration of peritoneal dialysis, daily dialysate volume, history of corticosteroid use, daily dosage of pills, residual renal Kt/V, peritoneal Kt/V, total Kt/V were available. Adjusted for history of corticosteroid use (yes = 1, no = 0).

corticosteroid therapy (b = 8.93, $P < 0.001$) and the dosage of pills patients took daily (b = 0.16, $P = 0.007$) were positively related to GSRS scores, whereas residual renal Kt/V (b = -3.47, $P = 0.009$) was negatively correlated to GSRS scores. Other suspected factors were not statistically related to GSRS scores, including age, BMI, hemoglobin, albumin, presence of diabetes, presence of predialytic GI symptoms, peritoneal Kt/V, total Kt/V and duration, type and daily dialysate volume of PD.

More than half of the PD patients had various gastrointestinal complaints and patients who had a history of corticosteroid therapy seemed to be susceptible to gastrointestinal symptoms. The more pills patients took daily, the more complaints of GI symptoms. Otherwise, residual renal function seemed to be a protective factor for GI symptoms in PD patients since the higher the residual renal Kt/V, the less GI symptom complaints. In this study, PD specific factors including peritoneal Kt/V, total Kt/V, duration, type and daily dialysate volume of PD, were proven to contribute little to these symptoms.

GI symptoms are common in PD patients with a prevalence ranging from 43% to 58%[5-7,12]. Our results with a high prevalence of eating dysfunction, indigestion and reflux symptoms are in line with these previous studies. Furthermore, these three symptoms were also shown to have the highest prevalence of all GI symptoms in PD patients in a recent study[5]. The underlying pathophysiological mechanisms might be (1) Delayed gastric emptying, which is common in CRF patients. Strid *et al*[13] found that PD patients had longer gastric emptying time than predialytic state, but other studies found no obvious effect of dialysate on gastric emptying[14-16]; (2) Increased intraperitoneal pressure (IPP). Dejardin *et al*[17] found the occurrence of GERS was not different for patients with elevated day and night IPP; (3) Decreased lower esophageal sphincter pressure (LESP). Kim *et al*[18] demonstrated that CAPD patients with upper GI symptoms had lower LESP at 2000 mL of infused dialysate than patients without. In contrast, Hylander *et al*[19] found no systematic changes in intragastric or LESPs at any time of CAPD; and (4) Other factors. Aguilera *et al*[20] discovered GI abnormalities were negatively associated with nutrition. Van *et al*[21] have demonstrated a glucose-based dialysate in the abdomen of PD patients with delayed gastric emptying.

As we know, PD patients are in a complicated clinical condition and clinical manifestations are affected by many factors, among which drug taking is an important one. However, drugs have some adverse effects. In general, patients who have a history of corticosteroid therapy are more susceptible to GI symptoms than patients who haven't, which also applies to PD patients. Not unexpectedly, we found corticosteroid taking history alone accounted for 18.9% of GSRS scores, which is probably due to injury of the digestive system caused by corticosteroids. High prevalence of GI symptoms was also found in a transplant population and a rheumatism population[22,23], who both had a large consumption of corticosteroids.

Besides drug history, the daily dosage of pills patients take also plays an important role in causing GI symptoms. To our knowledge, this is the first study counting pills of patients' daily intake and looking for an association between the amount of pills and GI symptoms. We did find that the more pills taken, the more severe the GI symptoms. In our study, the average amount of pills a PD patient took daily was almost 15, and the maximum amount was 51, which consisted of CCBs, angiotensin converting enzyme inhibitors (ACEIs), angiotensin receptor blockers (ARBs), statins, active vitamin D, iron agents, ketoacids, anti-platelet drugs and varieties of Chinese medicine, which were especially common in China. The underlying mechanisms are not fully understood.

Compared to hemodialysis (HD), PD is thought to provide better preservation of residual renal function (RRF), which in many studies partly accounts for reduction of mortality risk, decreasing inflammation factors, declining oxidative and carbonyl stress[24-27]. In addition, in our study, another highlight of RRF we discovered was that it can prevent PD patients from developing GI symptoms. Apart from residual renal Kt/V, peritoneal Kt/V and total Kt/V were not proven to be correlated to GI symptom scores. These results indicated that the beneficial effect of residual renal clearance and peritoneal clearance were not equivalent with regard to patient outcome, and residual renal function may play a much more important role. Previous study has also shown that for each mL/min per 1.73 m^2 increase in residual renal glomerular filtration rate (GFR), a 12% reduction in mortality rate was found[26]. In contrast, no significant effect of peritoneal clearance on patient survival was established[26]. Regarding this, GI symptoms in PD patients were more associated with the uremia itself, therefore PD specific factors were not involved.

Previous study has concluded that age < 60 and BMI ⩾ 27 predicted GERD in the general population, while diabetes and PD did not[6]. However, we found neither age, BMI nor diabetes with PD predicted GI symptoms in PD patients. This may be due to the limitation in sample

size. Furthermore, albumin, as an index of nutrition, and duration of PD were not related to GI symptoms in our study. However, other studies obtained controversial results. A negative correlation between GERD symptom score and nPCR, and a positive correlation between GERD symptom score and the duration of CAPD, were found through observation in 43 patients[7]. Moreover, analyses of 99 dialytic patients revealed that gastrointestinal symptom scores were not different in hypoalbuminemic and normoalbuminemic patients[28]. In addition, gastrointestinal life quality was found not to be correlated with the duration of PD treatment[29]. Factors which contributed to these conflicting results might be the sample size and the different ways used in evaluating the GI symptoms.

Our study included only CAPD and intermittent peritoneal dialysis (IPD) patients and neither of these groups was independently associated with GI symptom scores. Further evaluation in a larger population with different types of PD is needed for finding out the relation between PD type and GI symptoms.

Volume of dialysis fluid used was also a non-predictor. Another study recruited 61 PD patients and showed a strong linear correlation between IPP and intraperitoneal volume, but failed to find any influence of IPP on the occurrence of GERS except that patients with GERS had a higher BMI[17]. The increased IPP was still not a rational explanation for the high prevalence of GI symptoms in the PD population.

One limitation of the present study is the relatively small number of samples, which may influence the power of statistical tests. Some factors, such as age, daily dosage and PD type showed a tendency to be correlated with GI symptoms, but correlation did not reach statistical significance because of the fact that 31 of 112 samples were excluded from the multiple regression model for the missing value of Kt/V and we only recruited patients with CAPD and IPD. Another limitation refers to the probable subjective bias in answering the questionnaire. Only one self-administered questionnaire was used in the study. Still another limitation refers to the lack of a control group consisting of patients undergoing HD.

In conclusion, the present study demonstrates a high prevalence of troublesome GI symptoms in PD patients, a positive correlation between history of corticosteroid use, the amount of pills patients take daily, and GI symptoms, and a negative correlation between residual renal function and GI symptoms. GI symptoms are more common in PD than in HD patients as well as compared to the predialytic population[4] which strongly suggests that PD treatment is a putative cause of GI symptoms. However, the present study failed to prove a relationship between PD specific factors and GI symptoms. Therefore, further evaluation in a larger population of PD patients with a control group is needed.

ACKNOWLEDGMENTS

We thank the patients for participating in the study and the staff at the PD unit in Changhai Hospital, especially Nurse Hai-Yan Xu, for facilitating the conduct of this study. We thank Dr. Cheng Wu from the Department of Health Statistics, Second Military Medical University for assistance in statistics.

COMMENTS

Background

Gastrointestinal (GI) symptoms are more common in patients undergoing peritoneal dialysis (PD) than in patients with chronic renal failure undergoing hemodialysis, though the cause and the correlated factors are largely unknown. Uremia itself and the impaired digestive system caused by PD are the main suspected causes.

Research frontiers

PD patients are proven to have a higher prevalence of GI symptoms. Many studies have focused on the impact of dialysate on the gastrointestinal tract but obtained controversial results. In this study, the authors demonstrate that gastrointestinal complaints in PD patients are more related to a history of corticosteroid therapy, the number of pills taken daily and residual renal function rather than effects of the dialysate.

Innovations and breakthroughs

Recent reports have highlighted the high prevalence of GI symptoms in PD patients and their poor treatment. This is the first study exploring possible correlated factors from almost all details in the life of PD patients. In addition, this is the first study demonstrating that dialysate is not the main cause of GI symptoms in PD patients. Furthermore, this study suggests that GI symptoms in PD patients may be affected by residual renal function and drug history.

Applications

By understanding what factors are related to GI symptoms in PD patients, this study may represent a future strategy for prevention and intervention in the treatment of PD patients with GI symptoms.

Terminology

GSRS, Gastrointestinal Symptom Rating Scale, a self-administered questionnaire, includes 15 items and uses a 7-grade Likert scale defined by descriptive anchors such that 1 = none, 2 = minor, 3 = mild, 4 = moderate, 5 = moderately severe, 6 = severe, and 7 = very severe discomfort. The items can be grouped into five dimensions: abdominal pain syndrome (three items), reflux syndrome (two items), indigestion syndrome (four items), diarrhea syndrome (three items), and constipation syndrome (three items). One dimension, eating dysfunction, which was developed in a manner analogous to the GSRS, was also considered relevant for the study and added to the original GSRS.

Peer review

This is a straightforward, well done study with straightforward conclusions. I hope the authors will take the next step and perform a more rigorous study with 2 control arms (chronic renal failure and HD) in a prospective fashion.

Abstract

AIM: To explore the feasibility and therapeutic effect of total laparoscopic left hepatectomy (LLH) for hepatolithiasis.

METHODS: From June 2006 to October 2009, 61 consecutive patients with hepatolithiasis who met the inclusion criteria for LLH were treated in our institute. Of the 61 patients with hepatolithiasis, 28 underwent LLH (LLH group) and 33 underwent open left hepatectomy (OLH group). Clinical data including operation time, intraoperative blood loss, postoperative complication rate, postoperative hospital stay time, stone clearance and recurrence rate were retrospectively analyzed and compared between the two groups.

RESULTS: LLH was successfully performed in 28 patients. The operation time of LLH group was longer than that of OLH group (158 ± 43 min *vs* 132 ± 39 min, $P < 0.05$) and the hospital stay time of LLH group was shorter than that of OLH group (6.8 ± 2.8 d *vs* 10.2 ± 3.4 d, $P < 0.01$). No difference was found in intraoperative blood loss (180 ± 56 mL *vs* 184 ± 50 mL), postoperative complication rate (14.2% *vs* 15.2%), and stone residual rate (intermediate rate 17.9% *vs* 12.1% and final rate 0% *vs* 0%) between the two groups. No perioperative death occurred in either group. Fifty-seven patients (93.4%) were followed up for 2-40 mo (mean 17 mo), including 27 in LLH group and 30 in OLH group. Stone recurrence occurred in 1 patient of each group.

CONCLUSION: LLH for hepatolithiasis is feasible and safe in selected patients with an equal therapeutic effect to that of traditional open hepatectomy.

INTRODUCTION

Hepatolithiasis refers to the stone in branching bile ducts above the confluence of left and right hepatic ducts. It may occur alone or with extrahepatic bile duct stones and is a prevalent disease in Southeast Asia and its incidence is also higher in Chinese coast areas, southwest region, Hong Kong and Taiwan. Hepatectomy is a definite and effective approach for hepatolithiasis[1,2]. With the refinement of laparoscopic instruments and accumulated experience in both laparoscopic surgery and hepatic surgery, laparoscopic hepatectomy has been used in treatment of hepatic benign and malignant tumors and donor hepatectomy of live donor liver transplantation[3,4]. However, few studies are available on laparoscopic hepatectomy for hepatolithiasis[5-8]. We successfully used total laparoscopic left hepatectomy (LLH) to treat hepatolithiasis in

8 patients between November 2003 and May 2006, and have preliminarily accumulated surgical experience with it and considered this operation safe and feasible[9]. To further explore the therapeutic effect of total LLH on hepatolithiasis, clinical data about 61 consecutive patients with hepatolithiasis who underwent LLH or open left hepatectomy (OLH) were retrospectively analyzed and compared.

MATERIALS AND METHODS

Inclusion criteria and patients

The inclusion criteria for LLH for hepatolithiasis include (1) multiple stones in the left or left lateral intrahepatic ducts with fibrosis and atrophy of hepatic lobes or hepatic segments; (2) possibly combined with extrahepatic bile duct stones or a few stones in the right intrahepatic ducts, but with no extrahepatic bile duct stricture or stone incarceration in the lower part of common bile duct; and (3) liver function of Child A to B classification, with no portal hypertension, coagulation disorder, structural disease in the heart, lungs, liver and kidneys, intrahepatic biliary cancer, and abdominal surgical histories.

From June 2006 to October 2009, 61 consecutive patients with hepatolithiasis who met the inclusion criteria for LLH were treated in our institute. Of the 61 patients with hepatolithiasis, 28 underwent LLH (LLH group) and 33 underwent OLH (OLH group). Before operation, all patients had a complete medical evaluation, including liver function, renal function, electrocardiogram and chest X-ray. Preoperative ultrasonography, CT and MRCP were performed to identify the distribution of stones and changes in the bile duct tree. Of the 28 patients in LLH group, 10 were men and 18 women, with a mean age of 47 years (range 25-63 years). Twenty-one patients had left hepatolithiasis and 7 left and right hepatolithiasis. Twelve patients were accompanied with cholecystolithiasis, 13 with choledocholith, and 6 with mild jaundice. Liver function was classified as Child A and B in 22 and 6 patients, respectively. Two patients had a history of biliary surgery. Of the 33 patients in OLH group, 12 were men and 21 women with a mean age of 49 years (range 31-68 years). Twenty-three patients had left hepatolithiasis and 10 left and right hepatolithiasis. Twelve patients were accompanied with cholecystolithiasis, 15 with choledocholithiasis, and 9 with mild jaundice. Liver function was classified as Child A and B in 25 and 8 patients, respectively. Three patients had a history of biliary surgery. No significant difference was found in age, sex, stone distribution, liver function and surgical history between the two groups.

Operative techniques

Patients in LLH group, placed in supine position, underwent general anesthesia. The chief surgeon stood on the left of the patient and the first assistant on the right. Another surgeon who supported the mirror stood on the left of the chief surgeon. Two monitors were placed above each side of the patient's head. A 10-mm cut was made below the umbilicus and a CO_2 pneumoperitoneum was established at a pressure of 14 mmHg. A 30° angled laparoscope was introduced. Under direct vision, two 12-mm trocars were respectively inserted below the xiphoid bone and the costal margin of the left mid-clavicular line, and a 5-mm trocar was also inserted below the costal margin of the right mid-clavicular line.

Left lateral segmentectomy: Laparoscopy was performed with the round and falciform ligaments transected using an ultrasound knife (Johnson and Johnson, USA). By meticulous dissection, the artery and vein of left lateral segment were visualized, clamped with absorbable clips and divided. Interrupted bile ducts were not clamped temporarily. Left triangular and coronary ligaments were divided with the trunk or branch of the left hepatic vein carefully dissected properly away from the second hepatic portal. If the confluence point of left hepatic veins and inferior vena cava was very close to the posterior border of the left liver, the left hepatic veins were clamped extremely near the posterior border of the left liver, but not divided until complete removal of Couinaud. If the confluence point of left hepatic veins and inferior vena cava was away from the liver parenchyma, the left hepatic vein was dissected, clamped with absorbable clips and divided (Figure 1). Liver parenchyma was transected from left of the round ligament to liver inferior border of sagittal portion, vessels and bile ducts in the transection plane were bluntly dissected, clamped and divided. Dilated intrahepatic bile ducts in the transection plane were opened. According to the size, number and position of residual stones, stone forceps were introduced below the xiphoid bone to directly remove stones, or a fiber choledochoscope (Olympus, Japan) was used to remove stones from the transection plane. If the stones were near the distal common bile duct or bigger, or combined with right hepatolithiasis, common bile duct exploration was performed to remove the stones. Cholecystectomy was done routinely. Continuous or interrupted suture was performed for the transection plane with 3-0 Vicryl. Water was injected *via* a T tube to determine whether the suture was tight. The transection plane was coagulated with fibrin glue to seal capillary vessels or covered with absorbable hemostatic gauze. The integral specimen was packed into a plastic bag and removed *via* an extended trocar hole. A drainage tube was left in vicinity of the transection plane through the costal margin of the left mid-clavicular line. Whether a drainage tube is left near the first hepatic portal depends on the intraoperative conditions.

Left hemihepatectomy: In the first hepatic portal, the left hepatic artery and the left branch of portal vein were dissected. The proximal end of left hepatic artery was clamped with two absorbable clips, the left hepatic artery was clamped with a mental soft clip 2-3 mm away from the absorbable clips, and the left hepatic artery was divided between mental and absorbable clips. The left branch of portal vein was treated with the same method

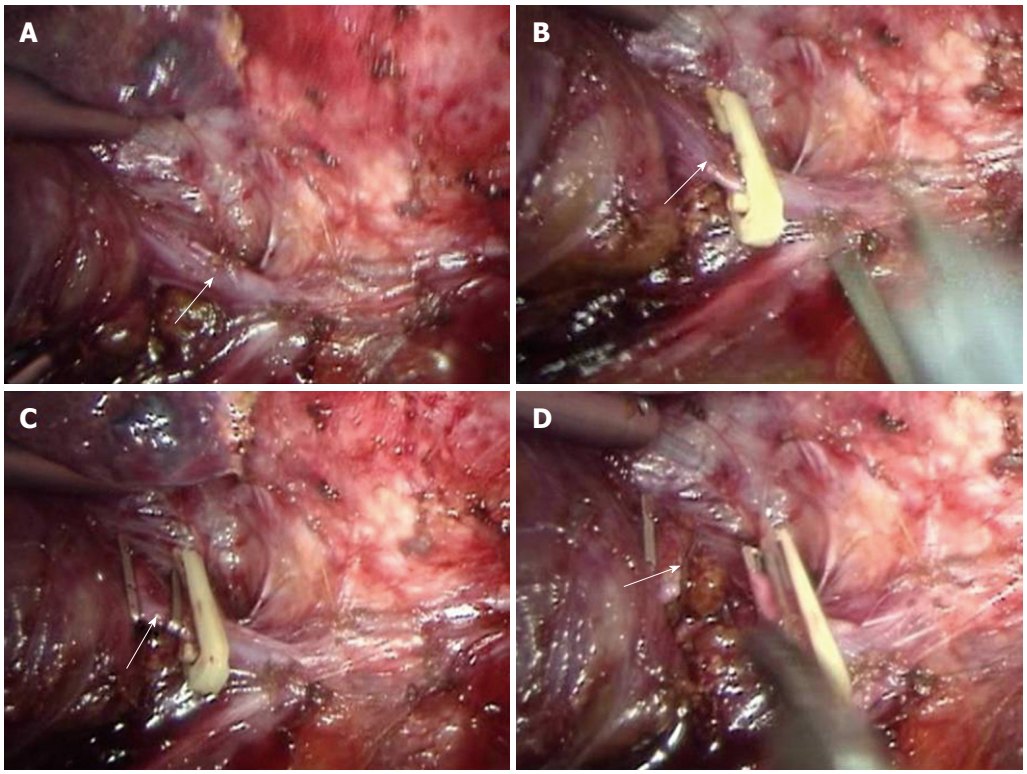

Figure 1 Laparoscopy showing dissected LHV (A, arrow), clamped LHV (B and C, arrow), and transected LHV (D, arrow). LHV: Left hepatic vein.

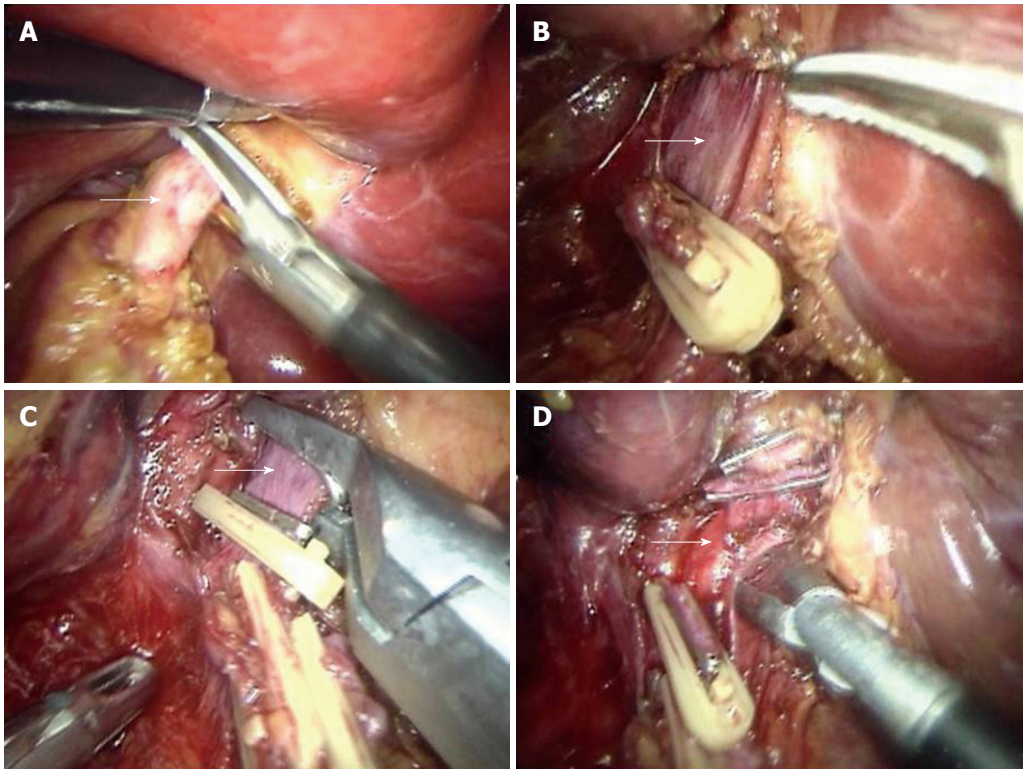

Figure 2 Laparoscopy showing dissected LBHA (A, arrow), exposed LBHV (B, arrow), dissected and clamped LBHV (C, arrow), and dissected left hepatic duct (D, arrow). LBHA: Left branch of hepatic artery; LBHV: Left branch of hepatic vein.

(Figure 2). Other surgical procedures were the same as those in left lateral segmentectomy.

In OLH group, an oblique incision was made along the right costal margin or along the right rectus abdominis with the patients in supine position under general anesthesia. Cholecystectomy was done routinely. Common

Table 1 Surgical procedure for hepatolithiasis in 61 patients

Variables	LLH (n = 28)	OLH (n = 33)
Left hemihepatectomy	3	5
Left lateral segmentectomy	25	28
Combined with cholecystectomy	26	30
Combined with CBD exploration	22	31
T tube drainage	16	27
Primary suture of CBD	6	4
Intraoperative choledochoscope	28	28

LLH: Laparoscopic left hepatectomy; OLH: Open left hepatectomy; CBD: Common bile duct.

Table 2 Comparison between LLH and OLH for hepatolithiasis n (%)

Variables	LLH (n = 28)	OLH (n = 33)
Operating time (min)	158 ± 43	132 ± 39
Intraoperative blood loss (mL)	180 ± 56	184 ± 50
Intraoperative blood transfusion	0 (0)	1 (3.0)
Postoperative complications	4 (14.2)	5 (15.2)
Postoperative hospital stay (d)	6.8 ± 2.8	10.2 ± 3.4
Intermediate residual stone	5 (17.9)	4 (12.1)
Final residual stone	0 (0)	0 (0)
Stone recurrence	1 (3.6)	1 (3.0)
Perioperative mortality	0 (0)	0 (0)

bile duct exploration was performed to remove stones. Couinaud was removed with a T drainage tube left.

Residual stones were completely removed by fiber choledochoscopy *via* the T tube sinus tract after operation in both groups.

Clinical data including operation time, intraoperative blood loss, postoperative complication rate, postoperative hospital stay time, and stone clearance and recurrence rate were compared between the two groups. Follow-up data were obtained from hospital charts or by telephone.

Statistical analysis

Categorical parameters of each group were compared by χ^2 test, and continuous parameters were compared using independent-sample t test. All analyses were performed using SPSS 12.0. $P < 0.05$ was considered statistically significant.

RESULTS

Laparoscopic left hepatectomy was successfully performed in 28 patients. Of the 28 patients, 3 underwent laparoscopic left hemihepatectomy, cholecystectomy, common bile duct exploration and T tube drainage, 18 underwent left lateral segmentectomy, cholecystectomy and common bile duct exploration. Of the 18 patients, 6 underwent primary suture of common bile duct, 12 underwent T tube drainage, 5 underwent left lateral segmentectomy with cholecystectomy, 1 underwent left lateral segmentectomy, common bile duct exploration and T tube drainage, and 1 underwent left lateral segmentectomy. All the 28 patients in LLH group underwent intraoperative cholangioscopic bile duct exploration or stone removal. Of the 33 patients in OLH group, 5 underwent open left hemihepatectomy, cholecystectomy, common bile duct exploration and T tube drainage, 23 underwent left lateral segmentectomy, cholecystectomy and common bile duct exploration. Of the 23 patients, 4 underwent primary suture of common bile duct, 19 underwent T tube drainage. Twenty-eight patients in OLH group underwent cholangioscopic bile duct exploration with stones removed (Table 1). Intraoperative findings and postoperative pathology displayed hepatolithiasis, cholangiectasis of Couinaud, chronic inflammation and fibration in all patients.

The mean operation time was longer in LLH group than in OLH group (158 ± 43 min *vs* 132 ± 39 min, $P < 0.05$). The intraoperative blood loss in two groups was similar (180 ± 56 mL *vs* 184 ± 50 mL). One patient in OLH group was transfused with 2 units of concentrated red blood cells, no patient in LLH group received blood transfusion. Bile leakage occurred in 2 patients of LLH group, and healed automatically 3 and 5 d after operation. Pleural effusion, observed in 2 patients, disappeared after thoracentesis. In OLH group, seroperitoneum occurred in 1 patient, hepatic abscess in 1 patient and infection of incision in 3 patients. No significant difference was found in complication rate (14.2% *vs* 15.2%) and intermediate stone residual rate (17.9% *vs* 12.1%) between the two groups. The mean postoperative hospital stay time was shorter in LLH group than in OLH group (6.8 ± 2.8 d *vs* 10.2 ± 3.4 d, $P < 0.01$), and the serum transaminase was transiently increased and jaundice disappeared at discharge with no death occurred in both groups (Table 2).

Of the 16 patients in LLH group discharged with their T tubes, 11 underwent T extubation 28-35 d after operation, 5 underwent it 42-60 d after operation when residual stones were completely removed by choledochoscopy. Of the 27 patients in OLH group discharged with their T tubes, 23 underwent T extubation 28-40 d after operation, 4 underwent it 50-60 d after operation when residual stones were completely removed by choledochoscopy. Fifty-seven patients (93.4%) including 27 in LLH group and 30 in OLH group were followed up for 2-40 mo (mean 17 mo). Stone recurrence was found in 1 patient of LLH group and in 1 patient of OLH group. Intrahepatic biliary cancer occurred in 1 patient of OLH group 29 mo after operation, and was surgically removed in another hospital.

DISCUSSION

In 1991, Reich *et al*[10] used laparoscope to remove a benign tumor located at the edge of liver, raising the curtain on laparoscopic hepatectomy. In 1993, Wayand *et al*[11] performed laparoscopic segmentectomy (segments Ⅵ) for metastatic carcinoma. In 1996, Azagra *et al*[12] first performed laparoscopic left lateral lobectomy (segments Ⅱ and Ⅲ) for hepatic adenoma in 1 patient. With the refinement of laparoscopic instruments and accumulated

experience in laparoscopic hepatectomy, indications for laparoscopic hepatectomy have gradually expanded from small, peripheral and benign diseases to large, central and malignant diseases[13,14]. Lesions located in Couinaud including Ⅱ, Ⅲ, Ⅳa, Ⅴ and Ⅵ segments are the best indications for laparoscopic hepatectomy, and regular left lateral lobectomy is expected to become its gold standard[8,15]. Most intrahepatic bile duct stones, especially left intrahepatic bile duct stones, manifested as a regional distribution, are usually combined with liver fibrosis and atrophy, which is also a good indication for laparoscopic hepatectomy[8,16]. The inclusion criteria for LLH for hepatolithiasis in this study were (1) multiple stones in the left or left lateral intrahepatic ducts with fibrosis and atrophy of hepatic lobes or segments, possibly combined with extrahepatic bile duct stones or a few stones in the right intrahepatic ducts; and (2) except for lots of stones in the right intrahepatic ducts, severe acute cholangitis, hepatic abscess, stone incarceration in the lower part of common bile duct and bile duct neoplasms. We believe that only LLH rather than common bile duct exploration is required for simple left hepatolithiasis. Chen *et al*[16] has described that endoscopic retrograde cholangiopancreatography (ERCP) and endoscopic sphincterotomy (EST) for left hepatolithiasis with extrahepatic bile duct stones, can completely remove common bile duct stones followed by laparoscopic hepatectomy. However, ERCP easily causes acute pancreatitis, thus making cholelithiasis heavier and EST destroys the integrity of duodenal papilla and sphincter Oddi, easily leading to biliary tract infection and difficulty to remove the stones with a diameter > 1.5 cm. Preoperative hospital stay time is significantly increased and secondary operation is required. In this study, common bile duct exploration was performed to remove stones followed by T-tube drainage or primary suture of common bile duct, which is suitable for different sizes of common bile duct stones, but is time-consuming and may lead to bile leakage. External drainage of bile may lead to electrolytical and digestive unbalance, which is not beneficial to postoperative recovery. Choledochoscopy can remove the stones through the stump of the left hepatic duct without cutting open the common bile duct, thus avoiding the above disadvantages. However, it is only suitable for a small number of patients. In this study, a few stones in the right hepatic bile duct were removed by intraoperative choledochoscopy through the common bile duct or by postoperative choledochoscopy *via* the T-tube sinus tract.

The liver possesses dual blood supply from hepatic artery and portal vein. Blood supply is abundant and bleeding easily occurs. During laparoscopic hepatectomy, since hepatic portal occlusion, hand pressure and saturation cannot be used for hemostasis, it is not easy to control intraoperative bleeding[17]. Therefore, how to prevent, control and reduce intraoperative bleeding is a key to surgical success and postoperative recovery[18]. In our study, full preoperative preparation was done for each patient. The patients with normal liver function and coagulation test were selected. Preoperative ultrasonography, CT or MRCP was performed to determine the distribution, location and size of stones and liver morphology. The stones were located in Couinauds Ⅱ and Ⅲ. The operators had rich experience in traditional hepatectomy and skilled laparoscopic technique. Excellent surgical instruments such as ultrasonic bleeding knife, vascular closure device and Ligasure vessel sealing system were provided. Each segment of the left liver was dissected in the first hepatic portal, and blocked with clips. The portal vascular structure of left liver was dissected outside Glisson sheath, and the branches of portal vein and hepatic artery were clamped with absorbable clips. The left hepatic vein trunk was dissected, clamped with clips and divided after transection of liver parenchyma. The transaction of liver parenchyma resulted in less tissue damage, less bleeding and good exposure of hepatic duct system. It was reported that Peng's multifunctional operative dissector can reduce bleeding and operation time[19]. The ideal level of regular left lateral lobectomy is at the sagittal plane 1 cm away from the left of falciform ligament. The main vessels at this plane include superior and inferior segment branch of Couinaud of portal vein, trunk of left hepatic vein, left and upper branches of left hepatic vein, which are distributed in 2/3 of the superior part. Choledochoscope can enter the common bile duct or the right hepatic duct through the broken end of left hepatic duct or incisional anterior wall of the common bile duct to remove stones[6,7]. If no biliary tract stricture is identified, small stones may not be completely removed, and then a T tube is left. The residual small stones can be removed by choledochoscopy 6 wk after operation.

Hepatolithiasis is common in China, accounting for about 10% of calculosis, or 40%-50% in some areas. Stone clearance rate for open hepatectomy can reach 81.7% with a reliable long-term therapeutic effect[20]. Laparoscopic hepatectomy can achieve the same stone clearance rate in the left liver[6]. Zhang *et al*[8] reported that the therapeutic effect of laparoscopic left lateral lobotomy for left hepatolithiasis and choledocholith is better than that of traditional open stone removal. Machado *et al*[21] reported one patient who underwent laparoscopic right hepatectomy for hepatolithiasis, showing that the learning curve can influence the feasibility and repeatability of laparoscopic hepatectomy[22]. In this study, the therapeutic effects of laparoscopic and open hepatectomy on intrahepatic and extrahepatic bile duct stones were compared as previously described[9]. Although randomized controlled trial data are lack, the blood loss, blood transfusion rate, complication rate and mortality in laparoscopic hepatectomy were equal to those in open hepatectomy. It was reported that the evacuating time, fasting time, use of analgesics, hospital stay time, time to return to work and degree of satisfaction are better in laparoscopic hepatectomy than in open hepatectomy, while operation time is longer and cost is higher in laparoscopic hepatectomy than in open hepatectomy[5,23,24]. In our study, the mean operation time of LLH group was longer than that of OLH group, the mean blood

loss and postoperative complication rate were similar in the two groups, the mean hospital stay time was significantly shorter in LLH group (6.8 ± 2.8 d) than in OLH group (10.2 ± 3.4 d) possibly due to the mini-invasive advantages, such as small incision, postoperative light inflammatory response, less interference with immune function. In addition, intermediate and final stone clearance rate and long term stone recurrence rate for the two groups were also similar with no CO_2 gas embolism occurred in patients of LLH group. Air embolism is a potential risk factor for laparoscopic hepatectomy.

In summary, LLH for hepatolithiasis is safe and feasible in selected patients if it is performed by surgeons with experience in laparoscopic and hepatic surgery. Its therapeutic effect is equal to that of traditional open hepatectomy. Laparoscopic hepatectomy has the advantages such as mini-invasion, less postoperative pain and rapid recovery.

COMMENTS

Background

Hepatolithiasis is a prevalent disease in Southeast Asia with a high incidence in coast areas, southwest region, Hong Kong and Taiwan of China. Hepatectomy is a definite and effective procedure for hepatolithiasis. With the refinement of laparoscopic instruments and accumulated experience in laparoscopic and hepatic surgery, laparoscopic hepatectomy has been used in treatment of hepatic benign and malignant tumors and donor hepatectomy for live donor liver transplantation. However, few studies are available on on laparoscopic hepatectomy for hepatolithiasis.

Research frontiers

The feasibility and therapeutic effect of total laparoscopic left hepatectomy (LLH) on hepatolithiasis are a hotspot.

Innovations and breakthroughs

This study explored the therapeutic effect of laparoscopic *vs* open left hepatectomy on hepatolithiasis and concluded that LLH for hepatolithiasis is feasible and safe in selected patients if it is performed by experienced surgeons. Its therapeutic effect is equal to that of traditional open hepatectomy.

Applications

Laparoscopic hepatectomy possesses the advantages such as mini-invasion, less postoperative pain and rapid recovery and worth of spreading.

Terminology

Hepatolithiasis: It refers to stones in the branching bile ducts above the confluence of left and right hepatic ducts, and may occur alone or in combination with extrahepatic bile duct stones.

Peer review

It is interesting and well-written. The results show that laparoscopic hepatectomy is worth of spreading due to its advantages such as mini-invasion, less postoperative pain and rapid recovery.

Abstract

We report a case of advanced gastric cancer, with cervical, axillary, and abdominal paraaortic lymph node metastases, that was successfully treated with chemotherapy and surgery. The disease was initially considered unresectable, and the patient was treated with orally administered S-1. Chemotherapy was effective, and all lymph node metastases disappeared after 6 courses. After 27 mo of chemotherapy, the patient underwent curative surgery, with subtotal gastrectomy and lymph node dissection. Histopathological examination revealed many viable poorly differentiated adenocarcinoma cells in the stomach, but no cancer cells in the lymph nodes. The patient is alive, without recurrence, 8 years later. This, therefore, is a case report of an 8-year survivor of advanced gastric cancer with distant lymph node metastasis.

Eight-year survival after advanced gastric cancer treated with S-1 followed by surgery. *World J Gastroenterol* 2010; 16(22): 2824-2827 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i22/2824.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i22.2824

INTRODUCTION

Improvements in early diagnosis of gastric cancer (GC) have led to an increase in the number of patients who are able to undergo curative resection[1]. However, the prognosis for patients with unresectable or metastatic disease is very poor, and long-term survival, particularly for more than 5 years, is rare. S-1 is a novel oral fluoropyrimidine that was developed in Japan. It has been available for patients with GC in Japan since 1999 and is currently being investigated worldwide. S-1 consists of tegafur, 5-chloro-2,4-dihydroxypyridine (CDHP) and potassium oxonate at a fixed molar ratio of 1:0.4:1. Tegafur is a prodrug of fluorouracil (5-FU), which is the cytotoxic component of this combination. CDHP is a potent reversible inhibitor of dihydropyrimidine dehydrogenase (DPD), the chief catabolic enzyme of 5-FU. Potassium oxonate selectively inhibits orotate phosphoribosyltransferase, the enzyme responsible for 5-FU activation in the gastrointestinal tract, thus reducing the gastrointestinal toxicity of the combination. Many reports have indicated the efficacy of this antitumor agent against gastric cancer.

We report a case of advanced gastric cancer (AGC) with unresectable lymph node metastases treated with S-1.

CASE REPORT

A 71-year-old man visited a local hospital in 2002, complaining of upper abdominal discomfort of one-month duration. Endoscopy revealed a concave lesion in the stomach, and the patient was subsequently referred to our hospital. Endoscopy showed a diffuse concave lesion with ulceration on the lesser curvature in the middle of the stomach. A biopsy specimen showed signet-ring cell carcinoma. Physical examination revealed a few elastic-hard masses in the left supraclavicular area (approximately 7 cm in diameter) and left axillary space (approximately 6 cm in diameter), suggesting lymph node metastases from the GC. Abdominal computed tomography (CT) showed marked swelling of several paraaortic lymph nodes (Figure 1A). We could not find metastasis to the liver, lung, or peritoneum. The patient's diagnosis was AGC with extensive lymph node metastases (stage Ⅳ: cT2 cN3 cP0 cH0 cM1). His general condition was good, with The Eastern Cooperative Oncology Group (ECOG) performance status 0, and biochemical analysis of blood and urine specimens showed no abnormalities. Serum levels of the tumor markers carcinoembryonic antigen (CEA) and carbohydrate antigen 19-9 (CA19-9) were not elevated (2.1 ng/mL and 12.0 U/mL, respectively). Since curative resection was impossible for this patient, chemotherapy with S-1 was started. As one course, 120 mg (80 mg/m^2) of S-1 was orally administered daily for 28 d, followed by a 14-d rest period; administration occurred primarily at the outpatient clinic. After 2 courses, endoscopy showed no remarkable change in the gastric tumor. However, abdominal CT showed remarkable reductions in the size of regional and paraaortic lymph nodes (Figure 1B), and also in cervical and axillary lymph nodes (Figure 2A and B). This indicated a partial response (PR). The evaluation after 6 courses of S-1 showed that there was no change at the primary site, but CT showed complete disappearance of paraaortic, cervical and axillary lymph nodes. Therefore, this revealed a complete response (CR), and this condition was stable up to the subsequent surgery. The patient did not experience any critical adverse event during S-1 administration, despite developing hematological toxicity; including leucopenia (2100/μL at the minimum), thrombocytopenia, and non-hematological toxicity; including grade 2 hand-foot syndrome and grade 1 stomatitis, according to National Cancer Institute Common Toxicity Criteria Version 2.0. After 19 courses of S-1, the tumor was limited to the primary gastric site, with no metastasis detected from neck to abdomen by CT or positron emission tomography (PET); only the detection of gastric tumor by PET. Therefore, we concluded that curative resection could be achieved. In 2004, distal gastrectomy and lymph node dissection (D2) were performed. We did not find cancer cells in the intraoperative peritoneal lavage, or in the abdominal paraaortic lymph node specimens. Figure 3 shows the resected gastric specimen. A concave lesion of 45 mm × 40 mm with an ulceration scar was located in the lesser curvature of the middle of the stomach (Figure 3). Histopathologi-

cal examination showed numerous poorly differentiated adenocarcinoma cells in the mucosal layer (Figure 4A). There were only a small number of poorly differentiated adenocarcinoma cells, but severe fibrosis, in the submucosal layer (Figure 4B). The histological effect of chemotherapy on the primary tumor was limited, and according to the Japanese classification of gastric carcinoma (second English edition)[2], it was classified as grade 1a. The only findings in the lymph nodes were remarkable fibrosis and giant cells, with no cancer cells seen; the histological effect on the lymph nodes metastasis was classified as grade 3 (Figure 4C). Therefore, a radical operation was considered to have been performed, and the final pathological stage assigned as Stage IA (pT1, pN0, sP0, sH0, sM0) according to the Japanese classification of gastric carcinoma (second English edition)[2]. There have been no signs of recurrence since the surgery, and the patient has survived for 8 years after initially receiving chemotherapy.

DISCUSSION

There have been some series that reported high response rates with the use of newer combinations of chemotherapy regimens for unresectable or metastatic GC[3]. However, standard regimens have not yet been established worldwide. S-1-based chemotherapy has shown survival benefits in recent randomized controlled trials. Boku *et al*[4] reported that S-1 monotherapy showed a significant non-inferiority benefit compared to continuously infused 5-FU in unresectable or metastatic GC ($P < 0.001$). Moreover, Koizumi *et al*[5] reported the results of a randomized controlled trial of S-1 *vs* S-1 with CDDP. The overall survival for S-1 with CDDP was superior to S-1 alone. The 1- and 2-year survival rates were 54.1% and 23.6%, respectively; whereas a 2-year survival rate of less than 10% was shown in the 5-FU+CDDP arm of a Japanese randomized controlled trial with a 10-year follow-up[6].

Although recent phase Ⅲ clinical trials indicated longer survival times[7,8], few patients with unresectable GC have survived longer than 5 years. During the last 10 years at our hospital, only 9 of more than 500 patients treated with chemotherapy for metastatic or recurrent

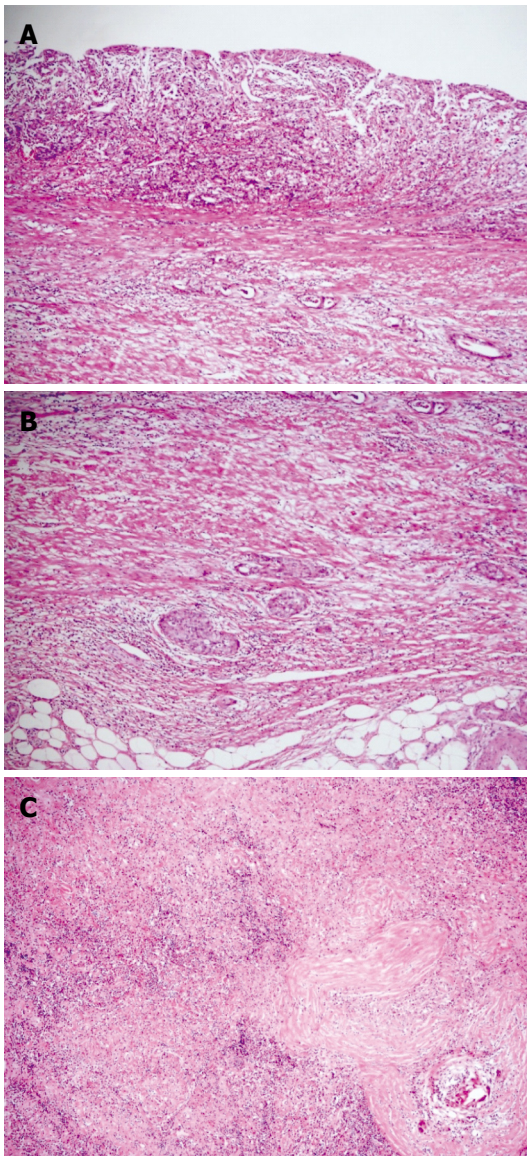

Figure 4 Histopathological examination. A: Histopathological examination showed numerous poorly differentiated adenocarcinoma cells in the mucosa; B: There were only a small number of poorly differentiated adenocarcinoma cells, but severe fibrosis, in the submucosal layer; C: The only findings in the lymph nodes were remarkable fibrosis and giant cells, with no cancer cells seen.

GC have survived for 5 years. Yoshida *et al*[9] reported a 5-year survival rate of 2% for registered Japan Clinical Oncology Group (JCOG) clinical trials and mentioned certain characteristics of these survivors. Most of the 5-year survivors had good performance status, macroscopically non-scirrhous-type tumors, only one metastatic site, a paraaortic node metastasis as the only unresectable factor, and achieved a CR after the initial chemotherapy. However, it is unclear whether such long survivals are because of biological non-aggressiveness or due to a good response to chemotherapy. There have been only five cases reported in the literature of AGC with neck lymph node metastasis in which there was no residual tumor following chemotherapy and surgical resection[10-14]. Ohyama *et al*[10] reported a case of a patient treated with combination chemotherapy, including 5-FU, leucovorin, cisplatin,

and etoposide, in which there was a good response. Chemotherapy was followed by curative resection, including subtotal gastrectomy and inguinal, neck, and abdominal lymph node dissection. Pathological examination showed cancer cells only in the abdominal lymph nodes, but not in the stomach or neck lymph nodes. Iwazawa *et al*[11] reported a case of AGC with cervical lymph node metastasis, in which a CR for cervical lymph nodes was achieved with S-1 alone treatment, and a curative resection of the residual tumor was performed. However, further outcomes of these cases were not described. It remains unknown whether adjuvant surgery for residual tumor after effective chemotherapy is beneficial for GC patients with distant metastasis or not. In our experience, if there is a long-maintained disappearance of inoperable metastasis, adjuvant surgery is considered beneficial.

In our case, there was no confirmation of the neck and axillary lymphadenopathy from imaging examinations before treatment began, and therefore no evidence that this lymphadenopathy was due to metastasis from GC. This is a limitation of our report and we assume responsibility for not obtaining all available evidence of metastasis from GC, although surgeons agreed on the non-operability of this patient in the preoperative conference. However, in patients with histologically diffuse type GC that is greater than 3 cm in size and which has invaded the submucosal layer, 7.5% have lymph node metastasis beyond the perigastric site[15]. Thus, our assumption that cervical and axillary lymphadenopathy was due to GC metastases was probably correct.

Abstract

Periampullary cancer may cause not only biliary but also duodenal obstructions. In patients with concomitant duodenal obstructions, endoscopic biliary stenting remains technically difficult and may often require percutaneous transhepatic biliary drainage. We describe a method of metal stent placement *via* a thin forward-viewing endoscope in patients with simultaneous biliary and duodenal obstruction. In two consecutive patients with biliary and duodenal obstruction due to pancreatic cancer, a new biliary metal stent mounted in a slim delivery catheter was placed *via* a thin forward viewing endoscope after passage across the duodenal stenosis without balloon dilation. In both patients, with our new placement technique, metallic stents were successfully placed in a short time without adverse events. After biliary stenting, one patient received curative resection and the other received duodenal stenting for palliation. Metallic stent placement with a forward-viewing thin endoscope is a beneficial technique, which can avoid percutaneous drainage in patients with bilio-duodenal obstructions due to periampullary cancer.

INTRODUCTION

Patients with periampullary malignancies occasionally experience not only biliary but also duodenal obstructions. Although biliary obstruction usually occurs first and is followed by duodenal obstruction, the two occur simultaneously in some cases. These patients often require percutaneous biliary stenting because the endoscopic procedure is difficult.

A new commercially available self-expandable metallic stent (SEMS) mounted in an extra slim delivery catheter can be passed through the working channel of a thin endoscope. Here, we assessed the outcome of metal stent placement *via* a thin forward-viewing endoscope in two patients with simultaneous biliary and duodenal obstruction.

CASE REPORT

Two consecutive patients with simultaneous biliary and duodenal obstructions due to pancreatic cancer between No-

Table 1 Summary of studied patients

Case	Age/sex	Level of duodenal obstruction	Level of biliary obstruction	Comorbidity	Purpose of biliary stenting	Subsequent procedures

2	81/M	Pars Ⅱ	Distal	Advanced esophageal cancer	Palliation	Duodenal and esophageal stenting

vember 2009 and January 2010 were investigated (Table 1). In both patients, duodenal obstructions did not allow the passage of a duodenoscope across the stricture without a dilating procedure. The patients underwent placement of SEMS *via* a slim forward-viewing gastroscope (GIF XP-240, Olympus, Tokyo, Japan) (a valid length of 1030 mm, an outer diameter of 7.7 mm, a working channel diameter of 2.2 mm). The SEMS used is a new uncovered SEMS, Zilver® 635 stent (10 mm in diameter) (Cook, Bloomington, IN, USA) which is a laser-cut nitinol stent mounted in an extra slim (6-Fr) delivery catheter. The study was approved by our institutional review board (OHASHI #21-017), and written informed consent was obtained from the patients.

A slim endoscope was inserted perorally and passed across the stricture. The ampulla was endoscopically visualized by retroflexing the endoscope in the distal second portion of duodenum. An endoscopic retrograde cholangiopancreatography (ERCP) catheter (PR-109Q, Olympus) was advanced into the bile duct using a wire-guided cannulation technique with a 0.025 "hydrophilic guidewire (Surf®, Piolax Medical Devices, Inc. Kanagawa, Japan). Then, the guidewire was replaced with a 0.035" Jagwire (Boston Scientific Inc., Natick, MA, USA), endoscopic papillary balloon dilation was performed with an 8-mm balloon dilator (Eliminator® PET biliary balloon dilator, ConMed, Utica, NY, USA), and the SEMS was released under endoscopic and fluoroscopic control.

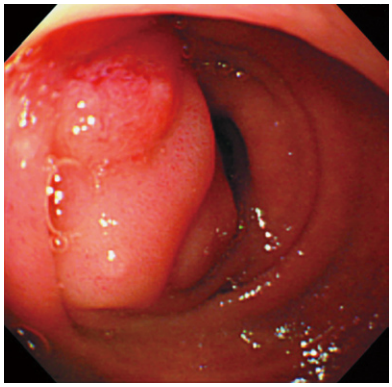

Figure 1 Endoscopic view of the forward-viewing endoscope showing duodenal stricture at the second portion of duodenum.

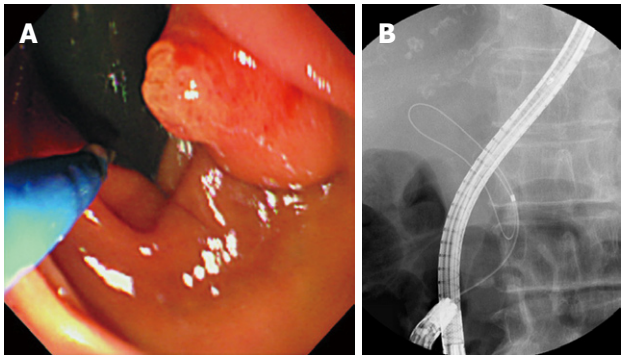

Figure 2 Selective biliary cannulation conducted with a thin forward-viewing endoscope. A: Endoscopic view showing endoscopic retrograde cholangiopancreatography (ERCP) catheter approaching to the papilla; B: X-ray picture showing common bile duct cannulation conducted with wire-guided technique without contrast injection.

Case 1

A 79-year-old woman was admitted to our hospital due to obstructive jaundice. Computed tomography (CT) revealed pancreatic cancer with duodenal invasion. The patient underwent ERCP for biliary stenting, during which a duodenoscope (JF-260V, 12.6 mm outer diameter, Olympus) could not be passed across the stricture in the second portion of duodenum. Despite the presence of duodenal stricture, she was able to take soft food orally.

The new stenting procedure with a thin forward-viewing endoscope was employed. In brief, a slim endoscope was inserted perorally and easily passed across the stricture (Figure 1). After successful biliary cannulation (Figure 2), a Zilver® 635 stent (8 cm in length) was placed and deployed at the optimal position (Figure 3). The entire procedure took 35 min, and no complications were encountered.

After biliary stenting, her cancer was considered resectable based on the assessment with detailed examinations. The patient successfully underwent pancreatico-duodenectomy on day 14 after stenting when her jaundice was relieved. The resected specimen revealed duodenal invasion from pancreatic cancer. Since then, the patient has received adjuvant chemotherapy with S-1.

Case 2

An 81-year-old man was admitted for epigastric pain, nausea and vomiting. Ultrasonography and CT revealed a 40-mm pancreatic mass with invasion to the extrahepatic bile duct, duodenum and portal vein. In addition, esophagogastroduodenoscopy revealed an advanced cancer in the lower part of esophagus and a duodenal stenosis due to pancreatic cancer. The cancer was therefore considered unresectable. Because of these gastrointestinal obstructions, the patient could not take food orally and both biliary and duodenal stenting for palliation were scheduled. Liver function tests showed abnormal results, although

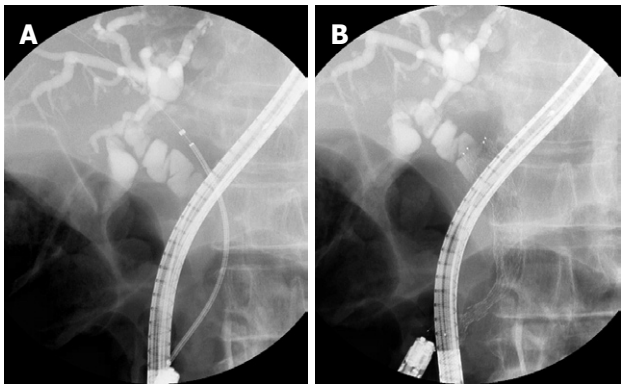

Figure 3 Biliary self-expandable metallic stent (SEMS) placement *via* a thin forward-viewing endoscope. A: An extra slim delivery catheter is inserted properly into the bile duct; B: SEMS is successfully placed.

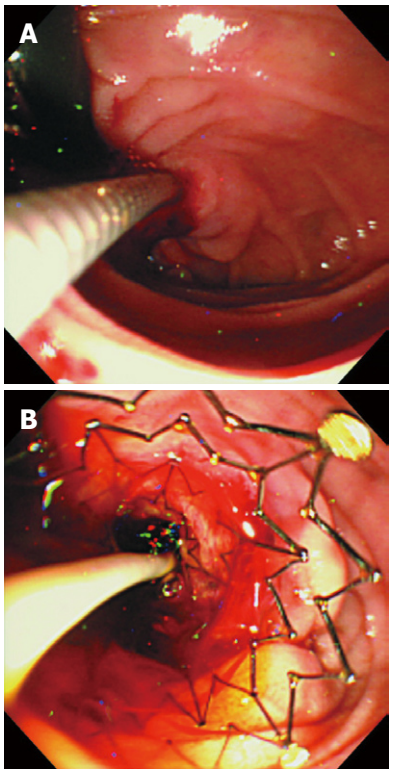

Figure 4 Endoscopic view showing biliary metallic stent placement *via* a thin forward-viewing endoscope. A: The delivery catheter is successfully introduced into the bile duct; B: SEMS is successfully placed.

jaundice was not identified. We carried out biliary stenting first in view of a treatment strategy based on scheduled palliative stenting, both biliary and duodenal[1].

Because it was impossible to pass a large-caliber side-viewing duodenoscope (JF-260V, Olympus) through the duodenal stricture, we employed the new biliary stenting procedure with a thin forward-viewing endoscope as in Case 1 and subsequently placed a duodenal stent. A thin endoscope was easily passed across the duodenal as well as esophageal obstruction, after which a Zilver® 635 stent (8 cm in length) was successfully placed without difficulty, even through the endoscope was retroflexed as in Case 1 (Figure 4). The total procedure time was 22 min.

Figure 5 X-ray picture indicating successful placement of biliary, duodenal and esophageal stents.

No procedure-related complications were found.

On day 10 after biliary stent placement, the patient underwent stent placement at the duodenal stricture. A duodenal stent (Niti-S® Pyloric/Duodenal Uncovered Stent, Taewoong Medical Inc. Seoul, Korea) was successfully placed with a through-the-scope placement procedure at the optimal position. Two weeks after the duodenal stenting, the patient also underwent stent placement at the esophageal obstruction with an Ultraflex™ (Boston Scientific) (Figure 5). Biliary, duodenal and esophageal stenting improved his dietary status, allowing intake of solid food.

DISCUSSION

We report here the successful endoscopic placement of a biliary SEMS using a thin forward-viewing endoscope in two patients with simultaneous biliary and duodenal obstructions. One patient underwent the procedure for presurgical decompression and the other for palliation.

The combination of biliary and duodenal obstruction in patients with periampullary cancer is relatively frequent, as 23% of the patients had both biliary and duodenal obstructions in a retrospective study of unresectable pancreatic head cancer[2]. In most cases, duodenal obstruction occurs after biliary obstruction, but simultaneous obstruction also occasionally occurs. Because stent placement in these simultaneous cases is more complicated, these patients often require percutaneous biliary stenting. Even if a duodenoscope can be passed across the duodenal stricture when a duodenal stent is first placed, access to the ampulla may be hampered by stent mesh covering the papilla. Biliary stenting before duodenal stenting is therefore recommended for these patients[1]. However, because the stricture is usually too narrow to allow passage of a large-caliber duodenoscope, hydrostatic balloon dilation is frequently required[2,3]. Even after dilation, passage of a side-viewing duodenoscope across the obstruction is sometimes difficult, and is at a risk for duodenal perforation owing to the presence of acute angulation in the duodenum. Because the endoscope used in the present study is much thinner and forward-viewing, we were able to pass it easily and safely across the stricture under direct vision. The present technique thus has the great advantage of allowing the easier and safer emplacement of a biliary stent than a previously published technique of biliary stenting after a duodenal dilation with a side-viewing duo-

denoscope in patients with combined biliary and duodenal obstruction[2,3].

Although usually selected when endoscopic stenting is difficult, percutaneous stenting has two drawbacks, namely a compromised quality of life owing to the need for an indwelling percutaneous transhepatic biliary drainage (PTBD) catheter for at least one week before stent placement, and the risk of cancer implantation in the catheter tract. A retrospective analysis of patients who underwent PTBD before resection of extrahepatic cholangiocarcinoma showed that catheter tract cancer-implantation develops in 6%[4]. Catheter tract cancer-implantation is reportedly observed in patients with pancreatic cancer as well as cholangiocarcinoma[5]. In recent years, endoscopic ultrasound (EUS)-guided biliary drainage has been introduced as an alternative to PTBD when ERCP is unsuccessful. However, this procedure is associated with procedure-specific complications, such as bile leak-attributable peritonitis[6,7], in addition to bleeding and cholangitis from stent dysfunction. Theoretically, it may cause cancer implantation in the peritoneal cavity and fistula track as in the case of PTBD. Transpapillary stenting is the only procedure conducted *via* a natural route and so must be the most desirable technique for presurgical as well as palliative decompression.

Recently, cholangiographic or cholangioscopic procedures with an ultra-slim endoscope have been reported[8,9]. A prospective comparison of transnasal ERCP with an ultrathin forward-viewing endoscope *vs* conventional ERCP with a large caliber side-viewing duodenoscope has reported no statistically significant difference in the rates or times of cannulation, albeit that the success rate of cannulation with the transnasal method is lower. The endoscope used in the present study (7.7 mm in diameter) is slightly larger than that used in the previous study (5.9 mm in diameter)[8]. Unlike the previous study, we introduced the endoscope into the duodenum perorally but were nevertheless able to accomplish biliary cannulation and stenting, without any difficulty. One previous case report of stent placement using an ultrathin forward-viewing endoscope *per os* has appeared[10], in which a patient with choledocholithiasis who received placement of two 5-Fr hand-made stents, subsequently underwent sphincterotomy and stone removal using a peroral ultrathin endoscope after relief of cholangitis. With plastic stents, thin endoscopes with a narrower working channel are restricted to accepting only 6 Fr or thinner stents. However, larger stents are generally more favorable than smaller ones, particularly for palliative use. We consider that the use of the new SEMS mounted in an extra slim delivery catheter takes full advantage of the possibilities of a thin endoscope with a thinner working channel.

When duodenal tumor invasion extends to the major papilla, endoscopic identification of the papilla is frequently difficult. Even if the papilla can be found, it is generally impossible to access the bile duct because of the difficulty of aligning the catheter with the bile duct axis. Under these conditions, therefore, stent placement would likely be difficult even with the present method and a percutaneous or EUS-guided transenteric procedure may be required instead. However, the number of such cases appears to be limited. The present report is a preliminary result with only two cases, and further study with more patients is warranted.

In conclusion, placement of the new SEMS mounted in an extra slim delivery catheter *via* a thin forward-viewing endoscope appears to be a safe and effective procedure for either presurgical or palliative decompression in patients with malignant biliary and duodenal obstruction. This study is preliminary, however, and further evaluation in a larger number of patients is warranted.

Abstract

The treatments for common bile duct (CBD) stones are being continually developed. Impaction of the lithotripsy basket during endoscopic removal of CBD stones was seen in 5.9% patients. We report the case of a 66-year-old woman who underwent surgery for the removal of an impacted biliary basket. She was admitted to our hospital with a complaint of right upper abdominal pain. Magnetic resonance cholangiopancreatography revealed a CBD stone (20 mm × 15 mm). We diagnosed her with choledocholithiasis and performed endoscopic retrograde cholangiopancreatography to remove the stone. However, unfortunately, the retrievable basket around the stone became impacted. An endotriptor along with forceps could not be used owing to the entrapment of the basket, and thus we performed urgent surgery. The basket containing the stone was removed through a longitudinal choledochotomy. The wires leading to the basket were cut, and the basket containing the stone was removed *via* the incision. A T-tube was inserted, and the choledochotomy was closed. The postoperative course was uneventful. In conclusion, if the diameter of a CBD stone is more than 20 mm, then the risk of basket impaction increases, and surgery may be necessary as the initial treatment of the CBD stone.

INTRODUCTION

Endoscopic procedures for the removal of common bile duct (CBD) stones are well established[1-3], and include endoscopic retrograde cholangiography (ERC), sphincterotomy, and basket or balloon extraction. However, endoscopic removal of large bile duct stones is difficult. The success or failure of lithotripsy depends on the size of the stone, number of stones, degree of jaundice, and presence or absence of gallbladder stone-induced cholecystitis. Here, we report the case of a patient with an impacted biliary basket.

CASE REPORT

A 66-year-old woman with right upper abdominal pain was admitted to our hospital. Laboratory analysis on admission

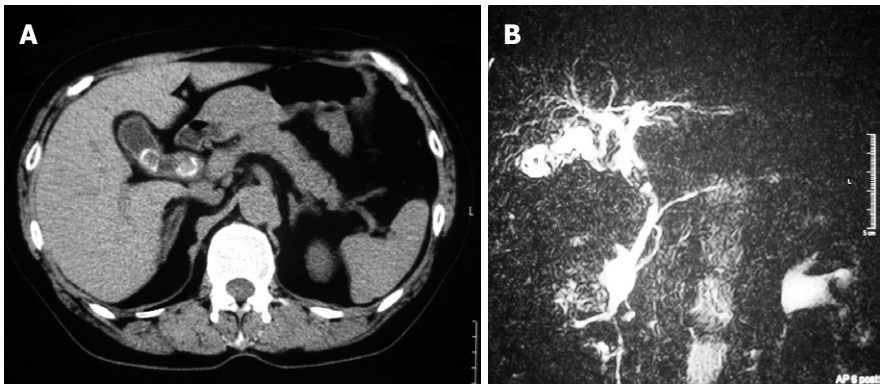

Figure 1 Computed tomography (CT) and magnetic resonance cholangiopancreatography (MRCP). A: Abdominal CT scan showing 2 stones in the gallbladder and a stone in the common bile duct; B: MRCP revealed a mass (20 mm × 15 mm in diameter) in the dilated common bile duct (20 mm in diameter).

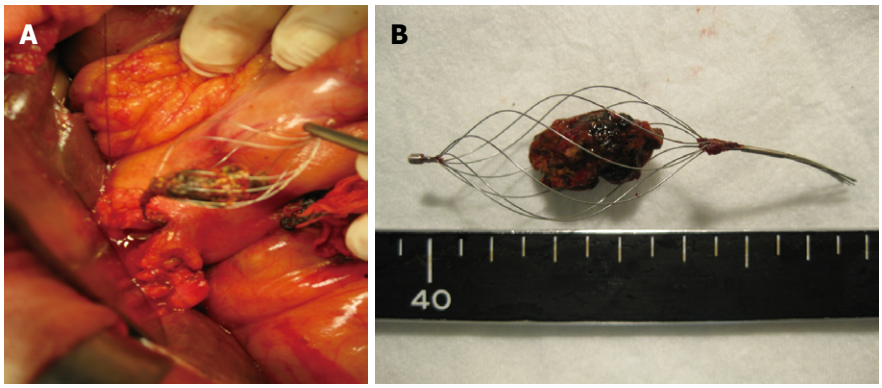

Figure 2 Intraoperative findings. A: During surgery, the impacted basket with stone were removed through a longitudinal choledochotomy; B: The size of the stone in the basket was 20 mm in diameter.

revealed elevated serum levels of the following biological parameters (the normal range for each parameter is in parentheses): alkaline phosphatase, 486 IU (109-335 IU); γ-glutamyl transpeptidase, 373 IU (12-48 IU); L-aspartate aminotransferase, 913 IU (12-32 IU); L-alanine aminotransferase, 449 IU (10-40 IU); total bilirubin, 2.3 mg/dL (0.2-1.4 mg/dL); and direct bilirubin, 1.3 mg/dL (0.0-0.3 mg/dL). The results of a complete blood count test and coagulation test were normal. The serum levels of tumor markers (carbohydrate antigen 19-9 and carcinoembryonic antigen) were within the normal ranges. Ultrasound examination and computed tomography revealed 2 stones in the gallbladder along with thickening of the gallbladder and a calcified stone in the CBD (Figure 1A). In addition, magnetic resonance cholangiopancreatography revealed a mass (20 mm × 15 mm in diameter) in the dilated CBD, which had a diameter of 20 mm (Figure 1B). We diagnosed the patient with choledocholithiasis-induced cholangitis and choledocholithiasis-induced cholecystitis. We planned endoscopic lithotripsy for the removal of the CBD stone as the initial treatment, followed by laparoscopic cholecystectomy.

ERC revealed the CBD stone as a large defect filling the upper part of the CBD. We performed endoscopic stone extraction, because the biliary tract was dilated after the endoscopic lithotripsy. The metal spiral sheath advanced to the basket containing the entrapped stone. However, unfortunately, the retrievable basket around the stone became impacted in the middle of the CBD. It was impossible to crush the stone because it had hardened owing to calcification; in addition, it was impossible to shut the opening wire and to replace the basket catheter with an endotriptor.

Subsequently, because the basket was trapped, we performed urgent surgery involving cholecystectomy and choledochotomy, because, in our department, we did not have an extracorporeal shock-wave lithotripsy.

During the operation, cholecystectomy was performed, and the CBD was explored. The basket containing the stones was removed through a longitudinal choledochotomy (Figure 2). The wires leading to the basket were cut, and the basket containing the stone was removed *via* the incision. Intraoperative choledochoscopy revealed no residual stones or fragments. A T-tube was inserted, and the choledochotomy was closed. The postoperative course was uneventful and the patient is clinically healthy.

DISCUSSION

The treatment of CBD stones has advanced from choledochotomy to endoscopic management, with a success rate of over 90% for the latter[4,5]. The techniques used for the management of CBD stones are endoscopic sphincterotomy and endoscopic papillary balloon dilatation. However, the complications of endoscopic management are hemorrhage, pancreatitis, sepsis, cholangitis, and occasionally, impaction of the lithotriptor basket during the endoscopic removal of a CBD stone. The reported incidence of impaction of a basket with an entrapped stone was 5.9%[4,6,7]; however, because of the developments in the therapeutic techniques for CBD stones, this incidence has decreased to 0.8%[8].

The main factor responsible for impaction of the

basket was reported to be the large size of the stone[4,6,7]. In the treatment of CBD stones with a diameter over 10-12 mm, a crush technique using endoscopic mechanical lithotripsy (EML) is employed, and the crushed stone is removed[9].

EML has been successfully used in 80%-90% of cases to crush CBD stones that were too large to be removed using conventional methods[10,11]. However, the management of very large stones with diameters of more than 25 mm, and of multiple stones in the ductus choledochus has failed[5]. In 4 studies that reported impaction of the basket, the average size of the stone was 17 mm (range, 13-20 mm)[4,7,12,13]. The success rate of EML for the treatment of large stones with diameters over 20 mm, was reported to be approximately 50%. However, the success rate is low if there are multiple stones and/or calcified stones. In our patient, the diameter of the stone was 20 mm: in addition, the stone was calcified and entrapped, and therefore could not be crushed and released in the lower part of the CBD. Impaction of the basket or CBD stone causes obstructive jaundice; furthermore, the likelihood of acute obstructive suppurative cholangitis, acute pancreatitis, and sepsis is great[14]. In the worst cases, failure of stone removal may result in the death of the patient. Garg *et al*[15] reported that stone size alone may not be an important factor that decides the success of EML; CBD dilatation with adequate working space between the stone and the wall of the CBD is also an important factor. In our patient, the size of the CBD stone was 20 mm and the CBD was dilated 20 mm, thus, there was no adequate space between the stone and the CBD wall to open the wire basket fully, and this may be one of the causes of failure of EML. In addition, cholecystitis with gallbladder stones may induce inflammatory changes in the CBD, leading to stiffness of the CBD, and, as a result, no adequate working space between the stone and the wall of the CBD.

In conclusion, we determined that if the size of CBD stone is over 20 mm in diameter and is calcified, the risk of an impacted basket is increased. In addition, if the CBD is not adequately dilated, there is insufficient space between the stone and the CBD wall to open the wire basket fully. In these cases, surgery may be selected as an initial treatment of CBD stones to prevent impaction of a basket.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in tahe field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Beijing Baishideng BioMed Scientific Co., Ltd.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

Plexiform angiomyxoid myofibroblastic tumor of the stomach is a unique mesenchymal tumor that we first described in 2007. The tumor is very rare, and to date, only 18 cases confirmed by immunohistochemistry have been reported in the literature. The patients' ages ranged from 7 to 75 years (mean, 43 years), and the male-to-female ratio was approximately 1:1. Representative clinical symptoms are ulceration, associated upper gastrointestinal bleeding (hematemesis), and anemia. The tumors are located at the antrum in all cases, and grossly, the tumor is whitish to brownish or reddish, and forms a lobulated submucosal or transmural mass. Microscopically, the tumor is characterized by a plexiform growth pattern, the proliferation of cytologically bland spindle cells, and a myxoid stroma that is rich in small vessels and positive for Alcian blue stain. Immunohistochemically, the tumor cells are positive for α-smooth muscle actin and negative for KIT and CD34. Differential diagnoses include gastrointestinal stromal tumor and other mesenchymal tumors of the gastrointestinal tract. Some authors proposed that this tumor should be designated as "plexiform fibromyxoma", but this designation might cause confusion. The tumor is probably benign and thus far, neither recurrence nor metastasis has been reported.

Takahashi Y, Suzuki M, Fukusato T. Plexiform angiomyxoid myofibroblastic tumor of the stomach. *World J Gastroenterol* 2010; 16(23): 2835-2840 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i23/2835.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i23.2835

INTRODUCTION

The majority of gastrointestinal mesenchymal tumors are gastrointestinal stromal tumors (GISTs) that are characterized by a high frequency of positive immunohistochemical reactivity for KIT and mutations of the *KIT* gene[1-6]. Mutations of the platelet-derived growth factor receptor α (*PDGFRA*) gene have been reported in GISTs that are negative for mutations in *KIT*[7,8]. The effect of molecular target therapy by imatinib mesylate was reported for GIST[9,10], and in recent times, the accurate pathological diagnosis of GIST has been gaining more importance.

Mesenchymal tumors other than GIST occur in the stomach although their frequency is very low. In 2007, we reported 2 cases of a unique gastric mesenchymal tumor that had not been previously described and designated it as "plexiform angiomyxoid myofibroblastic tumor (PAMT)" of the stomach. The tumor was characterized by a plexiform growth pattern, the proliferation

of bland spindle cells that were separated by an abundant intercellular myxoid matrix, and a myxoid stroma that was rich in small vessels and histochemically positive for Alcian blue stain[11]. Since then, several similar cases have been reported[12-14]. Some authors reported cases with more obvious smooth muscle differentiation of the tumor cells, and used the term "plexiform angiomyxoid tumor" removing the "myofibroblastic" designation[14]. Furthermore, Miettinen *et al*[15] recently reported 12 cases of the same tumor under the diagnostic name of "plexiform fibromyxoma".

In this article, we review the clinicopathological features of PAMT cases, including an unpublished case that we recently examined, and discuss differential diagnoses, the nature of the tumor cells, and the appropriate nomenclature.

CLINICAL FEATURES

Epidemiology

PAMT of the stomach is a very rare tumor. To date, only 18 cases of PAMT of the stomach confirmed by immunohistochemistry have been reported in the medical literature[11-15]. Miettinen *et al*[15] estimated that the frequency of PAMT is less than 1/150 compared with that of gastric GIST. Table 1 shows the clinicopathological features of the reported cases and our new unpublished case of PAMT. The patients' ages ranged from 7 to 75 years (mean, 43 years). Ten cases were male and 9 cases were female; thus, the male-to-female ratio is approximately 1:1.

Symptoms and signs

The representative clinical symptoms are ulceration, associated upper gastrointestinal bleeding (hematemesis), and anemia. Other clinical symptoms include nausea, emesis, weight loss, gastric mass, and pyloric obstruction. One case was found by acute abdominal pain due to perforation[11], and one case was incidentally found during a cholecystectomy[11].

Endoscopic and radiographic findings

The tumor is detected as a submucosal tumor-like elevated lesion by endoscopy and is often ulcerated. The tumor was also detected as a multinodular hypoechogenic lesion[13] or as an infiltrating mass[14] using ultrasonography. In one case with a very large tumor, it was detected as a solid and cystic tumor using abdominal computed tomography (unpublished case).

PATHOLOGICAL FEATURES

Gross appearance

The size of PAMT of the stomach ranges from 1.9 cm to 15 cm, with a mean value of 6.3 cm. Interestingly, the tumor was located in the antrum in all 19 cases. The tumor often involves the pylorus, and extends to the duodenal bulb in approximately one-third of cases. The tumor is whitish to brownish or reddish, and forms a lobulated submucosal or transmural mass. It is not encapsulated and protrudes from the serosa (Figure 1A) in many cases, which often has a granular or nodular appearance. The surface of the tumor is ulcerated in approximately two-thirds of cases, and is perforated in one case (Figure 1B)[11]. Cystic degeneration was observed in the case with a very large tumor mass (unpublished case).

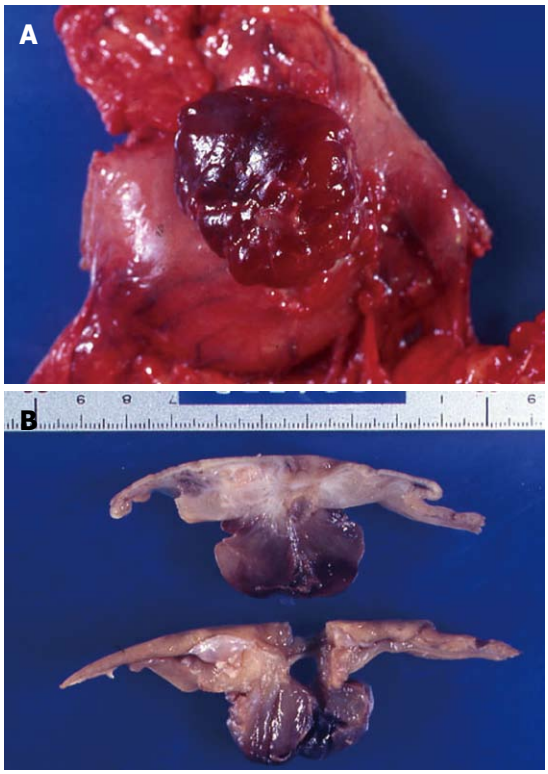

Figure 1 Gross appearance of a case of plexiform angiomyxoid myofibroblastic tumor (PAMT). A: A reddish and lobulated tumor protrudes from the serosa; B: The cut section of the tumor. The tumor causes ulceration and perforation.

Microscopic findings

PAMT shows a characteristic multinodular plexiform growth pattern in the gastric wall (Figure 2A). However, the extragastric tumor component does not show a plexiform pattern. The mucosa is often ulcerated. Spindle-shaped bland tumor cells are separated by an abundant intercellular myxoid or fibromyxoid matrix (Figure 2B). Fascicular or palisading arrangements of tumor cells are not usually observed. The tumor cells possess oval nuclei and a slightly eosinophilic cytoplasm. The nucleoli are inconspicuous and the cell borders are indistinct (Figure 2C). In the cases reported by Yoshida *et al*[14], a small number of tumor cells had morphological features reminiscent of smooth muscle cells (blunt nuclear ends and thin long eosinophilic cytoplasmic extensions). Mitoses are usually not detected (at most 4/50 high-power fields). The stroma is positive for Alcian blue stain (Figure 2D), and rich in small and thin-walled blood vessels. Dilated and arborizing blood vessels were also observed, and thrombi were formed in one case (unpublished case). Stromal collagenization was inconspicuous in some cases, but conspicuous in others (Figure 2E). The tumor cells

Table 1 Clinicopathological data of plexiform angiomyxoid myofibroblastic tumor of the stomach

Case	Age (yr)	Sex	Clinical presentation	Location	Tumor size (cm)	Mitoses	Ki-67 index	Operation	Prognosis	Ref.
1	50	M	Acute abdominal pain (due to perforation)	Antrum	4.0 × 4.0 × 2.5	None	< 1%	Distal gastrectomy	No data	[11]
2	68	M	None (incidental finding at cholecystectomy)	Antrum	4.5 × 3.5 × 3.0	None	< 1%	Partial gastrectomy	Alive without tumor (12 mo)	[11]

HPF: High power fields.

are sometimes surrounded by a pseudovacuolar lacunar space limited by a fibrous matrix network. Mast cells are scattered in the stroma, but infiltration of lymphocytes, plasma cells, or eosinophils is inconspicuous. Tumor necrosis is not usually observed, but hemorrhage, necrosis, and cystic degeneration were observed in one case (unpublished case).

Immunohistochemical staining

In all cases examined, the tumor cells were positive for vimentin and muscle actin, and negative for KIT (Figure 3A), CD34, S-100 protein, neurofilament, cytokeratin, epithelial membrane antigen, and ALK. Tumor cells were positive for α-smooth muscle actin (SMA) in 15 of the 17 cases examined (Figure 3B), but a significant SMA-negative component was found in 3 cases. Focal or partial immunoreactivity for desmin and caldesmon was occasionally observed. Tumor cells were focally positive for CD10 in 1 of the 4 cases examined. The Ki-67 labeling index is usually less than 1% (at most 2%).

Mutation analysis of the KIT and PDGFRA genes

Sequence analysis was performed for mutational hot spots in the *KIT* and *PDGFRA* genes in GISTs (i.e. exons 9, 11, 13, and 17 of *KIT* and exons 12 and 18 of *PDGFRA*) in 8 cases, and no mutations were found in any case[11,12,14,15].

Differential diagnosis

The primary histological differential diagnoses include GIST, leiomyoma, leiomyosarcoma, schwannoma, desmoid fibromatosis, solitary fibrous tumor (SFT), inflammatory fibroid polyp, and inflammatory myofibroblastic tumor.

GISTs consist of spindle and/or epithelioid cells. In tumor areas composed of spindle cells, these cells are arranged in short fascicles in several architectural patterns including storiform, herringbone palisades, and broad sheets. Conversely, epithelioid cells are arranged in organoid clusters or sheets. Approximately 90% of GISTs are immunohistochemically positive for KIT, and muta-

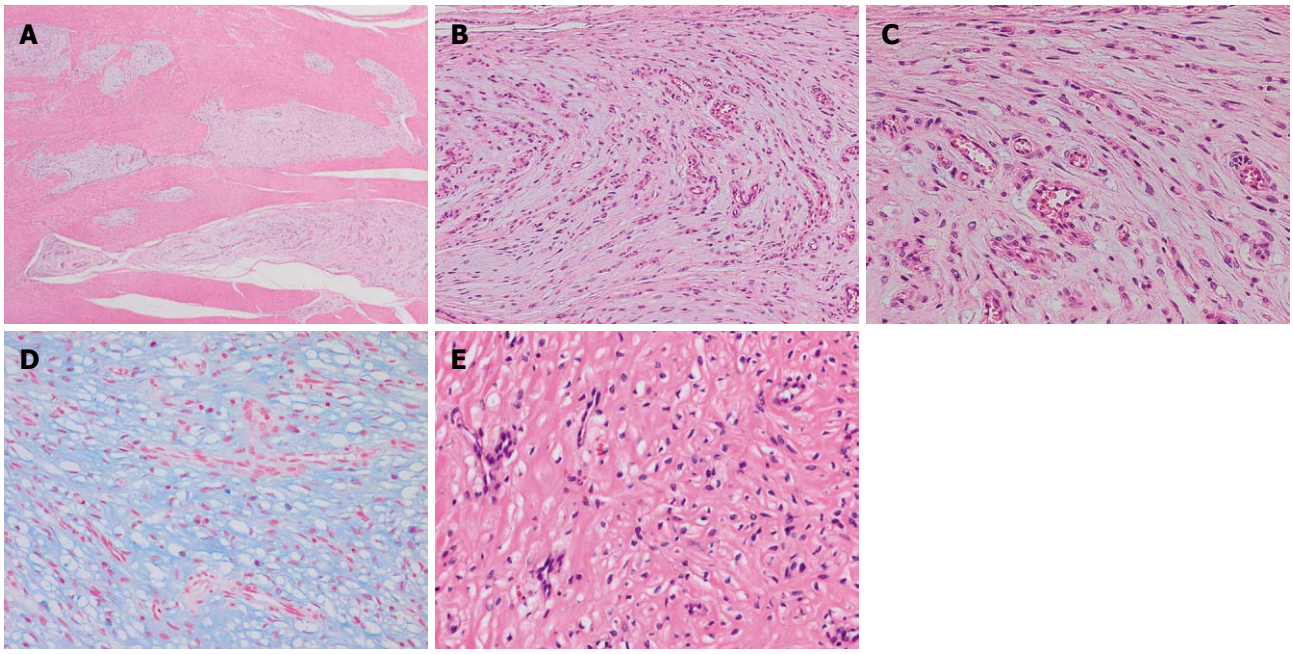

Figure 2 Histological appearance of PAMT. A: The tumor shows a multinodular plexiform growth pattern (HE stain, × 20); B: Spindle-shaped bland tumor cells are separated by an abundant intercellular myxoid matrix. The stroma is rich in small vessels (HE stain, × 100); C: Tumor cells possess oval nuclei and a slightly eosinophilic cytoplasm. The nucleoli are inconspicuous and the cell borders are indistinct (HE stain, × 200); D: The stroma is positive for Alcian blue stain (× 200); E: Stromal collagenization is occasionally observed (HE stain, × 200).

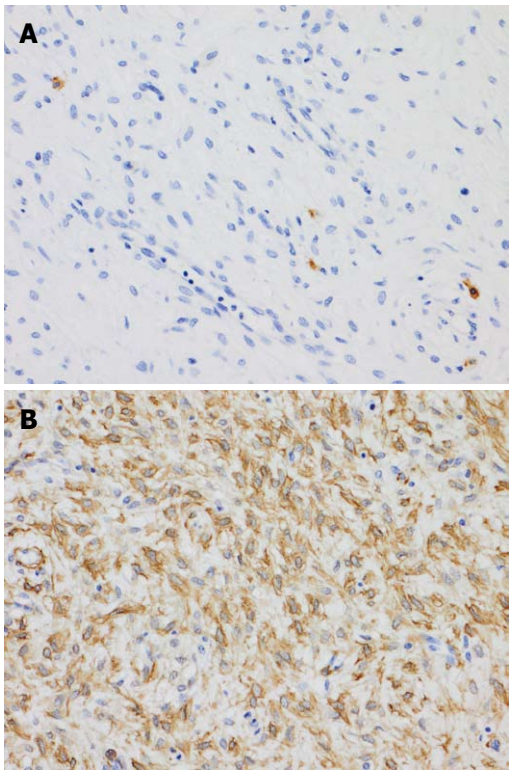

Figure 3 The results of immunohistochemical staining. A: The tumor cells are negative for KIT. The scattered KIT-positive cells are mast cells (× 200); B: The tumor cells are diffusely positive for smooth muscle actin (× 200).

tions of the *KIT* gene have been found in most of these KIT-positive GISTs[1-6]. *PDGFRA* gene mutations have been reported in some GISTs in the absence of *KIT* gene mutations[7,8]. In addition, immunohistochemical staining for CD34 is often positive in GISTs[16]. Accordingly, the histological appearance, negative immunoreactivity for KIT and CD34, and wild-type sequences of the *KIT* and *PDGFRA* genes differentiate PAMT from GIST.

Leiomyoma is characterized by the fascicular arrangement of tumor cells that possess spindle-shaped nuclei and markedly eosinophilic cytoplasm. Leiomyosarcoma shows high cellularity, cellular atypia, and remarkable mitoses. Gastric schwannoma is histologically characterized by wavy and palisading arrangements of spindle cells, lymphoid cuffing, and S-100 protein immunostaining. Desmoid fibromatosis shows long fascicular arrangements of spindle cells and dense collagen deposits. The alteration of hypercellular and hypocellular areas, deposition of dense keloid-type collagen, occurrence of hemangiopericytoma-like areas, and positive immunohistochemical staining for CD34 are the most distinguishing features of SFT. An inflammatory fibroid polyp is usually a small submucosal lesion characterized by bland spindle-cell proliferation in an onion skin-like pattern around vessels with eosinophilic infiltrates. Prominent lymphocyte and plasma cell infiltration, and positive immunoreactivity for ALK are the distinguishing features of inflammatory myofibroblastic tumors.

CELL NATURE AND NOMENCLATURE

In general, myofibroblasts are immunohistochemically positive for SMA, and negative for desmin and caldesmon[17]. Conversely, fibroblasts are negative and smooth muscle cells are positive for these three markers. Accordingly, the abovementioned immunohistochemical

characteristics of PAMT suggest that myofibroblastic tumor cells are predominant in most cases. The myofibroblastic nature of the tumor cells was also confirmed by ultrastructural analysis of PAMT[11]. However, the facts that focal immunoreactivity for desmin and caldesmon is occasionally observed in PAMT and the presence of a small number of tumor cells showing morphological features reminiscent of smooth muscle cells observed in some PAMT cases[14] suggest that PAMT may contain tumor cells with smooth muscle differentiation. Furthermore, Miettinen *et al*[15] confirmed the presence of tumor cells with fibroblastic traits. Accordingly, it is conceivable that PAMT is mainly composed of tumor cells with a myofibroblastic nature, but may also contain tumor cells with fibroblastic or smooth muscle characteristics.

We designated this tumor as "plexiform angiomyxoid myofibroblastic tumor" based on the plexiform growth pattern, a myxoid stroma that is rich in small vessels, and the myofibroblastic nature of the tumor cells[11]. Yoshida *et al*[14] reported cases with focal smooth muscle differentiation and used the term "plexiform angiomyxoid tumor", because the "myofibroblastic" designation might not be totally accurate. As mentioned above, we agree that this tumor is not a pure myofibroblastic tumor and may contain tumor cells with a fibroblastic or smooth muscle nature. However, we think that the "myofibroblastic" designation is not necessarily inappropriate, because myofibroblastic tumor cells are predominant in the majority of the reported cases. For example, inflammatory myofibroblastic tumors may also contain fibroblastic components as determined using ultrastructural analysis[18,19], and focally express desmin and calponin in 60%-70% of cases[18,20]. Miettinen *et al*[15] proposed that this tumor should be designated as "plexiform fibromyxoma" based on the plexiform architecture and combination of myxoid and fibromyxoid elements. However, most of the cases reported under the designation of "gastric fibromyxoma" or "gastric myxofibroma" were reported before the development of immunohistochemical techniques, and most of these cases are probably examples of other types of mesenchymal neoplasms with secondary regressive changes[21]. Currently, the term "gastric fibromyxoma" or "gastric myxofibroma" is used only in the case of pure fibroblastic tumors[22,23], and some different features from PAMT, such as positive immunoreactivity for CD34, are observed[22]. Superficial acral fibromyxomas possess different immunohistochemical features from those of PAMT, such as positive staining for CD34 and negative staining for SMA[24]. Thus, in using the designation "plexiform fibromyxoma", it is necessary to be careful to avoid confusion.

BIOLOGICAL BEHAVIOR AND PROGNOSIS

Follow-up data were obtained for 15 cases. The follow-up period ranged from 2 mo to 25.5 years (median, 3 years), and 12 patients were alive while 3 had expired. These 3 patients died 2 mo, 14.5 years, and 25.5 years after surgery, and the cause of death was unknown. Nine patients were alive without disease after 3 mo to 19.9 years (median, 12 mo), and 3 were alive for 3, 22, and 24 years with an unknown tumor status. Thus, neither recurrence nor metastasis was confirmed in any case.

CONCLUSION

PAMT of the stomach is a very rare mesenchymal tumor with a unique histological appearance, and it needs to be distinguished from GIST and other gastrointestinal mesenchymal tumors. It is very interesting that all of the reported PAMT cases were located at the gastric antrum, implying that this tumor might originate from a cell that is specifically distributed at this location. The absence of atypia of the tumor cells and a very low Ki-67 labeling index suggest the benign nature of this tumor, and neither recurrence nor metastasis was observed in any case. The clinicopathological features of the tumor should be elucidated by examination of a larger number of cases, and analysis of pathogenesis should be performed in the future.

Abstract

Endoscopic ultrasound (EUS) has become a well accepted test for the diagnosis of chronic pancreatitis. Advantages include its ability to detect subtle and severe changes of the pancreatic duct and parenchyma, and its relative safety compared with endoscopic retrograde cholangiopancreatography. Limitations include inter- and intra-observer variability, operator dependence, and an incomplete understanding of its true accuracy. The Rosemont classification has recently been proposed as a weighted, standardized method that may improve EUS chronic pancreatitis scoring. This paper reviews the published evidence regarding the accuracy of EUS in chronic pancreatitis diagnosis, and enumerates the emerging technologies that have been recently studied which may ultimately improve endosonographic imaging of the pancreas.

INTRODUCTION

Endoscopic ultrasound (EUS) has been used for the diagnosis of chronic pancreatitis (CP) for over two decades. Its primary attribute is its ability to detect mild parenchymal and ductal abnormalities not seen with computed tomography (CT) scans. EUS is of most use in patients with abdominal pain of suspected pancreatic origin and non-diagnostic cross-sectional imaging. In a report entitled "Minimal change chronic pancreatitis", Walsh described 16 patients with typical pancreatic pain and negative or equivocal CT and endoscopic retrograde cholangiopancreatography (ERCP) images[1]. All patients underwent pancreatic resection due to a strong suspicion of CP. Fifteen of the 16 patients had definite histological features of CP, including periductal fibrosis, duct dilation, intralobular inflammation, and atrophy. The histological features were often subtle and mild, out of proportion to the severity of pain. Had EUS been widely available, it might have been used to verify the presence of parenchymal and ductal abnormalities of CP prior to resection. This review focuses on the role of EUS in the diagnosis of CP, including its accuracy, strengths, and limitations. An update on emerging techniques to augment endosonographic diagnosis is also presented.

THE NORMAL PANCREAS

The normal endosonographic appearance of the pan-

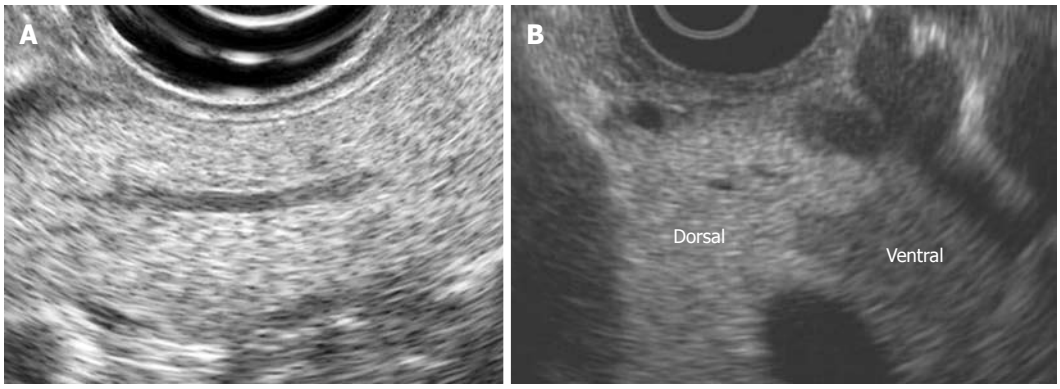

Figure 1 The normal endosonographic appearance of the pancreas. A: View of pancreatic body from gastric station. The parenchyma is homogeneous and granular ("salt and pepper"). The duct is neither dilated nor ectatic; B: Dorsal ventral anlage. The ventral pancreas is relatively echogenic compared with the dorsal pancreas. There is a distinct border between the dorsal and ventral pancreas.

creas has been characterized in three studies of healthy volunteers[2] and patients undergoing EUS for non-pancreatic indications[3,4]. The normal pancreatic parenchyma is homogenous and granular ("salt and pepper echotexture"), and echogenic relative to the liver parenchyma (Figure 1A). The border of the gland is smooth. The main pancreatic duct is also smooth in contour and tapers from the head to the tail. In one study, the upper limit of normal for duct diameter was 3.6 mm in the head, 3.0 mm in the body, and 2.0 mm in the tail[2]. The main pancreatic duct wall is not easily visible, and side-branches are difficult to visualize or narrow in caliber (< 1.0 mm). A ventral anlage is found in one-half of patients (Figure 1B). This is a relative echogenicity of the dorsal compared with the ventral pancreas.

CP CRITERIA

The endosonographic features that have been used for CP diagnosis have evolved since the inception of EUS. In the seminal studies of Dancygier *et al*[5] and Lees[6], a number of parenchymal and ductal features were characterized (Table 1). At that time, EUS diagnosis was qualitative and focused on the global separation of benign from malignant pancreatic diseases[7]. Subsequent studies codified these features into numbered scoring systems[2,5,8]. The most common scoring system includes 5 ductal and 4 parenchymal features (Figures 2 and 3)[8]. The criteria are counted and compared against a cutpoint. Typical cut-points range from 3 (maximizing sensitivity) to 5 (maximizing specificity).

A frequent criticism of standard scoring is that each criterion is counted equally, even though some criteria have more diagnostic importance than others. In April 2007, thirty-two international experts met in Rosemont Illinois, USA to create a consensus-based scoring system[9]. The Rosemont classification includes strictly defined major and minor criteria, and a four-level diagnostic stratification (Table 1). Although this new scoring system may help standardize the EUS diagnosis of CP, it requires further validation in multicenter studies.

TECHNICAL ASPECTS

A complete EUS examination to evaluate CP includes a careful inventory of all major and minor criteria. The body and tail is viewed from the gastric station, where the interpretation of CP criteria is consider most reliable. It is good practice to photograph, digitally annotate, count, and measure all identified features based on the Rosemont definitions. The main pancreatic duct should be carefully traced to ascertain the presence of $\geqslant$ 3 visible side-branches and echogenic wall. The duct diameter should be measured at the genu (in view of the portosplenic confluence) and in the pancreatic tail (in view of the splenic hilum). A 10-s video clip of the body and tail provides a useful frame of reference for future examinations. The scope should be advanced to the duodenum for a careful inspection of the head and uncinate process. Examination of the head detects cysts and main duct calculi (the only criteria properly detected in the head) and rules out biliary pathology, solid masses, and pancreas divisum.

Most validation studies have used mechanical radial scopes for CP diagnosis. However, most current endosonographers prefer linear scopes to examine the pancreas due to higher resolution, color flow Doppler capability, and capability for tissue sampling and celiac plexus blockade. In a blinded study, we found radial EUS to be non-inferior to linear EUS for CP diagnosis[10]. Newer electronic radial scopes have similar resolution and the same Doppler capability as older generation linear scopes.

TEST PERFORMANCE

The ideal study of EUS accuracy might include 1000 consecutive patients with non-diagnostic CT scans from multiple centers undergoing total pancreatectomy for suspected CP. Each patient would undergo a preoperative EUS examination and blinded histological analysis of the resection specimen. Of course, this study is unlikely to ever be performed. Even if it were carried out, some would quibble with the significance of mild or patchy fibrosis on the histological specimen!

Table 1 Evolution of endoscopic ultrasound criteria for chronic pancreatitis

	Lees[6] (1986)	Wiersema *et al*[2] (1993)	Sahai *et al*[8] (1998)	Catalano *et al*[9] (2009)[1]	Histological correlation
Number of criteria	Qualitative	11	9	3 major; 6 minor	
Parenchymal	X	Reduced echogenic foci Heterogeneity	X	X	
	Strongly echogenic foci	Echogenic foci (> 3 mm)	Hyperechoic foci	Hyperechoic foci without shadowing (minor). Echogenic structures ⩾ 2 mm in length and width with no shadowing	Focal fibrosis
				Hyperechoic foci with shadowing (major A). Echogenic structures ⩾ 2 mm in length and width that shadow	Calcifications in side-branches
	Echogenic bands	X	Hyperechoic strands	Stranding (minor). Hyperechoic lines of ⩾ 3 mm in length in at least 2 different directions with respect to the imaged plane	Fibrotic bands
	Cavities	Cysts (> 3 mm)	Cysts	Cysts (minor). Anechoic, rounded/elliptical structures with or without septations	Pseudocysts
	Accentuation of lobular architecture	Accentuation of lobular pattern	Parenchymal lobularity	Lobularity with honeycombing (major B). Well-circumscribed, ⩾ 5 mm structures with enhancing rim and relatively echo-poor center, with ⩾ 3 contiguous lobules	Edema separated by fibrotic bands
				Lobularity without honeycombing (minor). Well-circumscribed, ⩾ 5 mm structures with enhancing rim and relatively echo-poor center, with noncontiguous lobules	
	Enlargement	X	X	X	
Duct	X	Narrowing	X	X	
	Increase in caliber	Dilation	MPD dilation	MPD dilation (minor). ⩾ 3.5 mm in body or > 1.5 mm in tail	Obstructed duct
	Irregularity of the lumen	Irregular contour	Irregular MPD margins	Irregular MPD contour (minor). Uneven or irregular outline and ectatic course	Ductal fibrosis and strictures
	Increase echogenicity of duct wall	Duct wall echogenicity	Hyperechoic MPD margins	Hyperechoic MPD margin (minor). Echogenic, distinct structure greater than 50% of entire MPD in the body and tail	Periductal fibrosis
	Intraluminal echoes	Calculi	Shadowing calcifications	MPD calculi (major A). Echogenic structures within MPD with acoustic shadowing	Calcifications in the main duct
	Visualization of side branches	Side-branch dilation	Visible side-branches	Dilated side branches (minor). 3 or more tubular anechoic structures each measuring ⩾ 1 mm in width, budding from the MPD	Side-branch ectasia
	Strictures with dilation	X	X	X	
	Main or branch duct disruptions with cyst	X	X	X	

[1]Rosemont diagnostic stratification: Normal: < 3 minor features (excluding non-shadowing echogenic foci, visible side-branches, cysts, and MPD dilation) and no major features. Indeterminate: 3 or 4 minor features and no major features, or major B feature alone with < 3 minor features. Suggestive: 1 major A feature and < 3 minor features, or 1 major B feature and ⩾ 3 minor features, or ⩾ 5 minor features. Most consistent: 1 major A feature and ⩾ 3 minor features, or 1 major A feature and major B feature, or 2 major A features. MPD: Main pancreatic duct.

To estimate the test performance of EUS, we must interpret cross-sectional studies with flawed reference standards (e.g. ERCP or functional testing), small histological comparisons with significant selection, spectrum, or sampling biases, and post-EUS observational studies with insufficient follow-up time (Table 2). Sadly, the actual sensitivity and specificity of EUS for diagnosing CP may never be known.

ERCP

The earlier studies compared EUS with ERCP, since ERCP was the *defacto* radiographic reference standard and considered ethical at the time for diagnostic purposes[2-4,8,11]. These studies included performance of both EUS and ERCP in succession, and sometimes blinded independent interpretation of the EUS and ERCP images. Combining 273 patients from the three ERCP studies that used a cutpoint of ⩾ 3 EUS criteria, the sensitivity is 87% and the specificity is 75%[2,3,8]. Limitations of the ERCP reference standard include limited specificity (e.g. in advancing age or following acute pancreatitis), frequent inadequacy of the pancreatogram to interpret small duct changes, and inability to assess the parenchyma[12].

Pancreatic function testing

We might expect high accuracy for EUS in these ERCP comparison studies since one structural test is being compared to another. The comparison of EUS with a pancreatic function test (PFT) reference standard is based on the rationale that impaired exocrine function is a sensitive surrogate for early fibrosis. An unadjusted pooling of the 255 patients in the secretin PFT studies reveals a sensitivity of 72% and specificity of 74%[2,3,13-16], noticeably lower than ERCP studies. A shortcoming of these studies is substantial methodological variation in secretin- and CCK-based PFT protocols. Also, acinar-cell and duct-cell exocrine insufficiency do not perfectly correlate with histological fibrosis. A subset of patients even with advanced structural changes has preserved exocrine function[17].

Histology

Histological comparison may be the "Holy Grail" for

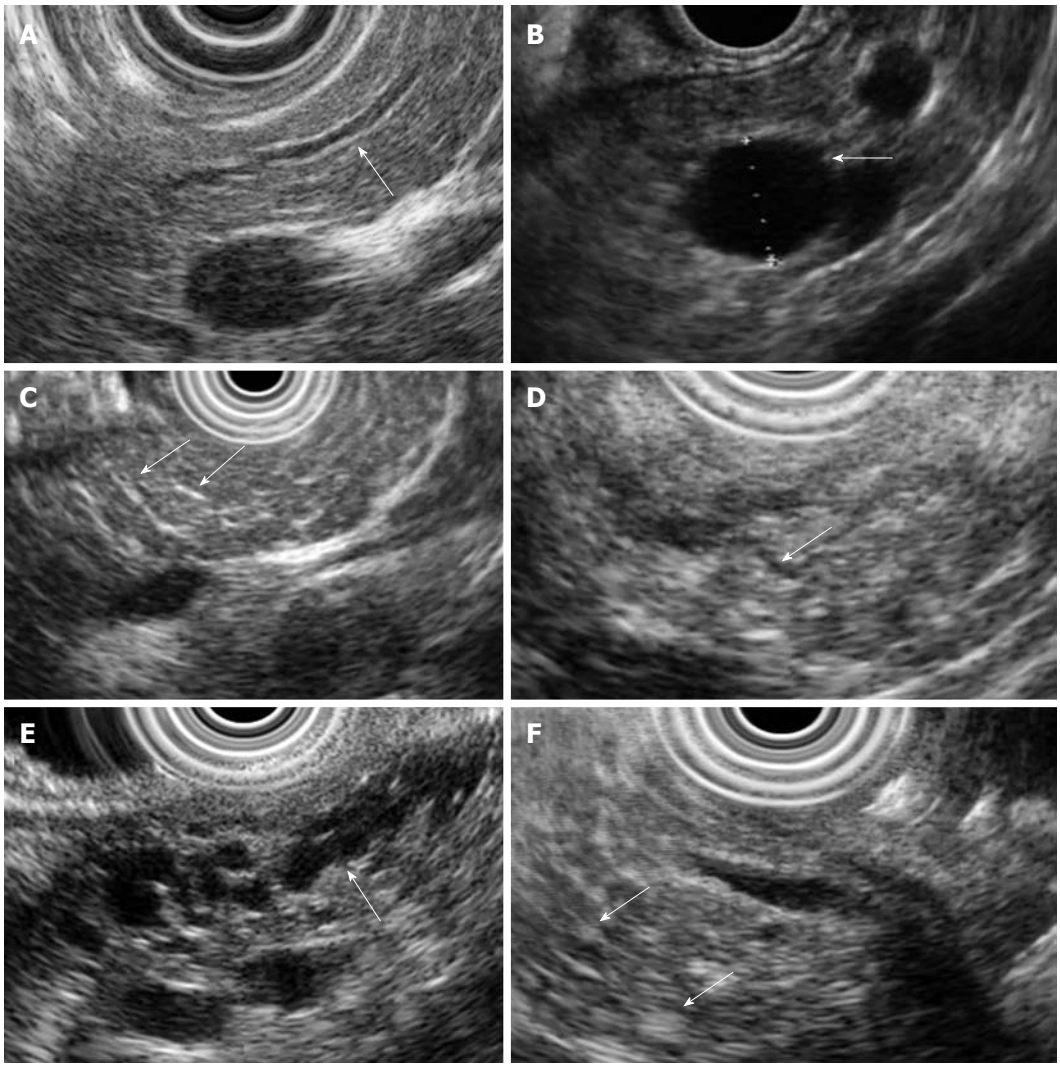

Figure 2 Examples of endoscopic ultrasound (EUS) chronic pancreatitis (CP) criteria. A: Hyperechoic duct wall (arrow); B: Cyst (arrow); C: Hyperechoic strands (arrows); D: Visible side-branch (arrow); E: Dilated and irregular main pancreatic duct with visible side-branches (arrow); F: Hyperechoic foci (arrows).

studying diagnostic tests for CP. There have been four studies comparing EUS with histology, two of which are published in abstract form only[18-21]. Varadarajulu evaluated 42 patients who underwent preoperative EUS within 2 mo of a partial or complete pancreatic resection[18]. Based on an ROC curve analysis, ⩾ 4 criteria optimized sensitivity (91%) and specificity (86%) of EUS. There was a very good correlation of the histological fibrosis score with the EUS score ($r = 0.85$, $P < 0.0001$). A strength of this study was the predominance of mild fibrosis which minimizes spectrum bias. Also, half the patients did not have histological fibrosis allowing a reasonable estimation of specificity. A limitation was that most patients underwent resection for pancreatic cancer, making it difficult to extrapolate the results to the typical patient with abdominal pain.

Chong *et al*[19] reported a larger study in 71 patients with abdominal pain and suspected CP who underwent resection or open biopsy. This study had a substantial proportion of patients with calcific CP. Sixteen of the patients had calcifications on CT; an additional 14 patients had small calcifications detected by EUS. In the 41 patients without calcifications (minimal change group), ⩾ 3 EUS criteria had 83% sensitivity (95% CI: 67%-94%) and 80% (95% CI: 28%-99%) specificity for the diagnosis of CP. The wide confidence limits surrounding the specificity estimate are due to only 5 patients without fibrosis.

These studies are quite helpful in providing histological correlations to validate individual EUS criteria and EUS scoring. One potential limitation of these studies is selection bias since only patients undergoing surgery were included. The increasing performance of total pancreatectomy with autologus islet cell transplant (TP/AIT) for earlier stages of CP may allow future multicenter histological studies in patients with milder fibrosis[20].

Long-term follow-up

Long-term follow-up may be a useful reference standard. Patients with normal and abnormal EUS can be observed to see whether obvious disease progression develops on subsequent imaging tests. This approach may shed light on the predictive value of minimal or mild EUS features. Kahl *et al*[22] followed 32 alcoholic patients with normal baseline

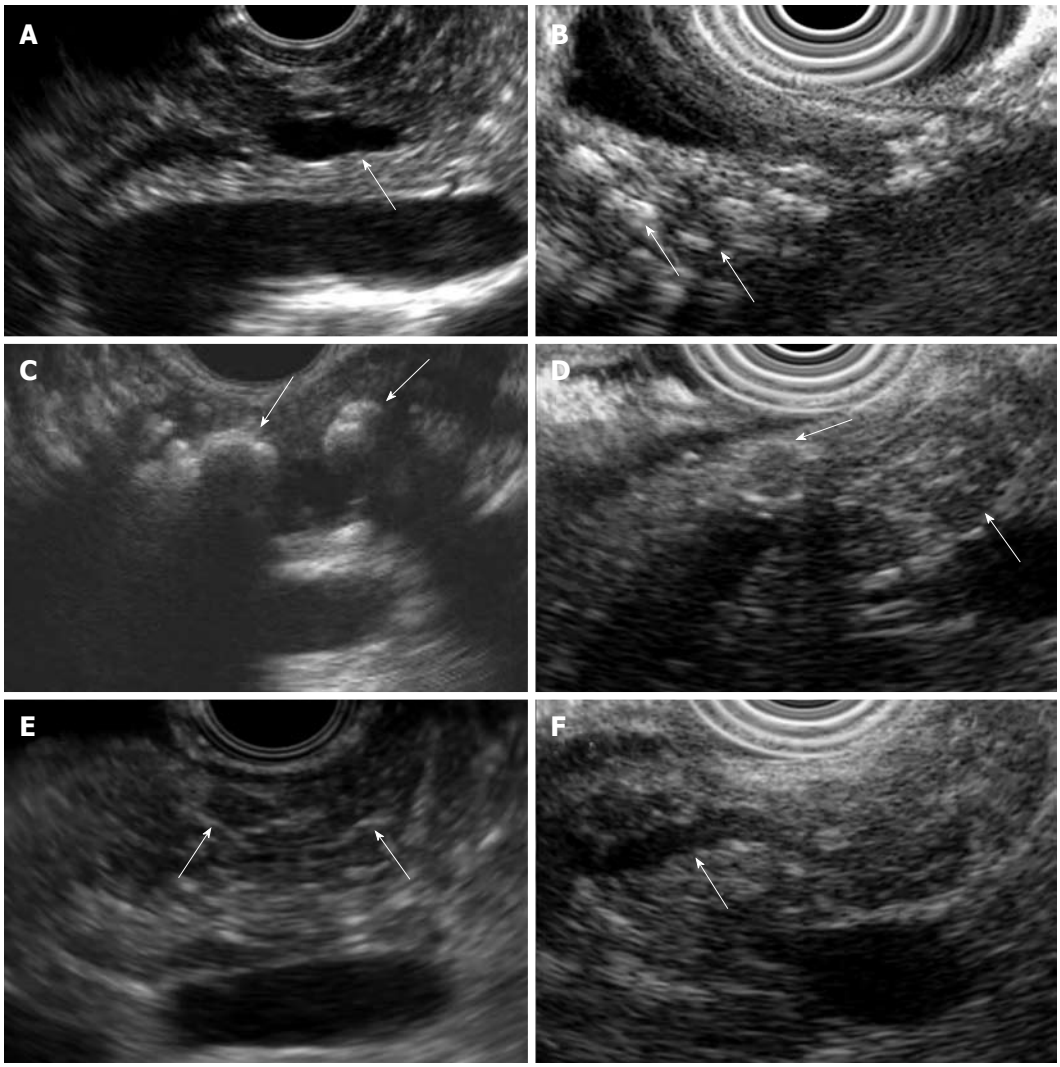

Figure 3 Examples of EUS CP criteria. A: Dilated main pancreatic duct (arrow); B: Parenchymal calcifications (arrows); C: Main duct calcifications (arrows); D: Lobules (arrows); E: Stranding (arrows); F: Irregular main pancreatic duct (arrow).

ERCP and abnormal EUS (≥ 1 criterion) for a median observation time of 18 mo (range 6 to 25 mo). During the follow-up period, ERCP was repeated in 22 patients, and demonstrated either Cambridge Class I (n = 12) or II (n = 10) ductal changes. The authors concluded that mild EUS changes had 100% sensitivity for CP, and predicted the development of CP at an earlier stage than ERCP. The conclusion of this study is based on subtle endpoints of questionable specificity (Cambridge I and II changes). It is not clear whether there were meaningful differences between the baseline and follow-up pancreatograms since interpretation was not blinded. Calcifications and atrophy may be more convincing endpoints, but would require longer follow-up. Natural history studies suggest that calcifications may develop after more than 10 years from symptom onset[23]. Also, Kahl *et al*[22] considered EUS positive if only 1 criterion was present. This cutpoint is likely to result in many false diagnoses. Finally, repeat ERCP was not performed in all patients, which produces verification bias and weakens the estimate of specificity.

Morris-Stiff *et al*[24] identified 16 patients who underwent EUS for evaluation of CP after normal conventional imaging (CT or MRCP). Thirteen of the patients had EUS changes of CP, and all 13 subsequently developed "progression of disease" on subsequent conventional imaging. Neither the follow-up time nor the specific imaging findings referenced as disease progression were reported in this publication.

Hastier *et al*[25] presented results that conflict with Kahl's and Morris-Stiff's findings. In this study, 18 alcoholic cirrhotic patients with isolated parenchymal features identified by EUS and normal ERCP were followed. After a mean duration of 22 mo, the EUS appearance was unchanged in all patients. The subsequent repeat pancreatograms were normal in all 10 patients who had a follow-up ERCP. This study raises doubts over the significance of the importance of minimal EUS features. Since follow-up time was short, firm conclusions cannot be drawn.

In summary, the test performance of EUS can only be estimated based on a variety of imperfect evidence. In interpreting these studies, it is useful to calculate the sensitivity and specificity estimates in the subset of pa-

Table 2 Test performance of endoscopic ultrasound in comparative studies

tients with non-calcific (minimal change) CP, where EUS is of most clinical value (Table 2). At the present time, we must take a "nihilistic" view of the diagnostic performance of EUS accuracy and interpret the results with care in the context of the history and ancillary laboratory, imaging, and functional test results.

RELIABILITY

The major strengths of EUS are its ability to detect mild structural abnormalities of the entire pancreas and its safety relative to ERCP. Unfortunately, there are also several caveats.

Questionable specificity

Minimal or mild parenchymal and ductal EUS features may have poor specificity, resulting in the "overdiagnosis" of CP. A number of clinical variables can lead to EUS changes that mimic those in CP. Rajan performed a prospective study of 120 patients undergoing EGD/EUS for non-pancreatic indications[26]. At least 1 EUS CP criterion was found in 38% of these non-alcoholic and asymptomatic patients. Patients in the > 60 years age group had a statistically insignificant trend toward more frequent EUS abnormalities (39%) compared with those in the < 40 years (23%) and 40-60 years (25%) age groups (P = 0.13). Male gender was a statistically significant predictor of an abnormal EUS (OR 2.9, 95% CI: 1.2-6.8).

In another study, 189 asymptomatic patients undergoing EUS for non-pancreatic indications were administered an alcohol questionnaire[27]. EUS features were more frequent in alcoholic patients (70%) compared with non-alcoholic patients (31%) (P < 0.001), suggesting the EUS changes may be present in alcohol drinkers who lack symptoms of CP. In a much larger study (n = 1157), heavy ethanol intake (OR 5.1, 95% CI: 3.1-8.5), male sex (OR 1.8, 95% CI: 1.3-2.6), clinical suspicion of pancreatic disease (OR 1.7, 95% CI: 1.2-2.3), and heavy smoking (OR 1.7, 95% CI: 1.2-2.4) were each independent predictors of severe EUS changes[28].

A fatty pancreas causes hyperechogenicity of the parenchyma that can imitate the echogenic changes of CP. In a logistic regression analysis, obesity, fatty liver disease, and alcohol intake were independent predictors of fatty infiltration of the pancreas[29]. Another study showed a high rate of EUS abnormalities in patients with dyspepsia (and low suspicion of pancreatic disease) compared with controls[30]. This may indicate that mild CP is a more common etiology of dyspepsia than previously thought. Other plausible explanations include tertiary referral bias and information bias, since the endoscopist was aware of the clinical history during the EUS examination[31]. In summary, age, gender, smoking, alcohol use, and BMI may influence EUS results. Future scoring systems may include these clinical variables in addition to EUS features.

Interobserver variability

Interobserver variability pertains to differences in interpretation of the same exam by multiple observers. In a study by Wallace, 45 videotaped examinations were privately scored by 11 expert endosonographers[32]. The κ (agreement beyond chance) for global diagnosis was only moderate (κ = 0.45). Interobserver agreement was worse (κ < 0.40) for most individual criteria, except for lobularity (κ = 0.51) and main duct dilation (κ = 0.61). Similar sub-optimal interobserver agreement was observed

in a study of CP criteria in familial pancreatic cancer kindreds ($\kappa < 0.40$ for all CP criteria except cysts)[33].

It was expected that the Rosemont classification might improve interobserver agreement because it incorporates more stringent definitions. In a recent study, 50 clips were interpreted by 14 experts on two occasions, first with standard scoring and then with Rosemont scoring[34]. The interobserver agreement was slightly higher for Rosemont scoring [$\kappa = 0.65$ (95% CI: 0.52-0.77)] compared with standard scoring [$\kappa = 0.54$ (95% CI: 0.44-0.66)]; however, the difference was not statistically significant ($P = 0.12$).

Intraobserver variability

Intraobserver variability relates to differences in scoring of the same images from multiple interpretations by the same observer. A single study has examined the intraobserver variability of EUS CP criteria[35]. Thirty still-frame images were scored by the same observers on repeat occasions over 6 wk. The intraobserver κ for overall diagnosis of CP was 0.77, and ranged from 0.61 to 0.88 for individual criteria. In other words, endosonographers have reasonable (but not perfect) agreement with themselves when interpreting the same image on multiple occasions.

Pretest probability

EUS is known as an operator dependent test. Even with Rosemont scoring, there is inherent subjectivity in measuring each criterion. Most endosonographers are aware of the patient's history as they are performing the examination, and may have already formed a "likelihood of disease" estimate in their mind. This pre-test probability may influence the interpretation of EUS results. For example, in a non-smoker with dyspepsia and no history of heavy alcohol intake or acute pancreatitis, many endosonographers would ignore mild stranding and lobularity in fear of mislabeling the patient. There are no available studies characterizing the affect of pretest probability on EUS interpretation.

ANCILLARY TECHNIQUES

Several supplementary techniques have been studied which may complement standard EUS scoring in the diagnosis of CP.

Tissue sampling

Linear EUS allows tissue acquisition through fine needle aspiration (FNA). Hollerbach *et al*[36] reported 27 patients with suspicion of CP who underwent targeted fine-needle aspiration of lobular or inflamed appearing areas of the pancreas. An average of 2.3 passes was required to obtain satisfactory tissue in all patients. The cytological findings were graded 0 to 2 based on the severity of chronic inflammation. The performance of FNA minimally increased the specificity of EUS (67% with FNA, 60% without FNA). Two patients developed mild acute pancreatitis following the procedure. Based on this study, routine FNA does not seem very useful given its minimal impact on test performance, potential for acute pancreatitis, and the lack of a validated cytological grading system.

Obtaining a core biopsy may provide sufficient tissue for a histological diagnosis. Dewitt performed EUS-guided Trucut biopsy (TCB) of the pancreatic body in 16 patients with suspected non-focal CP[37]. Only 1 patient had CP based on the histological analysis; 8 had normal pancreas; 6 had non-diagnostic findings; 1 had device malfunction. Interestingly, all of the patients with normal pancreatic histology had 3-5 features on EUS imaging. Most of the patients with non-diagnostic histopathology had severe ($\geqslant 5$) EUS features, with only connective tissue apparent on the pathologic specimen. There were 2 hospitalizations for post-procedural abdominal pain and pancreatitis. The authors concluded that EUS-TCB was not recommended based on low yield and risk of complications. However, a more favorable interpretation is that TCB lowers the number of false positive EUS results.

Digital image analysis

Digital image analysis (DIA) limits operator dependence by trading human interpretation for computerized pattern recognition. The colors, distribution, and patterns of individual pixels are algorithmically quantified within a specified region of interest. Irisawa *et al*[38] digitally quantified the parenchymal echogenicity in CP patients and controls. The mean parenchymal echogenicity was determined as the amount of field area over a threshold level of echogenicity. The mean size above the threshold area was significantly higher in CP patients compared to controls. Also, echogenicity correlated with disease severity.

In another study, a sophisticated program was used to compare images from patients with CP, pancreatic cancer, and controls[39]. A total of 256 statistical parameters were extracted from each region of interest and filtered into a compact dataset of 11 textural parameters. These 11 variables were used to train and validate a neural network model for interpretation of each image. The end model was 100% accurate in classifying normal pancreas from CP. Further refinement of existing software is required to make DIA an easy and reliable method for real-time image interpretation.

Spectrum analysis

B-mode ultrasound gray-scale images are derived from the amplitude of reflected radiofrequency waves. Additional information can be gained from the spectrum of hidden back-scattered radiofrequency signals. This frequency information is typically ignored and not used to generate the image. However, backscattering is related to the density and sound speed of the tissue, and may represent a useful parameter to quantify pancreatic fibrosis. In a pilot study, statistically significant differences in spectral parameters computed from the backscatter were observed between normal pancreas and CP[40].

Elastography

A method to measure the "hardness" of tissue may be

very applicable for early CP diagnosis. Tissue elastography assesses tissue stiffness by measuring the response of the tissue to mechanical compression. As the scope gently compresses the tissue, less tissue displacement occurs with hard relative to soft tissue. This displacement (or "strain") can be quantified, color coded, and superimposed over the B-mode image.

There have been two initial reports of EUS elastography for CP. Janssen compared the elastography images in controls, patients with CP, and patients with pancreatic masses[41]. A "honeycombed" elastography pattern was apparent in most of the CP patients and patients with pancreatic masses. Most of the controls lacked the honeycombed appearance. These results suggest that elastography is useful in separating normal pancreas from CP, and less helpful in differentiating benign from malignant masses.

Săftoiu *et al*[42] applied sophisticated image analysis to the interpretation of EUS elastography. Mean hue histograms were calculated for regions of interest from controls, inflammatory masses, and malignant masses. Receiver operating characteristics (ROC) analysis revealed that a mean hue histogram cutpoint of 175 had 91.4% sensitivity and 89.9% specificity for diagnosis of benign from malignant masses. Neural network analysis of the images was employed to refine the diagnostic performance. After training the neural network, accuracy was as high as 97%.

Although initial results with elastography and other image analysis approaches are encouraging, many questions remain. Do these new techniques improve upon standard EUS scoring? Are they easily applied in real time? How much does operator dependence affect the results? It is worth noting that many of these pilot studies have not incorporated blinded interpretation of the images.

Contrast-enhanced EUS

Venous contrast agents may improve EUS resolution of pancreatic tissue and help differentiate benign from malignant masses. In one study, injection of the contrast agent Albumex produced enhancement in 3 of 4 patients with inflammatory masses *vs* 0 of 11 patients with pancreatic cancer[43]. In a study of 86 patients with benign and malignant masses, contrast enhancement improved sensitivity from 73.2% to 91.1%, and specificity from 83.3% to 93.3%[44]. There are no published studies of contrast-enhanced EUS for the diagnosis of early CP.

Endoscopic pancreatic function testing

Some experts suggest that both structural and functional testing is needed to optimally diagnose early CP[45]. Mild exocrine insufficiency detected by direct pancreatic function tests is a surrogate marker for early fibrosis. Duodenal aspirates can be collected through the endoscope following secretin stimulation, and analyzed for bicarbonate as a measure of duct-cell exocrine function. This endoscopic pancreatic function test method (ePFT) has shown equivalent bicarbonate concentration results as the traditional "Dreiling tube" secretin pancreatic function test in a crossover study[46]. We have recently combined EUS and ePFT in a single 50-min endoscopic session to allow a simultaneous assessment of pancreatic structure and function[16,47]. Concordant normal results (< 4 EUS criteria and peak bicarbonate concentration ⩾ 80 mmol/L) rule out CP; concordant abnormal results (⩾ 4 EUS criteria and peak bicarbonate concentration < 80 mmol/L) rule in CP. The greater diagnostic challenge arises when the structural and function results are discordant. Long-term observational studies are underway to clarify the relative importance of early structural and functional changes in predicting early fibrosis. In the meantime, the EUS and ePFT results should be interpreted in the context of the patient's symptoms and risk factors.

Secretin enhanced EUS

Secretin may also be used to "dynamically" image the pancreatic duct in patients with suspected CP. Catalano *et al*[48] serially measured the pancreatic duct following secretin injection in 40 patients evaluated for suspected CP. Secretin-induced duct dilation was 80% sensitive and 96% specific for detecting ductal obstruction (stones and strictures, and also predicted response to minor papillotomy in patients with pancreas divisum.

CONCLUSION

Endoscopic ultrasound is a useful and safe technique for detecting pancreatic parenchymal and ductal abnormalities suggestive of chronic pancreatitis. Even after many comparative studies, the accuracy of EUS for diagnosing early chronic pancreatitis is poorly understood. In spite of this and other limitations, many gastroenterologists consider EUS the best available structural reference standard. It is hoped that emerging ancillary technologies will further refine the EUS diagnosis of chronic pancreatitis in coming years.

Abstract

For an electron microscopic study of the liver, expertise and complicated, time-consuming processing of hepatic tissues and cells is needed. The interpretation of electron microscopy (EM) images requires knowledge of the liver fine structure and experience with the numerous artifacts in fixation, embedding, sectioning, contrast staining and microscopic imaging. Hence, the aim of this paper is to present a detailed summary of different methods for the preparation of hepatic cells and tissue, for the purpose of preserving long-standing expertise and to encourage new investigators and clinicians to include EM studies of liver cells and tissue in their projects.

INTRODUCTION

For an electron microscopic study of the liver, expertise and complicated, time-consuming processing of hepatic cells and tissues is needed. The interpretation of electron microscopy (EM) images requires knowledge of the liver fine structure and experience with the numerous artifacts in fixation, embedding, sectioning, contrast staining and microscopic imaging. In addition, the considerable investment in equipment and the costs of personnel, together with the construction and maintenance of dedicated laboratory space and accessory equipment, makes EM investigation of cells and tissues one of the most cost-intensive approaches in biomedical research. The choice of the

right preparation method and the use of good criteria to evaluate the quality of the preparation, together with the right interpretation of the results, is crucial not only for getting the best out of the method, but also to avoid misuse of tax payers money. With sadness, we conclude that the old trade of traditional EM studies is disappearing, and is being partly replaced by immunological techniques and confocal or fluorescence microscopy[1,2]. Hence, the aim of this special paper is to present a detailed summary of different methods for the preparation of hepatic cells and tissue, for the sake of preserving long-standing expertise and to encourage new investigators and clinicians to include EM studies of liver cells and tissue in their projects. In a recent review and guidelines on the clinical use of liver needle biopsies by Rockey *et al*[3], it is stated that, at present, there is only a minor or even negligible role for the use of EM in the diagnosis, prognosis and management of patients with liver disease.

METHODS OF FIXATION AND PREPARATION

Fixation has several goals: (1) to stop metabolism; (2) to fix structures of organelles and molecules in their current position; and (3) to make material accessible and stable during further processing. When metabolic activity in tissues is not arrested, autolytic changes will develop within minutes or even seconds. The need to use extremely fresh tissue, preferably without touching and deformation is therefore of utmost importance. The fixation is also responsible for crosslinking and arresting many molecules with the result that cells, organelles and their substructures are preserved. After embedding, sectioning and contrast staining, these structures become visualized in the electron microscope at magnifications in the range of 50 to 1 000 000 times. The protocols given hereafter can be used for light microscopy, scanning electron microscopy (SEM) and transmission electron microscopy (TEM).

In a situation where experimental animals are used, the method of perfusing a fixative through the portal vein is by far the best method to choose[4-7]. When a complete liver is not available, injecting the fixative into a piece of tissue not smaller than 1 cm provides comparable results to portal vein perfusion. This method can be applied to experimental or clinical wedge biopsies[8-13]. An advantage of this method is the fact that it only requires a small opening of the peritoneal wall to collect a small piece of tissue. With regard to needle biopsies, there have been attempts to inject the fixative into the tissue of the biopsy, with quite good results[8,10,12,14-16]. Unfortunately, these attempts have not resulted in routine applications and immersion fixation remained the standard method of fixing liver needle biopsy specimens. Vascular perfusion through a partly resected liver not used for transplantation, has also been reported to be successful[17]. In order to complete the series of protocols, we have added a short description of fixation of liver cell cultures.

Important elements in fixation are the chemical composition of fluids and the physical conditions during their application. Fluids involved in the fixation process should be isotonic to the cells; in other words, the fixation fluid should be as physiological as possible, with the exception of the fixing compound[18]. To avoid temperature shock of cells and tissues before the actual fixation sets in, isothermic fluids should be used in principle. The major condition for fixation is to transfer cells and tissues from their natural environment to the fixing environment, as rapidly as possible: this should take not more than a few seconds, be it in the operating room or in the laboratory. Living cells and tissues should not be left alone, not even for a few seconds, when this can be avoided. One should avoid subjecting the cells or tissue to drying or dry conditions, keep them wet and well-immersed in fluid, and watch the meniscus carefully to ensure that it does not touch the cells, because it will destroy them.

Fixation should be applied at the cellular level, i.e. bring all cells instantaneously and simultaneously into contact with the fixative. Immersion fixation of small pieces of tissue by plunging them into a fixative has to be avoided as much as possible. The slow penetration of a fixative into a 1-mm piece of tissue results in bad fixation in the center of the block. During the penetration of the fixative, its constituents react differently with cellular components, thereby changing the composition of the fixative on its way to the center of the block. The vehicle (buffer) is supposed to penetrate more rapidly, at the same time slowing down the fixing compound. Immersion fixation might leave the center of a tissue block unfixed for the major part of an hour. Nevertheless, immersion-fixed liver biopsies might provide sufficient information on the ultrastructure of parenchymal cells, but unfortunately sinusoids and sinusoidal cells are destroyed by immersion fixation.

Perfusion protocols allow a regimen of different fluids to be flushed through the liver[18]. Since osmium is an expensive and very toxic substance, it is not recommended to apply this fixative by perfusion. We have tried osmium perfusion[4], but the results were poor[18]. For post-fixation, the tissue should be cut into pieces that are washed in buffer to avoid chemical reactions between glutaraldehyde and osmium. The tissue blocks are subsequently immersed in the buffered osmium tetroxide. By doing so, one has control over a toxic procedure, while there is free admission of osmium to the cells through open veins and sinusoids, and the rapid application of a second fixative with a different reaction mechanism[19]. Although ethanol is used to dehydrate the tissue, its capacity to precipitate proteins and harden the tissue contributes to the fixation process. In order to better preserve membranes and their contrast, several additives to the fixatives have been proposed and applied, such as Ca^{2+} or Li^{+} ions, ferrocyanide[20], tannic acid, and picric acid[19,21].

Cryotechniques, molecular identification of cellular components, and their three-dimensional reconstruction or cryofracture as an alternative method to chemical fixation are not the subject of this review.

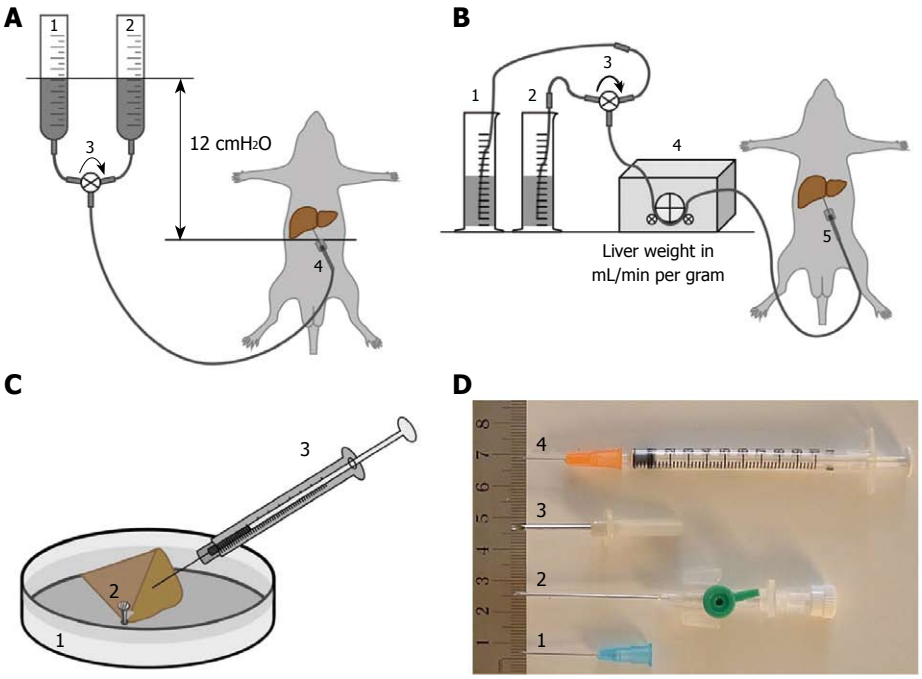

Figure 1 Diagram schematically depicting the different and most frequently used perfusion-fixation methods, including perfusion-fixation needles, to fix hepatic tissue. A: Gravity-mediated perfusion fixation using 12 cm water pressure: (1) pre-perfusion buffer; (2) fixative solution; (3) tri-valve system (e.g. Discofix® C, B. Braun, Switzerland) that facilitates the change-over between both solutions; and (4) cannulation of the portal vein; B: Roller pump-mediated perfusion fixation at a flow of 1 mL/g liver tissue: (1) pre-perfusion buffer; (2) fixative solution; (3) tri-valve system; (4) low-flow peristaltic pump; and (5) cannulation of the portal vein; C: Injection or puncture perfusion fixation, using a needle to inject fixative into a wedge biopsy of about 1 cm × 1 cm × 1 cm dimensions. Injection to approach a rate of 1 mL/min: (1) Petri dish filled with 37℃ physiological saline solution; (2) liver tissue wedge fixed by the tip of a forceps; and (3) syringe containing fixative solution; D: Different types of needles and their variants commonly used for portal vein insertion: (1) 18-23 G needle typically used for gravity-mediated perfusion for rat and mouse livers; (2) 18 G needle catheters are recommended for peristaltic-pump-mediated perfusion; (3) 12-13 G needles are typically used for larger animals such as rabbits; and (4) 25 G syringes are ideal for the injection of fixative solution in hepatic tissue. In case of accidental failure of procedure A or B, method C (injection perfusion) can be used to save the preparation.

FIXATION PROTOCOLS

Perfusion fixation of total liver in situ (mostly applied to experimental animals)[5,6,22,23]

The procedure for perfusion fixation of total liver *in situ* is as follows: (1) Anesthetize the animal, preferably with 4.5 mg/100 g body weight Nembutal (which also relaxes the musculature); (2) Fix the animal to a waterproof surgical support with its back down; (3) Shave and disinfect the animal's abdomen; (4) Open the abdominal cavity along the linea alba, with lateral cuts along the ribs and lower segment; (5) Gently move the intestines aside and cover them with surgical cotton or bandages wetted with warm physiological saline to keep them moist and warm (one could also use an infrared lamp); (6) Expose the portal vein and prepare separate, double ligatures around it; (7) Take care that the hepatic artery is included in the ligature; (8) Introduce the largest possible (just fitting) needle into the portal vein, after connecting it to a silicon tube that is connected to the perfusion system (fluids on room temperature, glass vessels or peristaltic pump, Figure 1A and B); (9) Constrict the ligatures independently, taking care not to puncture the portal vein, and make sure to close to the hepatic artery; (10) Start perfusion with glutaraldehyde solution by opening a valve or switching on the peristaltic pump; the flow rate in mL/min should be more or less equal the total weight of the liver in grams; (11) Incise the vena cava to allow fluids to escape from the vascular system, and aspirate fluids when necessary; (12) Watch the liver change in color and consistency. This process should start within the first minute (typically 15-30 s); (13) Stop the perfusion after 5 min; (14) Gently remove the liver or one or two well-perfused lobes and put them into a Petri dish that contains fixative. Well-perfused liver lobes change their color from dark red to yellow/brown, whereas the consistency changes from soft to hard like a boiled egg. Badly perfused parts of the liver that are entirely or partly soft and still dark red-brown in color should not be processed. Note that some lobes, e.g. the caudate lobe, often show better perfusion than other ones; (15) Clean a razor blade with ethanol and paper tissue (to remove protecting grease) and gently cut 1-mm slices of liver tissue. Do not put any pressure on the tissue while cutting, and make sawing movements with the razor blade; (16) Keep tissue slices covered with glutaraldehyde and cut multiple 1 mm × 1 mm strips under fluid; (17) Cut several strips simultaneously into 1 mm × 1 mm × 1 mm blocks for TEM, or 1 mm × 1 mm × 5 mm strips for SEM and/or 5 mm × 5 mm × 1 mm slices for light microscopy (LM) flat embedding; (18) Total time in glutaraldehyde should not be longer than 20 min; (19) Transfer blocks to washing buffer (which is the buffer of the glutaraldehyde fixative) to remove glutaraldehyde before contact with osmium; (20) Transfer blocks to 1% buffered osmium in small glass vessels and close these with a cap; (21) Postfix for 1 h in osmium, keep the small vessels at 4℃, and shake

Table 1 Dehydration and embedding for TEM and SEM

TEM		
Ethanol 70%	15 min	20℃
Ethanol 90%	15 min	20℃

Cutting of ultrathin sections on an ultramicrotome, contrast staining with lead and uranyl salts. TEM: Transmission electron microscopy; SEM: Scanning electron microscopy.

the fluid gently and regularly; (22) Transfer the tissue blocks to the second washing buffer (osmium-vehicle buffer), and wash once or twice to remove osmium; (23) Transfer the blocks to 70% ethanol (v/v); (24) Change 70% ethanol three times; and (25) Transport in 70% ethanol or follow the protocol for further dehydration in ethanol and embedding or critical point drying (see common trunk) (Table 1).

For a summary of necessary chemicals and solutions, composition of fluids, see Table 2.

Fixation of liver wedge biopsies (mostly applied to human liver tissue) (Figure 1C)

Wedge biopsies of roughly 1 cm × 1 cm × 1 cm (or less), including the Glisson's capsule at two sides of the wedge, are taken from the margin of a liver lobe as soon as the surgeon/operator has access to the liver. The operator should be cooperative in order to assure that freshness of the tissue is an absolute priority. Directly after opening of the abdomen *via* a chevron incision, the liver is visualized and a wedge is taken with a sharp scissor from the edge of segment 5 or 6, without manipulating the tissue. Bleeding at the biopsy site can easily be controlled using diathermia or argon laser. In a consecutive series of 150 patients no rebleeding at biopsy sites was reported (unpublished results). (1) The tissue is immediately transferred to a 50-mL vessel, filled with PBS (pH 7.4) at 37℃; (2) The tissue is transported to an annex to the operation theater, where injection perfusion with glutaraldehyde fixative is performed in a Petri dish filled with saline; (3) The wedge biopsy is held at a corner by a forceps and is injected by a 25 G syringe from multiple sides with 1.5% glutaraldehyde fixative, until a discoloration and hardening of the tissue, comparable to total liver perfusion, is obtained; (4)

Table 2 Addendum summarizing chemicals necessary for fixation of liver tissue

Compound	Quantity
Cacodylate buffer 0.2 mol/L, pH 7.4	700 mL
Sodium cacodylate trihydrate (Sigma, C0250)	22.9 g
MQ-(purified by ion-exchange)-water	674.8 mL
HCl (0.2 mol/L)	25.2 mL
Filter through 0.2 μm Millipore or Wattman filter paper	
Cacodylate buffer 0.15 mol/L, pH 7.4	
Cacodylate buffer 0.2 mol/L	900 mL
MQ-water	300 mL
Filter through 0.2 μm Millipore or Wattman filter paper	
Glutaraldehyde fixative, 1.5% in cacodylate buffer 0.067 mol/L	
Cacodylate buffer 0.2 mol/L	575 mL
Sucrose (Sigma, S0389)	17.215 g
Glutaraldehyde solution 70% (Sigma, G7776)	36.96 mL
MQ-water	1113.04 mL
Filter	
Osmium tetroxide 1% in phosphate buffer[1]	90 mL (6 × 15 mL)
Osmium tetroxide 4% for EM (Sigma, 75632)	22.5 mL
Phosphate buffer 0.2 mol/L	45 mL
MQ-water	22.5 mL
Washing buffer 1	
Cacodylate buffer 0.2 mol/L	30 mL
Sucrose	0.9 g
MQ-water	60 mL
Washing buffer 2	
Phosphate buffer 0.2 mol/L	45 mL
MQ-water	45 mL
Phosphate buffer 0.2 mol/L pH 7.4 (200 mL)	200 mL
0.2 mol/L $Na_2HPO_4.2H_2O$ (17.8 g in 500 mL MQ-water)	162 mL
0.2 mol/L $NaH_2PO_4.H_2O$ (13.8 g in 500 mL MQ-water)	38 mL

Fluids and chemicals (volumes to be adapted to needs). [1]An alternative to the osmium postfixation is addition of 1.5% potassium ferrocyanide to 1% osmium in veronal acetate buffer (pH 7.4) at 4℃ for 2 h, which strongly enhances the contrast of membranes in cells and tissues[20] (see Figure 13).

Care should be taken that the injection needle does not operate as a biopsy needle; it should be and stay completely filled with glutaraldehyde during injection into the tissue; (5) After injecting the needle into the tissue, parallel to the capsule rim, the needle should be withdrawn a few millimeters before starting injection of the fixative fluid. The idea is to create a space within the tissue in which the fixative can spread out; (6) Injections should be repeated several times until the blood is flushed out of the tissue and the consistency has changed to that of a hard-boiled egg; (7) The time between excision of the wedge and perfusion with fixative is critical. Total glutaraldehyde time (before washing and before osmication) should not exceed 20 min; and (8) After perfusion with glutaraldehyde, the biopsy is rapidly transported to the laboratory, where slices (1 mm thick), strips (1 mm × 1 mm × 5 mm), small flat slices (5 mm × 5 mm × 1 mm) and tissue blocks (1 mm × 1 mm × 1 mm) can be cut under fluid with a clean, sharp razor blade.

Immersion fixation of liver needle biopsies (Figure 1D)

The percutaneous liver biopsy procedure starts with local anesthesia with 1% lidocaine. Under real-time ultrasound guidance, the liver and the biopsy needle are imaged throughout the procedure. The biopsy is taken by a cut-

ting-type needle and a spring-loaded device. A 16-gauge needle is placed into the liver parenchyma before the device is triggered. This results in a liver specimen of 1-2 cm in length, with the diameter being dependent on the size of the biopsy needle (1-1.8 mm). After collecting the biopsy, the fresh tissue is placed in a Petri dish in which 3 mm × 1 mm × 1 mm pieces of the ends of the cylinder are cut. The remaining tissue is used for diagnostic purposes in the pathology department and separately undergoes routine pathology fixation. This procedure should not take longer than 30 s. The two cylinder-shaped tissue pieces of 3 mm × 1 mm are covered with fixative, cut into 1 mm × 1 mm × 1 mm pieces and transferred to a 15-mL vessel that is filled with 1.5% glutaraldehyde fixative at room temperature. The vessel is gently shaken a few times. The total glutaraldehyde time (before washing and osmication) should be no less than 1 h, in order to allow the fixative to penetrate the tissue. After glutaraldehyde, the tissue will be further processed in washing buffer, osmium fixative, and ethanol dehydration.

Fixation of liver cell cultures

The procedure is as follows: (1) cells are cultured on 1 cm diameter glass or plastic coverslips (0.17 mm thick) in wells of culture dishes; (2) cultures are washed three times with 37℃ buffer to rinse away dead cells, cellular debris and precipitates; (3) culture medium is replaced with glutaraldehyde fixative; (4) one should take care that the cells are always covered by a layer of fluid, so that the meniscus does not touch the cells; (5) fluids are changed several times to ensure complete replacement; (6) wash in cacodylate buffer; (7) postfix in 1% osmium tetroxide in phosphate buffer; (8) wash in phosphate buffer; and (9) dehydrate by starting with 70% ethanol (Table 1, Figures 2 and 3).

Critical point drying (CPD) is used routinely to dry samples for SEM[24]. Nation[25] has reported an alternative method that consists of air-drying of insect tissues by rapid evaporation of hexamethyldisilazane (HMDS), which has a very low surface tension. This is supposed to avoid fracturing and destruction of the specimen during drying. In spite of the advantages of HMDS, such as the absence of high pressure equipment, CPD seems to be the most frequently used method. Drying of biological samples by CPD also causes a shrinkage of about 30% of the volume[26]. We have routinely and successfully applied HMDS to cultured liver cells[27]. HMDS drying takes only 3 min instead of the laborious and time-consuming CPD process. We also have applied HMDS drying to perfusion-fixed liver tissue, and during a comparison with CPD, no differences could be seen between the two methods (Figure 3).

After 100% ethanol, samples are immersed for 3 min (cell cultures) or 10 min (liver tissue) in 100% HMDS. After HMDS, the samples are removed from the culture wells and excess HMDS is blotted away by filter paper. The samples are then transferred to a desiccator for 25 min to avoid water contamination. After drying, the samples are mounted on stubs (Figures 4 and 5) and are sputter-coated with 10 nm gold and made available for SEM investigation.

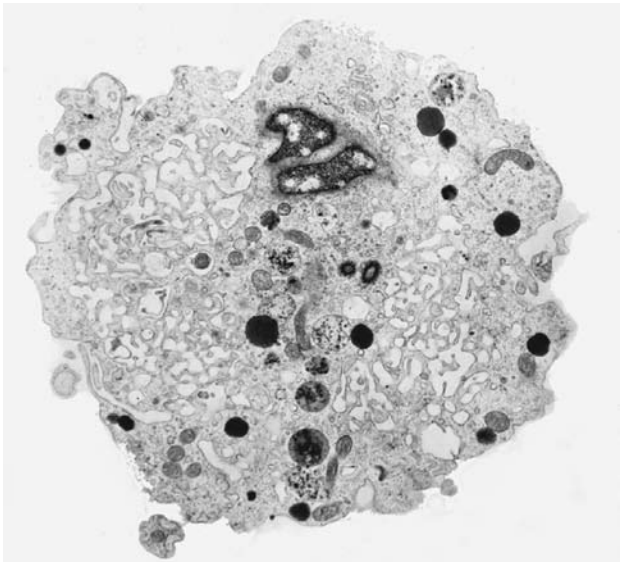

Figure 2 Transmission electron microscopy (TEM) image of an ultrathin section of a plastic-embedded liver sinusoidal endothelial cell after isolation. In the upper part of the picture is a small portion of the nucleus. The labyrinth-like structures in the cytoplasm represent fenestrae that are internalized during the isolation procedure. Electron-dense granules represent lysosomes that reflect the high digestive capacity of these cells. Magnification 6300 ×.

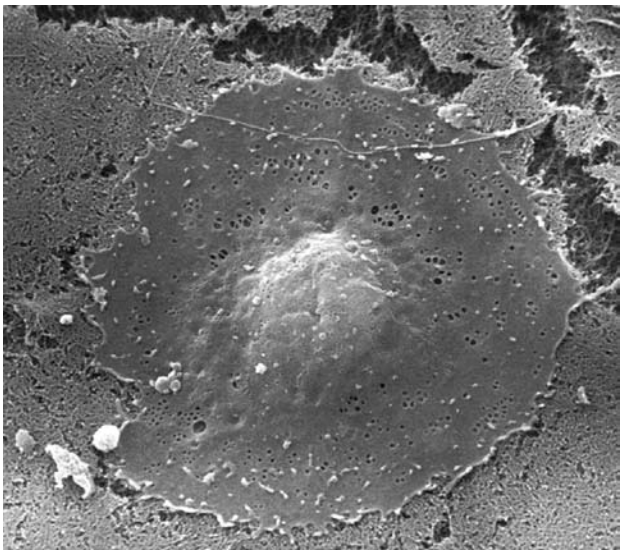

Figure 3 Scanning electron microscopy (SEM) image of a critical-point-dried liver sinusoidal endothelial cell in culture, 2500 ×. After isolation and purification, cells were seeded on a layer of collagen. Besides the centrally located, bulging nucleus, fenestrae can be easily observed in the surrounding thin, flat cytoplasm.

Preparing sections for LM

Follow the instructions given for TEM and make sections of 0.5-1 μm, stain with Toluidine Blue (1% with 2% borate in distilled water), cover sections with Entellan and a 0.17-μm glass coverslip. In case of sufficient contrast, use bright field microscopy, in case of low or insufficient contrast, use phase contrast or interference contrast.

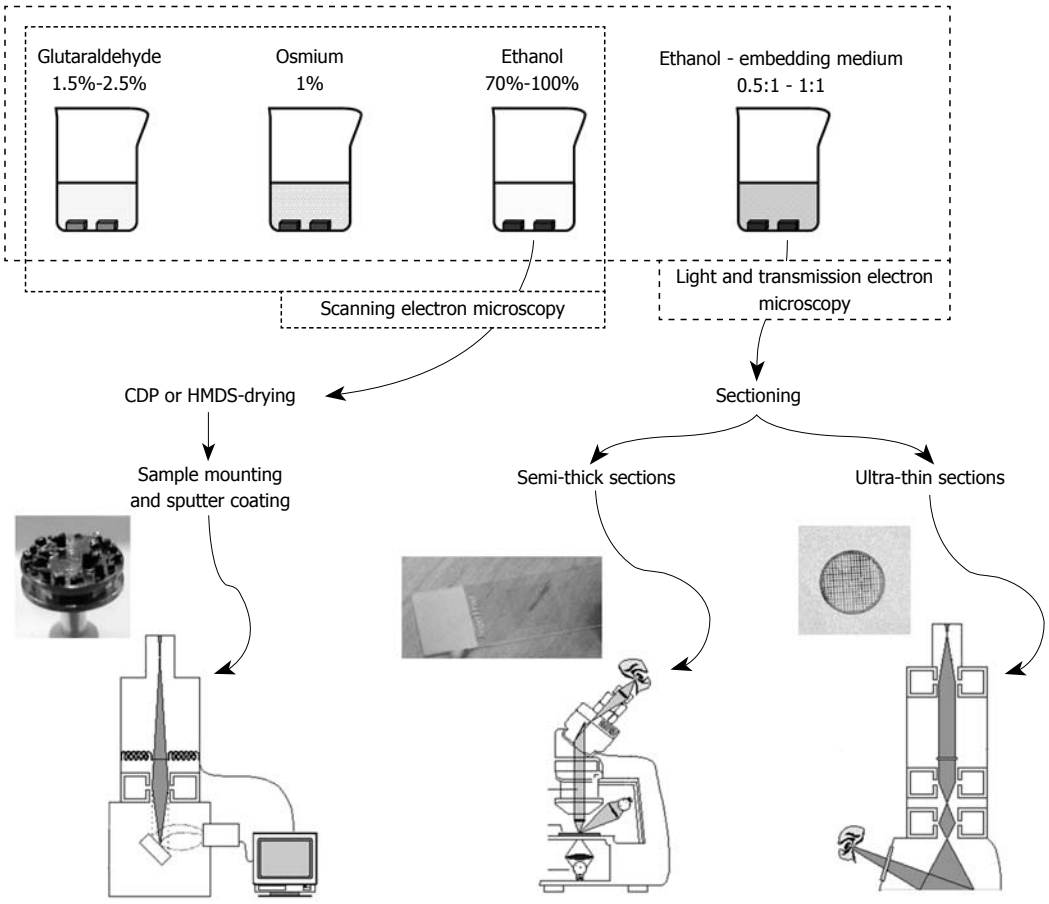

Figure 4 Summary of the different steps in the preparation of liver tissue after aldehyde fixation (top figure) and the subsequent tissue sample preparation steps for the different modes of microscopy (bottom figure). Good laboratory practice should involve all three visualization modes in order to collect fine structural and topological data, together with insights into the interior of the sample. Left: SEM; Middle: Light microscopy (LM); Right: TEM.

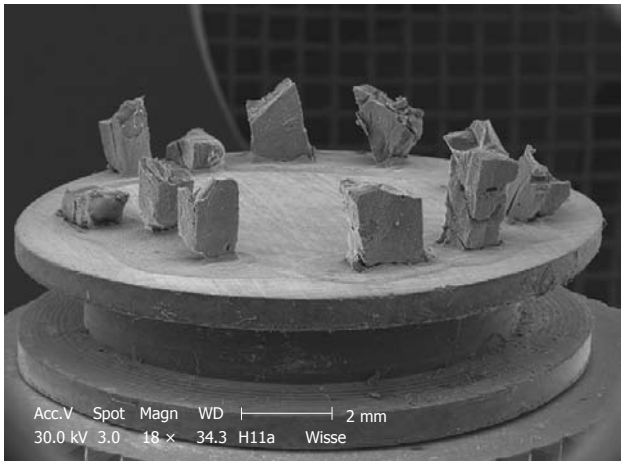

Figure 5 Typical stub of aluminum (diameter 1 cm) bearing 11 pieces of liver tissue of an injection-fixed human liver wedge biopsy observed by SEM at low magnification. Strips of tissue in 100% ethanol are frozen at -196℃, fractured, critical point dried, sputter coated and glued to this carrier. The top surface of the specimens is observed, and imaging is achieved with secondary electrons. This picture is taken by a small CCD camera fitted to the microscope to observe specimens directly.

KEY ASPECTS TO CONSIDER

Anesthesia

When using experimental animals, fixation should be preceded by anesthesia. Undoubtedly, the success of perfusion also depends on the handling of the animals. Animals should be minimally stressed before and during the operation. Therefore, it is recommended to have the animals about 2 h before the surgical procedure within the operating room to accustom them to the environment and reduce the level of stress. Stress hormones affect the physiology and fine structure of organs. Furthermore, animals in discomfort are not only difficult to manipulate, but the stress hormones might cause vasoconstriction and directly narrow or even block some vascular beds, thereby affecting the outcome of the perfusion procedure and also the fine structure of the cells.

Some researchers use ether as an anesthetic. Although this is a rapid procedure, it should be discouraged as it does not provide any pain relief, nor does it have muscle-relaxant properties. Furthermore, ether anesthesia is difficult to control, and often leads to an overdose, typically to be encountered during the initial stages of the operation, resulting in body temperature drop, shock and even accidental death of the animal. Animals that are in distress and anesthetized with ether are difficult to handle and operate on and chances for a successful liver perfusion are low. As outlined in the protocol section, agents such as pentobarbital and chloral hydrate, preferably combined with pain inhibitors, are the first-choice anesthetics. The

period of anesthesia should be as short as possible[22]. Anesthesia can be checked by gently touching the cornea of the animal, followed by gently squeezing the paw pads. When no reaction occurs, the animal is ready for operation. When laparotomy is performed, hypovolemia should be prevented and veins and arteries should be well perfused and red[22].

Preperfusion

The need for preperfusion with buffered physiological saline is still being discussed. The argument used in its favor is to wash plasma and blood cells away in order to avoid coagulation, precipitation of blood constituents and aggregation of blood cells by glutaraldehyde. Such precipitates could impair the flow of fixative through the liver. Theoretically this is correct, but experience has taught us that plasma constituents and blood cells do not have enough time to react and precipitate when glutaraldehyde is flushed through the liver straightaway. It is possible to flush the liver, e.g. of a rat, within 15-30 s without any notable obstruction. After 30 s, the way should be free to continue perfusion of the fixative. The point is that fixative and biological material need time to react, and perfusion might be successfully established before precipitation, coagulation and cellular aggregation occurs. A compromise might be to fill the tubes used for perfusion with buffered physiological saline, which results in a small "wave" of saline preceding the glutaraldehyde, the two being sequentially distributed through the entire microcirculation of the liver[22].

When preperfusion is still preferred, not more than 30 s preperfusion with buffered physiological saline at a physiological flow rate is necessary to free the liver of plasma and red blood cells. From this moment onwards, glutaraldehyde fixation can be started. The success of perfusion correlates with disappearance of red blood cells from the liver and can be followed by the change in color of the organ (dark red brown to yellow-brown). The presence of blood can also be monitored by observing the effluent. The success of fixation correlates with the change in consistency of the organ (from soft and pliable to rigid/stiff like a hard-boiled egg). Successful perfusion fixation shows the start of these phenomena within 20 to 30 s.

Air bubbles might form within the flexible tubing that connects the perfusion needle with the vessels that contain the perfusion fluids. Bubbles appear often when improperly cleaned tubing is used, or are caused by long waiting times or temperature differences between the different fluids. Air bubbles are disastrous in liver perfusion and act as blockers of the liver microcirculation. They are a major source of perfusion failure[5]. It is therefore recommended to check the tubing regularly. Air bubble traps are commercially available and are being used in clinical settings. They certainly are advised when using larger animals (e.g. rabbits, dogs or mini pigs) when high-volume perfusion is required.

As soon as perfusion is started, it is mandatory to open the vascular system by incising the vena cava in order to avoid the buildup of pressure. Enhanced pressure damages endothelial cells as well as parenchymal cells[28].

Formaldehyde has found no application in perfusion fixation of the liver. Glutaraldehyde has better stability in solution and has two reactive groups per molecule, therefore, it cross-links more easily, has lower osmotic pressure and gives better results[29]. Nevertheless, it might be useful to preperfuse the liver with formaldehyde. Since formaldehyde has a much slower reaction time than glutaraldehyde[29], it could be possible to preperfuse the liver with 3%-4% buffered (and freshly prepared) formaldehyde. Care should be taken for the high osmotic pressure of formaldehyde solutions. Formaldehyde preperfusion would allow flushing of blood and its constituents from the tissue (within 1 min) and starts mild fixation at the same time. Glutaraldehyde perfusion can be started directly thereafter and makes clear the way to do the real job of fixation in the absence of plasma and blood cells.

The choice of a roller pump *vs* gravity perfusion is a matter of personal preference. The roller pump releases moderate artery-like pulses of fluid (depending on the tube diameter), whereas gravity flow is constant and results in constant flow or pressure. The choice is considered not to be decisive for perfusion quality.

Since the liver circulation can be characterized as a high flow/low pressure system, discussions about perfusion pressure during fixation have limited value. It is believed that flow rates within wide limits do not enhance perfusion pressure, since the open system and sponge-like structure of this typical microcirculation do not allow pressure to build up. This situation changes when the fixative precipitates blood proteins, aggregates blood cells and introduces coagulation. When attention is paid to this condition, physiological flow rates (the rule of thumb: weight of liver in grams = milliliters of fluid per minute) should give good results.

Choice of the perfusion needle

Experience over the years has taught us that the outcome of fixation by perfusion also depends on the choice of the needle. The diameter of the needle, i.e. the gauge (G), determines the maximum flow to be delivered. This gauge value, together with the liver blood flow and pressure for a particular type of species, are important factors to consider. 18 G needles, for example, with a typical diameter of 1.2 mm, have a maximum perfusion flow by 12 cmH_2O gravity of 80 mL/min. This is evidently too low when livers of rabbits (177 mL/min) or dogs (303 mL/min) are concerned[30].

18-23 G needles (diameter 1.27-0.64 mm) are ideal for liver perfusion in animals such as rats and mice (Figure 1D1); whereas the 12 G (diameter 2.77 mm) needle type is recommended for larger species such as rabbits and minipigs (Figure 1D3). One can benefit from studying a catalogue of the needle catheter-type of needles that are on the market. A needle catheter (Figure 1D2) comprises a metallic needle-guide that consists of a cannula with an end grip - the catheter - that covers the needle-guide when it is retracted after cannulation. Hence, after the needle

catheter (inlet) is inserted into the portal vein and secured by ligatures, it is possible to insert the plastic tube (outlet) further into the portal vein, without rupture of the vessel. An additional benefit is that the atraumatic outlet of the catheter has a round shape, which results in more efficient perfusion when compared to the pointed-end needles. Accidental puncture of the wall of the portal vein at the start of perfusion is a major source of perfusion failure. In case of perfusion failure, an emergency solution is offered by the technique of injection fixation. In that case, the steps of protocol 2 should be followed. This might save losing an animal from the experimental setup.

A point of interest in choosing the right diameter of needle lies also in the effect of "jet streaming" that is caused by a too-small needle orifice. With an easy, moderate flow, the fluids probably distribute evenly through the branches of the portal vein, whereas a jet-stream might, simply because of its strength and direction, blow the fluids into one branch of the portal vein, thus causing uneven distribution and pressure of fixing fluids in the different liver lobes.

When injecting glutaraldehyde into a wedge biopsy, one should take care to introduce a fluid-filled needle into the tissue. When the needle cuts the tissue as it does in the case of a needle biopsy, the sampled tissue comes out at the moment the operator starts injecting the fixative. Instead, if the operator fills the needle with fluid and cuts through the tissue without allowing the tissue to enter the lumen of the needle, this effect can be avoided. Moreover, when the fluid-filled needle is retracted slightly after reaching the maximum track for injection (evidently before starting perfusion), a space will be created within the tissue, from where fluids will distribute easily in all directions as soon as the injection of the fixative solution starts.

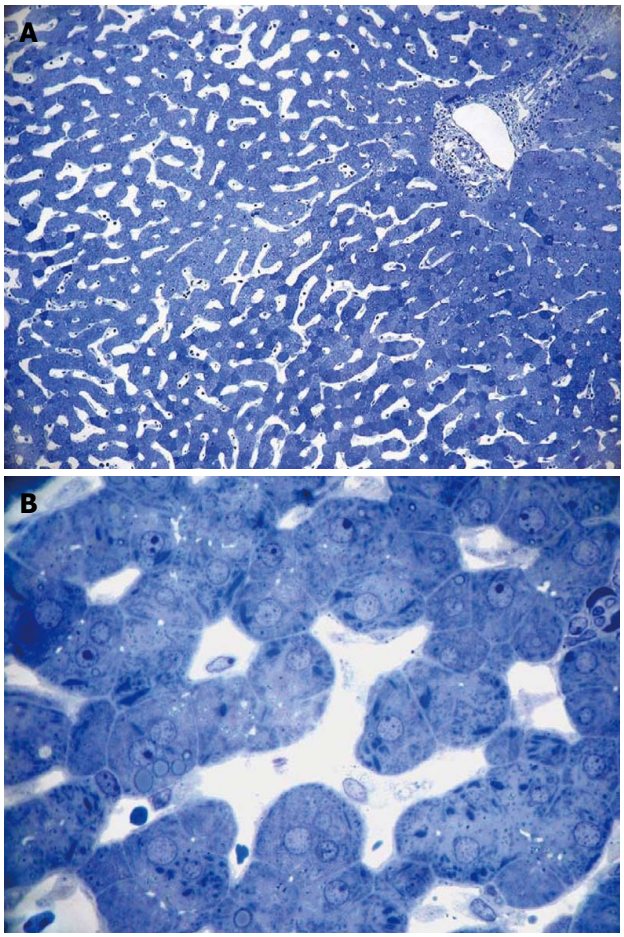

Figure 6 Light micrograph of a wedge biopsy of human liver, injected with glutaraldehyde, plastic section stained with Toluidine Blue. A: Original magnification 10 × objective lens. Note that, as a result of successful perfusion, sinusoids are open, and only a few red blood cells are present. A portal tract is present in the upper right corner; B: Original magnification 63 × oil-immersion lens. Details such as giant mitochondria are visible in the parenchymal cells, amongst others such as small mitochondria, lipid inclusions and bile canaliculi. Sinusoids are patent and show the presence of sinusoidal cells.

RESULTS OF THE DIFFERENT METHODS OF FIXATION

When LM sections, SEM preparations and ultrathin sections of liver tissue or cell cultures are studied, these three approaches provide information to the investigator, each in its own way.

Toluidine-Blue-stained 1-μm sections provide information at magnifications from 5 × to 1000 × over wide areas as compared to TEM sections (Figure 6A and B). These sections already show the criteria for good or bad fixation (see discussion), such as open sinusoids (Figure 7A and B), absence of blood cells, equal density of similar cells, and open bile canaliculi (particularly in the periportal area). Recognition of typical histological details such as the central vein, bile ducts and portal vein with its accessory structures and many cells, such as parenchymal, sinusoidal and visiting cells, together with conditions such as steatosis (Figure 8A and B), fibrosis and inflammation, can be observed at an estimated system resolution of about 0.2 μm. Crucial details such as endothelial fenestrae (measuring 140 nm in mice and rats, and 105 nm in humans and some rabbit strains) (Figures 9-12), although present, therefor escape observation by LM. Perfusion fixation and plastic embedding also add details to an LM study. In the case of immersion fixation, paraffin embedding and hematoxylin and eosin staining, observations are mainly restricted to the size, shape and position of entire cells and their nuclei. In the case of perfusion fixation and plastic embedding, intracellular details can be observed in the LM in greater detail, with the knowledge that the same structures of the same preparation can also be seen in maximal detail by TEM. For example, the typical giant mitochondria that occur in the human liver parenchymal cells (Figures 13 and 14) can easily be observed in plastic sections by LM, and can be seen in greater detail by TEM of the same specimen. Therefore, the Toluidine-Blue-stained plastic section is a useful histological introduction to further detailed study by TEM.

Perfusion-fixed total organs or injection-perfused wedge biopsies also make ideal preparations for SEM study. When tissue strips of 1 mm × 1 mm × 5 mm in 100% ethanol are frozen and fractured (before CPD) at the temperature of liquid nitrogen, the fracture surface is

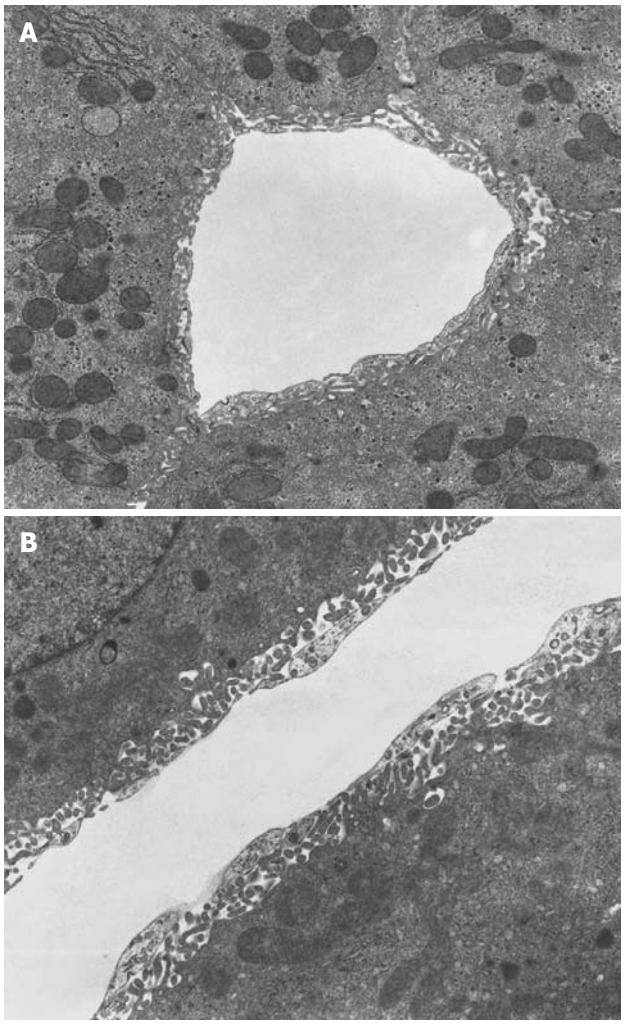

Figure 7 TEM micrograph of a transversely cut sinusoid of rabbit liver (A) and longitudinally cut sinusoid of mouse liver (B), fixed by perfusion through the portal vein. A: The Space of Disse shows the presence of microvilli extending from the parenchymal cells. Within the cytoplasm of the parenchymal cells, mitochondria, rough endoplasmic reticulum and glycogen are recognizable. Original magnification 6600 ×; B: Underneath the thin layer of fenestrated endothelium, bordering the sinusoidal lumen, the Space of Disse shows the presence of microvilli extending from the parenchymal cell surface. Within the cytoplasm of the parenchymal cells, mitochondria are recognizable. Original magnification 8900 ×.

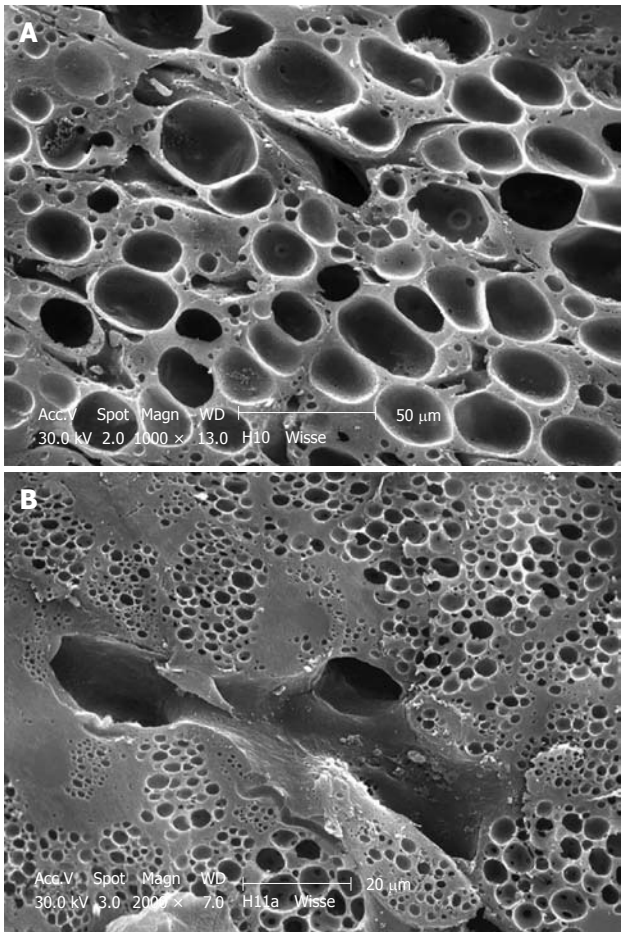

Figure 8 SEM micrograph of an injection-fixed human wedge biopsy showing macrovesicular steatosis (A) and microvesicular steatosis (B). A: Fat droplets are of such dimensions that one appears to fill the cytoplasm of an entire parenchymal cell; B: Fat droplets are smaller than those in Figure 8A and are spread within the cytoplasm of parenchymal cells.

more or less flat and easily correlates with a 2D histological section. Unfortunately, intracellular details are rare, but some cell surface details are abundant. SEM offers details about the endothelial lining of the sinusoids, easily shows the presence of fenestrae (Figures 11 and 12), reveals the presence of endothelial gaps (Figures 15 and 16), shows some details about the space of Disse, and shows the central and portal veins and the bile duct with its typical epithelial cells with one cilium each (Figure 17). Alternatively, fracturing the tissue in the already dry state after CPD (Figure 17) reveals the lateral cell membranes of parenchymal cells together with the 3D network of bile canaliculi, strictly separated from the network of sinusoids. SEM preparations are very useful in judging conditions such as sinusoidal dilatation (Figure 18) or sinusoidal obstruction syndrome[31]. Sinusoidal dilatation occurs in regions apparently different form normal, where the average sinusoidal diameter is measured as 4-6 μm by SEM. In SEM preparations, the dimensions of many structures are reduced by an average 30% shrinkage as a result of the drying procedure[23,24]. Therefore, the use of SEM preparations to measure or judge the size of any detail in the preparation should be avoided.

TEM of perfusion or injection fixed liver tissue reveals the fine structure of all the different cell types in the tissue. It is assumed that the histological topography and the shape of the cells are optimally preserved due to hardening of the intact tissue by glutaraldehyde perfusion. This initial hardening process needs only a few minutes for the entire organ. Important to note is the fact that this condition can be obtained without touching or deforming any part of the organ or tissue. It is assumed that the fluids themselves do not cause distortion as reported for immersion fixation[19].

Inherent to the observation with TEM, abundant details can be observed in all different cells and organelles at magnifications in the range of 50-1 000 000 ×, with a resolution in the order of about 5 nm. A low magnification survey of sections at 50-600 × (by using a different

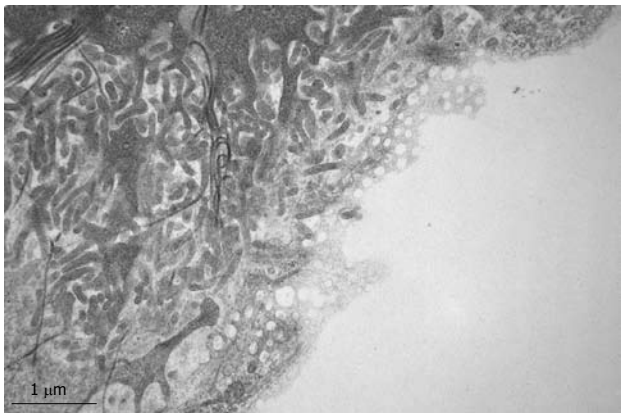

Figure 9 TEM micrograph of the tangentially cut endothelium of a human liver sinusoid, fixed by injection of glutaraldehyde fixative into a wedge biopsy. Underneath the thin layer of fenestrated endothelium, the Space of Disse shows the presence of microvilli, thin fibers of reticulin, and processes of fat-storing cells. Fenestrae in such preparations have an average diameter of about 105 nm. Original magnification 19 000 ×.

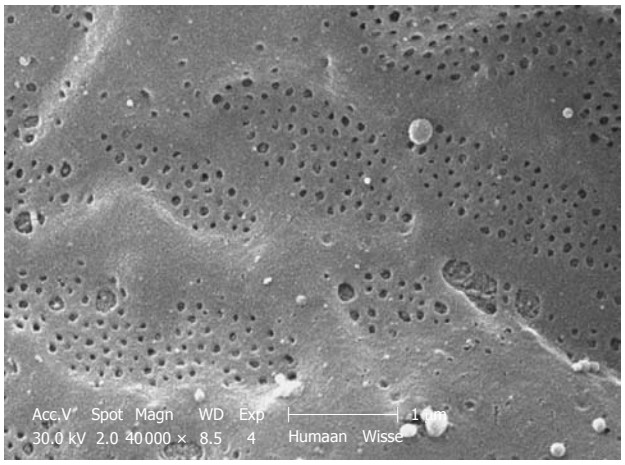

Figure 11 SEM micrograph of the fenestrated endothelial lining of a human injection-fixed wedge biopsy. Note the grouping of fenestrae in sieve plates. Compare this figure with Figure 12, which shows an SEM micrograph of a mouse sinusoid at the same magnification. Fenestrae are apparently sensitive to fixation and are lost during immersion fixation. Their presence can therefore be used as a criterion of good fixation.

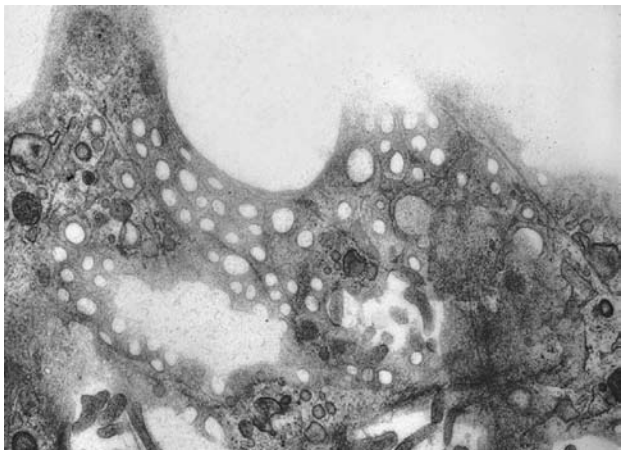

Figure 10 TEM micrograph of tangentially cut sinusoidal endothelium of a rabbit liver, fixed by perfusion through the portal vein. The fenestrae are grouped in sieve plates, but are intermingled with elements of the cytoskeleton, i.e. microtubules and microfilaments. Within the electron-dense sieve plate cytoplasm, saccular interconnecting cisternae are seen. These structures are fixation dependent and are only found in rabbit liver. Original magnification 21 000 ×.

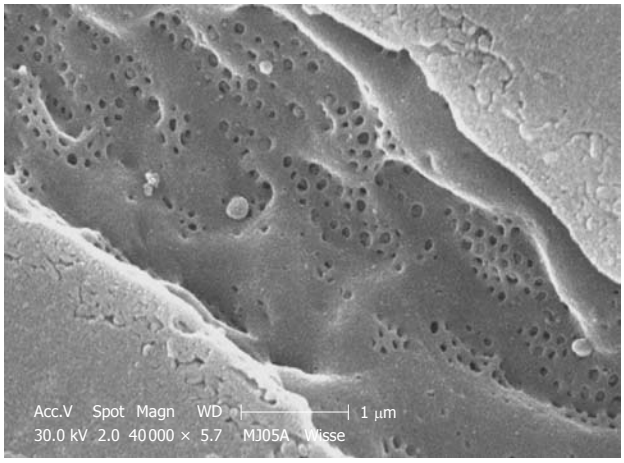

Figure 12 SEM micrograph of the fenestrated endothelial lining of a mouse portal-vein-perfused liver. Compare this figure with Figure 11, taken under exactly the same conditions. Comparison with TEM of plastic sections shows that mouse (and rat) fenestrae are bigger (140 nm) than human (and rabbit) fenestrae (105 nm). Measurements on this type of SEM preparation should be avoided, because the drying procedure results in about 30% shrinkage and incorrect measurement of all components in the tissue.

combination of TEM lenses) (Figure 19), provides information about the quality and content of the sections, and allows the preselection of interesting areas in the preparation. This low magnification TEM is also recommended as a bridge to the study of Toluidine-Blue-stained sections for LM. TEM observations also reveal the difference between sinusoids and capillaries (Figures 20 and 21). Perfusion fixation also reveals extraordinary structures such as pored domes[32] or defenestration centers (Figure 22)[33]. Higher magnifications provide supramolecular information about the cytoskeleton, glycogen rosettes, ribosomes, mitochondrial cristae, chromatin fine structure, nucleolar composition, unit membrane structure, Golgi apparatus, the presence of iron storage proteins, and lysosomal contents.

Results obtained with cell cultures follow the general pattern described for the three kinds of specimen already discussed. In the case of cultured cells, fixation at the cellular level is quite easy. A big difference is that fluids have direct access to the cells. Therefore, precautions should be taken to avoid over-fixation and extraction, which can result in damaged membranes and extracted cells.

GENERAL DISCUSSION

A detailed literature survey has revealed that there are three commonly used fixation methods for EM studies of liver tissue. For a review see Hayat[21]. Since Fahimi[5] and Wisse[6] have demonstrated that perfusion fixation, rather than immersion fixation, is essential in preserving the fine structure and architecture of the liver, perfusion-fixation has been the gold standard ever since, especially

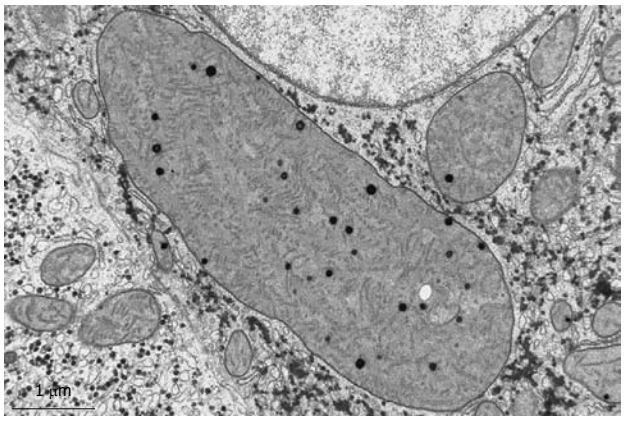

Figure 13 Typical structures that are often encountered in human liver parenchymal cells are the giant mitochondria. This wedge biopsy was fixed by injection, but during the osmium postfixation, ferrocyanide has been added. This compound enhances the contrast of membranes, including the cristae. Giant mitochondria also contain electron-dense granules, as normally seen in small mitochondria (compare Figure 14). Giant mitochondria can also be recognized in plastic sections observed by LM (see Figure 6B). Magnification 19 000 ×.

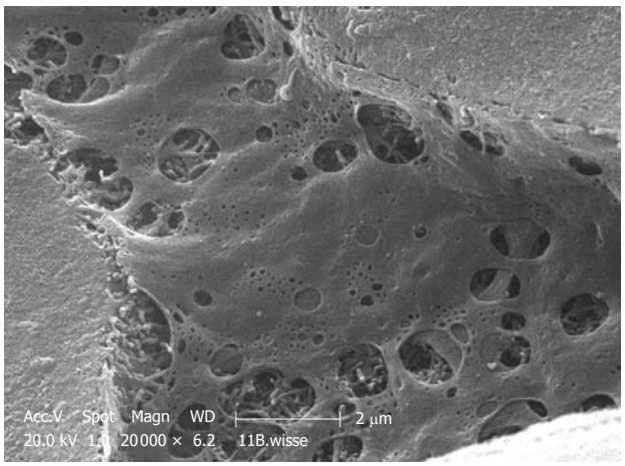

Figure 15 A major problem in EM preparations of liver tissue is the occurrence of gaps in the endothelial lining. It is assumed that they appear during fixation due to instability of the cytoskeleton, which allows the fusion of fenestrae or the *de novo* formation of gaps. This SEM picture is from a rabbit liver fixed by portal perfusion.

for the study of the sinusoids and sinusoidal cells in experimental animals[6].

Irrespective of the numerous methods available to prepare liver tissue for EM studies, perfusion-fixation *via* the portal vein is decidedly superior and more reproducible compared to other methods of fixation, in particular immersion fixation. Injection of the fixative into wedge biopsies, however, comes close and when Toluidine-Blue-stained LM sections are used to select tissue for the quality of fixation, this type of fixation can replace that through the portal vein. Perfusion-fixation *via* the portal vein and immediate arrest of the liver circulation (including the hepatic artery), meets the conditions of instantaneous and simultaneous fixation of all cells in the organ and restricts gradients of fixation to the cellular level. Fahimi[5] and Wisse *et al*[22] have reported

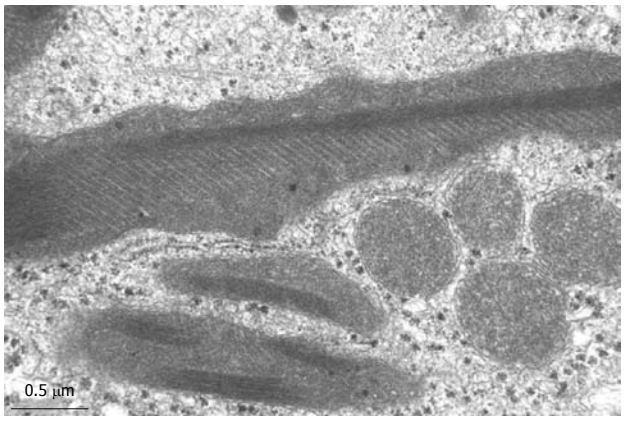

Figure 14 Giant mitochondria in a wedge biopsy fixed by injection. No ferrocyanide has been added during the osmium postfixation, therefore, membrane contrast is low. Within the giant mitochondria, the occurrence of typical crystals can be observed, together with a highly rhythmical pattern of the cristae. Magnification 34 000 ×.

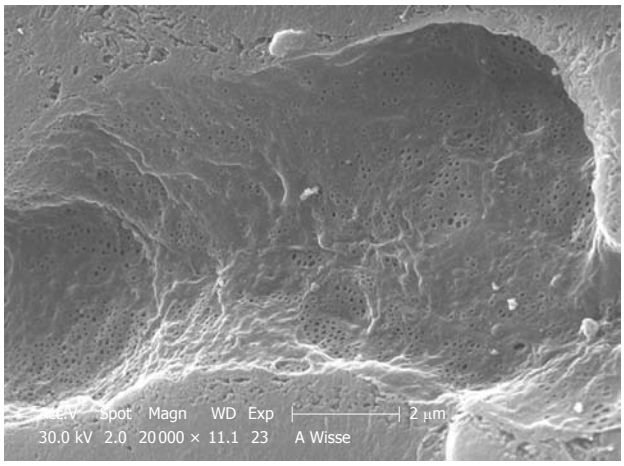

Figure 16 SEM micrograph of another portal-vein-perfused rabbit liver, which shows a complete intact sinusoid, and apparently no gaps have been formed. Fenestrae occur in sieve plates (groups), the space of Disse seems to be filled by microvilli of the parenchymal cells.

the success of portal vein perfusion, followed by retrograde perfusion with fixative through the hepatic vein, which results in more evenly fixed tissue. By staining with Schiff's reagent, we could demonstrate that within 5-7 min, liver tissue stains equally well after such "push-pull" fixation[22], which indicates that saturation of the tissue with glutaraldehyde is obtained over this short time interval. Perfusion through the aorta[28] or any other indirect route may be successful, but seems unnecessary when the portal vein is available. We can summarize the advantages of perfusion fixation as follows: (1) instantaneous and simultaneous fixation of all cells in the organ; (2) avoidance of hypoxia and autolysis; (3) fewer problems resulting from diffusion and exhaustion of the fixative during immersion; (4) use of lower concentrations of fixing chemicals is possible; (5) glutaraldehyde perfusion hardens the tissue, which allows easier cutting; (6) less mechanical damage, deformation or distortion; (7) empty vessels and sinusoids allow better penetration of

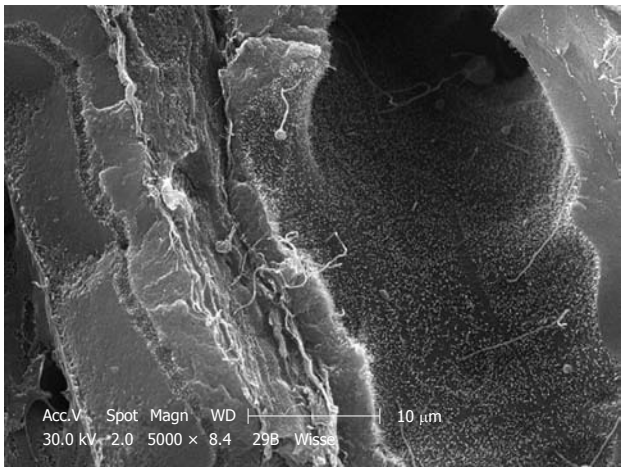

Figure 17 SEM micrograph of rabbit liver, fractured after CPD. In such preparations, the fracture plane separates the intact lateral cell membranes of parenchymal cells, which exposes the bile canaliculi, which are strictly separated from the sinusoids (to the extreme left). The right hand side of the picture shows a bile duct. The luminal surface of the bile duct epithelial cells is covered with numerous small microvilli and single cilia protruding into the lumen of the bile duct.

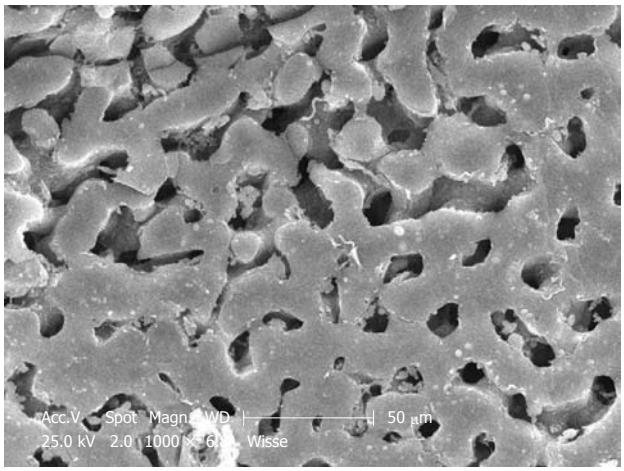

Figure 18 SEM micrograph of a human injection-fixed wedge biopsy that shows two populations of sinusoids, i.e. normal size (lower half of the picture), and those in the upper half of the picture show sinusoidal dilatation.

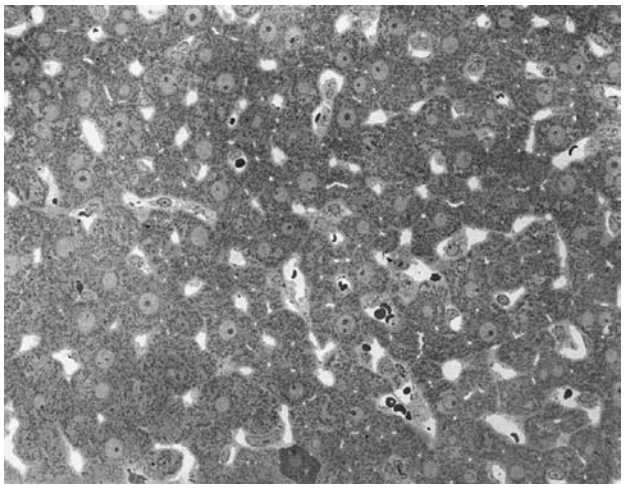

Figure 19 TEM image after perfusion fixation of rat liver through the portal vein, which results in an image of parenchymal cells of equal density (with one exception in the low middle part), open sinusoids and open bile capillaries. Original magnification 720 ×.

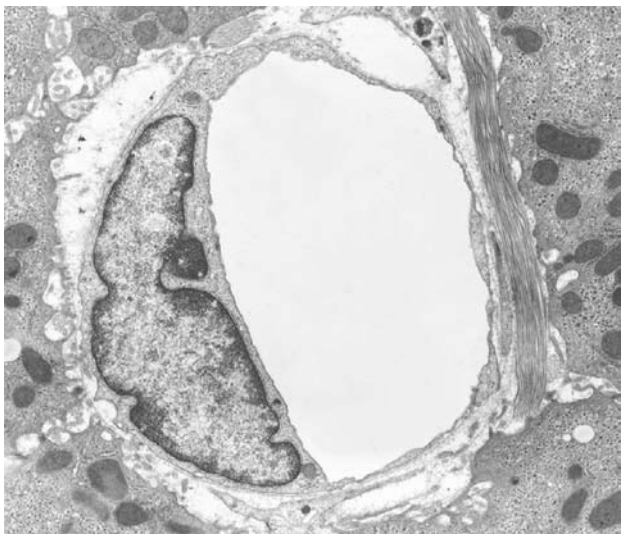

Figure 20 TEM micrograph of a capillary found in diseased human liver, fixed by injection of fixative into a wedge biopsy. Capillary endothelial cells are different from normal sinusoidal endothelial cells; their vacuolar apparatus (pinocytotic vesicles, endosomes, lysosomes, Golgi apparatus) is not developed. The thin cytoplasm contains fenestrae and the capillary is surrounded by a thin, continuous basal lamina that is not present in normal sinusoids. Magnification 6600 ×.

washing fluids, osmium and ethanol; (8) exact timing and shorter fixation times are possible; (9) more and better preservation of histological relationships and fine structural details; (10) better preservation of cytochemical reactive sites; (11) fewer artifacts; (12) perfusion can be extended to a program of reagents, fixatives and buffers without further manipulation; (13) less accessible organs and tissues may be fixed before excision; and (14) easy to directly judge good perfusion and fixation by change in color and hardening of the organ.

An additional advantage of the method is that perfusion-fixed liver tissue is firm enough to be cut into finer pieces without deformation, supposedly leaving cells in their right histological arrangement. Hand cutting by a sharp, thin razor blade allows the cutting of glutaraldehyde fixed tissue into tissue blocks of 1 mm × 1 mm × 1 mm (for TEM) or slices (1 mm × 10 mm × 10 mm) for flat embedding and large sections for LM, and strips of 1 mm × 1 mm × 5 mm for further preparation for SEM. It is assumed that the open vessels and sinusoids allow the penetration of osmium and other fluids in a much better way as compared to immersion fixation, for which a wall of fixed components at the outer rim of the tissue stands in the way of and will still react with the penetrating fluid.

Researchers may choose from two perfusion methods that both result in excellent preservation of hepatic tissue. One uses gravity to perfuse the vascular bed at 12 cm water pressure, a value that corresponds to the physiological portal pressure (Figure 1A); whereas the other method actively pumps solutions through the portal vein with the

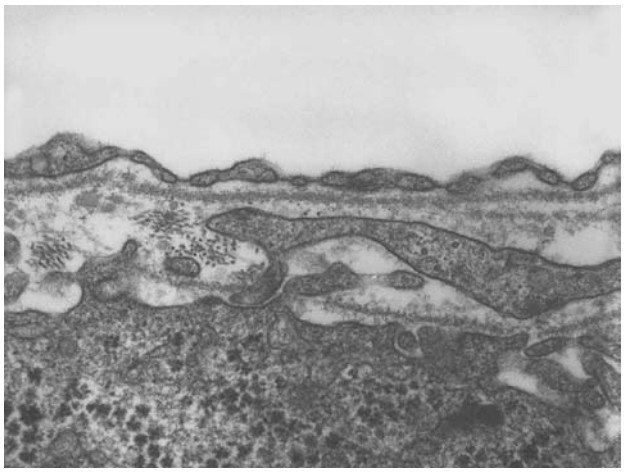

Figure 21 TEM micrograph of a capillary found in diseased human liver, fixed by injection of fixative into a wedge biopsy. The thin endothelial lining contains fenestrae, closed by a diaphragm. Underneath the endothelium, one can observe a continuous basal lamina. Fenestrae in this type of capillary are about 60 nm in diameter. It is supposed that transport from this capillary to the tissue is hampered by the structures mentioned. Magnification 28 500 ×.

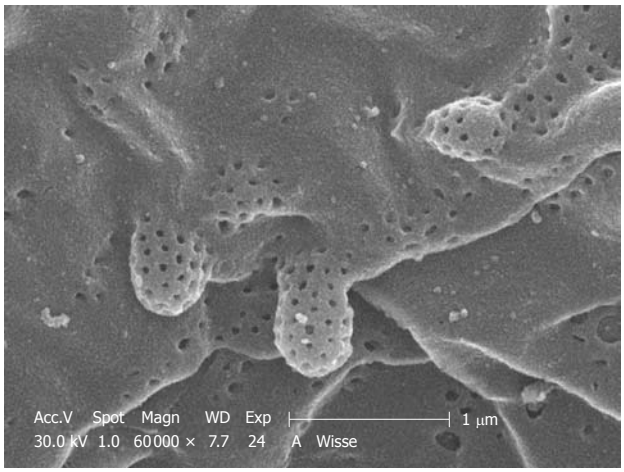

Figure 22 SEM micrograph of a portal-vein-perfused rabbit liver. Due to the quality of fixation, fenestrae are preserved, including a surprising detail, named pored domes[32], which are probably the *in vivo* equivalent of the defenestration center observed in endothelial cell cultures[33]. This structure was not seen in human, mouse, rat or pig liver.

aid of a low-speed peristaltic pump. In both cases the typical rate of 1 mL/min per g liver weight (Figure 1B) should be achieved.

Perfusion fixation seems to be difficult when a human needle biopsy is to be investigated by EM. Attempts have been made by Bioulac-Sage *et al*[14] and Balabaud *et al*[8] to flush fluids through the tissue of a liver needle biopsy arrested at one end of a narrowing Pasteur pipette (holding the tissue) with a slightly elevated pressure, while aspirating fluids at the other end with slightly negative pressure. Muto *et al*[10], Vonnahme[12] and De Wilde *et al*[15] have obtained good fixation results on human or rat liver needle biopsies by injecting glutaraldehyde with tiny glass or metal needles at intervals into the cylindrical tissue. De Wilde *et al*[15] have used low-melting-point agar to arrest and handle the tissue. Surprisingly, and in spite of good results, this technique has not found its way into clinical practice, and it is not mentioned in the needle biopsy review of Rockey *et al*[3].

It is evident that immersion-fixed needle biopsies have provided a wealth of information about the fine structure and deviations of parenchymal cells. David *et al*[34] have demonstrated by morphometric methods that there are only slight differences between parenchymal cells from immersion- or perfusion-fixed tissue. It is recommended to limit the study of immersion-fixed needle biopsies to the outer and middle zone of cells that are well fixed. They can easily be found when material is preselected by Toluidine-Blue-stained LM sections. Apparently, the structure of sinusoids and sinusoidal cells, as damaged as they are after immersion fixation, has not until now played a significant role in clinical practice.

With regard to artifacts, we remember a citation from one of the founding fathers of EM, George Palade, who said that one of the major difficulties in EM is to distinguish between genuine structures and artifacts. Some even say that EM is "an art of artifacts". It takes indeed a lot of experience and insight to distinguish between real structures and artifacts. Alternative methods are scarce, but sometimes it helps to compare results of chemical fixation (as summarized in this review) with alternative techniques such as freeze fracture of fresh tissue[6]. In equilibrium with the fact that artifacts are not easy to define and to prove, it is also difficult to indicate the true nature of real structures and their function. Artifacts in a specimen can be caused during one or more of the many steps of sample preparation, and can be caused by anesthesia, osmotic pressure, quality of the reagents, inadequate operation, pH, temperature, postmortem changes or autolysis, slow or incomplete fixation, cutting of the tissue, postfixation, dehydration, distortion, embedding, sectioning, contrast staining, microscope conditions, (digital) photography, image storage, and handling. Examples of possible artifacts are the occurrence of endothelial gaps, shrunken cells, light cells next to dark cells (Figure 23), widening of the Space of Disse, changes in cell shape, changes in the rounded shape of the nucleus of the parenchymal cells, condensation of chromatin[19], relocation or disappearance of subcellular components (such as endothelial fenestrae[6]), swollen mitochondria, collapsing and blebbing (Figure 24) of cell membranes and vesicle formation in intercellular spaces.

With regard to the occurrence of gaps larger than fenestrae in the endothelial lining (Figure 15) a lot of discussion has taken place[22,23]. Indirect proof of their artifactual nature is given by the fact that, in intact animals, endothelial fenestrae have an apparent sieving effect on, for example, adenoviral vectors of 93 nm used for gene transfer[35,36]. The appearance of large gaps in the sinusoidal lining can result from osmolarity problems, from destabilization of the cytoskeleton or from the use of a high perfusion pressure during the washing and subsequent glutaraldehyde fixation during the perfusion-fixation procedures[28,34].

Other subtle artifacts are caused by a process often

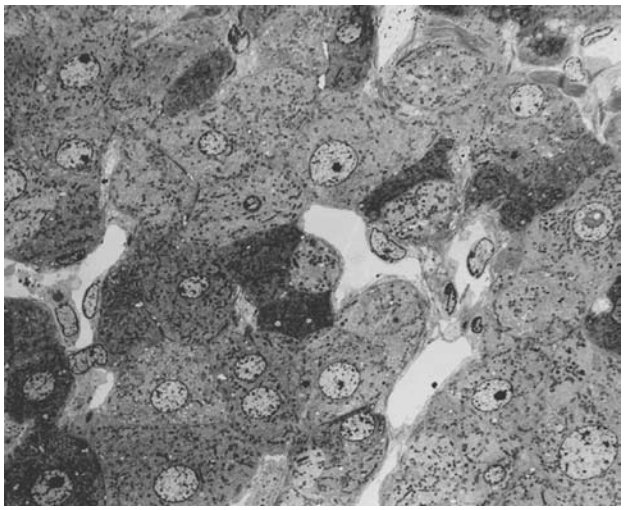

Figure 23 TEM micrograph of an injection-fixed human liver wedge biopsy at 700 × magnification, which shows the presence of dark and light cells next to each other. It is assumed that the differences in density reflect differences in fixation, which often occur in bad fixation.

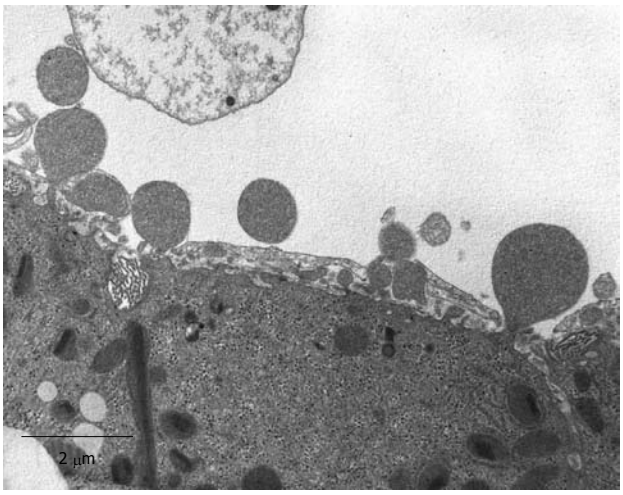

Figure 24 TEM micrograph of an injection-fixed human liver wedge biopsy, which shows the presence of blebbing, which occurs when cells survive in bad conditions. Incomplete fixation is thought to be the cause. Blebs are either swollen microvilli or originate from the peripheral cytoplasm of parenchymal cells. Original magnification 7900 ×.

referred to as over-fixation or "weekend fixation". People sometimes store their precious samples for hours, days or even weeks in glutaraldehyde fixative. Typical for those preparations is that they are rich in free vesicles that seem to form from loose phospholipids derived from the cell membrane. Conversely, blebbing of living parenchymal cells occurs at low oxygen and glutaraldehyde concentrations (Figure 24). Related to this is the clumping of individual glycogen inclusions, poorly staining cell membranes, and failure to achieve staining of glycogen in parenchymal cells. With regard to the transport of material between laboratories, we have good experience of sending samples in 70% ethanol by fast courier services, which are able to deliver between different continents within 1 or 2 d.

How does one assess the outcome of properly fixed liver tissue? In order to distinguish good quality of fixation of the liver, we recommend the following criteria: (1) sinusoids should be open; (2) plasma and blood cells should be practically absent in sinusoids; (3) similar cell types should show similar images; (4) endothelial fenestrae should be present; (5) bile canaliculi (especially in the periportal area) should be open[6,8,22,23]; and (6) nuclei of parenchymal cells should be round (When nuclei of parenchymal cells are elliptic, the nuclei are compressed in the direction of cutting in the ultramicrotome).

The following criteria can be use to distinguish bad fixation: (1) sinusoids are collapsed or largely destructed and still filled with plasma and blood cells; (2) dark and light cells occur next to each other; (3) different images of similar cells; (4) endothelial fenestrae are absent; (5) bile canaliculi are collapsed; and (6) irregularly shaped nuclei of parenchymal cells.

Fahimi[5] has immersed thin slices of perfusion-fixed liver tissue into distilled water. When they change to a white color, the fixation is insufficient. This is a simple, rapid and objective test for good fixation.

Although this paper focuses mainly on the study of ultrathin liver sections with TEM, SEM is also a powerful tool to assess the quality of perfusion-fixed liver tissue. The abundant presence of red blood cells within sinusoids is an indicator of improper perfusion. Sometimes investigators unwarily apply unrelated or unsuitable perfusion or fixation procedures that are fine-tuned for specific applications, tissues, species or even are not applicable for animal tissue material, such as microbial and plant sample preparation protocols. Animal tissue and their cell components have a typical osmotic pressure of 320 mOsmol. Since the osmolarity of the glutaraldehyde component of the fixative seems to be less important[19,37], the osmolarity of the buffers should match the osmotic values of the tissue. Isotonic solutions that include the osmotic pressure of glutaraldehyde have a swelling effect on cells[37]. The protocols described in this review have contributed to the success of EM studies in several groups. The composition of the fluids applied reports the use of sucrose, which is added to a 0.1 mol/L sodium cacodylate buffer to correct its osmotic value to 320 mOsmol.

In vitro perfusion of whole livers has been used often to study preservation conditions of livers for transplantation, or metabolic and physiological processes. It is important to note that perfusion fixation fits well into such schemes and provides essential information about the condition of those livers at the end of an experiment. In addition, perfusion can also be used to incubate the tissue for cytochemical reactions of enzymes, epitopes, and all other reactive elements within the tissue.

CONCLUSION

In a clinical environment, the immersion-fixed needle biopsy is an important standard. The role of needle biopsies in diagnosis, prognosis and management of patients with liver disease[3] makes the needle biopsy a gold standard,

notwithstanding immersion fixation, paraffin embedding, thick 5-μm sections, and the use of low-magnification LM. Together with immunological techniques, specific staining and the professional training of pathologists, needle biopsies fulfill clinical needs. Pathological diagnosis[38] uses pattern recognition in tissues that reveal conditions such as steatosis, inflammation, hyperplasia and neoplasia. EM seems to be of limited or no use in diagnosis[3], in contrast to its use in research. However, EM still has a potential value in a clinical environment.

However, at the other end of the spectrum, there is a group of scientists that knows that perfusion fixation, plastic embedding and the use of EM provides details about cells and tissues down to the nanometer level. Surprisingly, EM does not seem to succeed in helping pathologists to improve further their diagnosis with data derived at this supramolecular level. One of the key elements in this process is, according to the present authors, the lack of use of perfusion fixation for the study of liver tissue from patients. Indeed, we suppose that applying this type of fixation will provide evidence that might be used to the advantage of patients, for understanding the pathogenesis of certain diseases. This was the motivation for writing this review; to summarize the techniques and bring them to the attention of those involved in the process of using microscopic observations to support diagnosis and prognosis of liver diseases. There seems to be a gap between the use of low-resolution LM observations on immersion-fixed, paraffin-embedded, 5-μm sections and high-resolution microscopy of perfusion-fixed tissue. We hope that this review might help to bridge that gap. Essential to this approach is the recognition of the fact that liver tissue should be fixed at the cellular level with fluids that are as close to physiological and physical conditions as possible.

A good fundamental knowledge of the fine structure and histology of the normal liver is needed because some experimental conditions, pathological processes and severe liver diseases result in outcomes comparable to bad fixation. Although it is difficult to decide between genuine and artifactual structures in normal liver, the decision becomes even more difficult when disease conditions are added to the process.

Abstract

Acute pancreatitis (AP) is a common disease, which usually exists in its mild form. However, in a fifth of cases, the disease is severe, with local pancreatic complications or systemic organ dysfunction or both. Because the development of organ failure is the major cause of death in AP, early identification of patients likely to develop organ failure is important. AP is initiated by intracellular activation of pancreatic proenzymes and autodigestion of the pancreas. Destruction of the pancreatic parenchyma first induces an inflammatory reaction locally, but may lead to overwhelming systemic production of inflammatory mediators and early organ failure. Concomitantly, anti-inflammatory cytokines and specific cytokine inhibitors are produced. This anti-inflammatory reaction may overcompensate and inhibit the immune response, rendering the host at risk of systemic infection. At present, there is no specific treatment for AP. Increased understanding of the pathogenesis of systemic inflammation and development of organ dysfunction may provide us with drugs to ameliorate physiological disturbances.

INTRODUCTION

Acute pancreatitis (AP) is a common disease though its incidence varies considerably in different countries from 5 to more than 100 per 100 000 inhabitants/year[1-5]. AP is a disease with wide clinical variation. Most of the patients suffer from mild disease but in about 20% of the cases the patient develops a severe form of the disease, with a mortality of 7%-15%[1,6,7]. The major cause of death is organ failure which complicates severe AP in 20%-80% of the cases[8,9].

AP has many distinct etiologies, though approximately 80% of all cases are caused by either gallstones or alcohol[10]. The frequency of different etiologies varies markedly in different countries. In Finland, alcohol is the causative factor in about 70% of the cases and the incidence of AP correlates with the rate of alcohol consumption[11].

Prognosis of severe AP has improved mainly because of efficacious conservative treatment in intensive care units. Also the correct timing of surgery is important but is indicated only for infected organized pancreatic necrosis when percutaneous drainage techniques are ineffective[12]. In recent years, many minimally invasive

techniques, for example endoscopic and laparoscopic approaches, have been introduced to avoid the need for open necrosectomy[13]. However, in severe AP the incidence of intra-abdominal hypertension is 60%-80% and in some cases necessitates surgical decompression in the early phase of the disease[14]. The use of antimicrobial drug therapy does not protect against infected necrosis or reduce mortality in severe AP[15]. A factor which may affect the outcome is early endoscopic retrograde cholangiopancreatography (ERCP) in biliary AP with biliary obstruction[16]. Thus, despite extensive research during the recent decades, no mode of treatment has been developed that could dramatically improve the outcome of severe AP.

INFLAMMATORY RESPONSE IS SIMILAR IN AP AND SEPSIS

Previously, AP was considered to be a disease of the pancreas. Nowadays, however, there is strong evidence for systemic effects of the disease. The mechanisms of systemic inflammation resulting in organ failures are much alike in severe AP and in, for example, severe burn injury, multitrauma or sepsis[17] (Figure 1). Thus, a considerable amount of research data gained, for example, in sepsis studies could be applicable also in severe AP.

The initial phase of AP involves triggering events that lead to premature activation of pancreatic proteases as a result of intracellular co-localization of the digestive and lysosomal enzymes. This leads to disruption of the acinar cells[18-20]. Then, activated enzymes escape into the interstitium of the pancreas and cause pancreatic autodigestion[21,22]. Furthermore, pancreatic damage is followed by activation of local inflammatory cells and various inflammatory mediators (cytokines) (Figure 1). Localized inflammation is the body's initial physiologic protective response, which is generally strictly controlled at the site of injury. Loss of the local control results in excessive uncontrolled activation of inflammatory cells and mediators. This response is defined as systemic inflammatory response syndrome[23]. Proinflammatory cytokines, tumor necrosis factor-α (TNF-α) and interleukin-1β (IL-1β) are released *via* portal vein and lymph fluid drainage to the circulation[24]. In addition, the production of cytokines enhances proinflammatory signals. IL-6 stimulates the synthesis of acute phase proteins (i.e. C-reactive protein and procalcitonin) in the liver[25]. Proinflammatory cytokines activate the vascular endothelium in the whole body, which leads to enhanced leakage of the capillary veins and triggers migration of leukocytes into tissues. promoting activation of coagulation cascades. Circulating neutrophils and monocytes become activated, as evidenced by the increased expression of adhesion molecules (e.g. CD11b), and release their proteolytic enzymes and oxygen radicals, which damage vascular endothelial cells and organ parenchymal cells[26]. Enhanced amounts of tissue fluid together with impaired microcirculation lead to lack of oxygen, which results in dysfunction of vital organs and, ultimately, in organ failure[27,28]. While lungs and kidneys have a wide capillary bed, they are especially susceptible to phlogistic mediators inducing end organ injury.

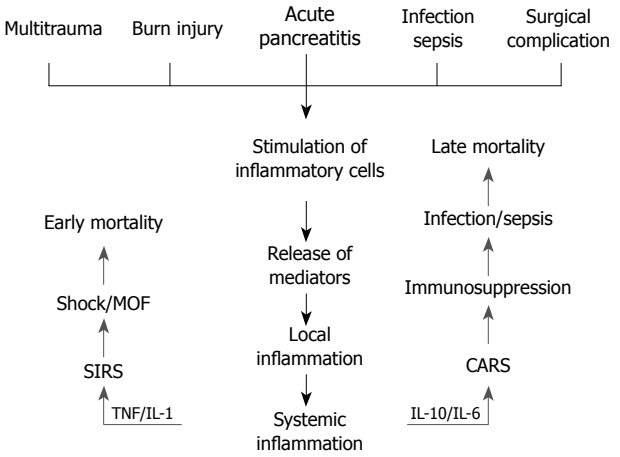

Figure 1 Two-phase hypothesis of development of multiorgan failure. MOF: Multiple organ failure; SIRS: Systemic inflammatory response syndrome; TNF: Tumor necrosis factor; IL: Interleukin; CARS: Compensatory anti-inflammatory response syndrome.

ANTI-INFLAMMATORY RESPONSE

Systemic inflammation in AP is concomitantly associated with rapidly-strengthening compensatory anti-inflammatory response syndrome (CARS)[29,30]. An anti-inflammatory response may be sufficient to control the systemic inflammatory reaction, a sign of good prognosis. However, CARS may be excessive leading to immune deficiency or suppression, which renders the host susceptible to secondary infections. In AP, an increased number of infections has been observed in a later stage of the disease[31], i.e. at the phase of immune suppression.

In immunosuppression, monocytes are characterized by a markedly reduced human leukocyte antigen-DR (HLA-DR) expression, and a profound reduction of their ability to produce proinflammatory cytokines, for example TNF-α[32,33]. Monocytes with low HLA-DR density show impaired antigen presentation capacity[34,35]. IL-10, the most potent anti-inflammatory cytokine, is responsible for the decreased monocyte HLA-DR expression[36]. IL-1 receptor antagonist (IL-1ra) and IL-6 are also important anti-inflammatory cytokines. IL-1ra binds competitively to the IL-1 receptor and blocks IL-1 mediated responses[37]. Previously, IL-6 was regarded as a proinflammatory cytokine. However, some years ago it was shown to act predominantly as an anti-inflammatory cytokine and, for example prevents synthesis of IL-1β and TNF-α[38].

Altered cellular immune function in AP was first reported by García-Sabrido *et al*[39] in 1989 when they showed a correlation between poor outcome and anergy to delayed-type hypersensitivity testing. In addition to proinflammatory mediators[40,41], the IL-10 plasma level has also been shown to be increased in severe AP[42] and predicts development of organ failure in the very early phase of AP[43]. In AP patients, decreased monocyte HLA-DR expression

is associated with development of secondary infections[30]. Decreased monocyte HLA-DR expression has also been shown to predict development of organ failure[44] and a fatal outcome[45]. In AP patients, high plasma levels of IL-10 and IL-6 correlate with decreased monocyte HLA-DR expression[30]. IL-10 and IL-6 can be measured by a chemiluminescent immunoassay that could be available on a 24-h basis at the hospital emergency unit. Flow cytometric measurement of monocyte HLA-DR expression can be used as a routine clinical test and provides results within 30-60 min of sampling. In addition to monocyte functions, there are changes also in lymphocyte count and proportion of T-helper cells that can be measured by flow cytometry in severe AP[46].

DEVELOPMENT OF ORGAN FAILURE WORSENS PROGNOSIS

The classification of AP severity is based on a consensus conference held in Atlanta in 1992[47]. According to the Atlanta classification, AP is classified as severe if systemic and/or local complications (for example pancreatic necrosis, pseudocyst or abscess) are present. Otherwise, AP is classified as mild. Organ failure occurs in half of patients with pancreatic necrosis[48].

The most common organ failure in severe AP is respiratory failure. Also other organs may fail, e.g. renal, hepatic, cardiovascular, digestive, neurologic, coagulation[17] or endocrine or immunologic systems[49]. Failure of different organs has different effects on the prognosis of the disease. Mortality rates in severe AP patients with respiratory, renal, and hepatic failure are 43%, 63%, and 83%, respectively[50]. Lately, the Atlanta classification has been criticized because it does not separate organ failure from local complications[51]. Furthermore, the definition of organ failure in the Atlanta classification is so wide that it includes many patients with a good prognosis. To overcome these shortcomings we have categorized the patients into 3 groups: patients who develop vital organ failure, patients who meet the Atlanta criteria for severe AP but do not develop organ failure, and patients who neither meet the Atlanta criteria nor develop organ failure[41,43,44,52,53]. Indeed, in terms of mortality and morbidity, the organ failure group is the critical one[8,9] regardless of the presence or absence of necrosis of the pancreas[54]. Organ failure often develops early in the course of AP. As many as 37%-76% of AP patients who will develop organ failure may have it already at admission[55,56] or develop it during the first 24 h[44]. Also a difference between transient (< 48 h) and persistent (> 48 h) organ failure has been noted[57,58]. Patients with transient organ failure have an uneventful recovery but persistent organ failure predicts death and local complications.

The mortality of AP is biphasic. Half of the mortality takes place during the first week of the disease and is related to severe multiorgan failure[6]. If the patient survives the first week, he/she may get infectious complications, such as sepsis, with worsening organ dysfunction. These events increase mortality during the second phase of the disease[6]. Knowing the biphasic nature of the mortality is highly relevant to treatment and research of novel treatment modalities in severe AP because the first peak occurs during on-going pro- and/or anti-inflammatory responses whereas the second peak occurs at the phase of immune suppression.

IMMUNE-MODULATION THERAPY

Current treatment of AP remains unspecific and supportive and is mainly targeted to aggressively prevent systemic complications by intensive care. Delayed admission to the intensive care unit results in a 4-fold excess in mortality[59]. Therefore, early identification of patients who develop a severe AP with organ failure is essential for improved prognosis by earlier intervention with appropriate resuscitation in specialized hospitals.

At present, no specific medical therapy for AP exists. Several experimental studies and clinical trials have attempted to discover medical treatment to inhibit the systemic inflammatory reaction and, thus, the development of multiple organ dysfunction. In a rat model of AP, in contrast to expectations, anti-TNF antibody was found to be harmful[60]. However, when given prophylactically anti-TNF antibodies decreased the severity of AP[61]. In experimental AP, block of the cytokine cascade at the level of the IL-1 receptor with a specific antagonist (IL-1ra) decreased pancreatic damage[62]. Furthermore, anti-inflammatory therapy with an IL-10 agonist[63,64] and an anti-IL-8 antibody[65] have shown beneficial effects. In addition, anti-adhesion therapy with anti-intercellular adhesion molecule-1 antibody ameliorates lung injury in mice with severe AP[66]. Platelet-activating factor antagonist lexipafant was promising in the first clinical trials[67,68] but in the final trial the results were disappointing[55]. In the complex network of inflammatory responses, a combination therapy to inhibit several proinflammatory agents could be useful.

In clinical AP, patients are typically admitted to the emergency unit in a fairly late stage of the disease when organ failure is about to develop or may already be present. Then the patient has CARS or probably even immunosuppression, initiation of anti-inflammatory therapies could worsen the prognosis. Thus, the therapeutic window for anti-inflammatory therapies may be too narrow in clinical practice[55]. The problem of early-occurring organ dysfunction in clinical trials is highlighted by the lexipafant study[55], in which 44% of the patients met the criteria of organ failure prior to receiving the first dose of the study drug, an inhibitor of platelet activating factor, or placebo.

In anergic septic patients immunostimulation with interferon-γ has proven to be beneficial[33]. In a clinical study of septic patients, granulocyte macrophage stimulating factor (GM-CSF) treatment was well tolerated and increased monocyte HLA-DR expression and TNF-α production capacity[69]. In severe AP, there is a defect in monocyte function. However, priming of monocytes *in vitro* by interferon-γ and GM-CSF increased HLA-DR expression and restored lipopolysaccharide-induced TNF-α secretion[70]. Yet, it is of note, that immunosup-

pression may be confined to the peripheral blood while the lungs and the other end organs may still be in the pro-inflammatory stage. Therefore, immunostimulatory treatment must be used cautiously and clinicians should have the means to monitor the patients' immunoinflammatory state. Currently, the best method is measurement of monocyte HLA expression by flow cytometry. It would be optimal to depress the pro-inflammatory reaction in the patients at risk of excessive immune suppression so that inappropriate CARS would be prevented. An interesting question is whether the patients in whom a deep immune suppression develops, benefit from antimicrobial prophylaxis, along with immunostimulation.

COAGULATION SYSTEM IS RELATED TO INFLAMMATION

In systemic inflammation, several proinflammatory cytokines activate the coagulation process in the body[71] and activated endothelial cells seem to have an important contributing role in that process. Systemic coagulation activation results in thrombosis in small and middle-sized vessels in many organs, resulting in disseminated intravascular coagulation (DIC), that leads to decreased blood circulation of organs and organ failure. In DIC, consumption of platelets is increased resulting in thrombocytopenia which is a common sign of severe AP[72]. The D-dimer level has been shown to be high in severe AP and serves as a marker of DIC[73]. In experimental severe AP, it was demonstrated that microcirculatory disorders affecting capillary blood flow, capillary permeability and leukocyte endothelial interaction are present not only in the pancreas but also in the colon, liver, and lungs[28].

Protein C is a natural anticoagulant in blood and seems to have an essential role in the regulation of the coagulation cascade in inflammation. Protein C is activated by the thrombin-thrombomodulin complex at the endothelial surface[74]. Activated protein C (APC) inactivates factor V and factor Ⅷ and inhibits thrombin generation. In experimental studies, APC has shown also to have anti-inflammatory effects[75,76]. Septic patients have a decreased protein C level in blood and it correlates with poor prognosis[77]. In meningococcemia patients with DIC, treatment with APC has prevented development of organ failure, and decreased mortality[78]. In patients with severe sepsis, treatment with APC was safe and resulted in decreased mortality[79,80]. In severe AP, protein C pathway defects have been shown to be associated with development of organ failure[81]. In a rat model of severe AP, APC treatment reduced inflammation in the pancreas and lungs and improved survival[82]. These findings encouraged us to perform a placebo-controlled clinical trial of APC in the treatment of severe AP at the Helsinki University Central Hospital.

FUTURE DIRECTIONS

Deeper understanding of the cell biology and physiology of AP is necessary to permit the design of effective interventions concerning the inflammatory response process. Improved methods to accurately identify those patients with severe AP in need of monitoring and treatment in intensive care units are urgently needed. A means to monitor the state of the immune response (monocyte HLA-DR expression) during hospitalization of severe AP patients is important. Whether monitoring signaling pathways of circulating leukocytes, such as nuclear factor κB, signal transducers and activators of transcription and members of the mitogen activated protein kinase family helps us to find the patients at risk for secondary infections and, thus, late organ failure is at present under research[83]. Future treatment strategies will probably focus on combination therapy aimed at suppressing excessive activation of the inflammatory response and preventing concomitantly overcompensating CARS and eventually immunosuppression. Because AP shares many features of sepsis, an urgent question is whether APC provides a means to alleviate severe AP, as it does in patients with life-threatening sepsis. Finally, the analysis of signaling patterns of leukocytes may reveal novel therapeutic targets in severe AP.

Abstract

AIM: To investigate the effects of the chemokine stromal cell-derived factor-1 (CXCL12) receptor (CXCR4) antagonist AMD3100 on colonic inflammation and epithelial barrier in dextran sulfate sodium (DSS)-induced colitis in mice.

METHODS: Experimental colitis was induced by administration of 5% DSS for 7 d, and assays performed on intestinal segments from the ileocecal valve to the anus. Colonic morphology was examined by hematoxylin and eosin staining. Colonic cytokines were determined by enzyme-linked immunosorbent assay. Myeloperoxidase (MPO) activity (indicator of inflammatory infiltration) was observed spectrophotometrically. Gut permeability was assessed by mucosal-to-serosal clearance of fluorescein isothiocyanate-conjugated dextran 4000 (FD4) in everted gut sacs. The apoptosis of colonic epithelium was assessed by Hoechst-33342 staining. To further elucidate the role of CXCR4 in colonic inflammation, we also investigated the effect of AMD3100 on migration and cytokine production of isolated peripheral blood mononuclear cells (PBMCs).

RESULTS: DSS-induced colitis was characterized by morphologic changes, as well as increased colonic cytokines, inflammatory infiltration, epithelial apoptosis, and intestinal permeability in mice. In AMD3100-treated mice, epithelial destruction, inflammatory infiltration, and submucosal edema were markedly reduced; colonic tumor necrosis factor-α (TNF-α), interleukin-6 (IL-6) and interferon-γ (IFN-γ) levels, as well as MPO activity were significantly decreased. Increased intestinal permeability in DSS-treated mice was significantly reduced by AMD3100. The number of apoptotic cells in colitis mice was markedly increased after DSS administration, and decreased when treated with the CXCR4 antagonist AMD3100. In pre-activated PBMCs, CXCL12 stimulation significantly increased the migration of PBMCs, and was inhibited by AMD3100. Moderately increased TNF-α, IL-6, and IFN-γ from CXCL12-treated PBMCs were also reduced by AMD3100.

CONCLUSION: The CXCR4 antagonist AMD3100 exerts therapeutic effects on experimental colitis by inhibiting colonic inflammation and enhancing epithelial barrier integrity.

INTRODUCTION

Ulcerative colitis (UC) is a chronic inflammatory bowel disease (IBD), clinically characterized by bloody diarrhea, fever, weight loss, and anemia[1,2]. Previous studies demonstrated that pathogenesis of UC involves the interaction of environmental, genetic, microbial, and immune factors, which can initiate an abnormal immune response, and consequent intestinal inflammation[3,4]. Uncontrolled local inflammation disrupts the epithelial lining, resulting in mucosal edema and ulceration, and even crypt abscess in the bowel wall[5]. As in other inflammatory processes, polymorphonuclear leukocytes infiltrating into colonic mucosa are believed to be the main source of cytokine and inflammatory mediators[6]. Chemokines, including growth-regulated oncogene-α and interferon-γ-inducible protein-10, which are expressed on various cells of the intestinal tissues, have been reported to regulate the recruitment of inflammatory cells[7,8]. Block of these chemokines or their receptors significantly attenuates intestinal inflammation and mucosal damage in UC animals, suggesting a pivotal role of chemokines in the pathogenesis of UC[2,8].

The chemokine stromal cell-derived factor-1 (CXCL12) is firstly characterized as a pre-B cell growth stimulating factor and its specific receptor is chemokine stromal cell-derived factor-1 receptor (CXCR4), which also functions as an entry receptor for human immunodeficiency virus[9]. The CXCL12/CXCR4 chemokine axis has an important role in the development of cardiovascular, hematopoietic, and central nervous systems[10,11], and is also involved in several inflammatory diseases such as rheumatoid arthritis, acute lung injury, and sepsis[12-15]. Recent studies demonstrated that CXCL12 and CXCR4 are constitutively expressed on intestinal epithelial cells, lamina propria T cells, and peripheral blood T cells of control patients, and the expression is increased in those of UC patients[16,17]. Block of CXCR4 significantly ameliorates murine experimental colitis[4], indicating a possible role of this chemokine axis in intestinal inflammatory response.

In UC patients, increased number of apoptotic epithelial cells is detected throughout the crypt[18]. Local massive apoptosis of epithelial cells disturbs the epithelial barrier, which can facilitate the infiltration of inflammatory cells, and aggravate mucosal damage[19]. Whether the CXCL12/CXCR4 chemokine axis plays a role in epithelial apoptosis and barrier function, however, needs to be further defined.

In the present study, we firstly assessed the effect of a CXCR4 antagonist, AMD3100, on dextran sulfate sodium (DSS)-induced colitis in mice. Morphology, colonic cytokines, myeloperoxidase (MPO) activity (an indicator of inflammatory infiltration), gut permeability, and epithelial apoptosis were all examined in the first series. To further elucidate the role of the CXCL12/CXCR4 interaction in colonic inflammation, we also investigated the effect ofAMD3100 on isolated peripheral blood mononuclear cells (PBMCs). In this series, cell migration and cytokine production were assessed.

MATERIALS AND METHODS

Animals

Female BALB/c mice (9 wk of age, weighing 20-22 g) were obtained from the Animal Facility of the Jinling Hospital (Nanjing, China). Animals were housed under controlled temperature, humidity and day-night cycles, with free access to standard laboratory feed and water. The Animal Studies Ethics Committee of Jinling Hospital approved all of the experiments.

Experimental design

For the induction of colitis, mice were given 5% DSS (5000 daltons; obtained from Wako Pure Chemical Industry, Japan) in their drinking water for 7 d. Normal control mice received regular drinking water throughout the experiment. The CXCR4 antagonist, AMD3100, was obtained from Sigma (St. Louis, MO, USA). Twenty-five micrograms of AMD3100 dissolved in 200 μL of phosphate-buffered saline (PBS) or 200 μL of PBS alone were administered intraperitoneally once daily during the study period. Eight mice were studied in each experimental group. On day 8, all mice were anesthetized with intraperitoneal administration of ketamine (50 mg/kg) and acepromazine (2 mg/kg), and the intestinal segments from the ileocecal valve to the anus (5-6 cm in length) were collected for subsequent assays.

Morphological examination

The distal segments of the colon (2 cm from the anal verge) were washed in PBS, fixed in 10% neutral buffered formalin, and embedded in paraffin wax. Five micrometers sections were deparaffinized with xylene, stained with hematoxylin and eosin, and examined by 2 experienced pathologists in blinded fashion. The following morphological criteria were considered: score 0, no damage; score 1 (mild), focal epithelial necrosis; score 2 (moderate), diffuse necrosis of the villi; score 3 (severe), necrosis with neutrophil infiltrate in the submucosa; score 4 (highly severe), widespread necrosis with massive neutrophil infiltrate and hemorrhage[1].

Measurement of colonic cytokines and MPO

The colonic levels of tumor necrosis factor-α (TNF-α), interleukin-6 (IL-6), and interferon-γ (IFN-γ) were evaluated using commercial colorimetric kits (Jingmei Biotech, Beijing, China) according to the manufacturer's instructions. The tissue homogenate enzyme-linked immunosorbent assay was determined with respect to the concentration of protein, and expressed as pg/mg tissue protein.

Sequestration of leukocytes within the colon was evaluated by measuring tissue MPO activity[2]. Briefly, tissue samples were homogenized with 0.5% hexadecyltrimeth-

ylammonium bromide (Sigma, ST. Louis, MO, USA) in 50 mmol/L phosphate buffer (pH 6.0). The homogenate was sonicated for 10 s, freeze-thawed 3 times, centrifuged at 14000 rpm for 15 min, and the resulting suspension was used for assay. The assay mixture consisted of 20 μL of supernatant, 10 μL of tetramethylbenzidine (final concentration 1.6 mmol/L), and 70 μL of H_2O_2 (final concentration 3.0 mmol/L). MPO activity was assessed photometrically at 630 nm. The results were expressed with respect to the concentration of protein, and expressed as the activity per mg protein of the tissue (U/mg protein).

Gut permeability measurement

Intestinal permeability was assessed by the mucosal-to-serosal clearance of fluorescein isothiocyanate-conjugated dextran (4000 daltons, FD4; obtained from Sigma, St.Louis, MO, USA) in everted gut sacs, as described in previous studies[20,21]. Intestinal segments from the ileocecal valve to the anus were excised, and prepared in ice-cold modified Krebs-Henseleit bicarbonate buffer (KHBB contained in mmol/L: HEPES 10, NaCl 137, KCl 5.5, $NaHCO_3$ 4.2, Na_2HPO_4 0.3, $KHPO_4$ 0.4, $MgSO_4$ 0.4, $MgCl_2$ 0.5, $CaCl_2$ 1.3, glucose 19.5). The intestinal segment first underwent lavage with 3 mL of PBS to remove fecal material, and was then closed at one end with a 4-0 silk ligature. The gut sac was everted using a thin metal rod, then connected to a 1 mL syringe containing 0.4 mL of the KHBB solution, and secured with a 4-0 silk ligature 4 cm from the tip. The everted gut sac was gently distended with 0.4 mL of KHBB, suspended in a 100 mL beaker containing FD4 (20 μg/mL) in KHBB, maintained at 37℃ in a water bath, and continuously bubbled with a gas mixture containing 95% oxygen and 5% CO_2.

At the beginning of the incubation, a 1 mL sample was withdrawn from the beaker to determine the initial external (mucosal surface) FD4 concentration (FD4muc). After a 30-min incubation period, the gut sac was removed from the beaker, its diameter (D) and length (L) were measured, and the fluid on the serosal side was aspirated into the syringe to determine the FD4 concentration (FD4ser). The serosal and mucosal samples were centrifuged for 10 min at 1000 *g*. One hundred microliters of the supernatant was diluted with PBS (900 μL), and fluorescence was measured (λex = 492 nm, slit width = 1.5 nm; λem = 515 nm, slit width = 10 nm) in a spectrofluorometer (model F-7000, Hitachi, Japan). The mucosal-to-serosal clearance of FD4 was calculated using the following equations:

Mucosal surface area (A) = πLD.

Mass of FD4 in the gut sac after 30 min incubation (M) = (FD4ser) × 0.4.

Mucosal-to-serosal permeation rate of FD4 (PR, ng/min) = M/30 min.

Mucosal-to-serosal clearance of FD4 (C, nL/min per cm^2) = (PR/FD4muc)/A.

Assessment of epithelial apoptosis

Apoptosis of the colonic epithelium was assessed using a *nuclear* stain Hoechst-33342 (Sigma, St.Louis, MO, USA). Briefly, tissue sections (5 μm) were dewaxed with xylene and graded alcohols, and finally washed in tap water. Endogenous peroxidase activity was blocked by 3% (v/v) H_2O_2, and the antigen was recovered by microwave in 0.1 mol/L PBS (pH 7.2). Sections were immersed in Hoechst dye (working concentration 5 μg/mL) for 5 min, and then washed in PBS, 5 min for 3 times. The signals were visualized by a fluorescence microscope (model IX71, Olympus, Japan), and the number of positive cells/high power field was counted in 5 fields for each section as described by Cuzzocrea *et al*[22].

Isolation and stimulation of PBMCs

For isolation of PBMCs, 12 normal mice were anesthetized with intraperitoneal administration of ketamine (50 mg/kg) and acepromazine (2 mg/kg). Blood samples were obtained from the inferior cava vein by direct puncture. PBMCs were isolated by Ficoll-Hypaque plus density gradient centrifugation. The isolated PBMCs were resuspended in F-12K Nutrient Mixture (Invitrogen, Carlsbad, USA) with 10% fetal bovine serum, 100 U/mL penicillin, 100 μg/mL streptomycin, and 100 ng/mL phytohemagglutinin (PHA, activator of PBMCs; obtained from Sigma, St.Louis, MO, USA). Six hours after resuspension, the PBMCs were split into 3 groups (1.5×10^6 cells/mL). Group 1 was cultured in medium with PBS. Group 2 was re-stimulated with 50 ng/mL CXCL12 (Chemicon, MA, USA), and group 3 was pre-treated with 20 μmol/L AMD3100 (30 min before re-stimulation), and then treated with 50 ng/mL CXCL12. The cells were incubated for 24 h, and the cytokine production in supernatant was measured using a colorimetric commercial kit (Jingmei Biotech, Beijing, China) according to the manufacturer's instructions.

For assessment of cell migration, a 24-well transwell migration chamber with 8 μm pores (Greiner Bio-One, Frickenhausen, Germany) was used[23]. The isolated PBMCs was resuspended in serum-free medium with 0.2% bovine serum albumin to an appropriate concentration (1×10^6 cells/mL), then placed in the top chambers of the transwell (200 μL/well). The lower chambers were filled with 600 μL of control medium (containing 2.5% fetal bovine serum) with or without 50 ng/mL of CXCL12. Some of the cells were preincubated with the CXCR4 antagonist AMD3100 (20 μmol/L) for 30 min before being placed in the top chambers. Twelve hours after incubation, PBMCs that had not migrated to the lower chambers were removed from the upper surface of the transwell membrane with a cotton swab. Migrating cells on the lower membrane surface were fixed with methanol, stained with 10% Giemsa, and photographed under a light microscope. Values of integrated optical density (IOD) from the pictures were employed to assess the migration of PBMCs.

Statistical analysis

Results are presented as mean and standard error of the mean ± SE. One-way repeated-measures ANOVA (followed by multiple pair-wise comparisons using the Student-Newman-Kleus method) were used for the analysis of differences between the experimental and control groups. All statistical analyses were carried out using the SPSS version 11.5 for Windows (Chicago, IL, USA), with statistical significance set at $P < 0.05$.

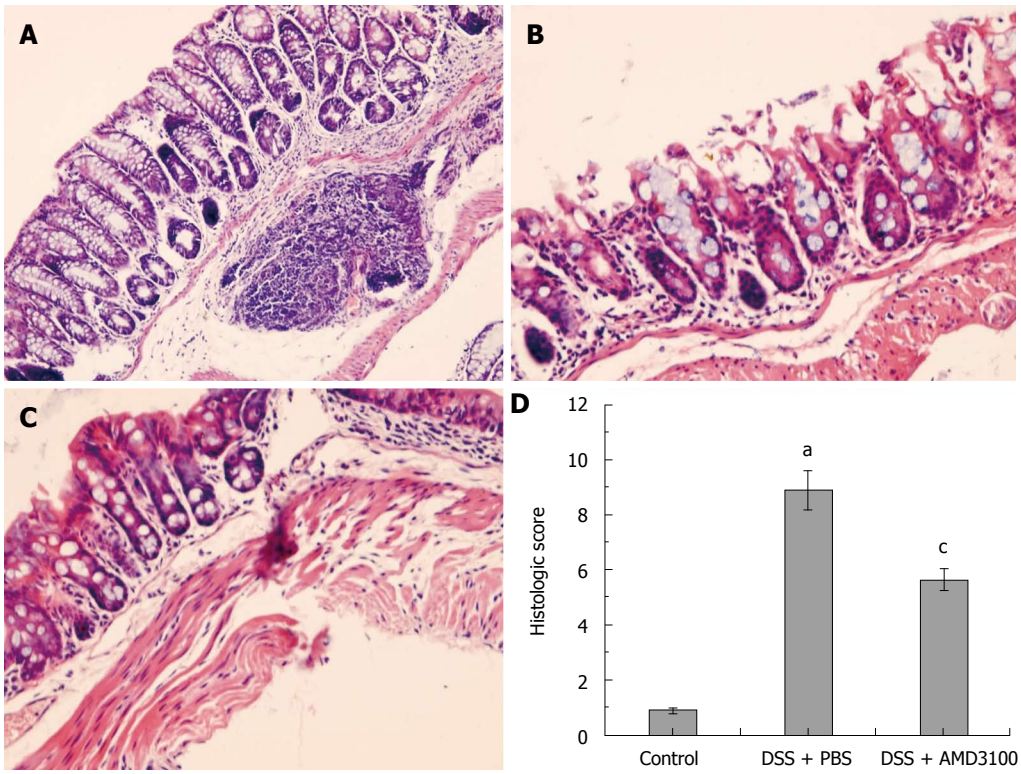

Figure 1 Effects of a chemokine stromal cell-derived factor-1 receptor (CXCR4) antagonist on mucosal damage in mice. Colitis was induced by administration of 5% dextran sulfate sodium (DSS) for 7 d. A: Common colonic morphologic characteristics are observed in tissue sections from control groups; B: Marked colonic injury is observed in tissue sections from the colitis group; C: Treatment with CXCR4 antagonist, AMD3100, significantly attenuates colonic damage; D: The histological score in mice. Eight mice were studied in each experimental group. Results are mean ± SE. $^{a}P < 0.05$ *vs* control group; $^{c}P < 0.05$ *vs* DSS + PBS group. Original magnification, × 200.

RESULTS

CXCR4 antagonist attenuated colonic mucosal damage in DSS-induced colitis

After induction of colitis with DSS, the colonic mucosa showed congestion, erosion, and hemorrhagic ulcerations. Histological findings demonstrated marked epithelial destruction, inflammatory infiltration, crypt distortion, and submucosal edema (Figure 1B). In AMD3100-treated mice, epithelial destruction, inflammatory infiltration, and submucosal edema were markedly reduced as compared with nontreated mice (Figure 1C). No histological alteration was observed in the intestinal segments from control mice (Figure 1A). As a result, the histological score in mice with DSS-induced colitis was significantly higher than that in control mice, and treatment with AMD3100 markedly reduced the histological score in mice with colitis (Figure 1D).

CXCR4 antagonist reduced colonic MPO and proinflammatory cytokines in DSS-induced colitis

Induction of DSS-induced colitis was assessed by histology and local cytokine production. In the present study, we also evaluated the effect of AMD3100 on colonic inflammation. As shown in Figure 2A-C, colonic TNF-α, IL-6, and IFN-γ levels were significantly elevated at 7 d after induction of colitis, as compared with control mice; treatment with AMD3100 markedly reduced colonic cytokines production in mice with colitis.

MPO activity, as a marker of local leukocyte sequestration, was also examined in this study. Figure 2D shows that colonic MPO activity was significantly increased 7 d after induction of colitis; treatment with AMD3100 decreased the colonic MPO level. These findings indicated that AMD3100 could inhibit the recruitment of inflammatory cells into the colonic segment.

CXCR4 antagonist enhanced colonic epithelial barrier in DSS-induced colitis

The mucosal-to-serosal clearance of permeability probe FD4 in everted gut sacs was measured to assess the epithelial barrier. The mucosal-to-serosal passage of FD4 was low in control mice, and the calculated clearance was 9.10 ± 1.10 nL/min per cm^2. DSS-administered mice demonstrated a marked increase in gut permeability, with the calculated clearance reaching 24.18 ± 1.83 nL/min per cm^2. In AMD3100 treated mice, there was a significant reduction in permeability, and the calculated clearance was 14.71 ± 1.43 nL/min per cm^2 (Figure 2E). These findings demonstrated that AMD3100 could enhance the colonic epithelial barrier.

CXCR4 antagonist ameliorated colonic epithelial apoptosis in DSS-induced colitis

According to the manufacturer of Hoechst-33342, the *nuclei* of apoptotic cells stain bright white, and are accompanied by apoptotic fragments, while the *nuclei* of live

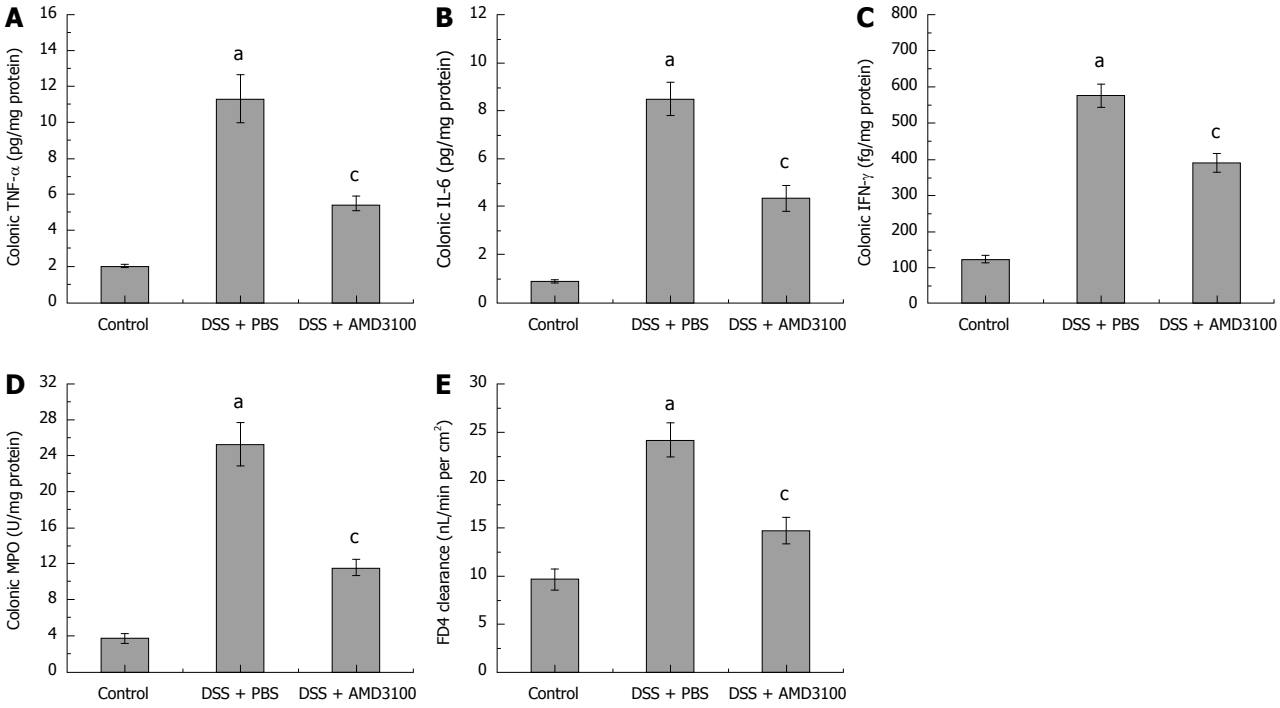

Figure 2 Effects of CXCR4 antagonist on colonic myeloperoxidase (MPO), proinflammatory cytokines, and gut permeability in mice. Colitis was induced by administration of 5% DSS for 7 d. Colonic levels of tumor necrosis factor-α (TNF-α) (A), interleukin-6 (IL-6) (B), interferon-γ (IFN-γ) (C), MPO (D), and FD4 clearance (E) are shown. Eight mice were studied in each experimental group. Results are mean ± SE. $^{a}P < 0.05$ *vs* control group; $^{c}P < 0.05$ *vs* DSS + PBS group.

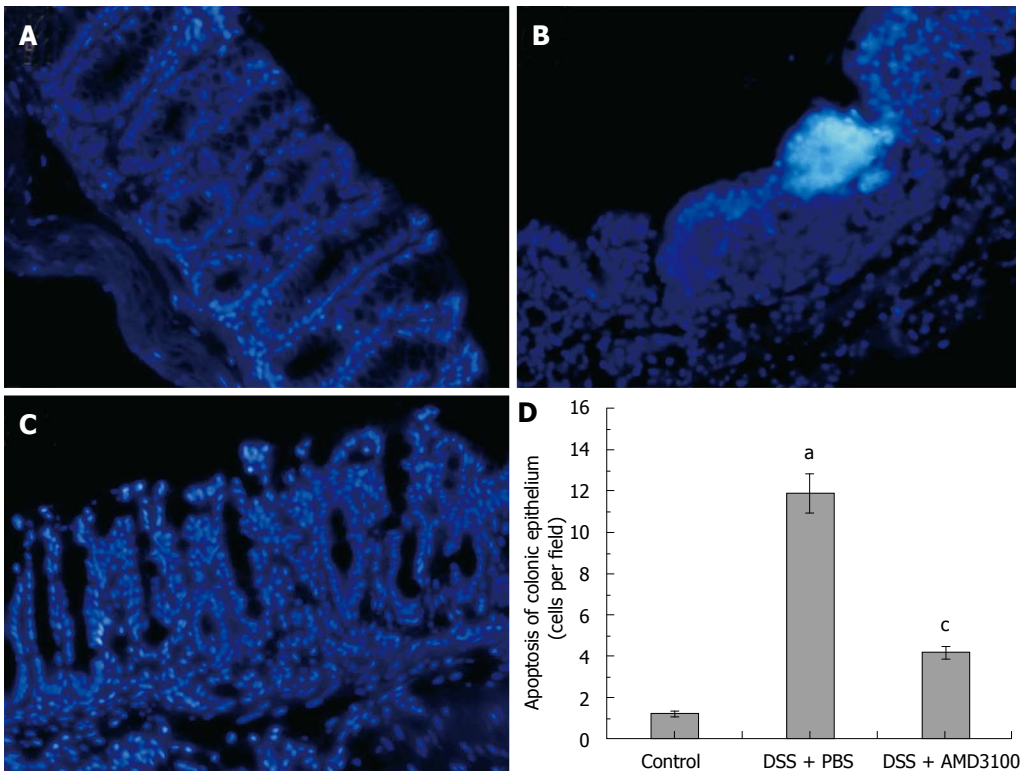

Figure 3 Effects of CXCR4 antagonist on colonic epithelial apoptosis in mice. Colitis was induced by administration of 5% DSS for 7 d. Tissue sections were stained with Hoechst-33342. A: Sporadic apoptotic cells were observed in intestinal segments from the control group; B: Clustered apoptotic cells were observed in tissue sections from the colitis group; C: Treatment with CXCR4 antagonist AMD3100 obviously decreased epithelial apoptosis; D: The numbers of apoptotic cells in intestinal segments. Eight mice were studied in each experimental group. Results are mean ± SE. $^{a}P < 0.05$ *vs* control group; $^{c}P < 0.05$ *vs* DSS + PBS group. Original magnification, × 200.

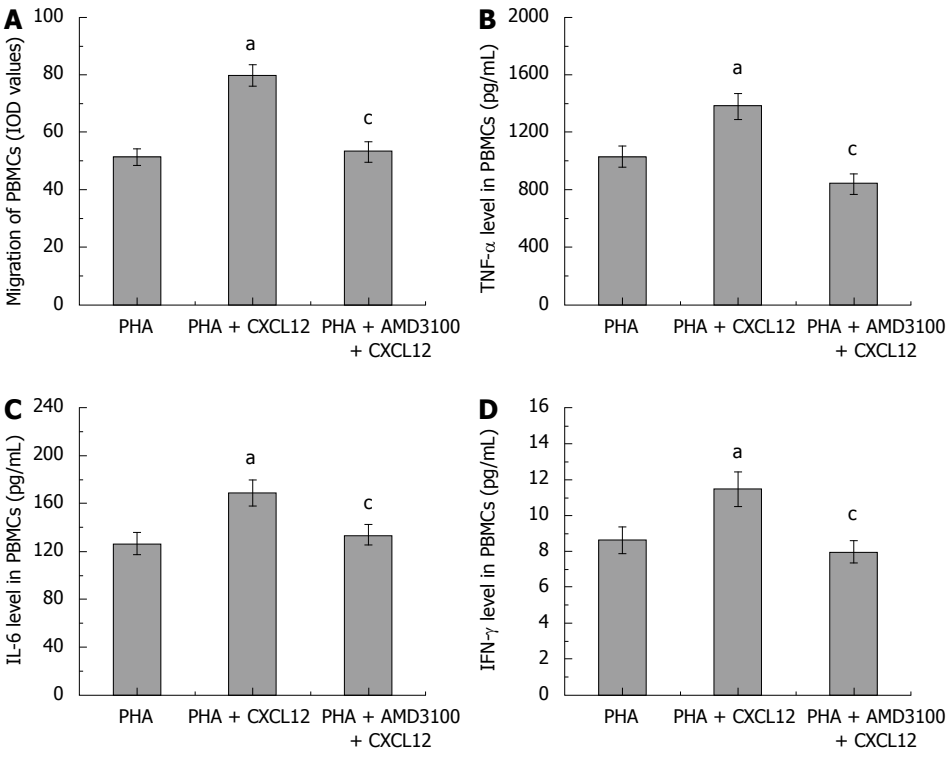

Figure 4 Effects of CXCR4 antagonist on migration and cytokine production of isolated PBMCs. To mimic the *in vivo* inflammatory response, the PBMCs were pre-activated with PHA. Migration of PBMCs (A) and levels of TNF-α (B), IL-6 (C), and IFN-γ (D) in PBMCs are shown. Six wells were studied in each experimental group. Results are mean ± SE. $^{a}P < 0.05$, chemokine stromal cell-derived factor-1 (CXCL12) group *vs* control group; $^{c}P < 0.05$, AMD3100 group *vs* CXCL12 group.

cells are stained as a uniform blue color. As in Figure 3, sporadic apoptotic cells were observed in the intestinal segments from control mice (apoptotic cells were 1.25 ± 0.12 per field). The number of apoptotic cells in the intestinal segments was markedly increased 7 d after induction of colitis, the apoptotic bodies mainly localized in the epithelium (apoptotic cells were 11.98 ± 0.81 per field). However, the presence of apoptotic cells was significantly decreased in the intestinal segments from AMD3100 treated mice (apoptotic cells were 4.23 ± 0.28 per field).

CXCR4 antagonist inhibited migration and cytokine production of isolated PBMCs

To evaluate whether AMD3100, the CXCR4 antagonist, could block PBMC migration, we performed an *in vitro* PBMCs chemotaxis assay. To mimic the *in vivo* inflammatory response, the PBMCs were pre-activated with PHA. The IOD values were employed to assess the number of migrated PBMCs. Figure 4A shows that CXCL12 treatment significantly increased the migration of PBMCs, as compared with the control group, the IOD values being 79.68 ± 3.76 and 51.28 ± 2.97, respectively, and the migration of PBMCs were inhibited by pretreatment with AMD3100 (IOD values 53.27 ± 3.70).

We also measured the cytokine production from isolated and PHA pre-activated PBMCs. As shown in Figure 4B-D, the supernatant levels of TNF-α, IL-6, and IFN-γ from CXCL12-treated PBMCs were moderately higher than that in the control group, and AMD3100 pre-treatment could attenuate the increase in TNF-α, IL-6, and IFN-γ in PBMCs.

DISCUSSION

The present study demonstrated that administration of the CXCR4 antagonist, AMD3100, decreased the severity of DSS-induced colitis in mice, as assessed by morphology, colonic cytokines, epithelial apoptosis, and gut permeability. More importantly, the CXCR4 antagonist also inhibited the migration and cytokine production of activated PBMCs. These results strongly suggest that the CXCR4 antagonist has a therapeutic effect on experimental colitis.

The CXCL12/CXCR4 axis is an efficacious leukocyte chemoattractant, which can attract lymphocytes and mononuclear cells from the bloodstream to the site of inflammation[24,25]. A previous study demonstrated that CXCL12 could promote natural killer cell migration into tissues by stimulating the production of matrix metalloproteinase-1 and subsequent degradation of the extracellular matrix proteins[26]. By provoking activation of protein kinase C, CXCL12 also induced adhesion of monocytes to human umbilical vein endothelial cells[25]. In patients with bursitis or acute lung injury, increased local CXCL12 and CXCR4 expression was associated with aggravated tissue damage, which could be attenuated by CXCL12 or CXCR4 blockade, suggesting a role of the CXCL12/CXCR4 chemokine axis in local inflammation[12-14,27].

Recently, several studies have been performed to investigate the role of the CXCL12/CXCR4 chemokine axis in IBD, particularly in UC. Katsuta *et al*[28] have previously demonstrated that the expression of CXCL12 mRNA in colonic mucosa of UC patients was higher than that in patients with Crohn's disease. Dotan *et al*[17] also reported that CXCL12 and CXCR4 were constitutively expressed on human intestinal epithelial cells (IECs), and were up-regulated in IBD IECs; $CXCR4^{+}$ cells were increased in the lamina propria of IBD patients, and antibodies against CXCR4 or CXCL12 significantly blocked the migration of

lamina propria and peripheral blood T cells, identifying an inflammatory role for the CXCL12/CXCR4 axis in the intestinal mucosa. In patients with refractory UC, increased CXCR4 expression was also observed on peripheral blood T cells[16]. In DSS-induced colitis, both CXCR4 expression on leukocytes and CXCL12 expression in colonic tissue were significantly increased; administration of a CXCR4 antagonist TF14016 ameliorates colonic inflammation in DSS-induced colitis and IL-10 knockout mice, and also reduced TNF-α and IFN-γ production in mesenteric lymph node cells, indicating a possible role of this chemokine axis in the pathophysiology of UC[4].

Consistent with previous reports, our present study also demonstrated marked mucosal damage and inflammatory responses in DSS-induced colitis. MPO activity, as an indicator of inflammatory infiltration, was significantly elevated 7 d after induction of colitis, in parallel with increased colonic TNF-α, IL-6, and IFN-γ. Administration of the CXCR4 antagonist, AMD3100, decreased the histological score, colonic cytokines, and inflammatory infiltration in DSS-induced colitis in mice. These results are in agreement with a previous report that the CXCR4 antagonist, TF14016, could also ameliorate DSS-induced colitis[4].

The intestinal epithelium is a single cell layer that forms the barrier between the body and the luminal gastrointestinal contents[29]. The central role of the intestinal epithelium is to limit access of toxins and microbes to underlying tissues, and intestinal barrier dysfunction has strong potential to result in IBD[30]. Accordingly, our results demonstrated that mice subjected to DSS developed significant intestinal barrier failure, as evidenced by a marked increase in gut permeability to FD4, while AMD3100 administration preserved the intestinal barrier function by reducing gut permeability. Although there is an unanswered question regarding IBD as to whether dysfunction of the intestinal barrier is a primary contributor to inflammation, or is a consequence of the action of inflammatory mediators[31], our present study clearly showed that AMD3100 treatment reduced both the inflammatory response and gut permeability in mice with colitis, identifying a therapeutic effect of the CXCR4 antagonist in experimental colitis.

A previous study also demonstrated that the maintenance of the intestinal epithelium was mainly dependent upon the regulation of proliferation and apoptosis[32]. Local massive apoptosis of epithelial cells would disturb the epithelial barrier, facilitate the infiltration of inflammatory cells, and aggravate mucosal damage[19,33]. In the present study, we found that the number of apoptotic cells in the colonic epithelium was markedly increased in DSS-induced colitis in mice. This was consistent with a previous study which demonstrated that apoptotic epithelial cells in the crypt of UC patients were much more abundant than in the control group[18]. Our present study also reported that AMD3100 treatment significantly decreased the presence of apoptotic cells in intestinal segments of DSS-induced colitis in mice, indicating that the CXCL12/CXCR4 axis also plays a role in epithelial apoptosis during the UC.

The infiltration of leucocytes into the colonic mucosa is believed to play an important role in tissue damage and clinical symptoms in both human and experimental UC[2,3]. Thus, in the present study, we further clarified the effect of the CXCR4 antagonist on migration and cytokine production of PBMCs. To mimic the *in vivo* inflammatory response, the PBMCs were pre-activated with PHA. We demonstrated that, although CXCL12 increased PBMC migration, the CXCR4 antagonist significantly attenuated the migration of PBMCs. In addition, AMD3100 moderately decreased cytokine production in PBMC culture. Taken together, the present data suggest that the amelioration of DSS-induced colitis by the CXCR4 antagonist can be mainly attributed to its effect on migration of PBMCs.

In conclusion, the present study demonstrated that the CXCR4 antagonist, AMD3100, decreased the severity of DSS-induced colitis in mice, by inhibiting the migration and cytokine production of activated PBMCs, and identified a therapeutic effect of the CXCR4 antagonist in experimental colitis. These data also suggested a pivotal role of the CXCL12/CXCR4 chemokine axis in the pathogenesis of UC.

COMMENTS

Background

Ulcerative colitis (UC) is characterized by frequent diarrheal attacks and anal bleeding. Histologic characteristics of UC are the invasion of the crypt epithelium and lamina propria by peripheral blood mononuclear cells (PBMCs), disruption of the epithelial lining, and consequently mucosal ulceration and crypt abscess formation in the bowel wall. Regulation of the migration of inflammatory leukocytes into the intestinal tissues is considered to be a therapeutic option for patients with UC.

Research frontiers

Chemokine stromal cell-derived factor-1 receptor (CXCR4) is specific receptor for chemokine chemokine stromal cell-derived factor-1 (CXCL12), and the latter is a potent chemoattractant for PBMCs. The expression of CXCL12 and CXCR4 on intestinal epithelial cells, lamina propria T cells and PBMCs are significantly increased in UC patients, and block of CXCR4 ameliorates the colonic inflammation in experimental colitis. Whether a CXCR4 antagonist enhances epithelial barrier function, however, has not been unequivocally addressed.

Innovations and breakthroughs

A recent report has highlighted the importance of CXCR4 in colonic inflammation of experimental colitis. Whether CXCR4 plays a role in the epithelial barrier is so far uncharacterized. This is the first study to report that, in addition to inflammation inhibition, the CXCR4 antagonist, AMD3100, also decreased epithelial apoptosis and gut permeability in experimental colitis, and consequently enhanced the epithelial barrier function.

Applications

By understanding the role of CXCR4 in colonic inflammation and epithelial barrier, this study may represent a future strategy for therapeutic intervention in the treatment of patients with UC.

Peer review

The authors present a concise argument for conducting the study which is the participation of the lymphocyte CXCR4 receptor in the augmentation of the immune response found in ulcerative colitis. Their contention that blocking this receptor with an experimental CXCR4 antagonist would ameliorate dextran sulfate sodium induced colitis was demonstrated by using the specific CXCR4 blocking agent known as AMD3100.The experimental model is well thought out and the conclusions are justified by the results obtained. The discussion is adequately developed and focused on the experimental results.

Abstract

AIM: To investigate the expression of toll-like receptor (TLR) 4, nuclear factor-κB (NF-κB) p65 and hypoxia-inducible transcription factor 1α (HIF-1α) in pancreatic ductal adenocarcinoma and their clinical significance.

METHODS: The mRNA of TLR4 and HIF-1α were investigated by real-time polymerase chain reaction in 30 cases of pancreatic ductal adenocarcinoma and its adjacent tissues, and expression of TLR4, NF-κB p65 and HIF-1α protein were detected by immunohistochemistry in 65 cases of pancreatic ductal adenocarcinoma tissues and 38 cases of corresponding adjacent tissues. The relationship between TLR4 or HIF-1α and pathologic features, as well as the association between TLR4 and HIF-1α, were also analyzed. Kaplan-Meier method was used to assess the impact of expression of TLR4 and HIF-1α on survival of patients with pancreatic cancer.

RESULTS: The relative quantification of TLR4 and HIF-1α mRNA in tumor tissues was 0.81 ± 0.10 and 0.87 ± 0.11, respectively, significantly higher than that in adjacent tissues (0.81 ± 0.10 *vs* 0.70 ± 0.16, $P = 0.002$; 0.87 ± 0.11 *vs* 0.68 ± 0.13, $P = 0.000$). The protein expression of TLR4, NF-κB p65 and HIF-1α in tumor tissues was 69.20%, 66.15% and 70.80%, respectively, being significantly higher than that in adjacent normal tissues (69.20% *vs* 39.50%, $P = 0.003$; 66.15% *vs* 31.58%, $P = 0.001$; 70.80% *vs* 36.80%, $P = 0.001$). There was no significant correlation between TLR4 or HIF-1α expression and the age, gender, tumor location, the degree of tumor differentiation in the patients ($P > 0.05$). However, there was significant correlation between the expression of TLR4 or HIF-1α and tumor size, lymph node metastasis, venous invasion and clinical staging ($P < 0.05$). The expression of TLR4 and HIF-1α had a significant impact on survival of patients with pancreatic adenocarcinoma.

CONCLUSION: TLR4, NF-κB p65 and HIF-1α are overexpressed in pancreatic adenocarcinoma, TLR4 may be partly involved in up-regulating HIF-1α, and both synergestically promote development of pancreatic adenocarcinoma.

INTRODUCTION

Because of pancreas insidious nature and anatomic location, pancreatic ductal adenocarcinoma (PDAC) is difficult to be detected early, often becomes advanced by the time of diagnosis. The 5-year survival rate is less than 5% and a median survival time is 5-6 mo[1]. Although 10%-15% of patients underwent potentially surgical resection, the median survival was only 10-18 mo with a 5-year survival of 17%-24%[2]. Most failures occur within 1-2 years after surgery because of local recurrence, hepatic metastases, or both[3]. Therefore, understanding the molecular biology of pancreatic cancer is important for diagnosis, prevention and treatment of PDAC.

Toll-like receptors (TLRs) are a family of pattern recognition receptors that are best-known for their role in host defense against infection. In human, 13 types of TLRs have been identified, mainly expressed by immune cells and epithelial cells. Recently, TLRs have also been detected in many tumor cell lines or tumors, especially epithelium-derived cancers[4]. TLRs may promote the proliferation and inhibit the apoptosis, and lead to migration, invasion and angiogenesis of tumor[5]. However, it remains unknown whether TLR4 is expressed and what role it plays in PDAC.

Hypoxia-inducible transcription factor 1 (HIF-1) is a heterodimer that consists of hypoxic response factor HIF-1α and the constitutively expressed HIF-1β[6]. HIF-1α is unstable in well-oxygenated tissues due to ubiquitin-mediated degradation, but rapidly becomes stable in hypoxic conditions[7]. In human cancers, HIF-1α is overexpressed as a result of intratumoral hypoxia and genetic alterations[8], HIF-1 targets the transcription of over 60 genes involved in many aspects of cancer biology including cell survival, glucose metabolism, cell invasion and angiogenesis[9]. However, the regulatory mechanisms of HIF-1α in tumor microenviroment are complex and still not fully understood. Recently, some studies have demonstrated that bacteria or Lipopolysaccharide (LPS)-induced HIF-1α stabilization even under normoxic conditions[10-12], and LPS-induced HIF-1α accumulation was TLR4 dependent[13] in immune cells, such as macrophage[10,12,13], monocytes[11]. Thus, we wonder whether there is some association between HIF-1α and TLR4 in tumor cells similar to immune cells.

In this study, TLR4 and HIF-1α mRNA and protein were detected in PDAC and its adjacent tissues by real-time polymerase chain reaction (PCR) and immunohistochemical methods. The association between TLR4 and HIF-1α, and impact of their expression on patients' survival were analyzed. The nuclear factor-κB (NF-κB) p65, which is an essential component in both TLR4 signal pathway and HIF-1 signal pathway, was also detected by immunohistochemistry.

MATERIALS AND METHODS

Patients and samples

The study group consisted of 65 patients with primary PDAC, 40 males and 25 females, ranged in age from 36 to 82 years, with a median age of 52 years. They underwent pancreaticoduodenectomy or distal pancreatectomy with lymph node dissection at Pancreatic Center of Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, between January 2007 and December 2008. Sixty-five cases of pancreatic cancerous tissues and 38 cases of corresponding adjacent normal tissues were collected, the adjacent normal tissues were taken from the edge of the tumor and confirmed by pathology. All samples were divided into two parts immediately after removed from patients, one was put into liquid nitrogen for real-time PCR, the other was fixed in 4% buffered formaldehyde and embedded in paraffin wax for immunohistochemistry. None of the patients received preoperative chemotherapy or radiation therapy. Among 65 patients, 25 (38.5%) cases were moderately differentiated, 21 (32.3%) well differentiated, and 19 (29.2%) poorly differentiated. Forty cases (61.5%) had lymph node metastases. Nineteen cases (29.2%) had venous invasion. According to the sixth edition of the TNM classification of the International Union Against Cancer (UICC), 24 patients were at pathological stage Ⅰ or Ⅱ, and 41 patients were at stage Ⅲ or Ⅳ. All patients received chemotherapy routinely after operation, and were followed up regularly for 5-35 mo (mean, 14 mo). The procedure had been approved by the Ethics Committee of Union Hospital, Tongji Medical College.

RNA isolation, reverse transcription and real-time PCR

The total RNA of PDAC and adjacent tissues were extracted using Trizol (invitrogen, USA) according to the manufacturer's protocol. The concentration was analyzed by ultraviolet spectrophotometer. Two micrograms of RNA was used for the reverse transcription. TLR4, HIF-1α and β-actin genes were amplified with SYBR Green in a fluorescence reader FTC-2000 (Feng Ling Bio-engineering Co., Ltd., Shanghai, China). The primer sequences for TLR4 gene were as follows: 5'-ACCTGTCCCTGAACCCTATGAA-3' (forward) and 5'-CTTCTAAACCAGCCAGACCTTG-3' (reverse); the primer sequences for HIF-1α gene were: 5'-TGAAGTGTACCCTAACTAGCCG-3' (forward) and 5'-AATCAGCACCAAGCAGGTCATAG-3' (reverse); and the primer sequences for β-actin gene were: 5'-GAAACTACCTTCAACTCCATC-3' (forward) and 5'-CGAGGCCAGGATGGAGCCGCC-3' (reverse). Cycling conditions were as follows: initial denaturation at 94℃ for 5 min, followed by 30 cycles at 94℃ for 30 s, at 58℃ for 30 s and at 72℃ for 30 s. The negative control was performed using normal pancreatic tissue taken far away from the cancerous tissues. The results were analyzed by the fluorescence reader program [calculation formula: folds = $2^{-\Delta\Delta Ct}$, $\Delta\Delta Ct$ = [(Ct target gene - Ct β-actin) experiment sample - (Ct target gene - Ct β-actin) control sample][14]. Each experiment was carried out in triplicate

using β-actin as an internal standard; the results were expressed as mean ± SD of representative triplicates.

Immunohistochemistry

The tissue specimens were fixed in 10% formalin buffered at pH 7.0 for 24 h and paraffin-embedded. Histologic slides (5 μm) were deparaffined in xylene and rehydrated through a series of graded ethanol. Endogenous peroxidase activity was blocked by incubation in 3% hydrogen peroxide in methanol for 10 min. Antigen retrieval was performed by microwaving the slides in citrate buffer (pH 6.0) for 20 min at 120℃. Then the sections were washed and blocked with normal goat serum (Streptavidin/Peroxidase immunohistochemical kit, Zhongshan Goldenbridge Biological Technology Co., LTD, Beijing, China) for 30 min at room temperature, subsequently exposed to the primary antibody (rabbit polyclonal anti-TLR4, 1:50, Santa Cruz, CA, USA; mouse monoclonal anti-HIF-1α, 1:50, Santa Cruz, CA, USA; NF-κB p65 rabbit monoclonal antibody, 1:50, Cell Signaling Technology Inc, MA, USA). overnight at 4℃. After washing in phosphate buffered saline (PBS), the slides were incubated with a biotinylated goat anti-mouse or anti-rabbit secondary antibody (1:200, Streptavidin/Peroxidase immunohistochemical kit) for 30 min at room temperature. After reactions with freshly prepared diaminobenzidine-tetrahydrochloride (DAB kit, Zhongshan Goldenbridge Biological Technology Co., LTD, Beijing, China), the slides were counterstained in haematoxylin and coverslipped in a systemic mounting medium. Negative controls were prepared without the primary antibodies.

The assessment of TLR4, HIF-1α and NF-κB p65 was based on previously described guidelines[15], which consist of the percentage of stained tumor cells and the staining intensity. At least 3 different high-power (× 400) fields of tumor infiltration were examined. The percentage of positive tumor cells was rated as follows: 1 point, ≤ 10% positive tumor cells; 2 points, 11%-50% positive tumor cells; 3 points, 51%-80% positive tumor cells; and 4 points, ≥ 81% positive tumor cells. The staining intensity was rated as follows: 1 point, weak intensity; 2 points, moderate intensity; and 3 points, strong intensity. Points for expression and percentage of positive cells were added, and specimens were attributed to four groups according to their overall score: negative, ≤ 10% of cells stained positive, regardless of intensity; weak expression, 3 points; moderate expression, 4-5 points; and strong expression, 6-7 points. Weak expression was rated as negative, and moderate and strong expressions were rated as positive for analysis. Two independent investigators (Zhang JJ and Tian Y) blinded to clinical data performed the analysis. Specimens scored differently by the two investigators were reinvestigated together using a multiheaded microscope.

Statistical analysis

For statistical analysis, SPSS 15.0 was used. The independent *t* test was used to compare the means of TLR4 or HIF-1α mRNA between PDAC and its adjacent tissues. The χ^2 test was used to analyze the difference in expression of TLR4, NF-κB p65 and HIF-1α protein between PDAC and its adjacent tissues, as well as correlation between TLR4, HIF-1α and clinicopathologic features. One-way analysis of variance was used for three groups. Survival curves were calculated using the Kaplan-Meier method and analyzed using the log-rank test. Differences at $P < 0.05$ were considered to be statistically significant.

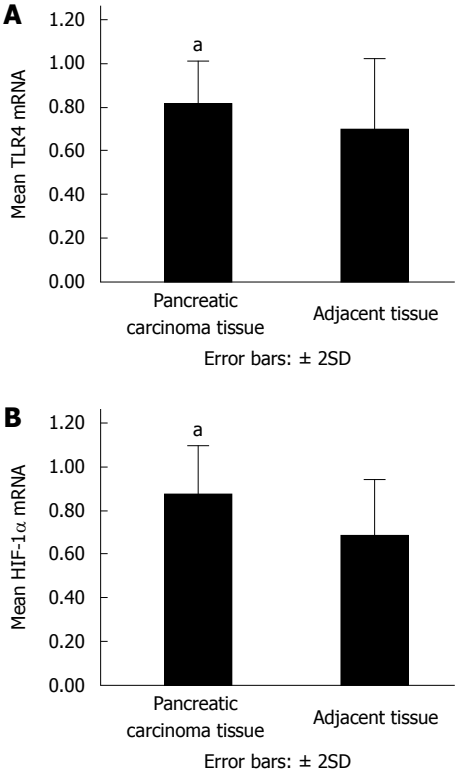

Figure 1 Toll-like receptor (TLR) 4 and hypoxia-inducible transcription factor-1α (HIF-1α) mRNA in pancreatic carcinoma and adjacent tissues. [a]*P* < 0.05 *vs* adjacent tissues. A: TLR4 mRNA in 30 cases of pancreatic carcinoma and adjacent tissues was determined by real-time polymerase chain reaction (PCR); B: HIF-1α mRNA in 30 cases of pancreatic carcinoma and adjacent tissues was determined by real-time PCR.

RESULTS

TLR4 is overexpressed in PDAC

To investigate whether TLR4 is expressed in PDAC, we first detected TLR4 mRNA by real-time PCR. The results showed that the mean level of TLR4 mRNA was 0.81 ± 0.10 in tumor tissues, and it was 0.70 ± 0.16 in adjacent normal tissues, with significant difference between them ($P = 0.002$, Figure 1A). We then detected TLR4 protein by immunohistochemistry, and found that TLR4 protein was localized in cytoplasm and membrane of tumor cells (Figure 2A and B), and the expression of TLR4 was 69.2% (45/65) in cancerous tissues, which was significantly higher than that in adjacent normal tissues (69.2% *vs* 39.5%, $P = 0.003$, Table 1). When analyzing the relationship between TLR4 and clinicopathological features, we found that the expression of TLR4 mRNA or protein was not correlated with age, gender, location and differentiation of the tumor ($P > 0.05$), but

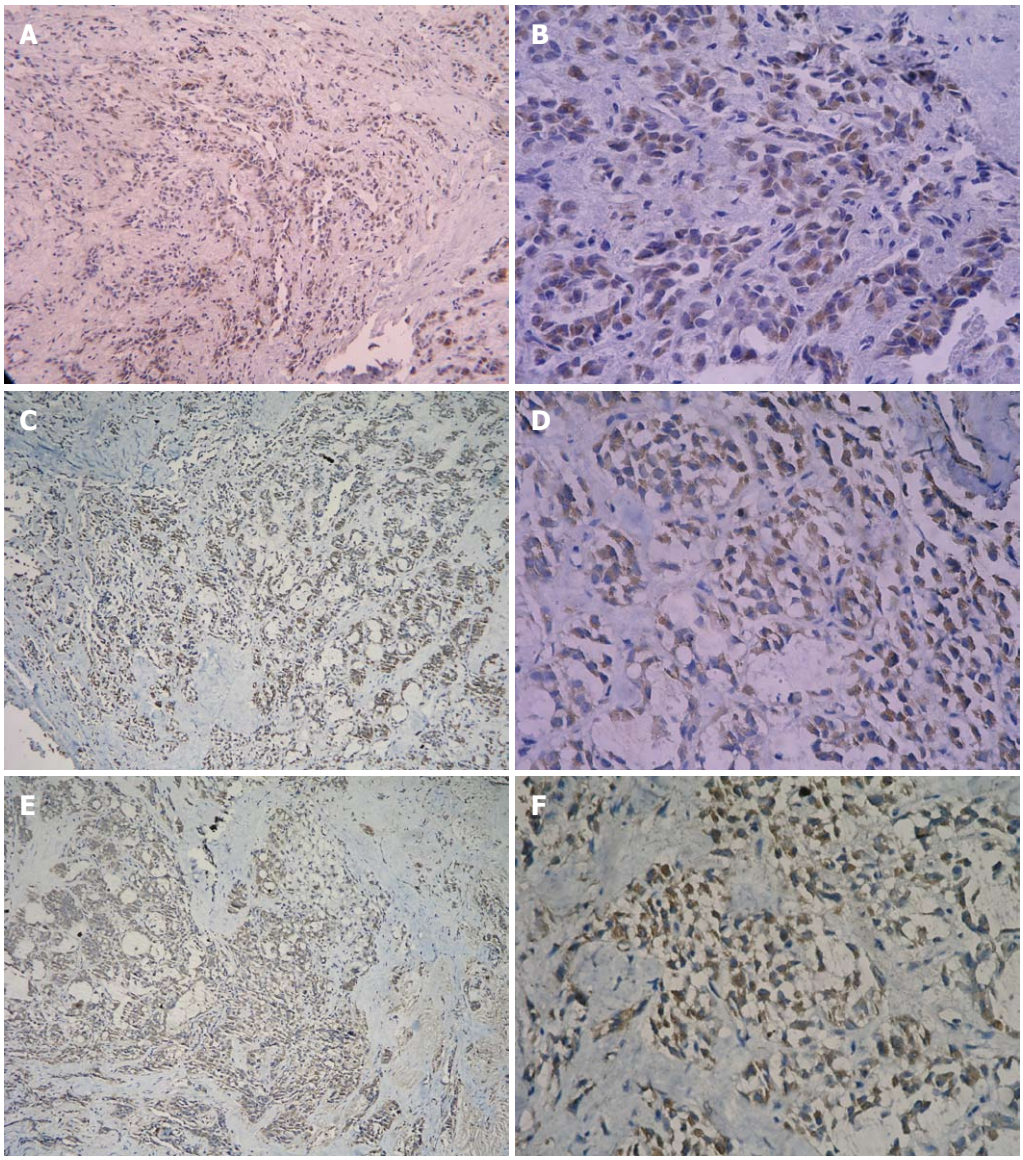

Figure 2 Expression of TLR4 and HIF-1α protein in pancreatic carcinoma tissue. Brown color displays the positive expression. A: Expression of TLR4 protein in carcinoma tissue (SP, × 100); B: Expression of TLR4 protein in carcinoma tissue (SP, × 400); C: Expression of HIF-1α protein in carcinoma tissue (SP, × 100); D: Expression of HIF-1α protein in carcinoma tissue (SP, × 400); E: Expression of NF-κB p65 protein in carcinoma tissue (SP, × 100); F: Expression of NF-κB p65 protein in carcinoma tissue (SP, × 400).

Table 1 Expression of TLR4 and HIF-1α protein in pancreatic carcinoma and adjacent tissues *n* (%)

	Cases	TLR4 protein		HIF-1α protein	
		Positive	*P* value	Positive	*P* value
Tumor tissues	65	45 (69.20)	0.003	46 (70.80)	0.001
Adjacent tissues	38	15 (39.50)		14 (36.80)	

TLR4: Toll-like receptor 4; HIF-1α: Hypoxia-inducible transcription factor-1α.

significantly correlated with tumor size, lymph node involvement, venous invasion and pathological stage ($P < 0.05$, Table 2).

HIF-1α is overexpressed in PDAC

We continued to detect HIF-1α in PDAC, and found that the mean level of HIF-1α mRNA in tumor tissues was 0.87 ± 0.11, being significantly higher than that in adjacent tissues, which was 0.68 ± 0.13 ($P = 0.000$, Figure 1B). Immunohistochemical results showed that HIF-1α was expressed in the nuclei and/or the cytoplasm of tumor cells (Figure 2C and D). The expression of HIF-1α was found in 46 of 65 (70.8%) cases of tumor tissues, and 14 of 38 (36.8%) cases of adjacent tissues, with significant difference between them (Table 1, $P < 0.05$). Furthermore, we also found that the expression of HIF-1α was correlated with tumor size, lymph node involvement, venous invasion and pathological stage ($P < 0.05$, Table 2).

Correlation of TLR4 and HIF-1α expressions in PDAC

In macrophages, LPS can raise the level of HIF-1α in a TLR4-dependent fashion[13], but it remains unknown in tumor cells. To study whether TLR4 is associated with HIF-1α in PDAC, we performed the correlative analysis.

Table 2 Relationship between TLR4, HIF-1α and clinical pathologic features

	TLR4 mRNA		TLR4 protein			HIF-1α mRNA		HIF-1α protein		
	mean ± SD	*P*	+	-	*P*	mean ± SD	*P*	+	-	*P*

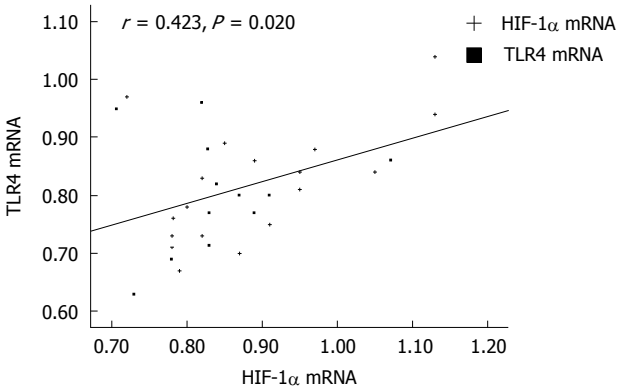

Figure 3 Correlation between TLR4 mRNA and HIF-1α mRNA.

The results showed that there existed a significant correlation between TLR4 mRNA and HIF-1α mRNA (r = 0.423, P = 0.020, Figure 3), similar result was also found between TLR4 and HIF-1α protein (r_p = 0.451, P < 0.05, Table 3), suggesting that TLR4 has a positive correlation with HIF-1α in PDAC.

NF-κB p65 is overexpressed in PDAC

NF-κB is an essential downstream component of TLR signal pathway[16], and HIF-1α is a target gene of NF-κB[17]. To further explore the association between TLR4 and HIF-1α, we investigated NF-κB p65 expression in PDAC by immunochemistry. The results showed that NF-κB p65 was expressed in the nuclei and/or the cytoplasm of tumor cells (Figure 2E and F), and the positive expression of NF-κB p65 was found in 43 (66.15%) of 65 cases of tumor tissues, being significantly higher than

Table 3 Correlation between TLR4 and HIF-1α protein

	TLR4 expression		r_p	*P* value
	Positive (n = 45)	Negative (n = 20)		
HIF-1α expression			0.451	0.000
Positive (n = 46)	38	8		
Negative (n = 19)	7	12		

in 12 (31.58%) of 38 cases of adjacent tissues (P = 0.001). Considering NF-κB is an essential component in TLR4 signal pathway and an important modulator of HIF-1α, we could speculate that NF-κB p65 may be a link in the association between TLR4 and HIF-1α.

Overexpression of TLR4 and HIF-1α in PDAC has a negative impact on patient survival

In order to understand whether over-expression of TLR4 and HIF-1α in PDAC has an impact on patient survival, the relationship between the expression of TLR4 or HIF-1α and life span of patients was analyzed. The mean survival of patients without over-expression of TLR4 in tumor tissues was 19.7 mo, and it was 12.4 mo in those with over-expression of TLR4, log-rank analysis showed there was a significant difference (P = 0.011, Table 4 and Figure 4A). Similarly, the mean survival of patients without over-expression of HIF-1α in tumor tissues was 20.1 mo, being significantly longer than those with over-expression of HIF-1α, which was 12.8 mo (P = 0.005, Table 4 and Figure 4B). In addition, the survival time of group with neither TLR4 nor HIF-1α over-expression

Table 4 Impact of TLR4 and HIF-1α on survival time

Protein	Expression	Estimated survival	95% CI		*P*
			Lower bound	Upper bound	
TLR4	Positive	12.4	10.8	14.0	0.011
	Negative	19.7	15.4	23.9	
HIF-1α	Positive	12.8	11.1	14.4	0.005
	Negative	20.2	15.2	25.1	
TLR4 positive	HIF-1α positive	11.8	10.1	13.4	0.132
	HIF-1α negative	15.0	10.9	19.2	
TLR4 negative	HIF-1α positive	16.5	12.5	20.6	0.089
	HIF-1α negative	21.6	15.1	28.2	0.014[1]

[1]*P* value compared between patients with both negative TLR4 and HIF-1α expression and those with both positive TLR4 and HIF-1α expression.

was 21.6 mo, significantly longer than those with both over-expressions, which was 11.8 mo ($P = 0.014$, Table 4 and Figure 4C).

DISCUSSION

TLR4 was studied first in TLRs, which is mainly expressed in immune cells and epithelial cells. The activation of TLR4 facilitates the activation of two pathways: the MyD88 (myeloid differentiation primary-response protein 88)-dependent and MyD88-independent pathways. The MyD88-dependent pathway involves the early phase of NF-κB activation, which leads to the production of inflammatory cytokines. The MyD88-independent pathway activates interferon (IFN)-regulatory factor (IRF3) and involves the late phase of NF-κB activation, both of which lead to the production of IFN-β and the expression of IFN-inducible genes. In 1998, TLR4 was identified as the signal transducer for LPS, a major cell-wall component of Gram-negative bacteria[18], in addition to microbial ligands, an increasing number of endogenous ligands are being reported as candidate stimulators of TLR4, including heat shock proteins (HSP60, HSP70, endoplasmin, HSPB8 and α-crystallin A chain), high mobility group box 1 (HMGB1), and various products of the extracellular matrix such as fibronectin, heparan sulphate, biglycan, fibrinogen, oligosaccharides of hyaluronan and hyaluronan breakdown fragments[5].

There are increasing evidences suggesting that TLR4 is also expressed in many tumor cell lines or tumors, especially epithelium-derived cancers[4]. In human head and neck squamous cell carcinoma[19], lung cancer[20], gastric carcinoma[21], ovarian tumors[22] and melanoma cells[23], TLR4 was all over-expressed, but not or lowly expressed in corresponding adjacent tissues or normal tissues. However, whether human pancreatic cancer cells express TLR4 remains to be understood.

In the present study, we found that not only TLR4 mRNA, but also TLR4 protein was over-expressed in PDAC compared with adjacent tissues. In addition, we found that the over-expression of TLR4 was related to tumor size, lymph node involvement, venous invasion and pathological stage. Kaplan-Meier analysis showed that the mean survival of patients without TLR4 expression in tumor tissues was significantly longer than those with TLR4 expression. These data indicated that TLR4 expressed in PDAC cells may contribute to its progression. Up to date, there have been increasing studies about effect and corresponding mechanism of TLR4 signal pathway on tumor progression. Pidgeon *et al*[24] found that endotoxin, a TLR4 agonist, introduced during surgery is associated with the enhanced growth of metastases following surgical trauma. In ovarian tumors, functional activity for TLR4 was demonstrated by stimulation of cell lines with specific ligands and subsequent activation and translocation of NF-κB and release of the proinflammatory cytokines interleukin-6 and CCL-2[22]. In human lung cancer cells[25], TLR4 ligation promoted production of immunosuppressive cytokines TGF-β, vascular endothelial growth factor (VEGF), proangiogenic chemokine IL-8, NF-κB was activated and contributed to apoptosis resistance of human lung cancer cells induced by LPS. Similar to other solid tumors, in pancreatic tumor microenviroment, there may also exist endogenous TLR4 ligands, which might be released during matrix degradation associated with tumor progression including HMGB1, heat shock proteins, hyaluronic acid and fibronectin fragment[22]. Many of these endogenous ligands may activate TLR4 signal pathway, induce inflammatory response, and promote tumor cells proliferation, apoptosis resistance, infiltration and metastasis. Thus, TLR4 might be a new marker of PDAC progression.

In solid tumors, cancer cells proliferation may outpace the rate of angiogenesis, result in tissue hypoxia, and cellular adaptation to hypoxia is a key step in tumor progression. This adaptation is regulated mainly by HIF-1 that is known to play an essential role in oxygen homeostasis[26]. In this study, we found the expression of both HIF-1α mRNA and protein was significantly higher in PDAC tissues than those in adjacent tissues, and the increased level of intracellular HIF-1α was associated with tumor size, lymph node involvement, venous invasion and pathological stage. These results were consistent with a previous study[27]. Wei *et al*[27] found that expression of HIF-1α was significantly higher in pancreatic cancer tissues, and there was significant difference in the expression of HIF-1α mRNA between Japanese Pancreatic Society stages Ⅰ-Ⅱ and stages Ⅲ-Ⅳ. Kaplan-Meier analysis also showed there was no significant

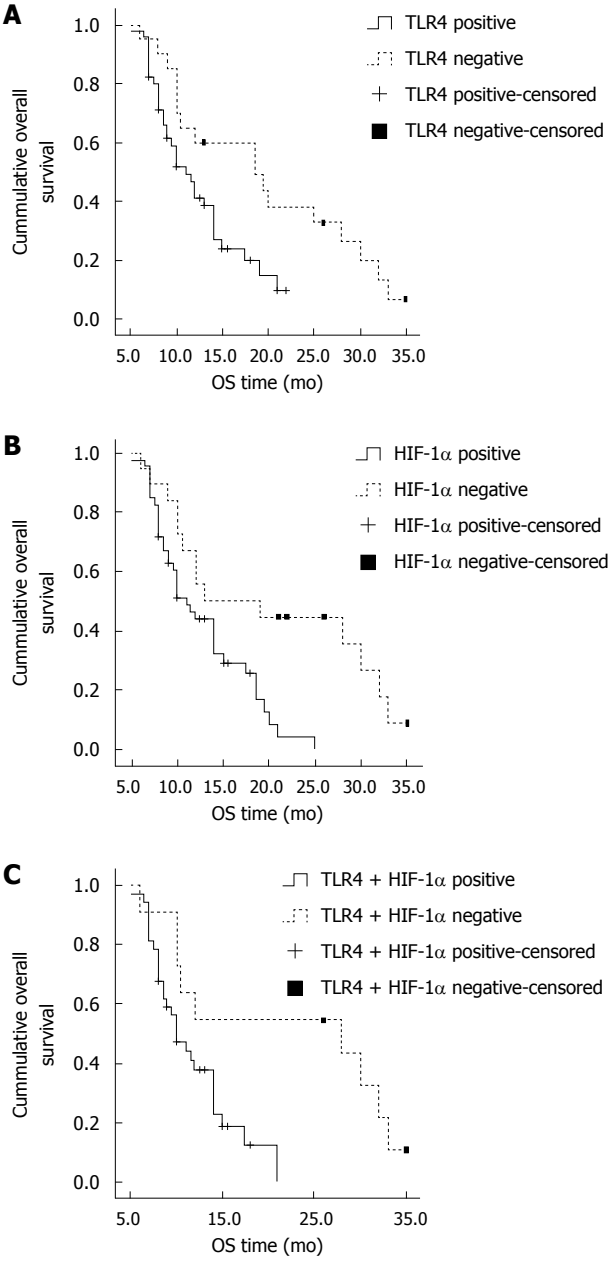

Figure 4 Kaplan-Meier analysis overall survival depending on TLR4 and HIF-1α expression in pancreatic ductal adenocarcinoma. A: The mean survival of patients with negative TLR4 expression in tumor tissues was significantly longer than those with TLR4 positive expression (P = 0.011); B: The mean survival of patients with negative HIF-1α expression in tumor tissues was significantly longer than those with HIF-1α positive expression (P = 0.005); C: Survival of patients with both negative TLR4 and HIF-1α expression was significantly longer than those with both positive TLR4 and HIF-1α expression (P = 0.014).

difference in the early stage of postoperation between negative and positive HIF-1α expression groups, but as time passed, the mean survival of patients without over-expression of HIF-1α in tumor tissues was significantly longer than those with over-expression of HIF-1α, which further demonstrated that patients with positive HIF-1α expression have worse prognosis. The main cause may be that upregulated and active HIF-1α forms complex with HIF-1β, translates into nuclear and activates the transcription of many genes that code for proteins involved in angiogenesis, glucose metabolism, cell proliferation, survival and invasion, metastasis[28]. Thus, the mortality of patients with over-expression of HIF-1α in the late stage increases because of recurrence, metastasis, chemotherapy and radiotherapy resistance. Thus, HIF-1α may serve as a useful molecular marker for prognosis of PDAC.

In the present study, we found that there was positive correlation between TLR4 and HIF-1α, indicating that there may exist a crosstalk between TLR4 signal pathway and HIF-1 signal pathway, which may act synergistically to promote the progression of PDAC. Recently, HIF-1α has also been shown to be up-regulated under normoxia in response to LPS[29]. In several reports, LPS, a ligand of TLR4, was found to induce accumulation and DNA-binding activity of HIF-1α protein in murine microglial cells[30], macrophage-differentiated cells[12], macrophages[31], and human myeloid monocytic leukaemia cells[32], which suggested that TLR4 signal pathway might regulate HIF-1α expression *via* some mechanism. van Uden *et al*[28] demonstrated that NF-κB was a direct modulator for HIF-1α expression. In our study, we also found that NF-κB p65 was over-expressed in PDAC. Considering NF-κB was an essential downstream component of TLR4 signal pathway[16], we speculated that the activation of TLR4 signal pathway in the microenviroment of PDCA might be partly involved in up-regulating HIF-1α *via* NF-κB pathway, then promoted progression of pancreatic adenocarcinoma.

In conclusion, the present study revealed that TLR4 and HIF-1α were over-expressed in pancreatic cancer, and both were related to the survival of patients with PDAC. On the other hand, there was positive association between TLR4 and HIF-1α. TLR4 signal pathway and HIF-1α signal pathway may synergistically promote development of the pancreatic cancer. However, the exact mechanism of crosstalk between HIF-1α and TLR4 in PDAC needs to be further studied.

COMMENTS

Background

Pancreatic ductal adenocarcinoma (PDAC) is a highly malignant digestive tumor with a very poor prognosis. Hypoxia-inducible transcription factor-1α (HIF-1α) is involved in malignant progression in many solid tumors, including PDAC, up-regulation of HIF-1α accelerates PDAC progression, but the exact regulatory mechanisms of HIF-1α in PDAC has not been unequivocally addressed. Recently, an increasing number of studies reported that toll-like receptors (TLRs) were upregulated in epithelial malignancies and involved in tumor progression, but whether TLRs, such as TLR4, is expressed on PDAC cells remains unknown. In immune- related cells, TLR signal pathway may induce expression of HIF-1α, but it is also still unclear whether there exists some association between TLR4 and HIF-1α in tumor microenviroment, such as PDAC.

Research frontiers

Activating TLRs pathway in tumor cells could promote the proliferation and inhibit the apoptosis, leading to migration, invasion and angiogenesis of tumor, but it remains unknown whether TLR4 is expressed and what role it plays in PDAC. In human cancers, HIF-1α is overexpressed as a result of intratumoral hypoxia. Recently, HIF-1α has also been shown to be up-regulated under normoxia in response to LPS, a potent agonist of TLR4, in immune-related cells, however, whether HIF-1α is regulated by TLR4 signal pathway in tumor is unknown. In this study, the authors demonstrate that TLR4 and HIF-1α are over-expressed in PDAC, and TLR4 expression is associated with HIF-1α. Nuclear factor-κB (NF-κB) p65, an important component in both TLR pathway and HIF-1 pathway, is also over-expressed in PDAC. The expression of TLR4 and HIF-1α has a

significant impact on survival of patients with PDAC. These results might indicate that TLR4 could be a potential factor for mediating HIF-1α in PDAC.

Innovations and breakthroughs

This is the first study to report that TLR4 is over-expressed in PDAC, and it is also the first report to show that TLR4 is associated with HIF-1α in PDAC.

Applications

The study demonstrated that TLR4, NF-κB p65 and HIF-1α were over-expressed in PDAC. The expression of TLR4 and HIF-1α was associated with tumor size, lymph node metastasis, venous invasion and pathological stage. Furthermore, the expression of TLR4 was positively correlated with expression of HIF-1α. Thus, TLR4 may be a novel marker for the progression and prognosis of PDAC, and may provide a new strategy for therapeutic intervention in the treatment of patients with PDAC in the future.

Peer review

This is an interesting study with valuable information regarding the expression and clinical correlation of TLR4 and HIF-1α in pancreatic ductal adenocarcinoma.

Abstract

AIM: To test whether colchicine would be an effective antifibrotic agent for treatment of chronic liver diseases in patients who could not be treated with α-interferon.

METHODS: Seventy-four patients (46 males, 28 females) aged 40-66 years (mean 53 ± 13 years) participated in the study. The patients were affected by chronic liver diseases with cirrhosis which was proven histologically (n = 58); by chronic active hepatitis C (n = 4), chronic active hepatitis B (n = 2), and chronic persistent hepatitis C (n = 6). In the four patients lacking histology, cirrhosis was diagnosed from anamnesis, serum laboratory tests, esophageal varices and ascites. Patients were assigned to colchicine (1 mg/d) or standard treatment as control in a randomized, double-blind trial, and followed for 4.4 years with clinical and laboratory evaluation.

RESULTS: Survival at the end of the study was 94.6% in the colchicine group and 78.4% in the control group (P = 0.001). Serum N-terminal peptide of type Ⅲ procollagen levels fell from 34.0 to 18.3 ng/mL (P = 0.0001), and pseudocholinesterase levels rose from 4.900 to 5.610 mU/mL (P = 0.0001) in the colchicine group, while no significant change was seen in controls. Best results were obtained in patients with chronic hepatitis C and in alcoholic cirrhotics.

CONCLUSION: Colchicine is an effective and safe antifibrotic drug for long-term treatment of chronic liver disease in which fibrosis progresses towards cirrhosis.

INTRODUCTION

Hepatic fibrosis results from excessive deposition of extracellular matrix components, namely fibril-forming collagen type Ⅰ and Ⅲ. Fibrosis and cirrhosis develop after chronic injury from many causes, including persistent viral and helminthic infections, alcohol, autoimmune hepatitis, and metal overload. Early stages of fibrosis are reversible either by removal of the specific stimulus or by treatment with antifibrotic medications, whereas late stages, progressing to cirrhosis, are less reversible[1,2].

Our current knowledge of the pathology of hepatic

stellate cells (HSC), the main producers of type I collagen in the liver, as well as the molecular mechanisms involved in the activation of HSC and collagen production, have resulted in the discovery of new sites for potential therapeutic intervention. Among the various medical treatments, colchicine is a safe and efficient drug, based on our current knowledge of its pharmacodynamic[3-5], pharmacokinetic[6] and therapeutic[7-11] properties, and its ability to prevent or delay the development of hepatocellular carcinoma (HCC) in viral-related liver cirrhosis[12].

In this communication we present our findings after 4.4 years of follow up of a group of 74 patients who were randomly assigned to colchicine or control treatment. Our results show that colchicine treatment decreased mortality and significantly lowered serum levels of type Ⅲ procollagen peptide (P-Ⅲ-P) as compared with the control group.

MATERIALS AND METHODS

Patients

Seventy-four patients (46 males and 28 females) aged 40-66 years (mean 53 ± 13 years) participated in the study. Inclusion criteria were on an intention-to-treat basis. Exclusion criteria were: age < 20 years or a known hypersensitivity to colchicine. Patients were recruited by referral from general practitioner or by self choice and gave informed consent to be assigned to intervention (colchicine) or control by using random allocation. Randomization was performed by giving 74 consecutive numbers to all patients coming to our clinic between the years 2000 and 2003. Both the intervention group (group A) and the control group (group B) consisted of 37 patients. Group A was treated with colchicine (1 mg/d per os). Group B received the usual treatment for cirrhosis (diuretics, β-blockers, ursodeoxycholic acid, withdrawal of alcohol). Sixty-two patients were affected by different chronic liver diseases + cirrhosis (CLD + C), which was proven histologically in 58 of them (93.5%). In the four patients lacking histology, cirrhosis was diagnosed from serum laboratory tests, esophageal varices and ascites, consistent with clinical history. Twenty-eight patients (15 in group A, and 13 in group B) had post-hepatitis C cirrhosis (12 had been previously treated unsuccessfully with α-interferon for 12 mo), 20 patients (9 and 11 in each group, respectively) had post-hepatitis B cirrhosis, 10 (5 and 5) alcoholic cirrhosis, 4 (2 and 2) primary biliary cirrhosis. Among the 12 patients in whom cirrhosis was not found, 4 patients (2 and 2 in each group, respectively) had chronic active hepatitis C, 2 (1 and 1) chronic active hepatitis B, and 6 (3 and 3) chronic persistent hepatitis C (Table 1). Reasons for excluding the use of α-interferon for post-hepatitis C cirrhosis were: (1) previous unsuccessful treatment; (2) withdrawal owing to severe side effects; (3) autoimmune disorders; (4) severe depression; (5) thrombocytopenia; (6) decompensated cirrhosis; and (7) refusal. For these reasons the involvement of an Ethical Committee was thought not necessary. The study protocol conforms, however, to the ethical guidelines of the 1975 Declaration of Helsinki. The patients were followed up for a mean of 4.4 years, from 2000 to 2007, at the Centre for Metabolic Diseases and Atherosclerosis of Cagliari, Italy. During the study ten died (3 in group A and 7 in group B) and 12 (9 in group A and 3 in group B) withdrew from the study due to personal reasons.

Table 1 Diseases and number of patients participating in the study

Disease	Group A	Group B	*P*
Post-hepatitis C cirrhosis	15	13	0.65
Post-hepatitis B cirrhosis	9	11	0.65
Chronic active hepatitis C	2	2	0.70
Chronic active hepatitis B	1	1	0.85
Chronic persistent hepatitis C	3	3	0.85
Alcoholic cirrhosis	5	5	0.90
Primary biliary cirrhosis	2	2	0.80
Total	37	37	

Differences between the two groups were not significant statistically.

Serological tests

The liver function tests performed every year (half year initially) were: aminotransferases (mU/mL, normal values < 40), prothrombin time (%, normal values 70-100), pseudocholinesterase (mU/mL, normal values 5600-13 000), albumin (g/dL, normal values 3.5-5.0) and globulins (g/dL, normal values 0.6-1.0) displayed as an electrophoretogram. Serum N-terminal peptide of type Ⅲ procollagen (P-Ⅲ-P) was determined by radioimmunoassay, using the Cobra γ-counter device (ng/mL, normal values 4-14), as a marker of fibrogenesis in place of liver biopsy during follow-up[13].

Statistical analysis

Survival curves were plotted with the use of the Kaplan-Meier approach[14]. Differences in cumulative survival between the colchicine and the control groups were analyzed by means of the log-rank test[15]. Paired *t*-test of liver function tests between groups A and B, and in the same groups between baseline and 4-year values was performed. Ninety-five percent confidence intervals (95% CI) were calculated through interval estimation. Factor analysis for reducing individual scores from many to three was used[16] when analyzing the treatment outcome in patients with chronic liver disease C and in alcoholic cirrhosis using the following three criteria: serum levels of P-Ⅲ-P and γ globulins; serum pseudocholinesterase and albumin; subjective state of health.

RESULTS

Colchicine treatment was well tolerated, with transient diarrhea in a few cases. Overall, the best results obtained after 4 years of colchicine treatment were in subjects with chronic hepatitis C (20 cases, $P = 0.001$). In post-hepatitis B cirrhosis the results were less favourable and 2 of the 9 initial patients died before the 4th year. Nonetheless, in the remaining 7 patients a good result was obtained ($P = 0.05$ *vs* controls) (Table 2).

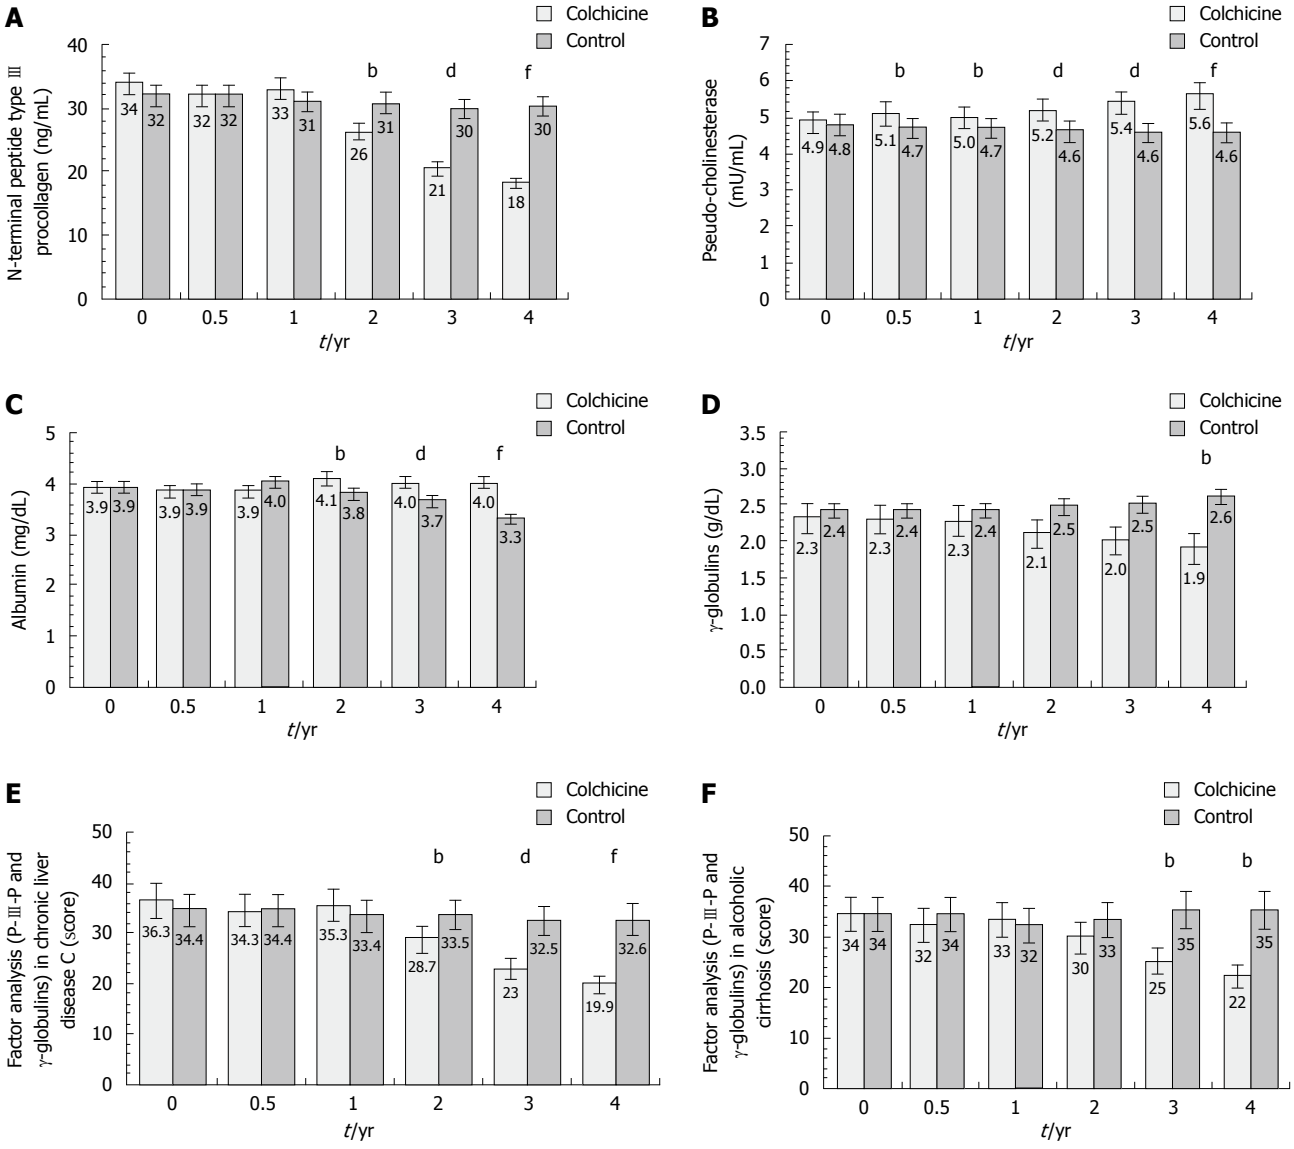

Figure 1 Type Ⅲ procollagen peptide (P-Ⅲ-P) (A), pseudo-CHE (B), albumin (C), γ-globulins (D), factor analysis (E, F) in colchicine and control groups. A-E: $^{b}P = 0.01$; $^{d}P = 0.001$; $^{f}P = 0.0001$; F: $^{b}P < 0.04$.

Table 2 Number of cases and number of improved patients for P-Ⅲ-P and pseudocholinesterase in the different liver disease groups treated for 4.4 years with colchicine

	Number of cases	Number of improved	*P vs* controls
Post-hepatitis C cirrhosis	15	13	0.001
Post-hepatitis B cirrhosis	9	11	0.05
Chronic active hepatitis C	2	2	0.001
Chronic active hepatitis B	1	1	0.50
Chronic persistent hepatitis C	3	3	0.001
Alcoholic cirrhosis	5	5	0.001
Primary biliary cirrhosis	2	2	0.55

P-Ⅲ-P: Type Ⅲ procollagen peptide.

Liver test values at baseline, 0.5, 1, 2, 3, and 4 years in the 37 patients treated with colchicine *vs* the 37 controls are reported in Table 3 and in Figure 1. In the colchicine group the most striking improvement was in serum P-Ⅲ-P values, which steadily declined from 34.0 at baseline to 26.2 at 2 years (-22.9%) and to 18.3 at 4 years (-46.2% from 34.0% to 18.3%, $P < 0.0001$, 95% CI: 19.4-17.1) (Table 3 and Figure 1A), and for pseudocholinesterase, the activity of which rose from 4900 at baseline to 5200 at 2 years (+6.1%) and to 5610 at 4 years (+14.5%, $P < 0.0001$, 95% CI: 5.7-5.5) (Table 3 and Figure 1B). These results are in striking contrast with the control group in which P-Ⅲ-P serum levels and pseudocholinesterase did not change significantly. Serum albumin and γ globulin levels also improved in the colchicine as compared with the control group ($P < 0.0001$, 4.1 to 3.9 and 2.2 to 1.5, respectively) (Figure 1C and D).

Survival of the 74 patients is reported in Table 4. Of the 37 patients in group A (colchicine), 36 survived at 2 years and 34 at 4 years. Of the 37 patients in group B (control), 35 survived at 2 years and 30 at 4 years. The survival figures showed a statistically significant benefit of colchicine ($P = 0.001$). The cumulative 4-year survival rate was 91.9% in group A and 81.1% in group B.

Table 3 Liver function tests at baseline and after 2 and 4 years

	Group A	%	*P*	Group B	%	*P*
P-Ⅲ-P baseline (ng/mL)	34.0			32.0		
P-Ⅲ-P 2 yr (ng/mL)	26.2	-22.9	0.01	30.8	-3.7	0.6
P-Ⅲ-P 4 yr (ng/mL)	18.3	-46.2	< 0.0001	30.2	-5.6	0.5
Pseudocholinesterase baseline (mU/mL)	4900			4800		
Pseudocholinesterase 2 yr (mU/mL)	5200	+6.1	0.05	4620	-3.7	0.6
Pseudocholinesterase 4 yr (mU/mL)	5610	+14.5	< 0.0001	4580	-4.6	0.6

Table 4 Survival of 37 patients treated with colchicines (Group A) and of 37 control patients (Group B) *n* (%)

	Group A	Group B	*P*
Baseline	37	37	
2 yr	36 (97.3)	35 (94.6)	0.05
4 yr	34 (91.9)	30 (81.1)	0.001

Table 5 Complications of cirrhosis in the two groups

Complications	Group A	Group B	*P*
Ascites	0	8	< 0.001
Encephalopathy	0	2	< 0.001
Esophageal hemorrhage	2	10	< 0.001

Group A: Colchicine, 20; Group B: Control, 18. Statistical significance of differences between the two groups: $P < 0.001$.

The complications of cirrhosis are reported in Table 5: ascites, encephalopathy and esophageal hemorrhage were almost absent in group A (2 esophageal hemorrhages *vs* 10 in group B, $P < 0.001$).

The factor analysis of serum P-Ⅲ-P and γ globulin levels in chronic hepatitis C showed a statistically significant improvement at 2, 3 and 4 years in the colchicine group (Figure 1E). In patients with alcoholic cirrhosis a significant change in the above parameters was reached at 3 and 4 years of colchicine treatment (Figure 1F). In contrast with these findings, a significant improvement in cholinesterase and albumin were observed until year 4 in chronic hepatitis C, while in alcoholic cirrhotic patients a statistically significant difference was found at 3 and 4 years of colchicine therapy. Regarding the overall subjective evaluation of colchicine patients with chronic hepatitis C and with alcoholic cirrhosis, a statistically significant difference, compared to controls, was found at 2, 3 and 4 years.

DISCUSSION

The striking improvement of CLD + C patients treated with colchicine, as compared with those on standard treatment, shows the effectiveness of colchicine for the treatment of hepatic fibrosis and cirrhosis[7-11]. Because this study was not designed to investigate a potential antiviral effect of colchicine, changes in viral DNA in patients with hepatitis B virus (HBV) were not investigated. Nonetheless, an antiviral effect of colchicine has been already documented by Floreani *et al*[9].

In the colchicine group, 9 patients stopped the treatment, *vs* only 3 patients in the control group, thus revealing a lower compliance with colchicine.

Multiple studies using colchicine for the treatment of chronic liver disease of different etiologies have shown variable results. In one study of hepatitis B patients, colchicine administered 5 mg/wk for 4 years showed a preventive effect towards evolution to cirrhosis (32.0% in treatment group A *vs* 73.2% in control group B), although of borderline significance[17].

In a study of hepatitis C, the combination of colchicine plus interferon resulted in worsening of alanine transaminase values and hepatitis C virus (HCV)-RNA levels compared to patients receiving only interferon[18].

In alcoholic cirrhosis treated with colchicine for up to 6 years, overall liver specific mortality was not reduced; however the alcoholic cirrhosis was advanced and, moreover, fewer patients on colchicine developed hepatorenal syndrome. The authors concluded that colchicine is not recommended for advanced cirrhosis[19], in agreement with Tome *et al*[20].

In primary biliary cirrhosis, where colchicine is indicated[4,7], the addition of colchicine to ursodeoxycholic acid was shown to result in a small but significant reduction in disease progression[21].

In addition to already cited papers[8,11], colchicine has been found to prevent the development of hepatocellular carcinoma in virally-related liver cirrhosis. However, the differences were not statistically significant when compared with a group receiving peginterferon (7.7% in interferon group and 5.9% in colchicine group ($P = 0.5$). The drug was less active than peginterferon alfa-2b in preventing variceal bleeding[22]. In 116 patients with virally-related liver cirrhosis on treatment with colchicine for a minimum of 3 years, hepatocellular carcinoma was prevented or delayed, compared with controls (9.0% *vs* 29.0%, $P = 0.01$), possibly through its anti-inflammatory effect[12].

In a study of 100 patients with various types of liver cirrhosis, colchicine was markedly better than control treatment as far as 10 years survival rates (56% *vs* 20%) and improvement of liver biopsies were concerned[23].

In another study in which the authors analyzed the combined results of 14 randomized clinical trials totalling 1138 patients, they concluded that colchicine should not be used for liver fibrosis or cirrhosis of various etiologies[24].

A study of the effect of colchicine combined with radiation showed that low doses of the drug possess radiosensitizing effects for HCC treatment[25].

Overall, our findings suggest that colchicine is anti-

fibrogenic based on the significant decrease in the levels of serum P-Ⅲ-P, a peptide derived from the processing of newly synthesized type Ⅲ collagen, an important component of liver scar tissue. This parameter has been used by others as a non-invasive procedure to follow liver fibrosis[13]. Thus, our findings together with the results obtained by Kershenobich *et al*[7] and other authors[8-11] clearly show that colchicine is effective for the treatment of some forms of liver cirrhosis. In this communication we report a significant improvement in patients with HCV who for various reasons declined to continue the use of interferon therapy. In the publication by Kershenobich *et al*[7] a significant improvement in patients with cryptogenic cirrhosis treated with colchicine was reported. Based on these findings it is possible to suggest that a better selection of patients, such as subjects with HCV who do not respond to interferon therapy, and early intervention could benefit a large population of patients for whom there is no alternative therapy.

In this study of patients with CLD + C, colchicine produced a clear-cut antifibrogenic effect, as indicated by the progressive decrease of serum P-Ⅲ-P and the parallel improvement of liver function tests.

Colchicine is an effective and safe antifibrotic drug for long-term treatment of chronic liver disease in which fibrosis progresses towards cirrhosis. It was shown not only to arrest, but even to reverse this process. With regard to the arrest of fibrosis, the stage of the disease at which colchicine treatment must be started is probably earlier than suggested at the present time. This does not mean that the drug provides an alternative to other well-established therapeutic strategies, but rather that colchicine should find its placement in association with the latter, except for combination with α-interferon in hepatitis C, where it displays unfavourable effects[18]. Removal of the initiating factor(s) is the best way, when feasible, to prevent the progression of hepatic disease[1,2]. With the addition of colchicine, this approach could be even more effective. Moreover, since liver cirrhosis is reversible[2,26], colchicine should be considered as a therapeutic agent. Histological evidence in addition to clinical non-invasive parameters could help in determining the antifibrogenic properties of colchicine. Accordingly, clinical trials of colchicine treatment in early stages of chronic liver disease are warranted.

COMMENTS

Background

Fibrosis and cirrhosis of the liver develop as a response to chronic injury from many causes. Early stages of fibrosis are reversible by treatment with antifibrotic drugs.

Research frontiers

Hepatic stellate cells provide a new site for potential therapeutic intervention with colchicine, which, besides its antifibrotic properties, can prevent or delay hepatocellular carcinoma.

Applications

There was a statistically significant survival benefit in the colchicine group, in which complications were almost absent. The plasma levels of P-Ⅲ-P declined progressively only in the colchicine group. The authors concluded that colchicine is an effective and safe antifibrotic drug.

Terminology

Fibrosis and cirrhosis develop after persistent viral and helminthic infections, alcohol abuse, autoimmune hepatitis or metal overload. Serum N-terminal peptide of type Ⅲ collagen (P-Ⅲ-P) is a marker of fibrogenesis, that can be exploited in place of liver biopsy. Plasma pseudocholinesterase and albumin can be measured as a response to P-Ⅲ-P.

Peer review

The article presents evidence for a drug, colchicine, which could prevent progression of liver disease.

Abstract

AIM: To test a strategy for endoscopic submucosal dissection (ESD) training in animal models designed to overcome the initial learning curve.

METHODS: ESD was attempted in *ex vivo* and *in vivo* pig models. Thirty ESD procedures were attempted in the esophagus (n = 9) or the stomach (n = 21). The *ex vivo* model was used until initial competence was achieved. In the *in vivo* model, several ESD procedures were performed in up to 3 sessions. The following variables were analyzed: specimen size, complete and *en bloc* resection rate, time for circumferential incision, time for submucosal dissection, total ESD duration, and complications.

RESULTS: Complete resection was achieved in 28 cases (*en bloc* 27); 2 could not be completed (one perforation, one technical difficulty). The mean ± SD time for circumferential incision was 36.2 ± 16.8 min (range: 8-87 min), and the mean ± SD time for submucosal dissection was 45.1 ± 35.7 min (range: 9-196 min). The mean ± SD size of the resected specimens was 45.2 ± 17.8 mm. The mean ± SD total resection time was significantly increased for the gastric cases performed in the first half of the study (n = 13) than in the second half (n = 8) (98.9 ± 62.4 min *vs* 61.7 ± 17.6 min, P = 0.04), although the specimen size did not differ.

CONCLUSION: Training in animal models could help endoscopists overcome the learning curve before starting ESD in humans.

INTRODUCTION

Endoscopic submucosal dissection (ESD) is an emerging technique for the treatment of early digestive neoplasms *en bloc*, which was developed in Japan and has been proven efficacious and safe in expert hands[1,2]. However, the applicability of ESD in Western countries is still unclear for several reasons. First, the most frequent indication for ESD is early gastric cancer, which is a common finding in Japan but rare in the Western world[3]. Second, ESD is a very operator-dependent technique, and a learning curve exists; it has been estimated that 30 gastric cases need to performed under the supervision of an expert to overcome this learning curve[4,5]. For endoscopists at the beginning of the learning curve, the perforation rate can reach 20%, especially in the colon. Third, colorectal ESD could probably become a frequent indication for ESD in Western countries, but that is the most difficult location in which to perform ESD[6]. Although experts have suggested that ESD should be carried out in pigs before starting to apply it in humans - especially when it is performed without the supervision of an expert - there is no full published study reporting the results of ESD in pigs as a part of the training for this difficult therapeutic procedure[5]. Our hypothesis is that the strategy of learning ESD from experts, followed by training in harvested pig stomachs and then in live pigs, may be useful for overcoming the learning curve. The aim of our study was to prospectively determine the results, efficacy, and safety of ESD performed in pigs by an endoscopist at the beginning of the learning curve prior to its application in humans.

MATERIALS AND METHODS

Prior learning

One author (Parra-Blanco A) spent 1 mo (November 2006) at the National Cancer Center Hospital (NCCH), Tokyo, where he observed approximately 25 cases of ESD (esophageal, gastric, and colonic). He also performed 7 gastric ESD procedures in harvested stomachs under the supervision of an expert. The results of these procedures were not recorded, but all of them were gastric resections with an approximate greater diameter of the resected specimen of 3 cm.

Animal models

***Ex vivo* model:** A model for training in isolated esophaguses and stomachs, similar to the one previously used at the NCCH, was prepared at the first author's institution. A plastic box (40 cm × 25 cm × 15 cm) was used that had a 15 mm in diameter hole in one of the short sides. Stomachs with the whole esophagus attached were obtained from female, 70 kg, domestic pigs. They were washed vigorously with lukewarm water and a mucolytic (10% N-acetyl-cysteine). The stomach was laid on a metal plate inside the plastic box. An overtube was introduced into the hole and then inserted into the esophagus. Plastic clamps were employed to tighten the esophagus to the overtube and prevent it from sliding with the movements of the endoscope.

A dedicated endoscope was used (Fujinon EG-200HR) for all procedures in this study.

***In vivo* model:** Live, *Sus scrofa,* female, 30 kg, domestic pigs were used. The pigs fasted for 48 h prior to the procedure, and clear liquids were allowed *ad libitum*. Intramuscular (im) ketamine (11 mg/kg) was administered as a premedication. Induction was accomplished with intravenous (iv) propofol (16 mg/kg) and inhalation anesthesia with isoflurane.

When the procedure was finished, im buprenorphine (0.01-0.04 mg/kg) and iv omeprazole (40 mg) were administered. After ESD, the pigs only had clear liquids for 24 h, hypercaloric enteral nutrition solution for the next 24 h, and then fodder. Esomeprazole (40 mg) *per os* was given daily until the sacrifice of the pigs.

Each pig could be subjected to general anesthesia a maximum of 3 times, with an interval of 2 wk between sessions. One to 3 ESD procedures were performed during each session at the endoscopist's will, depending on the duration of the procedures. The pigs were monitored by the veterinary staff for signs of sepsis, distress, pain, and changes in feeding habits or behavior. The animals were sacrificed either at the end of the third session or at any time before that in the event of complications that could not be easily managed endoscopically.

The study was approved by the Animal Study Committee of our university.

Endoscopic procedures

All endoscopic procedures were carried out by a single experienced endoscopist (Parra-Blanco A). During each session, both with the harvested stomach and the live pig, he performed as many ESD procedures as desired, although a maximum limit of 5 h for the whole session was set. The ESD technique applied was basically similar to the one generally performed at the NCCH. ESD was attempted in the gastric body or the antrum of the stomach, excluding the fundus and the subcardial area. In the esophagus, generally the middle portion was selected, avoiding the esophago-gastric junction.

A needle knife (Olympus, KD 10Q-1) was usually used for the marking of the periphery of the selected area and the initial cut. After submucosal injection of fluid (10% glycerin) to raise the submucosal layer, at least 2 cuts were made usually at the 12 and 6 o'clock positions on the endoscopic image 5-10 mm away from the marking line. The insulated-tip (IT) knife (Olympus KD-610L, Tokyo, Japan) was generally used for the circumferential cutting of the mucosa surrounding the lesion and the dissection of the submucosal layer under the lesion. However the endoscopist could switch to any of the other devices: needle knife, Flex knife (Olympus KD-630L, Tokyo, Japan), and Hook knife (Olympus

KD-620 LR, Tokyo, Japan). For the dissection phase, a transparent hood was used (Olympus D-201-12704, Tokyo, Japan). Snaring of the partially dissected mucosa was considered only as the last choice in cases in which it was not possible to resect the lesion *en bloc* with the other devices. The Erbotom ICC 200 ERBE system was used (ERBE, Elektromedizin GmbH, Tübingen, Germany) as a high-frequency generator.

In both models, the resected specimens were pinned on a cork and then measured.

The following variables were prospectively recorded: (1) location of the targeted area (esophagus *vs* stomach); (2) endoscopic accessories employed; (3) time required from the marking until the end of the circumferential incision (circumferential cutting); (4) time from the end of the circumferential cutting until the end of the dissection (submucosal dissection); (5) size of the resected specimen; (6) completeness of the resection (complete *en bloc*, complete piecemeal, incomplete); and (7) complications (immediate bleeding, delayed bleeding that occurred after completion of the ESD, open perforation, and nontransmural damage to the proper muscle layer when electrocoagulation produced a distinct depression in that layer but without any open perforation).

Statistical analysis

A global χ^2 test was used to compare qualitative data. Continuous variables were compared with the nonparametric Mann-Whitney *U* test, and mean ± SD are reported. Calculated *P* values < 0.05 were considered to indicate statistical significance.

RESULTS

Thirty ESD procedures were carried out, 8 in the *ex vivo* model (esophagus 2, stomach 6) in 6 harvested organs and 22 in the *in vivo* model (esophagus 7, stomach 15) in 6 live pigs, during a 51 wk period (0.57 ESD/wk). Specific technical aspects corresponding to the 30 cases, including the types of knives employed, are presented in Table 1.

The mean ± SD time to perform the circumferential incision was 36.2 ± 16.8 min (range: 8-87 min), and the mean ± SD time to perform the submucosal dissection was 45.1 ± 35.7 min (range: 9-196 min). One procedure had to be stopped before completion because of a technical difficulty (case 20). This and another case in which a large perforation occurred were the only 2 cases of incomplete resection. Therefore, the resection was complete in 28/30 (93.3%). In 2 cases, the dissection had to be completed with a snare; this resulted in a piecemeal resection in one of these cases (case 12). Therefore *en bloc* resection was achieved in 90% (27/30) cases. Prophylactic hemostasis was conducted on the post-resection ulcer in 16/22 (72.7%) cases in the live pig model (with the IT knife or Flex knife). The mean ± SD size of the resected specimens was 45.2 ± 17.8 mm (22-116 mm). Table 2 presents results of the ESD procedures performed in the *ex vivo* and *in vivo* models.

When the first half of the cases was compared with the second half, no significant difference in the duration of the procedures was observed (93.1 ± 59.9 min *vs* 70.1 ± 24.6 min, $P = 0.34$). However, when only the gastric cases were considered, the mean ± SD time required from the end of the circumferential cutting until the end of the dissection was significantly longer in the gastric cases performed in the first half of the study ($n = 13$) than in the second half ($n = 8$) (58.6 ± 47.8 min *vs* 25.2 ± 11.4 min, $P = 0.025$). The mean ± SD total time for the resection was also significantly increased in the initial 13 gastric cases compared to the last 8 cases (98.9 ± 62.4 min *vs* 61.7 ± 17.6 min, $P = 0.045$). However, the size of the resected gastric specimens did not differ between cases performed during the first *vs* the second half of the study (49.3 ± 23.1 mm *vs* 50.1 ± 10.7 mm, respectively, $P = 0.34$).

Comparison of the gastric cases revealed that the mean total procedure times for the 6 *ex vivo* cases, the first 8 *in vivo* cases, and the last 7 *in vivo* cases were not significantly different. The mean sizes of the resected specimens also did not differ among the groups (Table 2).

In the *ex vivo* model, the locations of the resected areas were the lesser curvature ($n = 4$) and the greater curvature ($n = 2$). In the first 8 *in vivo* cases, the locations of the resected areas were the lesser curvature ($n = 1$), greater curvature ($n = 6$), and anterior wall ($n = 1$), and in the last 7 *in vivo* cases, the locations were the lesser curvature ($n = 2$), greater curvature ($n = 3$), and anterior wall ($n = 2$).

Comparison of the esophageal cases revealed that the mean total procedure times for the 2 *ex vivo* cases, the initial 3 *in vivo* cases, and the last 4 *in vivo* cases were 55.0 ± 7.1 min, 98.7 ± 23.2 min, and 65.5 ± 26.5 min, respectively, without significant differences among the groups (Table 2).

Complications

In 5/22 (22.7%) cases there was bleeding requiring coagulation with hot biopsy forceps, and all were easily managed without hemodynamic instability. There was nontransmural damage to the muscular layer in 4/9 (44.4%) esophageal cases and in 3/21 (14.3%) gastric cases, which was generally closed with clips. In the fourteenth case, a large upper gastric perforation occurred when the Hook knife was being used, requiring animal sacrifice. The only complication observed during follow-up was one case of esophageal stricture, which was easily dilated endoscopically.

One pig died 1 wk after undergoing gastric and esophageal ESD procedures; a necropsy showed signs consistent with cardiac tamponade, apparently unrelated to the endoscopic resections.

DISCUSSION

ESD is an emerging technique that allows for safe and effective *en bloc* resection of gastrointestinal neoplasms in expert hands[7]. However, it is technically demanding and, therefore, very operator-dependent. In Japan and some other Asian countries, training in this technique relies on supervision by experts, who take over the examination

when the trainees face technical difficulties or when serious complications (e.g. perforation) occur[5,8]. Because the technique is seldom practiced in Western countries, the best training strategy and the applicability of ESD remain unclear. Dinis-Ribeiro *et al*[9] have published results from an initial series of gastric ESD procedures performed in humans in a Western country. The ESD procedures in that study were performed by a single endoscopist who was trained in Japan, and animal training preceded application to human cases. However, the authors did not specifically describe the nature of the animal cases performed. Probst *et al*[10] reported 71 epithelial or submucosal lesions treated by ESD in a single German institution. They showed good results, with open gastric perforations in only 2 cases. The authors found a significant reduction in the procedural time in the second half of the cases; however this improvement might be also related to the training by a Japanese expert at that time. No previous animal training was described in this study.

In this study, we proposed a strategy for training in ESD in the absence of experts to supervise the procedures and ensure the patients' safety. In some previous

studies, pig models have been used to investigate new methods for ESD[11-13]. A European study evaluated the usefulness of a new endoscope with a double channel[14]. Six expert endoscopists participated in this study, in which 17 ESD procedures were performed in live pigs and 10 in humans during the clinical part of the study. The mean number of resections per endoscopist in this study was less than 5 - less than the estimated 30 cases of ESD needed to overcome the learning curve - and the effect of learning was not assessed. Therefore, to our knowledge, ours is the first study to evaluate the usefulness of pig models for ESD training, including a significant number of cases. Vázquez-Sequeiros *et al*[15] recently described the use of porcine models similar to those employed in this study, prior to attempting a human gastric ESD which was successful.

Choi *et al*[4] showed that when prior knowledge of advanced resection techniques is limited and no supervision by an expert in ESD is available, there is a learning curve in which not only the *en bloc* resection rate and procedure duration improve with increasing experience but, more importantly, the perforation rate decreases too. However, the technique employed in that study was not really what is currently understood as ESD, because a snare was used to encircle the lesion after margin cutting. Therefore, it is likely that if the real ESD technique is applied without any previous experience or supervision by experts, the complication rate would be greater than what was reported by Choi *et al*[4]. Therefore, self-taught learning is not desirable[6]. On the contrary, there do not seem to be any differences in the perforation rates between trainees and experts when the former are supervised by the latter[8]. Hence, training in animal models may not be needed in Japanese institutions where supervision by experts is available.

The incidence of gastric cancer is higher in Japan compared to that in most Western countries, where the number of early gastric lesions detected is low[16]. In those countries, it could be expected that colorectal and esophageal lesions (mainly Barrett's dysplasia) could be a frequent therapeutic indication for ESD. Performing ESD in such locations is especially complex and technically demanding, with an increased perforation risk[7]. Training in animal models appears to be a compulsory step before attempting to perform ESD in the absence of experts, which is the current situation in Western countries. Otherwise, it can be expected that the development of ESD outside of Japan and neighbouring countries will be very limited. Besides, prior training in animal models may carry medico-legal implications, and such previous experience could support the idea that the endoscopist is fit to perform ESD.

Our results suggest that there exists a learning curve for ESD in animal models. In the gastric cases, the time required for dissection was significantly reduced in the second half of the study, although the sizes of the resected specimens were similar. A large perforation occurred in one of the live pigs in our study, for which suture by clipping was considered impossible. Had such a large perforation occurred in a real patient, emergent surgery would certainly have been required.

In our strategy, we included previous learning from world experts in ESD, although the effect of that variable was not been tested in our study. Training in pigs could be started without such previous learning. However, there are certain technical tricks and tips that are difficult to learn by oneself, and ESD involves manoeuvres that traditionally have not been used during flexible endoscopy, such as the lateral cutting. Thus, to achieve the ability to perform ESD safely in humans, we believe that learning from experts is a must. Other possible strategies would be to organize training courses (with animal and/or human training) under the supervision of experts, or to attempt ESD procedures supervised by means of a videoconference. We have carried out both actions in our department, but its impact on ESD performance has yet to be reported.

The main limitation of our study may be the fact that the effect of training was assessed only in animal models; thus, there is no description of results from when the technique is applied in humans by the same endoscopist. The endoscopist who performed the cases in the present study has performed thereafter 6 cases in humans (5 gastric, 1 rectum) without any serious complication. A greater number of cases in humans has to be performed and the results monitored in order to determine the usefulness of ESD training with the strategy described in this study.

Although the endoscopic manoeuvres are certainly similar, regardless of whether a human or a pig is being endoscoped, there are several differences between the pig and human stomach that may contribute to technical differences. Firstly, it is accepted that bleeding in the pig is more infrequent and subtle. Secondly, the pig's mucosal layer appears to be thicker, as suggested by the fact that the submucosal injection frequently becomes very difficult to accomplish. Thirdly, as normal mucosa is resected in the pig model, no significant fibrosis is expected to be encountered during pig ESD. In contrast, fibrosis is a relatively frequent finding during ESD in humans, which makes the procedure more challenging. Fourthly, *ex vivo* and *in vivo* models were analyzed together in our study, and there might be certain peculiarities related to the 2 different models that could have influenced our results. However, our *ex vivo* model was prepared just a few hours after the animal was sacrificed. This is in contrast to some *ex vivo* models that are prepared after having kept the stomach frozen, which makes the tissue harder and probably more difficult to resect. Moreover, the sizes of the organs in the *ex vivo* models were quite larger than those in the *in vivo* models, as the former organs were obtained from 70 kg pigs and the latter, from 30 kg pigs. It was our impression that in the cases involving large *ex vivo* stomachs (which more closely resembled real human stomach), it was much easier to approach the lesser curvature. However, in the cases involving small *in vivo* stomachs, the lesser curvature was short and difficult to approach adequately with the gastroscope. For that reason, more areas in the greater curvature were targeted in the *in vivo* cases.

In order to fully understand the usefulness of *ex vivo* and *in vivo* models, future studies should compare the results of ESD performed in similarly sized stomachs in *ex vivo* and *in vivo* models.

Lastly, 7 gastric ESD procedures performed in the *ex vivo* model by the author supervised by the Japanese experts were not included in this study, as they were not videotaped or the procedure times registered. As they were done at the beginning of the learning curve, they were especially time consuming. Had those cases been included, the evidence of a learning curve might have been stronger.

In conclusion, ESD is a technically challenging procedure and there seems to be a learning curve, as suggested by this study. As potentially serious complications can occur in the absence of local expertise, it should probably not be applied to humans by endoscopists without any previous animal training. The learning strategy described provided good results in terms of efficacy and safety, as a prior step to its application in humans.

ACKNOWLEDGMENTS

The authors are grateful to the members of the Division of Gastrointestinal Endoscopy and Oncology, National Cancer Center, Tokyo, Japan, for generously teaching the technique of ESD; the personnel of the Animal Research Laboratory in La Laguna University for their assistance with the care of the animals used in the study; the personnel of the Endoscopy Unit and the Endovascular Neurosurgery Unit in the University Hospital of the Canary Islands for their assistance in the preparation of the *ex vivo* and *in vivo* models; Dr. Luis Fuster for his cooperation and advice with the anesthesia procedures; and Olympus for providing some of the ESD accessories and ST Endoscopia for loaning the dedicated gastroscope.

COMMENTS

Background

Endoscopic submucosal dissection (ESD) allows for *en bloc* resection of early neoplasms in the gastrointestinal tract. However, it is associated with a high rate of perforations, and it should be learnt from experts. In the absence of experts in western countries, practising in animal models may be helpful to overcome the learning curve.

Research frontiers

The results of large series of ESD in humans after previous training with animal models have to be clarified.

Innovations and breakthroughs

In this study, a strategy was proposed for ESD training, which included visiting an expert center, and then practicing gastric and esophageal ESD on *ex vivo* and finally on *in vivo* porcine model. The results of these ESDs were analyzed. The number of cases included was 30, as this is considered to represent the workload required to overcome the initial learning curve.

Applications

Complete resection was achieved in 93% cases. The dissection phase was the most time consuming, and as suggested by other studies this seems to be the most challenging for beginners. There seems to be a learning curve for gastric ESD when this training model is applied; therefore it would be justified to start training on animal models instead of on real patients, if experts are not available to supervise the procedures.

Terminology

Endoscopic submucosal dissection: this is an endoscopic method for complete *en bloc* resection of early gastrointestinal neoplasms, whose major drawback is that it is technically challenging and associated with a significant risk of complications mainly during the learning curve.

Peer review

It is a useful, structured experiment to demonstrate the effectiveness of using a pig model for ESD training. It showed technical skill of ESD could be improved by practice in the pig. It provides an alternative way to learn ESD in the future.

Abstract

AIM: To study whether high-sensitivity C-reactive protein (hs-CRP) measurement can aid the assessment of disease activity and glucocorticoid treatment in paediatric inflammatory bowel disease (IBD).

METHODS: CRP levels were measured in 39 children with IBD undergoing colonoscopy [median age 12.8 years, Crohn's disease (CD) n = 20], in 22 other children with IBD followed for acute response to glucocorticoids, and in 33 paediatric non-IBD patients. When standard CRP level was below detection limit (< 5 mg/L), hs-CRP was analyzed.

RESULTS: Sixty-four percent (25/39) of the children with IBD undergoing colonoscopy displayed undetectable (< 5 mg/L) standard CRP levels. Of these, the hs-CRP measurement could not differentiate between active (median, 0.2 mg/L, range, 0.007-1.37, n = 17) or quiescent (0.1 mg/L, 0.01-1.89, n = 8, P = NS) disease. Patients with ileocolonic CD had higher CRP levels (14 mg/L, 0.06-45, n = 13) than patients with no ileal involvement (0.18 mg/L, 0.01-9, n = 7, P < 0.01) or ulcerative colitis (UC) (0.13 mg/L, 0.007-23, P < 0.05). In children with active IBD treated with systemic glucocorticoids, the standard CRP was undetectable in 59% of the patients. The hs-CRP levels did not differ between patients that responded to steroid therapy and in non-responders.

CONCLUSION: The measurement of hs-CRP did not prove useful in the assessment of disease activity or glucocorticoid treatment in paediatric IBD patients that had undetectable standard CRP.

High-sensitivity C-reactive protein in paediatric inflammatory bowel disease. *World J Gastroenterol* 2010; 16(23): 2901-2906 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i23/2901.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i23.2901

INTRODUCTION

C-reactive protein (CRP) is produced mainly in hepatocytes in response to acute phase stimuli such as inflammation[1]. Its production is driven by circulating cytokines interleukin-6 (IL-6), IL-1β and tumor necrosis factor-α (TNF-α) originating from the inflamed tissues[2]. Genetic

variation, as well as age and sex affect the CRP levels[3]. As an acute phase response, CRP concentration may increase rapidly up to 1000-fold[4].

CRP is commonly used to screen the activity of chronic inflammatory diseases including inflammatory bowel disease (IBD). A study comparing CRP with clinical, endoscopic and radiologic findings in adults with IBD found an association between CRP, clinical disease activity, endoscopic inflammation and active histological inflammation[5]. Very recently however, a Norwegian group reported that only 29% of adult patients with ulcerative colitis (UC) and 75% of patients with Crohn's disease (CD) had elevated CRP levels at diagnosis[6]. In general, CD patients have higher CRP levels than patients with UC[7]. Still, also in CD a subgroup of patients with clinically active disease present with low CRP. In two large clinical studies investigating new biological agents (CDP870 and natalizumab, respectively) in active CD, 60% of the patients had CRP levels below 10 mg/L and 25% below 3 mg/L[8,9].

In children, the data on CRP levels in active IBD is sparse. In a report from St Bartholomew's Hospital, all paediatric patients with active CD (n = 26) had CRP values higher than 5 mg/L; of patients with UC (n = 13), only 60% reached this cut-off level[10].

High-sensitivity CRP (hs-CRP) assays measure CRP levels that were previously thought to be under the detection limit. In adult IBD patients, hs-CRP correlates with clinical disease activity in both UC and CD[11]. In children, this question has not been addressed. Therefore, in this pilot study we investigated the association between hs-CRP and clinical and histological activity in paediatric IBD patients, and evaluated the effect of glucocorticoid treatment on the hs-CRP levels.

Table 1 The background data of the paediatric IBD patients with CRP measurement at the time of the colonoscopy (n = 39)

UC	19
M/F	10/9
Pancolitis	16
Left-sided disease	3
CD	20
M/F	14/6
Ileocolitis	13
Colitis	7
Age (median, range, yr)	12.8 (1.9-18)
BMI (median, range, kg/m^2)	18.40 (14.2-25)
Fresh diagnosis	20/39

Notably, all patients with Crohn's disease presented with colitis. IBD: Inflammatory bowel disease; CRP: C-reactive protein; UC: Ulcerative colitis; CD: Crohn's disease; BMI: Body mass index.

Table 2 The clinical characteristics of the 22 paediatric IBD patients followed for acute response to glucocorticoids

UC	14
M/F	9/5

IC	1 male
Age (median, range, yr)	13.1 (3.5-18)
BMI (median, range, kg/m^2)	16.9 (13.2-22.6)
Fresh diagnosis	7/22

IC: Indeterminate colitis.

MATERIALS AND METHODS

Subjects

Study group Ⅰ: Paediatric IBD patients studied at the time of colonoscopy: The first group was stratified from the consecutive paediatric IBD patients who underwent colonoscopies and agreed to participate in a follow-up study of IBD patients at the Hospital for Children and Adolescents, Helsinki, Finland. Inclusion criteria to the study were (1) endoscopy-based diagnosis of either UC or CD[12], and (2) age ⩽ 18 years. Exclusion criteria were (1) previous surgery, and (2) any signs of infection during the preceding week.

The clinical characteristics of the 39 patients are shown in Table 1. 20 patients were newly diagnosed. The other 19 patients received the following medication: 7 patients were on 5-ASA, 3 patients on 5-ASA and glucocorticoid, 3 patients were on 5-ASA, glucocorticoid and azathioprine, 1 patient on 5-ASA and antibiotics, 1 patient on glucocorticoid and azathioprine, and 1 patient on glucocorticoid, azathioprine, antibiotics and infliximab. Two patients had no medication due to quiescent disease and 1 patient had no medication due to non-compliance.

The patients who underwent colonoscopy due to fresh disease, aggravation of the symptoms or lack of response to conventional medication were defined as having clinically active disease according to Physicians Global Assessment (PGA). The patients who underwent colonoscopy in clinical remission according to PGA were categorized as having quiescent disease.

Study group Ⅱ: Paediatric IBD patients followed up for acute response to glucocorticoids: The second group was a prospectively collected group of 22 children and adolescents (median age 13.1 years, age range 3.5-18 years) with active IBD who were introduced to systemic glucocorticoid treatment due to active disease (Table 2) as described in detail[13]. Six patients in this study were recruited to the prospective extension of the previous study[13]. Other inclusion criteria to the study were similar to group Ⅰ. The maintenance medication of the patients at the onset of the steroid was: 5-ASA (n = 12), 5-ASA and azathioprine (n = 2), antibiotics (n = 4), no medication (n = 4).

The glucocorticoid treatment was started either with peroral prednisolone (1 mg/kg per day, Prednisolone®, Leiras, Finland, n = 20) or budesonide (9 mg/d, Entocort®, AstraZeneca AB, Sweden, n = 2). The venous blood samples were drawn before the treatment was started and at the clinical follow-up visit at 2-4 wk after starting the glucocorticoid.

Clinician's judgement (PGA) of clinical improvement (decrease in stool rate and the amount of blood in the stools, abating diarrhea) and decrease in the inflammatory markers [erythrocyte sedimentation rate (ESR) and faecal calprotectin] by the time of the follow-up visit (see above) was defined as therapeutic response. When these patients were recruited, no paediatric activity index for UC yet existed[14]. Acute (appearing during the first month of the treatment) glucocorticoid-related side effects (weight gain, development of moon face, striae or acne) were registered[13]. The therapeutic response and the development of side-effects were both graded with a two-grade scale (good/poor response, yes/no side effects)[15,16].

Controls: Thirty-three children and adolescents (median age 12.1 years, range 1.8-17.2 years) visiting the Outpatient Clinic of the Hospital for Children and Adolescents, Helsinki, Finland, due to gastrointestinal disorder (coeliac disease $n = 5$, loose stools $n = 4$, liver dysfunction $n = 3$, pancreatic dysfunction $n = 3$, abdominal pain $n = 2$, Helicobacter gastritis $n = 1$, gastro-oesophageal reflux disease $n = 1$), growth follow-up $n = 4$, derangement in laboratory tests (hypercholesterolemia $n = 3$, leukopenia $n = 1$, sideropenia $n = 1$) or other reasons (obesity $n = 1$, fatigue $n = 2$, talassemia $n = 1$, and toe pain $n = 1$) served as non-IBD controls. Patients with acute infection, fever or trauma were excluded.

Histology

During the colonoscopies, routine biopsies were taken from the ileum, caecum, colon ascendens, transversum, descendens, sigma and rectum. The histological findings were graded by an experienced paediatric pathologist (R.K.) with a modified histology score originally developed for CD (Table 3)[17,18]. The score was calculated: (1) separately for each segment (max 15 points) and (2) adding the scores of the caecum, colon ascendens, transversum, descendens, sigma and rectum to obtain the total score for the colon (max 90 points). Eosinophils were taken into account when analysing the quantity of the polymorphonuclear cells. Instead, lymphoid hyperplasia was omitted from the count, since it represents a normal variant. The presence of granulomas was registered, but not calculated in the score.

Laboratory analyses

The venous blood samples were scheduled between 11 am and 3 pm. Blood count, standard CRP (detection limit 5 mg/L), and ESR were analysed in a clinical laboratory. In patients with standard CRP levels under the detection limit, serum hs-CRP levels were measured. The hs-CRP analyses were performed with a human C-reactive protein Instant ELISA kit (Bender MedSystems GmbH, Vienna, Austria) that has an intra-assay coefficient of variation (C.V.) of 6.9%, interassay C.V. of 13.1% and detection limit of 3×10^{-6} mg/L. Faecal calprotectin was quantified as previously reported[19].

Statistical analysis

Mann-Whitney's *U* test, Kruskal-Wallis test, Wilcoxon's signed rank sum test, Fisher's exact test and Spearman's rank order correlation test were used when investigating associations between non-parametric variables. Statistical analyses were performed using SPSS by SPSS Inc. software. $P < 0.05$ was accepted to indicate statistical significance. Values are expressed as median (range) in the text.

Ethical considerations

The families were informed about the study, and a written informed consent was obtained from the patient and their guardians. The study protocol was approved by the Ethics Committee for the Hospital for Children and Adolescents, University of Helsinki.

RESULTS

The CRP levels in paediatric IBD patients at the time of the colonoscopy

Standard CRP testing was undetectable (< 5 mg/L) in 64% (25/39) paediatric IBD patients investigated at the time of the colonoscopy. Of the patients with standard CRP levels below the detection limit, hs-CRP was measurable in all cases (Figure 1).

The median CRP level in the whole IBD group was 0.4 mg/L (0.007-45 mg/L). In all IBD patients, either with a fresh (0.7 mg/L, 0.02-39) or existing (0.2 mg/L, 0.007-45) diagnosis of colitis, CRP levels were higher than in the control patients ($P < 0.01$, see below). However, in patients with standard CRP levels under the detection limit of 5 mg/L, the hs-CRP measurement could

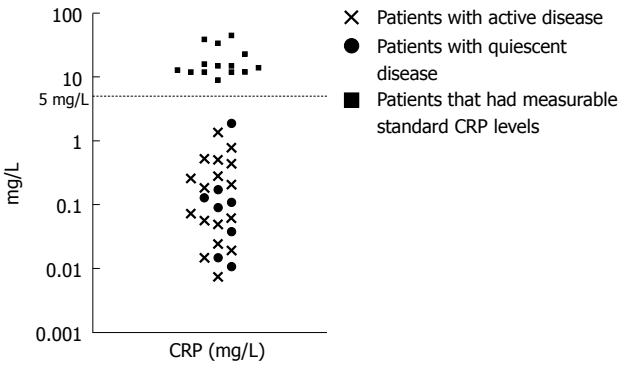

Figure 1 The C-reactive protein (CRP) levels in the 39 paediatric inflammatory bowel disease (IBD) patients undergoing colonoscopy. 14 patients had measurable (> 5 mg/L) standard CRP levels, the high-sensitivity CRP (hs-CRP) levels were analyzed in 25 patients that had undetectable standard CRP. For hs-CRP the detection limit is 3×10^{-6} mg/L.

not stratify the patients according to disease activity (active disease 0.2 mg/L, 0.007-1.37, $n = 17$ *vs* quiescent disease 0.1 mg/L, 0.01-1.89, $n = 8$, P = NS).

In CD patients, standard CRP was undetectable in 45% (9/20) of the patients, in UC in 84% (16/19) of the patients ($P < 0.05$). Patients with ileocolonic CD had clearly higher CRP levels (14 mg/L, 0.06-45, $n = 13$) than patients with CD colitis (0.18 mg/L, 0.01-9, $n = 7$, $P < 0.01$) whose CRP levels were similar to the patients with UC (0.13 mg/L, 0.007-23, P = NS). The CRP levels in CD patients were also higher in those presenting with granulomas (14 mg/L, 0.5-39, $n = 9$) than in those without granulomas (0.5 mg/L, 0.01-45, $n = 11$, $P < 0.05$). However, patients with granulomas did not have significantly more ileocolonic disease than colitis ($P = 0.07$).

The correlations between CRP levels, inflammatory markers and histology score, and the median (range) of these variables are presented in Table 4. The CRP levels did not correlate with age or weight; however, boys had higher CRP levels (4.9 mg/L, 0.007-45, $n = 24$) than girls (0.2 mg/L, 0.01-14, $n = 15$, $P < 0.05$).

The CRP levels in the non-IBD controls

The median CRP level in the 33 non-IBD controls was 0.03 mg/L (0.008-0.7 mg/L), significantly lower that in the above-mentioned group of 39 IBD patients ($P < 0.001$). In controls, the distribution of age (12.1 years, 1.8-17.2), sex (20 males, 13 females) and weight (37 kg, 12.8-84.6) were comparable to the 39 IBD patients (P = NS). Unlike in the IBD patients, CRP in the control patients correlated with weight ($r = 0.460$, $P < 0.01$). The control patients in the highest hs-CRP quartile were admitted due to obesity ($n = 1$), chronic autoimmune hepatitis ($n = 1$), leukopenia ($n = 1$), hypercholesterolemia ($n = 1$), talassemia minor ($n = 1$), gastro-oesophageal reflux disease ($n = 1$), coeliac disease ($n = 1$) and growth follow-up ($n = 1$).

The CRP levels in children with IBD during glucocorticoid therapy

The median pre-treatment CRP level of the 22 IBD patients starting peroral glucocorticoid therapy was 0.6 mg/L (0.01-39), similar to the level of CRP in the 39 IBD patients undergoing colonoscopy (P = NS). At the onset of the glucocorticoid treatment, the standard CRP levels were below the detection limit of 5 mg/L in 59% (13/22) of the patients. After 2-4 wk of treatment, the median level was 0.08 mg/L (0.004-60, $P < 0.05$). Of the 13 patients whose hs-CRP was measured (standard CRP undetectable), 7 patients responded well to the glucocorticoids; however the change in their hs-CRP levels during the glucocorticoid did not differ from those patients who had poor response ($P = 0.16$). The development of glucocorticoid-related side effects was not associated with serum CRP levels (data not shown).

Table 4 The median (range) levels of inflammatory markers and histology score and their correlation with the CRP levels in 39 paediatric patients with IBD

	Median (range)	Correlation with CRP
Inflammatory markers		
Calprotectin ($n = 35$)	690 μg/g (14-4400)	0.488[b]
ESR ($n = 37$)	18 mm/h (2-97)	0.618[d]
WBC ($n = 38$)	7.6 E9/L (3.2-17.4)	-0.011
Histology score		
Ileum ($n = 29$)[1]	0 (0-15)	0.475[a]
Caecum ($n = 38$)	4 (0-14)	-0.036
Ascendens ($n = 34$)	4.5 (0-13)	-0.198
Transversum ($n = 36$)	6 (0-15)	-0.158
Descendens ($n = 39$)	6 (0-15)	-0.077
Sigma ($n = 35$)	5 (0-14)	-0.014
Rectum ($n = 38$)	5.5 (0-14)	-0.051
Total colon ($n = 32$)	30 (0-74)	-0.083

[1]The histology score of the ileum was positive in only one UC patient (with backwash ileitis), all the other positive scores are from CD patients. [a]$P < 0.05$, [b]$P < 0.01$, [d]$P < 0.001$. ESR: Erythrocyte sedimentation rate; WBC: White blood cell count.

DISCUSSION

The aim of our study was to analyse whether hs-CRP can improve the assessment of disease activity in paediatric patients with IBD. We measured CRP with standard and high-sensitivity methods in children and adolescents presenting with colitis, and studied the association with other inflammatory markers (ESR, faecal calprotectin, and white blood cell count) and with the histological activity of the inflammation in the gut.

Even though CRP is commonly used as a marker of inflammatory activity in IBD patients, our findings support the concept that a significant number of patients with active IBD present with low CRP levels[6,10]. Here, standard CRP was under the detection limit of 5 mg/L in 60% of the paediatric patients with active colitis. All patients with undetectable standard CRP had measurable hs-CRP levels but there was no cut-off value for low CRP values with which to differentiate active and quiescent disease.

In this study all patients with CD presented with colitis. Thereby, it was somewhat surprising that there was a clear difference in the CRP values between UC and CD, the latter presenting with higher values. However, high CRP values associated with ileocolonic CD and

in CD colitis with no ileal involvement the CRP values were similar to UC. This is in contrast to previous studies in adults with IBD showing no difference between disease location and CRP levels in CD patients, or even opposing results - ileal disease associated with low CRP levels[6,20]. However, in our study we investigated also the association between CRP and histological activity of the colonoscopy biopsies, and found that the CRP levels correlated only with the histological score of the ileal biopsies, not with colonic inflammation. Studies in adults with CD have shown that an accumulation of intra-abdominal fat has been observed in CD patients, and that CRP levels correlate with radiological findings of small bowel perienteric inflammation (increased fat density)[21,22]. Since CRP is expressed in human adipose tissue, our findings may reflect higher local CRP production in the inflamed perienteric ileal region[23].

The association between granulomas and CRP levels in our study is a novel observation. In the literature, the evidence on the clinical significance of granulomas in CD patients is conflicting. Some studies associate the presence of granulomas with a more aggressive disease course, whereas others do not report any connection between granulomas and disease severity[24,25]. Recently, a study from the Children's Hospital of Philadelphia did not find a relationship between CRP levels and granulomas, although the presence of granulomas was associated with a more severe disease course[26]. The discrepancy between the CRP findings in these two studies could be explained by the fact that the patient populations differ, because the US study also included patients presenting granulomas only in the upper GI tract or terminal ileum. In an *in vitro* study, invasive *Escherichia coli* strains recovered from CD lesions caused macrophages to secrete TNF-α[27]. It is intriguing to speculate that higher local production of TNF-α in the granulomatous lesions of CD patients could explain the higher CRP levels associating with granulomas in our study. However, as yet the relationship remains elusive.

Only a few groups have studied the hs-CRP levels in IBD, and none of them have concentrated on the treatment-induced changes[11,28,29]. In this study, we additionally analysed a group of children and adolescents with IBD that started peroral glucocorticoid therapy due to the activation of the disease. In our small group of patients however, the measurement of hs-CRP did not provide any additional information as to the treatment of these patients.

Limitations of our study are the relatively small sample size, especially when the patients are divided into subgroups of UC and CD. In addition, apart from inflammation, minor trauma, acute infection, obesity and the use of NSAIDs, and genetic heterogeneity in the basal expression of CRP may affect the hs-CRP levels[30]. However, all patients undergoing colonoscopy had normal BMI and did not have any clinical signs of acute infection. As the subjects are children, we cannot rule out the possibility of minor bumps and bruises that might have affected the hs-CRP levels. Also, the possible intake of NSAIDs was unfortunately not recorded.

In conclusion, our study reinforces the concept that a significant number of paediatric patients with active IBD may present with CRP levels that are under the detection limit. Hs-CRP instead, was detectable in all the patients. Unfortunately, in this pilot study the measurement of hs-CRP levels in the patients that had undetectable standard CRP levels could not stratify the patients according to disease activity or response to treatment.

COMMENTS

Background

C-reactive protein (CRP) is used to assess disease activity in diverse inflammatory disorders including inflammatory bowel disease (IBD). However, in IBD a significant number of patients present with low CRP levels despite clinically active disease. In paediatric patients with IBD the performance of CRP is an understudied area.

Research frontiers

High-sensitivity CRP (hs-CRP) measures CRP levels that were previously thought to be under the detection limit. In paediatric IBD, this kind of highly sensitive marker is needed for the detection of the presence of inflammation. Thus, the authors studied the performance of hs-CRP in paediatric IBD to see whether it improves the assessment of inflammation in these patients and/or associates with the response to glucocorticoid therapy.

Innovations and breakthroughs

Hs-CRP is a sensitive marker of inflammation that is used in various conditions (asthma, cardiovascular disease). In paediatric IBD, the performance of the hs-CRP has not been studied previously. The authors show here that standard CRP test is negative in a considerable number of paediatric patients with active IBD and the routine measurement of CRP is thus not informative enough. Hs-CRP detects low levels of CRP but disappointingly it does not help to distinguish children with active intestinal inflammation from those with quiescent disease or those responding to glucocorticoid treatment from non-responders. Interestingly, the levels of hs-CRP correlated with the presence of ileal inflammation.

Applications

The determination of hs-CRP seems to be of minor aid in assessing the presence of inflammation in paediatric IBD. In ileal disease, however, hs-CRP correlates with the presence of histological inflammation, a finding warranting further studies.

Terminology

IBD comprising Crohn's disease (CD) and ulcerative colitis is a chronic, relapsing and remitting disease of the gastrointestinal tract characterized by diarrhea, abdominal pain and weight loss. CRP is an acute phase protein produced by liver that is used in the diagnosis of inflammatory disorders.

Peer review

This clinical study has originality, is well designed and executed; the results are well presented and interpreted. Although this study shows a negative result, it has still provided valuable information on the CRP measurement in children IBD patients. One of the weaknesses is the small sample size of subgroup patients particularly CD patients in Table 2. It would strengthen the conclusion if more patients were included in this study.

Abstract

AIM: To clarify the endoscopic and clinical findings of cytomegalovirus (CMV) gastritis after allogeneic hematopoietic stem cell transplantation (allo-SCT).

METHODS: Between 1999 and 2005, 523 patients underwent allo-SCT at our hospital, and 115 of these patients with gastrointestinal symptoms underwent esophagogastroduodenoscopy.

RESULTS: CMV gastritis was diagnosed pathologically in seven patients (1.3%) with the other 108 patients serving as controls. Six of the seven patients developed positive CMV antigenemia, and five complained of abdominal pain. Development of abdominal pain preceded CMV antigenemia in four of the five patients. Endoscopic examination showed oozing (n = 2), erosion (n = 6), and redness (n = 5) in the seven patients with CMV gastritis, while the control patients showed oozing (n = 3), erosion (n = 24), and redness (n = 100). Erosion and oozing were more frequently documented in patients with CMV gastritis compared with the controls, and the differences were statistically significant (P = 0.0012 and 0.029, respectively). CMV inclusion bodies were documented in 12 of 14 biopsy specimens obtained from erosive lesions, while they were identified in 4 of 15 biopsy specimens obtained from lesions other than erosions (P = 0.0025).

CONCLUSION: This study suggests that erosion and oozing, as well as abdominal pain, are useful indicators in the diagnosis of CMV gastritis following allo-SCT.

INTRODUCTION

Cytomegalovirus (CMV) disease is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-SCT)[1], which is widely accepted as a curative therapy for advanced hematological malignancies including leukemia and malignant lymphoma. CMV disease can involve many organs and the gastrointestinal (GI) tract is a common target[2].

CMV antigenemia is one of the most widely used methods to detect CMV reactivation in a variety of clinical settings[3]; however, it is of limited value in predicting and diagnosing GI CMV disease[4]. GI CMV disease is usually diagnosed based on pathological examination of endoscopically obtained mucosal biopsy specimens. Few reports have been published regarding endoscopic examination in diagnosing CMV gastritis after allo-SCT[5-7]. This study aimed to investigate endoscopic findings of CMV gastritis after allo-SCT in addition to its clinical features.

MATERIALS AND METHODS

Study patients

Between January 1999 and September 2005, 523 patients underwent allo-SCT at the National Cancer Center Hospital in Tokyo, Japan. Among them, 115 patients with GI symptoms underwent esophagogastroduodenoscopy (EGD). Written informed consent was obtained from all patients before EGD. We retrospectively reviewed records of medical, endoscopic and pathological examination in the 115 EGD patients. CMV gastritis was diagnosed pathologically in seven patients (1.3%) by hematoxylin-eosin staining and immunohistochemical staining with an anti-CMV antibody. The other 108 patients served as controls.

Endoscopic procedure

All EGD patients orally received 100 mL of a solution containing 1 g of pronase and 1 g of sodium bicarbonate to remove mucus and bubbles on the gastric mucosa before EGD. Antiperistaltic agents (scopolamine butylbromide 20 mg or glucagon 1 mg) and sedatives (pethidine hydrochloride 17.5-35 mg or midazolam 2-3 mg) were injected intravenously. Conventional endoscopic instruments (GIF Q240; Olympus Co, Ltd, Tokyo, Japan) were used, and biopsy specimens were obtained endoscopically from severely involved areas. When abnormal findings were not found, biopsy specimens were obtained from normal appearing areas.

Pathological examination

Biopsy specimens were fixed immediately in a 10% buffered formalin solution and subsequently stained with hematoxylin-eosin. All tissues were examined by expert pathologists. Diagnosis of CMV gastritis was based on histological identification of CMV inclusion bodies by hematoxylin-eosin staining and immunohistochemical staining with an anti-CMV antibody. Diagnosis of graft-versus-host disease (GVHD) was determined in accordance with a report published previously[8].

Management of CMV

All patients were monitored at least once a week for CMV reactivation by CMV antigenemia assay using monoclonal antibody against C7-HRP (Teijin, Tokyo, Japan) after engraftment.

A patient was considered to be infected with CMV when CMV antigenemia assay detected CMV in the blood. A patient was considered to have CMV disease when CMV was demonstrated in biopsy specimens by hematoxylin-eosin staining and immunohistochemical analysis. Ganciclovir was initiated when either more than 10 cells per 50 000 cells were positive according to the CMV antigenemia assay in patients transplanted from related donors, a single cell per 50 000 cells was positive in patients transplanted from unrelated donors, or a patient was diagnosed as having CMV disease[9].

Management of GVHD

Acute GVHD was graded according to the consensus criteria[10,11] and all patients with grades Ⅱ-Ⅳ acute GVHD were treated with 0.5-2.0 mg/kg per day of methylprednisolone.

Statistical analysis

Univariate analysis using Fisher's exact test was performed to compare differences in patient characteristics, clinical features, and endoscopic findings between the seven patients with CMV gastritis and the other 108 patients who had GI symptoms, but did not have CMV gastritis. Values of $P < 0.05$ were considered significant.

RESULTS

Patient characteristics

Patient characteristics are shown in Table 1. There was a significant difference in the number of patients given tacrolimus with methotrexate as GVHD prophylaxis between the two groups ($P = 0.018$).

Clinical features

Five of the seven patients with CMV gastritis complained of abdominal pain, while 31 of the 108 control patients complained of abdominal pain ($P = 0.030$) (Table 2). The pain was localized in the upper abdomen in all four patients with CMV gastritis whose medical reports provided the specific location of their pain (Table 3). Three patients required significant analgesia (morphine hydrochloride for one and pentazocine hydrochloride for the other two). Abdominal pain improved with ganciclovir in four of the five patients with abdominal pain, and the remaining patient (Case 1) died of bacterial pneumonia without any improvement in CMV gastritis.

Watery diarrhea was found in four of the seven patients with CMV gastritis, and was complicated by intes-

Table 1 Patient characteristics with and without CMV gastritis

Variables		Patients with CMV gastritis (n = 7)	Patients without CMV gastritis (n = 108)

EGD: Esophagogastroduodenoscopy; NA: Not applicable. [a]P = 0.030, [b]P = 0.0026, [c]P = 0.044, [d]P = 0.0023.

Table 3 Clinical features of CMV gastritis

	Demographics	Gastrointestinal symptoms			CMV antigenemia assay	
	Age (yr), gender, diagnosis	Any symptoms	Abdominal pain		Onset (d)	Level at EGD (cells per 50000)
			Onset (d)	Localization in abdomen		
Case 1	34, male, CML	Abdominal pain, tarry stool	81	Upper abdomen	88	8
Case 2	43, female, MDS	Nausea, abdominal pain, tarry stool, hematemesis, watery diarrhea	53	No description	69	2
Case 3	60, male, AML	Abdominal pain, watery diarrhea	62	Upper abdomen	73	143
Case 4	48, female, ML	Abdominal pain, watery diarrhea	36	Upper abdomen	31	10
Case 5	47, male, ML	Abdominal pain, watery diarrhea	30	Upper abdomen	32	4
Case 6	62, male, CML	Abdominal discomfort	NA	NA	47	32
Case 7	26, male, ML	Nausea, vomiting, abdominal discomfort	NA	NA	NA	0[1]

[1]CMV antigenemia remained negative throughout clinical course. CML: Chronic myelocytic leukemia; MDS: Myelodysplastic syndrome; AML: Acute myelocytic leukemia; ML: Malignant lymphoma.

tinal GVHD in three of these four patients. Watery diarrhea improved with ganciclovir in a patient with CMV gastritis who had no evidence of intestinal GVHD.

All seven patients with CMV gastritis had GVHD, while 65 of the 108 control patients had GVHD (P = 0.044) (Table 2). Five of the seven patients with CMV gastritis had grade Ⅱ-Ⅳ GVHD that was being treated by corticosteroids.

CMV antigenemia assay

Six of the seven patients with CMV gastritis and 28 of the 108 controls showed positive CMV antigenemia (P =

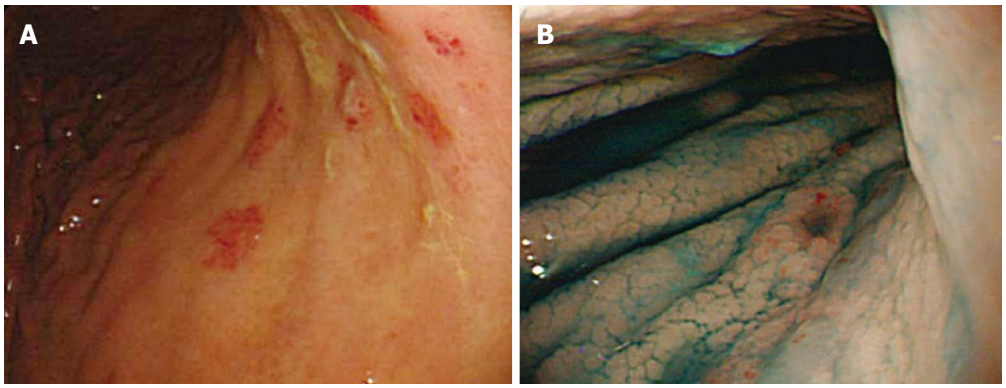

Figure 1 Erosion (Case 6). Multiple erosions are clearly shown in gastric body. A: Before indigo carmine dye spraying; B: After indigo carmine dye spraying).

Table 4 Endoscopic features in patients with and without CMV gastritis

Variables	Patients with CMV gastritis (n = 7)	Patients without CMV gastritis (n = 108)
Atrophic mucosa	3	36
Redness	5	100
Edema	2	9
Orange peel appearance	2	21
Mucosal sloughing	1	6
Erosion	6[b]	24[b]
Ulceration	0	2
Oozing	2[a]	3[a]

[a]P = 0.029, [b]P = 0.0012.

0.0026) (Table 2). The median number of positive cells in the CMV antigenemia test among the seven patients with CMV gastritis was 8 cells per 50 000 cells (range, 0-143) at the time of EGD.

Development of abdominal pain preceded the CMV antigenemia in four of the five patients who complained of it, and the median interval between onset of abdominal pain and the first positive CMV antigenemia was 7 d (range, -5 to 16 d) (Table 3).

Endoscopic findings

Erosion was observed in six of the seven patients with CMV gastritis and in 24 of the 108 control patients (P = 0.0012) (Table 4). The erosive lesions were located in the antrum (n = 2), body (n = 2), and antrum-body (n = 2) of the stomach. Two of the six patients had a solitary erosion, and the other four patients had multiple erosions of various sizes. Erosions were flat in four patients and raised in the other two. A representative example of erosion is shown in the accompanying figure; multiple erosions are clearly shown in the gastric body (Figure 1).

Oozing was observed in two of the seven patients with CMV gastritis and in three of the 108 control patients (P = 0.029). Oozing was located in the antrum with erosion (Case 3), and in the antrum-body with mucosal sloughing (Case 2).

Pathological findings

Detailed information regarding pathological findings is shown in Table 5. CMV inclusion bodies were documented in 12 of 14 biopsy specimens obtained from erosive lesions, while they were identified in 4 of 15 biopsy specimens obtained from lesions other than erosions (P = 0.0025) (Table 5).

Outcomes

Four patients died, and CMV disease was not the primary cause of death in any of them (Table 5). Two died from recurrences of their primary diseases, one died of bacterial pneumonia and one died of renal failure.

DISCUSSION

The present study clarifies the endoscopic findings of CMV gastritis following allo-SCT in addition to its clinical features. CMV gastritis was diagnosed pathologically in seven patients (1.3%) among 523 patients who underwent allo-SCT at our facility. The incidence is comparable to a previous study (1.7%)[12]. None of the seven patients died of CMV gastritis, while three patients complained of significant abdominal pain requiring analgesia which impaired their quality of life. CMV gastritis was a clinically important complication after allo-SCT.

No detailed information on clinical features of CMV gastritis has been previously reported. In the present study, abdominal pain was a common symptom of CMV gastritis. The pain was localized in the upper abdomen in all four patients whose medical reports provided the specific location of their pain. Ganciclovir administration improved abdominal pain in these four patients, supporting the likelihood that this symptom was attributable to CMV gastritis. Clinicians should pay particular attention to upper abdominal pain following allo-SCT as a possible symptom of CMV gastritis.

The association between watery diarrhea and CMV gastritis may be minimal as it remained unclear whether such diarrhea was due to CMV gastritis or overlapping intestinal GVHD. In the present study, ganciclovir improved symptoms in only one of four patients with diarrhea. In contrast, CMV gastritis was complicated by intestinal GVHD in three of those four patients. Our observations suggested that watery diarrhea in patients with CMV gastritis was more likely due to intestinal GVHD rather than the CMV gastritis itself.

Endoscopic findings characteristic of CMV gastritis

Table 5 CMV inclusion bodies and response to ganciclovir of CMV gastritis

	Positive specimens with CMV inclusion bodies/total specimens in EGD biopsy				Response to ganciclovir		Outcome	
	Total	Erosions	Mucosal sloughing	Other findings or normal mucosa	Abdominal pain	CMV antigenemia assay	Outcome	Cause of death
Case 1	1/2	1/2	None	0	Continued	Continued	Death	Bacterial pneumonia
Case 2	2/2	None	2/2[1]	0	Improved	Turned negative	Death	Recurrence of primary disease
Case 3	2/3	2/3[1]	None	0	Improved	Turned negative	Death	Renal failure
Case 4	5/7	4/4	None	1[2]/3	Improved	Turned negative	Alive	NA
Case 5	1/5	1/1	None	0/4	Improved	Turned negative	Alive	NA
Case 6	4/7	3/3	None	1[2]/4	NA	Turned negative	Alive	NA
Case 7	1/3	1/1	None	0/2	NA[3]	NA[4]	Death	Recurrence of primary disease
Case 7		26, male, ML		Nausea, vomiting, abdominal discomfort	NA	NA	NA	0[1]

[1]Oozing was accompanied in these findings; [2]The patient was not given ganciclovir, but CMV gastritis improved spontaneously; [3]The patient was not given ganciclovir, and CMV antigenemia remained negative throughout clinical course; [4]The patient was not given ganciclovir, and CMV antigenemia remained negative throughout clinical course.

after allo-SCT have not been fully investigated, but the present study indicates that erosion and oozing might be useful markers for early diagnosis of CMV gastritis. Vascular endothelium infected with CMV narrows vessels and induces local ischemia[13] eventually resulting in erosions and oozing. In fact, most CMV inclusion bodies were obtained from erosion sites. Erosions from CMV gastritis developed in all stomach sites and varied in size. Endoscopists should suspect CMV gastritis and obtain multiple biopsies whenever erosions are found in any stomach site.

In contrast, none of the seven patients with CMV gastritis had punched out ulcers which had previously been considered characteristic of GI CMV disease[14-16]. In the present study, early EGD might have enabled early diagnosis of CMV gastritis before progression to ulcers. In two patients (Cases 4 and 6), CMV inclusion bodies were identified pathologically from normal mucosa as well as erosions. This result demonstrates the necessity of biopsy even if only normal findings are identified when EGD is performed.

CMV antigenemia reflects the severity of CMV reactivation[3,17], but the clinical significance of CMV antigenemia remains unknown in the diagnosis of GI CMV disease because of the wide variation in positive findings, ranging from a low of 21%[4] to a high of 73%[18]. In this study, CMV antigenemia was positive in six of the seven patients with CMV gastritis. This result supports the usefulness of CMV antigenemia in the diagnosis of CMV gastritis. It should be noted that abdominal pain preceded CMV antigenemia in four of the five patients with positive CMV antigenemia and abdominal pain. Our observations suggest that elaboration of physical and endoscopic examinations is even more important than detection of CMV antigenemia in the early diagnosis of CMV gastritis.

Patients with GVHD, and patients given corticosteroids for treatment of GVHD, carry a high risk of CMV disease[19]. In this study, such increased risk was confirmed as all seven patients with CMV gastritis also had GVHD and five of them had grade Ⅱ-Ⅳ GVHD that was being treated by corticosteroids. GVHD, by itself and also accompanied by corticosteroid administration, are exacerbating factors in the existence of CMV gastritis.

The present investigation was a retrospective study based on our examination of medical records as well as endoscopic and pathological findings. The small size of the study does not exclude the possibility of unrecognized bias. Since EGD was not conducted in all allo-SCT recipients, underestimation of the frequency of CMV gastritis is a possibility. Consequently, further prospective evaluation is warranted to clarify the endoscopic findings for early diagnosis of CMV gastritis.

The results of this study suggest that endoscopic and clinical findings are useful indicators in the diagnosis of CMV gastritis following allo-SCT. Use of EGD is warranted for the establishment of an early diagnosis of CMV gastritis following allo-SCT.

ACKNOWLEDGMENTS

The authors thank Dr. Naoko Murashige for her helpful comments and suggestions on the manuscript.

COMMENTS

Background

Cytomegalovirus (CMV) disease is a serious complication after allogeneic hematopoietic stem cell transplantation (allo-SCT), which is widely accepted as a curative therapy for advanced hematological malignancies including leukemia and malignant lymphoma. CMV disease can involve many organs and stomach is a common target.

Research frontiers

Few reports have been published regarding endoscopic examination in diagnosing CMV gastritis after allo-SCT. In this study, the authors demonstrate the endoscopic findings of CMV gastritis after allo-SCT in addition to its clinical features.

Innovations and breakthroughs

The present study indicated that erosion and oozing might be useful markers for early diagnosis of CMV gastritis.

Applications

Endoscopists should suspect CMV gastritis and obtain multiple biopsies whenever erosions are found in any stomach site when performing esophagogastroduodenoscopy in patients after allo-SCT.

Peer review

This is an interesting manuscript on an important topic. The study presented here is a retrospective one with a small number of affected patients, but it offers some deeper insights into this complex problem. Limitations of this study and difficulties in diagnosis and interpretation are addressed by the authors in the discussion section.

Abstract

AIM: To assess risk factors for bleeding after gastric endoscopic submucosal dissection (ESD) and to develop preventive measures.

METHODS: This retrospective study was performed in a tertiary referral center. A total of 328 patients underwent ESD for 398 gastric neoplasms between July 2007 and June 2009. The main outcome was association between post-ESD bleeding and the following: age; sex; comorbidities; daily use of medicine potentially related to gastric injury/bleeding; location, size, and histological depth of lesions; ulceration; experience of operator coagulating the ulcer floor, and duration of operation. We also determined the relationship between the location of post-ESD bleeding and risk factors for hemorrhage.

RESULTS: Univariate analysis revealed significant risk factors: tumor location [odds ratio (OR), 2.86; 95% CI: 1.21-6.79, P = 0.024], coagulator experience (OR, 4.29; 95% CI: 1.43-12.86, P = 0.009), and medicine potentially related to gastric injury/bleeding (OR, 2.80; 95% CI: 1.14-6.90, P = 0.039). Multivariate logistic regression analysis confirmed significant, independent risk factors: tumor in lower third of stomach (OR, 2.47; 95% CI: 1.02-5.96, P = 0.044), beginner coagulator (OR, 3.93; 95% CI: 1.29-11.9, P = 0.016), and medicine (OR, 2.76; 95% CI: 1.09-6.98, P = 0.032). We classified cases of post-ESD bleeding into two groups (bleeding at the ulcer margin *vs* bleeding at the center) and found that bleeding at the margin occurred more frequently with beginner coagulators compared with experts (OR, 16.00; 95% CI: 1.22-210.59, P = 0.040).

CONCLUSION: Beginner coagulators, tumor in the antrum, and medicines were significant risk factors for post-ESD bleeding. Bleeding at the ulcer margin frequently occurred with beginner operators.

Risk factors for bleeding after endoscopic submucosal dissection for gastric lesions. *World J Gastroenterol* 2010; 16(23): 2913-2917 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i23/2913.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i23.2913

INTRODUCTION

Endoscopic submucosal dissection (ESD) is an excellent treatment for superficial gastric cancer because a large tumor or lesion with ulcer scar can be successfully resected *en bloc*[1]. Because ESD allows accurate histopathological diagnosis and reduces the risk of local recurrence[2], it is now a standard treatment for early gastric cancer with certain histopathological properties. However, ESD is technically more difficult and can result in more complications compared with conventional endoscopic mucosal resection (EMR)[1,3]. Bleeding after gastric ESD is reported to occur in up to 7% of cases[4] and can occur later than other complications like perforation, sometimes even after discharge from the hospital. Further, bleeding after gastric ESD may lead to serious conditions including massive bleeding and life-threatening hemorrhagic shock[5]; therefore, preventing post-gastric ESD bleeding is essential. Prophylactic coagulation of visible vessels in the resection area has been reported to reduce the bleeding rate[5], but preventive coagulation therapy cannot fully solve the problem of delayed bleeding. Thus, an assessment of risk factors for post-ESD bleeding is needed.

In the present study, we aimed to determine risk factors for post-gastric ESD bleeding and establish techniques to minimize these complications.

MATERIALS AND METHODS

Patients

A total of 329 patients underwent ESD for 399 gastric neoplasms, including early gastric cancers and gastric adenomas, between July 2007 and June 2009 in our institute. One lesion was excluded from the analysis because ESD for that lesion was stopped halfway during the procedure; it was considered unresectable by ESD because of massive submucosal invasion. Thus, 398 lesions in 328 patients were evaluated.

ESD procedure

All patients provided written informed consent before treatment. Patients fasted on the morning of the operation, and lansoprazole infusion (30 mg twice a day) was initiated. ESD was performed under conscious sedation with flunitrazepam and buprenorphine using a video endoscope (GIF-Q260J; Olympus Optical Co., Ltd., Tokyo, Japan) and high-frequency power supply unit (VIO 300D or ICC 200; ERBE, Tübingen, Germany).

The ESD procedure was as follows. First, marks were made 5 mm outside the tumor edge with a Flex Knife (Olympus Optical Co., Ltd.). Epinephrine (1:100 000 solution in saline) was injected into the submucosal layer around the lesion, and the mucosa 5 mm outside the marks was cut using IT-Knife 2 (Olympus Optical Co., Ltd.). After incision of the mucosa, submucosal dissection of the lesion was performed using IT-Knife 2. After resection of the lesion, all visible vessels on the ulcer floor were coagulated with hot biopsy forceps (Hoya Co., Ltd., Pentax Life Care Div., Japan) and VIO 300D (swift coagulation, effect 3, 45 W) or ICC 200 (forced coagulation, 65 W).

Patients who did not develop complications started a soft diet on day 1 after ESD and were discharged 5 d after the procedure. They received oral lansoprazole for 8 wk, beginning on day 1 after ESD. We defined bleeding after ESD as hemorrhage resulting in hematemesis or melena that required endoscopic treatment.

When hemorrhage occurred, we performed urgent endoscopy to determine the vessel responsible for the bleeding. When clots were lodged in the responsible vessel, they were removed and the responsible vessel was exposed. The vessel was grasped or touched with the hot biopsy forceps using the forced coagulation mode (ICC 200, 65 W).

Data analysis

We classified the 398 lesions into two groups: with bleeding and without bleeding. We reviewed patient medical records and collected the following data for each patient: age, sex, comorbidities, daily use of medicine related to gastric injury/bleeding, tumor depth, histological ulceration, tumor diameter, tumor location, and the operator performing coagulation of the ulcer floor (coagulator). The risk factors were analyzed based on individual tumors, because some patients had more than one lesion resected.

Comorbidities included hypertension (systolic blood pressure > 140 mmHg or antihypertensive treatment) and diabetes mellitus (oral hypoglycemic agent or insulin treatment). Medicines potentially related to gastric injury/bleeding included antiplatelet agents, anticoagulants, steroids, or nonsteroidal anti-inflammatory drugs (NSAIDs). Patients taking steroids or NSAIDs were instructed to discontinue their use 1 wk before ESD to 1 wk after ESD. Patients taking antiplatelet or anticoagulants were instructed to discontinue use according to "measures against patients undergoing antithrombotic regimen in endoscopic treatment" in the 3rd edition of the guidelines for gastroenterological endoscopy[6]. The cessation and restart of antithrombotic drugs in ESD is shown in Figure 1. Ulceration and depth were determined histopathologically after ESD; histological depth was classified as intramucosal (m) or involving the submucosal layer (sm). Based on the Japanese classification of gastric carcinoma[7], tumor location was classified into two groups: upper or middle third of the stomach (UM) or lower third (L). Coagulators were the physicians who coagulated the artificial ulcer floor after resection of the lesion. In our hospital, novice ESD operators begin their training with coagulation of the ulcer floor; therefore, the operator who resected the tumor was not always the one who coagulated the ulcer floor. Ulcer floor coagulators were categorized as beginners (performed < 50 cases of gastric ESD) or experts (performed > 200 cases of gastric ESD). In the present study, there were no coagulators who performed between 50 and 200 ESD procedures.

We also determined the relationship between the location of post-ESD bleeding and risk factors for hemorrhage. During the observation period, post-ESD bleeding occurred in 23 lesions (23 patients). The hemorrhage location

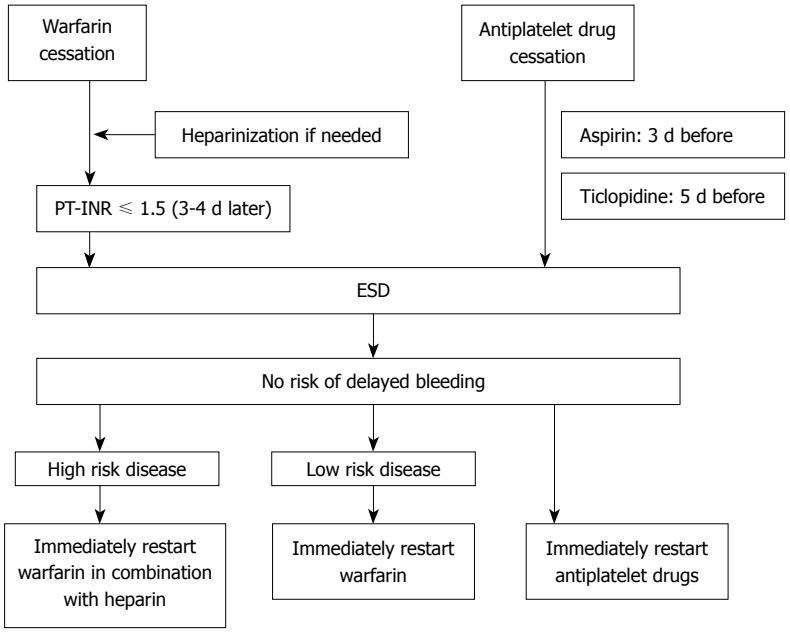

Figure 1 Flow chart summarizing the cessation and restart of antithrombotic drugs in endoscopic submucosal dissection (ESD)[6]. Warfarin is discontinued before ESD and heparin is initiated if needed. PT-INR is checked 3 to 4 d later; if PT-INR ≤ 1.5, ESD can be performed. After surgery warfarin is immediately restarted, and heparin is co-administered in patients at high risk for disease. Antiplatelet drugs are discontinued before ESD as well (aspirin, 3 d before ESD; ticlopidine, 5 d before ESD); they are immediately restarted after the procedure. PT-INR: Prothrombin time-international normalized ratio.

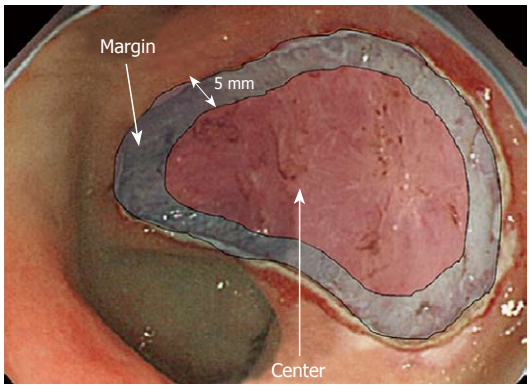

Figure 2 The margin and center areas of the ulcer floor. The margin includes the outer 5 mm edge of the ulcer, and the remaining area is defined as the center.

Quantitative data are presented as mean ± SD.

was categorized as ulcer margin (< 5 mm from the ulcer edge) or center (ulcer floor area other than the margin) (Figure 2).

Statistical analysis

Categorical data were compared using χ^2 test (with Yates correction) and Fisher's exact test. Differences in the means of continuous data were compared by Student's *t* test or Mann-Whitney *U* test. To identify important risk factors for bleeding after ESD, predictors with *P*-values < 0.2 in the univariate analysis were included in a backward, stepwise multiple logistic regression model. *P*-value < 0.05 was considered significant, and all tests were two-sided. Data are expressed as mean ± SD or as median (range). All statistical analyses were performed with PASW Statistics 18 for Windows (SPSS Japan, Tokyo).

RESULTS

During the treatment of the 398 lesions, 23 cases of post-ESD bleeding occurred (5.8%). Baseline characteristics of the study population are displayed in Table 1. A total of six operators (two experts and four beginners) were involved in this study. Among the 23 cases of post-ESD bleeding, 10 (43.5%) occurred within 24 h after ESD. All cases were controlled by endoscopic treatment and did not require surgical intervention; one case required blood transfusion.

The results of univariate analysis are displayed in Table 2. Significant risk factors for bleeding after gastric ESD included: tumor location [L *vs* UM; odds ratio (OR), 2.86; 95% CI: 1.21-6.79, *P* = 0.024], coagulators (beginner *vs* expert; OR, 4.29; 95% CI: 1.43-12.86, *P* = 0.009), and daily use of medicine potentially related to gastric injury/bleeding (user *vs* non-user; OR, 2.80; 95% CI: 1.14-6.90, *P* = 0.039). As an additional datum, the incidence of hemorrhage in relation to tumor location was estimated (U *vs* M *vs* L; 4.6% *vs* 3.2% *vs* 9.6%, *P* = 0.042).

Multivariate logistic regression analysis confirmed that the following were independent factors for bleeding after gastric ESD: tumors located in the lower third of the stomach (OR, 2.47; 95% CI: 1.02-5.96, *P* = 0.044), begin-

Characteristics	Odds ratio	95% CI	*P*
Drugs potentially related to gastric injury/bleeding	2.76	1.09-6.98[a]	0.032
Tumor in lower third of stomach	2.47	1.02-5.96[a]	0.044
Beginner coagulator	3.93	1.29-11.91[a]	0.016

[a]$P < 0.05$. ESD: Endoscopic submucosal dissection.

Table 4 Risk factors for post-ESD bleeding according to bleeding site

	Marginal bleeding (*n* = 17)	Central bleeding (*n* = 6)
Drugs potentially related to gastric injury/bleeding	6 (35.3)	3 (50.0)
Tumor in the lower third of stomach	9 (52.9)	5 (83.3)
Beginner coagulator	16 (94.1)	3 (50.0)[a]

[a]$P < 0.05$ *vs* marginal bleeding. *P* values by χ^2 test.

ner coagulators (OR, 3.93; 95% CI: 1.29-11.91, $P = 0.016$), and daily use of medicine potentially related to gastric injury/bleeding (OR, 2.76; 95% CI: 1.09-6.98, $P = 0.032$) (Table 3).

We classified cases of post-ESD bleeding into two groups (bleeding at the ulcer margin *vs* bleeding at the center), and determined the relationships between bleeding site and the three risk factors described above. We found that bleeding at the margin occurred more frequently with beginner coagulators compared with experts (OR, 16.00; 95% CI: 1.22-210.59, $P = 0.040$) (Table 4).

The interval between ESD and post-ESD bleeding was also determined. The median interval was 3 d (range, 0-14 d), and bleeding occurred significantly earlier in L lesions compared with UM lesions (UM *vs* L; 9 d (range, 0-14 d) *vs* 1 (0-9), $P = 0.019$). The relationship between patient medication and the interval between ESD and bleeding was also estimated. In the "medication" group, the median interval to bleeding was 3 d (range, 0-14 d), while in the "no medication" group, the median interval to bleeding was 1 d (range, 0-12 d). Based on the data medication did not appear to affect the interval between ESD and post-ESD bleeding ($P = 0.201$).

DISCUSSION

Previous studies[5,8-11] have evaluated measures against post-ESD bleeding. Takizawa *et al*[5] found that coagulating exposed vessels on the ulcer floor after ESD, which is known as post-ESD coagulation preventive therapy (PEC), reduced the risk for delayed bleeding. However, the incidence of bleeding after ESD was still 3.1% after PEC; therefore, additional measures are needed to prevent delayed bleeding.

In the present study, multivariate logistic regression analysis showed that tumors located in the lower third of the stomach, beginner operators coagulating the ulcer floor, and daily use of medicine potentially related to gastric injury/bleeding were significantly associated with bleeding after ESD.

Takizawa *et al*[5] also reported that tumor location was an independent risk factor for delayed bleeding. In that study, delayed bleeding occurred more frequently in the upper third compared with the middle and lower thirds of the stomach. In the present study, we compared UM lesions with L lesions, because we thought that antral active peristalsis and bile reflux might lead to a high incidence of post-ESD bleeding in the lower stomach. On the other hand, submucosal artery diameters were smaller in L lesions compared with UM lesions in a dog model[12]. For that reason, bleeding during gastric EMR may occur more frequently in UM lesions. Similarly, during ESD procedures, intraoperative bleeding frequently occurs in UM lesions. Intraoperative bleeding, however, may lead to more careful endoscopic hemostasis, which ultimately protects against delayed bleeding. In another study, an increased risk of delayed bleeding has been reported when immediate bleeding occurred during endoscopic mucosal resection[13]. However, sites of delayed bleeding often differed from the sites of immediate bleeding, suggesting that well-coagulated arteries seldom bleed.

Previous studies have reported that daily use of medicine potentially related to gastric injury/bleeding is not a risk factor for post-ESD bleeding[5,13]. However, multivariate logistic regression analysis in our study showed that use of these medicines was an independent risk factor for post-ESD bleeding. On the other hand, daily use of these drugs did not appear to affect the interval between ESD and bleeding. The median interval was 3 d, which was before medication was restarted; therefore, direct effects of these drugs on post-ESD bleeding appear to be limited. The mechanism underlying the association between daily use of medicine potentially related to gastric injury/bleeding and post-ESD bleeding is not known.

Our study also showed that post-ESD bleeding occurred significantly more often when beginners performed coagulation of the ulcer floor after ESD. The incidence

of hemorrhage was 2.2% when performed by experts, but 8.8% with beginners (Table 2). Beginners caused bleeding in the ulcer margin significantly more often. Coagulation of exposed vessels on the ulcer floor after ESD reduces the risk of hemorrhage, but potentially hemorrhagic vessels are often hidden in a fat layer that remains on the ulcer floor, especially at the edge of the ulcer. Thus, careful coagulation of vessels at the ulcer margin is important in preventing delayed bleeding.

In L lesions, hemorrhage occurred significantly earlier compared with UM lesions. The median interval between ESD and postoperative hemorrhage in L lesions was 1 d (range, 0-9 d), suggesting that second-look endoscopy 1 d after ESD may be helpful in preventing post-ESD bleeding in L lesions.

Limitations of the present study include its single-center retrospective study design.

In conclusion, risk factors for bleeding after gastric ESD included beginner operators coagulating the ulcer floor after ESD, tumor location in the lower third of the stomach, and medicine potentially related to gastric injury/bleeding. Careful coagulation of the vessels in the ulcer floor after ESD, especially around the ulcer margin, may reduce the incidence of post-ESD hemorrhage. In addition, a second-look endoscopy 1 d after ESD may be helpful in preventing post-ESD bleeding in tumors in the lower third of the stomach.

COMMENTS

Background

Endoscopic submucosal dissection (ESD) is an excellent treatment for early gastric cancer, but bleeding after ESD occurs in up to 7% of cases and remains a severe complication.

Research frontiers

Prophylactic coagulation of visible vessels in the resection area has been reported to reduce the bleeding rate, but preventive coagulation therapy cannot fully solve the problem of delayed bleeding. Thus, an assessment of risk factors for post-ESD bleeding is needed. The authors reviewed their 398 ESD cases and evaluated risk factors for post-ESD bleeding.

Innovations and breakthroughs

Beginner coagulators, tumor in the lower third of the stomach, and medicines potentially related to gastric injury/bleeding were significant risk factors for post-ESD bleeding. Bleeding at the ulcer margin occurred more frequently with beginner coagulators than with experts. Therefore, novice ESD operators should pay special attention to coagulating vessels in the ulcer edge after ESD. As to tumors in the lower third of the stomach, post-ESD bleeding happened earlier than in other areas. A second-look endoscopy 1 d after ESD may be helpful.

Applications

By overcoming post-ESD bleeding, ESD for gastric neoplasms will become a safer and more popular treatment.

Terminology

In this paper, experts/beginners were defined as endoscopists that have performed more than 200/less than 50 cases of gastric ESD.

Peer review

This is well written and important paper. Although it is not a prospective study, the topic is important for all gastroenterologists and gastrointestinal (GI) surgeons dealing with surgical endoscopy of the upper GI tract. The authors' work gives important information about one of the typical complications i.e. bleeding after ESD.

Abstract

AIM: To investigate whether a noninvasive measurement of tissue strain has a potential usefulness for management of nonalcoholic steatohepatitis (NASH).

METHODS: In total 26 patients, 23 NASHs and 3 normal controls were enrolled in this study. NASH was staged based on Brunt criterion. At a region of interest (ROI), a shear wave was evoked by implementing an acoustic radiation force impulse (ARFI), and the propagation velocity was quantified.

RESULTS: Shear wave velocity (SWV) could be reproducibly quantified at all ROIs in all subjects except for 4 NASH cases, in which a reliable SWV value was not calculated at several ROIs. An average SWV of 1.34 ± 0.26 m/s in fibrous stage 0-1 was significantly slower than 2.20 ± 0.74 m/s and 2.90 ± 1.01 m/s in stages 3 and 4, respectively, but was not significantly different from 1.79 ± 0.78 m/s in stage 2. When a cutoff value was set at 1.47 m/s, receiver operating characteristic analysis showed significance to dissociate stages 3 and 4 from stage 0-1 (P = 0.0092) with sensitivity, specificity and area under curve of 100%, 75% and 94.2%, respectively. In addition, the correlation between SWV and hyaluronic acid was significant (P < 0.0001), while a tendency toward negative correlation was observed with serum albumin (P = 0.053).

CONCLUSION: The clinical implementation of ARFI provides noninvasive repeated evaluations of liver stiffness at an arbitrary position, which has the potential to shed new light on NASH management.

INTRODUCTION

Nonalcoholic fatty liver diseases (NAFLD) are a pandemic over the globe, especially in the developed countries depending on a high calorie diet and sedentary life style. Nonalcoholic steatohepatitis (NASH) is a subgroup of NAFLD, in which chronic necroinflammatory response causes fiber accumulation in the liver[1]. Regardless of the etiology, accumulation of fiber in the liver is correlated with a deterioration of functional liver reserve. By semi-quantifying the density of fibrosis in the liver, histological evaluation is a standard strategy used to confirm the presence of chronic necroinflammation, and to evaluate a degree of the pathophysiological extent of liver damage[2]. Unfortunately, however, it is impractical to conduct liver biopsy in a large population of NAFLD and to repeat it through a course of NASH.

Several markers have been reported to be useful for the prediction of liver fibrosis, which can be categorized into three groups. One is a physical marker such as FibroScan®: transient elastography (TE)[3] and a digital quantification using contrast magnetic resonance imaging (MRI)[4]. The others are serum markers and can be further divided into two groups; direct and indirect markers. Serum markers are affected in both the inside and outside of the liver, while MRI may not be affordable for a large NAFLD cohort. TE is reported to be inaccurate for cases with higher body mass index (BMI) and hepatic steatosis[5].

Acoustic radiation force is a method exploiting energy in transmitted acoustic pulses to deliver a localized, precise force sufficient in magnitude to induce subtle tissue displacements[6]. The induced displacements can be tracked using conventional ultrasonic means and are indicative of local tissue mechanical properties[7]. Acoustic radiation force-based methods have been demonstrated for differentiating tissue structure *via* a mechanical property in various applications including the liver[8]. Here we report quantification of shear wave velocity (SWV) comparing with histology and serum biomarkers in NASH cases under ultrasound imaging coupled with the first clinical implementation of acoustic radiation force impulse (ARFI). The usefulness and limitations of SWV measurement are discussed.

MATERIALS AND METHODS

Patients

Twenty six cases, consisting of 23 patients suffering from NASH and 3 normal controls, were enrolled in this study. NASH was diagnosed when each of the following requirements were met; (1) abnormal values of alanine aminotransferase; (2) no positive results for hepatitis B surface antigen (HBsAg), anti-hepatitis C virus (anti-HCV), and anti-mitochondrial antibody; (3) histological findings consistent with NASH; and (4) neither suspicious drug usage, alcohol abuse, hereditary diseases nor any other clinical manifestations causing liver cell damage. Three normal controls were patients with each of chronic cholecystitis, chronic pancreatitis, and gallbladder polyps, who fulfilled all requirements for NASH diagnosis except for abnormal values of the transaminase and histological abnormalities, which were not evaluated. Two expert pathologists independently evaluated liver biopsy specimens and judged fibrous staging and inflammatory grading on the basis of Brunt criterion[9]. Informed consent was obtained from each patient, and the study protocol conformed to ethical guidelines of the 2008 Declaration of Helsinki as reflected in a prior approval by Niigata University Graduate School of Medical and Dental Sciences Human Research Committee.

Biochemical analyses

HBsAg and anti-HCV antibody were detected by a chemiluminescence immunoassay using ARCHITECT HBsAg QT and ARCHITECT HCV (Abbott Japan Co. Ltd., Chiba, Japan), respectively. Anti-mitochondrial antibody was quantified in sera using commercial kits of AMA; FluoroAID-1 test (MBL Co. Ltd., Nagoya, Japan). Hyaluronic acid was measured using a latex agglutination method, in which normal controls measure less than 50 ng/mL.

Measurement of shear wave velocity

SWV was measured using an ACUSON S2000 ultrasound system (SIEMENS Medical Solutions Inc., CA, USA). A single ultrasonic transducer array is used to both apply temporally short localized radiation forces within tissue and to track the resulting tissue dynamic response through time. During a regular ultrasound observation, region-of-interest (ROI) is set as a rectangle, and acoustic pulses are radiated to make tissues displace downward beside ROI. Once tissues are displaced, the shear stress starts to restore the tissue to its previous position and generate shear waves, which travel perpendicular to the direction of the acoustic push pulse in the process. The machine continuously monitors tissue positions in ROI and automatically calculates the speed of the wave in m/s unit. Fundamentally, SWV can be measured at any portion in the liver as long as the ROI can be placed under ultrasound imaging except for a position where the acoustic pulse cannot effectively displace tissues, such as deeper than 5 cm from a probe, or inside a vasculature, cyst or gallbladder. Using an ACUSON S2000, one can switch from regular ultrasound imaging to SWV measurements seamlessly and repeatedly with neither special preparation nor technique.

Statistical analysis

Categorical data was compared using ANOVA analysis among four fibrosis stages. Fisher's exact test was em-

ployed to compare the frequency in a contingency table of each factor consisting of BMI-Age-Alanine aminotransferase (ALT)-Triglyceride (TG) (BAAT) score[10]. Correlations between SWV and variable parameters were quantified by calculating the Spearman correlation coefficient. In order to judge the clinical usefulness of fibrosis indicators, an area under a receiver operating characteristic curve (AUROC) was calculated. All analyses were performed using GraphPad Prism 4 software (GraphPad Software, Inc. La Jolla, USA), and a two-sided *P*-value less than 0.05 was considered statistically significant.

RESULTS

Shear wave velocity is reproducible at the measurement site but is not constant throughout the entire liver

Aiming to evaluate reliability in SWV measurement, ROI was placed at each of the right and left lobes, and SWV was independently measured three times at the same lobe in four patients with fibrosis stage 3, cases 10 to 13. SWV was reproducibly determined at each ROI as the average coefficient of variance was 11.9% ± 8.0% (Figure 1). The speeds, however, largely varied between right and left lobes. These results strongly indicate that a repeated measurement may not be necessary at the same ROI for compensation of an implementation error, but is required by applying various ROIs throughout the liver in order to evaluate an average rigidity of a whole liver.

Shear wave velocity is getting faster along progression of fibrosis stage

According to inconsistent SWVs between the left and right lobes, SWV measurements were performed by placing four ROIs, which were located in each of the four segments; right posterior, right anterior, left medial and left lateral segments. Among the 23 NASH cases, a reliable SWV could not be calculated in 4 cases; listed as cases 23 to 26 in Table 1. Case 24 carried massive ascites and the others had a BMI of over 30 kg/m^2. In terms of BMI, SWV could be measured in all cases with BMI less than 30 kg/m^2, whereas SWV could not be measured in 3 out of 10 cases with BMI of more than 30 kg/m^2. None of the ROIs that could not return a reliable SWV value were located in the right segments, but in the left. The 4 cases missing at least one of four SWV values were excluded from further analyses.

An average of 4 SWVs in each case was compared among the fibrosis stages. When controls were designated as a stage 0, SWV was significantly correlated with fibrosis stages ($P = 0.0018$, $r = 0.63$). As only one case with fibrosis stage 1 was enrolled, 3 controls were combined with stage 1 and subjected to further analysis as one group of stage 0-1. The velocities in stages 0-1, 2, 3, and 4 were 1.34 ± 0.26, 1.79 ± 0.78, 2.20 ± 0.74, and 2.90 ± 1.01, respectively, and were significantly different among groups (Figure 2A, $P = 0.043$). Dunn's multiple comparison revealed that there was a significant difference between stages 0-1 and 4 ($P < 0.05$). When the velocity was compared in the right or left lobe, there was no significant difference in the right lobe ($P = 0.31$, Figure 2C), but there was a difference in the left lobe ($P = 0.02$, Figure 2D), in which SWVs were significantly different not only between stages 0-1 and 4, but also between 0-1 and 3 ($P < 0.05$, $P < 0.05$, respectively). There was no significant difference in SWV among inflammation activity grades ($P = 0.12$).

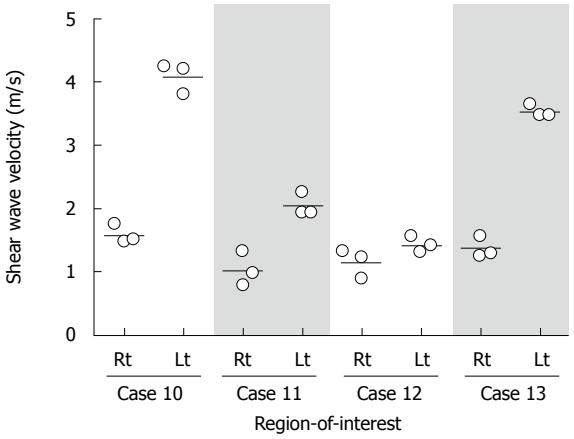

Figure 1 Reliability and variation of shear wave velocity (SWV) throughout the liver. SWV was measured independently three times at each of the right (Rt) or left (Lt) lobes in four patients with fibrosis stage 3, labeled cases 10 to 13. Each horizontal bar indicates an average SWV.

Shear wave velocity can identify fiber accumulation with high probability

Because it was suggested that SWV has a potential to discriminate fibrosis stage 3 or more from stage 0-1, a probability of the discrimination was evaluated using ROC analysis. SWV showed sensitivity and specificity of 100% and 75%, respectively when a speed of 1.47 m/s was selected as a cut-off value leading to a significant AUROC of 94.2% (Figure 3A, $P = 0.0092$). In contrast, platelet counts did not lead to a significant AUROC to distinguish stages 3 and 4 from 0-1 in our population (Figure 3B, $P = 0.52$, AUROC = 61%). Because several combinatorial systems were reported for identifying liver fibrosis in NAFLD, BAAT[10] and NAFLD fibrosis score[11] were calculated (Table 1). In the results, AUROCs of BAAT and NAFLD fibrosis score were 76.9% and 72.1%, respectively, and neither of these systems were significant in this setting ($P = 0.16$ and $P = 0.18$, respectively). Furthermore, none of the factors making up BAAT score; BMI, age, ALT and TG, showed a different frequency between fibrosis stage 0-1 and stages 3 and 4 ($P = 1.0$, 0.26, 1.0 or 1.0, respectively).

Shear wave velocity is correlated with markers not only for fibrosis but also for functional liver reserve

Next, a correlation was analyzed between SWV and serum markers. Hyaluronic acid was measured in sixteen out of nineteen NASH cases and showed a tight positive correlation with SWV (Figure 4A, $P < 0.0001$, $r = 0.84$). In addition, albumin concentration in the serum tended to be correlated with SWV in a negative fashion (Figure 4B, $P = 0.053$, $r = -0.42$). On the other hand, prothrombin time,

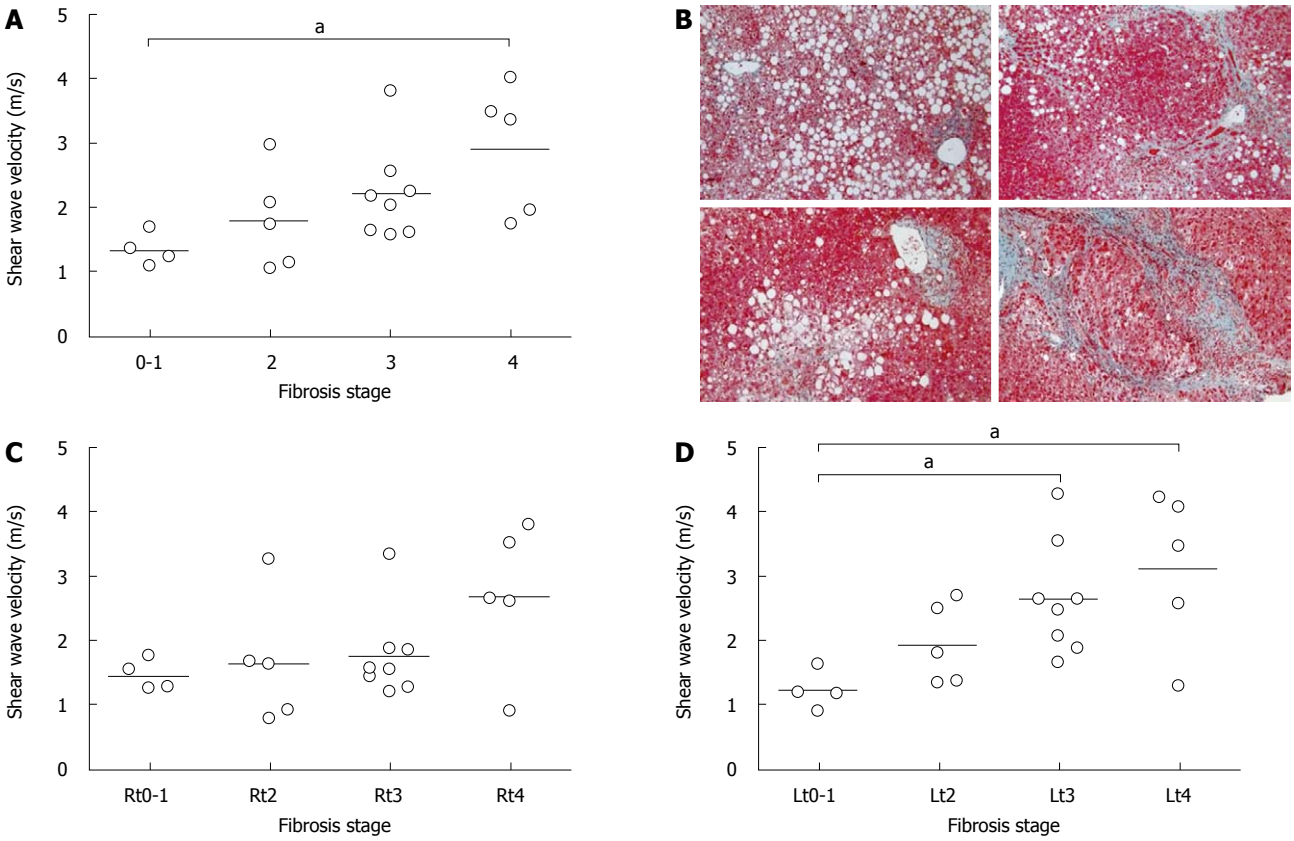

Figure 2 Average shear wave velocity (SWV) and representative photomicrographs in each fibrosis stage. SWV was measured in four segments; right anterior, right posterior, left medial and left lateral segments, and the average was calculated based on data from four segments (A) or from either one of right [Rt, (C)] or left [Lt, (D)] lobes. Histological fibrosis stages were judged along with Brunt criterion. Each horizontal bar indicates an average SWV. [a]$P < 0.05$. The photomicrographs (B) are representative Masson's trichrome stains for fibrosis stages 1, 2, 3 and 4 from upper left, lower left, and upper right to lower right panels, respectively. Original magnification is × 100.

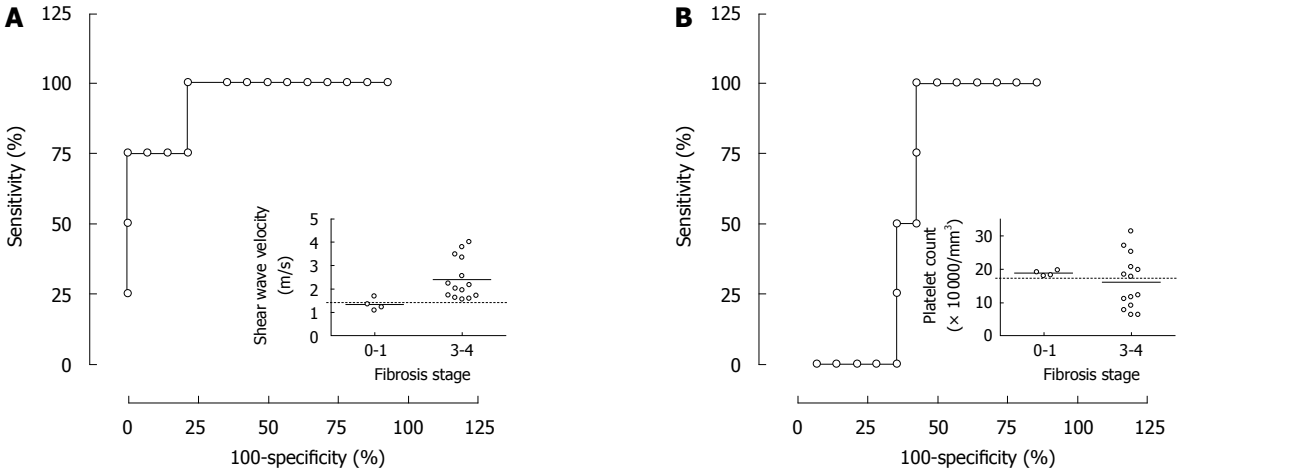

Figure 3 Receiver-operator characteristic curve (ROC) of SWV or platelet count to distinguish fibrosis stages 3 and 4 from stage 0-1. ROC to discriminate fibrosis stages 3 and 4 from stage 0-1 by SWV (A) or platelet count (B) revealed sensitivity, specificity and area under ROC of 100%, 75% and 94.2%, or 100%, 57.1% and 61%, respectively, when 1.47 m/s or 17.8 × 10 000/mm^3 was selected as a cutoff value. A small graph incorporated in each ROC graph shows the distribution of SWV or platelet count in fibrosis stages 0-1 and 3-4. The dotted line indicates the cut-off value selected.

age and BMI were not significantly associated with SWV ($P = 0.18$, $P = 0.42$ and $P = 0.46$, respectively).

DISCUSSION

Fundamentally, tissue displacements generated by acoustic push pulse used in ARFI are inversely related to tissue stiffness, while tissue recovery response is related to tissue viscoelastic properties[12]. In addition, SWV is positively correlated with the major mechanical properties indicating material rigidity[13]. Thus, assuming the liver is a linear, isotropic, elastic body, SWV is an indicative factor of tissue

[1]Fibrosis stage and inflammation grade in liver biopsy specimen based on Brunt criterion. NASH: Nonalcoholic steatohepatitis; BMI: Body mass index; SWV: Shear wave velocity; ALB: Albumin; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; TG: Triclyceride; Plt: Platelet count; PT: Prothrombin time; HA: Hyaluronic acid; NT: Not tested; BAAT: BMI, age, ALT and TG score; NFS: NAFLD (nonalcohlic fatty liver diseases) fibrosis score.

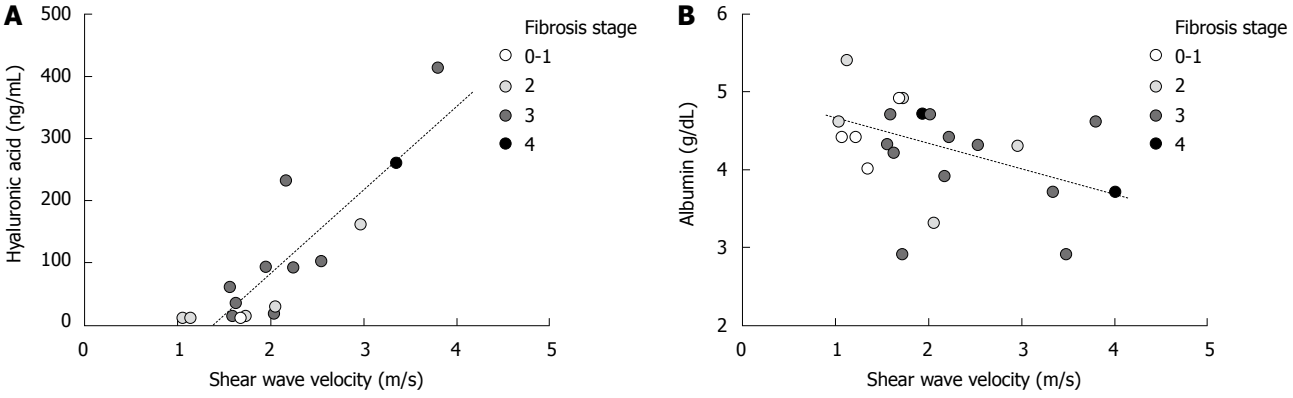

Figure 4 Correlation between SWV and serum biochemical parameters. SWV was plotted against hyaluronic acid (A) and serum concentration of albumin (B). A gray scale indicates the fibrosis stages, with white representing 0-1 through to dark gray for stage 4.

rigidity. Theoretically, the stiffer the tissue, the faster the shear wave will be propagated. Consistently, in this study SWV was correlated with histological progression of fibrosis and representative serum markers for fibrosis such as hyaluronic acid and collagen type Ⅳ (data not shown) as well. Although ARFI imaging has been used for delineating tissue structure *via* mechanical properties in numerous applications including chronic liver diseases[14,15], this is the first report to quantify SWV by implementing ARFI in the clinic and show a significant correlation with fiber deposition focusing on the NASH liver.

As a noninvasive methodology to quantify tissue stiffness in the liver, TE had been applied in the clinic[16]. TE mounts an ultrasound transducer on the axis of a vibrator, which transmits vibrations to propagate elastic shear waves. The major differences between TE and ARFI implemented SWV measurement are a real-time imaging capability, target size and target position. TE utilizes a vibration at audibility range and targets tissues without imaging supports as a 10 mm wide and 40 mm long cylinder, which is required to lie between 25 and 65 mm below the skin and to be free from large vascular structures. Given

those requirements, the area available for TE is limited to a portion of right lobe, and practically it is difficult to compare the stiffness at different parts of the liver. On the other hand, S2000 radiates the push pulse at MHz order to excite tissue displacement and scrutinizes SWV at ROI, which is substantially smaller (7 mm × 10 mm) and can be precisely placed at any position throughout the liver under real-time image guidance as long as it is not deeper than 5 cm from the probe. Because the interface evokes ultrasound-guided liver biopsy, "acoustic biopsy" may be coined for this technology. The major advantage of acoustic biopsy is the feasibility to be able to perform as many in time and space without a risk to patients. In this study SWV measurements were performed in four different segments at the same time point and revealed that SWV largely varied in different portions of the liver, while reproducible values were obtained at each ROI. Although the small number of subjects employed in this study limited the implication, these data support the idea that fibrogenesis and/or fibrolysis heterogeneously take place in the liver[17]. It must give us critical insight into the process of liver fibrosis to take acoustic biopsies from a wide area of the liver at different time points.

In terms of measurement failures, it was reported that TE frequently failed to compute liver stiffness in patients with massive ascites or BMI over 28 kg/m^2[5], and SWV measurements showed a similar tendency. One hypothesis is that the tissue displacement cannot be efficiently induced by radiation of acoustic push pulse through massive ascites or dense subcutaneous fat layers. However, it is noteworthy that SWV could be measured in right lobes of the four failed cases. All ROIs that returned ineffective SWV were located in left lobes. Although the exact reasons are not clear, oscillation of the liver due to heart beat may be an important factor to hamper accurate measurements. It has been shown that SWV in stiffer livers is associated with larger variability and smaller overall displacements[8], which suggest susceptibility of this technology to motion artifacts. A prospective study is required to clarify whether SWV in right lobes can be a useful indicator for liver fibrosis in those cases.

As for variability of SWV between right and left lobes, a considerable sampling variability was reported in liver biopsy specimens from patients with chronic hepatic diseases[18]. The concordance between two biopsy specimens that were simultaneously obtained from the same individual was reported to be moderate to low in terms of perisinusoidal fibrosis and other histological pathologic features of NAFLD[19]. The interlobar difference of SWV that was observed in this study seems to be consistent with the sampling variability suggesting nonhomogenous progression of NAFLD. Because sequential biopsies from multiple sites are practically impossible, longitudinal measurements of SWV at numerous locations of the liver in a large NAFLD cohort would be able to elucidate distribution of the pathological involvement in time and space.

Evaluation of liver fibrosis is aimed at two aspects of NASH management; one as a diagnostic tool and the other as a scrutiny of disease progression. Although histopathological examination is the current gold standard for evaluation of liver fibrosis, there are serious concerns for this strategy such as its invasive nature, sampling errors and diagnostic variability among observers[2]. To circumvent these limitations, surrogate serum markers have been reported such as BAAT score[10], NAFLD fibrosis score[11], hyaluronic acid[20], platelet count[21], and NashTest[22]. TE and MRI were also reported to show satisfying sensitivity and specificity to surrogate histological evaluation[4,16]. All noninvasive methodologies, however, have been shown to be effective in predicting advanced diseases rather than fibrogenic evolution, which is a hallmark to distinguish NASH from other NAFLD. Furthermore, it is impractical to perform an MRI study on a great number of NAFLD patients. Because SWV was not significantly different between fibrosis stages 0-1 and 2, and because the cohort in this study did not include NAFLD cases without fiber accumulation, the significance of SWV measurement in NASH diagnosis is also unclear. A further analysis should be conducted on a larger sample group including NAFLD cases without liver fibrosis to elucidate this issue.

As far as disease progression is concerned, platelet count, which has been confirmed as a useful surrogate marker for fibrosis in chronic hepatitis C[23], did not show significant AUROC in our cohort. A regulation of platelet count may be different between NASH and chronic hepatitis C. Although the NAFLD fibrosis score clearly distinguished fibrosis stage 4 from stages 0-1 (data not shown), AUROC was not able to distinguish stages 3 and 4 from stage 0-1, and there was no significant correlation between progression of liver fibrosis and the score, either. In BAAT, neither the score nor each factor used to calculate the score could discriminate fibrosis stages 0-1 from stages 3 and 4. Values of serum markers can be affected by extra hepatic conditions and/or a type of background diseases[24]. Furthermore, fibrosis markers have to be investigated over time to see pathophysiological progression. Serum markers at different time points would be affected by difference of systemic situation. Thus, it is most suspicious that the different populations among studies might cause different discrimination abilities in those indirect serum markers. As for the NashTest, it requires 13 parameters including α2-macroglobulin, apolipoprotein A1, and haptoglobin, which are not covered by public health insurance in Japan for patients with liver dysfunction, thus it is not affordable for significant numbers of patients. On the other hand, SWV tended to get faster along the progression of fibrosis in a stepwise fashion. Because a standard histopathological analysis has the same difficulty in discriminating adjacent stages of fibrosis[18], the usefulness in stepwise discrimination should be evaluated by a longitudinal study in a larger cohort.

There are a few reports that mention liver stiffness in association with biochemical properties of functional

liver reserve. Kawamoto *et al*[25] revealed positive correlations of TE with prothrombin time, platelet count and pre-albumin. Masuzaki *et al*[26] also reported a tendency of positive correlations with prothrombin activity, platelet count, and albumin concentration. In both reports the subjects were patients with chronic viral hepatitis type B and/or C. Interestingly, in our NASH cohort, prothrombin activity and platelet count were not significantly correlated with SWV, whereas serum albumin showed a tendency towards negative correlation. Although it is not difficult to suppose that TE/SWV and the direct markers for fibrosis will show positive correlation regardless of viral hepatitis or NASH, as in the case of hyaluronic acid, the indirect markers would be regulated in a different way depending on the disease responsible. The association between SWV and biochemical properties may implicate a significance of SWV measurement as a prognostic indicator.

The substitution of histopathological analysis of liver biopsy with a surrogate noninvasive marker would have a tremendous impact on both public health and health economics. Our data suggest that SWV measurements in implementation of ARFI have considerable potential to confirm or to exclude cirrhosis. Furthermore, this technology provides a repeated data acquisition for tissue mechanical properties from precise points throughout the liver. The actual longitudinal evaluation of fibrosis at different areas over the liver in a larger NAFLD population may prove not only useful for staging of NASH but also the process of fiber accumulation and value as a prognostic indicator.

COMMENTS

Background

Nonalcoholic steatohepatitis (NASH) is manifestation of metabolic syndrome in the liver and is a pandemic over the globe especially in the developed countries, based on a high calorie diet and sedentary life style. As in the other types of chronic hepatitis, collagen fibers continuously accumulate in the liver through the course of NASH toward cirrhosis and hepatocellular carcinoma development. Histological evaluation is a current gold standard for quantification of the fiber deposition. A tiny biopsy specimen, however, leads to considerable variability and is practically difficult to obtain repeatedly from multiple sites. Several surrogate markers have been developed for evaluation of fiber accumulation in a noninvasive way. Unfortunately, however, so far no methodology can satisfy both specificity for the liver and applicability for multiple sites.

Research frontiers

The significance of serum surrogate markers for histological evaluation of fibrosis has been reported, with examples including BMI-Age-Alanine aminotransferase-Triglyceride score, nonalcoholic fatty liver diseases (NAFLD) fibrosis score, hyaluronic acid, platelet count, and NashTest. Transient elastography and magnetic resonance imaging were also reported to show satisfying sensitivity and specificity to surrogate the histological evaluation. None of the serum markers, however, are specific for the liver but are affected by systemic involvement. Transient elastography requires a relatively large area to measure tissue rigidity, which prevents multifocal measurements. Magnetic resonance imaging is too laborious and expensive to target a large NAFLD cohort.

Innovations and breakthroughs

Using ACUSON S2000 ultrasound system, the research team led by Suda T from Department of Gastroenterology and Hepatology of Niigata University investigated the efficacy of shear wave velocity (SWV) measurement in the evaluation of NASH pathophysiology. ACUSON S2000 is the world's first ultrasound system implementing acoustic radiation force impulse to enable SWV measurement in the liver. The analyses revealed significant positive correlation between SWV and the histological fibrous stages and suggested the possibility to distinguish mild fibrosis from severe fibrosis or cirrhosis with substantial accuracy. Furthermore, the correlations of SWV with biochemical markers such as hyaluronic acid or albumin were presented. This is the first report suggesting that SWV can be reproducibly measured in NASH and varies through the liver.

Applications

Due to the non-invasive and easily accessible nature of SWV measurement, this technology makes it possible to conduct a longitudinal evaluation of liver rigidity at multiple sites of the liver in a large cohort. The actual longitudinal evaluation in a larger NAFLD population may prove not only useful for fibrous staging of NASH but also for the process of fiber accumulation and value as a prognostic indicator.

Terminology

SWV is the speed of a transverse wave propagating perpendicular to the direction of tissue displacement. Assuming the liver is a linear, isotropic, elastic body, SWV is an indicative factor of tissue rigidity. Theoretically, the stiffer the liver, the faster the shear wave will be propagated. Acoustic radiation force impulse is a phenomenon due to energy transfer associated with acoustic frequency higher than tissue attenuation capability. The energy results in a momentum transfer generating a force that causes tissue displacement.

Peer review

This is a well-conducted study that evaluates the usefulness of SWV in quantifying liver fibrosis in patients with NASH.

Abstract

AIM: To evaluate the influence of multiple samplings during esophagogastroduodenoscopy (EGD) on the accuracy of the rapid urease test, and the validity of newly developed rapid urease tests, HelicotecUT plus test and HelicotecUT test, CLO test and ProntoDry test.

METHODS: A total of 355 patients undergoing EGD for dyspepsia were included. Their *Helicobacter pylori* (*H. pylori*) treatment status was either naïve or eradicated. Six biopsy specimens from antrum and gastric body, respectively, were obtained during EGD. Single antral specimens and dual (antrum + body) specimens were compared. Infection status of *H. pylori* was evaluated by three different tests: culture, histology, and four different commercially available rapid urease tests (RUTs)-including the newly developed HelicotecUT plus test and HelicotecUT test, and established CLO test and ProntoDry test. *H. pylori* status was defined as positive when the culture was positive or if there were concordant positive results among histology, CLO test and ProntoDry test.

RESULTS: When dual specimens were applied, sensitivity was enhanced and RUT reaction time was significantly reduced, regardless of their treatment status. Thirty minutes were enough to achieve an agreeable positive rate in all the RUTs. Both newly developed RUTs showed comparable sensitivity, specificity and accuracy to the established RUTs, regardless of patient treatment status, RUT reaction duration, and EGD biopsy sites.

CONCLUSION: Combination of antrum and body biopsy specimens greatly enhances the sensitivity of rapid urease test and reduces the reaction duration to 30 min.

INTRODUCTION

Since the discovery of *Helicobacter pylori* (*H. pylori*) by Marshall and Warren in 1983[1], overwhelming evidence confirms that *H. pylori* infection plays a significant role in the development of chronic active gastritis, peptic ulcer, and even gastric adenocarcinoma[2-4]. *H. pylori* infection is very common throughout the world, occurring in 40%-50% of the population in developed countries, 80%-90% in developing regions[5], and 54.4% in Taiwan[6]. The treatment of gastrointestinal (GI) disorders resulting from *H. pylori* infection has become the leading issue in clinical practice.

A large number of methods have been utilized to diagnose the status of *H. pylori* infection, and most of them require endoscopic biopsies for tissue sampling. Nonetheless, to date, no single test other than culture is able to confirm *H. pylori* infection[7-9]. There are inherent advantages and disadvantages in each diagnostic test. For example, rapid urease tests (RUTs) are subject to false-negative results due to sampling errors. After *H. pylori* eradication, bacterial load may be reduced to patchy colonization, which is likely to result in false negative findings[10]. This prompts us to reappraise the feasibility of current sampling methods. One small piece of gastric mucosa specimen sampled from the antrum is the most popular method for RUT. A strategy for multiple samplings is required to improve the diagnostic yield. In spite of this, RUT is regarded of one of the best tests for diagnosis of *H. pylori* infection, given its high sensitivity and specificity. In addition, RUT is user friendly and cost effective[11-14]. Whereas some commercial kits may require at least 4 h[15,16], the ideal RUT reaction duration is 30 min because it enables endoscopists to obtain the results before patients leave the endoscopy suite.

The aim of this prospective study is to evaluate the validity of newly developed rapid urease tests, HelicotecUT plus test and HelicotecUT test, and the influence of multiple samplings during esophagogastroduodenoscopy (EGD) on the accuracy of the rapid urease test.

MATERIALS AND METHODS

Subjects

Between December 2008 and August 2009 355 patients in Kaohsiung Medical University Hospital, Kaohsiung, Taiwan were included in this study. They were scheduled to undergo EGD to evaluate dyspepsia and exclude organic lesions because their symptoms failed to improve after medication. All patients signed their informed consent and received complete EGD. Patients were separated according to their *H. pylori* treatment status: 200 patients (82 men, 118 women; mean age: 55.9 years, range: 17-86 years) in the treatment naïve group and 155 patients (69 men, 86 women; mean age: 58.0 years, range: 26-83 years) in the eradicated group. Patients meeting the following criteria were excluded: antibiotics, bismuth salts, or proton pump inhibitor used during the previous 1 mo; prior gastric surgery; presence of a bleeding peptic ulcer; severe concomitant diseases; and pregnancy or lactation.

Diagnostic tests for H. pylori infection

Histological examination was done in the pathology core lab, and the gastric specimens were fixed with formalin, embedded in paraffin and stained with hematoxylin and eosin. Culture of *H. pylori* was carried out on the second set of specimens, which were rubbed on the surface of a Campy-BAP agar plate [Brucella agar (Difco) + IsoVitalex (Gibco) + 10% whole sheep blood], and then incubated at 35℃ under microaerobic conditions (5% O_2, 10% CO_2, and 85% N_2) for 4-5 d. *H. pylori* culture was considered as positive if one or more colonies of gram-negative, oxidase (+), catalase (+), and urease (+) spiral or curved rods were present. The results of RUT were interpreted as positive if the color of the gel changed from yellow to pink or red within 24 h at room temperature, and the reaction duration was recorded in minutes accordingly. A total of four RUTs were examined, including HelicotecUT plus test (Strong Biotech Corp-Taiwan), HelicotecUT test (Strong Biotech Corp-Taiwan), CLO test (Kimberly Clark-USA), and ProntoDry test (Medical Intruments Corp-France). The media contained in the CLO test and HelicotecUT were semi-solid phase (agar gel) and in HelicotecUT plus and ProntoDry test were solid phase (dry plate). Single antral specimens and dual (antrum + body) specimens were compared as well.

Confirmation of H. pylori infection

Six biopsy specimens from the lesser curvature side of the antrum and the greater curvature side of the gastric body, respectively were obtained to afford culture, histology and 4 different RUTs. The infection status of *H. pylori* infection was considered positive if the results from either antrum or gastric body met the following criteria: (1) positive culture; or (2) concordant positive results among histology and both CLO and ProntoDry tests. The results of both the CLO test and ProntoDry test were interpreted independently. After we confirmed *H. pylori* status, the diagnostic accuracy of each RUT was evaluated.

Table 1 Validity of rapid urease tests in the treatment naïve group

Method	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Accuracy (%)	P^1
Sampling over antrum with reaction time: 30 min						
HelicotecUT plus	80.6	96.2	91.5	90.8	91.0	
HelicotecUT	77.6	98.5	96.3	90.0	92.0	
CLO	84.6	96.2	91.8	92.1	92.0	
ProntoDry	83.6	95.5	90.3	92.0	91.5	0.988
Sampling over antrum with reaction time: 24 h						
HelicotecUT plus	91.0	94.7	89.7	95.5	93.5	
HelicotecUT	85.1	94.7	89.1	92.6	91.5	
CLO	92.5	95.5	91.2	96.2	94.5	
ProntoDry	92.5	94.7	90.0	96.2	94.0	0.642
Sampling over antrum plus body with reaction time: 30 min						
HelicotecUT plus	98.5	92.5	86.8	99.2	94.5	
HelicotecUT	95.5	94.7	90.1	97.7	95.0	
CLO	97.0	94.0	89.0	98.4	95.0	
ProntoDry	97.0	91.7	85.5	98.4	93.5	0.902

[1]χ^2 test of four RUTs accuracy. RUTs: Rapid urease tests; PPV: Positive predictive value; NPV: Negative predictive value.

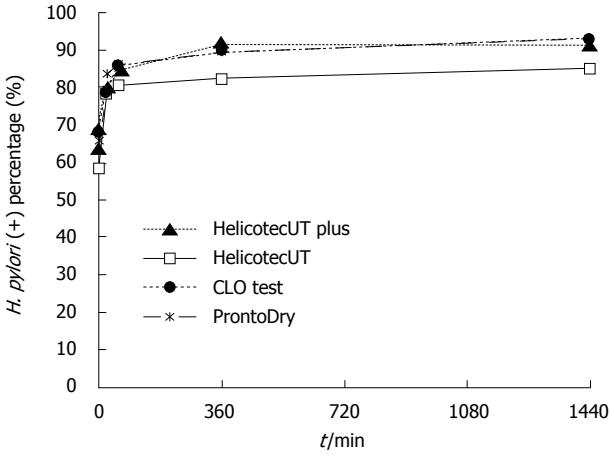

Figure 1 Detection rate and reaction time of four commercial rapid urease tests. *H. pylori*: *Helicobacter pylori*.

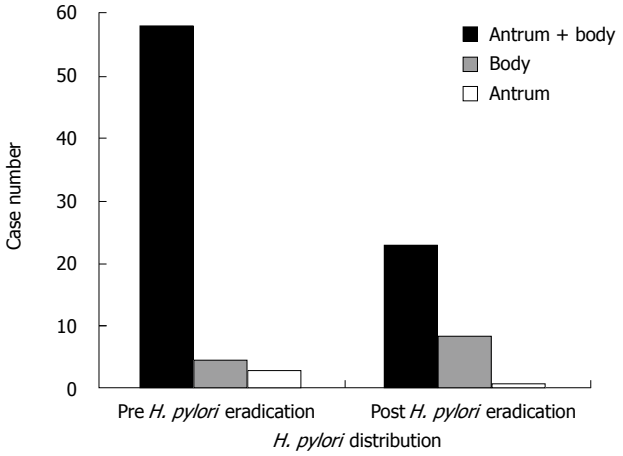

Figure 2 Distribution of *H. pylori* infection before and after eradication. The *P* value of χ^2 test was 0.03.

Statistical analysis

In this study, χ^2 test was chosen for statistical analysis.

RESULTS

The positive status of *H. pylori* infection was 33.5% (67/200) in the treatment naïve group and 21.9% (34/155) in the eradicated group. The culture yield in both groups was 67.2% (45/67) (21 men, 24 women; mean age: 57.8 years, range: 27-83 years) in the treatment naïve group and 44.1% (15/34) (6 men, 9 women; mean age: 55.0 years, range: 37-74 years) in the eradicated group. This result suggested the important role of other biopsy-based tests, particularly RUT, in establishing the diagnosis of *H. pylori* infection.

The diagnostic power including sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of the four different RUTs (HelicotecUT plus test, HelicotecUT test, CLO test, ProntoDry test, presenting in the same order afterwards) was shown in Table 1. In the treatment naïve group, all four RUTs showed comparable sensitivities, specificities and accuracy at 30 min (P = 0.988) and at 24 h (P = 0.642). Although the diagnostic yield of *H. pylori* infection was slightly improved at 24 h, the tests appeared readable and accurate at 30 min (30 min *vs* 24 h, χ^2 test of accuracy, P = 0.156) (Figure 1). Interestingly, the diagnostic accuracy of dual specimens at 30 min was as comparable as single specimens at 24 h (χ^2 test of accuracy, P = 0.346).

In the eradicated group, the distribution of *H. pylori* shifted from antrum to gastric body after *H. pylori* eradication was clearly observed in this study (Figure 2). Because of the lower bacterial loads and patchy distribution, in all 4 RUTs, the diagnostic accuracy of single specimens at 30 min was as low as single specimens at 24 h (χ^2 test of accuracy, P = 0.124). Both results were significantly inferior to dual specimens at 30 min (χ^2 test of accuracy, P = 0.01) (Table 2).

DISCUSSION

There are many diagnostic tests available for *H. pylori* infection. Overall, patients prefer non-invasive tests over invasive tests. Consequently, recent studies have been dedicated to non-invasive tests as a result[17]. No statistical difference

Table 2 Validity of rapid urease tests in the eradicated group

Method	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Accuracy (%)	P^1
Sampling over antrum with reaction time: 30 min						
HelicotecUT plus	50.0	100.0	100.0	87.7	89.0	
HelicotecUT	44.1	100.0	100.0	86.4	87.7	
CLO	55.9	100.0	100.0	89.0	90.3	
ProntoDry	50.0	100.0	100.0	87.7	89.0	0.913
Sampling over antrum with reaction time: 24 h						
HelicotecUT plus	61.8	100.0	100.0	90.3	91.6

CLO	88.2	98.3	93.8	96.7	96.1	
ProntoDry	82.4	100.0	100.0	95.3	96.1	0.987

[1]χ^2 test of four RUTs accuracy.

was reported between these two kinds of tests, given their comparable diagnostic performances[14,18]. However, during the initial diagnosis of *H. pylori* infection, biopsy-based diagnostic tests are usually considered in terms of costs for patients who receive endoscopic examination. RUT is the method of choice among biopsy-based diagnostic tests given their user friendliness and cost-effectiveness[13,19,20]. Short reaction duration and high diagnostic performance are the two attributes of RUT. Therefore, RUT has gained its popularity among most gastroenterologists.

RUT is made available in many commercial kits. The CLO test has been established for more than a decade and used as the main standard for rapid urease tests. Its good performance, with a sensitivity of 89.6%, a specificity of 100%, a PPV of 100%, and a NPV of 84.1%, has been acclaimed[14]. Compared with the CLO test, the newly developed HelicotecUT plus test and HelicotecUT test are equally competent in terms of their diagnostic yield. Our data showed similar results among all four RUTs, even in the eradicated group. Given their comparable diagnostic performance, the tests of lower cost, like HelicotecUT plus test and HelicotecUT test, are of more advantage.

Sampling error is the major drawback of RUT. The diagnostic yield of biopsy-based methods is usually compromised in older patients who are more likely to have extensive gastric mucosa atrophy and intestinal metaplasia. The latter, if happening in the antrum, prevents *H. pylori* colonization and consequently promotes the migration of *H. pylori* to the gastric body. Several mechanisms have been suggested, including loss of a *H. pylori*-specific receptor-like structure on the epitherlium and active secretion of secretory IgA for metaplastic mucosa[21-23]. In addition, after *H. pylori* eradication, the suppression of the density and urease activity of *H. pylori* by antibiotics may reduce the sensitivity of RUT. Despite this, Rollán *et al*[24] reported good sensitivity in the CLO test (91.7%) in their study of 12 *H. pylori*-positive patients and 47 *H. pylori*-negative patients with duodenal ulcers after eradication treatment. They took 3 biopsy specimens from different sites and put them in one test vial. This suggested that more specimens may prevent the false negative results due to sampling error. In this study, we also found that dual specimens improved the overall sensitivity of RUT, even after eradication. Furthermore, dual specimens achieved the highest performance even at 30 min. Our results further portray that more specimens for diagnosis can amend the inherent error of biopsy-based tests.

The major limitation of this study is a lack of global evaluation tests, such as urea breathing test or stool *H. pylori* antigen test (HpsA), which have been established as reliable tests to detect the presence of *H. pylori* in the hosts. Sampling bias may exist within our biopsy-based diagnostic tests, including culture, histology and RUT. In addition, the prevalence of *H. pylori* infection was low in our study cohort. It may be that our patients were mainly from urban area (Kaohsiung City) and might have a lower *H. pylori* infection rate[6].

In conclusion, a combination of antrum and body biopsy specimens for rapid urease test greatly enhances sensitivity and reduces the reaction duration to 30 min. The newly developed HelicotecUT plus test and HelicotecUT test are as effective as the established CLO test and ProntoDry test.

COMMENTS

Background

Helicobacter pylori (*H. pylori*) infection plays a significant role in the development of chronic active gastritis, peptic ulcer, and even gastric adenocarcinoma. *H. pylori* infection has become the leading issue in clinical practice. A large number of methods have been utilized to diagnose *H. pylori* infection. Rapid urease test (RUT) is regarded of one of the best tests for diagnosis of *H. pylori* infection, given its high sensitivity and specificity. However, sampling bias and reaction were clinical issues in clinical practice of RUT.

Research frontiers

This study aimed to evaluate the validity of newly developed RUTs, HelicotecUT plus test and HelicotecUT test, and the influence of multiple samplings during esophagogastroduodenoscopy (EGD) on the accuracy of the RUT.

Innovations and breakthroughs

The newly developed HelicotecUT plus test and HelicotecUT test are as effective as the established CLO test and ProntoDry test.

Applications

Combination of antrum and body biopsy specimens for rapid urease test greatly enhances sensitivity and reduces the reaction duration to 30 min.

Peer review

In this manuscript, the authors compared the diagnostic value of two new rapid urease test kits for detection of *H. pylori* and they compared the diagnostic accuracy when analysing only one antral sample or when analysing a antral and corpal samples. The golden standard used to confirm *H. pylori* status was either a positive culture or concordant result between two to three other tests.

Abstract

AIM: To investigate the impact of postoperative antiviral treatment on tumor recurrence and survival of patients with chronic hepatitis B virus (HBV) or hepatitis C virus (HCV) infection-related primary hepatocellular carcinoma (HCC) after curative therapy.

METHODS: We performed a meta-analysis of randomized and non-randomized control trials from electronic search and manual search. The fixed effect model of Mantel-Haenszel method and the random effect model of Der Simonian and Laird method were used for homogeneous and heterogeneous studies, respectively. Seven HCV-related studies, three HBV-related studies and three studies on HBV or HCV-related HCC were identified.

RESULTS: A total of 1224 patients were included in this analysis. The estimated odds ratios (OR) for the 1-, 2-, 3- and 5-year recurrence were 0.54 [15.4% *vs* 24.1%, 95% confidence interval (CI): 0.32-0.89, P = 0.02], 0.42 (36.9% *vs* 58.0%, 95% CI: 0.19-0.90, P = 0.03), 0.37 (47.9% *vs* 63.8%, 95% CI: 0.19-0.71, P = 0.003), and 0.32 (66.7% *vs* 74.3%, 95% CI: 0.15-0.66, P = 0.002), respectively; and the OR for the 1-, 2-, 3-, 5- and 7-year mortality were 0.23 (1.2% *vs* 9.1%, 95% CI: 0.07-0.71, P = 0.01), 0.31 (6.4% *vs* 22.1%, 95% CI: 0.12-0.79, P = 0.01), 0.43 (12.7% *vs* 20.8%, 95% CI: 0.21-0.89, P = 0.02), 0.42 (25.1% *vs* 42.0%, 95% CI: 0.27-0.66, P = 0.0002) and 0.28 (31.9% *vs* 52.2%, 95% CI: 0.13-0.59, P = 0.0008).

CONCLUSION: This meta-analysis indicates the postoperative antiviral therapy, interferon in particular, may serve as a favorable alternative to reduce recurrence and mortality in patients with HBV/HCV related HCCs.

INTRODUCTION

Hepatocellular carcinoma (HCC) is common worldwide, particularly in Asia where chronic hepatitis B virus (HBV) or hepatitis C virus (HCV) infection is the most common etiology. Generally, hepatectomy, percutaneous ethanol injection (PEI), percutaneous microwave coagulation therapy (PMCT), radiofrequency ablation (RFA) and orthotopic liver transplantation are recognized as curative treatment options for HCC, although liver transplantation can only be offered to a small proportion of patients due to graft availability, selection criteria, and high cost. The long-term prognosis, however, remains guarded because of the high frequency of recurrence, which is also the main cause of death, in addition to concomitant hepatic decompensation.

Interferons (IFNs) are cytokines possessing a variety of biologic properties, including antiviral, immunomodulatory, antiproliferative, antiangiogenic and tumoricidal effects[1]. They are effective in suppressing the replication of HBV/HCV. Response to IFN treatment is associated with improved clinical outcomes and less cirrhosis-related complications. It is also reported that the combination of IFN and certain cytotoxic drugs has resulted in a modest response in patients with inoperable HCC[2]. Certain nucleoside/nucleotide analogues (NAs), such as lamivudine, adefovir, and entecavir, which inhibit the reverse transcriptase activity of viral DNA polymerase, have been demonstrated to be useful for HBV-infected patients, by means of not only suppressing the viral load but also reducing fibrosis in the liver[3,4]. Lamivudine treatment has been reported to consistently reduce HBV replication, and thus might improve the remnant liver function, prevent liver failure and prolong survival[5-7].

Up till now, although several randomized controlled trials (RCTs) and non-randomized controlled trials (NRCTs) have evaluated the efficacy and outcome of antiviral therapies in patients with virus-related HCC after curative treatment, no clear recommendations have been proposed yet. Usually, it is the small sample size of the RCTs that has resulted in a lack of power to detect clinically meaningful differences. In order to test the hypothesis that postoperative antiviral treatment would reduce or postpone recurrence and improve overall survival in patients with chronic HBV/HCV infection-related HCC after curative therapy, we performed a meta-analysis on the basis of published data from both RCTs and NRCTs in the literature.

MATERIALS AND METHODS

Criteria for inclusion and exclusion

Two investigators independently assessed the generated papers for relevance. In case of discrepancies found between the two investigators, a third investigator would make the definitive decision for study eligibility and data extraction.

Eligible patients were those who had undergone a curative treatment for primary HCC associated with HBV or HCV. Curative treatment was defined as complete tumor eradication, with no residual tumor visible by computed tomography, or resection of all evident tumor tissues, which included percutaneous tumor ablation [PTA, e.g. percutaneous ethanol injection (PEI), percutaneous acetic acid injection (PAI), radiofrequency ablation (RFA), microwave coagulation therapy (MCT), *etc.*], surgical treatment (e.g. hepatectomy, ablation during laparotomy, *etc.*), or their combinations. Antiviral therapy included regularly administered IFN (IFNα, IFNβ, and recombinant IFN) for HBV or HCV, nucleoside/nucleotide analogue such as lamivudine for HBV, and other anti-hepatitis virus medications. Primary outcomes were cumulative survival rate, mortality rate, and cumulative recurrence rate at 1, 2, 3, 5 or 7 years.

Studies with the following situations were excluded: (1) those evaluating antiviral therapies before primary HCC developed or after non-curative treatment or liver transplantation; (2) those evaluating an antiviral therapy in combination with chemotherapy; (3) those with no information on cumulative probability of survival, mortality or recurrence; and (4) those evaluating patients with other subtypes of liver malignancy, e.g. cholangiocellular carcinomas or liver metastases.

Literature search

We performed an electronic search of Medline, Embase, Cancerlit, and the Cochrane Library covering a period from 1980 to March 2009 to identify full publications or abstracts of literatures using the terms "hepatocellular carcinoma ", "hepatitis ", "recurrence", "survival", "antiviral agents", "interferon", "lamivudine", "adefovir", "entecavir" and "ribavirin".

In addition, manual search for the abstracts published in major international conferences were also conducted and general reviews and the reference lists from the identified publications were cross-checked to obtain other relevant publications.

Data collection and analysis

We considered articles presenting data from RCTs and NRCTs originally published in English. When the data of a study were included in more than one publication, we excluded studies with duplicated publications on the same group of patients, including those reporting the early stages of study findings with incomplete sample size; only the most recent and complete studies were included in the meta-analysis.

The intention-to-treat method was used. The measure of interest was the OR for cohort studies and the corresponding 95% CI. When ORs were not available in the published article, they were computed from the exposure distributions. For each meta-analysis, χ^2 test was used to assess the statistical heterogeneity among studies

Table 1 Characteristics of the included studies

[1]3 were excluded from the final analysis as they had already experienced one recurrence. NA: Not available; NRCT: Non-randomized controlled trial; RCT: Randomized controlled trial; HBV: Hepatitis B virus; HCV: Hepatitis C virus; IFN: Interferon; SVR: Sustained virologic response; RFA: Radiofrequency ablation; PEI: Percutaneous ethanol injection; PMCT: Percutaneous microwave coagulation therapy; PAI: Percutaneous acetic acid injection.

and results were defined as heterogeneous when *P* values were less than 0.10. A fixed effect model, the Mantel-Haenszel method, was used for homogeneous studies, and when significant heterogeneity existed, a random effect model, the Der Simonian and Laird method, would be applied (RevMan, version 5; The Cochrane Collaboration, Copenhagen, Denmark). A significance level of 5% was taken as the α risk. Only meta-analyses of antiviral therapies that included two or more studies (RCTs or NRCTs) were performed.

To compute summary OR for different viral etiology, we calculated the study-specific estimates separately for HBV and HCV. Forest plots were given. Publication bias was evaluated using funnel plots and Egger's test.

RESULTS

One hundred and twenty-four abstracts were found through the search in literature; among them, 17 studies with 22 publications fulfilled the inclusion criteria. Three additional publications from the bibliographies of retrieved studies were also identified. Among them, ten publications[8-17] reported five studies at different time, therefore, only the five most recent articles[8,10,12,16,17] were used for the analysis; five studies[12,17-20] did not report the number of death or recurrence at 1, 2, 3, 5 or 7 years or provide data separately for the treatment and control groups and were thereby excluded; one study[21] enrolled not only patients who received postoperative antiviral therapy but also those who were preoperatively treated, another study[10] included patients who received palliative treatment before antiviral therapy, both of which did not provide separate data on survival or recurrence for different treatment approaches and were therefore excluded. The final analysis included seven studies of HCV-associated HCC with IFN therapy[8,22-27], three studies of HBV-associated HCC, two with lamivudine[28,29] and one with IFN therapy[30], and three studies of HBV/HCV-associated HCC with IFN therapy[16,31,32] (Table 1).

Among the seven HCV-related studies using IFN, two were RCTs[8,27], the rest five were cohort studies (NRCTs)[22-26]. A total of 768 patients were enrolled, and 210 received IFN treatment. The medium duration of follow-up ranged from 23 to 85 mo. The three HBV-related studies are all NRCTs, with a total of 199 patients included; 11 patients received IFN treatment and 46 received lamivudine. The medium duration of follow-up ranged from 31 to 53 mo. All of the three HBV/HCV-related studies are RCTs with a total of 260 patients, including 93 HBV-infected, 95 HCV-infected, and 72 HBV/HCV-co-infected HCCs; three of them were excluded from the final analysis as they had already experienced one recurrence. Among the rest 257 patients, 134 received IFN therapy. The medium duration of follow-up ranged from 27 to 45 mo.

Antiviral therapy and HCC recurrence

For 1-year recurrence, pooled data from nine studies[8,22,23,25-29,32] showed significantly more HCC recurrence cases in the control (24.1%) than in the antiviral therapy (15.4%) groups (OR: 0.54, 95% CI: 0.32-0.89, P = 0.02, Figure 1A). No statistical heterogeneity was found (I^2 = 0%, P = 0.60). Subgroup analysis of the six HCV-related studies[8,22,25-27,32] revealed significantly fewer HCC recurrences in IFN groups (12.1%) than in the control groups (20.8%) (OR: 0.52, 95% CI: 0.27-1.00, P = 0.05) with no statistical heterogeneity (I^2 = 16%, P = 0.31). In the two HBV-associated studies[28,29], which were also the only two lamivudine-treated studies, no statistically significant difference was found between lamivudine (21.7%) and control groups (28.8%) (OR: 0.59, 95% CI: 0.24-1.43, P = 0.24). Subgroup analysis of the seven IFN studies, which combined outcomes of the six HCV-related and 1 HBV/HCV-related HCC studies[31], revealed that compared with control (22.0%), IFN groups had a lower HCC recurrence rate (13.7%) (OR: 0.52, 95% CI: 0.28-0.95, P = 0.03). No statistical heterogeneity was found (I^2 = 0%, P = 0.43).

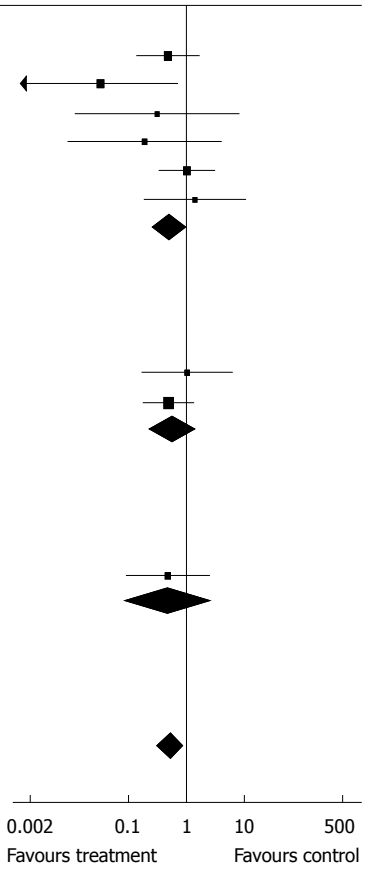
For 2-year recurrence, as statistical heterogeneity (I^2 = 51%, P = 0.06) was found, the randomized model was applied to the data from seven studies[23,25-29,32], revealing significantly fewer HCC recurrences in the treatment (36.9%) than the control (58.0%) groups (OR: 0.42, 95% CI: 0.19-0.90, P = 0.03, Figure 1B). Subgroup analysis of the four HCV-related studies[23,25-27] showed significantly more HCC recurrences in the control (63.0%) than in IFN groups (30.3%) (OR: 0.23, 95% CI: 0.06-0.99, P = 0.05) with statistical heterogeneity (I^2 = 65%, P = 0.03). In the two HBV studies[28,29], no significant difference was found between lamivudine (47.8%) and control groups (50.7%) (OR: 0.82, 95% CI: 0.38-1.74, P = 0.60). Subgroup analysis of the five IFN studies, which combined outcomes of the four HCV-related and 1 HBV/HCV-related HCC studies[32], revealed that there was significantly fewer HCC recurrences in IFN groups (31.0%) than in control (63.4%) (OR: 0.26, 95% CI: 0.09-0.78, P = 0.02). There existed statistical heterogeneity (I^2 = 54%, P = 0.07).

For 3-year recurrence, the randomized model of eight studies[8,22,23,25,26,28,30,32] revealed statistical heterogeneity (I^2 = 47%, P = 0.07) and significantly fewer recurrent cases in the treatment (47.9%) than in the control (63.8%) groups (OR: 0.37, 95% CI: 0.19-0.71, P = 0.003, Figure 1C). Subgroup analysis of the five HCV-related studies[8,22,23,25,26] showed significantly fewer recurrences in IFN (52.4%) than in the control groups (69.8%) (OR: 0.41, 95% CI: 0.17-0.99, P = 0.05). Statistical heterogeneity was found among these studies (I^2 = 61%, P = 0.04). In the two HBV studies[28,30], there was a trend of fewer recurrences in the treatment groups (33.3%) than in the controls (52.9%) (OR: 0.43, 95% CI: 0.17-1.07, P = 0.07). By combining data from the five HCV-, 1[30] HBV-, and 1[32] HBV/HCV-related studies, subgroup analysis of the seven IFN studies revealed that the recurrence rate in IFN groups (48.9%) was significantly lower than in the control groups (65.2%) (OR: 0.34, 95% CI: 0.16-0.73, P = 0.006). There existed statistical heterogeneity (I^2 = 55%, P = 0.04).

For 5-year recurrence, three studies[8,22,30] showed significantly fewer HCC recurrences in IFN (66.7%) than in the control (74.3%) groups (OR: 0.32, 95% CI: 0.15-0.66, P = 0.002) with no statistical heterogeneity (I^2 = 0%, P = 0.80, Figure 1D). Subgroup analysis of the two HCV-related HCC studies[8,22] revealed significantly fewer recurrences in IFN groups (71.4%) compared with the control groups (85.1%) (OR: 0.37, 95% CI: 0.16-0.86, P = 0.02). No statistical heterogeneity was found (I^2 = 0%, P = 0.90).

Antiviral therapy and survival

For 1-year survival, combined data from six studies[8,16,23,25,28,29] showed significantly more deaths in the control (9.1%) than in the treatment (1.2%) groups (OR: 0.23, 95% CI: 0.07-0.71, P = 0.01), with no statistical heterogeneity (I^2 = 0%, P = 0.99, Figure 2A). Subgroup analysis of the three HCV studies[8,23,25] failed to show a significant difference in mortality between IFN (1.2%) and control groups (5.4%) (OR: 0.39, 95% CI: 0.07-2.27, P = 0.30). No statistical heterogeneity was found (I^2 = 0%, P = 0.95). In the two HBV studies[28,29], there was no significant difference between lamivudine (0%) and control groups (9.6%) (OR: 0.19, 95% CI: 0.02-1.55, P = 0.12) and no statistical heterogeneity (I^2 = 0%, P = 0.98). Subgroup analysis of the four IFN studies which included three HCV-related and 1 HBV/HCV-related studies[16], revealed a significantly higher mortality rate in the control (8.8%) than in IFN groups (1.7%) (OR: 0.25, 95% CI: 0.07-0.96, P = 0.04) with no statistical heterogeneity (I^2 = 0%, P = 0.91).



For 2-year survival, pooled data from four studies[23,25,28,29] showed a significantly lower mortality rate in the treatment groups (6.4%) compared with the control groups (22.1%) (OR: 0.31, 95% CI: 0.12-0.79, P = 0.01, Figure 2B), with no statistical heterogeneity (I^2 = 16%, P = 0.31). In subgroup analysis, the two studies of HCV-related HCC[23,25] failed to show a significant difference between IFN (6.2%) and control (18.4%) groups (OR: 0.40, 95% CI: 0.09-1.73, P = 0.22), with no statistical heterogeneity (I^2 = 0%, P = 0.54). Among the two HBV studies[28,29], the mortality in lamivudine groups (6.5%) was lower than in the control groups (24.7%) (OR: 0.27, 95% CI: 0.08-0.89, P = 0.03).

For 3-year survival, the randomized model, including eight studies[8,16,22-25,28,31], revealed statistical heterogeneity (I^2 = 46%, P = 0.07) and a significantly lower mortality rate in the treatment (12.7%) than in the control (20.8%) groups (OR: 0.43, 95% CI: 0.21-0.89, P = 0.02, Figure 2C). Subgroup analysis of the 5 HCV-related studies[8,22-25] showed significantly fewer deaths in IFN groups (7.4%) compared with the control groups (17.5%) (OR: 0.37, 95% CI: 0.15-0.88, P = 0.02), with no statistical heterogeneity (I^2 = 16%, P = 0.31). Combined outcomes of the seven IFN studies which included data from the five HCV-related and two HBV/HCV-related studies[16,31], revealed that there were significantly fewer deaths in IFN (13.4%) than in the control (19.1%) groups (OR: 0.54, 95% CI: 0.34-0.84, P = 0.006). No statistical heterogeneity was found (I^2 = 22%, P = 0.26).

For 5-year survival, four studies[8,16,22,31] showed signifi-

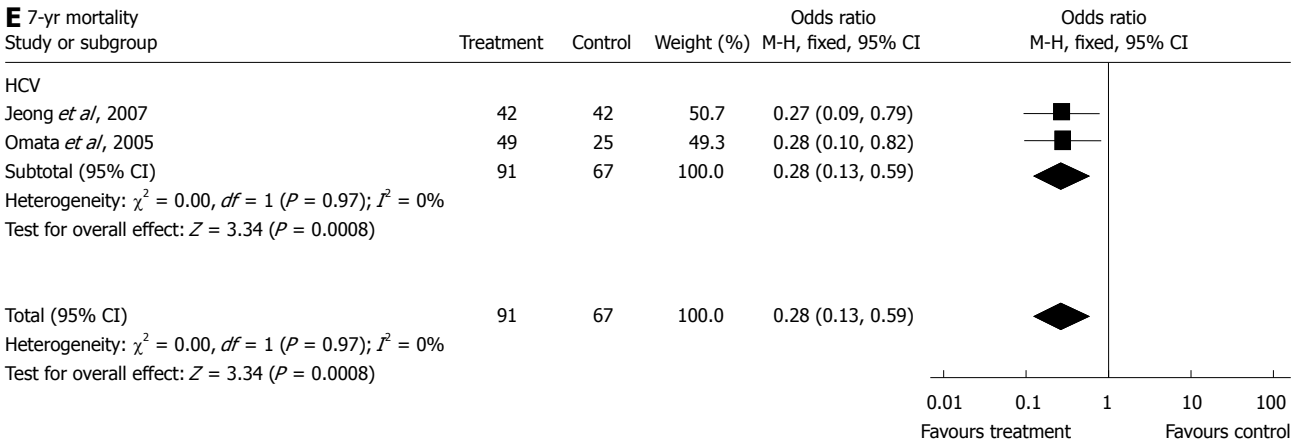

Figure 2 Forest plot of randomized (RCTs) and non-randomized (NRCTs) controlled trials evaluating the effect of post-operative antiviral therapy on HCC mortality after curative therapy (RevMan, version 5; The Cochrane Collaboration, Copenhagen, Denmark). A: 1-year mortality, the Mantel-Haenszel method. B: 2-year mortality, the Mantel-Haenszel method; C: 3-year mortality, the Der Simonian and Laird method; D: 5-year mortality, the Mantel-Haenszel method; E: 7-year mortality, the Mantel-Haenszel method.

(85.1%) (OR: 0.15, 95% CI: 0.01-2.67, $P = 0.20$) groups with a statistical heterogeneity ($I^2 = 73\%$, $P = 0.05$).

For 7-year survival, combined data from two HCV-related studies[8,22] including 158 patients revealed a significantly lower mortality rate in IFN (31.9%) than in the control (52.2%) groups (OR: 0.28, 95% CI: 0.13-0.59, $P = 0.0008$), with no statistical heterogeneity ($I^2 = 0\%$, $P = 0.97$, Figure 2E).

DISCUSSION

The prevention of recurrence constitutes one of the most important challenges to improve the prognosis of patients with HCC after curative therapies. Currently, there is insufficient evidence to reach a consensus on appropriate adjuvant therapies for secondary prevention. In the present meta-analysis, postoperative antiviral therapy as a whole has been shown to reduce HCC recurrence at year 1, 2, 3, and 5. Subgroup analyses have further demonstrated that this effect of reduction remained significant in IFN-treated HCCs as well as pure HCV-associated HCCs.

Generally, recurrences can be differentiated into early or late ones. Early HCC recurrences were assumed to be derived from residues of original HCC after a potentially curative therapy and usually appear within the first 2 years. Late recurrences, which typically occur more than 2 years after the elimination of primary tumors, develop on the basis of underlying liver diseases, resulting from new carcinogenesis[14]. Persistent active hepatitis is common in advanced stages of chronic HBV or HCV infection, including HCC. The prevalence of multicentric carcinogenesis increases during progression to active hepatitis and hepatic fibrosis[33]. Hepatocyte necrosis and inflammation may be closely involved in multifocal recurrence in chronic HBV/HCV-infected patients who had complete resection or ablation of HCC tumors. Hence, it is hypothesized that antiviral therapies would help prevent HCC recurrence by cleaning the carcinogenic soil and eliminating possibilities of novel tumorigenesis through their viral suppression and anti-inflammation action.

There have been studies indicating that IFN therapy for chronic hepatitis C has improved the histological features of hepatic inflammation and fibrosis, induced remission of active hepatitis, and thereby hindered HCC development[34,35]. Similarly, IFN may also suppress multifocal recurrence arising from multicentric carcinogenesis after resection or ablation in the same way. Nonetheless, the results of this meta-analysis have shown that IFN not only reduced late recurrent HCCs but also early ones, especially in patients with pure HCV infection, which indicates that more than one mechanism may actually contribute to the benefit of adjuvant therapy with IFN in lowering recurrent HCCs. Beside immunostimulant, antiviral, antiangiogenic, and anticarcinogenic properties, IFN has been found to have *in vitro* and *in vivo* antiproliferative and tumoricidal effects against HCC as well[1,16,36]. Therefore, postoperative IFN therapy might be of advantage to recurrence prevention due to a combination of chemopreventive effects on multicentric carcinogenesis and antiproliferative and tumoricidal effects on residual HCC cells.

Compared with recurrence, although the overall results of antiviral therapies or IFN alone at various years were almost positive in improving survival, subgroup analyses of HCV-related HCCs produced mixed results. For survival at year 1, 2, and 5, current data are insufficient to give out significant results; for survival at year 7, given the condition that only two studies with a total of 158 patients were available for analysis, the significant difference between IFN and control groups should be taken with a grain of salt; only the benefit for 3-year survival was based on a relatively larger sample size, but it also needs further confirmation by even larger studies.

Sustained virological response (SVR) is defined on the basis of the absence of serum HCV RNA at least 6 mo after completion of IFN therapy. All seven studies of pure HCV-related HCCs presented information on the response to IFN therapy (Table 1); however, the effects varied greatly as different IFN formulas with different doses, intervals, and durations were applied in different

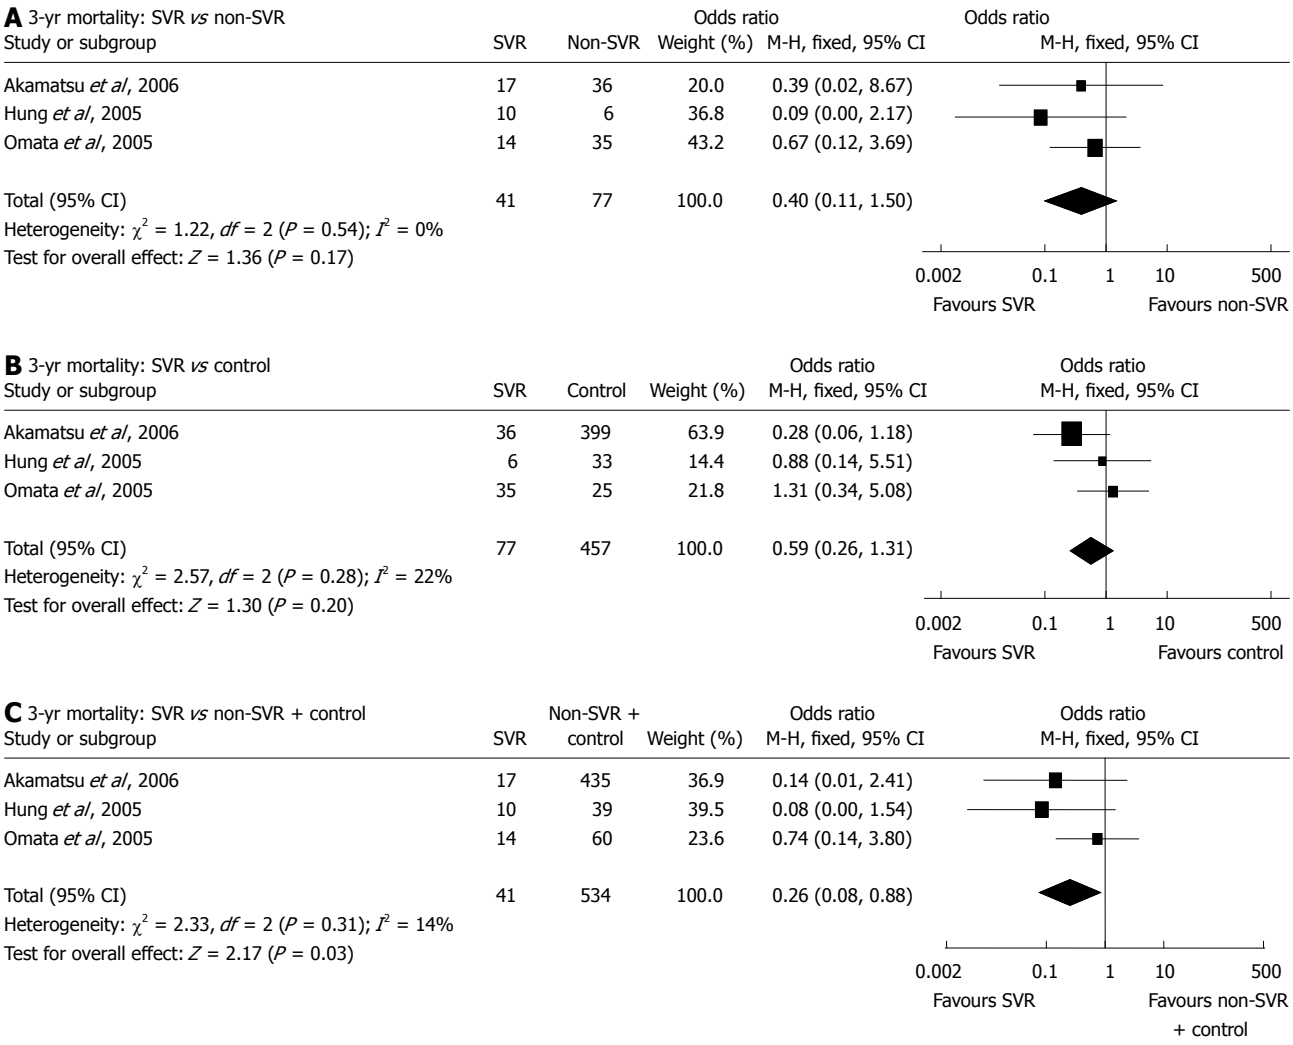

Figure 3 Forest plot of randomized (RCTs) and non-randomized (NRCTs) controlled trials evaluating the effect of post-operative antiviral therapy on the 3-year mortality of HCV-related HCC patients after curative therapy (RevMan, version 5; The Cochrane Collaboration, Copenhagen, Denmark). A: Comparison between patients with sustained virologic response (SVR) and those without sustained virologic response (non-SVR), the Mantel-Haenszel method; B: Comparison between non-SVR patients and control subjects, the Mantel-Haenszel method; C: Comparison between SVR patients and non-SVR patients plus control subjects, the Mantel-Haenszel method.

patient populations. The comparisons between patients with SVR and those without SVR or IFN treatment were performed in four studies; all showed a certain superiority of SVR, either in survival or the first/second HCC recurrence[8,22,24,25]. As among all nine endpoints, i.e. 1, 2, 3 and 5-year recurrence and 1, 2, 3, 5 and 7-year survival, only the data on the 3-year survival of SVR and non-SVR patients were available in two or more studies, a subgroup analysis was able to be performed. Although pooled data from three studies[8,24,25] did not reveal significant difference in the 3-year mortality between SVR patients (2.4%) and non-SVR ones (14.3%) (OR: 0.40, 95% CI: 0.11-1.50, $P = 0.17$, Figure 3A), or between non-SVR patients and control subjects (18.8%) (OR: 0.59, 95% CI: 0.26-1.31, $P = 0.20$, Figure 3B), it was shown that the mortality rate in SVR patients was significantly lower than that in non-SVR patients plus control ones (18.2%) (OR: 0.26, 95% CI: 0.08-0.88, $P = 0.03$, Figure 3C). Therefore, for HCV-related HCC, it may be worth considering whether it is reasonable to take SVR as a target of antiviral therapies in order to improve prognosis. If so, intensified or combined treatment, such as the combination of PEG-IFN and ribavirin, would be indicated as long as the adverse effects are well balanced and patients are tolerant to such treatment.

Regarding HBV-related HCC, analysis on the two lamivudine studies that provided data on recurrence and mortality at year 1, 2, and 3 failed to demonstrate significant differences but only a trend of superiority in late recurrence, although it showed significant benefit in the 2- and 3-year survival. Besides problems with the limited number of studies and small sample sizes, it may be partially explained by the fact that the emergence of YMDD mutations (e.g. rtM204V/I) reduces the benefit of lamivudine therapy, which is relatively frequent in clinical trials and generally associated with worse clinical outcomes, such as hepatitis flares, hepatic decompensation, fatal liver failure and death[28,37]. *In vitro* studies have shown that the rtM204V/I mutations decreased susceptibility of the viral polymerase to lamivudine and reduced functional capacity

of the viral polymerase[37]. As a result, serum HBV DNA remains at or relapses to a high level, which leaves the liver prone to HCC recurrence, as shown by one report that, during a median follow-up of 35 mo, patients in the non-viraemia (< 100 000 copies/mL) group had a lower 5-year cumulative recurrence rate than those in the viraemia group (54.7% *vs* 72.9%, $P = 0.043$), and sustained viraemia independently increased recurrence after surgery in multivariate analysis ($P = 0.041$)[38]. Therefore, antiviral therapy may be indicated in patients with detectable serum HBV DNA since lower viral load is important to reduce HCC recurrence; meanwhile, periodic assessment of serum HBV DNA using a sensitive assay should be applied to monitor the antiviral resistance. It is hypothesized that potent oral NAs with higher genetic barrier to resistance, such as entecavir, could overcome this disadvantage, but it needs further studies to confirm.

In conclusion, this meta-analysis demonstrates the benefit of antiviral treatment, IFN in particular, in reducing short-term and long-term HCC recurrence and mortality after curative therapies such as hepatic resection or ablation for primary HCC. The effects seem particularly striking for patients with pure HCV infection, and patients who have achieved SVR after IFN therapy may expect fewer recurrences and longer survival. These data are highly encouraging and should call for further evaluation and development of new regimens. For HBV-related HCCs, future randomized control trials with larger sample size, longer follow-up, and regular HBV DNA monitoring will be needed to substantiate the beneficial effects of antiviral therapies, such as IFN and entecavir, on the prognosis of HCC. Finally, based on these results, we hypothesize that if compared with other adjuvant therapies, such as systematic chemotherapy, molecular targeted therapy, some locoregional therapies, antiviral therapy may serve as a cost-effective and favorable alternative to improve the prognosis of patients with HBV/HCV-related HCCs because the underlying carcinogenic background can be reformed, which also warrants in-depth investigations.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is common worldwide, particularly in Asia where chronic hepatitis B virus (HBV) or hepatitis C virus (HCV) infection is the most common etiology. The prevention of recurrence remains as one of the most important challenges to improve the prognosis after curative therapies. Up till now, although several clinical trials have evaluated adjuvant antiviral therapies with interferon or lamivudine, no clear recommendations have been proposed.

Research frontiers

As a quantitative technique for therapeutic evaluation, meta-analysis may be used when controversy exists, particularly when trials have insufficient statistical power. In the present study, this mathematical tool is utilized to verify the hypothesis that antiviral therapy may serve as an alternative strategy to improve the prognosis of patients with HBV/HCV-related HCCs.

Innovations and breakthroughs

Although antiviral therapies using interferons or lamivudine have shown promising results in chronic hepatitis B or hepatitis C, their effects on patients with HCC after curative therapy remain controversial, mainly due to the small sample size and short follow-up time. By pooling data from available literature, the present study for the first time demonstrates the benefit of antiviral therapies, interferon in particular, in reducing both short-term and long-term HCC recurrence as well as mortality after curative therapies. The effects seem more remarkable for patients with HCV-related HCC. For HBV-related HCCs, this study warrants future randomized control trials with larger sample size and longer follow-up. This study intends to remind surgeons that basic treatment that targets underlying carcinogenic background might be more efficient than the so-called novel techniques which are attractive but still questionable.

Applications

The results of study indicate that postoperative antiviral therapy, interferon in particular, may serve as a favorable alternative to reduce recurrence and mortality in patients with HBV/HCV-related HCCs.

Peer review

This is a meta-analysis of postoperative antiviral treatment on tumor recurrence and survival in patients with chronic HBV or HCV infection-related HCC after curative therapy, which has been an interesting issue but still has no solid evidence. The authors conclude that postoperative antiviral treatment may reduce short-term and long-term HCC recurrence and mortality after curative therapy. Antiviral therapy may serve as a favorable alternative to improve the prognosis of patients with HBV/HCV-related HCCs. The authors have nicely analyzed the recent publications. Overall, these results are well laid out and logical.

Abstract

AIM: To analyze clinical and pathological characteristics of an aggressive subtype of perianal Paget's disease (PPD) and explore its rational treatment modalities.

METHODS: PPD patients were retrospectively collected in the institutional colorectal database of the Fudan University Shanghai Cancer Center. Detailed patient histories of past medical condition, diagnosis, treatment, and pathological findings were reviewed. Surgical specimen from diagnosis and surgery were reviewed by two independent pathologists for confirmation of diagnoses. Follow up was accomplished by clinical interview by cellphone.

RESULTS: In total, eight cases of PPD were analyzed. All patients had underlying anorectal adenocarcinoma, including seven with synchronous lesions and one with metachronous lesions. Moreover, all anorectal lesions had a mucin-producing component. The median age at diagnosis was 65 (range 29-81 years), and the male/female ratio was 7:1. The Median follow-up time of all patients was 61.5 mo (range 10-204 mo). One patient treated with abdominoperineal resection (APR) died from lung metastases 10 mo after the APR operation. The other patients are still free of disease at the time of this analysis.

CONCLUSION: PPD is a rare malignancy and is easily misdiagnosed. Underlying anorectal cancer was not unusual and was a significant prognostic factor. Rational treatment of both anorectal cancer and PPD lesion is essential for long-term survival.

Retrospective analysis of perianal Paget's disease with underlying anorectal carcinoma. *World J Gastroenterol* 2010; 16(23): 2943-2948 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i23/2943.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i23.2943

INTRODUCTION

Perianal Paget's disease (PPD) is a rare malignancy and less than 200 cases have been reported in literature. The prognosis of simple PPD is relatively favorable, both overall and disease-free survival are approximately 60% at 5-year[1-3].

However, one subtype of this malignancy, PPD with synchronous or metachronous carcinoma of the anorectum, has a poor prognosis, based on limited reports on this entity[1-5]. Due to the rarity of this condition, most of the published literature presented limited numbers of case reports. The natural course of the disease and its optional management is still unknown.

The current report aims to increase the current knowledge of PPD with underlying adenocarcinoma of the anorectum by retrospectively reviewing the natural history and treatment outcome of eight consecutive and non-selected patients diagnosed with this rare condition.

MATERIALS AND METHODS

All cases of PPD diagnosed and treated between January 1985 and December 2009 at the colorectal surgical service of Fudan University Shanghai Cancer Center were reviewed retrospectively. According to the institutional colorectal database, patients with histological confirmation of Paget's disease originating from the perianal area, as well as adenocarcinoma of the rectum and/or anal canal, were included in this analysis.

Detailed patient histories of past medical conditions, diagnosis, treatment, and pathological findings were reviewed.

Preoperative workup included fiberoptic full colonoscopy, computed tomography and/or magnetic resonance imaging of the abdomen and pelvis, and carcinoembryonic antigen tumor marker analysis to confirm the lesions of the perianal area and anorectum and to exclude lesions in other part of the colon.

Surgical specimens from diagnosis and surgery were reviewed by two independent pathologists for confirmation of diagnoses of both Paget's disease of the perianal area and anorectal adenocarcinoma. Only when the preoperative colonoscopy and postoperative pathological examination confirmed that there was no continuity between the two lesions through mucosa spread and interstitial invasion, were the patients included in the study.

Follow up was accomplished according to the NCCN guideline V2.2009 for rectal cancer and survival information was achieved by clinical and/or cellphone interview.

RESULTS

Patients' characteristics and diagnosis

Eight cases were diagnosed with PPD with synchronous or metachronous anorectal adenocarcinoma. Patients' characteristics are detailed in Table 1. The median age at diagnosis was 65 years (range 29-81 years), and the male/female ratio was 7:1. The median follow-up time of all patients was 61.5 mo (range 10-204 mo). One patient treated with APR died from lung metastases 10 mo after the APR operation. The other seven patients are still free of disease at the time of this analysis, one of whom had local recurrence of PPD and received salvage wide local excision.

Eczema-like symptoms including eczema-like skin change, itching, and pain were the most common presenting symptoms and occurred in five of eight cases as the only initial finding. Digestive tract symptoms, including hematochezia, increased frequency of defecation without diarrhea, and constipation, respectively, were observed in 3, 2, and 1 cases of the remaining three cases. The median time from symptom onset to diagnosis of Paget's disease was 27.3 mo (range 6-96 mo).

Table 1 General patient information

Patient	Gender	Age (yr)	Disease status	Treatment
1	Male	80	Synchronous	APR
2	Male	29	Synchronous	APR
3	Female	68	Synchronous	APR
4	Male	63	Synchronous	APR
5	Male	53	Synchronous	Excision biopsy of anorectal lesion + radical radiation therapy for both Paget's disease and anorectal cancer
6	Male	61	Synchronous	APR
7	Male	81	Synchronous	APR
8	Male	70	Metachronous	Radiation therapy; Inguinal node resection and APR for recurrence

APR: Abdominoperineal resection.

Six patients were pathologically diagnosed as PPD before surgery or definitive radiation, and pathological confirmation of PPD was obtained from specimens after radical surgery in two additional cases.

Treatment and clinical outcome

All patients received treatment for curative intent including surgery and radiation therapy. Seven patients received radical surgery. Five of the seven patients were treated with abdominoperineal resection (APR), and one had trans-anal excision followed by APR.

One patient was treated with induction radiation therapy to 50.4 Gy delivered over 5.5 wk (1.8 Gy/daily fraction) as the initial treatment for Paget's disease. He developed local recurrence of Paget's disease and lymphadenopathy in the left inguinal area one year after the completion of radiation therapy, and was diagnosed with adenocarcinoma of the lower rectum. The patient was treated with APR and adjuvant chemotherapy. One additional patient received excision biopsy of the rectal cancer followed by definitive radical radiation therapy then adjuvant chemotherapy. Radical surgery was not performed for rectal cancer due to his poor general health. The total dose for definitive radiation therapy was 59.4 Gy given at 1.8 Gy/daily fractions. Adjuvant chemotherapy (five cycles of capecitabine) was used in two patients.

Pathology study

Pathological study of the resected specimens of seven surgically treated patients and excisional biopsy of one case treated with definitive radiation revealed typical characteristics of Paget's cells as depicted by Marchesa *et al*[1]: large cytologically malignant cells (Paget cells) that had vesicular nuclei and prominent nucleoli and contained abundant pale or granular, sometimes vacuolated, cytoplasm.

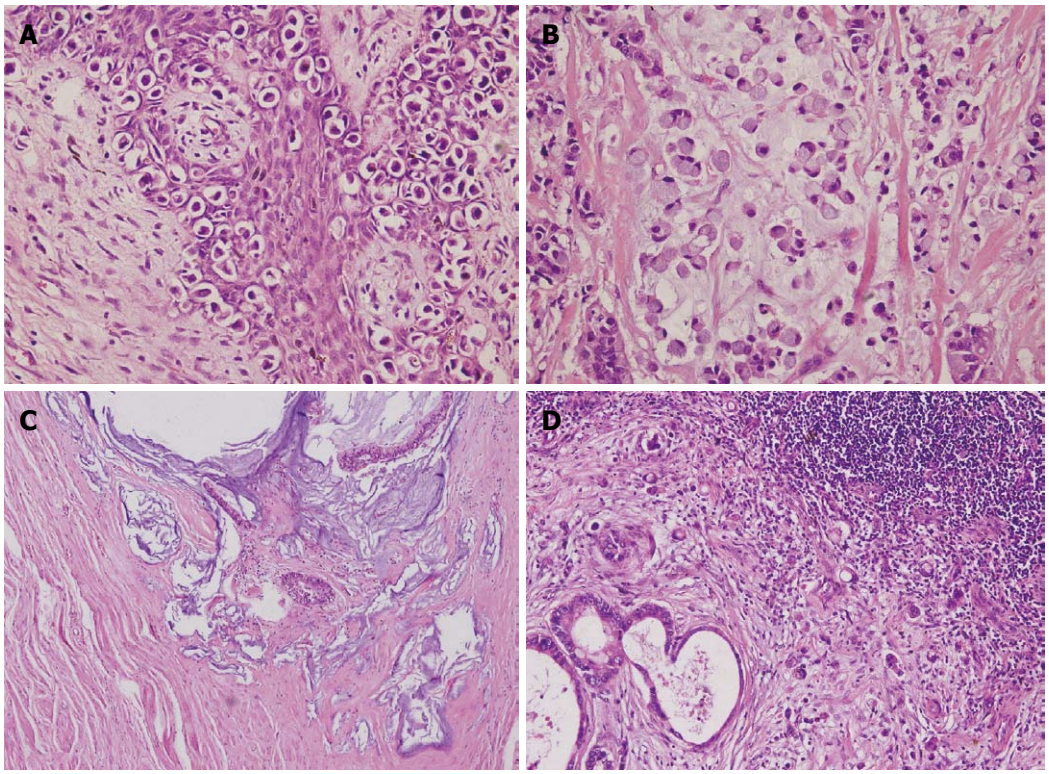

Figure 1 Histopathological images of perianal Paget's disease, rectal cancer, and metastases in a lymph node from one patient. A: Paget's disease under high-power magnification (× 400); B: Signet cell ring cancer component of rectal cancer under high-power magnification (× 400); C: Mucinous adenocarcinoma component of rectal cancer under high-power magnification (× 200); D: Metastases in inguinal lymph node under high-power magnification (× 400).

Table 2 Clinicopathological factors (mean ± SE) *n* (%)

Factors	Value
Distance to anal edge of anorectal cancer (cm)	2.69 ± 0.70
Diameter of anorectal cancer (cm)	3.13 ± 1.76
Diameter of PPD (cm)	4.81 ± 2.59

Mucinous adenocarcinoma	5/8 (62.5)
Signet ring cell cancer	1/8 (12.5)
Mix typed	2/8 (25)
Stages of anorectal cancer	
Ⅰ	5/8 (62.5)
Ⅱ	2/8 (25)
Ⅲ	1/8 (12.5)

PPD: Perianal Paget's disease.

Moreover, all cases had Paget's disease confined in the perianal area with clear margins from their synchronous anorectal adenocarcinoma. For the only case treated with definitive radiation therapy, colonoscopy before surgery showed a clear distance, without evidence of disease, between Paget's disease and the lower rectal lesion, and a clear margin was observed from the excised specimen from the rectum. Of all cases, the underlying adenocarcinoma originated from the lower rectum and involved the dentate line. All anorectal lesions had a mucin-producing component, which had rarely been reported previously in the published literature. Clinicopathological features of the seven surgically treated cases are detailed in Table 2. Figure 1 illustrates histopathological images of PPD, anorectal adenocarcinoma, and metastases in a lymph node from one typical case.

DISCUSSION

Paget's disease is an intra-epithelial adenocarcinoma and was first reported in the breast by Sir Paget J in 1874. Since then, Paget's cells and Paget's disease have been reported in several extramammary sites, including the axilla, perineum, groin, thigh, scrotum, and vulva[6]. In 1893, Darrier and Coulillaud reported the first case of Paget's disease in the perianal region.

PPD is often referred to as an intraepithelial adenocarcinoma within 6 cm scope around the anus and below the dentate line. Signet ring cells with pale, vacuolated cytoplasm are present, which are usually positive with a periodic acid-Schiff mucin stain under microscopic examination[7,8].

There is considerable controversy about the origin of PPD. Helwig *et al*[9] considered perianal and vulval Paget's disease to be a manifestation of a multicentric effect of an unknown carcinogenic stimulus on apocrine structures, epidermis, and glandular elements of the rectum and the urethra. Otherwise, some researchers observed histochemical similarity between the mucin in the intraepidermal cells and the underlying carcinoma cells, and formed the view that the cells in the epidermis represented metastatic spread[10-14]. In our group, eight anorectal carcinomas also had mucin-producing components, such as mucinous adenocarcinoma, signet ring cell cancer, or

mixed type. However, fiberoptic full colonoscopy confirmed disease-free distance between Paget's disease and the anorectal carcinoma. Moreover, pathologists failed to find continuity between the two lesions. This result reinforced the supposition of "metastatic origination of perianal Paget's disease" from a much bigger sample size basis. The mucin secretion character of the anorectal lesion and clinical manifestation of mucinous discharges suggested that mucin might play an important role in the histogenesis of PPD. We hypothesized that mucin may function in Paget's disease formation by two ways: cancer cell produced-mucin might stimulate carcinogenesis of apocrine structures/epidermis in the perianal area directly. On the other hand, mucinous tumor cells might infiltrate through the epidermal barrier and form a cancer nest beneath.

After PPD was first reported by Darrier and Coulilaud in 1893, new cases emerged gradually[4,15-19], but systemic analysis of this disease was scarce. Only in prestigious medical institutes, such as the Memorial Sloan-Kettering Cancer Center, the Mayo Clinic, and the Cleveland Clinic Foundation, was this type of disease collected and analyzed systemically; however, the sample sizes were very small (27, 13, and 14 cases, respectively)[1-3]. Unfortunately, these studies focused on simple PPD, and the aggressive subtype with underlying anorectal carcinoma was still unknown.

Interestingly, all patients with PPD in our group had underlying adenocarcinoma in the anorectum. Therefore, we attempted to summarize the natural history, clinicpathological characteristics, treatment experiences, and information about survival to boost the knowledge of this rare condition.

Eczema-like symptoms were the most common initial complaints, including eczema-like skin change, itching, and pain, which were easily underestimated by the patients themselves and by physicians. On the other hand, digestive symptoms could be the first presentation, but are usually ignored by the patients themselves. In our group, the median time from symptom onset to diagnosis of Paget's disease was 27.3 mo. PPD with underlying anorectal carcinoma in has been rarely reported. In some cases, anorectal carcinoma was neglected in the diagnosis and treatment modality after confirmation the diagnosis of Paget's disease. A total of 155 cases of Paget's disease have been reported. The median age of onset was 65.3 years and male/female ratio was 1.06. The proportion of underlying anorectal cancer was as high as 41.8%.

A wide range of treatment modalities have been previously reported, including surgery (wide local excision with or without reconstruction and grafting[20-23], abdominoperineal resection[1-3], Mohs micrographic surgery[24]), radiotherapy[25], chemo-radiotherapy[26-28], and photodynamic therapy[29,30].

Surgical methods are still the mainstay in the management of PPD. Table 3 shows the stage and management recommended by Shutze *et al*[31] in 1990 and followed by most oncologists.

According to this staging system, seven PPD with synchronous anorectal carcinoma should be grouped as stage Ⅱ B and APR should be recommended. For patient 8 in Table 1, he was diagnosed as stage Ⅲ metachronous anorectal cancer and radiation therapy, inguinal lymph node dissection, and APR were carried out sequentially.

Table 3 Stage and management of PPD

Stage	Description	Management
Ⅰ	Paget's cells found in perianal epidermis and adnexae without primary carcinoma	WLE
Ⅱ A	Cutaneous Paget's disease with associated adnexal carcinoma	WLE
Ⅱ B	Cutaneous Paget's disease with associated anorectal carcinoma	APR
Ⅲ	Paget's disease in which associated carcinoma has spread to regional nodes	ILND + WLE/APR
Ⅳ	Paget's disease with distant metastases of associated carcinoma	CT + RT + LPM

WLE: Wide local excision; ILND: Inguinal lymph node dissection; CT: Chemotherapy; RT: Radiotherapy; LPM: Local palliative management.

Brown *et al*[25] reported six cases of PPD treated by radiotherapy as adjuvant or radical modality. They found that PPD had a high recurrence rate after radiotherapy. However, only three patients had an associated underlying anal carcinoma: one 9 years pre-diagnosis of PPD, one at diagnosis (both adeno-and squamous carcinoma), and one 10 years after diagnosis of PPD. Reports of chemoradiation are also infrequent. Although promising, there have not been many subsequent reports following these initial cases[26-28]. In our study, two patients received radical radiotherapy and adjuvant chemotherapy with capecitabine. One patient had recurrence and inguinal lymph metastasis, and an APR operation confirmed the existence of underlying anorectal cancer. Subsequently, he had local recurrence in the perineum and received wide local excision and is presently tumor-free. The other received transanal excision of an anorectal lesion and followed by radical radiation therapy for both Paget's disease and rectal cancer, and five cycles of adjuvant chemotherapy with capecitabine. No evidence of recurrence has been found at the latest follow. The results of this research are promising; however, further research is required.

Photodynamic therapy has also been successfully used in early perianal skin tumors, such as Bowen's disease and PPD[29,30]. However, because of limitation of conditions, this technique could not be used in our patients.

Survival of simple PPD was favorable. McCarter *et al*[3] collected 27 cases of PPD in the Memorial Sloan-Kettering Cancer Center, and most patients (74%) were treated with wide excision. At a median follow-up of 67 mo, 56 percent (15/27) had no evidence of disease, and two patients had died of metastatic disease. The overall and disease-free survival at 5 years was 59% and 64%, respectively, which decreased to 33% and 39%, respectively, by 10 years. Sarmiento *et al*[2] reported 13 PPD patients in the Mayo Clinic over a 25-year history. Mean follow-up was 6.7 years. Eleven patients underwent local resection without adjuvant therapy. Almost all recurrences were treated by

wider local excision. The 5-year recurrence rate was 61%. Overall 5-year and 10-year survival was 67%. Marchesa *et al*[1] reviewed their experience in the Cleveland Clinic Foundation: ten patients with a mean follow-up longer than 5 years were studied to determine the outcome after surgical treatment. Two patients underwent local excision (LE) with macroscopic clearance of the surgical margins; the remaining eight patients underwent wide local excision (WLE), i.e. > 1 cm microscopic clearance of the surgical margins. The actuarial 8-year recurrence rate for patients treated with LE and WLE was 100% and 50%, respectively. Progression to invasive carcinoma occurred after a median time of 56 mo (range 23-72 mo) in two patients treated with LE, and in one of eight patients treated with WLE. All four patients with recurrence after WLE were successfully treated (no further recurrence) with a second WLE. Actuarial 8-year survival was 0% in the LE group and 40% (SE = 21.9) in the WLE group.

However, as shown above, most of the reports were limited in patient number and to the simple form of PPD. For patients with underlying anorectal cancer, the information was scarce and required documentation. In this study, eight patients with the aggressive subtype were presented, which is the largest group studied to date. One patient died from lung metastases of rectal cancer 10 mo after operation. The other seven cases are tumor-free. This result verified that underlying anorectal cancer was the most important prognostic factor of PPD. Successful management of this lesion is essential for survival.

ACKNOWLEDGMENTS

We thank the faculty of Molecular Pathological Laboratory, Central Laboratory, Department of Abdominal Surgery and Pathology of Cancer Hospital Fudan University for their kind assistance with the sample collection and the provision of clinicopathological data. We especially thank professor Lu of Department of Radiation Oncology, National University Cancer Institute, National University Health System, National University of Singapore for help in designing and writing this manuscript.

COMMENTS

Background

Until now, less than 200 cases of perianal Paget's disease (PPD) had been reported in the literature, most of which were case reports. Unfortunately, frequent misdiagnoses and/or neglect of underlying cancer occurred in the clinical practice. Thus it was necessary to comprehensively document this disease to summarize its clinical and pathological characteristics, to analyze its carcinogenesis, and to explore rational treatment modalities.

Research frontiers

In this study, the authors non-selectively and consecutively documented PPD treated in their institution. All of the cases were exclusively the aggressive subtype with underlying cancer. These clinical experiences provided strong reinforcement of the accumulated knowledge of this disease.

Innovations and breakthroughs

This study well delineated the clinical characteristics of this unusual disease and determined the fundamental modality of preoperative workup, surgery, and postoperative surveillance. In particular, the study demonstrated the mucin-producing character of underlying anorectal cancer and suggested its relationship with carcinogenesis of Paget's disease.

Applications

In this article, the clinical characteristics of PPD and its close relationship with anorectal cancer have been demonstrated. The data is a major contribution to the documentation of this disease and will help clinicians to make correct diagnoses and to choose rational treatment modalities.

Terminology

Paget's disease is a type of cancer with low invasiveness and often occurs in areas rich in sweat gland structures, such as the nipple, axilla, groin, scrotum, and vulva. However, Paget's disease in the perianal region usually has a feature of underlying anal or rectal cancer, is particularly aggressive, and deserves more attention.

Peer review

The authors have to be commended for this very large series of patients with perianal Paget's disease. This manuscript is very interesting and well written.

Abstract

AIM: To clarify the association between *CYP2E1 Pst I /Rsa I* polymorphism and susceptibility to colorectal cancer.

METHODS: A meta-analysis based on 10 eligible case-control studies involving 4979 cases and 6012 controls was carried out to summarize the data on the association between *CYP2E1 Rsa I /Pst I* polymorphism and colorectal cancer risk.

RESULTS: In comparison of the homozygote *c2c2* and *c2* carriers (*c1c2* + *c2c2*) and the homozygous wild-type genotype (*c1c1*), no association was found between *CYP2E1 Rsa I /Pst I* polymorphism and colorectal cancer risk [odds ratio (OR) = 1.24 (95% CI: 0.93-1.66) for *c2c2*; OR = 1.02 (95% CI: 0.88-1.19) for *c2* carriers]. In stratified analysis, Caucasians with *c2c2* homozygote appeared to have an increased risk of colorectal cancer (OR = 2.67, 95% CI: 1.03-6.89, *P* = 0.043), no significant associations were found in other groups.

CONCLUSION: *c2c2* homozygote of *CYP2E1 Pst I /Rsa I* polymorphism may be associated with the increased risk of colorectal cancer in Caucasians, which needs further investigations.

INTRODUCTION

Colorectal cancer is one of the most common cancers in developed countries and getting more and more attentions in developing countries for its morbidity and mortality. The definite mechanism of its development is still unknown, but both environmental factors and genetic susceptibility are believed to contribute to the onset of colorectal cancer[1,2].

Cytochrome P450 2E1 (CYP2E1), a member of the cytochrome P-450 superfamily, is a naturally ethanol-inducible enzyme and primarily responsible for the metabolic activation of many low molecular weight carcinogens[3,4], including certain nitrosamines believed to participate in the carcinogenesis of digestive tract[5]. Based on the biological significance of CYP2E1, a hypothesis has been proposed that *CYP2E1* polymorphisms may

be associated with cancer susceptibility[6]. Of the many known genetic polymorphisms in the *CYP2E1* gene, two point mutations in the 5'-flanking region (*Pst I*, *Rsa I*), which are in close linkage disequilibrium, have drawn much interest as it is known to alter the transcriptional activity of the gene[7]. Three genotypes consisting of wild-type allele (*c1*) and variant-type allele (*c2*) of *Pst I* / *Rsa I* polymorphism are defined as homozygous wild-type genotype (*c1c1*), heterozygote (*c1c2*) and rare homozygote (*c2c2*), respectively[8].

Recently, meta-analyses showed that *c2* allele carriers had a significantly lower risk of lung cancer in the Asian population, but a higher risk of gastric cancer. However, the conclusion regarding colorectal cancer remains to be established. Though several studies focusing on *Pst I* / *Rsa I* polymorphism and susceptibility to colorectal cancer have been conducted, the results are inconsistent due to the small sample size of individual study or other factors such as race, diet and tumor location[9-18]. For better understanding this relationship, a meta-analysis was performed.

MATERIALS AND METHODS

Study identification and selection

Inclusion criteria was defined as follows: (1) articles evaluating the association between *CYP2E1 Pst I* /*Rsa I* polymorphism and colorectal cancer risk; (2) studies designed as case-control; (3) sufficient data available to estimate an odds ratio (OR) with its 95% CI.

A literature search of Medline and Embase (updated to January 1, 2010) was conducted using the following terms: 'cytochrome p450 2E1/ⅡE1' or 'CYP2E1/ⅡE1', 'colorectal' and 'cancer' or 'adencarcinoma', without restriction on language. The retrieved literatures were then read in their entirety to assess their appropriateness for the inclusion in this meta-analysis by the two authors (Zhou GW, Hu J) independently. The reference lists of reviews and retrieved articles were searched simultaneously to find additional eligible studies. If more than one article was published by the same author using the same case series, we selected the study with the largest size of samples. If there was an disagreement, it was resolved through discussion between the two authors.

Data extraction

The following variables were extracted from each study if available: first author's surname, publication year, country, ethnicity, source of controls (hospital-based or population-based), matching criteria, number of cases and controls, and number of cases and controls in different *Pst I* / *Rsa I* genotypes.

Statistical analysis

The strength of association between *CYP2E1 Pst I* /*Rsa I* polymorphism and colorectal cancer risk was assessed by odds ratio (OR) with the corresponding 95% CI. The pooled OR was calculated by a fixed-effects model (the Mantel-Haenszel method)[19] or a random-effects model (the DerSimonian and Laird method)[20] according to the heterogeneity. Heterogeneity among studies was checked by the Q test[21] and $P < 0.10$ was considered statistically significant. The ORs of colorectal cancer associated with *c2* allele carriers (*c1c2* + *c2c2*) and homozygous *c2* genotype (*c2c2*) for the *CYP2E1 Pst I* /*Rsa I* polymorphism were estimated using the homozygous wild-type (*c1c1*) as the reference group. Influence analysis was performed by omitting an individual study each time to find potential outliers to the pooled OR[22]; sensitivity analysis was also performed, if necessary, by excluding the Hardy-Weinberg equilibrium (HWE)-violating studies to check the robustness of the result. Departure from HWE was detected in the control populations, but a deviation from HWE was allowed in mixed control populations. Subgroup analyses for different ethnicities (Asian, Caucasian and mixed population) and cancer locations (colon cancer, rectum cancer) were conducted. The possible publication bias was examined visually in a funnel plot of log[OR] against its standard error (SE), and the degree of asymmetry was tested by Egger's test ($P < 0.05$ was considered a significant publication bias)[23]. Meta-analysis was performed using the STATA version 10.0 software.

RESULTS

Study characteristics

A total of 13 publications met the inclusion criteria. Of these studies, two studies[24,25] were excluded as another two included studies[14,16] were based on the same population with a larger sample size. With 14 more cases but less information on the relationship studied in this paper, Chen's study[26] published in 2005 overlapped with Yu's work[11], and it was excluded after discussion. As a result, a total of 10 publications[9-18] containing 4979 cases and 6012 controls were included into this meta-analysis. Table 1 lists the main characteristics of these studies. Of these publications, only one was not published in English but in Chinese[11]. The sample sizes ranged from 419 to 2144. All of the cases were histologically confirmed as colorectal cancer. Controls were mainly healthy populations, and matched with age, sex, or cancer-free. There were three groups of Asians, six groups of Caucasians and one group of mixed populations. Four studies[10,11,16,18] provided information on *Pst I* /*Rsa I* polymorphism status associated with tumor locations classified as colon cancer and rectum cancer. Four studies[10,15,16,18] investigated the significance of *Pst I* /*Rsa I* polymorphism interacting with environmental factors with regard to susceptibility to colorectal cancer. Genotype distributions in the controls of all studies were in agreement with HWE except for one study with mixed control populations[10], without conducting sensitivity analysis by excluding the HWE-violating studies.

Meta-analysis results

Table 2 lists the main results of this meta-analysis. When the homozygote *c2c2* and *c2* carriers (*c2c2* + *c1c2*) were compared with the homozygous wild-type genotype (*c1c1*), the pooled ORs for all the 10 studies were 1.24 (95% CI:

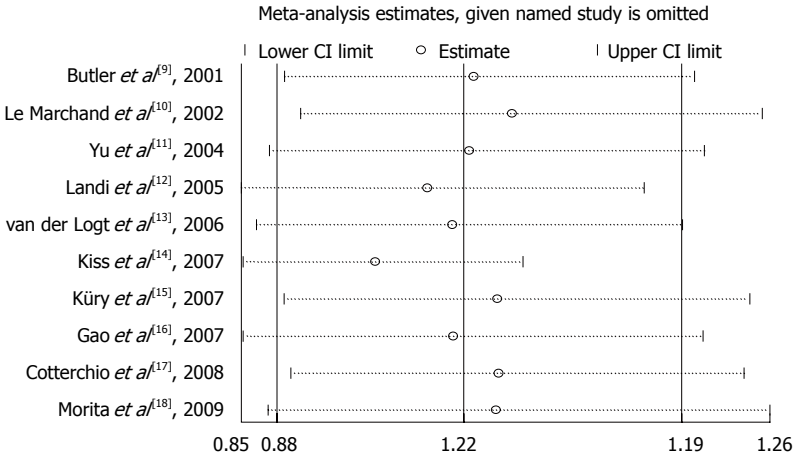

Figure 1 Influence analysis for *c1c2 + c2c2 vs c1c1* in the overall meta-analysis. It shows the influence of individual studies on the summary OR. The middle vertical axis indicates the overall OR and the two vertical axes indicate its 95% CI. Each hollow round indicates the pooled OR when the left study is omitted in this meta-analysis. The two ends of each broken line represent the 95% CI.

0.93-1.66, *P* = 0.148) and 1.02 (95% CI: 0.88-1.19, *P* = 0.780), respectively. In the subgroup analysis of ethnicity, Caucasians with c2c2 homozygote appeared to have an increased risk of colorectal cancer (OR = 2.67, 95% CI: 1.03-6.89, *P* = 0.043), while no significant association was found among Asians and mixed populations. In the subgroup analysis of cancer locations, no significant associations were discovered in both colon cancer and rectum cancer.

Sensitivity analysis

Influence analysis was performed to assess the effects of each individual study on the pooled OR in each analysis, by removing an individual study each time. The results

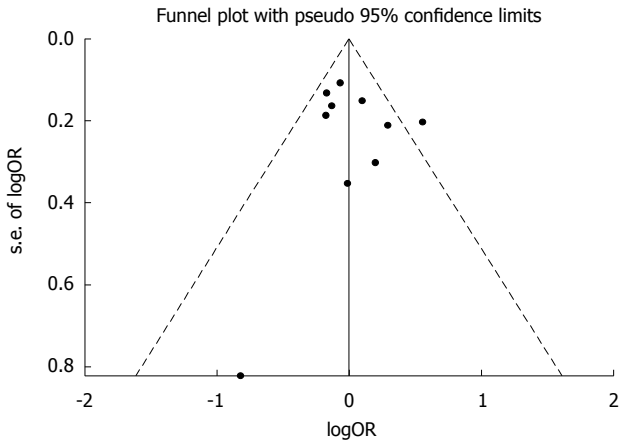

Figure 2 Funnel plot of *CYP2E1 Pst I /Rsa I* polymorphism and colorectal cancer risk for publication bias.

suggested that no individual study significantly affected the pooled ORs. Figure 1 shows the result of influence analysis for *c1c2 + c2c2 vs c1c1*.

Publication bias

Funnel plot and Egger's test were performed to assess the publication bias. The shape of the funnel plot did not indicate any evidence of obvious asymmetry (Figure 2) and no publication bias was found in the Egger's test $P = 0.647$).

DISCUSSION

The relationship between *CYP2E1 Pst I /Rsa I* polymorphism and colorectal cancer susceptibility has been studied in several researches[9-18], and the results are controversial. Kiss and his colleagues[14] reported that *c2* variant allele significantly increased the risk of colorectal cancer, while Gao *et al*[16] suggested that only *c2c2* homozygote was associated with colorectal cancer, and no significant association was found in other studies[10,13]. This is the first systematic study of the meta-analysis of this relationship.

Ten case-control studies were included in this meta-analysis, involving 4979 cases and 6012 controls. The results strongly suggested that there was no significant association between *CYP2E1 Pst I /Rsa I* polymorphism and colorectal cancer susceptibility. By sequentially removing individual studies during influence analysis, it was confirmed that all results were not materially altered by an individual study. In addition, no significant publication bias was found.

Analysis based on the ethnic subgroup showed that Caucasians with *c2c2* homozygote had an increased risk of colorectal cancer. This may be explained by various frequency distributions of *Pst I /Rsa I c2* allele[27] and different living habits and environment in different ethnicity. However, no study regarding African populations was done.

Sensitivity of colon and rectum tissue to carcinogens is inconsistent. In contrast to studies involving rectal cancer, animal studies suggested that nitrosamines may have no correlation with the development of colon cancer[28]. Based on this phenomenon, it is proposed that differences may exist between colon and rectal cancer susceptibility with respect to *Pst I /Rsa I* polymorphism. Morita *et al*[18] found that *c2* allele may significantly reduce the risk of rectal cancer, while in a similar study, Gao's results[16] were completely the opposite. On the other hand, no association was revealed between *c2* allele and colon cancer in these two studies. But Yu *et al*[11] suggested that *c2* allele may increase the susceptibility to colon cancer. In this meta-analysis, a stratified analysis was performed by tumor location due to these conflicting results, and no association was revealed in neither the colon cancer group nor the rectal cancer group (Table 2). A very noteworthy point was that subjects investigated in this stratified analysis were mainly Asians, and studies on Caucasians are needed.

Although the result of this meta-analysis is suggestive, some limitations still exist. Firstly, heterogeneity among the studies, resulting from different defined controls or some other factors, may influence the results of this analysis. In some studies, the controls were selected randomly from a healthy population, and in other studies from hospital-based cancer-free patients. Furthermore, the matching criteria of the control group differed across studies in age and gender. The variant risks of colorectal cancer in these different populations may affect the results. Secondly, OR value was obtained without correction. More accurate OR should be corrected by age, gender and other factors. Thirdly, no African population was included in these ten studies, and the frequency distribution of *CYP2E1 Pst I /Rsa I* genotype in Africans was significantly different from that in Caucasians and Asians[27]. Therefore, the conclusion of this study is not applicable to the African population, and further investigations are required. Fourthly, the relationship between *CYP2E1* gene polymorphism and colorectal cancer risk was analyzed without consideration of gene-environment interactions. Although evidence supported that *c2* allele combined with smoking, drinking and consumption of red meat intake can significantly increase the susceptibility to colorectal cancer[10,15,16,18], this study failed to draw any concrete conclusions due to the different classification criteria of environmental factors in these studies. In addition, there has been no study on the association between *Pst I /Rsa I* polymorphism gene-gene interactions and colorectal cancer risk, and this should be further investigated.

COMMENTS

Background

Cytochrome P450 2E1 (CYP2E1) is a member of the cytochrome P-450 superfamily, and its gene polymorphisms are supposed to be associated with cancer susceptibility. Several studies focusing on *CYP2E1 Pst I /Rsa I* polymorphism and colorectal cancer susceptibility have been conducted.

Research frontiers

The relationship between *CYP2E1 Pst I /Rsa I* polymorphism and cancer susceptibility has been studied in different tumor types. Recently, meta-analyses showed that c2 allele carriers had a significantly lower risk of lung cancer in Asian population but a higher risk of gastric cancer. However, the relationship with colorectal cancer remains controversial and no meta-analysis has been conducted.

Innovations and breakthroughs

This is the first meta-analysis which systemically studied the relationship between *CYP2E1 Pst I /Rsa I* polymorphism and colorectal cancer susceptibility, and suggested that Caucasians with *c2c2* homozygote may have a higher risk of colorectal cancer.

Applications

This study provided a potential biomarker for identifying high-risk populations of colorectal cancer in Caucasians.

Peer review

The article is meritoriously and methodologically well written. The presentation is rigorous and the approach used is robust.

Abstract

Autoimmune pancreatitis (AIP) is a rare cause of recurrent acute pancreatitis or chronic pancreatitis in middle-aged patients, and is characterised by a marked infiltration of lymphocytes and plasma cells in pancreatic tissue. Diagnosis of focal forms can be difficult as AIP may mimic pancreatic adenocarcinoma. Pediatric cases of AIP are exceptional. We report the case of a 15-year-old girl who had a focal AIP and associated cholangitis, with a very unusual vascularized mass that mimicked a pancreatic endocrine tumor. The diagnosis was obtained by a pancreatic biopsy, thus avoiding surgical resection, and all the clinical, biological and radiological abnormalities resolved after steroid therapy with 6 mo of follow-up.

INTRODUCTION

Autoimmune pancreatitis (AIP) is a rare cause of recurrent acute pancreatitis and chronic pancreatitis. First described by Sarles in 1960, AIP is characterised by a marked infiltration of lymphocytes and plasma cells in pancreatic tissue (lymphoplasmocytic sclerosing pancreatitis)[1-5]. It can be associated with extrapancreatic lesions (including sclerosing cholangitis, retroperitoneal fibrosis, nephritis, sialoadenitis, chronic inflammatory bowel disease) and is the pancreatic manifestation of a systemic inflammatory disease called IgG4-associated systemic disease in about one third of cases[6-9]. Two radiological types are described: a diffuse form (the most frequent, 70% of cases) and a focal form (30% of cases) that may mimic pancreatic adenocarcinoma[7,10,11].

Most cases have been reported in male patients (sex ratio = 3:1), and in patients older than 55 years (average age: 65 years); less than 10 pediatric cases have been reported[9,12-19]. We report the case of a 15-year-old girl who had a focal AIP and associated cholangitis, with atypical clinicoradiological features, that mimicked a pancreatic endocrine tumor.

CASE REPORT

A 15-year-old girl was referred to our unit for the exploration of a pancreatic mass. She had a 1-mo history of epigastric pain and nausea, associated with jaundice and pruritus for 5 d, without either fever or weight loss. She had a personal history of asthma in childhood, and no family medical history. She was not taking any drugs. Over the previous 3 years, she had had several episodes of weakness, with fainting, tremor, sweating and hunger, which resolved after eating.

Examination was normal except for the finding of jaundice. Total bilirubin was 142 μmol/L (conjugated: 104 μmol/L), aspartate aminotransferase was 6 times the upper limit of normal (ULN), alanine aminotransferase was 16 ULN and γ-GT was 4 ULN; blood ionogram results including serum creatinine level, blood cell counts and prothrombin time were normal.

Abdominal ultrasonography showed enlargement of the intrahepatic and common bile ducts (common bile duct diameter: 11 mm), an enlarged gallbladder without either lithiasis or thick wall, and enlargement of the main pancreatic duct due to an oval mass located in the head of the pancreas which was quite well limited, hypoechogenic and homogeneous, measuring 22 mm × 15 mm. Abdominal multi-detector computed tomography (MDCT) revealed a lesion of the head of the pancreas, isodense before intravenous contrast medium injection and that moderately enhanced after injection, measuring 20 mm in diameter, with bicanalar dilation and gallbladder enlargement, without invasion of the duodenum or the vascular structures, and with neither suspicious lymph nodes nor liver metastasis (Figure 1A and B). Bilio-pancreatic magnetic resonance imaging (MRI) showed that the lesion was hypointense in T1-weighted sequences and isointense in T2-weighted compared with surrounding pancreatic parenchyma, and enhanced after intravenous contrast medium injection in arterial and portal venous phases; the main pancreatic duct was enlarged, irregular, and the terminal part of the common bile duct had a thick enhanced wall suggesting cholangitis (Figure 2A and B).

Because the mass was hypervascular on imaging and the patient reported episodes of weakness suggesting hypoglycemia, we considered the diagnosis of pancreatic insulinoma. A 72-h fast test and the blood levels of insulin and C-peptide were normal. Chromogranin A and neuron specific enolase levels were also normal.

Due to all these atypical features, we preferred performing a pancreatic biopsy rather than a somatostatin-receptor scintigraphy at this stage of investigation. Endoscopic ultrasonography (EUS) showed a heterogeneous

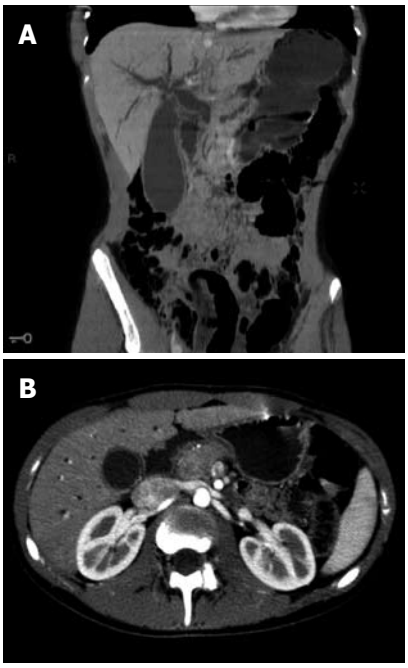

Figure 1 Initial multi-detector computed tomography scan imaging. A: CT scan before contrast injection, coronal reconstruction: enlargement of the main pancreatic duct and the biliary ducts, with enlarged gallbladder; B: CT scan after contrast injection, arterial phase, axial slice: lesion of the head of the pancreas, moderately enhanced after contrast injection.

area in the head of the pancreas measuring 23 mm × 35 mm. The main pancreatic duct was much enlarged (maximal diameter: 6 mm) along its whole length, with a moniliform aspect; the accessory pancreatic duct was also abnormally visible. The terminal part of the common bile duct had a thick wall. There was a narrowing of the terminal part of the superior mesenteric vein, without invasion of its wall. All these features were not evocative of a malignant tumor. The fine needle aspiration specimen was moderately cellular and consisted of cellular stromal fragments in a mesenchymal and lymphocytic background. At higher magnification, the stromal fragments contained bland spindled mesenchymal cells with a lymphocytic infiltrate. Rare plasma cells were also present in the stromal fragments. No granulomas were seen. There were no malignant cells. Histological examination of the duodenal biopsy showed normal mucosa with scattered plasma cells; examination of the adjacent pancreatic parenchyma revealed chronic pancreatitis with atrophic acini surrounded by a fibrous stroma, associated with periductal lymphoplasmocytic infiltration and obliterative phlebitis (Figure 3A and B). The plasma cells expressed IgG4 (Figure 3C and D).

Based on these results, the diagnosis of focal AIP associated with cholangitis was proposed. IgG4 serum level was normal (100 mg/mL, N < 140 mg/mL) and the antinuclear antibody test was negative (< 1/80).

Jaundice decreased spontaneously 1 wk after admission (total bilirubin: 69 μmol/L; conjugated bilirubin: 50 μmol/L). As there was remaining abdominal pain and pruritis, steroid therapy was started at the dose of 40 mg of oral prednisone per day. After 2 wk of treat-

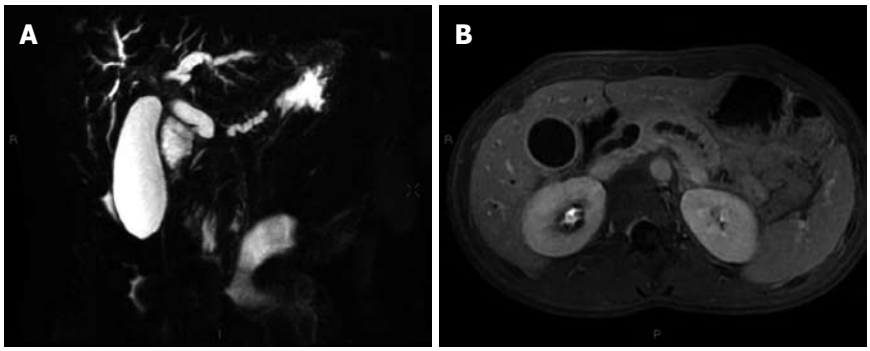

Figure 2 Initial magnetic resonance imaging (MRI) imaging. A: T2-weighted MRI, coronal slice: bicanalar dilation and enlarged gallbladder; B: T1-weighted MRI, axial slice: main biliary duct and gallbladder enlargement with a thick wall evocative of cholangitis; the main pancreatic duct is also irregularly enlarged.

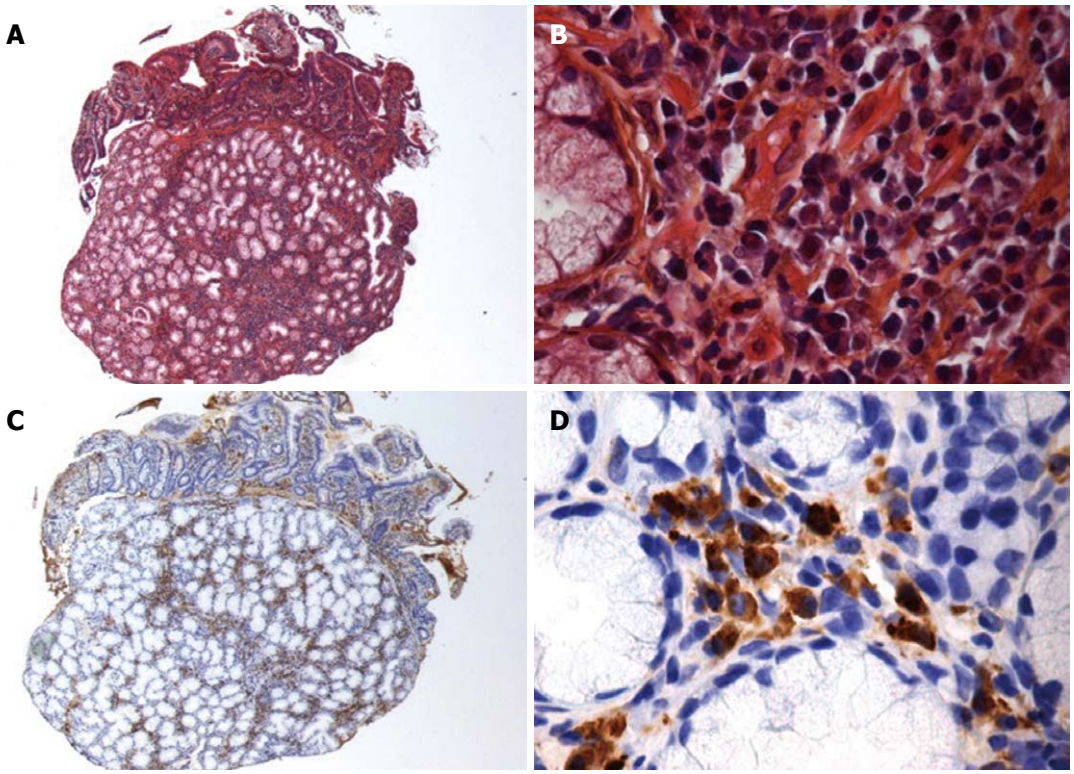

Figure 3 Histological examination of periampular biopsies (notice that both duodenal mucosa and pancreatic parenchyma are visible). A, B: Hematoxylin-eosin staining (A: × 125, B: × 500): atrophic acini surrounded by a fibrous stroma, associated with periductal lymphoplasmocytic infiltration; C, D: Anti-IgG4 immunostaining (C: × 125, D: × 500): the plasma cell infiltration expresses IgG4.

ment, the patient was asymptomatic and hepatic blood tests had returned to normal values. The steroid therapy was continued at the same dose for two additional weeks and progressively decreased and stopped after 3 mo. Bilio-pancreatic MRI at the end of the treatment was normal (Figure 4). Six months after the end of the steroid therapy, the patient remained asymptomatic and the blood tests were normal.

DISCUSSION

Most cases of AIP occur in middle-aged patients and about half of the patients are affected when in their sixties[9,12,13]. Cases occurring in childhood or adolescence are exceptional: to our knowledge, only five pediatric cases have been reported (range: 10-16 years), including one in association with a hereditary chronic pancreatitis[14-19].

The most frequent morphological aspect of AIP is the diffuse "duct destructive" form (70% of cases): the pancreas is diffusely enlarged and a loss of lobularity is commonly seen ("sausage-like" appearance); the swollen parenchyma is hypodense on MDCT, hypointense on MRI in T1-weighted sequences and there is a delayed and moderate enhancement after intravenous contrast medium injection due to fibrosis[7,11,20,21]. A typical capsule-like rim appearing as a low-density area on MDCT and a hypointense T2 area on MRI surrounding the pancreas is often present[20,21]. The main pancreatic duct is diffusely narrowed, irregular, or even not visible, because of the pericanalicular inflammatory infiltration[20,21]. Pancreatic atrophy and calcifications are rare but have been reported in some chronic cases[7,11,20,21]. In the focal (pseudo-tumoral) form, the lesion typically appears as a hypovascular mass compared with surrounding pancreatic parenchyma: isodense on MDCT and hypointense on MRI in T1-weighted sequences, with a low enhance-

Figure 4 MRI at the end of steroid therapy. T1-weighted MRI with gadolinium injection: normal main pancreatic duct and gallbladder; the mass in the head of the pancreas has totally disappeared.

ment after intravenous contrast medium injection[7,11,21]. This imaging presentation may be difficult to differentiate from a pancreatic adenocarcinoma in a middle-aged patient with pancreatic symptoms[10,11,21,22].

Atypical imaging in patients with AIP is not uncommon; diverse imaging features have been reported. However, this report describes enhancement suggestive of a vascular lesion which has not been described before in AIP and which was suggestive of an endocrine tumor[23]. This could be due to the diagnosis being performed at an early stage thus the pancreatic parenchyma mostly contained acute inflammatory changes and minimal fibrosis. Another noticeable feature was major enlargement of the main pancreatic duct, which was suggestive of an upstream expansion due to a malignant tumor[21]. An upstream pancreatic duct dilation was reported in up to 57% of patients with focal AIP in an earlier study[24]. Similar main pancreatic duct abnormalities have recently been reported in a 14-year-old girl with AIP[19]. Again, this may have resulted from the association of an early stage diagnosis of the AIP and its focal location: pericanalicular fibro-inflammatory infiltration may not have been present at this stage and the pancreatic duct would have been free to enlarge in its distal part upstream from the stenosis due to the extrinsic compression exerted by the mass located in the head of the pancreas. The vascular narrowing in our case was also evocative of malignancy, but this has already been reported in AIP[11,21]. In contrast, the features of cholangitis supported the diagnosis of AIP since IgG4-associated cholangitis is a common extrapancreatic lesion associated with AIP[8,9,21]. Due to the difficulty of differential diagnosis, we preferred performing a pancreatic biopsy rather than a somatostatin-receptor scintigraphy.

Hence, our report underlines the helpfulness of performing pancreatic biopsy for the diagnosis of a pancreatic mass in the case of negative IgG4 serology and atypical imaging findings according to the HISORt criteria, to avoid an unjustified pancreatic resection[25,26]. From our observations, the histologic features were characteristic of lymphoplasmocytic sclerosing pancreatitis[2,5,9]. The positivity of the IgG4 immunostaining also reinforced the suspicion of AIP, despite the fact that the sensitivity of this technique for the diagnosis of AIP is only 21% to 47% in the literature[27,28]. The absence of malignant cells was also helpful in the diagnostic discussion[22]. Several studies have shown the usefulness of the EUS controlled fine-needle biopsy for the diagnosis of AIP[29-32].

Another original element in this observation was the demonstration of IgG4 plasma cell expression by immunostaining in an extrapancreatic location, i.e. duodenal site. Deheragoda *et al*[33] reported that 85% of biopsies in any organs (liver, stomach, duodenum, colon, kidney, bone marrow, salivary gland) from AIP patients exhibited positive IgG4 immunostaining compared with 0.6% of specimens from controls, a result which was independent from the IgG4 serum concentration. In our observation, the presence of IgG4 positive plasma cells outside of the pancreas (periampulla duodenal mucosa) was contributive to the diagnosis, as previously reported[34]. Altogether, these findings support the hypothesis that AIP is likely be a part of a multisystemic disease.

Whereas the common differential diagnosis of focal AIP in adults is pancreatic adenocarcinoma, the originality of our report is that the mass was evocative of endocrine tumor because of its hypervascular aspect on imaging[10,11,22,23]. Pediatric cases of endocrine tumors have been described: the Surveillance, Epidemiology, and End Results (SEER) register of the National Cancer Institute registered 19 cases between 1973 and 2004 in North America[35]. Jaundice is very uncommon in endocrine tumors (< 5% of cases), whereas about one third (up to 70%-80%) of AIP patients have jaundice[13,36]. The pancreatic biopsy examination and the favorable evolution before and after steroid therapy allowed us to rule out other differential diagnoses such as a solid-pseudopapillary tumor, a pancreatoblastoma (10 cases each reported in the SEER register) or other malignant pancreatic tumors (canalar adenocarcinoma, sarcoma and acinar adenocarcinoma: 7, 4 and 5 cases, respectively in the SEER register)[3,6,35]. Overall, pancreatic biopsies may be useful to avoid misdiagnosing and delaying the treatment of a malignant pancreatic lesion in pediatric cases[10,11,22,37].

The particular problem in pediatric cases of AIP is the risk of pancreatic insufficiency due to recurrence and pancreatic atrophy, as well as extrapancreatic involvement with occurrence of other autoimmune disorders, such as chronic inflammatory bowel disease[7,9,11,38-40]. Consequently, it is important to carefully follow up these young patients in order to diagnose early and treat these complications, paying particular attention to steroid therapy side effects.

Abstract

We report the case of a female patient with severe acute necrotizing pancreatitis associated with hypercalcemia as first manifestation of primary hyperparathyroidism caused by a benign parathyroid adenoma. Initially the acute pancreatitis was treated conservatively. The patient subsequently underwent surgical resection of the parathyroid adenoma and surgical clearance of a large infected pancreatic pseudocyst. Although the association of parathyroid adenoma-induced hypercalcemia and acute pancreatitis is a known medical entity, it is very uncommon. The pathophysiology of hypercalcemia-induced acute pancreatitis is therefore not well known, although some mechanisms have been proposed. It is important to treat the provoking factor. Therefore, the cause of hypercalcemia should be identified early. Surgical resection of the parathyroid adenoma is the ultimate therapy.

INTRODUCTION

Acute necrotizing pancreatitis is a severe condition with a high mortality rate[1]. In the Western world, alcohol and biliary stones are the main causes of acute pancreatitis[2,3]. As shown by the Ranson[4] grading of acute non-alcoholic pancreatitis, severe pancreatitis is associated with a decrease in serum calcium levels. However, the relationship between increased serum calcium levels and acute pancreatitis may be a diagnostic clue to primary hyperparathyroidism (PHPT)[5]. Acute pancreatitis caused by hypercalcemia due to PHPT is a very rare condition[6]. We present a case report of a young female patient with hypercalcemia-induced acute necrotizing pancreatitis as first manifestation of a benign parathyroid adenoma.

CASE REPORT

A 42-year-old female presented at the emergency room with a sudden attack of severe epigastric pain and vomiting. Years ago she had undergone surgery for a benign ovarian cyst and a right nephrectomy for ureterolithiasis-

induced hydronephrosis. Her medical history also mentioned three episodes of deep vein thrombosis in the lower limb.

She was a non-smoker and consumed alcohol only sporadically. There was no recent use of alcohol. She did not take medication and did not travel abroad. Family history mentioned a brother infected with hepatitis B virus.

Clinical examination revealed a severely ill patient, a silent abdomen which was distended with painful percussion and palpation of the epigastrium.

Blood analysis showed signs of inflammation with an elevated C-reactive protein (CRP) of 6.77 mg/dL (< 0.5 mg/dL) and leukocytosis of 30.8 × 10E9/L (4.3-10 × 10E9/L) with elevated neutrophils of 28.1 × 10E9/L (2.0-7.0 × 10E9/L). Pancreatic enzymes were elevated, serum amylase was 1033 U/L (24-72 U/L) and serum lipase was 7189 U/L (13-300 U/L). There was a slight impairment of renal function as shown by an increase in serum creatinine 1.23 mg/dL (0.6-1.1 mg/dL). Both liver transaminases and canalicular liver tests were normal. In contrast to what was expected in a case of severe pancreatitis, serum calcium was increased to 11.7 mg/dL (8.5-10.2 mg/dL), the albumin-modified serum calcium concentration was 11.9 mg/dL. IgG4 was normal as were triglycerides.

Based on the clinical picture and blood analysis she was diagnosed with acute pancreatitis. Abdominal ultrasound was carried out and showed no evidence of cholelithiasis or dilated bile ducts. Abdominal computed tomography (CT) scan confirmed the diagnosis of exudative pancreatitis (Figure 1A). The patient was admitted to the ward and was treated conservatively with intravenous fluids and analgesia. Because of slow improvement of paralytic ileus, enteral feeding was started through a nasojejunal tube. The patient improved gradually during the following weeks. At day 20 after admission, abdominal CT scan was repeated and showed the development of pancreatic pseudocysts and necrosis of the pancreas with few remnants of normal pancreatic tissue (Figure 1B).

After exclusion of alcohol-induced and biliary pancreatitis as well as auto-immune pancreatitis, elevated serum calcium levels remained another potential etiology of acute pancreatitis. On reviewing her medical records, normal serum calcium levels at the time of previous surgical interventions was noted. Serum levels of intact parathyroid hormone (iPTH) were determined and showed an increase up to 82 pg/mL (13-54 pg/mL). This result confirmed hypercalcemia caused by hyperparathyroidism. Ultrasound of the parathyroid glands showed no abnormalities. A 99mTc-Sestamibi scintigraphy was then carried out which was consistent with a lower left side parathyroid adenoma (Figure 2).

The patient underwent surgical resection of this tumor, and histological examination confirmed the diagnosis of benign parathyroid adenoma. In the postoperative period, serum levels of iPTH and calcium decreased and the patient required calcium supplements. Following clinical resolution, the patient was discharged from hospital.

A few weeks later she was re-admitted to the emergency room due to abdominal pain and fever. Blood analysis showed elevated CRP of 15.18 mg/dL (< 0.5 mg/dL), serum amylase and serum lipase were normal. Serum calcium was slightly decreased: 8.3 mg/dL (8.5-10.2 mg/dL). Infection of the previously diagnosed pancreatic pseudocysts was suspected. Abdominal magnetic resonance imaging (MRI) and endoscopic ultrasonography showed debris in the large pseudocyst (Figure 3). Initially she was treated with broad spectrum antibiotics, however, she suffered recurrent episodes of fever and abdominal pain. Abdominal CT scan revealed rupture of the largest pancreatic pseudocyst. Surgical cystogastrostomy and necrosectomy of the pancreatic corpus was performed. She recovered well and the patient remained free of symptoms without signs of exocrine or endocrine pancreas insufficiency.

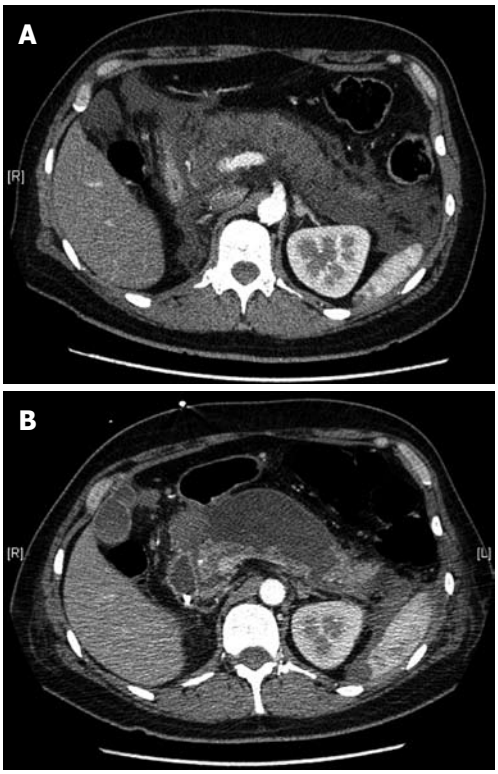

Figure 1 Abdominal computed tomography scan at the level of the pancreas. A: On the day of admission showing acute exudative pancreatitis. Note the history of a right nephrectomy; B: On day 20 showing the development of pancreatic pseudocysts and few remnants of normal pancreatic tissue.

DISCUSSION

Acute pancreatitis caused by PHPT-induced hypercalcemia is a rare condition. It was first described in 1957 by Cope *et al*[5]. Since then, the relationship between PHPT and pancreatitis has been questioned, but nowadays PHPT has been acknowledged as an accepted etiology of pancreatitis[1,7,8]. The prevalence of acute pancreatitis in patients with PHPT is estimated between 1.5% and 7%[6]. Some studies have associated hyperparathyroidism with pancreatitis, however, the prevalence of acute pancreatitis in patients with PHPT seems no different from that in the general population[9,10]. Therefore, there appears

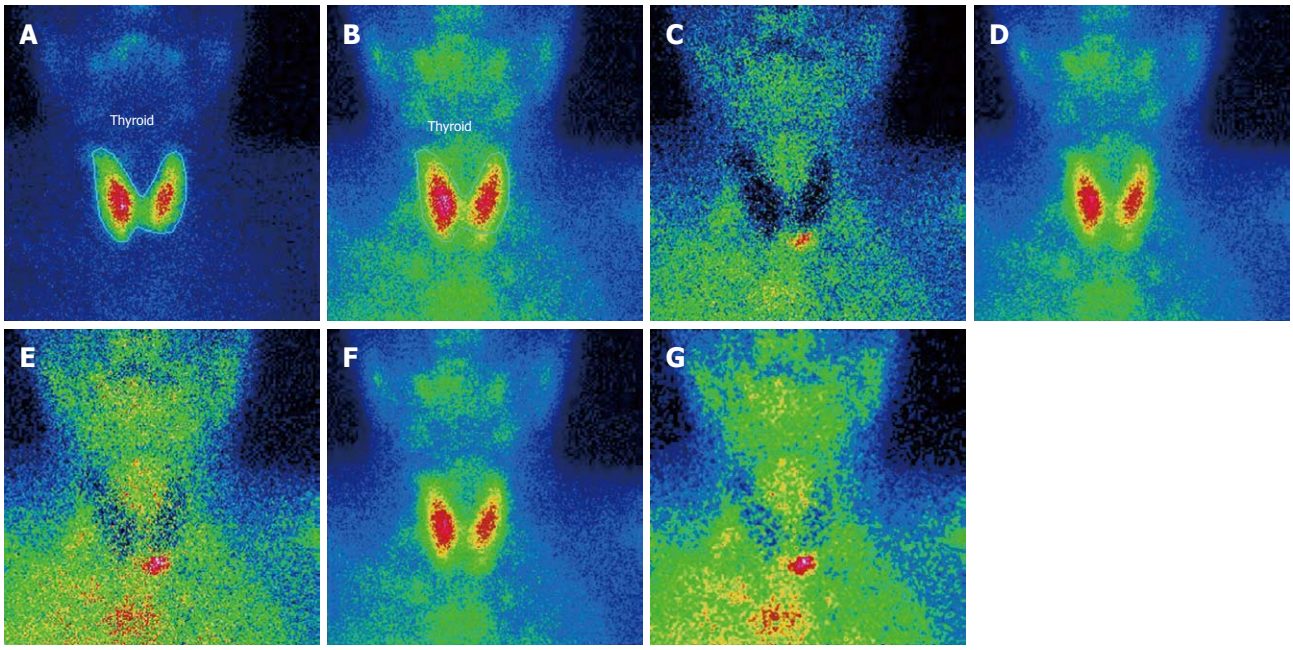

Figure 2 99mTc-Sestamibi scintigraphy showing a lower left side parathyroid adenoma. A: Thyroid SKM: SK ELUAAT, -Tc-99mANT; B: Parathyroid SKM: SK MIBI, -Tc-99mH1; C: Normalized subtracted f = 1; D: Registered parathyroid; E: Normalized subtracted f = 1.25; F: Normalized parathyroid f = 1.25; G: Smoothed subtracted f = 1.25.

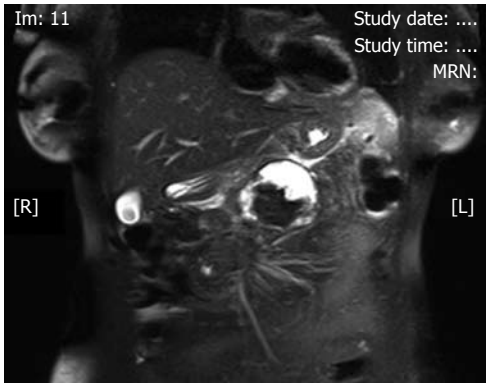

Figure 3 Abdominal magnetic resonance imaging at the level of the pancreas showing debris in the pancreatic pseudocyst.

to be no direct causal relationship between PHPT and acute pancreatitis based on epidemiological data. However, it has been shown that hypercalcemia of any cause can lead to acute pancreatitis[11]. When this combination occurs, pancreatitis is likely to be severe and the degree of hypercalcemia may play an important role in this association[12,13]. Three pathophysiological mechanisms are suggested. The deposition of calcium in the pancreatic duct may cause pancreatic duct obstruction[14]. Hypercalcemia may also lead to activation of trypsinogen within the pancreatic parenchyma causing autodigestion of the pancreas[15]. Finally, genetic variants in SPINK 1 (serine protease inhibitor Kazal type 1) and CFTR (cystic fibrosis transmembrane conductance regulator) genes in combination with hypercalcemia increase the risk of developing acute pancreatitis in patients with PHPT[16].

Usually, acute pancreatitis is associated with a decrease in serum calcium levels. Based on the Ranson[4] grading, low serum calcium levels have prognostic importance. Therefore, it is uncommon to detect hypercalcemia in a patient presenting with severe acute pancreatitis. This unusual condition should always alert physicians to the presence of hyperparathyroidism or malignancy[17,18]. In order to complete the diagnosis, parathyroid hormone levels should be determined and imaging of the parathyroid glands is important. It is also important to take into account the possibility of an ectopic localization of a parathyroid adenoma as a cause of acute pancreatitis[19,20]. In the present case, diagnosis of the parathyroid tumor was made by 99mTc-Sestamibi scintigraphy. Surgical resection and histological examination of the tumor is the ultimate therapy and parathyroidectomy may prevent the recurrence of pancreatitis[7,12]. Subsequent rapid hypocalcemia may develop requiring calcium supplementation. Good cooperation between gastroenterologists, endocrinologists and surgeons is important in treating this rare phenomenon of acute necrotizing pancreatitis caused by PHPT-induced hypercalcemia.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in tahe field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

World Journal of Gastroenterology

Contents

Weekly Volume 16 Number 24 June 28, 2010

EDITORIAL

2963 Antiproliferative effect of somatostatin analogs in gastroenteropancreatic neuroendocrine tumors

Strosberg J, Kvols L

2971 Gastrointestinal involvement in systemic lupus erythematosus: Insight into pathogenesis, diagnosis and treatment

Tian XP, Zhang X

TOPIC HIGHLIGHT

2978 Small intestinal bacterial overgrowth syndrome

Bures J, Cyrany J, Kohoutova D, Förstl M, Rejchrt S, Kvetina J, Vorisek V, Kopacova M

OBSERVATION

2991 Mesenteric lymph node cavitation syndrome

Freeman HJ

ORIGINAL ARTICLE

2994 Emodin enhances alveolar epithelial barrier function in rats with experimental acute pancreatitis

Xia XM, Wang FY, Wang ZK, Wan HJ, Xu WA, Lu H

3002 Sulforaphane protects liver injury induced by intestinal ischemia reperfusion through Nrf2-ARE pathway

Zhao HD, Zhang F, Shen G, Li YB, Li YH, Jing HR, Ma LF, Yao JH, Tian XF

BRIEF ARTICLE

3011 Management of recto-vaginal fistulas after prosthetic reinforcement treatment for pelvic organ prolapse

Ouaïssi M, Cresti S, Giger U, Sielezneff I, Pirrò N, Berthet B, Grandval P, Consentino B, Sastre B

3016 Vitamin D receptor gene polymorphisms and hepatocellular carcinoma in alcoholic cirrhosis

Falleti E, Bitetto D, Fabris C, Cussigh A, Fontanini E, Fornasiere E, Fumolo E, Bignulin S, Cmet S, Minisini R, Pirisi M, Toniutto P

3025 Glycated hemoglobin and antidiabetic strategies as risk factors for hepatocellular carcinoma
Donadon V, Balbi M, Valent F, Avogaro A

3033 *Helicobacter pylori* in dental plaque and stomach of patients from Northern Brazil
Assumpção MB, Martins LC, Melo Barbosa HP, Barile KAS, Almeida SS, Assumpção PP, Corvelo TCO

3040 Predisposing factors and surgical outcome of complicated liver hydatid cysts
Akcan A, Sozuer E, Akyildiz H, Ozturk A, Atalay A, Yilmaz Z

3049 Is inconsistency of α-fetoprotein level a good prognosticator for hepatocellular carcinoma recurrence?
Hsieh CB, Chen TW, Chu CM, Chu HC, Yu CP, Chung KP

3056 Combined resection and radiofrequency ablation for multifocal hepatocellular carcinoma: Prognosis and outcomes
Cheung TT, Ng KK, Chok KS, Chan SC, Poon RT, Lo CM, Fan ST

3063 Evidence-based appraisal in laparoscopic Nissen and Toupet fundoplications for gastroesophageal reflux disease
Shan CX, Zhang W, Zheng XM, Jiang DZ, Liu S, Qiu M

3072 Simultaneous detection of different serum pepsinogens and its primary application
Zhang J, Guo JZ, Xiao HL, Zhu L, Liu HY, Zhang Y, Huang B

3078 Construction and characterization of calreticulin-HBsAg fusion gene recombinant adenovirus expression vector
Ma CL, Wang GB, Gu RG, Wang F

CASE REPORT

3083 Obstructing fungal cholangitis complicating metal biliary stent placement in pancreatic cancer
Story B, Gluck M

3087 Stone extraction balloon-guided repeat self-expanding metal stent placement
Kim HH, Moon JS, Ryu SH, Lee JH, Kim YS

AIM AND SCOPE		*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries. The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

Somatostatin analogs were initially developed for the control of hormonal syndromes associated with neuroendocrine tumors (NETs). In recent years, accumulating data has supported their role as antiproliferative agents, capable of stabilizing tumor growth in patients with metastatic neuroendocrine malignancies, including carcinoid and pancreatic endocrine tumors. A phase Ⅲ, randomized, placebo-controlled trial has now demonstrated that octreotide long-acting repeatable (LAR) 30 mg can significantly prolong time to tumor progression among patients with metastatic midgut NETs regardless of functional status, chromogranin A level or age. In addition to significantly lengthening time to tumor progression in the overall study population, subset analysis suggests that patients with low tumor burden are most likely to experience disease stabilization with octreotide LAR 30 mg, supporting the early use of octreotide LAR in patients with metastatic disease. Further research efforts are underway to evaluate the use of somatostatin analogs as antiproliferative agents in other types of gastroenteropancreatic-NETs. Ongoing studies are also evaluating novel somatostatin analogs and somatostatin analogs in combination with other anti-tumor therapies.

INTRODUCTION

The human hormone somatostatin was first isolated in 1973 and identified as a hypothalamic inhibitor of growth hormone[1-4]. It was subsequently discovered in multiple tissues, including the central nervous system, endocrine system and gastrointestinal tract[3]. Somatostatin has been characterized as a universal endocrine "off-switch" due to its exocrine, endocrine, paracrine and autocrine inhibitory effects[5-7]. In the digestive tract, it reduces secretion and motility, decreases portal blood flow, inhibits gallbladder contraction and reduces the secretion of other gastrointestinal hormones[8]. The effects of somatostatin are mediated through interaction with five somatostatin receptors (sst_{1-5})[9], belonging to a family of G-protein coupled receptors with seven transmembrane domains.

The clinical utility of native human somatostatin is limited by its short half life of approximately two minutes. Both bioactive forms of the hormone, the fourteen-peptide somatostatin-14 and a C-terminally extended form, somatostatin-28, contain multiple enzymatic cleavage sites resulting in rapid circulatory degradation[6]. In order to improve the pharmacokinetic profile, synthetic somatostatin

analogs (SSAs) have been developed by shortening the polypeptide chain while retaining binding affinity to somatostatin receptors (Figure 1)[10]. The two commercially available analogs, octreotide and lanreotide, are octapeptides that bind with high affinity to somatostatin receptor subtype 2 (sst_2) and with moderate affinity to sst_5 (Table 1).

Octreotide has been used in clinical practice since data emerged in the 1980s confirming its ability to palliate carcinoid syndrome[14], as well as other hormonal syndromes caused by metastatic gastroenteropancreatic neuroendocrine tumors (GEP-NETs). Octreotide was initially available in an immediate-release formulation suitable for deep subcutaneous or intravenous administration[15]. Octreotide subcutaneous (sc) has been tested primarily at doses ranging from 100 to 500 μg two to three times daily. During the past decade, a long-acting repeatable (LAR) depot formulation of octreotide (Sandostatin LAR®) has been available, which allows monthly intramuscular dosing. Octreotide LAR has demonstrated similar efficacy to octreotide sc in the control of flushing and diarrhea associated with carcinoid syndrome[16]. The dose of octreotide sc and octreotide LAR should be titrated per symptom control for optimal patient care[17]. A second somatostatin analog, lanreotide, was licensed in Europe in 1998 for the treatment of symptoms associated with neuroendocrine (particularly carcinoid) tumors. A long-acting formulation of lanreotide (Somatuline Autogel®)[18] has also been developed as a deep subcutaneous injection.

Early on, clinical trials of SSAs tested their ability to inhibit the release of neuroendocrine hormones such as serotonin, glucagon, insulin, gastrin and vasoactive intestinal peptide (VIP)[14,19-22]. These trials formed the basis for the approval of octreotide and lanreotide as antisecretory agents indicated for treatment of hormonally active GEP-NETs. It was not until several years after the approval of octreotide that evidence of antineoplastic activity emerged. Although objective radiographic responses associated with SSAs were rare, many cases of prolonged disease stability were documented in the literature, leading to the hypothesis that SSAs exert an inhibitory effect on tumor growth. Recently, this hypothesis was tested in a Phase Ⅲ, randomized, placebo-controlled clinical trial evaluating octreotide LAR 30 mg. This review summarizes the preclinical and clinical evidence supporting the role of SSAs as antiproliferative agents in the treatment of patients with GEP-NETs. To date, most data (including the results from the only phase Ⅲ randomized, placebo-controlled trial) have been generated in studies evaluating octreotide sc and LAR.

BIOLOGICAL BASIS FOR THE ANTIPROLIFERATIVE EFFECTS OF SSAS

Over the past two decades there has been significant progress in our understanding of the molecular basis for the antiproliferative effects of somatostatin and its analogs. Antitumoral activity appears to be mediated *via* direct and indirect mechanisms. Direct mechanisms involve the activation of somatostatin receptors on tumor cells leading to modulation of intracellular signaling transduction pathways. Multiple *in vitro* studies using cell lines transfected with somatostatin receptors indicate that all receptor subtypes (sst_{1-5}) may mediate inhibition of cell proliferation[23], whereas specific receptor subtypes ($sst_{2,3}$) may mediate apoptosis (Table 2)[24-26]. These actions appear to be regulated primarily *via* the MAP-kinase signaling pathway and through activation of phosphotyrosine phosphatases (Figure 2)[27-29]. Indirect antiproliferative mechanisms include inhibition of mitogenic growth factors such as insulin-like growth factor (IGF), as well as inhibition of tumor angiogenesis through interaction with somatostatin receptors on endothelial cells and monocytes[30].

Table 2 Receptor mediation of cell proliferation

	sst_1	sst_2	sst_3	sst_4	sst_5
Induction of G1 cell cycle arrest	+	+		+	+
Induction of apoptosis		+	+		

Activation of phosphotyrosine phosphatases

Several phosphotyrosine phosphatases (PTPs), including SHP-1 and SHP-2, have emerged as important regulators of intracellular signaling pathways[27]. Somatostatin receptor-mediated activation of SHP-1 results in arrest of cell proliferation in various cell lines, including cells derived from pancreatic, breast and prostate carcinomas[31,32]. In pituitary adenoma cells, activation of sst_2 inhibits PI3 kinase activity and causes cell growth arrest *via* stimulation of SHP-1[33]. The enzymatic activity of SHP-1 has also been implicated in sst_3-dependent apoptosis in transfected Chinese Hamster Ovary (CHO) cells[34]. Stimulation of SHP-1 in sst_2-expressing CHO cells has led to G1 cell cycle arrest *via* induction of the cyclin-dependent kinase inhibitor p27[35]. SHP-2 has also been identified as a mediator of the antiproliferative effects of somatostatin receptors,

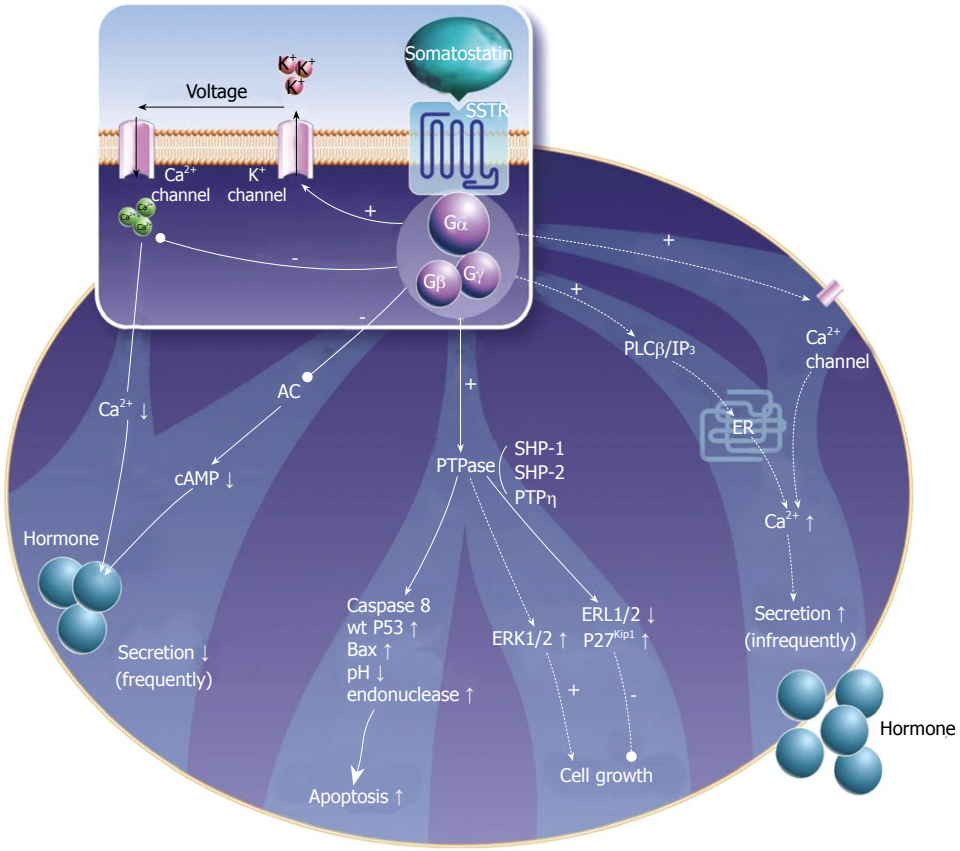

Figure 2 Somatostatin receptor-mediated effects on neuroendocrine cells (adapted from[23]).

primarily through inactivation of tyrosine kinase receptors for insulin and epidermal growth factors[36]. Moreover, activation of PTPs has been shown to down-regulate Raf-1[37] and block the MAP-kinase pathway[38].

Modulation of the mitogen activated protein-kinase pathway

Both inhibition and stimulation of the mitogen activated protein (MAP)-kinase pathway have been linked to the antiproliferative effects of somatostatin and its analogs. In a glioma cell line, the receptor-like PTP, PTPeta, mediated the antiproliferative effects of somatostatin through inhibition of ERK1/2[39]. Conversely, another study of sst_1-expressing CHO cells demonstrated that somatostatin robustly activated MAP-kinase, which in turn enhanced the expression of the cyclin-dependent kinase inhibitor p21, thereby inhibiting cell proliferation[40]. Another study in CHO cells demonstrated that activation of p38 MAP-kinase *via* sst_2 and sst_4 mediated the inhibitory effects of somatostatin on fibroblast growth factor induced proliferation[41].

Indirect antiproliferative mechanisms

Suppression of tumor growth may occur *via* inhibition of various circulating growth factors, including insulin-like growth factor (IGF), epidermal growth factor (EGF) and growth hormone (GH). Inhibition of GH is thought to be mediated primarily *via* sst_2 and sst_5, which are strongly expressed in the anterior pituitary[42-44]. Octreotide has been shown to suppress circulating levels of IGF-1, both *via* suppression of pituitary secretion of GH as well as through direct inhibition of IGF-1 production in the liver[45,46].

The antiangiogenic effects of octreotide have been demonstrated in multiple *in vitro* tumor models[47,48]. Octreotide has been shown to inhibit proliferating endothelial cells that over-express sst_2 and sst_5[49]. The primary mechanism of angiogenesis inhibition may be suppression of endothelial nitric oxide release[50]. Inhibition of circulating vascular-endothelial growth factor (VEGF) appears to also play a role in suppression of peritumoral vessel growth[51,52].

EARLY CLINICAL EVIDENCE FOR THE ANTIPROLIFERATIVE EFFECTS OF SSAS

Since the introduction of SSAs, multiple phase Ⅱ trials and retrospective series have demonstrated that SSA treatment is associated with prolonged survival and disease stabilization in a large proportion of patients. For example, a single-institution retrospective study of 146 patients with metastatic mid-gut NETs, 91% of whom received long term octreotide treatment, demonstrated a 5-year survival rate of 75% (compared to 19% historically)[53]. Additionally, an analysis of the US-based Surveillance, Epidemiology and End Results (SEER) database found a significant increase in survival from 1988 to 2004 compared with 1973 to 1987, coinciding with the introduction of octreotide[54].

In general, early clinical studies evaluating the dis-

ease-stabilizing effect of SSAs in patients with GEP-NETs are characterized by their lack of randomized design and enrollment of heterogeneous populations of patients with GEP-NETs. Although objective radiographic response rates have been rare (generally < 5%), the rate of tumor stabilization observed in most studies has ranged from 40%-60%, with higher rates observed in patients without documented disease progression at onset of treatment[55].

Among the first prospective studies documenting the antiproliferative effects of SSAs in GEP-NETs was one conducted by the German Sandostatin Study Group[56]. In this study, 103 patients with metastatic carcinoid and pancreatic endocrine tumors were treated with octreotide 200 μg thrice daily until evidence of radiographic progression. Among patients who had disease progression documented at treatment outset, the rate of disease stability lasting at least 3 mo was 37%, whereas among patients with documented stable disease at treatment outset, disease stability lasting at least 12 mo was documented in 54% of patients[57]. No objective tumor responses were observed. Another phase Ⅱ clinical trial testing octreotide as an antiproliferative agent in 34 patients with progressive metastatic NETs demonstrated a disease stabilization rate of 50% lasting a median of 5 mo[58].

The antiproliferative effect of intramuscular lanreotide SR 30 mg every 10 or 14 d was evaluated in a phase Ⅱ trial of 46 patients with carcinoid and pancreatic endocrine tumors. Two patients (4%) achieved an objective radiographic response while 19 patients (41%) experienced stable disease for a mean duration of 9.5 mo[59]. In another phase Ⅱ study of lanreotide SR 30 mg in 55 patients with GEP-NETs (48 with carcinoid tumors, six with gastrinomas and one with a VIPoma), 7% of 31 assessable patients achieved a partial response and 81% experienced disease stability[60]. In one study of patients with progressive tumors, participants received either octreotide LAR 30 mg or lanreotide SR 60 mg (this study considered all patients as a single cohort). Among 31 assessable patients, 14 (45%) achieved disease stability *vs* 55% who continued to progress radiographically[61]. Overall survival was considerably prolonged among patients with stable *vs* progressive disease. In multivariate analysis, pancreatic endocrine tumors appeared significantly less likely to achieve disease stabilization compared to intestinal carcinoid tumors. Extra-hepatic metastases were also associated with a poor prognosis. Table 3 summarizes the results of multiple non-randomized clinical trials evaluating the antineoplastic effects of octreotide and lanreotide in GEP-NETs.

THE PROMID TRIAL

Although providing initial evidence for the antitumor effects of SSAs, studies described in the previous section have a number of features that prevent them from providing conclusive evidence. Examples of these features include relatively small patient cohorts, lack of a randomized placebo control group, and analysis of heterogeneous populations. As such, to prove or to disprove an antiproliferative effect of octreotide LAR 30 mg, the PROMID (Placebo-controlled, Prospective, Randomized study in patients with metastatic neuroendocrine midgut tumors) study was initiated. This randomized, double-blind, placebo-controlled, phase Ⅲ trial, was among the very few randomized trials performed in patients with this rare tumor type. To avoid confounding variables, only patients with well-differentiated inoperable or metastatic midgut tumors were included. Additionally, octreotide LAR 30 mg was the only dose of octreotide LAR evaluated.

High-level evidence of the antiproliferative effects of octreotide emerged after publication of the PROMID trial[69]. Eighty-five participants with well-differentiated carcinoid tumors originating in the distal intestine and proximal colon were randomized to receive either octreotide LAR 30 mg or placebo until radiographic evidence of progression or death. The primary endpoint was time to tumor progression. Most patients (75%) had evidence of somatostatin receptor expression as evidenced by radiotracer uptake on Octreoscan. Nearly half of patients (38%) manifested the carcinoid syndrome (flushing and/or diarrhea associated with elevation in urine 5-HIAA). Only patients with mild carcinoid syndrome who tolerated flushing without intervention or responded to treatment with loperamide and/or cholestyramine in cases of diarrhea were included.

Median time to tumor progression was 14.3 mo in the octreotide LAR 30 mg group *vs* 6.0 mo in the placebo group (P = 0.000072, Figure 3). This significantly lengthened time-to-tumor progression was seen in the overall study population, regardless of tumor functionality, chromogranin A level or age. At 6 mo, tumor progression was observed in 24% of patients on the octreotide LAR 30 mg arm *vs* 66% of patients receiving placebo (P = 0.0079). Serious adverse events were nearly evenly balanced (11 patients in the octreotide LAR 30 mg arm and 10 patients in the placebo arm). On multivariate analysis, the highest rates of disease stabilization were observed in patients

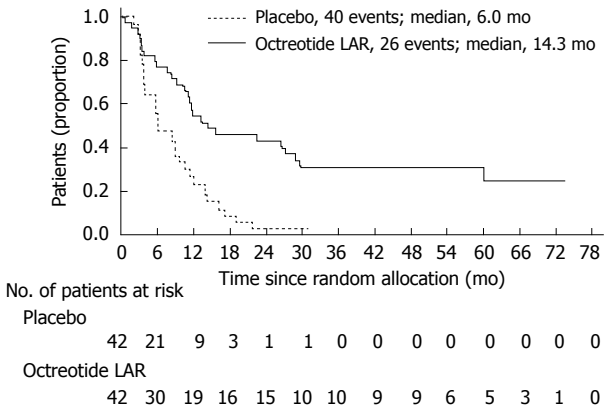

Figure 3 Kaplan Meier curve demonstrating time to tumor progression in patients treated with octreotide long-acting repeatable (LAR) *vs* placebo[69]. Log-rank test stratified by functional activity: P = 0.000072, HR = 0.34 (95% CI: 0.20-0.59).

with low hepatic tumor load (< 10%) and resected primary tumor, however both of these subgroups contained the majority of study patients. Even patients with higher hepatic tumor burden (> 10%) experienced a near doubling in time to progression on the octreotide LAR arm of the study. The small number of deaths in both treatment arms (seven in the octreotide LAR 30 mg arm; nine in the placebo arm) precluded any analysis of differences in survival.

FUTURE DIRECTIONS

Novel somatostatin analogs

NETs generally express multiple somatostatin receptors[13,70], all of which may mediate the antiproliferative effects of SSAs. These receptor subtypes can undergo heterodimerization with each other and with other receptor families (such as the dopamine receptor family), enhancing their binding affinities and internalization[71,72]. Thus, novel SSAs that bind to multiple receptor subtypes as well as analogs capable of binding to different families of receptors may prove to be effective antisecretory and antiproliferative agents in patients refractory to octreotide or lanreotide.

Pasireotide is one such novel somatostatin analog; it binds avidly to four of the five somatostatin receptors ($sst_{1,2,3}$ and sst_5). Compared with octreotide, pasireotide has a 40-, 30- and 5-fold higher binding affinity for sst_5, sst_1 and sst_3, and a slightly lower affinity for sst_2[73]. Pasireotide also has a 2-times higher binding affinity for sst_5 than endogenous somatostatin[73]. In an *in vitro* study evaluating the use of octreotide and pasireotide on HEK293 cells expressing somatostatin receptor subtype sst_2 on the cell membrane, treatment with octreotide resulted in an internalization of sst_2 receptors at 30 min whereas treatment with pasireotide did not lead to sst_2 internalization. Such findings may suggest that a persistent and more durable efficacy could be obtained with pasireotide[74].

An open-label trial evaluated the activity of pasireotide sc in patients with carcinoid syndrome whose symptoms (flushing and diarrhea) were inadequately controlled with octreotide LAR[75]. Preliminary data indicated activity in this refractory population. Future clinical trials are being designed to test the antiproliferative effects of pasireotide in neuroendocrine carcinomas. Other compounds capable of interacting with sst_2 as well as with the dopamine D2 receptor (DAD2) are in clinical development[76].

Radioactive labeling of SSAs is another promising approach to treatment of neuroendocrine malignancies which express high levels of somatostatin receptors. Early clinical trials employing ^{111}In-pentetreotide produced limited objective responses, probably due to the small particle range and short tissue penetration of Auger electrons emitted by the ^{111}In isotope[77]. The next generation of radiolabled SSAs used ^{90}Y-DOTATOC, a β-particle emitter with a tissue range of approximately 12 mm[78-80]. Objective response rates of 10%-30% were reported in phase Ⅰ and Ⅱ clinical trials. Dose-limiting side effects included bone marrow and renal toxicity.

The latest research efforts in radiolabeled SSAs have focused on ^{177}Lu octreotate, a β-and γ-emitting radionuclide with a shorter range of tissue penetration (2 mm) than ^{90}Y. A recent phase Ⅱ clinical trial reported an objective radiographic response rate of 30% among 310 patients with GEP-NETs, and a median progression-free survival duration of 40 mo[81].

CONCLUSION

SSAs were initially developed as antisecretory agents used primarily for the control of hormonal syndromes associated with NETs. In recent years, accumulating laboratory and clinical data has supported their role as antiproliferative agents, capable of stabilizing tumor growth in a large proportion of patients with metastatic carcinoid and pancreatic endocrine tumors. The recently-published PROMID study provides high-level evidence validating the role of octreotide LAR 30 mg as an antiproliferative agent in patients with metastatic carcinoid tumors of the midgut. Subset analysis suggests that patients with low tumor burden are most likely to experience disease stabilization, supporting the early use of octreotide LAR 30 mg in patients with metastatic disease. Further research efforts are underway to evaluate the use of novel SSAs, SSAs as antiproliferative agents in other types of GEP-NETs, and SSAs in combination with other anti-tumor agents.

Abstract

Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disease characterized by the presence of a plethora of autoantibodies and immune complex formation. Virtually every system and organ can be affected by SLE. Gastrointestinal symptoms are common in SLE patients, and more than half of them are caused by adverse reactions to medications and viral or bacterial infections. Though not as common as lupus nephritis, SLE-related gastrointestinal involvement is clinically important because most cases can be life-threatening if not treated promptly. Lupus mesenteric vasculitis is the most common cause, followed by protein-losing enteropathy, intestinal pseudo-obstruction, acute pancreatitis and other rare complications such as celiac disease, inflammatory bowel diseases, *etc*. No specific autoantibody is identified as being associated with SLE-related gastroenteropathy. Imaging studies, particularly abdominal computed tomography scans, are helpful in diagnosing some SLE-related gastroenteropathies. Most of these complications have good therapeutic responses to corticosteroids and immunosuppressive agents. Supportive measures such as bowel rest, nutritional support, antibiotics and prokinetic medications are helpful in facilitating functional recovery and improving the outcome.

INTRODUCTION

Systemic lupus erythematosus (SLE) is a systemic autoimmune inflammatory disease with protean clinical manifestations. The gastrointestinal tract is one of the most commonly affected systems in SLE. However, most gastrointestinal manifestations are caused by adverse reactions from therapeutic agents and infections, while the symptoms related to the disease *per se* are not as common as other organ involvement such as lupus nephritis[1-6]. On the other hand, the incidence of gastrointestinal manifestations may be underestimated clinically because some of them are indistinct and may not have abdominal symptoms. One autopsy study found that 60%-70% of SLE patients had evidence of peritonitis, whereas only around 10% of them were recognized clinically[1]. It is noteworthy

that gastrointestinal vasculitis and thrombosis can lead to life-threatening ischemia, perforation and infarction, and surgical interventions are usually needed if not treated promptly with immunosuppressant. In this paper, clinically important gastrointestinal complications of SLE are reviewed for the purpose of improving treatment efficacy and outcome.

LUPUS MESENTERIC VASCULITIS

Epidemiology and pathogenesis

A number of terms have been used to describe lupus mesenteric vasculitis (LMV), including mesenteric arteritis, lupus enteritis, lupus arteritis, lupus vasculitis, gastrointestinal vasculitis, intra-abdominal vasculitis and acute gastrointestinal syndrome. LMV is one of the main causes of acute abdominal pain in SLE patients. It can be classified into an acute ischemic enteritis that involves mainly small intestine and chronic multiple ulcers occurring mainly in the colon[2]. About 8%-40% of SLE patients have acute abdominal pain during the stage of active disease[3], but LMV is generally an uncommon condition in SLE patients. In Asia, the reported overall prevalence of LMV in patients with SLE is 2.2%-9.7%[4-6]. However, the prevalence of LMV in America seems to be much lower: 0.9%[7]. Ju *et al*[8] reported that the global prevalence of LMV ranges from 0.2% to 9.7% among all SLE patients and from 29% to 65% in patients who had acute abdominal pain. LMV occurs almost always in patients with active disease[6].

The predisposing factors for LMV are unknown. The proposed trigger factors include bacterial infections that lead to changes of intestinal flora, cytomegalovirus infection, eosinophilia, non steroidal anti-inflammatory drugs, chemicals, metallic particulates, animal viruses, helminth infection, caffeine, phosphodiesterase-4-inhibitors, adenosine diphosphate, certain foods and herbal medicines[6].

Inflammatory vasculitis secondary to immune complex deposition and thrombosis of the intestinal vessels secondary to circulating anti-phospholipid antibodies are the proposed pathogenic mechanisms of LMV[9-12]. Both types of microvasculopathy can activate each other reciprocally, resulting in worsening cascades of vasculitis and thrombosis. Autoantibodies, such as lupus anticoagulant, anti-cardiolipin antibody and anti-β2-glycoprotein antibody, are associated with LMV. A study suggests that some cryptic antigens which can stimulate the production of anti-endothelial antibodies are exposed when endothelial cells are disrupted[10]. In a study by Kwok *et al*[6], the authors found that the serum levels of anti-endothelial cell IgG were significantly higher in SLE patients with LMV than in those without LMV or in healthy controls. Macroscopically, the appearance of LMV varies from segmental edema to ulceration, gangrene and perforation[8]. Both small arteritis and venulitis are found in LMV. Microscopically, fibrinoid necrosis of subserosal vessels and leukocytoclasis on the vascular wall, as well as edematous submucosa with mild diffuse inflammatory infiltration of mononuclear cells, can be observed. In the muscular layer, intravascular fibrin thrombus and hemorrhage around the small veins can be found.

Clinical features

Both the inflammatory and thrombotic mesenteric vasculopathy of LMV can cause mesenteric ischemia. LMV can cause very severe abdominal symptoms and signs and sometimes is diagnosed as acute surgical abdomen. Typically, the abdominal pain caused by LMV is diffuse in pattern, in some cases accompanied by rebound tenderness and abdominal muscle guarding. The symptoms of LMV vary from mild, nonspecific abdominal pain, bloating or loose stool, to necrosis and intestinal perforation which manifest as severe extensive gastrointestinal bleeding or acute surgical abdomen. It is noteworthy that in LMV patients with bowel perforation, the typical signs can be absent. Other manifestations of LMV include anorexia, nausea, vomiting, dysphagia, hematemesis, postprandial fullness, diarrhea and melena. Kishimoto *et al*[13] reported two cases of "acute gastrointestinal distress syndrome". Patients with this syndrome have recurrent lupus enteritis on the basis of mesenteric vasculopathy characterized by reversible intestinal wall edema accompanied by significant hypocomplementemia. These attacks are not complicated by bowel infarction, perforation or hematachezia and respond quickly to corticosteroid treatment.

Diagnosis

Accurate diagnosis of LMV is critical to allow prompt treatment to avoid unnecessary surgical intervention. As the clinical symptoms and laboratory parameters are non-specific, and bowel specimens are not always available, the diagnosis of LMV relies on abdominal computed tomography (CT) scan which allows both the bowel wall and the abdominal vasculature to be visualized. Advances in CT technology have been extremely helpful in detecting ischemia and for evaluating the causes of abdominal pain.

Common CT findings in patients with LMV include dilated bowel, focal or diffuse bowel wall thickening, abnormal bowel wall enhancement which is also called "target sign", mesenteric edema, stenosis or engorgement of mesenteric vessels which is also called "the comb sign" and ascites (Figure 1). Segmental or multifocal involvement of the small and large bowel loops with intervening normal bowel segments indicates ischemic change, which is almost always indicative of vasculitis.

Ultrasonography is also useful for both the diagnosis and follow-up of LMV. Small intestinal wall edema and thickening can be visualized under ultrasonography. Irregular thickening and projection of folds in multiple segments of the duodenum and the terminal ileum accompanied by "thumb print" signs in double-contrast radiography suggest ischemic changes. Gastroscopy and colonoscopy can show ischemia and ulcerative changes. However, endoscopy-guided biopsy might not yield a definitive diagnosis of LMV because the affected vessels are usually located in an inaccessible area. Laparoscopy can be used in the diagnosis of LMV[8,9].

Figure 1 Stenosis of artery mesenterica superior (SMA) in a patient with systemic lupus erythematosus.

Management

Early diagnosis and appropriate intervention can avoid potentially fatal complications of LMV. Because the primary lesions of LMV are inflammatory ischemic vasculitis, immediate and aggressive anti-inflammatory immunosuppressive treatment should be initiated as soon as the diagnosis of LMV is made. The treatments include high dose intravenous infusion of methylprednisolone or an equivalent agent and complete bowel rest. For patients with recurrent LMV and those who do not have adequate response to intravenous prednisolone alone, intravenous cyclophosphamide should be initiated. The initial dosage of cyclophosphamide is 1 mg/kg daily and the dosage is gradually tapered when LMV is stabilized[6]. In Kim's study, they found that a bowel wall thickness greater than 9 mm usually indicated the presence of recurrent LMV and should be considered a high risk factor for recurrence[14]. They suggested that for patients with high risk of recurrence, immunosuppressive agents should be initiated as early as possible.

When a rapid response to immunosuppressive therapy is not achieved, surgical intervention for possible bowel perforation or large area of ischemia should be considered. Early laparotomy within 24 to 48 h is critical for improving the prognosis of LMV patients. Medina *et al*[15] found that 10 of 11 LMV patients who underwent surgery after 48 h died, while none of 33 patients who were operated on within 24-48 h died.

Prognosis

The prognosis of LMV varies in reports from different areas of the world. This might be due to genetic differences. Reports from Europe and North America indicate that the prognosis of LMV is poor and some fatalities can occur. Some reports claimed that the mortality of LMV could be as high as 50%[6,15]. The prognosis of LMV depends on the extent of vascular involvement, the prompt implementation of immunosuppressive therapy, and the time of surgical intervention. On the basis of published reports, the prognosis of LMV can be improved if abdominal CT is used to aid the diagnosis and if prompt immunosuppressive therapy is implemented.

PROTEIN-LOSING GASTROENTEROPATHY

Epidemiology and pathogenesis

Protein-losing gastroenteropathy (PLGE) is a condition characterized by profound edema and severe hypoalbuminemia secondary to excessive loss of serum protein from the gastrointestinal tract, clinically indistinguishable from nephrotic syndrome. Clinically significant PLGE seems uncommon in SLE. Besides two large series reported by Mok and our group with 16 and 15 patients respectively, most are isolated case reports or small series[16,17]. So far, less than 60 patients with SLE-related PLGE have been reported in the literature, and the majority of these patients are Asians; whether this is due to genetics or environmental factors remains to be elucidated. In Mok's study, the point prevalence of their Chinese patients is 3.2% for PLGE, while in our series the prevalence is 1.9%. PLGE may occur in SLE patients of any age and occurs with a female predominance. In most circumstances, the typical features of PLGE develop before the diagnosis of SLE. In our study, 53.3% of patients had PLGE as the initial presentation of SLE, but PLGE could also occur 17 years after the establishment of SLE[17]. Gornisiewicz *et al*[18] have concluded that PLGE often happens in patients with clinically severe SLE with multiple system involvement.

The exact pathogenesis of SLE-related PLGE is still unclear. Mucosal ulceration, non-necrotizing mesenteric or intestinal blood vessel vasculitis, increase in capillary permeability caused by intravascular activation and conversion of complement, cytokine- (such as tumor necrosis factor-α and interleukin-6) or complement-mediated vascular or mucosal damage, and intestinal lymphangiectasia have been postulated as the pathogenic mechanisms[16,19].

Clinical features

The most predominant clinical manifestation of PLGE is profound peripheral pitting edema. Patients may have pleural, pericardial effusion and ascites due to severe hypoalbuminemia. Nausea, vomiting and diarrhea are also common in these patients. Diarrhea is present in 50% of cases, which is generally liquid in nature and can be as frequent as 20 times a day, but steatorrhea is absent[17,20]. No particular autoantibodies have been found to be associated with PLGE. Severe hypoalbuminemia and hypocomplementemia are the most predominant laboratory findings of PLGE. Kim *et al*[19] found in their study that hypercholesterolemia was common in SLE-related PLGE, but rare in idiopathic PLGE[16]. This might be due to the leakage of cholesterol-rich lipoprotein particles in the intestinal lymph. Most PLGE patients also have hypoglobulinemia because immunoglobulin can also leak into the intestinal lumen. The presence of anti-dsDNA and anti-ENA antibodies is not significantly different from patients without PLGE. Eighty percent of PLGE in our series occurred at the stage of active lupus, and

non-specific chronic inflammation were detected in all pathological specimens obtained.

Diagnosis

The diagnosis of SLE-related PLGE mainly relies on the exclusion of other causes of hypoalbuminemia such as lupus nephritis, abnormal liver function, decreased protein synthesis or malabsorption. In recent years, Tc-99m albumin scintigraphy has become the most frequently used diagnostic method. It is noninvasive and safe in demonstrating gastrointestinal loss of blood albumin to intestinal lumen. It also has the potential to localize protein leakage and can be used to monitor the efficacy of treatment. Gastroenteroscopy is usually not diagnostic, as 50% of SLE-related PLGE patients present with non-specific intestinal wall edema and 10% of patients have no abnormalities under endoscopy examination[21]. Histologically, lymphangiectesia, edematous villi and non-specific inflammation can be found in the intestine, but histology can also be normal because of the inaccessibility of the involved area under gastroendoscopy. An elevated α-1 antitrypsin can be used as a diagnostic alternative[22].

Management

Due to limited number of patients, there is no controlled clinical trial to demonstrate the efficacy of treatment for SLE-related PLGE. Corticosteroid is the mainstay of treatment. Response to corticosteroid alone is excellent in more than 60% of patients. For those refractory to steroid, immunosuppressive agents such as azathioprine, cyclosporine A and cyclophosphamide could be added into the therapeutic regimen. Albumin infusion, nutritional support and diuretics are used as supplemental measures for the treatment. Octreotide can reduce intestinal microvasculature blood flow, decrease local lymph formation and ameliorate lymphatic dilatation, therefore can also be used in the treatment of PLGE. In addition, octreotide has immunomodulatory effects since it specifically binds with the somatostatin receptor. Prophylaxis for thromboembolic complications with warfarin should be considered in patients with severe and persistent protein loss, especially if antiphospholipid antibodies are present[16-18,20].

Prognosis

The outcome of most SLE-related PLGE cases is generally good since most patients respond well to steroid therapy. Relapse of PLGE occurs in 20%-30% of patients, particularly in patients undergoing maintenance therapy with low-dose prednisolone alone, but they respond again to an increased dosage of steroid. Mok *et al*[16] suggested that long-term maintenance treatment with low dose prednisolone plus azathioprine could reduce the rate of recurrence.

INTESTINAL PSEUDO-OBSTRUCTION

Prevalence and pathogenesis

SLE-related intestinal pseudo-obstruction (IPO) is a rare but well-recognized clinical syndrome that reflects the dysfunction of the visceral smooth muscle, the enteric nerve and/or the visceral automatic nervous system[23]. It usually coincides with ureterohydronephrosis and/or interstitial cystitis, rarely with biliary dilatation (megacholedochus)[24]. IPO is associated with ureterohydronephrosis in 63.3% of cases[25]. IPO may appear during the course of SLE, but it can also be the initial presentation of SLE[26]. It usually occurs in patients with active lupus. So far, only 28 cases have been reported in the English literature; half of the cases were Oriental and female patients predominated[23].

The pathogenesis of SLE-related IPO is unknown. Histopathological evidence of intestinal leiomyocyte damage suggests a systemic autoimmune process targeting smooth muscle cells[24]. Vasculitis leading to chronic ischemia of the bowel smooth muscle, which in turn leads to muscular damage and hypomotility, has been postulated as one of the possible mechanisms. Another possible mechanism is an intrinsic muscle dysmotility affecting the muscularis propria. The apparently high association between pseudo-obstruction and ureterohydronephrosis suggests a possible common smooth muscle dysmotility due to primary myopathy or neurogenic pathology, secondary to either immune complex-mediated vasculitis or common circulating autoantibodies against smooth muscle. Biopsied specimens have shown fibrotic process and atrophy in the muscularis layer, decreased number of smooth muscle cells and inflammatory cell infiltration associated with fibrinoid deposits, indicative of vasculitis[26].

Clinical features

The characteristic clinical manifestation of IPO is ineffective intestinal propulsion with the presence of clinical features of intestinal obstruction without an identifiable organic obstructive lesion and an abdominal distension with a very sluggish or absent peristalsis. Antroduodenal manometry demonstrates intestinal hypomotility and esophageal aperistalsis. Symptoms of IPO include a subacute onset of abdominal pain, nausea and vomiting, abdominal distension, constipation, diarrhea and weight loss. Laboratory findings are non-specific. Anti-proliferative cell nuclear antigen antibody (anti-PCNA) was found to be more frequently detected than in lupus patients without IPO in one study[27]. Mok *et al*[28] reported that SLE-related IPO patients had higher frequency of positive anti-Ro and anti-RNP antibodies compared to lupus patients without IPO.

Radiological examination can detect dilated fluid-filled bowel loops, with thickened bowel wall and multiple fluid levels. Bilateral ureter dilatation with a reduced urinary bladder capacity can be found if ureterhydronephrosis is the concurrent situation. Abdominal CT scan frequently reveals the presence of dilated small and large bowel with thickened intestinal wall.

Pathological examination of the gastrointestinal tract of SLE-related IPO patients can reveal widespread myocyte necrosis in the muscularis propria with active inflammatory cell infiltration, severe atrophy of muscularis, active serositis with serosal thickening and fibrosis, but little or no evidence of vasculitis and absence of thromboembolism.

Diagnosis

The diagnosis of this clinical syndrome is based on imaging findings consistent with the presence of dilated small and large bowel loops with thickened intestinal wall and multiple fluid levels. Other possible causes of intestinal obstruction should be excluded. Invasive diagnostic procedures should be avoided.

Management

Corticosteroids, immunosuppressive agents combined with supportive measures such as parenteral nutrition, oral broad-spectrum antibiotics to diminish bacteria overgrowth and pharmacological stimulation of small bowel motility are effective medical management options for SLE-related IPO. Timely diagnosis and early intervention are critical to rehabilitate the peristaltic activity of both the gastrointestinal tract and the genitourinary viscera; delayed treatment has been associated with failure to regain functional peristalsis and leads to histopathological progression to fibrosis and atrophy of the intestinal wall, and secondary impairment of the myenteric plexuses[24]. SLE-related IPO usually responds well to high dose corticosteroids. Erythromycin in particular is the appropriate antibiotic in this situation due to its prokinetic effect. Other prokinetic agents such as cisapride and octreotide are also helpful in stimulating small bowel motility. Octreotide appears to be effective in improving both clinical symptoms and manometric patterns[26]. Azathioprine, cyclophosphamide and cyclosporine A are the immunosuppressive agents that could be used as one component of a maintenance therapeutic regimen with oral corticosteroids. Other immunosuppressive agents against B cells, immune complex formation and pathogenic autoantibody formation could be the alternatives.

Prognosis

High dose intravenous corticosteroid treatment is effective in most patients, leading to clinical remission and disappearance of abnormal imaging findings. Long-term outcome of SLE-related IPO varies. Some patients may have recurrent attacks of IPO without other major organ involvement despite maintenance treatment with steroids and immunosuppressive agents. The reported mortality rate is 18%[26]. Early diagnosis and prompt treatment is critical to improve the overall outcome of SLE-related IPO patients.

PANCREATITIS

Epidemiology and pathogenesis

About 160 cases of SLE-related acute pancreatitis have been reported in the literature. Pancreatitis is a rare but life-threatening complication of SLE and our knowledge about this complication is mainly based on individual case reports. Based on the literature reports, the annual incidence of SLE-related pancreatitis is estimated to be 0.4-1.1/1000 lupus patients[29,30]. Reports from Europe and the United States showed that the rate of pancreatitis with SLE is between 0.7%-4%[31,32]. However, the rate of SLE-related pancreatitis may be underestimated because cases of subclinical pancreatitis with elevated pancreatic enzymes but no symptoms are not diagnosed or reported. It is estimated that 30.5% of asymptomatic SLE patients have hyperamylasemia[33].

Sixty percent of cases develop acute pancreatitis within 2 years of the diagnosis of lupus, and in 22% of patients, pancreatitis is the initial clinical presentation. In most cases, acute pancreatitis is associated with active lupus. In addition to traditional predisposing factors such as hypertriglyceridemia, steroid and azathioprine use were proposed as the possible causes of pancreatitis in lupus patients. However, in Pascual-Ramos's study, they could not prove the association between steroid and/or azathioprine administration and the development of pancreatitis even after they "rechallenged" the onset of pancreatitis with these medications[34].

The pathogenic mechanism of SLE-related pancreatitis is unclear. Vascular damage has been stressed as a cause of this problem. Necrotizing vasculitis, occlusion of arteries and arterioles by thrombi resulting from severe hypertension or antiphospholipid syndrome, intimal thickening and proliferation and immune complex deposition with complement activation in the wall of pancreatic arteries have been postulated[31]. Sixteen specimens of pancreatic tissue from SLE-related pancreatitis patients were examined in one series; evidence of inflammation and necrosis could be found in all specimens, but vasculitis could only be found in one case[31]. It is possible that an autoimmune reaction involving abnormal cellular immune response or antibody reaction, rather than vasculitis, is responsible for the inflammation reaction.

Clinical features

Eighty-eight percent of SLE-related pancreatitis cases have abdominal pain; in only 23% of them the pain radiates to the back. Two-thirds of patients have nausea and vomiting, and half of them have fever. Diarrhea is uncommon and a few patients have panniculitis.

Elevated serum amylase and lipase are the most commonly detected biochemical abnormalities. Additional biochemical abnormalities include hypoalbuminemia, abnormal liver function tests, elevated serum creatinine and hypocalcemia. Anti-La antibody is the only autoantibody reported to be associated with this particular complication[32].

Diagnosis

The diagnosis is based on the laboratory evidence of elevated serum amylase or lipase levels. Clinical symptoms and suggestive tomographic findings are helpful. However, lupus patients may develop acute pancreatitis secondary to other "non-SLE" causes such as mechanical (including cholelithiasis), toxic chemicals (such as alcohol ingestion, some medications), hypertriglycemia and hypocalcemia, as well as viral infections or sepsis. The diagnosis of SLE-related pancreatitis can only be confirmed when these possible causes are excluded.

Management

Corticosteroids should be used as the medical management of SLE-related acute pancreatitis as long as this drug can be excluded as the cause of pancreatitis. Immunosuppressive agents such as azathioprine or cyclophosphamide can be used in combination with corticosteroid. In severe cases, plasmapheresis and intravenous gamma-globulin infusion may be helpful.

Prognosis

As many as 57% of SLE-related acute pancreatitis cases may develop complications if not treated promptly[30]. Many of these complications can be fatal, with a mortality rate of 45%, whereas it is only 3% in patients without complications. Lupus activity is significantly associated with increased mortality. It is reported that SLE-related acute pancreatitis concurrent with central nervous system and cardiac involvement has the highest mortality rate. Increased serum creatinine, hypoalbuminemia, anti-DNA antibodies, thrombocytopenia, low complement, hypocalcemia, hyperglycemia and elevated liver enzymes are risk factors for increased mortality.

About 22% of patients may experience recurrent acute pancreatitis attacks, while 12% of patients develop pancreatic pseudocysts and 5%-14% become chronic[30,32].

OTHER SLE-RELATED GASTROINTESTINAL PROBLEMS

Celiac disease

The coexistence of SLE and celiac disease is rare. So far, only 17 cases have been reported in the literature. Both diseases have an autoimmune nature and share HLA-B8 and HLA-DR3 histocompatibility antigens[35]. Celiac disease can occur before or after the diagnosis of lupus[36]. Most patients have positive serum antigliadin antibodies and histological findings of duodenal biopsy which are consonant with celiac disease. Patient's response to steroid along with gluten-free diet is excellent. The prognosis is generally good.

Inflammatory bowel disease

The coexistence of SLE and inflammatory bowel disease (IBD) is difficult to diagnose since both diseases share some common gastrointestinal features and some medications used in treating IBD may cause drug-induced lupus. The estimated prevalence of ulcerative colitis (UC) in SLE patients is around 0.4%[37]. So far, 27 cases of SLE-related UC have been reported, and numbers of SLE-related Crohn's disease are even less. UC may occur either before or after the diagnosis of SLE. The majority of patients have excellent response to steroids combined with hydroxychloroquine or azathioprine. However, some patients with Crohn's disease may have life-threatening massive gastrointestinal bleeding and need high dosage methylprednisolone[38]. The prognosis of SLE-related IBD is usually good.

Eosinophilic enteritis

Eosinophilic enteritis is a rare clinical condition. SLE-related eosinophilic enteritis is even rarer. Only 3 cases of SLE-related eosinophilic enteritis have been reported in the literature[39]. The clinical symptoms include abdominal pain, nausea, vomiting and sometimes diarrhea. Peripheral hypereosinophilia presents in most of the patients. The diagnosis depends on clinical symptoms and intestinal biopsy which shows eosinophils in the deep layers of the intestinal wall[39]. The recommended treatment regimen is prednisone 0.5-1 mg/kg per day in divided doses for 7-10 d followed by slow tapering over 2 to 3 mo. Immunosuppressive agents can be used in patients with recurrence or corticosteroid non-responders.

Pneumatosis cystoides intestinalis

This is an uncommon disorder characterized by the presence of gas within the walls of the gastrointestinal tract. The most common rheumatic disease that is associated with pneumatosis cystoides intestinalis (PCI) is systemic sclerosis. Only 14 SLE-related PCI cases have been reported in the literature. It might be caused by injury of the mucosa and immune barrier due to lupus vasculitis and impaired healing due to corticosteroid therapy[40]. Pathological evidence of vasculitis can be found in at least half of the patients. Increased intraluminal pressure, mucosal injury and production of gas from bacteria in the mucosa may be involved in the pathogenesis of SLE-related PCI. The diagnosis depends on the abdomen findings on CT, which show thickened bowel walls with multiple linear and cystic radiolucencies. Therapeutic strategy for each PCI patient should be individualized. Oxygen inhalation or hyperbaric oxygen therapy is reported to promote removal of the gas from the cysts. Antibiotics are effective in reducing bacterial overgrowth and gas production. Bowel rest and prokinetic agents are the supportive measures in treating patients with SLE-related PCI.

CONCLUSION

Gastrointestinal manifestations are common in SLE patients, but most of them are due to adverse reactions to medications and infection. SLE-related gastrointestinal involvement is not rare, and sometimes can be life-threatening. Most SLE-related gastrointestinal complications are caused by vasculitis and immune complex deposition, and respond well to corticosteroids and immunosuppressive agents. Early diagnosis and timely treatment are critical to improve the prognosis. Supportive measures such as bowel rest are beneficial, and in some situations such as IPO and PCI antibiotics are helpful to facilitate functional restoration.

Abstract

Human intestinal microbiota create a complex polymicrobial ecology. This is characterised by its high population density, wide diversity and complexity of interaction. Any dysbalance of this complex intestinal microbiome, both qualitative and quantitative, might have serious health consequence for a macro-organism, including small intestinal bacterial overgrowth syndrome (SIBO). SIBO is defined as an increase in the number and/or alteration in the type of bacteria in the upper gastrointestinal tract. There are several endogenous defence mechanisms for preventing bacterial overgrowth: gastric acid secretion, intestinal motility, intact ileo-caecal valve, immunoglobulins within intestinal secretion and bacteriostatic properties of pancreatic and biliary secretion. Aetiology of SIBO is usually complex, associated with disorders of protective antibacterial mechanisms (e.g. achlorhydria, pancreatic exocrine insufficiency, immunodeficiency syndromes), anatomical abnormalities (e.g. small intestinal obstruction, diverticula, fistulae, surgical blind loop, previous ileo-caecal resections) and/or motility disorders (e.g. scleroderma, autonomic neuropathy in diabetes mellitus, post-radiation enteropathy, small intestinal pseudo-obstruction). In some patients more than one factor may be involved. Symptoms related to SIBO are bloating, diarrhoea, malabsorption, weight loss and malnutrition. The gold standard for diagnosing SIBO is still microbial investigation of jejunal aspirates. Non-invasive hydrogen and methane breath tests are most commonly used for the diagnosis of SIBO using glucose or lactulose. Therapy for SIBO must be complex, addressing all causes, symptoms and complications, and fully individualised. It should include treatment of the underlying disease, nutritional support and cyclical gastro-intestinal selective antibiotics. Prognosis is usually serious, determined mostly by the underlying disease that led to SIBO.

INTRODUCTION

Human intestinal microbiota create a complex polymicrobial ecology. This is characterised by its high population density, wide diversity and complexity of interaction. The duodenum and proximal jejunum normally contain small numbers of bacteria, usually lactobacilli and enterococci, gram-positive aerobes or facultative anaerobes ($< 10^4$ organisms per mL). Coliforms may be transiently present ($< 10^3$ bacteria per mL) and anaerobic *Bacteroides* are not found in the jejunum in healthy people. Up to one third of jejunal aspirates might be sterile in healthy volunteers. The distal ileum is a transition zone between sparse populations of aerobic bacteria of the proximal small intestine and very dense populations of anaerobic micro-organisms in the large bowel[1-3]. The epithelial surface of the small intestine in a healthy human is not colonised. Occasional groups of bacteria can be found in low concentrations within the lumen. Bacteria do not form clusters and spatial structures, and the luminal contents are separated from the mucosa by a mucus layer[4].

Any dysbalance of this complex intestinal microbiome, both qualitative and quantitative, might have serious health consequences for a macro-organism, including small intestinal bacterial overgrowth syndrome (SIBO).

DEFINITION

SIBO is a very heterogeneous syndrome characterised by an increased number and/or abnormal type of bacteria in the small bowel. Most authors consider diagnostic of SIBO to be the finding of $\geqslant 10^5$ bacteria [i.e. colony-forming units (CFU)] per mL of proximal jejunal aspiration. The normal value is $\leqslant 10^4$ CFU/mL[3, 5-7].

PREVALENCE

The overall prevalence of SIBO in the general public is unknown. In general, SIBO is substantially underdiagnosed. There are several reasons for this fact. Some patients may not seek healthcare or SIBO may not be properly diagnosed by medical investigations. SIBO might be asymptomatic or with non-specific symptoms only, and last but not least, all symptoms might be incorrectly ascribed to the underlying disease (leading to SIBO). Of course, diagnostic yield also depends on the methods used for investigation. According to different studies with the investigation of small sets of clinically healthy people as a control, findings consistent with SIBO were found in 2.5% to 22%[8-17].

In particular diseases and disorders, literature data on prevalence differ substantially. For instance, the prevalence of SIBO in patients fulfilling diagnostic criteria for irritable bowel syndrome was 30%-85%[9-11,16,18,19]. The prevalence of SIBO in coeliac disease non-responding to a gluten-free diet was up to 50%[20]. In liver cirrhosis, SIBO was diagnosed in more than 50% of cases[21,22]. In a small group of elderly people (70 to 94 years old) with lactose malabsorption, SIBO was documented in 90%[23]. An interesting study was performed on asymptomatic morbidly obese subjects and SIBO was found in 17% (compared to 2.5% in non-obese persons)[15].

AETIOLOGY

There are several endogenous defence mechanisms for preventing bacterial overgrowth: gastric acid secretion, intestinal motility, intact ileo-caecal valve, immunoglobulins within intestinal secretion and bacteriostatic properties of pancreatic and biliary secretion[24].

The aetiology of SIBO is usually complex, associated with disorders of protective antibacterial mechanisms (e.g. achlorhydria, pancreatic exocrine insufficiency, immunodeficiency syndromes), anatomical abnormalities (e.g. small intestinal obstruction, diverticula, fistulae, surgical blind loop, previous ileo-caecal resections) and/or motility disorders (e.g. scleroderma, autonomic neuropathy in diabetes mellitus, post-radiation enteropathy, small intestinal pseudo-obstruction). In some patients more than one factor may be involved. "Aetiological" and "predisposing" factors cannot be separated in some patients. SIBO may occur in elderly people without any evident underlying small intestinal pathology.

In some cases, a vicious circle arises: an underlying disease is complicated by SIBO and then SIBO directly (as a morphological impact) or vicariously (by malabsorption or nutrient deficiency) causes further deterioration of the underlying disease.

Out of all diseases and disorders associated with SIBO (listed below in detail), 90% of cases comprise small intestinal motility disorders (of various aetiology) and chronic pancreatitis[2].

Achlorhydria

Achlorhydria (due to chronic atrophic gastritis) and long-term administration of proton pump inhibitors may cause bacterial overgrowth in the stomach and duodenum. Proton pump inhibitors not only increase duodenal bacterial colonisation but also accelerate intestinal transit[24].

Exocrine pancreatic insufficiency

Chronic pancreatitis is complicated by SIBO in 30%-40% of cases[7,25]. Multiple factors can be involved: exocrine pancreatic insufficiency (with absence of anti-bacterial effect of proteolytic enzymes), abnormal chyme in the small intestinal lumen, motility disorders, administration of painkillers and ongoing alcohol consumption in some of patients. Cystic fibrosis is also associated with increased risk of SIBO. Fridge *et al*[26] diagnosed SIBO in 14/25 (56%) patients with cystic fibrosis. SIBO may be a causative fac-

tor of diarrhoea in advanced pancreatic cancer[27] apart from pancreatic exocrine insufficiency, chemotherapy or previous surgery.

Immunodeficiency syndromes

Various immunodeficiency syndromes, such as IgA deficiency, common variable immunodeficiency, AIDS and others, are complicated by miscellaneous infection complications, including SIBO[28,29].

Small intestinal obstruction and stagnation

All anatomical pathology associated with small intestinal obstruction and stagnation could be associated with SIBO, e.g. strictures, adhesions, tumours of the small bowel. Large and/or multiple duodenal and jejunal diverticula are often complicated by SIBO. Sequelae of previous abdominal surgery (afferent loop syndrome after Billroth-Ⅱ gastric resection, Roux-en-Y stasis syndrome, bariatric bypass surgery) may also lead to SIBO (with metabolic and nutritional disarrangement)[7,30-32]. Small intestinal pseudo-obstruction and some neurological diseases (e.g. myotonic dystrophy, Parkinson disease, Chagasic enteropathy) can be complicated by SIBO that is responsible for malabsorption and weight loss[33-36]. Spinucci *et al*[37] described an interesting case of endogenous ethanol production in a patient with chronic intestinal pseudo-obstruction and SIBO.

Tursi *et al*[38] investigated bacterial overgrowth in the small bowel in patients with acute diverticulitis of the colon. Small intestinal overgrowth was found in 53/90 (59%) subjects. The authors assumed that the primary mechanism is a slow large bowel transit with stasis of faeces in the colon. This results in dysmicrobia in the large bowel with metabolic changes and induction of inflammation. Subsequent reverse peristalsis facilitates colonisation of the small intestine by bacteria coming from the large bowel. SIBO deteriorates symptoms of acute colonic diverticulitis, protracts the course of the disease and thus could be an independent risk factor for future relapses of acute diverticulitis of the large bowel. Rifaximin was effective in the treatment of both acute colonic diverticulitis and SIBO in these patients[38].

Irritable bowel syndrome

The aetio-pathogenesis of irritable bowel syndrome has not yet been satisfactorily clarified. Symptoms of SIBO and irritable bowel syndrome overlap to a large degree. As mentioned earlier, SIBO is frequently found in persons fulfilling criteria of irritable bowel syndrome (30%-85%)[9-11,16,18,19]. According to authors of the bacterial hypothesis, SIBO is the primary event and irritable bowel is secondary to SIBO. In some patients, the onset of irritable bowel is preceded by infective gastroenteritis (so-called post-dysenteric bowel disturbance)[39]. Analysis of the microbial genome found different faecal microbiota in healthy people and patients with irritable bowel (e.g. phylotypes *Coprococcus*, *Collinsella*, *Coprobacillus*)[40-42]. Believers in an opposite hypothesis stated that irritable bowel is a primary factor (with motor disturbance, visceral afferent hypersensitivity, psycho-social dysfunction) in which motility disorders enable "secondary" bacterial overgrowth[40,43]. A third group of authors recommend strict distinction between irritable bowel syndrome (the hydrogen breath test with lactulose must be negative) and SIBO (in such a case, it is not irritable bowel despite the diagnostic criteria having been met) in patients with identical symptoms[44]. The last authors stated an opinion that SIBO does not play any significant role in the pathogenesis of irritable bowel[45].

Pimentel *et al*[12] found abnormal lactulose breath test results in 93/111 (84%) patients with irritable bowel syndrome. Successful treatment of SIBO using neomycin (in 35% of patients) was associated with relief of subjective symptoms. There was another interesting finding in this study: a subgroup of persons with a methanogenic phenotype was associated with constipation in 100% (constipation-predominant irritable bowel syndrome)[12]. Another study found that methanogenic status was never associated in irritable bowel syndrome with diarrhoea and Crohn's disease or ulcerative colitis with diarrhoea[13]. The association of methanogenic phenotype and constipation was also revealed by other authors[8].

Coeliac disease

A wide range of 9% to 55% of patients have been diagnosed with SIBO as a complication of coeliac disease[20,46-48]. The prevalence of SIBO is high, especially in patients who do not respond to a gluten-free diet and/or have lactose intolerance[20,46,47].

Crohn's disease

SIBO is frequently found in Crohn's disease (in about 25%). Loss of the ileo-caecal valve (due to previous ileocaecal resection) and/or large entero-enteric and enterocolic fistulae are important predisposing factors[49-55]. Castiglione *et al*[56] found bacterial overgrowth more frequently in those who underwent surgery (30%) compared to non-operated patients (18%). Furthermore, SIBO may mimic an acute flare of Crohn's disease (including increased bowel movements and lower body weight)[57]. Smokers may exhibit increased H_2 production which could lead to false positive test results. However, in the study by Klaus *et al*[57] there was no difference in the proportion of smokers and their respective daily consumption of cigarettes between patients with Crohn's disease with and without SIBO.

Short bowel syndrome

The problem of short bowel syndrome is not limited only to the reduced absorptive surface area. The loss of the ileocaecal valve and the loss of the ileal break from resection of the distal small bowel would accelerate the transit of chyme throughout the entire gastrointestinal tract. Undigested food becomes a substrate for bacterial fermentation. Large intestinal bacterial flora colonise proximally into the small intestine to result in SIBO. Because digestion and absorption cannot be completed without adequate time, these patients face chronic postprandial diarrhoea.

These problems may be exacerbated by SIBO that further accelerates transit and worsens digestion, absorption and malnutrition[58].

SIBO is an independent negative factor deteriorating adaptation of the small intestine in children after excessive bowel resections. SIBO lengthens the dependence of these patients on total parenteral nutrition and deteriorates malabsorption and hepatopathy associated with short bowel syndrome[59,60]. SIBO may lead to intestinal failure in these patients[61].

Non-alcoholic steatohepatitis

Wigg *et al*[17] found a higher prevalence of SIBO (11/22, 50%) in non-alcoholic steatohepatitis (NASH) compared to healthy control subjects (5/23, 22%). Higher values for the xylose-lactulose test in patients with NASH correlated with higher serum levels of tumor necrosis factor-α (TNF-α). However, they were not associated with increased intestinal permeability or increased serum endotoxin[17]. In another study of NASH[62], SIBO was diagnosed in half of the patients (6/12) but only in one subject (1/11, 9%) in the healthy control group. Treatment with ciprofloxacin suppressed bacterial overgrowth, increased serum insulin and decreased endogenous ethanol production but did not influence serum acetylated ghrelin (half values compared to controls). Changes in fasting insulin and ethanol following ciprofloxacin suggest that these parameters may be influenced by small intestinal bacterial activity[62]. In an experimental model of NASH in rats, there was a slower transit time and higher quantity of coliform bacteria (*Escherichia coli*). Treatment with gentamicin (cidomycin) accelerated the transit time, decreased TNF-α levels and alleviated severity of liver involvement in experimental animals. Thus SIBO might play an important role in the pathogenesis of NASH[63].

Liver cirrhosis

Portal hypertension in liver cirrhosis substantially changes the intraluminal milieu of the gut. Liver cirrhosis is an independent risk factor for SIBO. Small intestinal motility disorder, especially slow transit in advanced liver disease (Child-Pugh C) may partake in SIBO[64,65]. SIBO was diagnosed in 50%-60% of patients with liver cirrhosis[66,67]. SIBO is a risk factor for the development of spontaneous bacterial peritonitis[22,68], however, its role in the pathogenesis has not yet been fully clarified[22]. Prevalence of SIBO was higher in those patients with liver cirrhosis who had spontaneous bacterial peritonitis (14/20, 70%) compared to those without it (4/20, 20%)[64]. However, this finding was not confirmed in other studies[66]. SIBO might correlate with systemic endotoxaemia[69]. It is necessary to remind ourselves that glucose hydrogen breath test in liver cirrhosis correlates only to a small degree with microbiological analysis of jejunal aspirates (sensitivity 27%-52%, specificity 36%-80%)[70].

Scleroderma

Scleroderma (systemic sclerosis) is a chronic connective tissue disease that affects the gastrointestinal tract in more than 80% of patients[71]. Severe small bowel involvement by scleroderma can present as chronic intestinal pseudo-obstruction and SIBO. The reported prevalence of SIBO in scleroderma was 43% to 56%[72,73]. In our series, SIBO was proved in 4/15 (27%) patients with systemic sclerosis by means of glucose hydrogen and methane breath tests. Half the cases of SIBO had neither diarrhoea nor other signs of malassimilation at the time of examination. There was a tendency towards a higher dose of systemic glucocorticosteroids in persons with positive hydrogen and methane breath tests[74].

Autonomic neuropathy in diabetes mellitus

Gastrointestinal symptoms are present in 50%-70% of patients with diabetes mellitus. Delayed gastric emptying (or even diabetic gastroparesis) and intestinal motility disorders are the most important findings (with an unfavourable impact on glycaemic control). Impaired intestinal motility is often followed by SIBO[75-77]. In diabetes mellitus, first and foremost all results must be interpreted according to the diagnostic method that was used. Cuoco *et al*[78] performed the lactulose hydrogen breath test and found that 21/74 (28%) of subjects were affected by SIBO and delayed oro-caecal transit time. After treatment with rifaximin, three patients still showed SIBO, five persistent delayed transit time without SIBO and 13 persons (62%) experienced a significant improvement in their oro-caecal time (without SIBO)[78]. Reddymasu *et al*[79] used hydrogen and methane breath tests after glucose challenge. Thirty out of fifty (60%) patients had a positive breath test result for SIBO on the basis of hydrogen (63%), methane (27%) or both criteria (10%). SIBO was more likely in diabetic patients with gastroparetic symptoms of longer duration[79].

In about one third of patients with diabetes, SIBO was associated with cardiovascular autonomic neuropathy[77]. SIBO in diabetes may rarely manifest itself as protein-losing enteropathy[80].

Radiation enteropathy

SIBO and lactose intolerance may occur during and/or after pelvic (or abdominal) radiotherapy[81-83].

Fibromyalgia

Pimentel *et al*[14] found that 42/42 (100%) patients with fibromyalgia had an abnormal lactulose hydrogen breath test. This was a significantly higher rate compared to patients with irritable bowel syndrome (93/111, 84%) and clinically healthy persons used as a control (3/15, 20%). Patients with fibromyalgia also had a higher hydrogenic profile that correlated with somatic pain[14].

Other disorders and diseases associated with SIBO

Various diseases and disorders have been described to be associated with or complicated by SIBO, such as lymphoproliferative diseases (lymphoma, chronic lymphocytic leukaemia), benign lymphoid hyperplasia of the ileum, metabolic bone disease, acromegaly, hypothyreosis, alcoholism and rosacea[7,84-87]. The prevalence of SIBO rises with age (about 50% in persons > 75 years old)[88].

MICROBIOLOGY, PATHOGENESIS, PATHOPHYSIOLOGY AND PATHOLOGY

The total bacterial count in the proximal jejunum is < 10^4 bacteria per mL of jejunal content in healthy people. In the ileum, enteric bacterial populations increase in amount (including coliforms) up to 10^9 CFU/mL in the terminal ileum. There are several beneficial effects of normal small intestinal bacteria to the host. They can be extrapolated from experimental studies in germ-free animals. The small intestinal villi of these animals are thin and unusually regular, with relatively shortened crypts. The enterocytes are cuboidal rather than columnar. In addition, the number and size of Peyer's patches, the degree of leukocyte infiltration in the lamina propria, and the rate of mucosal regeneration are reduced. The introduction of micro-organisms rapidly restores the normal morphologic appearance and physiologic function of the small bowel mucosa[7].

Normal autochthonous bacterial flora of the gastrointestinal tract is an important factor for preservation of its integrity and normal functioning in humans. They participate in the protection of macro-organisms against pathogenic micro-organisms, stimulate the human immune system and influence the metabolic and trophic function of the intestinal mucosa. Enteric bacteria produce some nutrients (e.g. short-chain fatty acids) and vitamins such as folates and vitamin K. Last but not least, they impact the sensor and motor function of the gut. On the other hand, intestinal bacteria are influenced by many factors, first of all by the amount and composition of food, but also by environmental (and geographic) effects, drugs, alcohol and probably by several other factors (lifestyle, psychosomatic stress, *etc.*)[5,89]. The prevalence of bacteria in different parts of the GI tract appears to be dependent on several factors, such as pH, peristalsis, redox potential, bacterial adhesion, bacterial co-operation and antagonism, mucin secretion, diet and nutrient availability[90].

There are several host defence mechanisms to prevent excessive colonisation of the small bowel by bacteria: antegrade peristalsis prevents attachment of ingested micro-organisms; gastric acid and bile destroy many micro-organisms before they leave the stomach; digestion by proteolytic enzymes helps destroy bacteria in the small intestine; the intestinal mucus layer traps bacteria; an intact ileo-caecal valve inhibits retrograde translocation of bacteria from the colon to the small bowel; the immune system plays a role as evidenced by the high prevalence of bacterial overgrowth in patients who have immunodeficiency; the largest fraction of immunoglobulins secreted in the human body is the secretory IgA originating in the gastrointestinal tract, which aids in preventing bacterial proliferation[7,91]. SIBO may develop if some of the natural defensive mechanisms of a macro-organism (listed above) are disrupted.

In most patients, SIBO is not caused by a single bacterial strain. In general, there is an extension of colonic bacteria into the small bowel. Less frequently, the "normal" amount of small intestinal bacteria increases. Bouhnik *et al*[92] investigated samples of jejunal juice in 63 patients with diarrhoea and/or malabsorption. The diagnostic criteria of SIBO were fulfilled in 55 persons (87%). The authors identified 141 micro-aerophilic strains (*Streptococcus* 60%, *Escherichia coli* 36%, *Staphylococcus* 13%, *Klebsiella* 11% and others) and 117 anaerobes (*Bacteroides* 39%, *Lactobacillus* 25%, *Clostridium* 20% and others)[92].

SIBO may be accompanied by both maldigestion and malabsorption. Bacteria in SIBO might significantly interfere with enzymatic, absorptive and metabolic actions of a macro-organism. Due to injury of the brush-border of enterocytes, the activity of disaccharideses may be decreased. If bacteria simultaneously metabolise fructose, lactose and sorbitol, malabsorption of saccharides may occur. Injured small intestinal mucosa can have undesirable consequences in increased intestinal permeability and/or protein-losing enteropathy. Deficiency of vitamin B_{12} results from the consumption of this vitamin by anaerobic micro-organisms. Bacteria may also utilise intraluminal protein in the small bowel, this may lead to protein deficiency for the macro-organism and excessive production of ammonia by bacteria. Deconjugation of bile acids by bacteria results in malabsorption of fat and liposoluble vitamins. Extensively formed lithocholic acid is poorly absorbable and acts enterotoxically[5,7,93-95].

Bacteria produce various toxic agents that may have surprising systemic effects. These agents are ammonia, D-lactate, endogenous bacterial peptidoglycans and others. SIBO is regularly associated with increased serum endotoxin and bacterial compounds stimulating production of (pro)inflammatory cytokines[7,96]. SIBO might be associated with endogenous production of ethanol (probably synthesised by *Candida albicans* and *Saccharomyces cerevisiae*). Serum ethanol disappears after successful treatment of SIBO[37].

Small intestinal bacterial overgrowth has a negative impact not only on the function but also on the morphological structure of the small bowel. Microscopic inflammatory changes (especially in the lamina propria) and villous atrophy are found regularly. In such a case, the villous atrophy in SIBO must be distinguished from that of coeliac disease. Macroscopic changes may also be visible in some patients. Hoog *et al*[97] found small intestinal mucosal breaks (erosions or ulcers) in 16/18 patients with chronic myopathic or neuropathic motility disorders of the small bowel by means of wireless capsule endoscopy.

In some patients with short bowel syndrome, bacterial overgrowth can, to some extent, paradoxically exert a favourable effect on the macro-organism. Bacteria may partly metabolise saccharides and thus form some further energy substrates more easily utilisable by a diseased human.

CLINICAL FEATURES

Clinical symptoms are expressed more or less according to the severity of involvement and they are modified by a primary underlying disease. SIBO may be clinically asymptomatic or can resemble irritable bowel syndrome with

non-specific symptoms (bloating, flatulence, abdominal discomfort, diarrhoea, abdominal pain). In more severe cases, there are signs of malabsorption (weight loss, steatorrhoea, malnutrition), liver lesion, skin manifestation (rosacea), arthralgias and deficiency syndromes (anaemia, tetany in hypocalcaemia induced by vitamin D deficiency, metabolic bone disease, polyneuropathy due to vitamin B_{12} deficiency, impaired barrier function of the gut, *etc.*). Anaemia is usually macrocytic (megaloblastic) due to vitamin B_{12} deficiency. It could also be microcytic iron deficiency (due to occult gastrointestinal blood loss) or normocytic (as anaemia of chronic disease)[3,5-7]. Serum folate and vitamin K levels are usually normal. Serum vitamin K can even be increased owing to its bacterial overproduction. Moreover, there are some concerns as to whether endogenous intestinal production of vitamin K by bacteria might interfere with warfarin treatment in SIBO[98-100]. In the case of oedema of lower extremities, the aetiology is usually more complex (anaemia, malnutrition, hypoproteinaemia, vitamin B_{12} deficiency).

D-lactic acidosis is a severe complication of patients with short bowel syndrome (with intact large bowel). It is caused by an excessive overgrowth of lactobacilli. Non-absorbed saccharides pass from the small intestine to the large bowel and they are fermented down to the D-isomer of lactic acid. There is no human pathway to metabolise D-lactic acid. D-lactic acid is absorbed from the large bowel; its serum concentration is regularly increased in these patients. Nevertheless, most patients remain asymptomatic. In clinically expressed cases, leading symptoms comprise characteristic neurologic abnormalities including confusion, cerebellar ataxia, slurred speech, and loss of memory. Patients exhibit some degree of altered mental status. They may complain of or appear to be drunk in the absence of ethanol intake. In the treatment, it is necessary to compensate metabolic acidosis and administer peroral antibiotics (metronidazole, rifaximin). To prevent this serious complication, it is important to reduce peroral intake of simple sugars, polysaccharides given in smaller amounts together with a higher intake of fat[101].

DIAGNOSTICS

It is mandatory to consider SIBO in all cases of complex non-specific dyspeptic complaints (bloating, abdominal discomfort, diarrhoea, abdominal pain), in motility disorders, anatomical abnormalities of the small bowel and in all malassimilation syndromes (malabsorption, maldigestion)[3,5-7].

Physical investigation usually provides non-specific findings and could be modified by a primary underlying disease. The abdomen may be distended and a small intestinal succussion splash might be identified. Physical investigation can further reveal latent tetany, polyneuropathy and skin manifestation (rosacea).

Laboratory tests usually find anaemia, low serum vitamin B_{12} levels and laboratory signs of malnutrition (lymphopenia, low serum prealbumin and transferrin).

The gold standard for diagnosing SIBO is still microbial investigation of jejunal aspirates. Such a sample can be obtained by a special sonde or by means of enteroscopy. Nowadays, there are commercially available special aspiration catheters (with a spiral pattern of holes at the distal tip) for contaminate-free collection of fluids. Microbial investigation places high demands on the quality of laboratory work (determination of quantitative proportion of anaerobes) and has several difficulties (low reproducibility and identifying cultivation-resistant bacteria). Distribution of bacterial overgrowth might be irregular and that is why a single investigation might not detect it. Bacterial overgrowth may be restricted to a particular, difficult-to-access area for aspiration (e.g. a blind loop)[7].

Hydrogen and methane breath tests are currently the most important diagnostic methods. The principles and methods of hydrogen and methane breath tests were described in detail elsewhere[102-105]. In humans, hydrogen and methane are exclusively produced by intestinal bacteria, namely in the large bowel in healthy people and also in the small intestine in the case of SIBO. About 80% of hydrogen and methane is expelled by flatus, 20% is exhaled by lungs and can be measured in breath[106]. Hydrogen and methane breath tests to diagnose SIBO are performed after peroral glucose or lactulose challenge. Most authors (including our Department) use gas chromatography for breath analysis. A parallel measurement of CO_2 and correction of hydrogen values to CO_2 concentration make the measurement more precise[7,74,103,104]. Low humidity (< 25%) must be maintained in the laboratory atmosphere to obtain consistent measurements. There is an early increase in breath hydrogen and/or methane (single early peak) after glucose administration due to bacterial glucose fermentation in the small bowel. There are two peaks in the lactulose breath test, the first one owing to bacterial activity in the small intestine, the second one after lactulose reaches the colon. Unfortunately, hydrogen and methane breath tests have not yet been standardised, particular protocols differ in dose (and concentration) of the test substrate, duration of tests, time intervals of breath sampling and basic and peak cut-off values. According to most authors, basal cut-off values of hydrogen and/or methane in positive breath tests are $\geqslant$ 20 parts per million (ppm), 10-20 ppm is a grey zone. After a glucose challenge, an increase $\geqslant$ 12 ppm at 120 min is a positive result for bacterial overgrowth. A lactulose breath test is assessed as positive if there is a biphasic course or an early plateau pattern with a hydrogen increase of $\geqslant$ 12 ppm is found (possibly with an increase in methane at the second peak)[104,107-110].

The hydrogen breath test is considered to be more accurate for the diagnosis of SIBO compared to the methane breath test according to most authors[111-114]. There is a sensitivity of 62.5% and specificity of 82% (diagnostic accuracy of 72%) after glucose and 52% and 86% (diagnostic accuracy of 55%) after lactulose administration[109]. Hydrogen alone, methane alone or both gases simultaneously might be found in breath samples. That is why it is important to always determine both gases in the breath samples. There are several advantages of hydrogen and methane breath tests. They are non-invasive, non-toxic,

relatively easily available and performed at a low cost.

However, hydrogen and methane breath tests have some drawbacks with possible false results and difficulties in their interpretation. Very rapid absorption of glucose in the proximal jejunum can be responsible for a false negative result. In the case of bacterial overgrowth in the terminal ileum, it might be difficult to distinguish a pathological ileal peak from a "normal peak" after the caecum is reached. In short bowel syndrome (with intact large bowel), the test substrate may reach the colon very quickly and cause a false positive result. In the case of a low density of anaerobes, breath can be false negative[109,113,115-117]. If there is only one peak of hydrogen recorded in the lactulose breath test and the second peak is absent for hydrogen and methane, this could be assessed as a combination of SIBO and fermentative colopathy[108]. Results of hydrogen and methane breath tests are usually difficult to interpret in the case of advanced lung disease. In the case of a high concentration of hydrogen and low concentration of methane, analytical precision for methane determination is less accurate[104].

All hydrogen and methane are produced by so called "hydrogenic and methanogenic" bacteria in humans[103,104,106,118]. However, most authors usually do not specify which particular bacteria constitute these producers. Nitrogen, oxygen, carbon dioxide, hydrogen and methane account for more that 99% of expelled intestinal gas. Hydrogen is produced by bacterial fermentation of saccharides in the intestinal lumen. Concurrently, hydrogen is consumed by other intestinal bacteria to synthesise methane, acetate and hydrogen sulphide. Methane is synthesised solely by bacteria in the intestine (four mmols of hydrogen and one mmol of carbon dioxide create one mmol of methane and water). This reaction reduces the volume of gas that would otherwise be present in the colon[119-124]. The question of intestinal methane producers has not been definitely solved yet. *Methanobrevibacter smithii*, *Methanosphaera stadtmanae* and other *Methanobacteriales* are able to synthesise methane and some authors consider *Methanobrevibacter* to be the major producer of methane in the gut of humans[125,126]. It was assumed (based on 16S ribosomal DNA studies) that *Methanobrevibacter smithii* could make up about one in ten of all the prokaryotes in the human gut[127]. However, there is no final proof available that *Archea* (*Methanobrevibacter* and others) would be the prevailing microorganisms in the methanogenic phenotype of the human gut. We hypothesised that common coliform bacteria could also synthesise methane[128], however, this assumption was not proved by our further studies[129,130]. McKay *et al*[131] found that several anaerobes (*Bacteroides*, *Clostridium* and others) produced hydrogen but rarely methane. Hydrogen is also produced by *Enterobacteriaceae*[128,132].

In adult Caucasians, only 30%-50% of persons produce methane while hydrogen is produced by 90%-98% of people[104]. Most subjects with lactose intolerance who do not produce hydrogen would form methane after lactulose administration instead of hydrogen[133]. Bile in the intestinal lumen is an important suppressor of methanogenesis in humans[134]. According to some authors, a methanogenic phenotype is associated with constipation[8,12]. Methane production has been related to more severe colonic impaction in children with encopresis[135]. Higher production of methane has been detected in colorectal adenomas and cancer[136]. However, there is a general agreement that constipation itself is not a risk factor for the development of colorectal cancer.

Hydrogen and methane breath tests can be combined with a simultaneous D-xylose breath test[107,110]. This combination increases the sensitivity of non-invasive diagnostics of SIBO[107,114]. The cholyl-1-^{13}C-glycine hydrolase breath test is another possible alternative for the diagnosis of SIBO. The principle of this test is based on the fact that bacterial overgrowth will cause more rapid deconjugation of cholyl-1-^{13}C-glycine[137]. The reported sensitivity for this test was 70%[138]. The lack of sensitivity was attributed to bacterial overgrowth with species lacking cholylglycine hydrolase[137]. On the other hand, patients with bile acids malabsorption in the ileum might have a false positive result in this breath test after rapid deconjugation of cholylglycine in the proximal colon[139]. Berthold *et al*[140] recently proposed a lactose-^{13}C-ureide breath test for the diagnosis of small bowel bacterial overgrowth. This test should have 100% specificity (and thus predict positive culture in SIBO) but lower sensitivity (66%)[140].

There are several other tests to diagnose SIBO, for instance evaluation of short-chain fatty acids in jejunal aspiration[141], serum non-conjugated bile acids, urinary output of p-aminobenzoic acid (after peroral administration of colil-PABA) or urinary indican[6]. However, none of these tests has yet acquitted itself well in routine clinical practice.

If it is impossible to perform any diagnostic test for SIBO (if no test is available for a particular department) on a patient with legitimate suspicion of SIBO, it is possible to consider the exceptional use of an empiric therapeutic test with rifaximin (for 7-10 d). Quick disappearance of symptoms supports a possible diagnosis of SIBO, however, this is not definite outright proof of SIBO. On the other hand, demonstration of SIBO is not 100% proof of causal association between bacterial overgrowth and clinical symptoms (or laboratory abnormal results).

In some patients with SIBO, secondary inflammatory changes might be found not only in the small bowel but also in the colon as a response to absorbed bacterial antigens. This inflammatory involvement can cause separate symptoms[7]. Successful treatment with 5-aminosalicylates and glucocorticosteroids supports this theory[142].

DIFFERENTIAL DIAGNOSIS

Diagnosis and differential diagnosis of SIBO is difficult if this possibility is not considered. It is necessary to distinguish functional disorders (of no organic cause) and chronic gastrointestinal infections (e.g. giardiasis).

The relationship between SIBO and irritable bowel syndrome was discussed above. Esposito *et al*[44] proposed use of the lactulose breath test to distinguish SIBO and

irritable bowel syndrome. Parodi *et al*[143] recommend differentiating patients fulfilling the diagnostic criteria of irritable bowel syndrome (IBS-like symptoms) from functional bloating. If SIBO is proved, the first group will profit from antibiotic treatment while the second group will not[143].

It is always necessary to consider SIBO in the case of unexplained deterioration of the clinical status of patients with Crohn's disease, chronic pancreatitis or scleroderma. SIBO must be taken into account in coeliac disease non-responding to adequate gluten-free diet. SIBO is a crucial point in the differential diagnosis of short bowel syndrome and all other malassimilation syndromes (both with maldigestion and malabsorption).

On the other hand, some other intestinal disorders might mimic SIBO and must be considered in the differential diagnosis. Flatulence, abdominal bloating and distension, and malabsorption of mono- or disaccharides (like fructose or lactose) must be taken into account. Pneumatosis cystoides intestinalis is usually asymptomatic but it may be associated with abdominal pain, bloating and/or diarrhoea[106].

PRINCIPLES OF TREATMENT

Therapy for SIBO must be complex (addressing all causes, symptoms and complications) and fully individualised. It should include treatment of the underlying disease, nutritional support and cyclical gastro-intestinal selective antibiotics.

The most important thing is always treatment of the basic underlying disease if possible. Nutritional support is mandatory in SIBO associated with malnutrition, weight loss and nutrient deficiency. We usually use individualised diet, enteral nutrition by fine-bore naso-jejunal tube or nutritional support by sipping of polymeric formulas. In several patients, it is necessary to exclude lactose from the diet, to reduce other simple sugars, to increase coverage of energy needs by fat and to administer MCT oils (medium-chain triacylglyceroles).

Antibiotic treatment should selectively target those bacterial strains that cause SIBO. The choice of antibiotics should be based on sensitivity testing to particular antibiotics. However, this requirement is difficult to achieve in clinical practice as various bacteria are usually found simultaneously, each with different sensitivity to antibiotics. There is no common agreement concerning choice, dosing and duration of antibiotic therapy. In general, long-term treatment with broad-spectrum antibiotics is not the optimal solution as such a therapy is associated with several problems (intolerance by the patient, dysmicrobia, diarrhoea, *Clostridium difficile* expansion, possible increased resistance to antibiotics, financial cost, *etc.*).

Tetracycline was considered the treatment of choice for a long time. Di Stefano *et al*[144] administered tetracycline to patients with SIBO for 7 d (1000 mg/d) and achieved normalisation of the hydrogen breath test together with relief of symptoms in only 3/11 (27%) subjects[144]. Various antibiotics were tried in other small clinical studies. Attar *et al*[145] administered a placebo, norfloxacin (800 mg/d), amoxicillin clavulanate (1500 mg/d) and *Saccharomyces boulardii* (1500 mg/d) successively in 7-d intervals in 10 patients. Norfloxacin and amoxicillin clavulanate significantly decreased the frequency of diarrhoea compared to the placebo (in 9/10 and 6/10 patients, respectively), but the hydrogen breath test was normalised in only 3 and 5 subjects[145]. In Crohn's disease, Castiglione *et al*[56] achieved normalisation of the hydrogen breath test in 13/15 (87%) persons treated with metronidazole (750 mg/d) and in 14/14 (100%) treated with ciprofloxacin (1000 mg/d)[56]. Di Stefano *et al*[146] divided 21 patients with a blind loop syndrome into three different treatment groups: (1) rifaximin followed by metronidazole, or (2) two courses of metronidazole, or (3) two courses of rifaximin. Both antibiotics were effective; metronidazole markedly reduced both hydrogen breath tests and patients' symptoms[146]. However, rifaximin was more effective than metronidazole in another study (63% *vs* 44%)[147]. A drawback in all of these studies was not only the small set of patients but also the absence of long-term follow-up. Pimentel *et al*[12] administered neomycin or a placebo to 111 patients with irritable bowel syndrome (84% abnormal lactulose breath test). Neomycin improved both symptoms and the breath test in 35% of persons compared with 11% in the placebo group[12]. Some other peroral antibiotics, such as cephalexin, trimethoprim-sulfamethoxazole, levofloxacin and gentamicin were used for the therapy of SIBO[7].

The greatest experience for treatment of SIBO was acquired with rifaximin[43,148-154]. Rifaximin is a semi-synthetic rifamycin-based non-systemic antibiotic, with a low gastrointestinal absorption and good bactericidal activity. The antibacterial action covers Gram-positive and Gram-negative organisms, both aerobes and anaerobes[155]. According to different studies, rifaximin improves symptoms in 33%-92% and eradicates small intestinal bacterial overgrowth in up to 80% of patients[151,152]. Most authors recommend administering rifaximin for 7-10 d as one treatment course or as a cyclic therapy. Higher doses (1200 or 1600 mg/d) are more effective than standard doses (600 or 800 mg/d)[148,154]. Rifaximin is probably the only antibiotic that is capable of achieving a long-term favourable clinical effect in patients with irritable bowel and SIBO[43].

Prebiotics and probiotics exert various beneficial effects in the macro-organism, they strengthen the barrier function of the gut, inhibit several pathogens, modify the inflammatory response of the bowel, and they also reduce visceral hypersensitivity[156-159]. They seem to be more effective in influencing the clinical symptoms of irritable bowel syndrome compared to a placebo[159,160]. Studies dealing with the therapeutic use of prebiotics or probiotics in SIBO (except irritable bowel syndrome) are limited[161-163], and it is not therefore possible to recommend them for general clinical use[157,158]. *Lactobacilli*-based probiotics are contraindicated in patients with a risk of D-lactic acidosis. Very little data are available from experimental studies. Short-term administration of the hydrogenic probiotic *Escherichia coli 1917 Nissle* (3.5×10^{10} bacteria per

day for 14 d) did not influence methanogenic phenotype of experimental non steroidal anti-inflammatory drug-enteropathy in pigs[129].

Prokinetics seem to be a logical therapeutic step in SIBO due to motility disorders. Several studies tried metoclopramide, cisapride (which was later withdrawn from the market), domperidone, erythromycin, itopride, tegaserod and octreotide. However, there are only limited data suggesting that this treatment would be effective over the long term[7,71]. Cyclic lavages of the small bowel (e.g. by polyethylene glycol) can be considered as supportive therapy in cases of relapsing SIBO[7].

Surgical treatment must always be considered where possible to correct gastrointestinal pathology (entero-colic fistulae, blind loops, bowel obstruction, multiple small intestinal diverticula, *etc.*). Specialised non-transplant surgery can provide interventions in short bowel syndrome improving intestinal motility (STEP - serial transverse enteroplasty), slowing intestinal transit (valves, reversed segments, colon interposition) or increasing mucosal surface area of the gut (creation of "neo-mucosa", sequential intestinal lengthening)[164].

PROGNOSIS

The prognosis of SIBO is determined mostly by the underlying disease leading to bacterial overgrowth. Ultimately SIBO might result in intestinal failure[61]. In scleroderma with gastrointestinal involvement (SIBO, intestinal pseudo-obstruction, malnutrition), the overall 5-year mortality is more than 50%[71].

The relapse rate of SIBO after successful treatment is high. Lauritano *et al*[165] found recurrence of SIBO in 44% (35/80) of patients nine months after successful treatment with rifaximin. Apart from the basic underlying disease, further risk factors for recurrence of SIBO have been identified including older age (OR 1.1), appendectomy in the patient's history (OR 5.9) and long-term treatment with proton pump inhibitors (OR 3.5)[165].

CONCLUSION

SIBO is defined as an increase in the number and/or alteration in the type of bacteria in the upper gastrointestinal tract. The aetiology of SIBO is usually complex, associated with disorders of protective antibacterial mechanisms (e.g. achlorhydria, pancreatic exocrine insufficiency, immunodeficiency syndromes), anatomical abnormalities (e.g. small intestinal obstruction, diverticula, fistulae, surgical blind loop, previous ileo-caecal resections) and/or motility disorders.

SIBO is often misdiagnosed and generally underdiagnosed. Clinical symptoms might be non-specific (dyspepsia, bloating, abdominal discomfort). Nevertheless, SIBO can cause severe malabsorption, serious malnutrition and deficiency syndromes. Non-invasive hydrogen and methane breath tests after glucose or lactulose challenge are most commonly used for the diagnosis of SIBO. Therapy of SIBO must be complex and should include treatment of the underlying disease, nutritional support and cyclical gastrointestinal selective antibiotics. Prognosis is usually serious, determined mostly by the underlying disease that led to SIBO.

Abstract

The mesenteric lymph node cavitation syndrome consists of central necrosis of mesenteric lymph nodes and may occur with either celiac disease or a sprue-like intestinal disease that fails to respond to a gluten-free diet. Splenic hypofunction may also be present. The cause is not known but its development during the clinical course of celiac disease is usually indicative of a poor prognosis for the intestinal disorder, a potential for significant complications including sepsis and malignancy, particularly T-cell lymphoma, and significant mortality. Modern abdominal imaging modalities may permit earlier detection in celiac disease so that earlier diagnosis and improved understanding of its pathogenesis may result.

INTRODUCTION

Over 50 years ago, mesenteric lymph node changes were described in celiac disease[1-3]. At that time, definition of most changes in abdominal lymphoreticular structures relied largely on surgical observation or postmortem evaluation. In addition, altered abdominal lymphoreticular function was also evident, reflected in reduced splenic function[4-6]. In recent years, refinements in abdominal imaging, i.e. ultrasound, computed tomography (CT), magnetic resonance imaging (MRI) and positron emission tomography, have led to improved and earlier documentation of lymphoreticular changes in celiac disease. Neoplastic (i.e. lymphoma) and non-neoplastic changes, including mesenteric lymph node cavitation, have been recorded.

MESENTERIC LYMPH NODE CAVITATION SYNDROME

Detailed descriptions of this entity appeared largely in the French literature[7-9]. These reports described an unusual syndrome that seemed to complicate the clinical course of adult celiac disease. While typical small intestinal mucosal biopsy changes of celiac disease were present, the most intriguing observation was the definition of cavitated mesenteric lymph nodes. In addition, splenic atrophy or splenic hypofunction appeared to be present, raising the spectra of impaired immune function and a specific infectious cause.

Matuchansky and collegues[10], in a seminal report, noted details of 6 cases that included 4 females and 2 males. Within the jejunoileal mesenteric nodes, pseudocystic lesions were detected that consisted histologically of a large central cavity occupied by hyaline-type material surrounded by fibrous tissue and lymph node remnants. Evidence of mesenteric panniculitis or malignant lymphoma was not detected. Persistent diarrhea or childhood diarrhea along with malabsorption accompanied the small intestinal changes. An unequivocal mucosal response to a gluten-free diet was shown in some cases confirming that celiac disease was present. In others, a definitive response to a gluten-free diet could not be documented suggesting

that either a resistant form of celiac disease or sprue-like intestinal disease was present. Similar features have been noted with other complicating disorders (e.g. lymphoma) in both adult celiac disease or sprue-like intestinal disease[11]. Microscopic examination of the lymph nodes in these cases usually shows some common features. Atrophic cavitated lymph nodes are usually present without evidence of infection or malignancy in the lymph nodes. Central acidophilic lipid-containing fluid is usually present surrounded by a rim of residual lymph node tissue that includes follicles, sinus and capsular components. The changes historically have appeared to be confined to the mesenteric lymph node chain.

HYPOSPLENISM

Another important, although not essential[4-6], component of this clinical syndrome appears to be splenic atrophy or splenic hypofunction. While splenic changes have been previously noted in other intestinal disorders (e.g. inflammatory bowel disease)[12], mesenteric lymph node cavitation was seen only in those with pathological changes of celiac disease or sprue-like small intestinal disease, and not with inflammatory bowel disease[10]. In early studies, splenic atrophy was often defined structurally during postmortem evaluation or abdominal surgery. More recently, these changes tended to be defined with modern imaging methods. Hyposplenism, indicative of reduced splenic function, appeared to reflect this structural change in the spleen, and depending on its mode of measurement, seemed to be quite common in celiac disease[6]. The latter disorder may be suspected from a peripheral blood smear with Howell-Jolly bodies, monocytosis, lymphocytosis and increased platelet counts, and confirmed with pitted red blood cells counts or radiolabeled colloid scanning of the spleen[13-15]. In celiac disease, for example, 76.2% of patients were found to have pitted red blood cells[6]. These may also occur during the clinical course of many other disorders, apart from celiac disease or sprue-like intestinal disease[13-15]. These disorders include dermatitis herpiformis[16], collagenous sprue[17], collagenous colitis[18] and abdominal lymphoma[14,19], all disorders intimately linked to celiac disease[19-21]. Hyposplenic patients have been reported to be at increased risk for bacterial sepsis, especially with encapsulated organisms such as pneumococcus, sometimes with a fatal outcome[22], so vaccination using the pneumococcal conjugate has been recommended[14]. The risk of sepsis appears to be more significant if a diagnosis of celiac disease is established during adult years rather than in childhood[23]. There may also be a higher risk for vascular, autoimmune and thrombotic disorders along with solid tumors[14]. In celiac disease with associated autoimmune or malignant complications, IgM memory B-cells were reduced suggesting a possible mechanism leading to infections by encapsulated bacteria[14]. Resolution of reduced splenic function appears to be possible, but only after improvement of small intestinal mucosal changes has occurred[6].

LONG-TERM NATURAL HISTORY AND COMPLICATIONS

Most early reports indicated that cavitation of mesenteric lymph nodes was associated with a very poor prognosis with a mortality of about 50%[24]. Nevertheless, dramatic improvement has also been recorded with complete normalization of the mesenteric lymph nodes[25,26].

In celiac disease with associated dermatitis herpetiformis, recurrent diarrhea, steatorrhea and protein-losing enteropathy were defined followed later by hyposplenism, mesenteric lymph node cavitation and malignant lymphoma of the small intestine[27]. In another case of mesenteric lymph node cavitation, lymphoma also developed with a sprue-like intestinal lesion that did not respond to a gluten-free diet[28]. Cavitation of mesenteric lymph nodes may also occur without celiac or other small bowel disease[29]. Bacterial infections may be associated with necrosis of lymph nodes (e.g. mycobacteria, *Yersinia*) and lymph node cavitation has been reported with Whipple's disease[30]. Necrotizing lymphadenitis may also occur with systemic lupus erythematosus[31], and this appears to be pathologically similar to Kikuchi-Fujimoto disease, a self-limited form reported in young Asian adults[32]. In celiac disease, however, malignant lymphoma may also be the cause of necrotic mesenteric lymph node changes[33]. In one report, these necrotic lesions were seen in the liver and spleen due to hepatosplenic type lymphoma, a rare type of peripheral T-cell lymphoma with T-cell receptor rearrangement[33]. In a more recent case report, progressive encephalopathy and focal lesions of the cerebellum and brainstem were associated with abnormal T-cell clones in a sprue-like disorder with mesenteric and mediastinal lymph node cavitation[34]. Finally, a case of necrotizing hepatitis with celiac disease and mesenteric lymph node cavitation was recently described, but lymphoma was not detected[35].

CONCLUSION

This syndrome is an intriguing entity or group of entities frequently associated with celiac disease or sprue-like intestinal disease consisting of cavitated mesenteric lymph nodes and, often, splenic hypofunction. Cavitated mesenteric nodes should be differentiated from other causes of mesenteric cystic lesions, including lymphatic cysts or cystic lymphangioma. These have also been recorded with celiac disease and hyposplenism[36]. Although diagnosis is usually confirmed by pathological evaluation of mesenteric lymph nodes, imaging studies may be very helpful. Ultrasound may show anechoic cysts up to 8 cm in size. CT may reveal low attenuation (fluid or fat) lymphadenopathy suggesting celiac disease, Whipple's disease, infections such as tuberculosis, lymphoma or necrotic metastases, including germ cell tumors[37]. Occasionally, fluid-fat levels are appreciated in the lymph node, reported only in celiac disease[37]. MRI may be useful as the fluid and fat layer may be appreciated in T2- and T1-weighted axial images, even if fluid-fat levels are not seen on CT[38]. In some cases, image-guided fine-needle aspiration of the

cyst may be performed[38]. The cause of cavitation syndrome is usually not defined. The mesenteric lymph node cavitation changes have been hypothesized to represent excess antigen exposure via damaged small bowel mucosa causing lymphoid cell depletion in the lymph nodes and spleen. Alternatively, changes may reflect necrosis in the mesenteric nodes triggered by localized immune-mediated complement activation and intravascular coagulation[38]. Specific infections and malignant lymphoma may complicate its natural history and clinical course and contribute to its poor prognosis.

Abstract

AIM: To investigate the effect of emodin on expression of claudin-4, claudin-5 and occludin, as well as the alveolar epithelial barrier in rats with pancreatitis induced by sodium taurocholate.

METHODS: Experimental pancreatitis was induced by retrograde injection of 5% sodium taurocholate into the biliopancreatic duct. Emodin was injected *via* the external jugular vein 3 h after induction of acute pancreatitis. Rats from sham operation group and acute pancreatitis group were injected with normal saline (an equivalent volume as emodin) at the same time point. Samples of lung and serum were obtained 6 h after drug administration. Pulmonary morphology was examined with HE staining. Pulmonary edema was estimated by measuring water content in lung tissue samples. Tumor necrosis factor-α (TNF-α) and interleukin-6 (IL-6) level were measured by enzyme-linked immunospecific assay. Serum amylase and pulmonary myeloperoxidase (MPO) activity were detected by spectrophotometry. Alveolar epithelial barrier was assessed by pulmonary dye extravasation. Expression of claudin-4, claudin-5 and occludin in lung tissue samples was examined by immunohistology, quantitative real-time reverse transcription polymerase chain reaction and Western blotting analysis, respectively.

RESULTS: Pancreatitis-associated lung injury was characterized by pulmonary edema, leukocyte infiltration, alveolar collapse, and elevated serum amylase level. The pulmonary damage, pulmonary pathological scores, serum amylase and MPO activity, TNF-α and IL-6 levels, and wet/dry ratio were decreased in rats after treatment with emodin. Immunostaining of claudin-4, claudin-5 and occludin was detected in lung tissue samples from rats in sham operation group, which was distributed in alveolar epithelium, vascular endothelium, and bronchial epithelium, respectively. The mRNA and protein expression levels of claudin-4, claudin-5 and occludin in lung tissue samples were markedly decreased, the expression level of claudin-4, claudin-5 and occluding was increased, and the pulmonary dye extravasation was reduced in lung tissue samples from rats with acute pancreatitis after treatment with emodin.

CONCLUSION: Emodin attenuates pulmonary edema and inflammation, enhances alveolar epithelial barrier function, and promotes expression of claudin-4, claudin-5 and occludin in lung tissue samples from rats with acute pancreatitis.

INTRODUCTION

Acute pancreatitis is a common disease with a considerable morbidity and mortality of 20%[1,2]. Its mortality is attributed to inflammation-related complications, such as pancreatitis-associated lung injury, clinically presenting as adult respiratory distress syndrome[2-4]. Intervention can reduce its morbidity and mortality, although its mechanism remains unclear[4].

Pancreatitis-associated lung injury is characterized by significant pulmonary edema, hyperemia and inflammatory infiltration in alveoli[5]. It has been established that pulmonary edema is related to increased permeability and loss of barrier function[2-5]. Although elevated levels of pancreatic enzymes and pro-inflammatory cytokines are attributed to pulmonary vasculature damage and increased endothelial permeability[6], the molecular basis for these damages remains largely undefined. Tight junctions are intimately involved in epithelial and endothelial permeability[7]. Fernandez *et al*[8] recently demonstrated that claudins, the key components of tight junctions, restrict the paracellular movement of water, proteins, and solutes across cellular barriers including alveolar epithelium. In mammals, the claudin family includes at least 24 members. With small interfering RNA and a blocking peptide, Wray *et al*[9] described that inhibition of claudin-4 decreases transepithelial electrical resistance in primary rat and human epithelial cells, as well as air space fluid clearance, resulting in pulmonary edema in mice, suggesting that claudin-4 plays an important role in alveolar epithelial barrier function. Moreover, claudin-5 and occludin are also decreased in models of acute lung injury accompanying increased paracellular permeability, indicating that claudin-5 and occludin may also play a role in alveolar epithelial barrier function[10-12]. However, the relation between expression of claudin-4, claudin-5, and occludin in lung tissues of patients with acute pancreatitis and pancreatitis-associated lung injury remains largely undefined.

It was reported that emodin (1,3,8-trihydroxy-6-methyl-anthraquinone), an anthraquinone derivative from the Chinese herb *Radix et Rhizoma Rhei*, inhibits the production of inflammatory cytokines such as tumor necrosis factor-α (TNF-α)[13]. Our previous study demonstrated that emodin significantly reduces serum TNF-α and interleukin-6 (IL-6) levels, thus attenuating lung injury in rats with acute pancreatitis[14]. The effect of emodin on pulmonary tight junction expression and alveolar epithelial barrier function, however, needs to be further defined.

In the present study, the effect of emodin on pancreatitis-associated lung injury and alveolar epithelial barrier function was assessed by examining pulmonary morphology, myeloperoxidase (MPO) activity (indicator of inflammatory infiltration), expression of claudin-4, claudin-5 and occludin, as well as dye extravasation, in lung tissue samples from rats with acute pancreatitis.

MATERIALS AND METHODS

Animals

Adult male Sprague-Dawely rats, weighing 200-250 g, obtained from Animal Facility of Jinling Hospital (Nanjing, China), were housed under controlled temperature and humidity in a day-night cycle, with free access to standard laboratory foot and water. The study was approved by Animal Studies Ethics Committee of Jinling Hospital.

Experiment model

Acute pancreatitis was induced as previously described[15]. Briefly, animals were anesthetized with intraperitoneal ketamine (80 mg/kg) and acepromazine (2.5 mg/kg). The biliopancreatic duct was cannulated through the duodenum, and the hepatic duct was closed with a small bulldog clamp. Pancreatitis was induced by retrograde injection of 5% sodium taurocholate (Sigma, St. Louis, MO, USA) into the biliopancreatic duct (1 mL/kg body weight), at a constant infusion pressure of 20 mmHg. Rats in sham operation group received retrograde sterile saline infusion.

Experiment design

Effect of emodin on expression of claudin-4, claudin-5 and occludin, as well as on pulmonary dye extravasation, a marker to evaluate alveolar epithelial barrier, was detected in rats with acute pancreatitis. Time course of pulmonary edema and inflammation was recorded. Rats with acute pancreatitis were randomly allocated into pancreatitis group and emodin treatment group. Rats in pancreatitis group were injected with emodin (2.5 mg/kg body weight) *via* the external jugular vein 3 h after sodium taurocholate infusion. Rats in sham operation group were injected with normal saline (equivalent volume as emodin) at the same time point and served as a control group.

Lung tissue samples were obtained 6 h after emodin injection, and maintained at -80℃ until assay. Blood samples were obtained from the inferior cava vein by direct puncture. Lung tissue samples were fixed in 4% neutral phosphate-buffered formalin and embedded in paraffin wax for histology examination. Serum amylase activity was detected to confirm the appropriate induction of pancreatitis.

Measurement of serum amylase level

Serum amylase level was measured by incubating serum with 4,6-ethylidene (G7)-p-nitrophenyl (G1)-1-D-maltoheptoside for 2 min at 37℃, with its absorbance detected once a minute for 2 min at 405 nm by high through universal microplate assay (BMG Lab Technologies, Germany).

Histological examination

Lung tissue sections were stained with hematoxylin and eosin. An experienced pathologist and a pancreatic specialist assessed tissue alterations under light microscope in a blinded fashion and scored them with a grading system[16]. The grading involved measurements of inflammatory infiltration, pulmonary edema and alveolar collapse, each on a scale of 0-3, giving a maximum score of 9.

Measurement of pulmonary cytokine level and MPO activity

TNF-α and IL-6 levels in lung tissue samples were measured using a sandwich enzyme-linked immunospecific assay (Jingmei Biotech, Beijing, China) according to its manufacturer's instructions. Absorbance was measured at 450 nm by high through universal microplate assay. Tissue homogenate was corrected with the protein concentration and expressed as per protein in lung tissue (pg/mg protein).

Sequestration of neutrophils in lung tissue samples was evaluated by measuring tissue MPO activity[15,17]. Briefly, lung tissue samples were homogenized with 0.5% hexadecyltrimethylammonium bromide (Sigma, St. Louis, MO, USA) in 50 mmol/L phosphate buffer (pH 6.0). Homogenate was sonicated for 10 s, freeze-thawed three times, and centrifuged at 14000 *g* for 15 min. The resulted suspension was used for assay. The assay mixture contained 20 μL of supernatant, 10 μL of tetramethylbenzidine (final concentration 1.6 mmol/L), and 70 μL of H_2O_2 (final concentration 3.0 mmol/L). MPO activity was assessed photometrically at 630 nm. The results were corrected with the protein concentration and expressed as the activity of per protein in lung tissue (U/mg protein).

Evaluation of pulmonary edema and alveolar epithelial barrier function

Severity of pulmonary edema was estimated by measuring water content in lung tissue samples. Freshly blotted lung tissue samples were weighed on an aluminum foil, dried for 24 h at 95℃, and reweighed. Difference in wet and dry tissue weights was calculated and expressed as wet/dry ratio.

Alveolar epithelial barrier function was evaluated by measuring Evans blue (Sigma, St. Louis, MO, USA) extravasation[18]. Briefly, Evans blue (20 mg/kg body weight) was injected into the jugular vein of rats, 30 min before duct infusion. Lung tissue samples were obtained 6 h after duct infusion, sectioned and immersed in a formamide solution, homogenized for 2 min. After incubation at room temperature for 24 h, the suspension was centrifuged at 4000 *g* for 30 min. The amount of dye extracted was determined spectrophotometrically at 620 nm and calculated from a standard curve established with a known amount of Evans blue. Results were corrected by the wet/dry lung tissue ratio and expressed as the dye content per dry weight of lung tissue (μg/g tissue).

Western blotting analysis

Western blotting analysis was performed as previously described[19]. Total protein (20 μg) was separated from each sample by electrophoresis on a 4%-20% SDS-polyacrylamide gel and electroblotted onto polyvinylidene difluoride membranes. Membranes were blocked in a blocking solution, incubated overnight with primary antibodies, and developed with a horseradish peroxidase-conjugated secondary antibody (Kangchen Biotech, Shanghai, China) diluted at 1:1000. Primary antibody (Zymed Laboratories, South San Francisco, CA, USA) was diluted as follows: claudin-4 at 1:100, claudin-5 at 1:100, and occludin at 1:300. The immune complexes were then visualized on X-ray film using chemiluminecent HRP substrate (Millipore, Boston, MA, USA). Additional immunoblots were performed using GAPDH antibody (Abcam, OFW, UK) as the primary antibody to evaluate equal loading.

Immunohistological analysis

Lung tissue sections (4 μm) were dewaxed in graded alcohols, and washed with tap water. Endogenous peroxidase activity was blocked with 3% (v/v) H_2O_2, and antigen was retrieved with microwave in 0.01 mol/L citrate buffer. The sections were then washed with phosphate-buffered saline (PBS, 0.1 mol/L). Mouse anti-rat claudin-4 and claudin-5, and rabbit anti-rat occludin polyclonal antibodies (Zymed Laboratories, South San Francisco, CA, USA) were diluted at 1:100 and incubated overnight at 4℃. The sections were washed 4 times with PBS, 5 min once. Power vision two-step histostaining reagent (ImmunoVision Technologies, Norwell, MA, USA) was used for detection of claudin and occludin expression. All sections were developed using diaminobenzidine and counterstained with hematoxylin.

Quantitative reverse transcriptase-polymerase chain reaction analysis

Total RNA was extracted with a TRIzol kit (Invitrogen Carlsbad, CA, USA) and converted to cDNA with a first strand cDNA synthesis kit (Fermentas, Burlington, Canada). Quantitative reverse transcriptase-polymerase chain reaction (RT-PCR) was performed using SYBR Green SuperMix-UDG (Invitrogen Carlsbad, CA, USA). The primer sequences used for PCR are as follows: claudin-4 (forward 5'-CCTTTCCCATACGGTCTTGCT-3', reverse 5'-CCCGTACCTTCCACAGACTG-3'), claudin-5 (forward 5'-TACTCAGCACCAAGGCGAACCAC-3', reverse 5'-GCGGCTTCCCACATCGGTC-3'), occludin (forward 5'-AGTACATGGCTGCTGCTGATG-3', reverse 5'-CCCACCATCCTCTTGATGTGT-3'), GAPDH (forward 5'-CAGTGCCAGCCTCGTCTCATA-3', reverse 5'-TGCCGTGGGTAGAGTCATA-3'). Amplification was performed at 50℃ for 2 min (UDG incubation), at 95℃ for 2 min, followed by 40 cycles of denaturing at 95℃ for 15 s and annealing at 60℃ for 30 s. All reactions were performed in triplicate. Melting curve analysis was performed to ensure the specificity of quantitative PCR. Data analysis was performed as previously described[20], with GAPDH used as a reference gene.

Statistical analysis

Data were expressed as mean ± SD. ANOVA was used to analyze differences between experimental and control groups. Student-Newman-Kleus method was used for multiple pair-wise comparisons. All statistical analyses were carried out using the SPSS version 11.5 for Windows (Chicago, IL, USA). $P < 0.05$ was considered statistically significant.

RESULTS

Emodin attenuated pulmonary edema and inflammation in rats with acute pancreatitis

The appropriate induction of pancreatitis-associated lung injury was demonstrated by histology and elevated serum amylase activity (Figure 1 and Table 1). Lung injury was characterized by pulmonary edema, leukocyte infiltration, and alveolar collapse. Pulmonary pathological scores and serum amylase activity were significantly lower after treatment with emodin.

Pulmonary edema was evaluated by measuring the water content in lung tissue samples and expressed as wet/dry ratio, which was significantly decreased after treatment with emodin (Table 1).

In the present study, the effect of emodin on pulmonary inflammation and MPO activity was evaluated. The TNF-α and IL-6 levels and MPO activity were decreased after treatment with emodin (Table 2).

Emodin promoted expression of claudin-4, claudin-5 and occludin in rats with acute pancreatitis

The expression levels of claudin-4, claudin-5, and occludin were markedly lower in experimental group than in control group (data not shown). Immunolocalization of claudin-4, claudin-5 and occludin in lung tissue samples was investigated with immunohistochemical staining. Moderate immunostaining of claudin-4, claudin-5, and occludin was detected in control group, which was distributed in alveolar epithelium, vascular endothelium, and bronchial epithelium, respectively (Figure 2A, D and G). Immunostaining of claudin-4, claudin-5, and occludin was markedly decreased in experimental group (Figure 2B, E and H), and moderately elevated after treatment with emodin (Figure 2C, F and I).

RT-PCR analysis showed that emodin could increase the expression levels of claudin-4, claudin-5, and occludin mRNA in rats with acute pancreatitis (Figure 3A).

Western blotting analysis showed that the expression levels of claudin-4, claudin-5, and occludin were significantly higher in emodin treatment group than in pancreatitis group (Figure 3B and C).

Emodin enhanced alveolar epithelial barrier function in rats with acute pancreatitis

The pulmonary dye extravasation, as a marker of local paracellular permeability, was significantly reduced in rats with acute pancreatitis after treatment with emodin, indicating that emodin can augment alveolar epithelial barrier function (Figure 4).

Table 1 Serum amylase level and pulmonary pathological scores in different groups (mean ± SD)

Group	Amylase (U/mL)	Edema (wet/dry)	Pathological score
Sham	3.5 ± 0.4	1.7 ± 0.2	0.3 ± 0.1
Pancreatitis	13.8 ± 1.6[a]	6.4 ± 0.5[a]	7.4 ± 0.8[a]
Emodin	8.2 ± 1.1[c]	4.1 ± 0.6[c]	4.8 ± 0.7[c]

Six rats were studied in each experimental group. [a]$P < 0.05$ *vs* sham group; [c]$P < 0.05$ *vs* pancreatitis group.

Table 2 Pulmonary cytokines and MPO in different groups (mean ± SD)

Group	TNF-α (pg/mg protein)	IL-6 (pg/mg protein)	MPO (U/mg protein)
Sham	2.8 ± 0.3	25.8 ± 2.9	3.1 ± 0.3
Pancreatitis	34.1 ± 3.5[a]	114.4 ± 12.6[a]	25.8 ± 2.9[a]
Emodin	25.4 ± 2.4[c]	93.0 ± 9.8[c]	20.3 ± 1.9[c]

Six rats were studied in each experimental group. [a]$P < 0.05$ *vs* sham group; [c]$P < 0.05$ *vs* pancreatitis group. MPO: Myeloperoxidase; TNF: Tumor necrosis factor.

DISCUSSION

In the present study, we identified the down-regulation of claudin-4, claudin-5, and occludin in rats with acute pancreatitis induced by sodium taurocholate. Intravenous administration of emodin promoted the down-regulation of tight junctions, enhanced alveolar epithelial barrier function, attenuated pulmonary edema and inflammatory infiltration in rats with acute pancreatitis.

Among the systemic complications of severe acute pancreatitis, pulmonary complication, also known as pancreatitis-associated lung injury, is the most frequent and serious[6]. Pancreatitis-associated lung injury is characterized by significant pulmonary edema, hyperemia and inflammatory infiltration in alveoli[5]. Increased interstitial edema cuts down the transport of carbon dioxide through the alveolar barrier, causing respiratory distress syndrome. It has been recently reported that claudins, the key components of tight junctions, restrict paracellular movement of water, proteins, and solutes across cellular barriers including pulmonary vascular endothelium and alveolar epithelium[8]. Disruption of claudins impairs barrier function and increases paracellular permeability, which may allow noxious contents to enter pulmonary interstitium and alveoli, further aggravating pulmonary edema and inflammation[5-9].

Recently, several studies have demonstrated the localization and function of claudin-4 in pulmonary cellular barriers[9-11]. In human airway epithelia, elevated claudin-4 level is associated with increased transepithelial electrical resistance, indicating that claudin-4 plays a role in alveolar epithelial barrier function[10]. Although increased claudin-4 expression has been found in a mice model of acute lung injury, inhibition of claudin-4 can lead to pulmonary edema in mice by decreasing transepithelial electrical

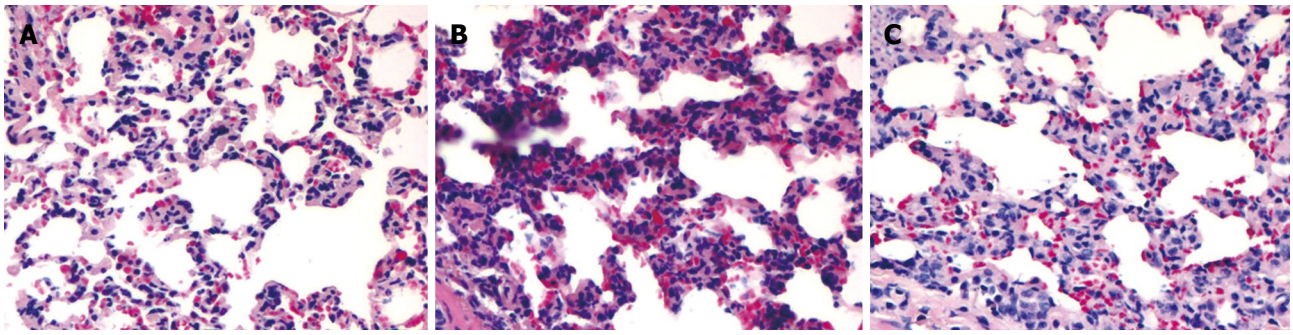

Figure 1 Effects of emodin on pancreatitis-associated lung injury in sham operation group (A), pancreatitis group (B), and emodin group (C) (original magnification, × 200).

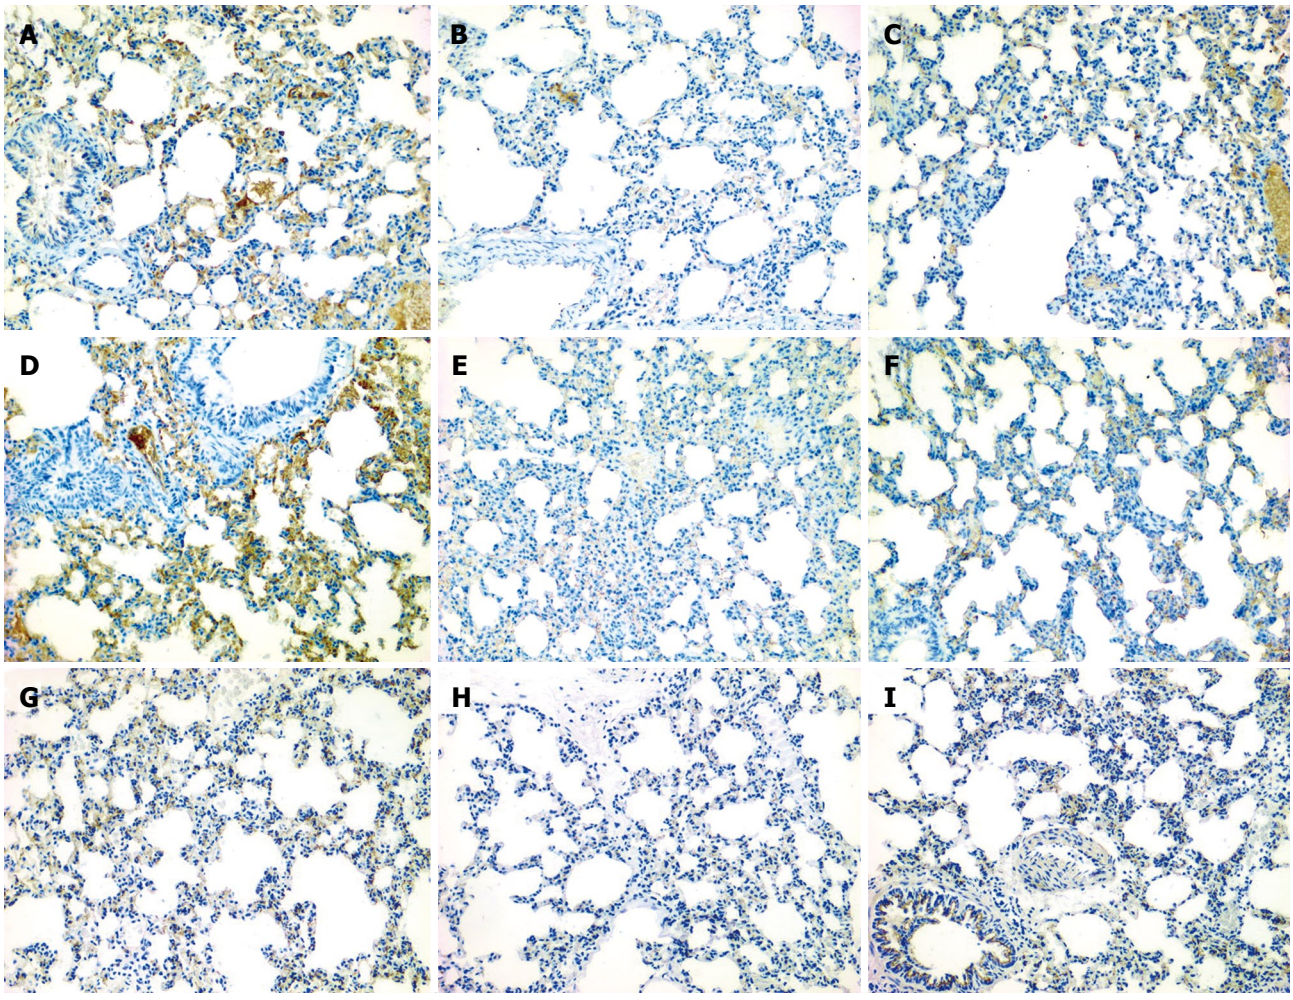

Figure 2 Immunohistochemical staining of claudin-4 (A-C), claudin-5 (D-F) and occludin (G-I) in sham operation group (A, D, G), pancreatitis group (B, E, H), and emodin group (C, F, I) (original magnification, × 200).

resistance and air space fluid clearance, suggesting that claudin-4 plays an important role in alveolar epithelial barrier function, and early increased claudin-4 expression may represent a mechanism by which pulmonary edema is limited[9]. Similar to claudin-4, claudin-5 also plays a role in cellular barrier function. Recombinant claudin-5 protects brain microvascular endothelial cell cultures against increased paracellular permeability induced by VEGF, showing that claudin-5 is a key determinant of blood-brain barrier function[21]. It has been recently reported that expression of pulmonary claudin-5 is decreased in models of carrageenan-induced acute lung inflammation, associated with the decreased pulmonary paracellular permeability, suggesting that claudin-5 may play role in alveolar epithelial barrier function[11].

Occludin shares a very similar membrane location with claudin. Based on the staining feature of claudins and occludin along the endothelial cell borders, Persid-

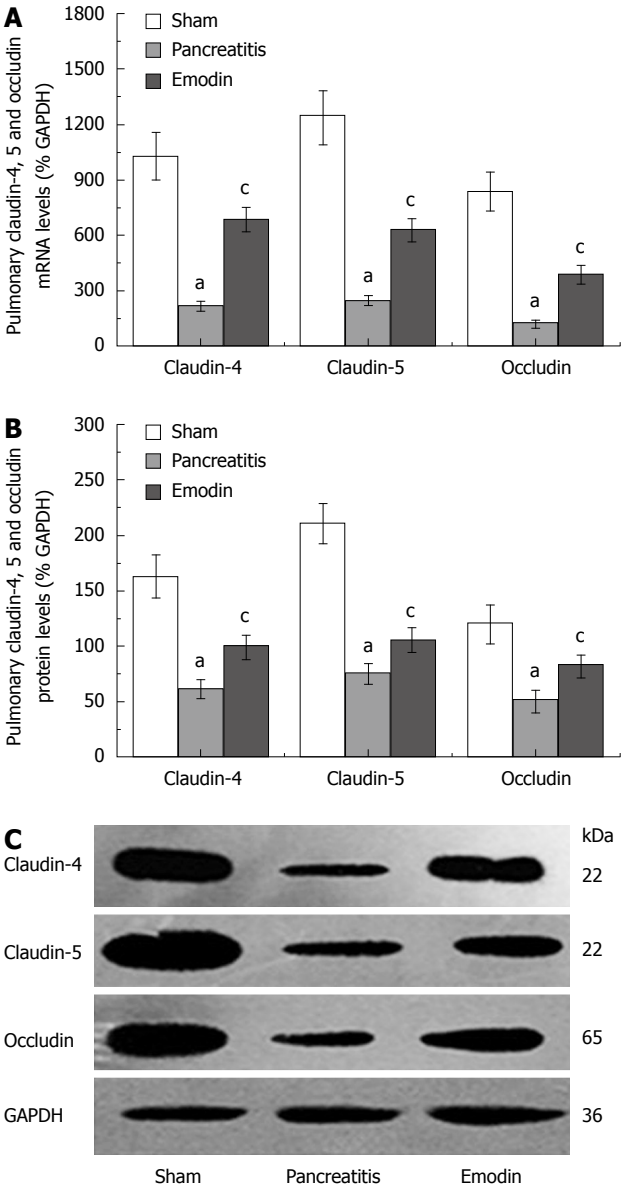

Figure 3 Effects of emodin on claudin-4 (A), claudin-5 (B), and occludin (C) mRNA transcription and protein synthesis in rats. Six rats were studied in each experimental group. Results are expressed as mean ± SD. $^{a}P < 0.05$ *vs* sham group; $^{c}P < 0.05$ *vs* pancreatitis group.

sky *et al*[22] speculated that claudins form the primary "makeup" of the tight junctions, and occludin further enhances tight junction tightness. In ethanol abused rats, which is decreased mRNA and protein expression of occludin has also been observed in lung tissues, associated with increased bronchoalveolar epithelial permeability[12]. Azithromycin-induced processing of occludin is accompanied by increased transepithelial electrical resistance[10], suggesting that occludin alteration may be related with alveolar barrier function.

In the present study, we identified the localization of claudin-4, claudin-5, and occludin in lung tissue samples from rats with acute pancreatitis, and found that claudin-4 and claudin-5 were uniformly and continuously distributed along the alveolar epithelium and vascular endothelium in normal lung tissue samples, which are consistent with the reported findings[9-11]. Furthermore, occludin was uniformly and continuously distributed along the alveolar epithelium, vascular endothelium, and bronchiolar epithelium, which is in line with the reported results[10,12]. In this study, RT-PCR and Western blotting showed that the expression of claudin-4, claudin-5 and occludin was down-regulated in lung tissue samples from rats with acute pancreatitis. Aggravated pulmonary edema and increased paracellular permeability (marked by extravasation of Evans blue) were in parallel with the down-regulation of claudin-4, claudin-5 and occludin expression, which is consistent with the findings in previous studies[9-12], suggesting that claudin-4, claudin-5 and occludin may play a role in alveolar barrier function.

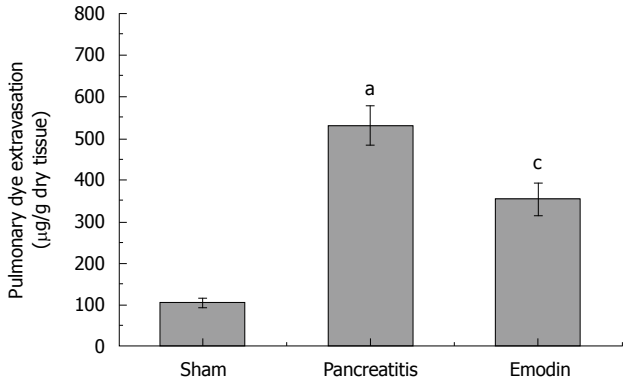

Figure 4 Effects of emodin on alveolar epithelial barrier in rats. Six rats were studied in each experimental group. Results are expressed as mean ± SD. $^{a}P < 0.05$ *vs* sham group; $^{c}P < 0.05$ *vs* pancreatitis group.

In the present study, emodin significantly promoted the expression of claudin-4, claudin-5 and occludin at mRNA transcription and protein synthesis level, and decreased pulmonary edema and paracellular permeability. Based on the previous and present studies, we speculate that emodin may contribute, in part at least, to the expression of claudin-4, claudin-5 and occludin by increasing the alveolar barrier function.

Emodin has long been used for anti-inflammatory purposes. Many studies have demonstrated that emodin intervention can significantly decrease TNF-α and IL-6 levels, or MPO activity in lung tissues[13,23,24], and the mechanism of emodin underlying cytokine inhibition is involved in NF-κB activity suppression[23-26]. Moreover, emodin also has antioxidant effects, promotes generation of ATP and antioxidant components, such as glutathione, α-tocopherol, and superoxide dismutase[27], and exhibits a promising free radical scavenging activity[28]. It has been shown that emodin markedly reduces serum amylase, TNF-α and IL-6 levels, attenuates lung damage in rats with acute pancreatitis[14,29,30], which is in line with the present study. Considering that MPO activity is a marker of local leukocyte sequestration[30], the results of our present study suggest that emodin ameliorates pancreatitis-associated lung injury by inhibiting the production of cytokines and the infiltration of leukocytes in lungs.

In conclusion, emodin can attenuate pulmonary edema and inflammation, enhance alveolar epithelial barrier function, and promote expression of claudin-4, claudin-5 and occludin in lung tissues.

COMMENTS

Background

The mortality associated with acute pancreatitis is attributed to inflammation-related complications such as pancreatitis-associated lung injury. Interventions with emodin are likely to reduce its morbidity and mortality of the disease.

Research frontiers

Claudins and occludin, the key components of tight junctions, restrict the paracellular movement of water, proteins, and solutes across cellular barriers including alveolar epithelium. Emodin, an anthraquinone derivative from the Chinese herb *Radix et Rhizoma Rhei*, has been used for anti-inflammatory purposes. Weather emodin has effects on pulmonary tight junction expression and alveolar epithelial barrier has not been defined.

Innovations and breakthroughs

A recent report has highlighted the importance of tight junction components in a model of ethanol-induced lung injury, or carrageenan-induced acute lung inflammation. This is the first study to report that down-regulation of pulmonary claudin-4, claudin-5 and occludin is parallel with pancreatitis-associated lung injury. Emodin can promote expression of claudin-4, claudin-5 and occluding in lungs, enhance alveolar epithelial barrier, and inhibit pulmonary inflammation.

Applications

The results of this study may improve our understanding of the pathogenesis of pancreatitis-associated lung injury. The present study also provides evidence for emodin in treatment of lung injury.

Peer review

This is a largely observational study representing an incremental advance in treatment of acute pancreatitis with emodin.

Abstract

AIM: To investigate the effect of sulforaphane (SFN) on regulation of NF-E2-related factor-2 (Nrf2)-antioxidant response element (ARE) pathway in liver injury induced by intestinal ischemia/reperfusion (I/R).

METHODS: Rats were divided randomly into four experimental groups: control, SFN control, intestinal I/R and SFN pretreatment groups (n = 8 in each group). The intestinal I/R model was established by clamping the superior mesenteric artery for 1 h and 2 h reperfusion. In the SFN pretreatment group, surgery was performed as in the intestinal I/R group, with intraperitoneal administration of 3 mg/kg SFN 1 h before the operation. Intestine and liver histology was investigated. Serum levels of aspartate aminotransferase (AST), and alanine aminotransferase (ALT) were measured. Liver tissue superoxide dismutase (SOD), myeloperoxidase (MPO), glutathione (GSH) and glutathione peroxidase (GSH-Px) activity were assayed. The liver transcription factor Nrf2 and heme oxygenase-1 (HO-1) were determined by immunohistochemical analysis and Western blotting analysis.

RESULTS: Intestinal I/R induced intestinal and liver injury, characterized by histological changes as well as a significant increase in serum AST and ALT levels (AST: 260.13 ± 40.17 U/L *vs* 186.00 ± 24.21 U/L, $P < 0.01$; ALT: 139.63 ± 11.35 U/L *vs* 48.38 ± 10.73 U/L, $P < 0.01$), all of which were reduced by pretreatment with SFN, respectively (AST: 260.13 ± 40.17 U/L *vs* 216.63 ± 22.65 U/L, $P < 0.05$; ALT: 139.63 ± 11.35 U/L *vs* 97.63 ± 15.56 U/L, $P < 0.01$). The activity of SOD in the liver tissue decreased after intestinal I/R ($P < 0.01$), which was enhanced by SFN pretreatment ($P < 0.05$). In addition, compared with the control group, SFN markedly reduced liver tissue MPO activity ($P < 0.05$) and elevated liver tissue GSH and GSH-Px activity ($P < 0.05$, $P < 0.05$), which was in parallel with the increased level of liver Nrf2 and HO-1 expression.

CONCLUSION: SFN pretreatment attenuates liver injury induced by intestinal I/R in rats, attributable to the antioxidant effect through Nrf2-ARE pathway.

INTRODUCTION

Intestinal ischemia/reperfusion (I/R) is considered to be a grave and triggering event in development of local and distant organ dysfunction[1-4], which occurs in many clinical settings including acute mesenteric ischemia, hemorrhagic, traumatic or septic shock, severe burns, resuscitation, small bowel transplantation and thoracoabdominal aortic aneurysm repair[5,6]. The mechanism of liver injury induced by intestinal I/R is complicated, and it has not been fully elucidated although many studies have been done to mimic the pathophysiologic process by both cell culture and animal models in the past a few years[7-10].

Traditionally, decreased basement membrane integrity and barrier function of the intestine, which facilitate bacterial translocation and local production of inflammatory cytokines[11], promotes the systemic inflammatory response syndrome and multiple organ dysfunction syndrome[12,13]. Recent studies showed that reactive oxygen species (ROS) generated during tissue reperfusion, play an important role in intestinal I/R injury[14], which can initiate lipid peroxidation, oxidize proteins to inactive states and cause DNA strand breaks, and initiation of apoptotic and necrotic cascades[15]. Additionally, ROS also has a function as a second messenger to modulate the secretion of pro-inflammation cytokines and chemokines that can destroy the intestinal barrier, which is a critical junction point to amplify the inflammation reaction described above[11-13]. The administration of antioxidants has been shown to exert beneficial effects in the prevention of ischemia-reperfusion injury[16].

Sulforaphane (SFN) is a natural product derived from isothiocyanate which is present in cruciferous vegetables such as broccoli that has been used as a chemopreventive compound[17]. The cytoprotective effect of this compound is mediated by transcription factor NF-E2-related factor-2 (Nrf2), which binds to the antioxidant response element (ARE) in the promoter region of a number of genes, encoding for antioxidative and phase 2 enzymes, including heme oxygenase-1 (HO-1), NAD(P)H: quinoine oxidoreductase 1, glutathione reductase, and glutathione peroxidase (GSH-Px)[18-20]. Phase 2 enzymes play a major role in the detoxification of ROS during ischemia/reperfusion[21,22]. Nrf2 is held in the cytoplasm by a cytoskeletal-associated specific inhibitory protein (Kelch-like ECH associated protein 1, Keap1) under circumstances of normal cellular quiescent state. Upon stimulation of oxidative stress, cysteine residues within the hinge region of Keap1 can be modified and cause a conformational change in KEAP1 with the loss of Nrf2 binding, then Nrf2 translocated into the nucleus, where it heterodimerizes with members of the maf protein family, and coordinates upregulation of cytoprotective genes[20]. SFN can disrupt the Nrf2-Keap1 complex, and permit Nrf2 to translocate into the nucleus to activate the ARE-driven genes[23,24]. Studies suggest that Nrf2 activation by SFN results in effective protection from cancers[25] and renal I/R[26] by upregulating ARE-related detoxification enzymes. These studies have focused on the chemoprevention by SFN, and to our knowledge, no one has evaluated SFN to determine if it can protect liver injury induced by intestinal I/R.

In this study, we investigated the effect of SFN on liver injury following intestinal I/R and explored the mechanism of its protective action through Nrf2-ARE pathway.

MATERIALS AND METHODS

Animal and experimental design

Male Sprague-Dawley rats weighing 190-220 g (from the Animal center of Dalian Medical University, Dalian, China) were used in this study, which was approved by the Institutional Ethics Committee. All rats were provided with standard laboratory chow and water and were housed in accordance with institutional animal care policies.

The rats were divided into four experimental groups randomly: control (A), SFN control (B), intestinal I/R (C) and SFN pretreatment group (D) (n = 8 in each group). The rats in the control group underwent surgical preparation including isolation of the superior mesenteric artery (SMA) without occlusion; the rats in the SFN control group underwent surgery as in the control group with intraperitoneal administration of 3 mg/kg SFN 1 h before the operation (SFN was purchased from Sigma Chemical Company and was dissolved in 10% dimethylsulfoxide before administration); the rats in intestinal I/R group were subjected to 1 h intestinal ischemia and 2 h reperfusion after the SMA was isolated and occluded[27]; the rats in the SFN pretreatment group underwent surgery as in the intestinal I/R group with intraperitoneal administration of 3 mg/kg SFN 1 h before the operation.

The dose of SFN administration was determined according to the previous studies with modification from preliminary experiments. The rats in the control and intestinal I/R groups were treated with an equal volume of 10% dimethylsulfoxide. Two hours after reperfusion, blood, intestine and liver tissue samples were obtained for further analysis.

Intestine and liver morphological analysis

The isolated intestine and liver tissues were harvested and fixed in 10% formalin. After being embedded in paraffin, the tissues were stained with hematoxylin and eosin for light microscopy.

Measurement of serum aspartate aminotransferase and alanine aminotransferase

The serum levels of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were measured with an OLYMPUS AU1000 automatic analyzer (AusBio Laboratories Co., Ltd. Beijing, China).

Liver superoxide dismutase, myeloperoxidase, GSH and GSH-Px activity assay

The liver tissues were harvested and homogenized im-

mediately on ice in 5 volumes of normal saline. The homogenates were centrifuged at 1200 r/min for 10 min to remove debris. The superoxide dismutase (SOD), myeloperoxidase (MPO), GSH and GSH-Px activity in the supernatant were determined using an assay kit (Nanjing Jiancheng Corp., China), following the manufacturer's recommendations.

The SOD activity was determined by hydroxylamine assay developed from xanthine oxidase assay. One unit of SOD sample inhibited the reaction by approximately 50% of the initially measured xanthine oxidase reaction at 37℃. SOD activity in the liver tissues was expressed as units per milligram protein (U/mgprot).

One unit of MPO activity is defined as degrading 1 μmol of hydrogen peroxide at 37℃ and MPO activity of tissue was expressed as units per gram (U/g).

Concentrations of GSH were determined by the 5,5' dithio-bis 2-nitrobenzoic acid (DTNB)-GSSG reductase-recycling assay. The amount of GSH was expressed as milligrams per gram protein (mg/gprot).

GSH-Px was measured by the enzymatic reaction which was initiated by addition of H_2O_2 to the reaction mixture containing reduced glutathione, NADPH and glutathione reductase, and the change in the absorbance at 340 nm was monitored by spectrophotometer. Activity was given in units per milligram protein (U/mgprot).

Liver Nrf2 and HO-1 immunohistochemical analysis

Paraffin-embedded tissue sections, 4 μm in thickness, were stained with SP immunohistochemical technique for Nrf2 and HO-1. The immunohistochemical experiments were performed according to the manufacturer's recommendations. After being dewaxed or washed in PBS, tissue sections were cultured in 3% hydrogen peroxide to eliminate intrinsic peroxidase, and quenched in normal goat serum for 30 min. The sections were incubated overnight at 4℃ with polyclonal rabbit anti-rat Nrf2 antibody (Santa Cruz Corp., Ltd.), followed by the addition of the anti-rabbit immunoglobulin and streptavidin conjugated to horseradish peroxides. Finally, 3,3'-diaminobenzidine was used for color development, and hematoxylin was used for counter staining. The brown or dark brown staining in cytoplasm and/or nucleus was considered to be positive. The results were evaluated semi-quantitatively according to percentage of positive cells in five fields at a 400 multiple signal magnification. The protein expression in tissue sections was graded as 0: less than 5%; 1: from 6% to 25%; 2: from 26% to 50%; 3: from 51% to 75%; and 4: more than 75%[28].

Western blotting analysis of liver Nrf2 and HO-1

Nrf2 is a nuclear transcriptional factor that binds to the ARE in the promoter region of a number of genes, encoding for antioxidative and phase 2 enzymes such as HO-1 and GSH-Px. The level of Nrf2 in the nucleus was examined by Western blotting to assess Nrf2 activation.

Cellular plasma and nuclear protein were extracted from frozen liver tissues with a protein extraction kit (Pierce, Meridian Road, Rockford, IL, USA) for HO-1 and Nrf2 measurement separately. The protein was separated by 10% SDS-PAGE gel electrophoresis. The protein was electroblotted onto NC membranes (Millipore, Bedford, MA, USA) at 9 V for 30 min. The transferred membranes were then incubated overnight at 4℃ with rabbit polyclonal antibody HO-1, Nrf2, GAPDH and PCNA (Santa Cruz Corp., Ltd.) against rat in TBS-T (10 mmol/L Tris-HC1, pH 7.5, 150 mmol/L NaC1, 0.1% Tween-20) containing 5% skim milk. After washing three times in TBS-T, the membranes were incubated for 1 h at 37℃ with an anti-rabbit IgG conjugated with horseradish peroxidase. The signals were visualized using the DAB assay kit (Fuzhou Maixin Biological Technology Co., Ltd, Fuzhou, China) and documented with a gel imaging system (UVP Bioimaging System). The signals were analyzed with software Gel-Pro Analyzer 4.0.

Statistical analysis

All data, which expressed as the mean ± SD, were compared using the paired Student's *t* test with the SigmaStat 3.5 statistical software package. One-way analysis of variance (ANOVA) was used to determine significant differences in antioxidant enzyme activities between the groups. A value of $P < 0.05$ was considered significant.

RESULTS

Changes of liver histology and serum AST and ALT levels

Intestinal I/R induced apparent intestine and liver injury at 2 h after reperfusion, manifested as histological changes in the intestine and liver with edema, hemorrhage and neutrophil infiltration (Figure 1), as well as a significant increase in serum AST and ALT level (AST: 260.13 ± 40.17 U/L *vs* 186.00 ± 24.21 U/L, $P < 0.01$; ALT: 139.63 ± 11.35 U/L *vs* 48.38 ± 10.73 U/L, $P < 0.01$, Figure 2) when compared with the control group. Compared with the intestinal I/R group, the intestinal and liver pathological damage was improved in the SFN pretreatment group. In addition, there was a significant difference in the liver function between the intestinal I/R and SFN pretreatment group in serum AST and ALT levels (AST: 260.13 ± 40.17 U/L *vs* 216.63 ± 22.65 U/L, $P < 0.05$; ALT: 139.63 ± 11.35 U/L *vs* 97.63 ± 15.56 U/L, $P < 0.01$, Figure 2), which indicates that SFN significantly attenuated the intestinal I/R-induced liver injury. There was no significant difference between the SFN control group and the control group in liver pathological damage (Figure 1) and serum AST (AST: 193.38 ± 34.63 U/L *vs* 186.00 ± 24.21 U/L, $P > 0.05$, Figure 2) and ALT (ALT: 48.00 ± 8.52 U/L *vs* 48.38 ± 10.73 U/L, $P > 0.05$, Figure 2).

Changes of liver SOD and MPO activity

SOD is the major enzyme for scavenging ROS, and its activity can reflect its functional status. The liver homogenate SOD activity in the intestinal I/R group decreased significantly at 2 h of reperfusion in comparison with the control group ($P < 0.01$, Figure 3). SOD activity was elevated markedly after SFN pretreatment compared

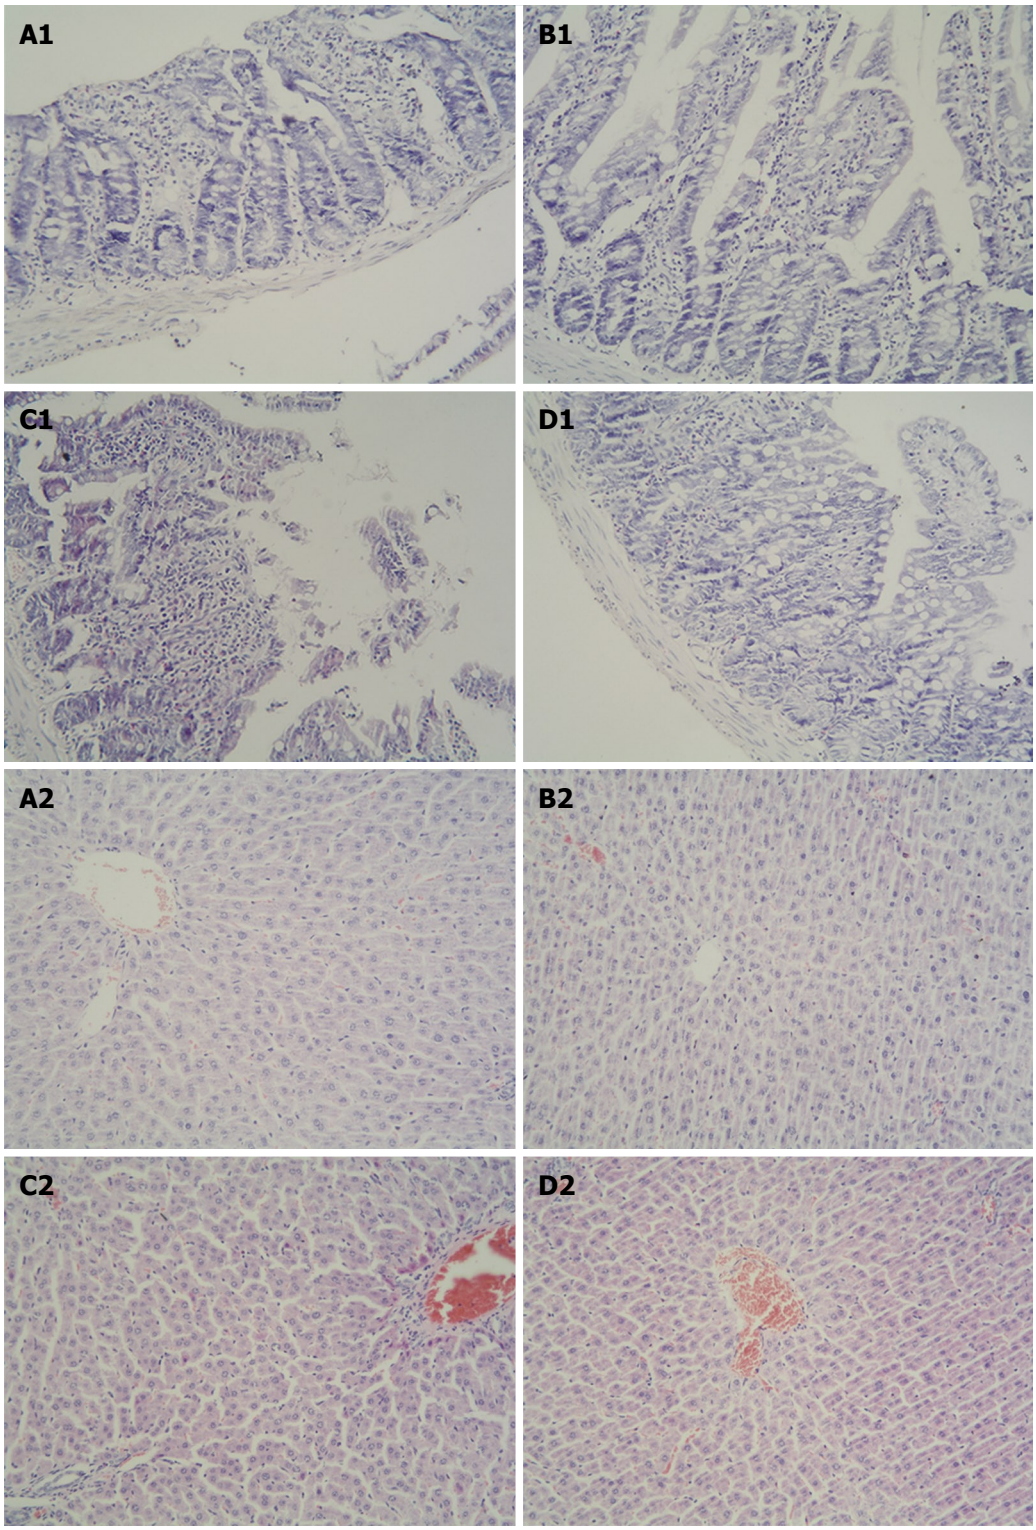

Figure 1 Changes in histology of intestine (A1-D1) and liver (A2-D2) tissues (HE stain, × 200) in the control (A), sulforaphane (SFN) control (B), intestinal ischemia/reperfusion (I/R) (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups. A, B: Normal structure of intestine and liver; C: Edema, hemorrhage and neutrophil infiltration were observed in intestinal mucosa and liver tissue; D: Relatively normal histology of intestine and liver with less inflammatory cell infiltration.

with the intestinal I/R group ($P < 0.05$, Figure 3).

MPO activity in the liver homogenate was measured for estimating the leukocyte recruitment to liver tissues. The liver tissue MPO activity increased significantly after intestinal I/R at 2 h of reperfusion compared with the control group ($P < 0.05$, Figure 3). The administration of SFN reduced the MPO activity in liver tissues significantly in comparison with the intestinal I/R group ($P < 0.05$, Figure 3), thus indicating that SFN alleviated the leukocyte recruitment to liver tissues.

GSH is a kind of antioxidant which can scavenge ROS. Phase 2 enzyme GSH-Px present in the cell can

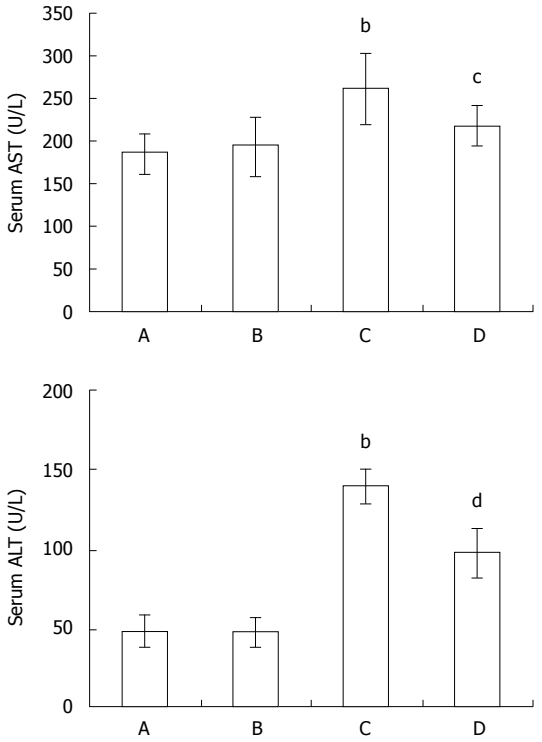

Figure 2 Serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) (mean ± SD, U/L) levels in the control (A), SFN control (B), intestinal I/R (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups. $^{b}P < 0.01$ *vs* control group; $^{c}P < 0.05$, $^{d}P < 0.01$ *vs* intestinal I/R group.

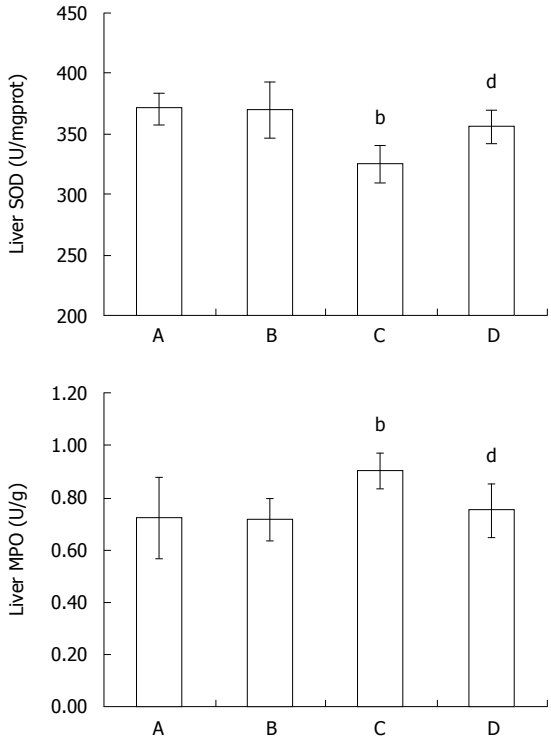

Figure 3 Liver tissue superoxide dismutase (SOD) (mean ± SD, U/mgprot) and myeloperoxidase (MPO) (mean ± SD, U/g) level in the control (A), SFN control (B), intestinal I/R (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups. $^{b}P < 0.01$ *vs* control group; $^{d}P < 0.01$ *vs* intestinal I/R group.

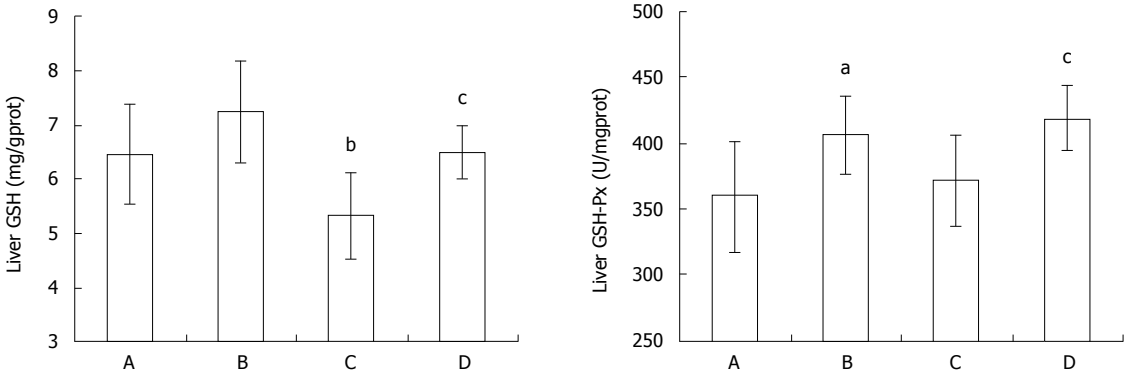

Figure 4 Liver tissue glutathione (GSH) and glutathione peroxidase (GSH-Px) (mean ± SD, U/gprot) level in the control (A), SFN control (B), intestinal I/R (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control group; $^{c}P < 0.05$ *vs* intestinal I/R group.

catalyze this reaction. The liver homogenate GSH activity in the intestinal I/R group decreased significantly at 2h of reperfusion as compared with the control group ($P < 0.01$, Figure 4). GSH activity was elevated markedly after SFN pretreatment in comparison with the intestinal I/R group ($P < 0.05$, Figure 4).

The increased activity of the liver tissue GSH-Px was significant after SFN pretreatment as against the control group ($P < 0.05$, Figure 4). GSH-Px activity was elevated markedly after SFN pretreatment in comparison with the intestinal I/R group ($P < 0.05$, Figure 4), thus supporting the hepatoprotective effect of SFN.

Immunohistochemical expression of liver Nrf2 and HO-1

The expression of Nrf2 in control group showed light brown immunostaining in cytoplasm and no staining in the nuclei. The significantly positive expressions of Nrf2 as strong brown staining in cytoplasm and nuclei were observed in the intestinal I/R group and SFN control groups ($P < 0.01$, $P < 0.01$, Figures 5 and 6). Compared with the intestinal I/R group, the positive rates of Nrf2 expression increased significantly in SFN pretreatment group ($P < 0.01$, Figures 5 and 6).

The expression of HO-1 in the control group showed little brown immunostaining in cytoplasm while signifi-

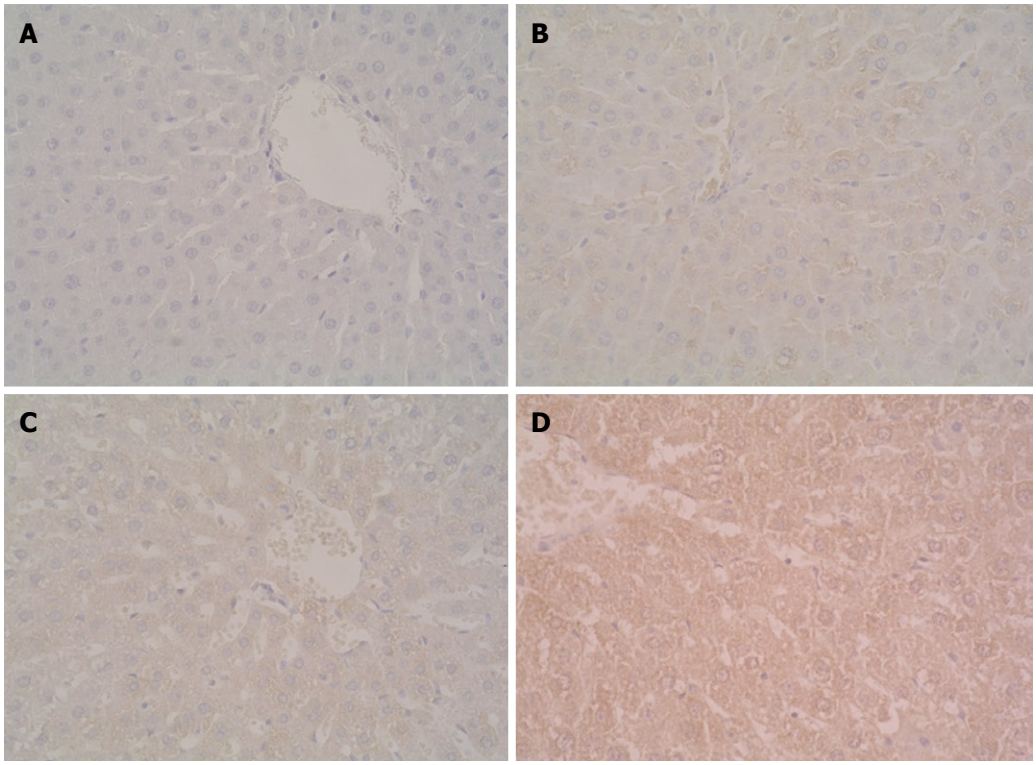

Figure 5 Immunohistochemical staining of liver NF-E2-related factor-2 (Nrf2) expression (original magnification × 400) in the control (A), SFN control (B), intestinal I/R (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups.

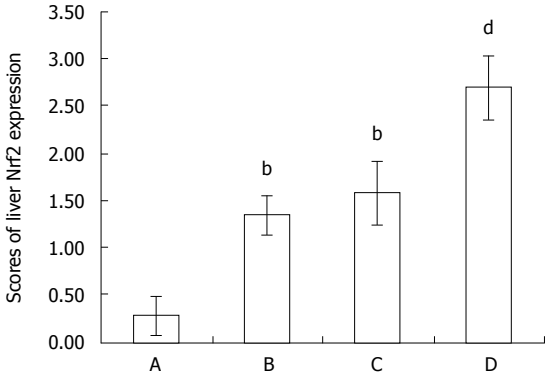

Figure 6 Immunohistochemical results (semi-quantitative analysis) of liver Nrf2 expression in the control (A), SFN control (B), intestinal I/R (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups. Data are presented as mean ± SD of eight animals. $^{b}P < 0.01$ *vs* control group; $^{d}P < 0.01$ *vs* intestinal I/R group.

cant positive expression of HO-1 as brown staining in cytoplasm was observed in the intestinal I/R group and SFN control groups ($P < 0.01$, $P < 0.01$, Figures 7 and 8). Compared with the intestinal I/R group, the positive rates of HO-1 expression increased significantly in cytoplasm in SFN pretreatment group ($P < 0.01$, Figures 7 and 8).

Western blotting analysis of liver Nrf2 and HO-1 expression

The expression of nuclear Nrf2 of the liver tissues in animals with 2-h reperfusion is shown in Figure 9. The results showed a weak Nrf2 positive signal in the liver of the control group. However, a strong Nrf2 protein signal was found in the intestinal I/R group ($P < 0.01$, Figure 9). The signal enhanced significantly in the SFN pretreatment group in comparison with the intestinal I/R group ($P < 0.01$, Figure 9), thereby indicating that SFN could increase the Nrf2 activation in liver tissues.

Western blotting showed weak positive staining for HO-1 in the liver in the control group. However, a significant HO-1 signal was observed in the intestinal I/R group. Compared with the control group, IOD level of HO-1 increased markedly ($P < 0.01$, Figure 9). The signal enhanced significantly in the SFN pretreatment group in comparison with the intestinal I/R group ($P < 0.01$, Figure 9), hinting that HO-1 was activated in liver tissues caused by SFN.

DISCUSSION

Intestinal I/R is not only necessary to the intestine itself, but involves severe distant organ dysfunction. The liver is the first distant organ involved in the severe attack from intestinal I/R[8] due to its vasculature being coupled in series with that of the intestine[29]. During the reperfusion, ROS formed as participants in the I/R-induced leukocyte-mediated liver inflammation responses[30-32], and many clinical and experimental studies showed that ROS plays a crucial role in the pathogenesis of I/R[7,33].

ROS can be restrained by endogenous free radical scavengers such as SOD, catalase, the glutathione peroxidase/glutathione/glutathione reductase system and the thioredoxin peroxidase/thioredoxin/thioredoxin reduc-

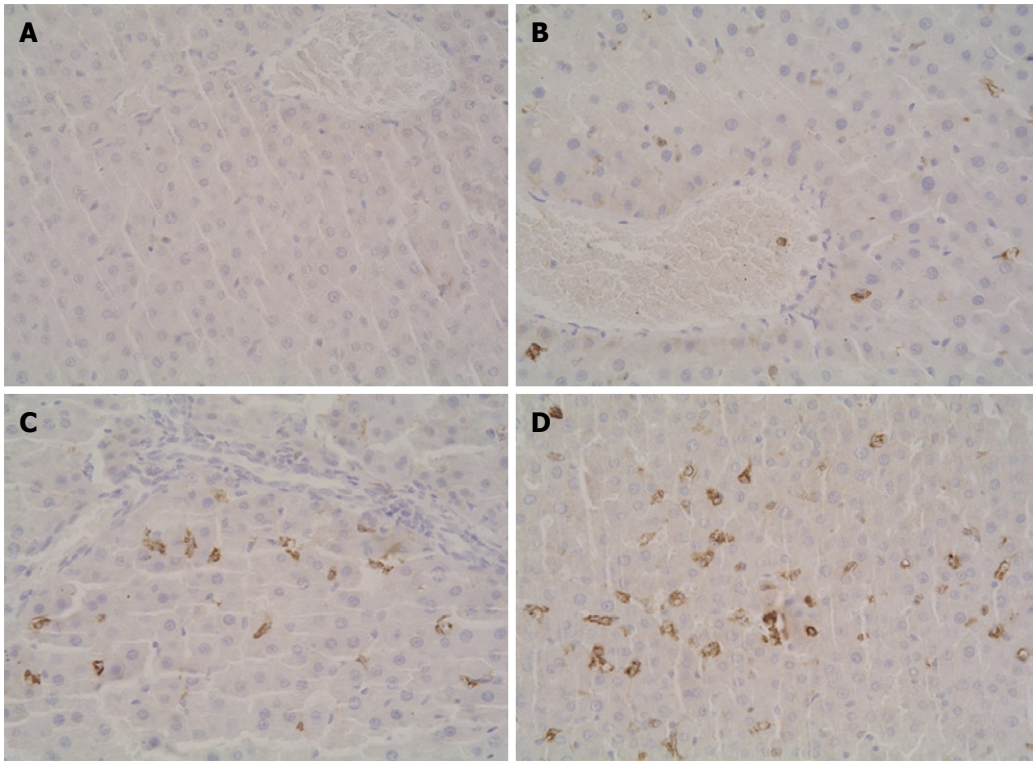

Figure 7 Immunohistochemical staining of liver heme oxygenase-1 (HO-1) expression (original magnification × 400) in the control (A), SFN control (B), intestinal I/R (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups.

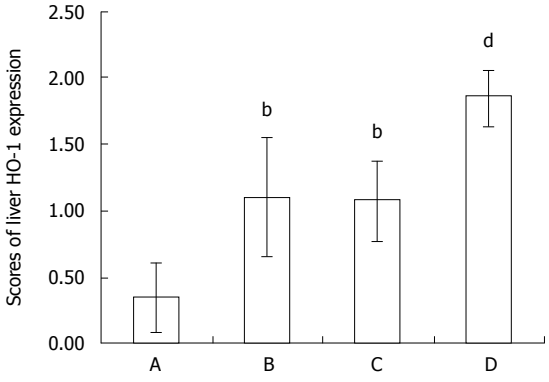

Figure 8 Immunohistochemical results (semi-quantitative analysis) of liver HO-1 expression in the control (A), SFN control (B), intestinal I/R (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups. Data are presented as mean ± SD of eight animals. $^{b}P < 0.01$ *vs* control group; $^{d}P < 0.01$ *vs* intestinal I/R group.

tase system[34]. SOD catalyses the dismutation of the superoxide anion ($O_2^{\cdot}$) into H_2O_2, which can be transformed into H_2O and O_2 by catalase (CAT). GSH as a kind of endogenous free radical scavenger can be regulated by GSH-Px. Ros also oxidizes proteins, induces lipid peroxidation and initiates DNA stand breaks, which can be blocked by the above-mentioned antioxidative agents.

ARE is an enhancer element that initiates the transcription of a battery of genes encoding phase 2 enzymes[35]. Activation of gene transcription through the ARE is mediated primarily by Nrf2[36]. Under basal conditions, Nrf2 is sequestered in the cytoplasm by Keap1, and upon exposure of cells to inducers such as oxidative stress and certain chemopreventive agents, Nrf2 dissociates from Keap1, translocates to the nucleus, binds to ARE, and transactivates phase 2 detoxifying and antioxidant genes[37]. Recent studies have implied that the activation of Nrf2/ARE pathway attenuate ischemia/reperfusion injury of the heart, brain and kidney[26,38,39]. And SFN induces Nrf2-driven phase 2 enzyme expression by modulating the activation in kidney ischemia reperfusion injury[40].

In this study, we evaluated the effect of SFN on regulating Nrf2/ARE in liver injury of the animal intestinal I/R model. We found that Nrf2 activation by sulforaphane pretreatment protected liver against injury induced by intestinal I/R, which was characterized by improved alternation in liver tissue pathology and liver function, and an enhanced antioxidant capacity, being consistent with the Nrf2 expression and content changes.

GSH-Px and HO-1 are two kinds of phase 2 enzymes. HO-1 is a ubiquitous heat shock protein (HSP32) that is highly induced by diverse stress-related conditions[41]. It is upregulated in response to oxidative stress in many tissues, providing generalized endogenous protection against oxidative stress[42]. Our results indicated that GSH-Px and HO-1 can be upregulated by SFN pretreatment through Nrf2-ARE pathway. Therefore, development of a kind of strategy to reduce oxidative stress by inducing endogenous phase 2 enzymes is attractive, which can be regulated by Nrf2. In order to clarify the mechanism comprehensively, further researches should determine the indexes of cell death such as apoptosis and inflammation in this pathophysiology process.

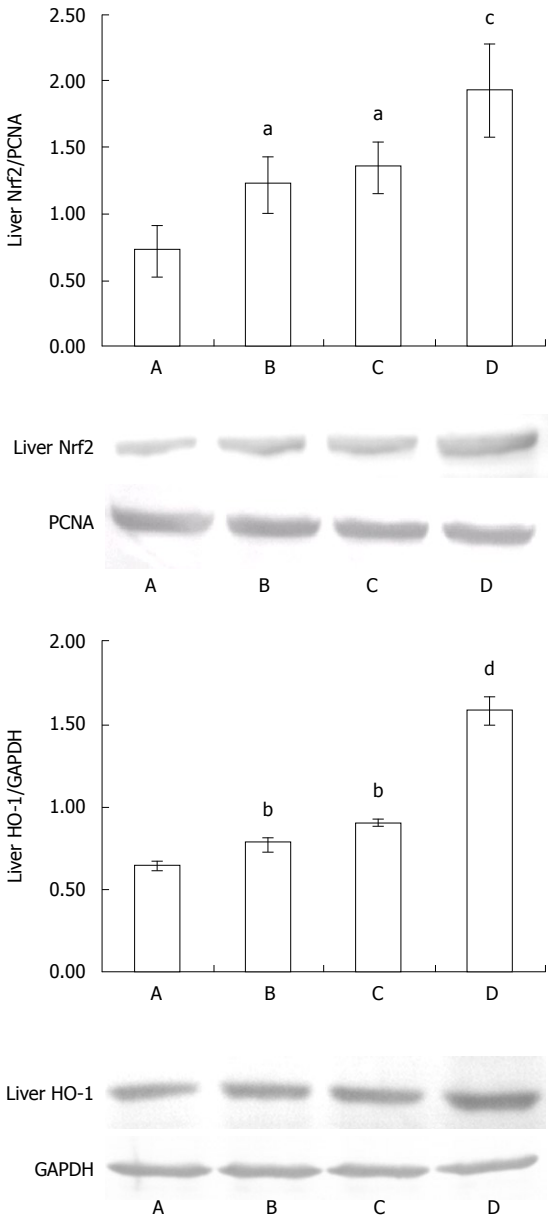

Figure 9 Western blotting analysis of expression of liver Nrf2 and HO-1 in the control (A), SFN control (B), intestinal I/R (C) (1 h ischemia and 2 h reperfusion) and SFN pretreatment (D) groups. PCNA and GAPDH were as the internal control respectively. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control group; $^{c}P < 0.05$, $^{d}P < 0.01$ *vs* intestinal I/R group.

In conclusion, ROS plays an important role in the pathogenesis of liver injury induced by intestinal I/R. SFN exerted the protective effect on the liver injury induced by intestinal I/R, attributable to the antioxidant effect through Nrf2-ARE pathway.

COMMENTS

Background

Sulforaphane (SFN) is a natural product derived from isothiocyanate which is present in cruciferous vegetables such as broccoli that has been used as a chemopreventive compound. The cytoprotective effect exerted by this compound is mediated by transcription factor NF-E2-related factor-2 (Nrf2), which binds to the antioxidant response element (ARE) in the promoter region of a number of genes, encoding for antioxidative and phase 2 enzymes. SFN can disrupt the Nrf2-Keap1 complex, and permit Nrf2 to translocate into the nucleus to activate the ARE-driven genes.

Research frontiers

Studies suggest that Nrf2 activation by SFN results in effective protection from cancers and renal ischemia/reperfusion (I/R), but no one has evaluated SFN to determine if it can protect liver injury induced by intestinal I/R.

Innovations and breakthroughs

The study for the fist time showed that SFN exerted the protective effect on the liver injury induced by intestinal I/R, attributable to the antioxidant effect through Nrf2-ARE pathway.

Applications

This study has indicated that SFN pretreatment attenuates liver injury induced by intestinal I/R in rats, attributable to the antioxidant effect through Nrf2-ARE pathway.

Terminology

Nrf2 is sequestered in the cytoplasm by Keap1, and upon exposure of cells to inducers such as oxidative stress and certain chemopreventive agents, Nrf2 dissociates from Keap1, translocates to the nucleus, binds to ARE, and transactivates phase 2 detoxifying and antioxidant genes. The activation of Nrf2/ARE pathway attenuates ischemia/reperfusion injury.

Peer review

The paper is well-written and data are convincing. All data confirm the hypothesis and adequately discussed.

Abstract

AIM: To communicate our findings on successful treatment of recto-vaginal fistulas (RVFs) after prosthetic reinforcement surgery of pelvic organ prolapse (POP).

METHODS: A retrospective single center study between 1998 and 2008 was performed. A total of 80 patients with RVF were identified, of which five patients (6%), with a mean age of 65 years (range: 52-73), had undergone previous surgery for POP with prosthetic reinforcement.

RESULTS: All patients complained about ongoing vaginal infections and febrile episodes. These symptoms were reported after a mean period of 18 mo after POP repair. As a first intervention, three patients underwent ablation of the prosthetic material (PM). As a second intervention, open proctectomy with a primary anastomosis, an omental patch, and a protective ileostomy were performed in two patients. One patient required a terminal colostomy due to complete destruction of the anal sphincters. In two other patients, ablation of the PM and proctectomy was performed as a one-step procedure. The postoperative course in all patients was uneventful, with a mean length of hospitalization of 20 d (range: 15-30). Closure of the ileostomy was achieved in all four patients within four months. After a mean period of 35 mo (range: 4-60) of follow-up, no recurrence was observed with normal continence in four patients.

CONCLUSION: In our experience, the definitive treatment of high RVFs after PM repair for POP necessitates ablation of the PM, proctectomy with a primary colorectal anastomosis, an omental patch interposition, and a temporary ileostomy.

Management of recto-vaginal fistulas after prosthetic reinforcement treatment for pelvic organ prolapse. *World J Gastroenterol* 2010; 16(24): 3011-3015 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i24/3011.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i24.3011

INTRODUCTION

Pelvic organ prolapse (POP) is a significant health issue in women worldwide. Approximately 250 000 procedures are performed annually in the United States alone[1,2]. The search for a permanent cure for POP has been ongoing for more than a century and remains a challenge today. A number of different approaches have been described for POP repair, including abdominal (open, laparoscopic, and robotic) and vaginal techniques. Recently, the use of prosthetic material (PM) in pelvic floor surgery has become increasingly popular due to the high incidence of recurrence with primary repairs and no surrogate material. Nevertheless, our knowledge about the possible benefit of PM reinforcement for POP repair remains limited. Currently, randomized trials support the superiority of techniques using PM for cystocele repair, whereas the results for colpo- and rectocele repair remain unclear or controversial[3,4].

With the use of PM, new and specific complications occur; these include PM infection, PM erosion or shrinkage, and visceral extrusion. In a systematic review of 2653 patients who underwent surgery for apical vaginal prolapse, Feiner *et al*[5] reported mesh erosion as the single most frequent complication in 4.6% to 10.7%, depending on the different PMs used. In a retrospective study of monofilament mesh placement in the anterior and posterior compartment for POP repair, Dwyer *et al*[6] reported a patient that had developed an recto-vaginal fistula (RVF). Two years later, Hilger *et al*[7] published a case study of RVF formation three months after a posterior intravaginal slingplasty and mesh augmented rectocele repair was performed, which ended in a permanent colostomy after two unsuccessful attempts to correct the fistula. Our knowledge on the incidence of RVF formation after prosthetic material repair for POP is still limited. In addition, uncertainty over the best management of this complication remains. This is in part due to the small number of case reports present in the medical literature. Here, we report our experience with POP management; to the best of our knowledge, this is the largest case series in the literature of RVFs after previous reinforcement surgery for POP.

MATERIALS AND METHODS

This was a retrospective single center study between 1998 and 2008. During that period, a total of 80 patients with RVF were treated at the Department of Visceral- and Oncological Surgery, Hôpital Timone, Marseille, France. Five female patients, with a mean age of 65 years (range: 52-73), were identified that had undergone previous surgery for POP with PM reinforcement. All patients had POP surgery done elsewhere. Details on previous POP repair were as follows: one Prolift® procedure (Ethicon Women's Health and Urology, Somerville, NJ) for urinary stress incontinence, one vaginal wall sling procedure (Bologna technique) and a laparoscopic repair with two multifilamentous polypropylene meshes implanted in both cases for a colpocystocele. Two other patients had open transabdominal implantation of a multifilamentous polypropylene mesh for a colpocysto- and a colporectocele, respectively, with the mesh fixed to the sacrospinous ligaments. Three patients were referred to our department after the PM had been removed transperinealy or transabdominaly, with creation of a temporary colostomy in one case.

At our department, all patients underwent a Gadolinium enhanced magnetic resonance imaging (MRI) of the pelvis using T1 and T2 weighted sequences, such as ano-rectoscopy or endorectal ultrasound (EUS), to evaluate the anal sphincter and a full gynecological work-up. Finally, in all cases, a complete colonoscopy to search for other underlying pathologies that could provoke RVF was routinely performed.

All surgical interventions were performed under general anesthesia and antibiotic cover. The definitive surgical therapy at our department consisted of an open proctectomy, colo-rectal anastomosis, an omental patch, and a protective ileostomy. One patient underwent a Hartmann procedure. A closed suction pelvic drainage was used in all patients.

For postoperative follow-up, all patients in our department underwent an initial clinical control (including Wexner score[8]), ano-rectoscopy, gynecological examination, and an MRI of the pelvis six months after final surgery had been performed.

RESULTS

Patient characteristics, details of surgery and follow-up are summarized in Table 1. The mean time interval between POP repair and the onset of ailments was 18 mo (range: 2-48). All five patients complained about vaginal discharge, dyspareunia, repetitive vaginal infections, and febrile episodes. However, in one patient (No. 3) the leading clinical symptom was complete stool incontinence. Patients No. 1, 2, and 3 underwent ablation of the PM before they had been referred to our department. Patient No. 1 had undergone open transabdominal ablation of the PM with creation of a temporary colostomy. Ablation of the PM in patients No. 2 and 3 was done *via* a transperineal or laparoscopic approach, respectively.

Pelvic MRI at our department provided evidence of a high RVF in all five patients. In patient No. 3 a complex low RVF with a destruction of the internal and external anal sphincter complex was additionally diagnosed (Figure 1).

EUS examination was normal in three patients; however, in patients No. 1 and 3, the anal sphincters were found with an inflammatory inhibition or destruction at a circumference of 20° and 180°, respectively. Nevertheless, in all patients, except for one (No. 3, Wexner score 19[8]), the preoperative Wexner score was normal. Diagnostic colonoscopy (including routine biopsies) was normal except for patient No. 5, where the mesh had completely eroded and migrated into the rectum (Figure 2).

The intra- and postoperative course was uneventful in all patients. Ileostomy closure was achieved in all four patients within four months after final surgery. The

Table 1 Patient characteristics and details of surgery and follow-up

Patients No.	Age (yr)	Primary pathology POP surgery/type of PM	Onset of symptoms (mo)	Primary surgery	Delay to secondary surgery (mo)	Secondary surgery	Follow-up (mo)/ Wexner score
1	73	Colpo-cystocele laparoscopic approach/two polypropylene meshes	24	Temporary colostomy + ablation of PM	6	Open proctectomy, omental patch + PI	36/3
2	65	Colpo-cystocele Bologna procedure/ two polypropylene meshes	12	Laparoscopic ablation of PM	12	Open proctectomy, omental patch + PI	36/2
3	60	SUI Prolift® procedure/two polypropylene meshes	6	Transperineal ablation of PM	6	Hartmann	36/NA
4	52	Colpo-rectocele transabdominal approach/one polypropylene mesh	2	-	-	Open proctectomy, omental patch + PI	60/0
5	73	Cysto-colpocele transabdominal approach/one polypropylene mesh	48	-	-	Open proctectomy, omental patch + PI	6/0

POP: Pelvic organ prolapse; NA: Not applicable; PM: Prosthetic material; SUI: Stress urinary incontinence; PI: Protective ileostomy.

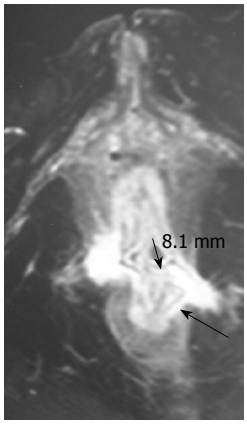

Figure 1 Pelvic magnetic resonance imaging (MRI) showing a transverse section of patient No. 3 with a complex recto-vaginal fistula (RVF) and destruction of the anal sphincter complex. The black arrows show a collection of 8.1 mm with complete destruction of the anal sphincter.

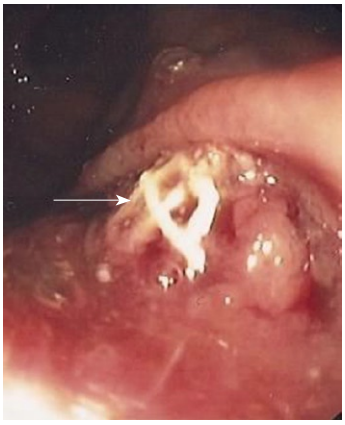

Figure 2 Colonoscopy. Recto-vaginal fistula (arrow) due to polypropylene mesh erosion and migration into the rectum.

mean hospitalization (including closure of the ileostomy) was 20 d (range: 15-40).

After a mean postoperative follow-up period of 34 mo (range: 6-60), no fistula recurrences were observed. In all patients where colo-rectal continuity could have been preserved, only patients No. 1 and 2 suffered from mild postoperative stool incontinence, with Wexner scores of 3 and 2, respectively. Stool continence in patients No. 4 and 5 was found to be completely normal (Wexner 0).

DISCUSSION

POP is a significant health problem in women worldwide, with an estimated 250 000 annual procedures performed in the United States alone[1,2]. These figures are predicted to rise by 45% over the next 30 years due to the increased life expectancy of women in the Western world, and an increasing prevalence of pelvic floor dysfunction with age[9].

Hundreds of techniques have been reported in POP surgery, whether vaginal, abdominal, or laparoscopic, but there is little or no real consensus on which procedure is most appropriate. This is in part due to the lack of high-quality, randomized controlled trials assessing the long-term anatomical and functional outcomes using validated tools and procedures[10].

As traditional surgical techniques for POP utilizing the patient's own tissue do not restore normal anatomy and have a very high failure rate, the use of PM has recently become more frequent. As far as the treatment for cystocele is concerned, better results are reported compared to the traditional surgical approach without use of PM[3,4].

However, with the more liberal use of different types of PM, new adverse effects and complications in patients who underwent POP surgery have been observed. In a public health notification published in October 2008 by the U.S Food and Drug Administration (FDA) it is stated, that over a period of three years, nine different mesh manufacturers reported about 1000 complications associated with transvaginal placement of surgical mesh in repair of POP and SUI. Furthermore, it stated that specific characteristics of patients at increased risk for complications have not been determined. However, contributing factors might include the overall health of the patient, the mesh material, the size and shape of the mesh, the surgical technique used, concomitant procedures undertaken (e.g. hysterectomy), and possibly estrogen status[11].

In our current series of five patients with high RVF after mesh repair of POP, all patients were in good overall health at the time of POP surgery. None of them had previous POP surgery or were under a concomitant medication or medical treatment that could have promoted RVF formation.

The type of mesh implanted has been found to be critical (reported to be pivotal). Mesh erosion through the vaginal epithelium is the most frequently observed mesh-related complication. However, this complication

differs between the different types of meshes used. A high rate of mesh erosion has been reported for non-resorbable synthetic meshes such as Gore-Tex®, Marlex®, and Mersilene®[12].

In our case series, RVF formation was related to multifilamentous polypropylene mesh implantation in all five cases, although the use of polypropylene mesh is currently promoted due to good biocompatability characteristics with a somewhat lower incidence of mesh related complications compared to other mesh types reported in the literature[12,13].

Information concerning RVF formation after mesh surgery for POP is rare in the medical literature. In a retrospective study of monofilament mesh placement in the anterior and posterior compartment for POP repair in 97 patients, Dwyer *et al*[6] observed one patient (1%) who had developed an RVF. In a case report, Hilger *et al*[7] reported an RVF that developed three months after a posterior intravaginal slingplasty and mesh augmented rectocele repair was performed. In another retrospective multicenter study of 687 patients who underwent a vaginal cure with the Prolift® procedure, one patient with an RVF (0.15%) in the postoperative follow-up period was found. However, in the same series, an intraoperative rectal erosion (0.15%), a rectal lesion (0.15%), and a recto-vesical fistula (0.15%) were also reported[14]. The exact incidence of this serious complication remains unknown, and is currently between 0.15% and 1%, as reported in the literature. However, the true incidence of RVF is probably somewhat higher, as the formation of RVFs is very likely the sequel of mesh infection and/or mesh extrusion, which are quite common.

Mesh extrusion after POP is generally observed between four and sixteen months postoperatively[15]. In our study, patients started to complain of vaginal discharge, repetitive vaginal infections, and febrile episodes after a mean period of 18 mo (range: 2-48) after POP repair. Therefore, the symptoms outlined above, even several years after POP surgery, should prompt clinicians to search for an RVF. In all five of our patients, MRI of the pelvis revealed a high RVF and furthermore helped to estimate the extent of pelvic inflammation and tissue destruction. Three patients underwent ablation of the PM before they were referred to our department. In one patient, a temporary colostomy had also been performed at the time of PM ablation. In cases of mesh infection, ablation of the mesh by a minimal invasive procedure, if possible, is currently recommended as a first treatment option[16]. This manoeuvre is generally facilitated by a bacterial biofilm, which isolates the PM from the surrounding tissue[13,17]. The definitive surgical treatment should then be performed after a delay of three to six months after pelvic inflammation has minimized[15]. In cases of a simple RVF, it is thought that once the infected PM has been removed, a spontaneous cicatrisation of the initially inflamed tissue will lead to spontaneous RVF closure[18].

However, in the three patients who underwent ablation of the PM in a primary surgical intervention outside our department, pelvic inflammation did not substantially minimize within 6 to 12 mo. Even protective colostomy did not resolve pelvic inflammation and closure of the RVF. This might be explained, in some part, by the finding that in all three patients some parts of PM were still found in the pelvis during final surgery, which might have promoted the ongoing pelvic inflammatory process. Therefore, it is unlikely that simple ablation of the PM, with or without the creation of a temporary colostomy, will completely resolve pelvic inflammation and lead to a permanent cure. In those two patients who were directly transferred to our department, ablation of the PM, proctectomy, colo-rectal anastomosis, an omental patch, and temporary ileostomy was performed as a one-step procedure. In cases of severe sphincter destruction, a definitive colostomy is the procedure of choice.

RVF after mesh surgery for POP is a rare, but severe, complication. The exact incidence of this complication depends on the type of PM implanted and the type of previous surgeries performed, and is currently about 0.15% to 1%, as reported in the medical literature. However, it is likely that the true incidence is somewhat higher. Ablation of the PM in a first surgical procedure is unlikely to remove all PM and there is a risk that parts of the infected mesh are left in place, which probably promotes an ongoing inflammation of the pelvis. If the general condition of the patient allows, we recommend a radical one-step surgical procedure with open PM ablation, proctectomy, an omental patch, colo-rectal anastomosis, and creation of a temporary ileostomy.

COMMENTS

Background

An estimated 11% of women will require surgery for pelvic floor dysfunction, with 29% requiring at least a second surgery. To improve upon the results obtained with the use of native tissue, many surgeons have turned to different graft materials, especially synthetic mesh. Polypropylene mesh has been widely used and studied in such procedures, as abdominal sacral colpopexies and numerous mid-urethral slings. Over the last several years, the use of polypropylene mesh has been extended to augment vaginal repair of the anterior and/or posterior vaginal wall. With the use of prosthetic material (PM), new and specific complications have occurred. These include PM infection, PM erosion or shrinkage, and visceral extrusion. In a systematic review of 2 653 patients that underwent surgery for apical vaginal prolapse, Feiner *et al* reported mesh erosion as the single most frequent complication in 4.6% to 10.7%, depending on the different PMs used.

Research frontiers

Knowledge on the incidence of rectovaginal fistula (RVF) formation after prosthetic material repair for pelvic organ prolapse (POP) is still limited. In addition, uncertainly on the best management of this complication remains. This is in part due to the small number of case reports present in the medical literature. Here, the authors report on their experience with POP management, and to the best of their knowledge this is the largest case series the literature of RVFs after previous reinforcement surgery for POP.

Innovations and breakthroughs

In case of a simple RVF, it is thought that once the infected PM has been removed, a spontaneous cicatrisation of the initially inflamed tissue will lead to

spontaneous RVF closure. However, in three patients who underwent ablation of the PM in a primary surgical intervention outside our department, pelvic inflammation did not substantially minimize within 6 to 12 mo. Even protective colostomy did not resolve pelvic inflammation and closure of the RVF. This might be explained, in some part, by the finding that, in all three patients, some parts of the PM were still found in the pelvis during final surgery, which might have promoted the ongoing pelvic inflammatory process. Therefore, it is unlikely that simple ablation of the PM, with or without the creation of a temporary colostomy, will completely resolve pelvic inflammation and lead to a permanent cure.

Applications

RVF after mesh surgery for POP is a rare, but severe and complication. The exact incidence of this complication depends on the type of PM implanted and the type of previous surgeries performed, and is currently about 0.15% to 1%, as reported in the medical literature. However, it is likely that the true incidence is somewhat higher. Ablation of the PM in a first surgical procedure is unlikely to remove all PM and there is a risk that parts of the infected mesh are left in place, which probably promotes an ongoing inflammation of the pelvis. If the general condition of the patient allows, the authors recommend a radical one-step surgical procedure with open PM ablation, proctectomy, an omental patch, colo-rectal anastomosis, and creation of a temporary ileostomy.

Peer review

This is a good report of uncommon problem with clear-cut guidelines for this problem.

Abstract

AIM: To assess the relationship between vitamin D receptor (*VDR*) gene polymorphisms and the presence of hepatocellular carcinoma (HCC).

METHODS: Two-hundred forty patients who underwent liver transplantation were studied. The etiologies of liver disease were hepatitis C (100 patients), hepatitis B (37) and alcoholic liver disease (103). A group of 236 healthy subjects served as controls. HCC in the explanted liver was detected in 80 patients. The following single nucleotide gene polymorphisms of the VDR were investigated by polymerase chain reaction and restriction fragment length polymorphism: FokI C>T (*F*/*f*), BsmI A>G (*B*/*b*), ApaI T>G (*A*/*a*) and TaqI T>C (*T*/*t*) (BAT).

RESULTS: The frequencies of genotypes in patients without and with HCC were for FokI *F*/*F* = 69, *F*/*f* = 73, *f*/*f* = 18 and *F*/*F* = 36, *F*/*f* = 36, *f*/*f* = 8; BsmI *b*/*b* = 45, *B*/*b* = 87, *B*/*B* = 28 and *b*/*b* = 33, *B*/*b* = 35, *B*/*B* = 12; for ApaI *A*/*A* = 53, *A*/*a* = 85, *a*/*a* = 22 and *A*/*A* = 27, *A*/*a* = 38, a/a = 15; for TaqI *T*/*T* = 44, *T*/*t* = 88, *t*/*t* = 28 and *T*/*T* = 32, *T*/*t* = 38, *t*/*t* = 10. Carriage of the *b*/*b* genotype of BsmI and the *T*/*T* genotype of TaqI was significantly associated with HCC (45/160 *vs* 33/80, $P < 0.05$ and 44/160 *vs* 32/80, $P < 0.05$, respectively). The absence of the A-T-C protective allele of BAT was significantly associated with the presence of HCC (46/80 *vs* 68/160, $P < 0.05$). A strong association was observed between carriage of the *BAT* A-T-C and G-T-T haplotypes and HCC only in alcoholic liver disease (7/46 *vs* 12/36 *vs* 11/21, $P < 0.002$, respectively).

CONCLUSION: *VDR* genetic polymorphisms are significantly associated with the occurrence of HCC in patients with liver cirrhosis. This relationship is more specific for patients with an alcoholic etiology.

INTRODUCTION

Hepatocellular carcinoma (HCC), the fifth most common cause of cancer and the third leading cause of cancer-related death worldwide[1], accounts for 85% to 90% of primary liver cancers. It is characterized by dynamic temporal trends and marked demographic, geographic and ethnic variations[1]. In western countries, HCC is most often superimposed on cirrhosis, its major risk factor[2,3]. Alcohol, hepatitis B virus (HBV) and hepatitis C virus (HCV) are the main etiologic agents of cirrhosis and HCC worldwide. HBV and HCV supposedly exert a direct carcinogenic effect, accounting for the high prevalence of liver cancer among infected patients[2,3]; the same might not be true for alcohol[1]. Overall, it is prudent to affirm that differences in the incidence rates and the strong gender distribution in HCC are not entirely due to differences in the exposure to the three causative agents mentioned above. Genetic factors could also contribute, particularly gene polymorphisms of inflammatory cytokines and growth factor ligands and receptors[4].

The vitamin D receptor (VDR) is a member of the nuclear receptor super-family of ligand-inducible transcription factors which are involved in many physiological processes, including cell growth and differentiation, embryonic development and metabolic homeostasis. The transcriptional activity of this receptor is modulated by ligands, such as steroids, retinoids and other lipid-soluble compounds, and by nuclear proteins acting as co-activators and co-repressors[5,6]. The liganded VDR heterodimerizes with the retinoid X receptor and binds to vitamin D response elements in the promoter of target genes, thereby affecting their transcription. The genomic organization of the *VDR* at locus 12q13.1 shows that the *VDR* gene itself is quite large (over 100 kb) and has an extensive promoter region capable of generating multiple tissue-specific transcripts[7].

Several single nucleotide restriction fragment length polymorphisms have been described in the *VDR* gene in association with neoplastic and non-neoplastic diseases. In particular, *VDR* polymorphisms have been related to, although with conflicting observations, cancers of the breast, prostate, skin, colon-rectum, bladder and kidney[8-10]. Furthermore, *VDR* polymorphisms were found to influence the prognosis of prostate and breast cancer, renal cell carcinoma and malignant melanoma[11]. *VDR* polymorphisms have been investigated in the context of some chronic liver diseases, such as primary biliary cirrhosis and auto-immune hepatitis[12-16]. Surprisingly, however, there are no data in the literature on the possible association between *VDR* polymorphisms and the occurrence of HCC.

The aims of the present paper were (a) to investigate the possible relationship between *VDR* polymorphisms and the occurrence of HCC in patients with liver cirrhosis and (b) to assess whether the etiology of their liver disease exerts a role in modulating such a relationship.

MATERIALS AND METHODS

Patients

The study included 240 consecutive patients who underwent liver transplantation (LT) for end-stage liver disease due to hepatitis B (n = 37, 15.4%), hepatitis C (n = 100, 41.7%) and alcoholic liver disease (n = 103, 42.9%). The main demographic and clinical characteristics are reported in Table 1. Two-hundred thirty-six healthy community blood donors served as controls. They were 164 males (69.5%) and 72 females (30.5%); the median age was 48 years with a range of 18-77 years. The male gender distribution in the patients and controls (74% *vs* 70%) was similar, whereas these two groups differed in age: 54 ± 8 years *vs* 46 ± 13 years (mean ± SD, $P < 0.0001$). Control subjects did not have any clinical and/or laboratory evidence of liver disease or other major pathological conditions, such as diabetes mellitus. All patients and controls were Caucasian. Informed consent to participate in the study was obtained from each subject in accordance with the Declaration of Helsinki and following the guidelines of our ethical committee. All study participants approved the storage of their frozen DNA specimens for research purposes in our laboratory.

Histology

All total hepatectomy specimens were sectioned at intervals of approximately one cm to search for suspicious focal hepatic lesions. Standard histological staining techniques were applied to confirm the presence of HCC and to evaluate the characteristics of the identified tumors, such as pathologic tumor grade (Edmondson grade) and macro- or micro-vascular invasion.

Vitamin D assay

In 113 patients (47.1%), serum samples, which were collected the day before the transplant operation and were separated and stored at -80℃ until analysis, were available to assay the pre-LT serum vitamin D concentration. Circulating 25-hydroxyvitamin D levels were measured using a chemo-luminescent immunoassay implemented on a Liaison automatic analyzer (DiaSorin Inc, Stillwater, MN, USA). Data were expressed in ng/mL. Reference values of serum vitamin D adopted in this study were in accordance with those proposed by the Scientific Advisory Committee of Nutrition[17], which considers serum vitamin D levels < 10-15 ng/mL to be inadequate for bone and overall health in healthy individuals.

Molecular biology

Genomic DNA was isolated from whole blood using the QIAamp DNA Blood Mini Kit (Qiagen, Milan, Italy) according to the manufacturer's instructions. Four diallelic polymorphisms of the *VDR* were genotyped: FokI C>T

Table 1 Main demographic and clinical characteristics of liver transplant recipients (*n* = 240) according to the presence (*n* = 80, 33.3%) or absence (*n* = 160, 66.7%) of HCC

The continuous variables are reported as means (standard deviation), whereas the categorical variables are reported as frequencies (%). Statistical analysis was performed using the Student's *t*-test for continuous variables and the Pearson χ^2 test for categorical variables. [1]At transplant operation. HCC: Hepatocellular carcinoma; HBV: Hepatitis B virus; HCV: Hepatitis C virus; NS: Not significant.

(rs10735810) and TaqI T>C (rs10735810) polymorphic sites on the coding sequence, BsmI A>G (rs1544410) and ApaI G>T (rs7975232) on the last intron. For the detection of the *VDR* polymorphisms, the polymerase chain reaction (PCR) technique was applied and followed by restriction fragment length polymorphism assays. The PCR amplifications were carried out in a total volume of 10 μL containing 10 mmol/L Tris-HCl (pH 8.3), 50 mmol/L KCl, 0.01% Tween-20, 0.2 mmol/L deoxyribonucleotides, 2-4 pmol of each primer, 2.0 mmol/L $MgCl_2$ and 0.5 U hot-start *Taq* DNA polymerase (RighTaq, Euroclone, Milan, Italy). The sequences of primers used for FokI were (*f*) 5'-TGCAGCCTTCACAGGTCATA-3', (*r*) 5'-GGCCTGCTTGCTGTTCTTAC-3'; for TaqI and ApaI were (*f*) 5'-ACGTCTGCAGTGTGTTGGAC-3', (*r*) 5'-TCACCGGTCAGCAGTCATAG-3'; for BsmI were (*f*) 5'-CAGTTCACGCAAGAGCAGAG-3', (*r*) 5'-ACCTGAAGGGAGACGTAGCA-3'. All the primers were newly designed with the aid of the NCBI Primer-Blast Tool (http://www.ncbi.nlm.nih.gov/tools/primer-blast/). The cycling conditions for all the *VDR* polymorphisms were set as 40 cycles at 95℃ for 30 s, 61℃ for 30 s and 72℃ for 1 min. In a total volume of 20 μL, amplified DNA (10 μL) was digested overnight with 2 U of restriction endonucleases using the buffers and temperatures recommended by the manufacturers. The presence of restriction sites for the FokI, TaqI, BsmI and ApaI enzymes were coded as '*f*', '*t*', '*b*' and '*a*' and the absence of restriction sites as '*F*', '*T*', '*B*' and '*A*', respectively. The FokI C>T (*F*/*f*) polymorphism was analyzed by digestion of a 157-bp PCR product with FokI (New England Biolabs, Hitchin, UK), which resulted in two fragments of 121 and 36 bp in the presence of the '*f*' allele and in an uncut fragment in the presence of the '*F*' allele. The TaqI T>C (*T*/*t*) and ApaI T>G (*A*/*a*) polymorphisms were analyzed by digestion of a 211-bp PCR product with TaqI (New England Biolabs, Hitchin, UK), which resulted in two fragments of 172 and 39 bp in the presence of the '*t*' allele. These same polymorphisms were also analyzed by digestion with ApaI (New England Biolabs, Hitchin, UK), which resulted in two fragments of 121 and 90 bp for the '*a*' allele. The BsmI A>G (*B*/*b*) polymorphism was analyzed by digestion of a 236-bp PCR product with BsmI (New England Biolabs, Hitchin, UK), which resulted in two fragments of 197 and 39 bp in the presence of the '*b*' allele. All PCR reactions were carried out in a Techne TC-412 thermal cycle, and PCR products were sized by electrophoresis on a 3% agarose gel stained with ethidium bromide.

Statistical analysis

The statistical analysis of data was performed using the BMDP Dynamic Statistical Software Package 7.0 (Statistical Solutions, Cork, Ireland). Continuous variables were presented as median (range) or mean ± SD, whereas categorical variables were expressed as frequencies (%). Differences between continuous variables were assessed by the Student's *t*-test, whereas differences between categorical variables were evaluated using the Pearson χ^2 test. The χ^2 *G* test "Goodness of Fit" was employed to verify whether the proportions of the four polymorphisms were distributed in controls and in patients in accordance with the Hardy-Weinberg equation. Differences in the allelic and genotypic frequencies between different groups were assessed by means of the Pearson χ^2 test and calculation of odds ratios with 95% confidence intervals (CI). Haplotype reconstruction from population genotype data and inferred phased diplotype calculation for each control subject or patient with liver cirrhosis were performed by means of the ARLEQUIN integrated software package for population genetics, version 3.1[18]. Analysis of molecular variance (AMOVA) with a global and a pair-wise approach was performed to assess whether haplotype allelic content differed among groups. Locus-by-locus AMOVA was utilized to assess the statistical contribution of each polymorphism. Pairwise differences in haplotype frequencies were assessed using the exact test for sample differentiation. Linkage disequilibrium between the four analyzed VDR poly-

Table 2 Allelic and genotypic frequencies of the VDR FokI C>T (*F*/*f*), BsmI A>G (*B*/*b*), ApaI T>G (*A*/*a*) and TaqI T>C (*T*/*t*) polymorphisms in controls and liver cirrhosis patients *n* (%)

The odds ratios were constructed with the wild type for each polymorphism as the reference. The statistical analysis was carried out using the Pearson χ^2 test. [1]Pearson χ^2 test; OR: Odds ratio; CI: Confidence interval; VDR: Vitamin D receptor.

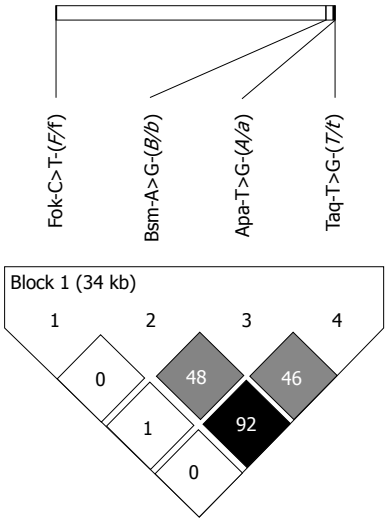

Figure 1 Schematic representation of linkage disequilibrium in the studied population (*n* = 476) between the four VDR polymorphisms: FokI C>T (*F*/*f*), BsmI A>G (*B*/*b*), ApaI T>G (*A*/*a*) and TaqI T>C (*T*/*t*). R^2 for linkage disequilibrium between each marker is reported. Shades of gray are proportional to the R^2 value, expressing the strength of the linkage disequilibrium.

morphisms in the studied population was determined by means of the Haploview software[19]. Stepwise logistic regression analysis with a forward approach was used to verify whether the absence or presence of specific VDR haplotypes was an independent predictor of HCC.

RESULTS

Liver histology

HCC foci were detected in the native livers from 80 (33.3%) of the patients with end-stage liver disease; 33 patients (41.2%) were HCV positive, 17 (21.2%) HBV positive, and 30 (29.1%) had alcoholic liver disease. Table 1 illustrates the distribution of the values of the main demographic and clinical variables of cirrhotic patients according to the presence of HCC. Sixteen patients (20.0%) had an Edmondson grade of one, forty-eight patients (60.0%) had a grade of two, fifteen patients (18.8%) had a grade of three and one patient (1.2%) had a grade of four. Macro- and micro-vascular invasion was only observed in five cases (6.2%).

VDR polymorphisms in liver cirrhosis and controls

FokI C>T (*F*/*f*), BsmI A>G (*B*/*b*), ApaI T>G (*A*/*a*) and TaqI T>C (*T*/*t*) allele and genotype frequencies are reported in Table 2. No departure from the Hardy-Weinberg equilibrium equation was observed for each polymorphism in patients or controls. No significant difference was detected between patients and controls in allele or genotype frequencies. A strong linkage disequilibrium was detected between BsmI and TaqI (R^2 = 0.92); linkage disequilibrium was also detected between ApaI and TaqI (R^2 = 0.46) and between BsmI and ApaI (R^2 = 0.48) (Figure 1).

VDR polymorphisms in patients and controls in relationship to the etiology of liver disease

AMOVA was performed by grouping the liver cirrhosis patients according to the etiology of their liver disease: patients with cirrhosis of viral origin (*n* = 137) and patients with cirrhosis of alcoholic origin (*n* = 103); a third group consisted of control subjects (*n* = 236). A significant difference was detected among these three populations ($P < 0.05$) by global AMOVA; the comparison of

The statistical analysis was performed by means of the exact test for sample differentiation based on haplotype frequencies. Alcoholic *vs* viral liver cirrhosis $P < 0.05$.

pairs of population samples demonstrated a significant difference between patients with cirrhosis of viral and alcoholic origin ($P < 0.01$). Locus-by-locus AMOVA showed the following significant differences for the single nucleotide gene polymorphisms tested: FokI C>T (*F/f*) $P = 0.720$, BsmI A>G (*B/b*) $P = 0.047$, ApaI T>G (*A/a*) $P = 0.052$ and TaqI T>C (*T/t*) $P = 0.065$. Estimated VDR haplotype frequencies of FokI C>T, BsmI A>G, ApaI T>G and TaqI T>C polymorphisms are reported in Table 3. A significant difference in haplotype frequencies was detected between patients with cirrhosis of viral and alcoholic origin.

VDR polymorphisms in liver cirrhosis with and without HCC

Table 4 illustrates the genotype frequencies of FokI C>T (*F/f*), BsmI A>G (*B/b*), ApaI T>G (*A/a*) and TaqI T>C (*T/t*) polymorphisms in patients with liver cirrhosis grouped according to the presence (n = 80) or absence (n = 160) of HCC. Patients with HCC were more likely to carry the *b/b* genotype compared with the *B/B* + *B/b* genotypes of the BsmI A>G (*B/b*) polymorphism and the *T/T* genotype compared with the *T/t* + *t/t* genotypes of the TaqI T>C (*T/t*) polymorphism. Considering the BsmI A>G (*B/b*), ApaI T>G (*A/a*) and TaqI T>C (*T/t*) (*BAT*) polymorphisms, carriage of the A-T-C haplotype was associated with the absence of HCC and carriage of the G-T-T haplotype with the presence of HCC. We then grouped the patients as follows: group (a) carriers of the *BAT* A-T-C haplotype (n = 126), group (b) carriers of both *BAT* A-T-C and G-T-T haplotypes or of none of the two haplotypes (n = 75) and group (c) carriers of the *BAT* G-T-T haplotype (n = 39). A significantly linear trend for increasing frequencies of HCC was detected starting with group (a) (34/126, 27.0%) to group (b) (29/75, 38.7%) to group (c) (17/39, 43.6%, $P < 0.05$). Stepwise logistic regression analysis was performed to verify whether carriage of the *BAT* A-T-C and G-T-T haplotypes was a predictor of HCC independent of gender, age (≤/> 50 years), body mass index (</≥ 25 kg/m^2), Child-Pugh score (≤/> 8) at the transplant operation, viral etiology of liver disease and presence of diabetes mellitus. The analysis confirmed that carriage of the *BAT* A-T-C and G-T-T haplotypes was a predictor of HCC occurrence (improvement of χ^2 $P < 0.05$, OR, 1.95, 95% CI: 1.06-3.57) independent of age > 50 years (improvement of χ^2 $P < 0.001$, OR 3.81, 95% CI: 1.75-8.29), male gender (improvement of χ^2 $P = 0.001$, OR 4.01, 95% CI: 1.80-8.96), viral etiology of liver disease (improvement of χ^2 $P < 0.05$, OR 2.19, 95% CI: 1.18-4.05) and body mass index ≥ 25 kg/m^2 (improvement of χ^2 $P < 0.05$, OR 1.82, 95% CI: 0.99-3.35).

VDR polymorphisms in liver cirrhosis with and without HCC in relationship to the etiology of liver disease

AMOVA was performed by grouping the patients with liver cirrhosis according to the etiology of their liver disease (viral origin n = 137 and alcoholic origin n = 103) and the presence (n = 80) or absence (n = 160) of HCC. A significant difference was detected among these four populations ($P < 0.002$); the comparison of pairs of population samples demonstrated significant differences between patients with liver cirrhosis of alcoholic origin with HCC *vs* (a) patients with liver cirrhosis of viral origin with HCC ($P < 0.0001$), (b) patients with liver cirrhosis of viral origin without HCC ($P < 0.0001$) and (c) patients with liver cirrhosis of alcoholic origin without HCC ($P < 0.01$). Locus-by-locus AMOVA showed the following significant differences for the single polymorphisms: FokI C>T (*F/f*) $P = 0.923$, BsmI A>G (*B/b*) $P = 0.000$, ApaI T>G (*A/a*) $P = 0.033$ and TaqI T>C (*T/t*) $P = 0.000$. Estimated VDR haplotype frequencies of FokI C>T, BsmI A>G, ApaI T>G and TaqI T>C polymorphisms are reported in Table 5. A significant difference in haplotype frequencies was detected between patients with alcoholic liver cirrhosis with HCC *vs* patients with viral liver cirrhosis without HCC ($P < 0.01$) and patients with viral liver cirrhosis with HCC ($P < 0.05$). Although no relationship was detected between carriage of the *BAT* A-T-C and G-T-T haplotypes and the pres-

Table 4 Genotypic frequencies of the VDR FokI C>T (*F/f*), BsmI A>G (*B/b*), ApaI T>G (*A/a*) and TaqI T>C (*T/t*) polymorphisms in liver cirrhosis patients grouped according to the presence or absence of HCC

The statistical analysis was performed by means of the exact test for sample differentiation based on haplotype frequencies. Non-viral liver cirrhosis with HCC *vs* (a) viral liver cirrhosis without HCC, $P < 0.01$, (b) viral liver cirrhosis with HCC, $P < 0.05$.

ence of HCC in patients with viral liver disease, a strong association was observed between carriage of the *BAT* A-T-C and G-T-T haplotypes and HCC in alcoholic liver disease (27/80 *vs* 17/39 *vs* 6/18, P = NS) (7/46 *vs* 12/36 *vs* 11/21, $P < 0.002$).

Vitamin D levels and VDR haplotypes in relationship to HCC occurrence

A significant linear trend was detected when patients were grouped according to gender and vitamin D serum levels (cut-off level 15 ng/mL) in relation to HCC occurrence. Group A and B comprised female patients with vitamin D serum levels ≤ 15 ng/mL and > 15 ng/mL, respectively; group C and D comprised male patients with serum levels of vitamin D ≤ 15 ng/mL and > 15 ng/mL, respectively. HCC was detected with increasing frequency starting with group A (0/12, 0.0%) to group B (2/12, 16.7%) to group C (16/38, 42.1%) to group D (26/51, 51.0%, $P < 0.0005$). A synergistic effect was found between vitamin D serum levels > 15 ng/mL and carriage of the *BAT* ATC haplotype; in these patients, HCC occurred in 5/26 (19.2%) cases compared with 39/87 (44.8%) of the remaining cases ($P < 0.02$).

DISCUSSION

In the present study, patients with liver cirrhosis were found to present allele and genotype frequencies of FokI C>T (*F/f*), BsmI A>G (*B/b*), ApaI T>G (*A/a*) and TaqI T>C (*T/t*) polymorphisms close to those observed in control subjects. Associations between specific polymorphisms and auto-immune hepatitis and primary biliary cirrhosis have been observed in several studies, although with conflicting results. In fact, the presence of the *B* allele of the BsmI A>G (*B/b*) polymorphism was found to be associated with the occurrence of primary biliary cirrhosis in three studies involving Caucasian and Japanese populations[12-14], whereas in two other studies performed in Caucasian and Chinese populations[15,16], primary biliary cirrhosis was related to the presence of the *b* allele. Similarly, Vogel *et al*[15] found an association between chronic auto-immune hepatitis and the *F* allele of the FokI C>T

(*F*/*f*) polymorphism, whereas the opposite results were observed by Fan *et al*[16]. Our study of patients affected by liver cirrhosis of viral (HBV or HCV) and alcoholic origin did not demonstrate any differences in the allele and genotype frequencies of the *VDR* polymorphisms between the patients and controls. The data agree with the only report in the literature on *VDR* polymorphisms in patients with chronic liver disease of a non-auto-immune origin. In fact, Suneetha *et al*[20] did not demonstrate differences in *VDR* polymorphism allele frequencies between controls and patients with chronic viral hepatitis due to HBV.

Some novel findings were provided by the present investigation. The first is represented by the observation of differences in the *VDR* polymorphisms in patients with liver cirrhosis in relationship to the etiology of their liver disease. The analysis of molecular variance found a significant difference in allele frequencies between patients with viral (HBV and HCV) and alcoholic liver cirrhosis; this was accounted for by the significant differences of the BsmI A>G (*B*/*b*), ApaI T>G (*A*/*a*) and TaqI T>C (*T*/*t*) (*BAT*) polymorphisms for which a strong linkage disequilibrium was detected. On the contrary, the FokI C>T (*F*/*f*) polymorphism was non-significantly distributed between these two groups. Consequently, haplotype analysis highlighted a different distribution between the two groups with liver cirrhosis; the *BAT* A-T-C haplotype was more represented in patients with viral cirrhosis (0.460%) than in those with alcoholic cirrhosis (0.339%). We are unable to provide a clear explanation of this previously unreported finding especially because the BsmI A>G (*B*/*b*), ApaI T>G (*A*/*a*) and TaqI T>C (*T*/*t*) (*BAT*) polymorphisms are located in a *VDR* gene region of unknown function. Two possible explanations are hypothesized: (a) the real genetic risk for liver cirrhosis might be in linkage disequilibrium with the observed haplotypes of these polymorphisms and/or (b) gene-environment interactions have a causative role.

The second novel finding of this paper is the significant association between *VDR* polymorphisms and the presence of HCC in patients with liver cirrhosis. HCC was found to be associated with the *b* allele of the BsmI A>G (*B*/*b*) polymorphism and with the *T* allele of the TaqI T>C (*T*/*t*) polymorphism. The *BAT* A-T-C haplotype was inversely related to the occurrence of HCC, whereas the *BAT* G-T-T haplotype was directly associated with this cancer; these associations were independent of the main demographic and clinical variables known to be strong predictors of the occurrence of HCC. *VDR* polymorphisms have been explored in cancers of epithelial origin, such as breast, ovarian, prostate, lung and skin cancers[20,21]. Even though some studies did not detect associations between the *VDR* polymorphisms and these diseases, e.g. Gsur *et al*[23] in prostate cancer and Dunning *et al*[24] in breast cancer, the majority of the authors found a significant association between the *VDR* polymorphisms and cancer[8-10,20]. In particular, carriage of the *B* BsmI A>G (*B*/*b*) allele and of the *t* TaqI T>C (*T*/*t*) allele has been described to exert a protective effect in prostate cancer[24], malignant melanoma[25,26] and breast cancer[27]; these results support our findings in the present series on HCC in liver cirrhosis.

The third observation that may be derived from these data concerns the strong interaction between the presence of HCC and the etiology of liver cirrhosis in relationship to *VDR* polymorphisms. Both the analysis of molecular variance and the estimated haplotype frequencies highlighted the different behaviors that were detected in the *VDR* polymorphisms in alcoholic patients with HCC, patients with alcoholic cirrhosis without HCC and patients with liver cirrhosis of viral origin complicated or uncomplicated by the presence of HCC. Locus-by-locus analysis demonstrated that the major contribution was provided by the BsmI A>G (*B*/*b*) and TaqI T>C (*T*/*t*) polymorphisms; the *BAT* A-T-C haplotype was strongly protective, whereas the G-T-T haplotype was associated with HCC in patients with alcoholic cirrhosis but not in patients with liver cirrhosis of viral origin.

Besides the classic action involving calcium and phosphate homeostasis, vitamin D possesses non-classic actions also known to be mediated through the VDR[28]. First, vitamin D exerts immune modulation activity either by stimulating innate immune function[29] and/or by inhibiting hyper-activity of adaptive immunity[30]. More closely related to the subject of the present study, vitamin D has been extensively evaluated for its potential anticancer activity in animal and cell studies. It has been suggested that the anticancer activity of vitamin D is due to its anti-proliferative and pro-differentiating action in most cell types[31]. From an epidemiological point of view, there is some evidence that low vitamin levels are associated with a higher incidence of cancer[32] even though there is no known beneficial effect of treating cancers with vitamin D[33].

Patients with liver cirrhosis are known to be at high risk for vitamin D deficiency in direct proportion to the severity of their chronic liver disease[34,35]. This observation applies particularly to cirrhotic patients with end-stage liver cirrhosis who are subjected to liver transplantation[36], such as those investigated in the present study. In contrast, chronic alcohol abuse is a factor that can interfere in multiple ways with vitamin D metabolism either through malnutrition with an assumption of reduced nutrient intake and/or reduced exposure to sunlight. Reduced vitamin D levels have been detected in the majority of alcoholic patients without chronic liver disease[37]. It is conceivable, therefore, that in patients with liver cirrhosis, the synergistic action of severely reduced serum vitamin D levels and of a specific *VDR* haplotype facilitates HCC development. In fact, supporting this hypothesis, we found vitamin D insufficiency ($\leqslant$ 15 ng/mL) in a large proportion (55.8%) of our patients with end-stage chronic liver disease; moreover, a gender-adjusted association between vitamin D insufficiency and the occurrence of HCC was also detected. Finally, HCC foci were observed less frequently in the native livers of patients carrying the protective *BAT* A-T-C haplotype and simultaneously possessing serum vitamin D levels > 15 ng/mL.

In conclusion, *VDR* genetic polymorphisms are signif-

icantly associated with the occurrence of HCC in patients with liver cirrhosis. This relationship is more specific for patients with an alcoholic etiology.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the fifth most common cancer and the third leading cause of cancer-related death worldwide. Liver cirrhosis due to alcohol consumption or to chronic infection by hepatitis C virus (HCV) and hepatitis B virus (HBV) are considered the main etiologic agents for the development of HCC. The differences in the incidence rates and the strong gender distribution of HCC are probably not entirely due to differences in exposure to the three causative agents mentioned above. Recently, several genetic factors regarding gene polymorphisms of inflammatory cytokines and growth factors have been considered.

Research frontiers

The vitamin D receptor (VDR) is a member of the nuclear receptor superfamily of ligand- inducible transcription factors which are involved in cell growth and differentiation. Several single nucleotide restriction length polymorphisms have been described in the *VDR* gene in association with cancers of the breast, prostate, colon, bladder and kidney. There are no data in the literature concerning the prevalence of *VDR* polymorphisms in HCC of different etiologies.

Innovations and breakthroughs

This is the first study to examine the potential role of *VDR* genetic polymorphisms in the occurrence of HCC in humans. In this study, the authors investigate the *VDR* single nucleotide gene polymorphisms FokI C>T (*F/f*), BsmI A>G (*B/b*), ApaI T>G (*A/a*) and TaqI T>C (*T/t*) (BAT) in a large series of patients who underwent liver transplantation due to liver cirrhosis with or without HCC. They demonstrate that carriage of the *b/b* genotype of BsmI and the *T/T* genotype of TaqI was significantly associated with HCC, whereas carriage of the *BAT* A-T-C and G-T-T haplotypes was significantly more prevalent in patients with alcoholic liver disease and HCC.

Applications

The characterization of *VDR* genetic polymorphisms in patients with liver cirrhosis could help to identify those who are at high risk of developing HCC. This observation could be used to modify the strategy of periodical ultrasound surveillance in this category of patients.

Peer review

In this paper, the relationships between *VDR* gene polymorphisms and the presence of HCC have been evaluated in patients with viral or alcoholic cirrhosis. The most important result of this study is the observation that some *VDR* genetic polymorphisms are associated with the occurrence of HCC in patients with liver cirrhosis. The results are convincing, well presented and of some interest.

Abstract

AIM: To evaluate the relationship between glycemic control [assessed by glycated hemoglobin (HbA1c)], antidiabetic therapies and the risk of hepatocellular carcinoma (HCC).

METHODS: We recruited 465 patients with HCC, 618 cases with liver cirrhosis and 490 controls with no liver disease. Among subjects with type 2 diabetes mellitus (DM2), the associations between the antidiabetic strategies and HbA1c level with HCC were determined through 2 series of multivariate logistic regression models using cirrhotic patients and controls as comparison groups.

RESULTS: DM2 prevalence was 31.2% in patients with HCC, 23.2% in cirrhotic patients and 12.6% in controls ($P < 0.0001$). In 86% of study subjects, DM2 had been diagnosed for more than 1 year before the HCC diagnosis. HCC patients with DM2 had a 1.5-2.5-fold increased risk of liver cancer. The HbA1c mean levels were significantly higher in DM2 patients with HCC than in cirrhotic and control DM2 patients. Antidiabetic treatment with metformin was more common among cirrhotic and control DM2 subjects than among cases with HCC. In both series of multivariate analyses, treatment with metformin significantly reduced the risk of HCC by more than 80% compared with sulphonylureas and insulin therapy. No significant differences were seen between sulphonylureas and insulin treatment. Elevated HbA1c levels were positively related to the risk for HCC in diabetic patients, with a 26%-50% increase in risk for each 1% increase in HbA1c values.

CONCLUSION: In patients with preexisting DM2, the risk of HCC is positively associated with poor chronic glycemic control and significantly decreased by metformin therapy.

INTRODUCTION

The incidence and mortality rates of hepatocellular carci-

noma (HCC) have significantly increased in recent years, particularly in Western countries[1,2]. The main known risk factors for HCC are hepatitis C and B virus (HCV, HBV) infections and chronic alcohol abuse, but at least 25% of HCC cases do not have any recognized etiology. Diabetes mellitus has been proposed to be associated with HCC development[3], and several investigations in recent years clearly indicated that type 2 diabetes mellitus (DM2) is a risk factor for HCC[1,4-9]. During the past 2 decades, the prevalence of diabetes mellitus, and in particular of DM2, has dramatically increased in many countries, including Italy[10]. Sedentary lifestyles, excessive food consumption and obesity appear to be the main causes of the current diabetes mellitus epidemic[11].

It is unclear how DM2 influences hepatocarcinogenesis. Insulin resistance (IR) is a basic feature of DM2, a disorder characterized by hyperglycemia associated with IR and consequent hyperinsulinemia. Several reports have suggested that the mechanism underlying the effects of DM2 and antidiabetic therapies on hepatic carcinogenesis could be related to IR and hyperinsulinemia[12-16]. In DM2 patients, insulin plasma levels are chronically increased by therapies based on both exogenous insulin or insulin secretagogues, such as sulphonylureas. An excess of insulin plasma levels is the proposed mechanism underlying the well established association of DM2[16-18] and obesity[19] (the so called diabesity) with several types of solid tumors[20,21]. In a previous study, we found that DM2 in our population was an independent risk factor for HCC, and that it precedes HCC development[12]. In addition, in male chronic liver disease (CLD) patients with DM2, the risk of HCC is increased by insulin or sulphonylurea treatment. We also reported that the association between IR and CLD began in the early stages of liver fibrosis, and that DM2 significantly increased IR in HCC patients. Therefore, IR together with the consequent hyperinsulinemia, seems to play a major role in the link between DM2 and hepatocarcinoma[13].

Recent reports have shown that liver carcinogenesis is increased not only in HCV infected patients with previously diagnosed and/or treated DM2[22,23], but also in HCV infected subjects with no pre-existing history of DM2 and in the early stages of glucose intolerance, as diagnosed by a 75 g oral glucose tolerance test[24]. In addition, , a positive association between high dietary glycemic load and risk of HCC in patients with chronic HBV and HCV infection has been reported[25]; the pathogenesis and outcome of cryptogenic HCC seems to be more closely associated with the risk factors for metabolic syndrome than with HBV and HCV[26].

Despite extensive literature linking glucose intolerance with hepatocarcinogenesis, it remains unclear whether blood glucose control may influence the malignant potential that DM2 exerts on the liver. Only one prospective study reported that hyperglycemia was associated with increased total cancer risk in women and men, independently of obesity[27]. As far as we know, the effect of glycemic control on liver carcinogenesis and the role of treatment strategies to achieve the metabolic control in DM2 patients with CLD have not been investigated yet.

Therefore, the aims of our study were to explore the association between HCC and DM2 in CLD subjects, and to assess the relationships between glycemic control, as determined by glycated hemoglobin (HbA1c) measurement, antidiabetic strategies and the risk of HCC in DM2 patients with CLD.

MATERIALS AND METHODS

Ethics

This work has been carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association. All of the studies were performed retrospectively by collecting and analyzing data from the patient records. This study had been approved by the Institutional Review Board of our hospital.

Design and case selection

For this retrospective, hospital based case-control study, subjects were recruited from patients attending the 3rd Internal Medicine of Pordenone General Hospital (Pordenone, Italy). The 3rd Internal Medicine is a tertiary referral center for liver diseases and diabetes mellitus. The case group consisted of patients with incident HCC admitted to the hospital. We then recruited two comparison groups: the first consisted of patients admitted for liver cirrhosis (LC); the second consisted of control individuals admitted for a wide spectrum of acute conditions other than diabetes mellitus and liver disease as primary diagnoses.

HCC group

The HCC group consisted of 465 (364 male, 101 female) consecutive patients with newly diagnosed HCC attending the 3rd Internal Medicine from January 1994 to June 2006. Of these, 398 (85.6%) were diagnosed by cytological or histological examination of hepatic focal lesions; the remaining 67 (14.4%) were diagnosed according to the following acknowledged criteria[28]: ultrasound examination (also by using micro-bubbles of sulfur hexafluoride as contrast dye in the last 3 years), α-fetoprotein (AFP) > 400 ng/mL, computerized tomography liver scan and/or magnetic resonance imaging. Based on the type of presentation, the HCC patients were subdivided into two groups: (1) 305 subjects from our surveillance program of HCC in cirrhotic patients (follow-up group: FU); and (2) 160 subjects presenting with symptomatic and advanced neoplastic disease of the liver (clinically overt: CO). The FU group included patients with a small single hepatic tumor who received the diagnosis within the HCC surveillance program in cirrhotic patients based on ultrasound examinations and AFP determinations every 3-6 mo; the CO group included cases with advanced, large size and symptomatic HCC at diagnosis. Clinical data, biochemical parameters and the antidiabetic treatment of patients were considered at the time of HCC diagnosis during the first admission to our Hospital.

In order to gain complete and accurate information on the time interval between DM2 onset and the diagnosis of HCC and to determine the levels of HbA1c testing before the HCC diagnosis, we reviewed, starting from October 1985, all medical documentation stored at the Diabetes Clinic.

Liver cirrhosis group

We enrolled 618 patients (450 male, 168 female) with LC, by selecting from 3560 cirrhotic patients treated at our Department subjects frequency-matched with the HCC cases, according to age (± 5 years), gender, body mass index (BMI), transaminases, serologic markers of HBV and HCV infections, alcohol consumption, time of hospital admission. The diagnosis of cirrhosis was performed either by hepatic biopsy or by ultrasound examination in the fasting state, showing the presence of splenomegaly, hypertrophy of the left or caudal lobes and surface irregularity or by transient elastography using the Fibroscan (Echosens, Paris) with a liver stiffness > 12.5 kPa[29]. LC patients were admitted to our Hospital for diagnosis, staging or therapy of LC. Clinical data, biochemical parameters and antidiabetic treatment were considered at the time of the first admission to our Hospital. According to Child's classification of cirrhosis, patients were classified as follows: class A: 55.5%; B: 24.3% and C: 20.2%. In cirrhotic patients, the presence of HCC was ruled out through ultrasound examinations, computed tomography or magnetic resonance imaging of the upper abdomen and AFP determination.

Control group

We enrolled 490 control subjects (385 male, 105 female) as follows: from 28740 inpatients of our hospital, we generated a pool of 7610 subjects with available tests as possible controls. Then we selected from them a frequency-matched subject for each HCC or LC patient, according to age (± 5 years), gender, BMI, time of hospital admission. Clinical data, biochemical parameters and therapeutic schedule of control subjects were considered at the time of the first admission to our Hospital. Subjects admitted for malignancies, alcohol-related disease, liver disease and DM2 as primary diagnoses were excluded from the study. The primary diagnoses of admission were: chronic heart failure (34.9%), hypertension (21.4%), chronic obstructive broncho-pneumopathies or pneumonia (16.5%), atrial fibrillation (7.8%), deep venous thrombosis (6.5%), fever of unknown origin (5.3%), benign tumors (4.1%), gastritis (3.5%). These subjects were assumed to represent our Region's general population as regards the prevalence of HCV, HBV infection, alcohol consumption and DM2. The prevalence of these parameters[30-33] in the free living population of the Pordenone area with an age range of 60-75 years and a similar age sub-sample of our control group is reported in Table 1.

Table 1 Mean prevalence of HCV infection, HBV infection, alcohol abuse and DM2 in the free living population of the Pordenone area and controls in this study

	General population (%)		Control group of the study (%)
	Global	60-75 yr age interval	
HCV positive	3.2	5.0	5.3
HBV positive	1.2	1.7	1.2
Alcohol abuse	4.5	5.0	4.7
DM2	4.8	12.4	12.6

HCV: Hepatitis C virus; HBV: Hepatitis B virus; DM2: Type 2 diabetes mellitus.

Methods

DM2 was diagnosed using the American Diabetes Association criteria[34]. Biochemical parameters were determined at the Pordenone Hospital central laboratory, using standardized and validated methods. Venous blood samples were taken in the morning after 12 h overnight fasting. Blood samples were available for 460 HCC cases and for all LC patients and controls. HbA1c was measured by high performance liquid chromatography (A1cHA-8160 Menarini, Italy)[35] for all diabetic subjects in our study. The nondiabetic range for our method of HbA1c testing was 4.0%-6.0% using a DCCT (Diabetes Control Complications Trial)-based assay[36]. For each subject we used the mean of 2 samples, taken on 2 consecutive days at the time of enrollment.

To assess the chronic diabetes controls in HCC patients with pre-existing DM2, we evaluated the individual HbA1c values tracked in the time before liver cancer diagnosis. Based on the records of the Diabetes Clinic, we determined the mean HbA1c levels of at least 3 tests/patient carried out approximately every 2 years before HCC clinical occurrence.

HBV surface antigen (HBsAg), anti-HBV surface antigen (anti-HBs), anti-HBV core antigen (anti-HBc), and hepatitis B e antigen (HBeAg) were determined using commercial assays (Abbott Diagnostic Division, Wiesbaden, Germany). Sera were also screened for antibodies against HCV (anti-HCV) using a third-generation microparticle enzyme immunoassay (AxSYM HCV version 3.0, Abbott Diagnostic Division). Positive samples were tested for anti-HCV using a third-generation line immunoassay (Immunogenetics, Gent, Belgium) and for serum HCV-RNA using the Roche Amplicor version 2.0 (Roche Molecular System, Pleasenton, CA, USA).

Information on consumption of alcoholic drinks was collected through a structured questionnaire which was returned by 455 HCC patients and by all LC and control subjects. Average alcohol content was estimated as 5% for beer, 12% for wine and 40% for spirits[37]. Alcohol abuse was defined as a daily consumption of over 30 g for males and over 20 g for females.

Statistical analysis

All the data were collected in a computerized database. Normality of the distributions of all continuous variables was tested by the Shapiro-Wilk test. The Student *t*-test and ANOVA were used to assess the statistical significance of

differences among groups for continuous variables with normal distribution; the Wilcoxon rank sum and Kruskal-Wallis tests were used for continuous variables with non-normal distribution. The χ^2 test was used to evaluate the significance of differences among groups for categorical variables. Multivariate logistic regression was used to assess the association between HCC and DM2, antidiabetic therapy, and glycemic control after adjusting for potentially confounding factors. Separate models were built considering LC patients and controls as the comparison groups. When assessing the association of DM2 with the risk of HCC using LC patients as the control group, we considered sex, age (⩾ 65 years *vs* < 65 years), BMI (⩾ 25 kg/m^2 *vs* < 25 kg/m^2), HBV and HCV infection, alcohol abuse, alanine transaminase (ALT) level (> 53 IU/L *vs* ⩽ 53 IU/L); when we used control subjects as the comparison group, potential confounders included only sex, age, BMI, and alcohol abuse. When evaluating which DM2 characteristics were associated with risk of HCC among diabetics, covariates included sex, age, BMI, HBV and HCV infection, alcohol abuse, ALT level, triglycerides, cholesterol, type of antidiabetic therapy (metformin, sulphonylureas, insulin), HbA1c levels (continuous and in categories using the following cut-offs: 6.5%, 7.5%, 8.5%), DM2 duration (continuous and using the following 3 cut-offs: 5, 10, 15 years) when we used LC patients as the comparison group and sex, age, BMI, HBV and HCV infection, alcohol abuse, ALT level, triglycerides, cholesterol, type of antidiabetic therapy, HbA1c levels, and DM2 duration when we used the controls. Among HCC cases, HbA1c levels at the time of cancer diagnosis were compared with an average of at least 3 tests carried out approximately every 2-3 years before the diagnosis of HCC. The Wilcoxon signed rank test and Spearman's correlation coefficient (*r*) were used to compare the paired differences and the kappa statistic to evaluate concordance of categories. Since at enrollment DM2 duration was either unknown or < 12 mo duration in 14% of diabetic subjects and 1-2 years duration in an additional 8%, in the study of the association between DM2 and HCC we performed a sensitivity analysis considering as non-diabetic subjects those whose diagnosis of DM2 occurred in the 12, 24, 60, and 120 mo before enrollment to allow for adequate induction time. For the same reason, we performed a sensitivity analysis excluding from the analyses regarding diabetes therapy and glycemic control, those patients with diagnosis of DM2 in the 12, 24, 60, and 120 mo before enrollment. All *P*-values < 0.05 were considered statistically significant. Analyses were conducted with SAS v9.1 (SAS Institute Inc., Cary, NC, USA).

RESULTS

Demographic characteristics of the three groups studied, and exposures relevant to liver diseases are illustrated in Table 2. The prevalence of DM2 was significantly higher ($P < 0.0001$) in HCC patients (31.2%) than in the LC group (23.2%) and in controls (12.6%). Using control subjects as a comparison group, after adjusting for age, BMI and alcohol abuse, DM2 significantly increased the odds ratio (OR) of HCC by 2.5 times (Table 3). Using LC patients, after adjusting for sex, age, BMI, alcohol abuse, HBV and HCV infection, and ALT level, DM2 significantly increased the OR of HCC by 1.5 times (Table 3). Alcohol abuse was the strongest predictor of HCC using controls subjects as comparison; it also increased the risk of HCC, as did HBV and HCV infections by comparing HCC with LC patients.

Table 4 illustrates the levels of BMI, cholesterol, triglycerides, and HbA1c, in HCC, LC and control subjects with DM2. BMI, cholesterol and triglycerides were not different between the three groups of subjects studied. The HbA1c levels evaluated at the time of enrollment in the study were significantly higher in HCC patients (7.5%, with 8.1% ± 1.8% in FU and 6.3% ± 1.1% in CO subgroups $P < 0.0001$) than in controls (6.8%) and in LC patients (6.6%). Among HCC diabetic cases, current HbA1c levels were on average only 0.2 percentage points lower than the average value of 3 previous values that we assumed to be representative of glycemic control in the past years. Current and average past HbA1c levels were highly correlated ($r = 0.77$, $P < 0.0001$) and agreement between categories (using 6.5%, 7.5%, and 8.5% as the cut-offs) was moderate to good, as expressed by the weighted kap-

pa 0.5456. Mean HbA1c levels were not different among HCC patients with or without HBV, HCV and alcohol abuse (data not shown).

Table 4 also shows the time interval between DM2 diagnosis and enrolment in the study. Duration of diabetes was not significantly different among the three groups of subjects and, on average, it was approximately 12 years. In addition, Table 4 displays the distribution of antidiabetic treatments in the three study groups. Treatment with metformin was less frequent among HCC patients than among the others; sulphonylureas were the most frequently used drugs among controls, whereas insulin was the most common treatment among HCC and LC patients.

At enrolment, DM2 had been diagnosed for more than 1 year in 86% of study subjects. Based on the records of our Diabetic Clinic, the mean duration of insulin treatment in HCC insulin-treated patients was 5 years; before insulin therapy, patients were treated only with diet. The mean period of treatment with the 2 antidiabetic oral agents was 10 years and before oral antidiabetic therapy patients had only dietary therapy.

Among diabetic subjects, the association of HbA1c levels, antidiabetic therapy, and DM2 duration with the risk of HCC is reported in Table 5. Both when using controls and when using LC as the comparison groups, after adjusting for the potential confounders shown in Table 5, therapy with metformin was associated with a strong and statistically significant reduction (> 80%) of the risk of HCC as compared with the use of sulphonylureas or insulin. In our HCC diabetic patients we found a significant 26%-50% increase in the HCC risk for each 1% increase in HbA1c level. Results did not significantly change in the sensitivity analysis after removing or moving from the diabetic to the non-diabetic category subjects whose diagnosis of diabetes occurred < 12, 24, 60, or 120 mo previously (data not shown).

[1]Patients with unknown therapy not included in analysis.

DISCUSSION

The results of our study show that chronic poor glycemic control, evaluated by HbA1c testing, is positively associated with risk of HCC in diabetic patients. In addition, therapy with metformin was associated with a strong and statistically significant reduction in the risk of HCC as compared with the use of sulphonylureas and insulin therapy.

Several studies have reported the relationship between DM2 and carcinogenesis in the liver[4-9], but, as far as we know, there are no investigations on the relationship between glycemic control and HCC risk in DM2 patients. In our study, we found that the prevalence of DM2 patients was significantly higher in HCC patients whereas in the LC group it was intermediate between those of HCC cases and controls. After adjusting for potential con-

founders, in our HCC patients DM2 was associated with an increased risk of HCC. The HbA1c mean levels were significantly higher in diabetic HCC patients than in LC and controls but not different between HCC patients with or without HBV and HCV infection or alcohol abuse. In HCC patients (above all in the FU subgroup), the HbA1c values were significantly higher and the mean levels during previous years of diabetic life were similar to those recognized at HCC occurrence. Multivariate analysis showed that high levels of HbA1c among diabetic HCC patients were associated with a significantly increased risk of liver cancer.

Because of IR, patients with DM2 have a long-term exposure to increased circulating insulin levels. It is well known that insulin stimulates cellular mitosis by direct action[14], and indirectly by stimulating the insulin-like growth factor-1 intracellular pathway, a major mitogenic and anti-apoptotic effector in carcinogenesis[15]. Sulphonylurea treatment increases insulin secretion and its circulating levels: this effect is detrimental in terms of weight gain and insulin levels[38]. In contrast, metformin treatment can ameliorate IR and reduce weight gain. The ability of metformin to reduce the insulin plasma levels and to activate cellular AMP-activated protein kinase (AMPK) represents, respectively, its direct and indirect proposed anti-oncogenic mechanisms. In fact, metformin not only lowers blood glucose and insulin levels but, through AMPK activation, also attenuates the *in vitro* response of cancer cells to insulin[39,40].

Several *in vivo* studies showed that cancer risk was lower in patients exposed to metformin than in unexposed patients[41,42]. Metformin has also been shown to be potentially beneficial in patients with specific types of cancer. For example, DM2 patients receiving neoadjuvant chemotherapy for breast cancer as well as metformin were more likely to have a complete remission than patients not receiving metformin[43]. In 2 studies patients receiving metformin seemed to have a lower incidence of prostate and pancreas cancer[44,45]. Furthermore, in the ZODIAC study[46], metformin use was associated with lower cancer mortality when compared to non metformin use.

In diabetic patients, good glycemic control prevents the onset and progression of acute and long-term diabetes-related complications[47]; however, it is presently unknown if poor metabolic control of diabetes could enhance or accelerate liver carcinogenesis in patients with CLD and DM2. Furthermore, it is not known whether an optimized control of diabetes can reduce the risk or delay the development of liver cancer. In the European Prospective Investigation into Cancer Study, a 1% increase in HbA1c levels was associated with a 1.3-fold increase in the risk of colorectal cancer[48]; recently it was reported that poor glycemic control is a predictor of clinically aggressive course for the colorectal cancer[49]. HbA1c reflects average glycemia over 3 mo; in our HCC patients, particularly in FU cases, the mean levels of HbA1c were above the recommended target level of 7%; HbA1c was significantly higher in HCC than in controls and LC patients, in which we found mean levels below 7%. Nonetheless it must be emphasized that the HbA1c levels observed in the three groups of subjects in this study were consistent with those seen in the vast majority of Italian diabetic patients[10].

It is known that diabetes is associated with more advanced lesions and poor outcomes in patient with HCC[50] but the observation that DM2 precedes the diagnosis of HCC in the majority of our cases, suggests that glucose intolerance and glycemic control are an outstanding feature of the hepatic tumor that may not always be related to the liver cancer.

This was a retrospective, hospital-based study drawn from a clinical series and not from the community: therefore the results may not be representative of those of the general population. There is no evidence that successful treatment for glucose intolerance can reduce hepatic carcinogenesis: therefore only a prospective study is required to demonstrate that optimized glycemic control can modify the risk of HCC in DM2 patients with CLD. However, this is the first study on the relationship between different antidiabetic strategies and the presence of HCC. In our diabetic HCC patients, HbA1c test results are available for years before HCC diagnosis, so a reliable assessment of prior glycemic control was possible. Our study was a single center investigation and all patients of the three groups studied were directly diagnosed and followed-up by us; all biochemical parameters were determined in a single laboratory. The study population was large. The controls, even though recruited from inpatients, were representative of the general population of our Region as regards the prevalence of HCV and HBV infection, alcohol consumption and diabetes mellitus.

To distinguish the temporal relationship between exposure and outcomes, due to the complex and reciprocal relationships between DM2, LC and HCC, we conducted a study on a large group of HCC patients comparing them with both a control group with no liver diseases and a group with LC, that represents the majority of patients with the clinical underlying cause of HCC. To have complete and accurate information on the time interval between the onset of DM2 and the diagnosis of HCC, we reviewed all medical documentation kept, from a period of 9 years before the enrollment of the first patient in the study, at our Diabetes Clinic. All our diabetic patients were on monotherapy of antidiabetic drugs and the selection of the antidiabetic therapy was based on the physician's clinical choice. In particular, in HCC and LC groups, diabetic patients treated with different antidiabetic oral agents had similar basic features as regards alcohol consumption, and hepatic and renal function. To make sure that a temporal relationship existed between diabetes and HCC, a sensitivity analysis was conducted excluding or reclassifying patients with recent diabetes diagnosis, but the results did not change.

Our study confirms that DM2 is associated with an increased risk of HCC. It also shows that in diabetic HCC patients metformin treatment is associated with a strong and statistically significant reduction (> 80%) in the risk of HCC compared with the use of sulphonylureas or

insulin. In diabetic patients with CLD, chronic poor glycemic control, evaluated by HbA1c testing, significantly increases the risk of HCC by 26%-50% for each 1% increase in HbA1c level. It has to be emphasized that in diabetic patients with CLD, it is important not only to attain an optimized glycemic control in order to prevent HCC, but also antidiabetic strategies may have an important effect on the relationship between DM2 and solid tumors.

COMMENTS

Background

In recent years, several investigations clearly indicated that type 2 diabetes mellitus (DM2) is a risk factor for hepatocellular carcinoma (HCC). The aims of the present study were to explore this association and to assess the relationships of antidiabetic therapy and glycemic control with the risk of HCC in DM2 patients with chronic liver disease.

Research frontiers

At the present time the relationship between DM2 and solid cancers is under intensive investigation. It remains unknown if DM2 has a direct carcinogenic effect on the liver and on other parts of the human body.

Innovations and breakthroughs

This study found that DM2 precedes HCC in the majority of patients. The cancer risk seems to be increased by chronic poor glycemic control. Metformin treatment is associated with a strong and statistically significant reduction (> 80%) in the risk of HCC compared with the use of sulphonylureas or insulin.

Applications

The study indicated that in diabetic patients with chronic liver disease it is important not only to attain an optimized glycemic control in order to prevent HCC, but also that antidiabetic strategies may have an important effect on the association between DM2 and solid tumors.

Peer review

This is a potentially important paper that continues to evaluate the link between diabetes and the risk of HCC. Its strength is in its numbers despite being from one institution.

Abstract

AIM: To establish whether virulence factor genes *vacA* and *cagA* are present in *Helicobacter pylori* (*H. pylori*) retrieved from gastric mucosa and dental plaque in patients with dyspepsia.

METHODS: Cumulative dental plaque specimens and gastric biopsies were submitted to histological examination, rapid urease test and polymerase chain reaction (PCR) assays to detect the presence of *cagA* and *vacA* polymorphisms.

RESULTS: Detection of *H. pylori* from dental plaque and gastric biopsy samples was greater by PCR compared to histological examination and the rapid urease test. DNA from *H. pylori* was detected in 96% of gastric mucosa samples and in 72% of dental plaque samples. Sixty-three (89%) of 71 dental plaque samples that were *H. pylori*-positive also exhibited identical *vacA* and *cagA* genotypes in gastric mucosa. The most common genotype was *vacAs1bm1* and *cagA* positive, either in dental plaque or gastric mucosa. These virulent *H. pylori* isolates were involved in the severity of clinical outcome.

CONCLUSION: These pathogenic strains were found simultaneously in dental plaque and gastric mucosa, which suggests that gastric infection is correlated with the presence of *H. pylori* in the mouth.

INTRODUCTION

Helicobacter pylori (*H. pylori*) gastric infection is considered one of the most common human infections[1]. It occurs in half of the world's population[2,3] and is the most common cause of adenocarcinoma of the distal stomach[4].

The risk in developing gastric cancer is believed to be related to differences among *H. pylori* strains and the inflammatory responses mediated by host genetic factors[3]. Therefore, it is presumed that severe gastric diseases are seen more often in patients who have been chronically infected with *H. pylori* isolates that bear both the *cagA* and *vacA* s1/m1 genes[1,5,6].

H. pylori is known to be acquired early in life[7,8], and is likely to be transmitted from person to person. The transmission is supported by crowded living conditions, accompanied by poor hygiene and intra-familial clustering. Nevertheless, the exact manner of transmission is not completely understood[4,9,10].

The accepted evidence is that the *H. pylori* strains reach the stomach by ingestion through the mouth, and because of its non-invasive nature, the stomach is the definitive site for colonization[10]. Evidence of transmission *via* the oral route includes the high prevalence of *H. pylori* among African children whose mothers premasticate their food before offering it to them[11], and to the higher prevalence of the infection in people who share chopsticks[12].

The presence of *H. pylori* in the oral cavity was first reported in 1989 when the bacterium was cultured from dental plaque of a patient with gastric disease associated with *H. pylori* infection[13].

Dental plaque is a biofilm that is formed by a microbial community of multiple species and represents a strategy to allow survival and evolution of microbial co-aggregation in a dynamic equilibrium, in a favorable environment with selective advantages[14,15]. Hence, bacterial biofilms are considered as sanctuaries, due to being protected from host defense mechanisms and antibiotic therapy. Additionally, antibiotic resistance is increased due to horizontal gene transfer[14,15].

The purpose of this study was to evaluate the prevalence of *H. pylori* isolates, in relation to *vacA* and *cagA* genotypes, in dental plaque and gastric antral biopsy samples in dyspeptic patients from a North Brazilian population.

MATERIALS AND METHODS

Patients and sampling

We studied the presence of *H. pylori* in the stomach and dental plaque in 99 adult patients (69 women and 30 men; mean age: 37 years, age range: 17-59), who underwent upper gastrointestinal endoscopy due to gastric problems. Most of them were of lower socioeconomic status and lived in the state of Pará, Brazil.

None of the patients had received antimicrobial drugs, H2-receptor antagonists, acid pump inhibitors, non-steroidal anti-inflammatory drugs, or any medication for at least 60 d before sampling, to avoid interference with *H. pylori* detection methods. During endoscopy, three antral gastric biopsy sections were taken from the stomach of each patient. One biopsy was analyzed by molecular methods, and the other sections were also analyzed with histological methods and the rapid urease test. Before endoscopic examination, cumulative dental plaque samples were collected by scraping tooth surfaces with sterile curettes and transferred into tubes that contained physiological saline solution. Dental plaque samples were frozen immediately and stored at -20℃ until required for DNA extraction. This study was approved by the Ethics Committee of Hospital Universitário João de Barros Barreto, Belém, PA, Brazil. All patients gave their informed consent to participate in the study.

Histological evaluation

The biopsy specimens were fixed in 10% buffered formalin solution, embedded in paraffin, cut into sequential 0.4-μm sections, and stained with hematoxylin and eosin (H&E). The presence of *H. pylori* in the sections was determined by using a modified Gram staining protocol and taking into consideration its morphological characteristics: curved and spiral form and intense purple coloring. The histological parameters were graded (0-3) using the criteria described in the update Sydney classification system[16] for analysis of chronic inflammation, polymorphonuclear activity and intestinal metaplasia.

H. pylori detection by the rapid urease test in the stomach and dental plaque

Additional fresh biopsies as well as dental plaque samples were placed in the gel of the CLOtest as recommended by the manufacturer (Uretest; Renylab, Barbacena, MG, Brazil). After 1 h, the CLOtest was inspected for a change in color. Yellow was interpreted as negative, indicating absence of urease. Red or pink was interpreted as positive. For comparison, a similar reading of each biopsy was also performed after 3 and 24 h. Results of the rapid urease test were compared with polymerase chain reaction (PCR) results and histological examination.

DNA isolation

Total DNA was extracted from frozen gastric biopsy and dental plaque specimens using the following procedure[17]: 10 μL proteinase K (Amresco, Cleveland, OH, USA) and 300 μL lysis buffer (200 mmol/L Tris-HCl, 25 mmol/L EDTA, 300 mmol/L NaCl, 1.2% SDS) were added to the biopsy or dental plaque pellets specimens. The mixture was incubated at 55℃ for 12 h. The lysate was extracted with an equal volume of phenol-chloroform, precipitated with isopropanol, and washed with 70% ethanol. The DNA pellet of each sample was dried and resuspended in 200 mL sterile distilled water. DNA extracts were stored at -20℃. Extensive care was taken to avoid contamination during all steps of collecting and preparing the samples.

PCR amplification and detection of amplified DNA products

PCR amplification for detection of *H. pylori* DNA in dental plaque and gastric mucosa was performed as described previously[18]. Briefly, one set of primers (p1-F and p2-R) that amplifies a 26-kDa antigen gene (fragment of 298 bp) present in all strains of *H. pylori* was used to detect bacteria[18]. The previously described F1-F and B1-R primers[19] were used to detect *cagA* gene. The amplification of *vacA* gene was performed by PCR with oligonucleotide primers described by Atherton *et al*[1], *vacA* signal (*vacA s1a, s1b* or *s2,* primers SS1- F, SS3-F, SS2-F/VA1-R, respectively) sequences and middle regions (*vacA m1* or *m2,* primers VA3-F/VA3-R and VA4-F/VA4-R).

All PCR mixtures were prepared in a volume of 25 μL that contained 0.5 nmol/L each primer; 1 × PCR buffer; 1.5 nmol/L $MgCl_2$, sterilized water, 0.2 nmol/L deoxynucleoside, 1.25 μL *Taq* DNA polymerase Platinum (Invitrogen Life Technologies, São Paulo, Brazil), and 2 μL DNA sample. The mixtures were placed in a thermal cycler. PCR amplification was performed under the following conditions: initial denaturation at 95℃ for 2 min, followed by 35 cycles of denaturation at 95℃ for 1 min, annealing and extension for 1 min, and final extension at 72℃ for 10 min. Annealing temperatures were set at 58℃ for primers VA3-F/VA3-R, VA4-F/VA4-R, F1/B1, and at 63℃ for SS1- F, SS3-F, SS2-F/VA1-R. Negative (sterile water) and positive (positive strain) controls were used in all reactions. PCR products were visualized by electrophoresis in 2% agarose gel, stained with ethidium bromide, and examined under UV illumination.

Statistical analysis

Data were analyzed with Biostat 4.0 version software[20]. Mann-Whitney and G tests were used to assess the association between *H. pylori* isolates in dental plaque and stomach and the distribution of *vacA* and *cagA* genotypes in both these specimens. Differences were considered statistically significant for P values less than 0.05.

RESULTS

Identification by PCR of *H. pylori* DNA in gastric biopsies and dental plaque

H. pylori was found in gastric biopsies of 96% (95/99) of the patients and the detected frequency of this organism in dental plaque was 72% (71/99). Both were detected by PCR, but none of the four patients that lacked *H. pylori* in the stomach had this organism in dental plaque. This difference was statistically significant, which indicated that the detection frequency of *H. pylori* in dental plaque was lower than in the stomach ($P < 0.001$).

Relationship of *H. pylori* DNA in dental plaque and stomach with age and sex

In the relative distributions of age and sex of the patients studied, no significant difference was observed between the groups with or without positive DNA for *H. pylori* simultaneously in the gastric mucosa and dental plaque. Nine of 30 (30%) men and 16 of 69 (27.5%) women were *H. pylori*-negative in dental plaque. Among these, 19 of 62 individuals belonged to the 17-39 years age group and eight of 33 to the 40-59 years group. Furthermore, three individuals in the first group and one in the second were *H. pylori*-negative in dental plaque and gastric mucosa.

Relationship of *H. pylori* DNA in dental plaque and stomach with clinical and histopathological parameters

All patients presented an inflammatory process in the gastric mucosa, with a diagnosis of functional dyspepsia. Ulcers or premalignant lesions, such as intestinal metaplasia, which were considered as lesions of higher severity, occurred in 17% (17/99) of the patients. Among these, 82.4% of cases harbored *H. pylori* in the stomach and dental plaque.

The genotypic frequencies of *vacA* and *cagA* of the positive *H. pylori* samples in the gastric biopsies and dental plaque DNA samples in relation to the endoscopic clinical diagnosis and histopathological findings are shown in Table 1. The *vacAs1m1/cagA*-positive genotype was found in 51 of 95 *H. pylori* gastric biopsies, which comprised 44 gastritis specimens and seven peptic ulcer samples, with 46 patients being *H. pylori*-positive in dental plaque DNA samples.

The presence of *H. pylori* mixed strains with *vacA s1*, *s2*, *m1*, *m2* and *cagA*-positive multiple genotypes was detected in 12 of 95 gastric biopsies of patients with gastritis and their corresponding dental plaque DNA samples.

The *vacAs2m2/cagA*-positive genotype was observed in four of 95 *H. pylori* gastric biopsies, which included one patient with peptic ulcer and three with chronic gastritis. The *vacAs2m2/cagA*-negative genotype was found in 28 of 95 *H. pylori* isolates from 27 gastritis specimens and one peptic ulcer sample, with 13 patients being simultaneously *H. pylori* positive in dental plaque DNA samples.

When comparing all these genotypes, there was 66% (63/95) agreement between *H. pylori* biopsy isolates and their corresponding dental plaque DNA samples. In addition, seven of nine patients with peptic ulcer and eight of 86 with chronic gastritis and diagnosed with intestinal metaplasia or gastric atrophy expressed *H. pylori* isolated with *vacAs1m1*- and *cagA*-positive genotypes, which indicated more severe gastritis and peptic ulceration (Table 1). In the same way, in relation to the histopathological data of these patients, a significant association has been observed between the presence of a bacterial virulence genotype and the high levels of inflammation and the neutrophilic activity, as well as an increased risk of developing atrophy and intestinal metaplasia in the gastric mucosa.

Detection of *H. pylori* in dental plaque and gastric biopsies by different diagnostic tests

In addition to the evaluation of *H. pylori* by PCR assay, bacteria in the stomach were also detected by the histological examination and the rapid urease test. However, the analysis of urease test indicated gastric colonization by *H. pylori* in only 49% of the patients. Similarly, evidence of *H. pylori* was detected in 52% of dental plaque speci-

Table 1 Frequency of *vacA* and *cagA* genotypes in patients positive for *H. pylori* DNA in dental plaque and stomach

H. pylori genotypes					Histopathological parameters[a]						Endoscopic diagnosis[b]		Total

mens, using the rapid urease test (Table 2). There were significant differences among *H. pylori* positivity detected by PCR and the other methods used ($P < 0.001$).

Comparison of *H. pylori* vacA and cagA genotypes in dental plaque and gastric mucosa samples

Overall, 63 (89%) of 71 dental plaque samples, which were positive for the presence of the bacteria, revealed identical *H pylori* virulence factors in relation to *vacA* and *cagA* genotypes in the gastric mucosa. *H. pylori* isolates found in 71% (67/95) of gastric mucosa specimens were *cagA*-positive and 82% (58/71) were also *cagA*-positive for dental plaque, with significant correlations among the prevalence of *H. pylori cagA*-positive isolates in the stomach and dental plaque samples (Table 3).

In relation to the *vacA* gene, the *s1m1* genotype had a higher frequency, with 54% (51/95) of gastric biopsies and 59% (42/71) of dental plaque samples However, the *vacAs2m2* subtype combination was found among the patients that harbored *H. pylori* in 34% (32/95) of the stomach and in 13% (9/71) of the dental plaque samples, whereas *vacAs1bm1/s2m2* genotypes were detected in 13% (12/95) of gastric biopsies and 22% (16/71) of dental plaque samples (Table 3). The most common genotype was *vacAs1bm1* and *cagA*-positive, either in dental plaque (37%) or gastric mucosa (37%).

DISCUSSION

H. pylori infections of the stomach are common worldwide. These bacteria are also found in dental plaque, where the presence of this organism may be very low and the numbers of microorganisms appear to vary from one site to another within the mouth[21].

The present study detected DNA from *H. pylori* in 95% of clinical gastric biopsy samples. Likewise, as described in previous studies[6,22,23], the occurrence is very high in this community. In fact, *H. pylori* infection is influenced by precarious sanitation and low socioeconomic level, so that the prevalence of *H. pylori* infected subjects in Brazil can reach over 80%[24,25]. Furthermore, 72% of subjects with stomach infection showed a concomitant presence of *H. pylori* in dental plaque by PCR assay.

The high detection rate for *H. pylori* DNA in the dental plaque is sufficiently significant to support the assumption that *H. pylori* reaches the oral cavity by reflux[21], assisted by the finding that no positive case was found in dental plaque that was negative in gastric mucosa. This result is especially important because, in our sample, only untreated patients were selected, since treatment would likely eradicate the bacteria from the stomach but rarely from dental plaque, due to known resistance to systemic therapy in dental plaque, as has been reported by Gurbuz *et al*[26].

Similar results have been reported by Banatvala *et al*[13], who have verified a 63% correlation between *H. pylori* in the stomach and in dental plaque samples in patients from London. Also, Song *et al*[27] have found *H. pylori* in 97% (41/42) of dental plaque samples obtained in a German population.

Other studies have suggested a positive association between dental plaque and gastric *H. pylori*[28-32], but some others have failed to find *H. pylori* in oral samples[33-35]. In support of the former studies, our results indicate that the frequency of *H. pylori* in dental plaque is related to the existence of gastric infection.

In the patients studied, no significant difference was observed in the rate of *H. pylori* DNA in dental plaque and gastric mucosa of the diverse age groups. These results are similar to the infection patterns in developing countries[7,36]. A similar result was found in relation to sex, which indicated that there was no relation between sex ratio and *H. pylori* infection in the stomach and dental plaque DNA samples. However, Berroteran *et al*[34] have detected a higher level of *H. pylori* in gastric samples from women than from men, but in dental plaque, this difference was not observed.

On the other hand, these data indicate that, in the strains that harbor *vacAs1m1, cagA* genotypes are involved in the severity of gastritis and the final outcome of *H. pylori* infection. In addition, *H. pylori* isolates with *cagA* and *vacAs1m1* genotype are associated with an increased risk of developing distal gastric adenocarcinoma[37].

In the present study, different methods were used for detecting *H. pylori* in dental plaque and gastric mucosa. In this regard, the PCR assay has been demonstrated to be more efficient for the detection of *H. pylori* in clinical specimens, compared to the rapid urease test in dental plaque and gastric biopsies, as well as to the histopathological examination of the gastric mucosa. This result is supported by other studies[27,30,34,38].

Dönmez-Altuntaş and Güven[39] have detected higher specificity and sensitivity of the PCR assay in relation to the urease test, with 93.8% *vs* 65.6% of DNA from *H. pylori* being positive in both tests respectively. Zsikla *et al*[40] have reported that *H. pylori* DNA could be detected by PCR in 20.8% of biopsies with chronic gastritis but without histologically detectable bacteria. These results agree directly with our findings. Despite this, one of the critical points of the studies using PCR is the absence of uniformity of results, due to the establishment of distinct laboratory procedures[27,41-43]. Controlled trials with robust methodology are required to prove if there is any clinical or epidemiological relevance to the colonization of this bacterium in the oral cavity.

The molecular characterization of the *H. pylori* virulence factors, *cagA* and *vacA*, has revealed the existence of indistinguishable genotypes from oral cavity and gastric mucosa samples of the same patient[44]. Our results showed that, in 89% of the 71 cases in which the dental plaque samples were positive for bacteria, the vacA and cagA genotypes were similar to those in the gastric mucosa (Table 3). Thus, these data suggest that similar types of *H. pylori* isolates, in relation to *vacA* and *cagA* genotypes, are present in the mouth and stomach.

We found that the most common genotype was positive for *vacAs1bm1* and *cagA*, either in dental plaque or gastric mucosa (Table 3). In addition, the *H. pylori* isolates that were *vacAs1m1*/*cagA*-positive were detected in dental plaque at a higher percentage than the *vacAs2m2*/*cagA*-negative genotype. It seems that *H. pylori* in dental plaque is related more to severe gastrointestinal diseases, such as gastroesophageal reflux, which could facilitate oral colonization by *H. pylori* with a *vacAs1m1*/*cagA*-positive genotype.

In this context, several investigators have reported that reinfection is caused by the strains in the oral cavity, because they have isolated identical strains of *H. pylori* in the oral cavity and stomach[32,45-49]. Therefore, it seems necessary to apply additional molecular tests in the dental plaque to assist the diagnosis and therapy of gastric infection.

Finally, based on our findings we cannot exclude the possibility that transient colonization of the mouth with *H. pylori* may occur by reflux activities within symptomatic patients, which leads to the spread these organisms by direct transmission from person to person. In this way, it is a risk factor for the occurrence of diseases in the oral cavity and the stomach.

COMMENTS

Background

Infection by *Helicobacter pylori* (*H. pylori*) remains one of the most prevalent chronic bacterial diseases worldwide, with a distribution related to the degree of economic development in each country. The organism is transmitted from person to person, and some researchers have suggested that the oral cavity is an important reservoir of *H. pylori* besides the stomach. Although the oral cavity may be a source of transmission, it is unknown whether the mouth could be a common source for reinfection of the stomach after treatment.

Research frontiers

The variability of clinical manifestations in the population could be related to an interaction between the bacterial virulence factors and genetic susceptibility of the host. *H. pylori* strains that have *cagA*-positive and *vacAs1/m1* genotypes are associated with an intense inflammatory response in the stomach, which leads to peptic ulcer and other severe gastric diseases. For this reason, there is an increasing interest in generating different non-invasive diagnostic tests that allow the epidemiological and clinical study of *H. pylori* infection.

Innovations and breakthroughs

In this study, dental plaque and gastric biopsies were submitted to rapid urease test and polymerase chain reaction (PCR) assays to detect *H. pylori* and the virulence factors, *cagA* and *vacA* genotypes, respectively. In addition, gastric biopsies were evaluated by histological techniques. It was found a high correlation between the most pathogenic strains (*vacAs1m1/cagA*-positive) in dental plaque and gastric mucosa. It seems that the severity of gastrointestinal diseases, such as gastroesophageal reflux, could be facilitated by oral colonization by *H. pylori*.

Applications

The simultaneous presence of the *H. pylori* isolates with similar *cagA* and *vacA* genotypes in dental plaque and gastric mucosa was detected in a high percentage in patients with chronic gastritis and peptic ulcer, which suggests the necessity to apply additional molecular tests to dental plaque to assist with the diagnosis and therapy of gastric infection. This will add to the available knowledge about the pathogenetic relevance of *H. pylori* in the oral cavity.

Terminology

Bacterial virulence factors are expressed by the vacuolating cytotoxin gene (*vacA*) and cytotoxin-associated gene (*cagA*).

Peer review

The authors studied by means of PCR whether *H. pylori*-positive subjects also had the bacterium in the dental plaque. They found that the vast majority of patients with stomach colonization by *H. pylori* also had oral bacterial infection, thus lending further support to the concept that oral to oral transmission of *H. pylori* is highly possible. The manuscript is well written.

Abstract

AIM: To evaluate the predisposing factors for peritoneal perforation and intrabiliary rupture and the effects of these complications on surgical outcome in liver hydatid disease.

METHODS: A total of 372 patients with liver hydatid cysts who had undergone surgical treatment were evaluated retrospectively. Twenty eight patients with peritoneal perforation, 93 patients with spontaneous intrabiliary perforation, and 251 patients with noncomplicated hydatid cysts were treated in our clinics.

RESULTS: When the predisposing factors for complications were evaluated, younger age, superficial position, and larger cyst dimensions ($P < 0.05$; range, 0.001-0.017) increased peritoneal perforation rates. It was shown that older age increased cyst dimensions, and presence of multiple and bilobar cysts increased intrabiliary rupture rates ($P < 0.05$; range, 0.001-0.028). Partial pericystectomy and drainage was the most frequent surgical procedure in all groups (71.6%). The incidence of postoperative complications in the peritoneal perforated group, in the intrabiliary ruptured group, and in the noncomplicated group was 25%, 16.1% and 5.5%, respectively. When compared, complication rates were significantly different ($P = 0.002$). When length of hospital stay was compared, there was no significant difference between the groups ($P > 0.05$). The overall recurrence rate was 3.8% (14 patients), but there was not any statistical difference among the patient groups ($P = 0.13$). The early postoperative mortality rate was 1.1%.

CONCLUSION: In peritoneally perforated and intrabiliary ruptured cases, the most important steps are irrigation of the peritoneal cavity and clearance of the cystic material from the biliary tree.

INTRODUCTION

Echinococcosis is a zoonosis transmitted by dogs that

accidentally infects humans. Both sheep and humans are intermediate hosts. Developing countries with poor hygiene where sheep and cattle are raised are high-risk areas for acquiring cystic echinococcosis. Endemic regions of human cystic disease include South America; the Mediterranean region, including North Africa, Spain, Portugal, and Turkey; the Middle East; central Asia; and many regions in China[1,2]. The prevalence of the disease increased in Europe and North America in recent years. In the United States and Europe, most infections are seen in immigrants from endemic areas[3].

In humans, 50% to 75% of hydatid cysts occur in the liver, 25% are found in the lungs, and 5% to 10% are distributed along the arterial system[4]. The majority of the patients have single-organ involvement (87%) and a solitary cyst (72%) at the right part of the liver[5]. If the cyst ruptures, scolices can grow in the peritoneum, pleura, bronchial tree, and bile ducts[5-7]. Cyst sizes range from 1 to 30 cm, and cyst growth varies from 1 to 30 mm per year[6,8].

The clinical picture can be severe, and complications may occur, making the already difficult treatment even more so[9,10]. Complications are observed in one third of patients with liver hydatid cysts. In large series, incidences of peritoneal perforation were reported at between 10% and 16%[11,12], and communications between the cyst and the biliary tree are seen in 9% to 25% of cases[13-15]. Without treatment, cysts grow and eventually may form fistulas into the peritoneal cavity or intrabiliary rupture, requiring emergency surgery[2,9,10]. Operative treatments vary from complete resection to minimal invasive procedures, but the ideal treatment is still controversial[16,17]. The choice of therapy depends on several factors: number and localization of the cysts, surgeon expertise, and presence of complications.

Only a few studies have reported the management and outcome of patients with complicated liver hydatid disease[13,18]. Surgery is the mainstay of treatment, although there is no consensus on the respective advantages of conservative and radical methods. Besides, in the treatment of peritoneal perforated cases, profuse peritoneal lavage with hypertonic solutions appears to be more necessary; in the setting of intrabiliary rupture, T-tube drainage, sphincteroplasty, and choledochoduodenostomy are appropriate treatment strategies to reduce the pressure in the biliary tree. In this study, we aimed to evaluate the predisposing factors for peritoneal perforation and intrabiliary rupture and the effects of these complications on morbidity, length of hospital stay (LOS), mortality, and recurrence in hydatid disease.

MATERIALS AND METHODS

Patients

We retrospectively evaluated medical records of 372 patients with liver hydatid cysts who were admitted to the Department of General Surgery, Faculty of Medicine, Erciyes University, between June 1990 and January 2008. In this period, 28 patients with peritoneal perforation (group Ⅰ), 93 patients with spontaneous intrabiliary perforation (group Ⅱ), and 251 patients with noncomplicated hydatid cysts (group Ⅲ) were treated in our clinics. The ratios of intrabiliary rupture and peritoneal perforation cases to noncomplicated cases were 37% and 11.1%, respectively.

Diagnosis

Patient age and sex, initial complaints, physical findings, cyst characteristics, imaging results, surgical procedures, reasons for peritoneal perforation and intrabiliary rupture, morbidity, LOS, recurrence rates, and mortality were evaluated. The patients with extrahepatic organ involvement were excluded.

Preoperative evaluation

The preoperative evaluation included blood tests (complete blood count, blood type, liver function tests), chest radiography, abdominal ultrasonography (US), and computed tomography (CT). Chest and abdominal radiography and abdominal US were performed in all patients at admission. The most important indications for CT were a need for additional anatomical and cystic details, the presence of multiple hydatid cysts, findings of a solid appearance, and findings of cyst infection. If intrabiliary rupture was suspected, magnetic resonance imaging (MRI) cholangiography was performed. Intraoperative ultrasound (IOUS) was used for identification of intraparenchimal cyst localization and selection of the best approach sight.

Surgical procedure

In all cases of liver hydatid cysts, the area around the cyst was covered with packs soaked in 3% hypertonic saline solution to prevent the further spread of the parasite during evacuation of the cyst. Cyst contents were aspirated from a suitable surface with a needle, which opened a nearly 1-2 cm incision; this was examined carefully for bile content. Subsequently, an aspirator was inserted into the cystic cavity to empty the remaining fluid, and then the incision was widened. The germinative membrane and daughter cysts were removed with forceps or spoons. With the roof excision of the redundant part of the cyst, an excellent exposure was obtained. After evacuation of the cyst, the cyst cavity was irrigated with 3% hypertonic saline for 10-15 min. Any orifices of bile ducts observed on the inner surface of the cavity were sutured with nonabsorbable sutures. To prevent peritoneal spreading in peritoneally perforated cases, the abdominal cavity was irrigated with 3% hypertonic saline or with povidone-iodine. Next, a surgical procedure, such as partial pericystectomy (PP) and capitonnage, PP and omentoplasty, PP and drainage, or PP and intraflexion, was performed. For pericystectomy, the hepatic pedicle was prepared for the Pringle maneuver. The cyst was then dissected along its boundary with healthy liver tissue. Blood vessels and small biliary structures passing through the plane between normal liver tissue and the cyst were clamped and divided. If the patient was fit and the cysts were away from the hepatic veins, large bile ducts, or major branches of the por-

tal vein and hepatic artery, pericystectomy was performed. Liver resections were performed only if multiple cysts were localized in one lobe and peripherally.

If the preoperative evaluation suggested a probability of a connection between the cyst and the biliary duct, or this was suspected during surgery, choledochotomy, placement of a T-tube, and an intraoperative cholangiographic and/or choledochoscopic evaluation were performed. In the case of any doubt about free biliary drainage, biliodigestive anastomosis or sphincteroplasty was added.

Medical treatment

Since 1993, medical treatment for hydatidosis has consisted of albendazole 10 mg/kg per day (Andazol, Biofarma, Istanbul, Turkey), beginning after surgery and continuing for 3 mo. Until 5 years ago, the therapy was performed over 3 mo and included 20 d of drug administration and 10 d drug free intervals. Over the last 5 years, the drug has been administered continuously with monthly blood liver function tests and complete blood count controls.

Follow-up

During follow-up, US was performed twice a year for 2 years, and then annually. CT scans were performed as needed.

Statistical analysis

Differences among categorical variables were compared using χ^2 tests, and Kruskal-Wallis tests were used for age, diameter, and number of cysts and LOS. Multinominal logistic regression analysis was performed to analyze the effects of variables (age; sex; previous hydatid disease surgery; location, number, position, and presence of cyst infection) influencing peritoneal perforation or biliary rupture. Data were analyzed with the SPSS software package (version 13.0; SPSS, Inc., Chicago, IL). Significance was set at $P < 0.05$.

RESULTS

The mean age (mean ± SD) of peritoneal perforated and intrabiliary ruptured patients was 36.32 ± 11.86 and 50.26 ± 13.88, respectively. When calculated, it was 45.62 ± 16.01 in the noncomplicated group. The mean age factor in the peritoneal perforation group was significantly different from others ($P = 0.001$). The sex ratio of the patients was not statistically different among the groups ($P = 0.95$, Table 1).

Previous hydatid disease surgery, cyst localization, number of cysts, and presence of infection were not statistically different among groups ($P > 0.5$; range, 0.109-0.683), whereas the differences in cyst diameters and positions (superficial or deep) were significant ($P = 0.001$ and 0.017, respectively; Table 1). Macroscopic appearance of an hydatid cyst that originates in the right lobe of the liver was seen in Figure 1.

The most common complaint was abdominal pain in all groups (67%). Other common complaints were nausea, vomiting, abdominal distension, and allergenic reactions in peritoneally perforated cases, jaundice (21%) in intrabiliary ruptured cases, and abdominal swelling (41%) in noncomplicated hydatid cysts. The most common physical examination findings were abdominal sensitivity and guarding (100%), acute abdomen findings (39%), distension (22%) in peritoneally perforated cases, hepatomegaly (28%) and jaundice (21%) in intrabiliary ruptured cysts, and finally, hepatomegaly (27%) in noncomplicated patients. In 49 (13%) patients, diagnosis was made incidentally by abdominal US or CT during a medical checkup or after a trauma.

When the predisposing factors for complications

Group Ⅰ = 28, group Ⅱ = 93, group Ⅲ = 251 (reference value).

were evaluated, younger age, superficial position, and larger cyst dimensions increased peritoneal perforation rates. It has been seen that older age, increased cyst dimensions, and presence of multiple and bilobar cysts increases intrabiliary rupture rates. Sex, primary or recurrent disease, and cyst infection were not as effective variables in both logistic models (Table 2).

Abdominal US was done in 326 (87.6%) patients and demonstrated hepatic cysts with 96.7% sensitivity (Figure 2). CT was used as the second most frequent (n = 148, 46%) diagnostic modality, with 96.5% sensitivity. In 24 (6.5%) patients with intraparenchymal cysts, IOUS was performed for identification of cyst localization and selection of the best approach sight. MRI cholangiography was performed after 1996 to assess the spread of disease to the biliary tree but was not used routinely and was done in 37 patients (9.9%) (Figure 3). The indications for MRI cholangiography are the presence of jaundice seen during the physical examination, elevation of serum bilirubin and alkaline phosphatase levels, and other obstructive jaundice symptoms and demonstrated 98% sensitivity.

Surgical procedures used for the cysts of the 372 patients are shown in Table 3. Partial pericystectomy and drainage was the most frequent surgical procedure in all groups. Three of 4 jaundiced patients underwent cholecystectomy plus T-tube drainage, and the other patient underwent cholecystectomy plus sphincteroplasty in the peritoneal perforation group. In all intrabiliary rupture cases, cholecystectomy and common bile duct exploration were performed. Intraoperative cholangiography was performed in all patients, and choledochoscopy was also performed in 62 (66.6%) patients. Cyst remnants and daughter vesicles in the bile ducts were evacuated

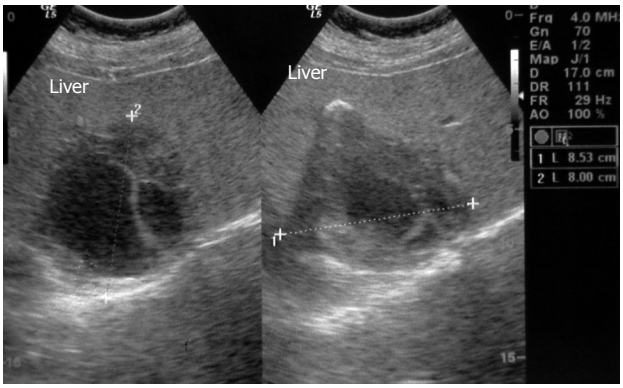

Figure 2 Ultrasonographic appearance of an hydatid cyst of the liver.

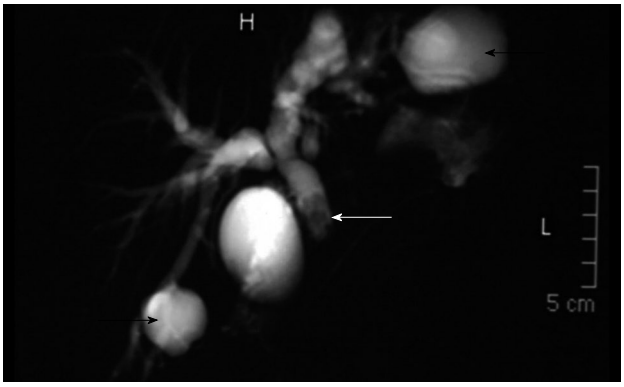

Figure 3 Magnetic resonance imaging cholangiography. Two biliary ruptured (right and left lobe) hydatid cysts (black arrows) and daughter vesicles in common bile duct (white arrow).

with Dormia forceps or a Fogarty catheter in 16 (17.2%) patients. A T-tube drainage was performed in 72 (77.4%) patients, choledochoduodenostomy was performed in 15 (16.1%) patients, and sphincteroplasty was performed in 6 (6.4%) patients.

The most frequent postoperative complications were wound infection (5.6%) and pulmonary complications (2.9%). In the peritoneal perforation group, 10 surgical complications occurred in 7 (25%) patients; in the intrabiliary rupture group, 18 complications occurred in 15 (16.1%) patients; and in the noncomplicated group, 16 complications occurred in 14 (5.5%) patients. When compared, complication rates were significantly different (P = 0.002, Table 4). When compared according to Dindo & Clavien Classification of Surgical Complications[19], the differences between grade Ⅰ, grade Ⅳa and grade Ⅳb surgical complications were not significant (P > 0.05, range, 0.08-0.57), however differences between grade Ⅱ, grade Ⅲa and grade Ⅲb complications were statistically significant (P < 0.05; range, 0.003-0.036).

Median postoperative LOS in the peritoneal perforation group, intrabiliary ruptured group, and noncomplicated group were 12 (range, 5-21), 13 (range, 5-37), and 9 (range, 4-19) d, respectively. When LOS was compared, there was no significant difference between the groups (P > 0.05). According to the additional surgical procedures,

[b]Values indicate a significant difference. [1]Cardiac complications included heart failure and myocardial infarction; respiratory complications included atelectasis, pneumonia, adult respiratory distress syndrome, and pulmonary embolus; other complications included urinary tract infection and acute thromboembolic disease of the lower extremities.

the median LOS was 8 (range, 4-19) d in patients on which choledochotomy had not been performed, compared to 15 (range, 11-37) d in the choledochotomy with T-tube group and 10 (range, 6-13) d in the bilioenteric anastomosis group. There was a significant difference in LOS between the groups with choledochotomy with T-tube and without choledochotomy ($P < 0.05$). In contrast, no difference between the groups with biliodigestive anastomosis and without choledochotomy was seen ($P > 0.05$).

The follow-up data were complete for 28 (100%) of the peritoneal perforated group, 76 (82%) of the intrabiliary ruptured group, and 198 (79%) of the noncomplicated group. The mean follow-up periods were 37.3 ± 26.3 (range, 2-144) mo. The overall recurrence rate was 3.8% (14 patients), but there was not any statistical difference among the patient groups ($P = 0.13$, Table 4). The early postoperative mortality rate was 1.1% ($n = 4$). The causes of death were pulmonary embolism in one patient, myocardial infarct in one patient, and postoperative hemorrhage in two patients (Table 4). These causes were identified clinically, without necropsy.

DISCUSSION

Peritoneal perforation into the abdominal cavity and the spontaneous intrabiliary rupture of liver hydatid disease are not rare complications and cause serious problems. In our study, the ratios of peritoneal perforation and intrabiliary rupture cases to noncomplicated cases were 11.1% and 37%, respectively. The most common complication is rupture of the cyst, either internally or externally, followed by anaphylactic reaction and jaundice[5,9,10]. Systemic anaphylactic reactions have been reported in 1% to 12.5% of patients with intraperitoneal perforation, and these reactions may be life threatening[9,10]. Jaundice is the most important sign of intrabiliary rupture within a range of 9% to 30%[20,21]. In patients with peritoneal perforation and intrabiliary rupture, specific management has not been evaluated sufficiently. The presence of complications must be considered in the surgical treatment.

One third of 372 patients (32.5%) who underwent an operation for liver hydatid disease presented with complications. When compared, sex factor was not statistically different among groups ($P = 0.95$), but the mean age in the peritoneal perforated group was significantly different ($P = 0.001$, Table 1). Trauma is the most frequent etiological cause of perforation[9,22]. No patients in the current series experienced spontaneous peritoneal rupture. Hydatidosis is endemic in Turkey and the frequency of traffic accidents there is high[23]. Traffic accidents generally affect younger individuals, and the age risk factor found in our study may relate to this phenomenon. In superficial and bigger cysts, lack of normal liver tissue around the cyst to protect against trauma may be a cause of frequent rupture.

The differences in factors such as previous hydatid disease surgery, cyst localization, cyst number, and cyst infection were not significant among groups ($P > 0.05$, range, 0.109-0.683). Besides age, cyst diameter and cyst position (superficial or deep) were also significantly different factors ($P = 0.001$ and 0.017, respectively; Table 1). When compared to the same parameters with multinominal logistic regression analyses, young age, superficial position, and large diameter are significant predisposing factors for peritoneal perforation (Table 2). The hydatid cyst wall consists of an inner germinal layer and an outer laminated membrane. Surrounding the wall is the pericyst, which has an outer zone of compressed liver cells. A lack of presence of normal liver tissue around superficial cysts plays a role in relatively higher perforation rates. Similarly, an increase in cyst diameter may increase perforation risk either by becoming more superficial during growth or by increasing intracystic pressure.

Additionally, liver hydatid cysts at the dome of the liver grow progressively and have a tendency to erode

the diaphragm[24]. In our study, it has been shown that older age, bigger dimensions, multiplicity of the cysts, and bilobar cysts are predisposing factors for intrabiliary rupture. The relationship between older age and intrabiliary rupture probably depends on cyst age. Hydatid disease is a slowly growing disease, and in early times, most of the cysts produce no symptoms. In advanced cases, the intracystic pressure may cause tension on cyst walls and thinner wall formations. The communications between the cysts and the biliary tree usually involve small cholangioles, and direct extension into major bile ducts is rare[25,26]. The most probable theory may be the fenestration of the cyst and minor bile ducts, which have low pressure in the surrounding liver tissue. In the case of multiple and bilobar cysts, this communication rate may increase. Factors such as sex, primary or recurrent disease, or infection did not show effectiveness in both logistic models (Table 2).

Cyst dimension and age (younger age for peritoneal perforation and older age for intrabiliary rupture) have been determined as significant predisposing factors for the two complications. We do not believe a direct relationship exists between the two complications, but we can speculate that risk of peritoneal perforation risk may decrease in intrabiliary ruptured cysts because of the lower intracystic pressure probability. In our study the ratio of intrabiliary ruptured cysts was 97 out of 372 (26%), whereas intrabiliary rupture was 4 out of 28 (14.3%) peritoneally perforated cases, but this was not statistically significant.

The principles of hydatid surgery are (1) removal of all infective cyst parts; (2) inactivation of the cyst cavity; (3) avoidance of intra-abdominal spillage of cyst contents; and (4) management of the residual cavity. A lot of surgical techniques have been proposed for liver hydatid disease during the last three decades. Some authors suggest that obliteration procedures, such as capitonnage, intraflexion, or omentoplasty, are simple and safe methods[27]. In the past, obliteration procedures such as omentoplasty, capitonnage, and intraflexion were used for most patients in our clinic. However, in the last 10 years use of these management options decreased gradually and for the last 5 years we have not shown a preference for them. Recently, some authors have favoured the use of pericystectomy and liver resections because complete surgical resection is the ideal treatment for hydatid disease[18]. In our study, liver resections were performed only if multiple cysts were localized in one lobe, located peripherally, and were pedunculated, and pericystectomy was performed if the cysts were away from the major vascular and biliary structures of the liver. The most important advantages of these resections are that no dead space is left behind and that all the cyst wall is removed, which prevents liver regeneration. The need for sufficient technical infrastructure and surgical experience in the field of hepatic surgery limit these treatments in small centers, especially in developing countries. Relatively small-sized subcapsular cysts can be managed by nonanatomic resection of the cysts with a rim of healthy hepatic tissue but routine application of pericystectomy and liver resection may increase the operative complications, such as bleeding and postoperative morbidity and mortality.

For almost 15 years, our preferred surgical technique for treatment of liver hydatid cysts has been PP and drainage, which has been performed in 70% of the patients (Table 3). Leaving the cyst cavity open, the peritoneum has more support in recent years[13]. After controlling the relation between the biliary tree, it has been stated that this procedure does not increase recurrence or cause adhesion. The most important superior aspect of this technique is its applicability to every cyst at every localization. Other advantages of the procedure are the simplicity, no requirement of advanced experience, effectiveness, and a shorter operation time. The most important detail of this procedure in our experience is to perform the partial pericystectomy as widely as possible, and the drainage procedure should be added after the cyst contents are removed completely. After the cyst management, in peritoneal perforated cysts, the most important step is irrigation of the peritoneal cavity with a sufficient amount of scolicidal agents and removal of all cystic content, and in intrabiliary ruptured cases, clearance of the cystic material from the biliary tree is most important; also, the restoration of normal bile flow should be performed. The fistula was large enough to allow daughter cysts and debris to migrate into the biliary tree. For this reason introperative cholangiography was performed in all patients who presented with abnormal liver function tests preoperatively, bile-stained cyst fluid, and bile leak from the cyst wall. During the introperative cholangiography, visible bile fistulas must be sutured by using late absorbable suture materials.

After the intervention to the cyst, the most important step is irrigation of the cyst cavity with a sufficient amount of scolicidal agents and careful removal of all cystic content from the patient. Numerous solutions, such as hypertonic saline solutions (15%-30%), have been used as scolicidal agents for the purpose of inactivation[5,28]. The concentration of hypertonic saline solutions has diminished gradually. Now we use only 3% concentrations. Gargouri *et al*[29] used 3%-5% saline and stated that the application time is more important than the concentration. Although Derici *et al*[30] reported that hypertonic saline is not appropriate because it may damage the peritoneal surfaces and may cause hypernatremia, we have not encountered any significant complications with the use of this solution. Additionally, we believe that profuse peritoneal lavage with hypertonic sodium chloride is mandatory for preventing intra-abdominal recurrence of intraperitoneal ruptured hydatid disease.

The most effective surgical procedures following the cleaning of hydatid material from the biliary tree remain controversial. Some authors prefer T-tube[13-15]; in contrast, some reported that wide choledochoduodenostomy decreases morbidity and mortality[31]. In our study, complication rates in patients with bilioenteric anastomosis and T-tube were 21% and 27%, respectively.

In the literature, reported complication rates are be-

tween 6% and 47%; recurrence rates are 8% to 15%[32]. In this study, the overall postoperative complication and recurrence rates were 18% and 3.8%, respectively. Most often, surgical complications were wound infection (n = 21) and biliary fistulas (n = 12); the difference between groups was significant (P = 0.001, Table 4). The important causes of higher wound infection rates in the peritoneal perforation group were coinjuries, which were seen in 10 patients. There were small intestine and colon perforations in five cases; in addition, splenic, pancreatic, and renal injuries were each seen in one patient. Retroperitoneal hematoma was seen in the remaining two coinjured patients. External biliary fistulas did not develop in 68 of the T-tube patients and in none of the biliodigestive anastomosis or sphincteroplasty patients in the intrabiliary rupture group. T-tubes were removed after a control cholangiography, which was done after a mean period of 12 d postoperatively. External biliary fistulas developed in 9 (9.7%) patients. If the fistulas did not close with conservative follow-up, endoscopic sphincterotomy was performed after a mean period of 19 d. The causes of fistulas were remnant germinal vesicles and debris in the distal common bile duct in 5 patients and papillary stenosis in 4. In the peritoneally perforated and noncomplicated groups, biliary fistulas developed in 3 patients who had hepatic resections, and the problem was resolved with endoscopic sphincterotomy. Endoscopic procedures have been used not only for diagnostic purposes, but for treatment as well. Dumas *et al*[33] treated 7 of 28 patients with cholangitis due to cystic material with ERCP. Tekant *et al*[34] and Vignote *et al*[35] reported that endoscopic sphincterotomy achieved closure of fistulas within 5-7 d. In our series, fistulas closed in all external biliary fistula patients within a mean time of 7 (range, 3-17) d. At our center, intraoperative cholangiography with or without subsequent duct exploration remains the method of choice to prevent or decrease incidence of associated injuries and external biliary fistula. Several authors have advocated pre-operative or post-operative ERCP[33-35]. If performed in conjunction with a sphincterotomy, an ERCP may be used to clear the biliary tree as a planned procedure, thereby avoiding the need for an intraoperative cholangiography and bile duct exploration.

Recurrence occurred in 14 nonperforation cases (3.8%). When compared with the reported rates, the recurrence of our study is low. The cause of this may be the routine use of albendazol for 3 mo postoperatively. Recurrence rates were not significantly higher in peritoneal perforation and intrabiliary rupture cases when compared with noncomplicated cases (P = 0.132, Table 4). Recurrences of hydatid disease are usually due to inadequate cystic content removal, spillage of cystic liquid intraoperatively, undetected cysts, and satellite lesions and reinfestations. Readmissions in our series due to recurrent disease were generally after a long time and mostly from rural areas. Another clinical finding that suggests reinfestation is the presence of hydatid cyst at the same localisation which seen was 4 of 14 recurrent cases. For these reasons, the probability of reinfestation is high in endemic countries like Turkey. When compared with the literature, in our study the recurrence rate was low. Albendazole treatment may play an important role in this low rate. Although the efficacy of perioperative prophylaxis with albendazole has been controversial, recent studies suggest that medical treatment is effective in the prevention of recurrence after surgery[36,37]. To diminish recurrence and potential spread of the organism, we believe that medical treatment should apply as an adjuvant therapy to surgery when complete removal of the cyst is impossible or when the cyst contents threaten to disseminate due to peritoneal rupture. It is indicated in patients who are at high risk for surgery, and in the presence of bilateral multiple small cysts. Those with small cysts (< 4 cm) and cysts with thin walls are the best group for effective medical treatment. In addition, exogenous vesiculations have been pronounced in hydatid cyst recurrences[38]. The importance of medical treatment which is mainly effective on small cysts, may indicate the usefulness of the effect on recurrence.

Although there is insufficient published evidence to support a clear recommendation for the use of albendazole preoperatively[39], we highly recommend this treatment for one week before surgical exploration. Preoperative therapy may reduce the risk of intraperitoneal seeding of infection that develops *via* cyst rupture and spillage occurring spontaneously or during surgery. In our study no correlation was found between recurrence of cysts and albendazole use.

Serology detect specific serum antibodies or circulating antigen by a variety of immunodiagnostic methods. Of these, the enzyme immunosorbent assay (ELISA) employing hydatid fluid antigen for detection of echinococcal antibodies (IgG) in the serum is the most widely used. Serological tests are of little clinical use in monitoring patients after operation for cystic echinococcosis or patients on chemotherapy. The antibody titers rise following surgical treatment. The titers start falling at 3 mo and become negative in a period of 12-24 mo. False positive tests can occur in normal persons from endemic areas and in those with other parasitic infections[16]. In our study, 86 (58.9%) of 146 (42.4%) serologically evaluated patients of group Ⅱ and Ⅲ were positive, and 41 (28%) of these were also serologically positive 2 years after surgery. However, recurrence occurred in only 1 of the patients that was serologically positive for a long term. We think that the value of serological screening in areas endemic for cystic echinococcosis is enhanced by combining it with abdominal US.

Mortality rates of the study groups were not statistically different (P = 0.814, Table 4). Liver resections were performed in two mortality cases that were due to intraoperative and postoperative bleeding. One of the patients who had PP and drainage died because of myocardial infarct, and one patient had PP and omentoplasty cases of pulmonary thromboembolism. When compared, mortality rates were significantly different among groups (P < 0.001). This result requires discussion of the controversial radical methods in hydatid disease. Chautems *et al*[38] recommended complete resection of hepatic hydatid cysts. In contrast, Daali *et al*[40] preferred

conservative procedures. We think that radical methods should not be performed routinely for such a slowly growing benign pathology. It is wise to reserve radical surgery for peripheral, easily accessible cysts and for unilober multiple cysts.

LOS did not differ between the cases of peritoneal perforation and intrabiliary rupture when compared with noncomplicated cases ($P > 0.05$), whereas, according to the additional surgical procedures, there was a significant difference in LOS between choledochotomy with T-tube and procedures without choledochotomy ($P < 0.05$). An external biliary fistula formation and T-tube procedure, wherein the T-tube may be taken out after approximately 7-10 d, may affect LOS. In contrast, there was no difference between the groups with biliodigestive anastomosis and without choledochotomy ($P > 0.05$). Biliodigestive anastomosis may be a good alternative surgical procedure to T-tubes, with lower complication rates and shorter LOS.

According to this study's multinominal logistic regression analysis, peritoneal perforation risk increases with younger age, superficial localization, and larger dimensions of cysts, and older age, multiple and larger cysts, and bilobar localization are established as predisposing factors for intrabiliary rupture. Morbidity rates significantly increased in peritoneally perforated and intrabiliary ruptured cases, but there was no difference in recurrence rates and hospital stay times. Our preferred surgical technique for liver hydatid cysts is partial pericystectomy and drainage because the rate of postoperative complications and recurrence, and the duration of hospital stay are satisfactory. We believe that radical methods should not be performed routinely for such a benign pathology. The localization and number of cysts, relation to blood vessels and bile ducts, and general status of the patient are parameters influencing the choice of surgical procedure. In peritoneal perforated and intrabiliary ruptured cysts, the most important steps are irrigation of the peritoneal cavity with a sufficient amount of scolicidal agents, removal of all cystic contents from the peritoneum, and clearance of the cystic material from the biliary tree. However, randomized controlled studies are needed to establish the best surgical management for peritoneal perforated and intrabiliary ruptured liver hydatid cysts.

COMMENTS

Background

The development of hydatid disease associated with *Echinococcus granulosus* is still an important health problem. The clinical picture can be severe, and complications may occur, making the already difficult treatment even more so. Complications are observed in one third of patients with liver hydatid cysts. The most common complication is rupture of the cyst, either internally or externally.

Research frontiers

Only a few studies have reported the management and outcome of patients with complicated liver hydatid disease. Surgery is the mainstay of treatment, although there is no consensus on the respective advantages of conservative and radical methods. In this study, the authors evaluated the predisposing factors for peritoneal perforation and intrabiliary rupture and the effects of these complications on morbidity, length of hospital stay, mortality, and recurrence in hydatid disease.

Innovations and breakthroughs

According to this study's multinominal logistic regression analysis, peritoneal perforation risk increases with younger age, superficial localization, and larger dimensions of cysts, and older age, multiple and larger cysts, and bilobar localization are established as predisposing factors for intrabiliary rupture. Morbidity rates significantly increased in peritoneally perforated and intrabiliary ruptured cases, but there was no difference in recurrence rates and hospital stay times.

Applications

In peritoneal perforated and intrabiliary ruptured cysts, the most important steps are irrigation of the peritoneal cavity with a sufficient amount of scolicidal agents, removal of all cystic contents from the peritoneum, and clearance of the cystic material from the biliary tree. However, randomized controlled studies are needed to establish the best surgical management for peritoneal perforated and intrabiliary ruptured liver hydatid cysts.

Terminology

Echinococcus granulosus is a parasitic tapeworm that lives in the bowels of dogs. Humans contract the disease through enteral exposure and become accidental intermediate hosts.

Peer review

Alper Akcan *et al*, evaluate the predisposing factors for peritoneal perforation and intrabiliary rupture and the effects of these complications on surgical outcome in liver hydatid disease. This is one of the largest and well treated series of patients that had been publish. The structure and methodology followed by the authors is correct in my opinion and the techniques they applied for the treatment of these complex patients are modern and correct.

Abstract

AIM: To identify the clinical outcomes of hepatocellular carcinoma (HCC) patients with inconsistent α-fetoprotein (AFP) levels which were initially high and then low at recurrence.

METHODS: We retrospectively included 178 patients who underwent liver resection with high preoperative AFP levels (≥ 200 ng/dL). Sixty-nine HCC patients had recurrence during follow-up and were grouped by their AFP levels at recurrence: group Ⅰ, AFP ≤ 20 ng/dL (n = 16); group Ⅱ, AFP 20-200 ng/dL (n = 24); and group Ⅲ, AFP ≥ 200 ng/dL (n = 29). Their preoperative clinical characteristics, accumulated recurrence rate, and recurrence-to-death survival rate were compared. Three patients, one in each group, underwent liver resection twice for primary and recurrent HCC. AFP immunohistochemistry of primary and recurrent HCC specimens were examined.

RESULTS: In this study, 23% of patients demonstrated normal AFP levels at HCC recurrence. The AFP levels in these patients were initially high. There were no significant differences in clinical characteristics between the three groups except for the mean recurrence interval (21.8 ± 14.6, 12.3 ± 7.7, 8.3 ± 6.6 mo, respectively, P < 0.001) and survival time (40.2 ± 19.9, 36.1 ± 22.4, 21.9 ± 22.0 mo, respectively, P = 0.013). Tumor size > 5 cm, total bilirubin > 1.2 mg/dL, vessel invasion, Child classification B, group Ⅲ, and recurrence interval < 12 mo, were risk factors for survival rate. Cox regression analysis was performed and vessel invasion, group Ⅲ, and recurrence interval were independent risk factors. The recurrence interval was significant longer in group Ⅰ (P < 0.001). The recurrence-to-death survival rate was significantly better in group Ⅱ (P = 0.016). AFP staining was strong in the primary HCC specimens and was reduced at recurrence in group Ⅰ specimens.

CONCLUSION: Patients in group Ⅰ with inconsistent AFP levels had a longer recurrence interval and worse recurrence-to-death survival rate than those in group Ⅱ. This clinical presentation may be caused by a delay in the detection of HCC recurrence.

INTRODUCTION

Serum α-fetoprotein (AFP) level is widely used as a tumor marker for the diagnosis and detection of both occurrence and recurrence of hepatocellular carcinoma (HCC)[1,2]. For a patient with a history of liver disease, consensus for the diagnosis of HCC can be achieved with an elevated AFP level (≥ 200 ng/dL), along with a dynamic imaging study showing a hepatic tumor, with enhancement in the arterial phase and wash-out in the venous phase[3,4].

A high serum AFP level in HCC also indicates poor tumor differentiation, larger tumor burden, recurrence after tumor resection, and an unfavorable outcome[5-10]. In clinical practice, a dramatic decline in serum AFP level indicates that the tumor has been surgically removed[11]. The AFP level is broadly applicable both pre- and postoperatively.

AFP is secreted in only about 70% of HCC cases, so both false-negative and false-positive rates are high when using AFP as the serological marker for the detection of HCC[12]. In general, patients have an initially high serum AFP level when HCC is diagnosed. Serum AFP level is also considered an effective tumor marker in the surveillance of HCC recurrence[13,14]. Recurrent HCC is expected to have the same bioactivity as the primary tumor and to secrete high levels of AFP, making AFP a seemingly reliable choice. Regular checks of serum AFP levels in patients who initially had high AFP levels to identify HCC recurrence is suggested as a practice guideline by the National Comprehensive Cancer Network (NCCN) version 1, 2009[15].

However, inconsistent AFP levels have been found in patients diagnosed with HCC where initial AFP levels were high, but were normal when HCC recurred. A true relapse of HCC and a second primary tumor due to chromosomal aberration are possible mechanisms[16], and inconsistent AFP levels may differentiate them *via* AFP secretion bioactivity. If we depend on the AFP level to signal an HCC recurrence, we may miss or delay the diagnosis of recurrence. We may expect the clinical outcome of patients with inconsistent AFP levels to be similar to those with normal AFP levels. However, this clinical presentation has not been investigated before. Therefore, it is important to study the prognosis of this subgroup of HCC patients whose AFP levels are high initially and normal at recurrence. It is possible that the findings of this study could modify the surveillance principle for this subgroup of HCC patients and improve the quality of medical care.

MATERIALS AND METHODS

Patients

From 1996 to 2008, 642 patients newly diagnosed with HCC who underwent liver resection were entered into a computer database at the Tri-Service General Hospital, a tertiary referral medical center in Taipei, Taiwan. The diagnosis of HCC in all patients was established histologically from surgical specimens. HCC patients with an initial serum AFP level ≥ 200 ng/dL (n = 178) were selected and 82 had HCC recurrence during follow-up. Thirteen patients were excluded because of an American Joint Committee on Cancer (AJCC) stage Ⅳ diagnosis, lost to follow-up or missing data. Therefore, 69 patients were included in this study and grouped according to their serum AFP levels when HCC recurred (Figure 1).

Grouping by AFP level at recurrence

Sixteen patients with normal AFP levels (≤ 20 ng/dL) during HCC recurrence were assigned to group Ⅰ; 24 patients with AFP levels between 20 ng/dL and 200 ng/dL were assigned to group Ⅱ; and, 29 patients with AFP levels of 200 ng/dL or higher were assigned to group Ⅲ. In our hospital, the normal AFP level is ≤ 20 ng/dL measured by radioimmunoassay using an anti-AFP antibody (ELSA 2-AFP kit, CIS Bio International, Cedex, France).

Comparing the parameters of each group

Preoperative clinical characteristics were collected from the database and compared. These characteristics included age, gender, tumor size, serum alanine aminotransferase (ALT) level, total serum bilirubin, serum albumin level, platelet count, vessel invasion, tumor number, clinical stage (AJCC, Child-Pugh classification), hepatitis B virus, hepatitis C virus, presence of cirrhosis, mean recurrence interval, mean recurrence-to-death time, mean survival time and location of recurrence. Salvage treatments for recurrent HCC included repeat liver resection, liver transplantation, transarterial chemo-embolization, radiofrequency ablation, and thalidomide therapy. The mean AFP levels at operation (AFP op) and at recurrence (AFP recur) were calculated for these three groups. Intra-hepatic metastasis was defined as recurrent HCC located at the adjacent segment, section and same lobe. In contrast to intra-hepatic metastasis, multicentric recurrence was defined as recurrent HCC located at the contralateral liver lobe. The pathological grade was defined as: grade Ⅰ - well differentiated, grade Ⅱ - moderate, and grade Ⅲ - poorly differentiated, according to the report by the pathologist (Dr. Yu CP).

Endpoint

The mean recurrence interval was defined as the interval between the operation and HCC recurrence. The starting point of overall survival was the operation date, and recurrence-to-death was the date of recurrence diagnosis. The endpoint of accumulated recurrence rate was defined as the date of recurrence and the endpoint of recurrence-

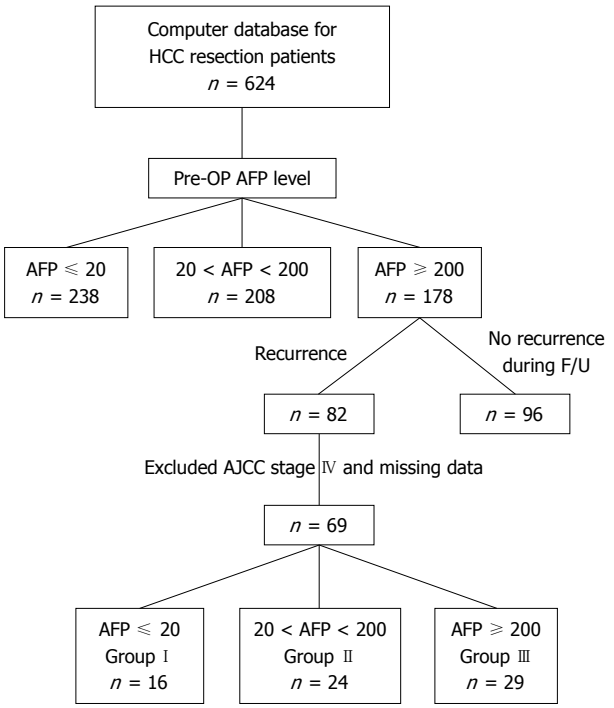

Figure 1 Flow chart for patient selection. HCC: Hepatocellular carcinoma; AFP: α-fetoprotein; AJCC: American Joint Committee on Cancer.

to-death survival was the date of death or the last follow-up date if the patients survived. The choice of salvage therapy was according to the willingness of the patient, the degree of tumor progression, and the criteria for treatment guidelines of the Cancer Committee at the Tri-Service General Hospital. The recurrence interval was defined as the day of the initial liver resection to the day of HCC recurrence diagnosis.

AFP immunohistochemistry

Three patients, one from each group, underwent a second liver resection for tumor recurrence. Surgical specimens from both operations in each of these three patients were reviewed by a pathologist (Dr. Yu CP). The specimens were examined by hematoxylin and eosin staining and immunohistochemistry for AFP levels and the differences were compared.

Follow-up

All patients were followed up regularly every month in the first year and every 3 mo thereafter. AFP level was monitored at each follow-up. Abdominal ultrasound imaging or computed tomography (CT) was performed every 3-6 mo in first two years, then annually, according to the NCCN practice guideline[15]. In some patients, magnetic resonance imaging, hepatic angiography, and percutaneous needle biopsy were considered if the CT images were not conclusive for a new hepatic lesion. All clinicopathological data were collected in the computer databases of the Cancer Board at the Tri-Service General Hospital, and the follow-up data were regularly updated. This study was approved by the Institutional Review Board of Tri-Service General Hospital. The follow-up period of this study ended on June 30, 2009.

ALT: Alanine aminotransferase; T Bil: Total bilirubin; Plat: Platelet; Child: Child-Pugh classification; AJCC: American Joint Committee on Cancer; HBV (+): Hepatitis B virus infection; HCV (+): Hepatitis C virus infection; Cirrhosis (+): Cirrhotic change by pathologic finding; AFP (op): α-fetoprotein level preoperatively; AFP (recur): α-fetoprotein level at tumor recurrence; Recur interval: The interval from operation to tumor recurrence; Recur-to-death: The interval from tumor recurrence to patient's death; Survival time: The time from operation to last follow-up date or death date; Intra-hepatic recur: Hepatocellular carcinoma (HCC) recurrence located at the adjacent segment, section and same lobe/HCC recurrence located at contralateral liver lobe.

Statistical analysis

Continuous clinical data were analyzed using the Student's *t* test and ANOVA, and the categorical data were analyzed using Fisher's exact test or the χ^2 test. Kaplan-Meier and Cox regression analyses were performed to determine the survival curves, and the survival relative ratio between the three groups of HCC patients. $P < 0.05$ was considered statistically significant. All statistical analyses were performed using statistical software (SPSS version 15.0 for Windows, Chicago, IL, USA).

RESULTS

Of the 69 HCC patients with initially high AFP levels who underwent liver resection, 16 had normal serum AFP levels (⩽ 20 ng/dL) at recurrence. There were no significant differences between the three groups in terms of clinical characteristics such as age, gender, tumor stage, virology status, tumor pattern, biochemical examination results, and cirrhotic status (Table 1). Significant differences between the three groups were observed for recurrence intervals, survival times and location of recurrence ($P < 0.001$, $P = 0.013$, $P = 0.001$, respectively).

Recurrence interval among the groups

The accumulated recurrence rates in the three groups were

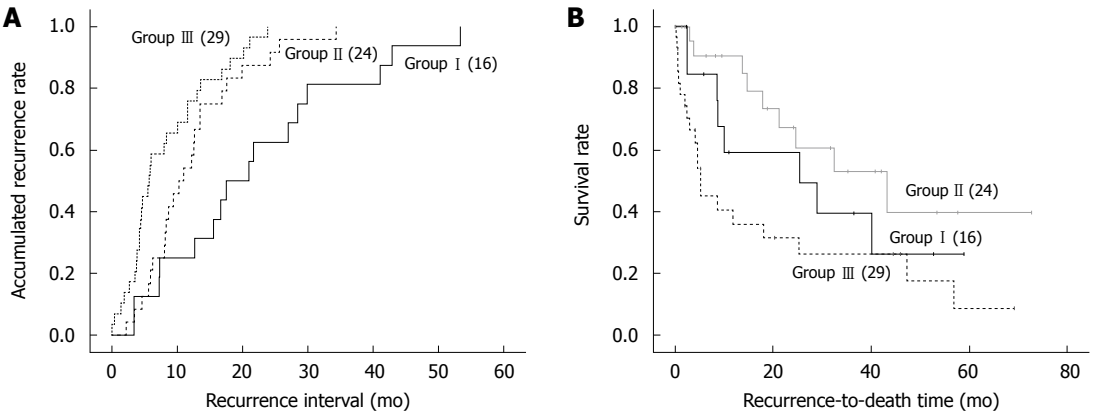

Figure 2 Accumulated recurrence rates and recurrence-to-death survival rates. A: Accumulated recurrence rates were calculated from the first liver resection date to recurrence date and compared between groups Ⅰ, Ⅱ, and Ⅲ ($P < 0.001$); B: Recurrence-to-death survival rates were calculated from the recurrence date to last follow-up date and compared between groups Ⅱ, Ⅰ, and Ⅲ ($P = 0.016$).

Path grade Ⅰ, Ⅱ, Ⅲ: Histopathologic grade of HCC. Ⅰ: Well differentiated; Ⅱ: Moderately differentiated; and Ⅲ: Poor or undifferentiated.

calculated using the Kaplan-Meier method (Figure 2A). Accumulated recurrence rates were calculated from the first liver resection date to the recurrence date. Recurrence took place in all patients and was compared among groups Ⅰ, Ⅱ, and Ⅲ ($P < 0.001$). The relative ratios [95% confidence interval (CI)] of groups Ⅱ and Ⅲ compared with group Ⅰ patients were 0.244 (0.119-0.498) and 0.591 (0.340-1.027), respectively, with group Ⅰ as the reference.

Independent factors affecting survival among the groups

The risk factors for clinical outcome related to survival are shown in Table 2. The six factors affecting clinical outcome by Cox proportion hazard analysis were tumor size (> 5 cm), total bilirubin (> 1.2 mg/dL), vessel invasion (+), recurrence interval (< 12 mo), Child-Pugh classification (B), and group Ⅰ and Ⅲ. When Cox regression analysis was performed, vessel invasion, group Ⅲ, and recurrence interval were identified as independent risk factors.

Recurrence-to-death survival rates among the groups

The recurrence-to-death survival rates were calculated from the recurrence date to the last follow-up date and compared among groups Ⅰ, Ⅱ, and Ⅲ as shown in Figure 2B ($P = 0.016$). Group Ⅱ had a significantly better survival rate than the other two groups. The relative ratios (95% CI) of groups Ⅱ and Ⅲ compared with group Ⅰ were 0.550 (0.241-1.253) and 0.337 (0.153-0.743), respectively.

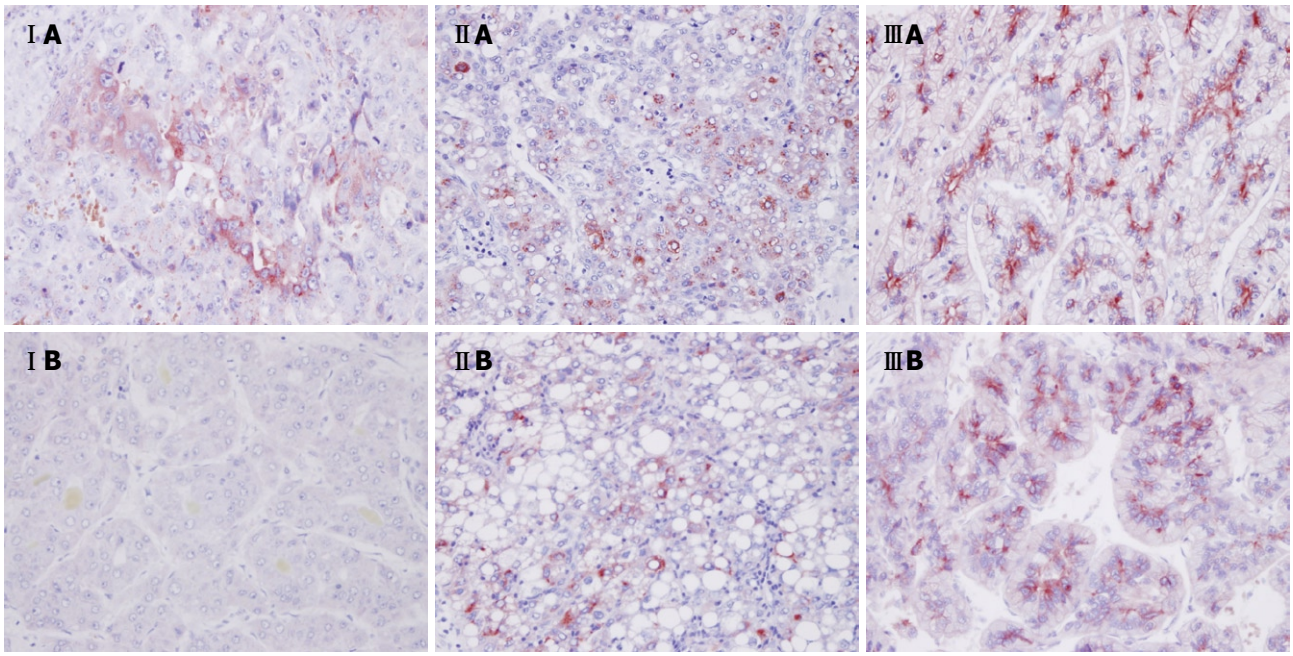

Figure 3 Immunohistochemical staining of AFP in representative specimens from the primary (A) and recurrent (B) HCC resections from each group (Ⅰ, Ⅱ, Ⅲ) × 400.

AFP immunohistochemistry in groups Ⅰ, Ⅱ, and Ⅲ

We compared the AFP immunohistochemistry results for a pair of specimens from each group. All groups revealed strong AFP staining in the primary HCC liver resection specimens. In the liver resection specimens from recurrent HCC, groups Ⅱ and Ⅲ showed strong AFP staining, but the specimen from group Ⅰ showed reduced staining (Figure 3).

DISCUSSION

Twenty-three percent of the patients in our study had inconsistent serum AFP levels between the time of initial HCC diagnosis and its recurrence. These patients had a longer recurrence interval. However, they did not have a better recurrence-to-death survival than patients with higher AFP levels at recurrence. We propose the following possible explanations: First, there was *de novo* HCC after the first resection, and the behavior or biological activity of the recurrent tumor was more malignant than the first. Second, a delay in the detection of the recurrent tumor as a result of normal AFP levels decreased the recurrence-to-death survival. This meant that these patients seemed to have a longer recurrence interval due to the delayed diagnosis caused by normal AFP levels. Once HCC recurrence was diagnosed *via* clinical symptoms, the recurrent tumor was advanced, which then shortened the time from recurrence to death.

In general, the principle we follow in HCC patients after resection is according to the NCCN guideline. For patients with initially high AFP levels, such as the patients of our study, the AFP level is followed every 3 mo, and imaging studies are carried out every 3-6 mo in the first two years. After 2 years, the AFP level is followed every 3 mo and imaging studies are carried out annually. If the AFP level is elevated, suggesting HCC recurrence then further intervention is arranged. However, in the group with inconsistent AFP levels, the imaging studies were carried out annually due to normal AFP levels. Once HCC recurrence based on the NCCN guideline is diagnosed, the recurrence will be detected late resulting in poor quality medical care and legal problems.

Histopathological change in a group Ⅰ patient and a possible mechanism

In our patients, some underwent resection twice for removal of HCC. The first and second specimens from liver resection did not show consistent histopathological findings in a patient from group Ⅰ, but did show similar histopathological findings in patients from groups Ⅱ and Ⅲ. Although these paired pathological findings are not conclusive, they do hint at an inconsistent pathological presentation. In a previous study, the authors proposed that the chromosomal changes and clonality relationship between primary and recurrent HCC could be proved using a comparative genomic hybridization technique[16]. In that study, 35% of HCC patients were considered to have a second primary HCC. In our study, the mechanism of HCC recurrence in group Ⅰ patients may be due to *de novo* HCC with low secretion of AFP. This mechanism in groups Ⅱ and Ⅲ may be due to intra-hepatic metastasis from the primary HCC. Many possible reasons for this phenomenon have been reported, including *de novo* HCC[16,17], a biologic tumor changed by dedifferentiation[18], or a multicentric origin[19].

Possible explanations for the clinical outcome

In our study, we used Cox regression analysis of the risk

factors for accumulated recurrence rate and no confounders were identified. Patients with inconsistent AFP levels had a longer accumulated recurrence rate than those in groups Ⅱ and Ⅲ. The second primary HCC might have needed a longer time to develop, resulting in a longer recurrence period. In groups Ⅱ and Ⅲ, the recurrent tumor was probably from an intra-hepatic metastasis or residual HCC resulting in a shorter recurrence interval than that suggested by other articles[20,21]. The recurrence-to-death survival rate of patients with inconsistent AFP levels was worse than that in group Ⅱ where the AFP level was consistent.

Dissociation of the tumor marker means inconsistent AFP, the clinical ramifications

Elevated serum AFP is useful for the diagnosis of HCC, and also implies a large tumor burden at presentation[6]. A low serum AFP level at recurrence in patients with an initially high AFP level at HCC diagnosis may be a good prognostic factor of survival[6]. However, this was not supported by our results. This poor outcome may be caused by a biological change in the malignancy or delayed diagnosis. Physicians need to diagnose recurrence as early as possible by regular surveillance to improve patient outcome. In the NCCN practice guidelines, version 1, 2009[15], surveillance for HCC recurrence in patients with initially elevated AFP levels includes checking AFP levels every 3 mo and performing imaging studies annually for 2 years after resection[15]. When physicians follow the NCCN guidelines, they should bear in mind that AFP level is not as sensitive as generally believed for tumor recurrence in this subgroup of HCC patients, similar to group I patients in our study. The results of our study showed that regular checks of AFP levels should be conducted every 1-3 mo, followed by imaging studies every 3 mo for patients with an initially elevated AFP level. Regular imaging studies should not be omitted even when the serum AFP level is normal. The results of our study are important for reminding practicing physicians that regular imaging is still the benchmark in the surveillance of HCC patients.

Limitations of this study

There were some limitations in this study. First, these preliminary data were from one medical center and the conclusion needs to be validated by a meta-analysis of multicentric data. Second, the diagnosis of HCC recurrence was not proven by pathologic findings. We diagnosed HCC recurrence by dynamic imaging studies, hepatic angiography, and clinical disease progression. In a further study, tumor biopsy should be performed before salvage therapy if possible. The results of histochemical staining in the recurrent tumor could explain the exact mechanism of this clinical presentation in patients with inconsistent AFP levels.

In conclusion, 23% of our selected patients demonstrated an inconsistency in serum AFP level between initial HCC diagnosis before resection and HCC recurrence diagnosis. To improve medical care and avoid missed or delayed diagnoses, regular checks of AFP level and imaging studies every three months are strongly recommended during follow-up, even for patients with normal serum AFP levels.

COMMENTS

Background

Serum α-fetoprotein (AFP) level is widely used as a tumor marker for the diagnosis and detection of both occurrence and recurrence of hepatocellular carcinoma (HCC). A high serum AFP level in HCC also indicates a poor outcome. However, inconsistent AFP levels have been found, where patients' AFP levels were initially high when HCC was diagnosed, but were normal when HCC recurred. There is no research on the prognosis of this subgroup of HCC patients.

Research frontiers

When clinical physicians follow the National Comprehensive Cancer Network guideline, they should bear in mind that AFP level is not as sensitive as generally believed for tumor recurrence in this subgroup of HCC patients. Regular checks of AFP level and imaging studies every three months are strongly recommended during follow-up, even for patients with normal serum AFP levels.

Innovations and breakthroughs

This is the first article to investigate the clinical outcomes of patients with inconsistent AFP levels. The clinical outcomes in this subgroup of HCC patients were not as good as those with normal AFP levels. To improve medical care and avoid missed or delayed diagnoses, clinical physicians should bear these findings in mind.

Applications

The authors modified the surveillance principle for this subgroup of HCC patients following the results of this study to improve the quality of medical care.

Peer review

This is a retrospective analysis of a cohort of patients with HCC, it maybe interesting for the readers.

Abstract

AIM: To analyze the combined treatment of resection and intraoperative radiofrequency ablation (RFA) for multifocal hepatocellular carcinoma in terms of prognosis and surgical outcomes.

METHODS: This study was a retrospective case comparison study using prospectively collected data. The study covered the period from April 2001 to December 2006. The data of 200 patients with histologically confirmed hepatocellular carcinoma were reviewed. Nineteen patients (17 men and 2 women) having received resection in combination with RFA were chosen as subjects of the study (the combination group). Fifty-four patients (43 men and 11 women) having received resection alone were selected for comparison (the resection group). The two groups matched tumor number and tumor size, and all the patients in the two groups displayed no tumor rupture, major vascular involvement and distant metastasis. Their demographics, preoperative assessment, disease recurrence patterns, overall survival and disease-free survival were compared.

RESULTS: In the combination group, the median age was 65 years (range, 34-77 years), the median tumor number was 3 (range, 2-9), and the median tumor size was 6 cm (range, 1.2-14 cm). In the resection group, the median age was 51.5 years (range, 27-80 years, P = 0.003), the median tumor number was 3 (range, 2-9, P = 0.574), and the median tumor size was 6 cm (range, 1-14 cm, P = 0.782). The two groups were similar in characteristics of tumors and comorbidities, and had comparable results in preoperative liver function tests. All patients had Child-Pugh class A status. Bilobar involvement occurred in 14 patients (73.6%) in the combination group and 3 patients (5.5%) in the resection group (P = 0.04). Six patients (32%) in the combination group and 35 patients (65%) in the resection group underwent major hepatectomy. Thirteen patients (68%) in the combination group and 19 patients (35%) in the resection group underwent minor hepatectomy (P = 0.012). The combination group had fewer major resections (32% *vs* 65%, P = 0.012), less blood loss (400 *vs* 657 mL, P = 0.007), shorter operation time (270 *vs* 400 min, P = 0.001), and shorter hospital stay (7 *vs* 8.5 d, P = 0.042). The two groups displayed no major differences in surgical complications (15.8% *vs* 31.5%, P = 0.24), disease recurrence (63.2% *vs* 50%, P = 0.673), hospital mortality (5.3% *vs* 5.6%, P = 1), and overall survival (53 *vs* 44.5 mo, P = 0.496).

CONCLUSION: Safe and effective for selected patients with multifocal hepatocellular carcinoma, the combination of resection and intraoperative RFA widens the applicability of surgical intervention for the disease.

INTRODUCTION

Management of hepatocellular carcinoma (HCC) in patients with cirrhosis is always a great challenge for clinicians. Prognosis of most HCC patients is poor due to the low rate of tumor resectability (20%-37%)[1,2]. Although resection is regarded as the gold-standard treatment for HCC, many patients are not suitable for it because of unfavorable anatomical location, major vessel involvement, multifocal involvement, distant metastasis, or poor liver function[3-7]. In the hope of improving the survival of patients having unresectable HCC, locoregional treatment aiming at local tumor control has been developed.

Radiofrequency ablation (RFA) is a locoregional treatment which has gained recognition in the management of liver diseases including HCC. During RFA treatment, heat energy generated by high-frequency alternating currents (460-480 kHz) targeted at the living tissues causes protein denaturation at a temperature of 60℃ through ionic vibration; coagulative necrosis of the target lesion then follows. RFA outperforms other locoregional treatments by its effective tumor ablation, minimal liver damage, low morbidity, and low mortality[3,8-12].

Lately, there have been detailed studies on RFA treating small HCC as well as isolated reports on the combined employment of resection and RFA for the treatment of liver metastasis of HCC[13-15]. Curley *et al*[16] reported a series of RFA treatment on 123 patients bearing unresectable primary (n = 48) or metastatic (n = 75) liver tumors. A total of 169 tumors were ablated with a clearance rate of 100%. There was no operative mortality. However, the efficacy of RFA on large tumors is still questionable. Although several reports showed that RFA with multiple processes and overlap of ablation zones was feasible for treating large liver tumors, the high recurrence rates did not favor it as a primary treatment tool for them[17-22]. Resection is still considered the first treatment option for large HCC.

Patients with multiple HCCs can opt for multiple resections, but multiple resections entail a higher risk of liver failure for patients with cirrhosis. Hence, in the management of multifocal HCC, combined employment of resection (for large tumors) and RFA (for small tumors) sounds like a reasonable measure for the achievement of complete tumor clearance.

Both resection and RFA are good treatment options for HCC while at the same time they both have their own limitations. Resection is limited by the patient's liver function and the location of tumor, and RFA is limited to small tumors only. In general, around one-fourth of patients with HCC are amenable to surgical intervention, and among them, around one-fourth develop multiple tumors on presentation. The combination of resection and RFA can subject more patients to potentially curative surgical intervention.

This study compared the combined treatment of resection and RFA with conventional hepatectomy alone in terms of prognosis and surgical outcomes in treating multifocal HCC.

MATERIALS AND METHODS

This study was a retrospective case comparison study using prospectively collected data. In our hospital, the data of all patients of liver surgery are input into a detailed computerized database by the surgeon-in-charge after patient discharge. Data collected include demographics, preoperative investigation results, operative details, and postoperative investigation results. This study covered the period from April 2001 to December 2006. The data of 200 patients with histologically confirmed HCC were reviewed. Nineteen patients having received resection in combination with RFA were chosen as subjects of the study (the combination group). Fifty-four patients having received resection alone were selected for comparison (the resection group). The two groups matched in terms of tumor number (range, 2-9) and tumor size (within 14 cm), and all patients in the two groups displayed no tumor rupture, major vascular involvement and distant metastasis. Their demographics, preoperative assessment, disease recurrence patterns, overall survival and disease-free survival were compared.

All the 73 patients had their medical history reviewed and were fully assessed with physical examination. They received chest X-ray (CXR) and computed tomography (CT) scan of the abdomen. They also received serum laboratory tests which yielded information on complete blood count, platelet count, coagulation profile, hepatitis B and hepatitis C serology, total serum bilirubin, serum albumin, serum alanine aminotransferase, serum aspartate aminotransferase, serum gamma-glutamyl transferase, serum alkaline phosphatase, serum α-fetoprotein (AFP), electrolytes, renal function, and indocyanine green (ICG) clearance rate. Resectability of tumor was confirmed upon three criteria: first, there was no distant metastasis according to the results of CXR and CT scan; second, the ICG rate was less than 14.4% at 15 min; and third, the estimated mass volume of the residual liver after resection was more than 30% of the original liver.

Surgical approaches

Each patient in the combination group underwent resection and RFA in one single operation intended to cure. The operation was performed with the open approach, starting with an initial exploration of the abdomen and pelvis to confirm the absence of extrahepatic lesion.

Intraoperative ultrasound was used to identify tumor location and number as well as the relation between the tumors and the vasculature of the liver. Anatomical resection was performed for the largest tumors or the largest groups of tumors which were deemed surgically resectable with clear margins. The extent of resection was determined by lesion location, the relation between the lesion and the surrounding vasculature, and biliary involvement. Parenchymal transection was performed with a Cavitron ultrasonic surgical aspirator. Segmental pedicles and other major vasculatures were divided with vascular staplers or ligatures. Pringle's maneuver was not applied.

Lesions not treated with resection were then subjected to RFA with standard treatment algorithm. Intraoperative ultrasound was used to guide the placement of the RFA needle at the target lesion. Single needle or needle cluster was used according to the size of the target tumor. For tumors larger than 3 cm, cluster probe was used. A margin of 1 cm was included in ablation. The Cool-tip™ system which consisted of a generator that supplied power up to 200 W was used. The electrode was optimally positioned to achieve complete tumor destruction and a normal parenchymal ablation zone of at least 1 cm.

All the patients were originally enlisted for resection only, but due to various reasons, the operative surgeon adopted RFA as an additional treatment modality with curative intention for complete control of tumors. The reasons for the adoption of a combination therapy are listed in Table 1.

Table 1 Reasons for adopting combination therapy *n* (%)

	Combination group (*n* = 19)
Bilobar disease	14 (73.6)
Proximity to major vessel or bile duct	5 (26.3)
Dense adhesion	3 (15.8)
Large resection required for small tumors	5 (26.3)
ICG rate at 15 min > 14.4%	5 (26.3)
Low platelet count (< 100 × 10^9/L)	3 (15.8)
Severe cirrhosis	9 (47.4)

ICG: Indocyanine green.

Table 2 Patient demographics

	Combination group (*n* = 19)	Resection group (*n* = 54)	*P* value
Age (yr)	65 (34-77)	52 (27-80)	0.003
Gender (M:F)	17:2	43:11	0.492
Comorbidities	10 (53%)	20 (37%)	0.235
Renal impairment	0 (0%)	2 (3.7%)	1.000
Diabetes mellitus	5 (26.3%)	10 (18.5%)	0.469
Chest infection	1 (5.3%)	3 (5.6%)	1.000
Coronary complications	6 (31.6%)	14 (25.9%)	0.635
Hepatitis B infection	16 (84.2%)	42 (77.8%)	0.745
Hepatitis C infection	2 (10.5%)	2 (3.7%)	0.478
Child-Pugh class A	19	54	1.000
Platelet count (× 10^9/L)	165 (91-64.5)	177 (86-458)	0.396
ICG (% at 15 min)	11.8 (3-25.7)	9 (3.7-18.2)	0.083
AFP level (ng/mL)	248 (6-38 040)	133 (2-530 600)	0.915
Tumor size (cm)	6 (1.2-14)	6 (1-12.5)	0.782
Tumor number	3 (2-9)	3 (2-9)	0.574

AFP: α-fetoprotein.

Postoperative follow-up

Monitoring of complete blood picture, coagulation profile, blood gas, liver function and renal function was carried out on day 1 and day 7 as part of the standard protocol. ICG clearance test was done on day 7 if possible. CXR, CT scan of the abdomen and serum AFP investigation were performed at one month, then quarterly in the first two years, and half-yearly afterwards.

Statistical analysis

All clinical data were analyzed with SPSS version 11.5 under the Window 98 operating system. Categorical variables were compared by a χ^2 test or Fisher's exact test. Continuous variables were compared by the Mann-Whitney *U* test. Survival rates were calculated by the Kaplan-Meier method, and differences in survival were analyzed by the log rank test. *P* value < 0.05 was considered statistically significant. The primary outcome measurement was overall survival and the secondary outcome measurement was disease-free survival. Immediate postoperative performance was also analyzed.

RESULTS

In the combination group, 17 men and 2 women, the median age was 65 years (range, 34-77 years). The median tumor number was 3 (range, 2-9) and the median tumor size was 6 cm (range, 1.2-14 cm). In the resection group, 43 men and 11 women, the median age was 51.5 years (range, 27-80 years, $P = 0.003$). The median tumor number was 3 (range, 2-9, $P = 0.574$) and the median tumor size was 6 cm (range, 1-14 cm, $P = 0.782$). The two groups were similar in characteristics of tumors and comorbidities, and had comparable results in preoperative liver function tests on serum bilirubin, serum albumin, prothrombin time, platelet count and ICG clearance. All patients in the two groups had Child-Pugh class A status (Table 2). Bilobar involvement occurred in 14 patients (73.6%) in the combination group and 3 patients (5.5%) in the resection group ($P = 0.04$).

Six patients (32%) in the combination group and 35 patients (65%) in the resection group received major hepatectomy. Thirteen patients (68%) in the combination group and 19 patients (35%) in the resection group received minor hepatectomy ($P = 0.012$). The types of resection performed are listed in Table 3. In the combination group, 5 patients had small tumor but received a large volume of resection for clearance, and 5 patients had tumors located close to major vessel, bile duct, or junction of hepatic veins. A total of 31 tumors were ablated, and the median size of the tumors was 1 cm (range, 1-3.8 cm). Ten patients had 1 tumor ablated, 6 patients 2, and 3 patients 3. Biopsies of the ablation sites were

Table 3 Types of resection performed according to Brisbane terminology (2005) of liver resection *n* (%)

	Combination group (*n* = 19)	Resection group (*n* = 54)
Right hepatectomy	1 (5.3)	17 (31.5)
Extended right hepatectomy	0 (0)	6 (11.1)
Right trisectionectomy	0 (0)	2 (3.7)
Left hepatectomy	3 (15.8)	3 (5.6)
Extended left hepatectomy	2 (10.5)	4 (7.4)
Left trisectionectomy	0 (0)	3 (5.6)
Left lateral sectionectomy	3 (15.8)	1 (1.9)
Segmentectomy	1 (5.3)	11 (20.4)
Wedge resection of liver	9 (47.4)	7 (13)

taken and all proven to be positive for HCC. The ablated sites were monitored with CT scan with contrast at one month, and no incomplete ablation was noted.

The combination group demonstrated certain advantages over the resection group in terms of surgical outcomes: the former had median blood loss of 400 mL (range, 20-1650 mL) whereas the latter had 657 mL (range, 50-3750 mL) (P = 0.007), the former had median operation time of 270 min (range, 150-465 min) whereas the latter had 400 min (range, 165-773 min) (P = 0.001), and the former had median hospital stay of 7 d (range, 1-20 d) and the latter had 8.5 d (range, 4-69 d) (P = 0.042). There was no difference in overall complications (15.8% *vs* 31.5%, P = 0.241) and hospital mortality (5.3% *vs* 5.6%, P = 1) between the two groups. Only one patient from the resection group needed blood transfusion. The median serum bilirubin level at day 1 was 21 μmol/L (range, 10-37 μmol/L) in the combination group and 25 μmol/L (range, 9-110 μmol/L) in the resection group (P = 0.012). The median serum albumin level at day 1 was 31.5 g/L (range, 10-37 g/L) in the combination group and 32 g/L (range, 17-39 g/L) in the resection group (P = 0.215). The median serum bilirubin level at day 7 was 18 μmol/L (range, 11-27 μmol/L) in the combination group and 21 μmol/L (range, 3-190 μmol/L) in the resection group (P = 0.075). The median serum albumin level at day 7 was 30 g/L (range, 24-39 g/L) in the combination group and 32 g/L (range, 26-41 g/L) in the resection group (P = 0.036).

Histopathology

With regard to the pathology of tumors, the combination group and the resection group shared similar characteristics. Margin involvement happened on none of the patients in the former group while on 4 patients (7.4%) in the latter (P = 0.567). Vascular permeation happened on 7 patients (36.8%) in the former group and 31 patients (57.4%) in the latter (P = 0.123). Microsatellite lesions appeared in 3 patients (15.8%) of the former group and 14 patients (25.9%) of the latter (P = 0.53). Poorly differentiated cell types by Edmondson classification appeared in 2 patients (10.5%) of the former group and 8 patients (14.8%) of the latter (P = 0.857). There was no statistical difference in histopathology between the two groups (Table 4).

Table 4 Histopathological results of tumors *n* (%)

	Combination group (*n* = 19)	Resection group (*n* = 54)	*P* value
Margin involvement	0 (0)	4 (7.4)	0.567

HCC: Hepatocellular carcinoma.

Recurrence

Twelve patients (63.2%) in the combination group were found developing recurrence at the end of the study. Intrahepatic recurrence occurred in 8 patients (42.1%), and among them 4 patients (20.5%) had ablation site local recurrence, which happened at a median time of 3.6 mo (range, 3-24 mo). Extrahepatic recurrence occurred in 1 patient (5.3%) and intrahepatic and extrahepatic recurrence in 3 (15.8%). In the resection group, 27 patients (50%) were found developing recurrence. Among them, 15 patients (27.8%) had intrahepatic recurrence, 4 patients (7.4%) extrahepatic recurrence, and 8 patients (14.8%) intrahepatic and extrahepatic recurrence (P = 0.673).

Survival

The median follow-up period was 18.4 mo for the entire study period, 21 mo (range, 0.03-53 mo) for the combination group and 15.1 mo (range, 0.37-68.4 mo) for the resection group. No patient was lost to follow-up. The rates of overall survival at 1 year and 3 years were 88.8% and 62.6%, respectively for the former group (median 53 mo), and 88.9% and 51.8%, respectively for the latter (median 44.5 mo) (P = 0.496) (Figure 1A). The median disease-free survival of the former was 8.8 mo and that of the latter was 9.8 mo (P = 0.64) (Figure 1B). The two groups showed no statistically significant differences in survival.

DISCUSSION

A variety of treatment options are available for HCC. Liver transplantation offers good hope of cure to HCC patients, even those with poor liver function. However, donated livers are scarce, and patients having tumors exceeding the size limit for liver transplant or having low score in Model for End-stage Liver Disease are not suitable for transplantation. So, the first-line option is still, if technically feasible, hepatectomy[1,4,23,24]. Hepatectomy with clear margin can provide long postoperative survival to patients. Unfortunately, poor liver function poses extra challenge to hepatectomy because hepatectomy will diminish the already limited liver function reserve, thus risking liver failure. In Southeast Asia including Hong Kong, HCC patients usually have poor liver function because their HCC often coexists with hepatitis B cirrhosis.

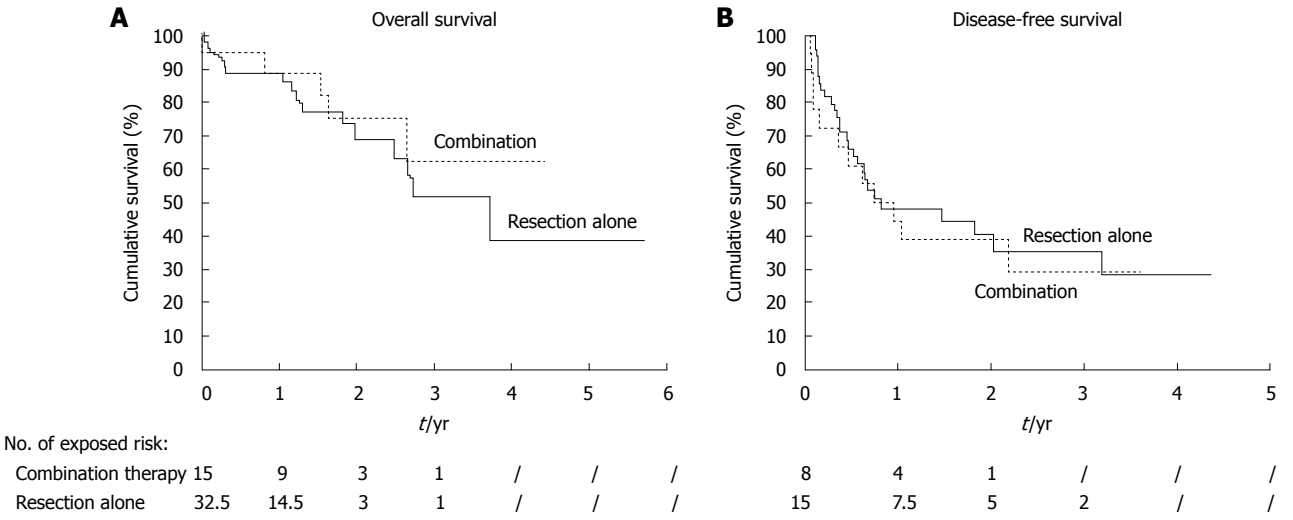

Figure 1 Survival curves showing overall survival and disease-free survival of the two groups of patients. A: Overall survival of patients; B: Disease-free survival of patients.

Striking a balance between achieving adequate resection and preventing liver failure is not easy at all. In patients with multifocal HCC, equilibrium between complete tumor clearance and minimal hepatectomy volume is even more difficult to grasp. Multiple partial resections, on the one hand, can achieve complete tumor clearance but, on the other hand, carry a higher risk of liver failure with doubtful long-term oncological outcomes.

RFA is another treatment option for HCC. Several clinical trials showed that RFA was as effective as hepatectomy for HCC smaller than 5 cm with a morbidity rate of less than 15%[22,25,26]. Hence, RFA has been gaining recognition in treating liver cancer including advanced HCC. Nonetheless, the efficacy of RFA on larger HCC is still questionable. In a study using a porcine model, RFA of 30%-35% of liver and hepatectomy of the same volume were compared, and it was found that the former resulted in significantly adverse systemic inflammatory response syndrome[27-29]. Hoshida *et al*[30] showed in another study that large parenchymal RFA volume was an independent poor prognostic factor for HCC patients. With recent advances in the design of radiofrequency electrodes and refinements of ablation techniques, favorable outcomes of RFA treatment on large tumors have been reported. However, extra caution should always be taken in treating large tumors with RFA since ablation of large tumors is associated with a high incidence of local recurrence, and the large amount of necrotic tissue left behind can cause serious problems for the patients. To ensure better outcome of RFA, careful patient selection, meticulous techniques and close monitoring of hepatic and renal functions after the procedure are essential.

Combined employment of hepatectomy and RFA for metastatic liver cancer has been documented. This combination of treatments can improve the tumor resectability rate for patients having multiple tumors. In this comparatively novel treatment, large tumors are resected and smaller ones at difficult locations are ablated. Currently, data on its performance in the management of HCC are very limited[14-16,22,25,26,31]. In our present study, the surgical outcomes of the combined treatment of hepatectomy and RFA on patients with multifocal HCC were investigated, and it was shown that patients having bilobar HCC could be treated safely with it. In the study, considerably less major hepatectomies were performed for the combination group, yet complete tumor clearance was still achieved. This is of crucial importance as hepatectomy in a lesser extent means better preservation of liver reserve, less liver failure, and quicker recovery[32,33].

For managing multifocal HCC, one may argue that multiple anatomical resections can achieve similar results as the combination approach. But in our study, we found that there are situations in which the combination approach is easier, if not better, than resection alone. First of all, if a tumor is small but requires a large resection volume for tumor clearance, RFA comes in as a safer option in terms of liver function preservation. Secondly, if a tumor is close to an important anatomical structure such as major vessels or bile ducts, RFA together with bile duct cooling can offer complete tumor clearance, obviating major hepatectomy. Thirdly, in the case of reoperation at a site where there is dense adhesion, RFA is a less traumatic treatment option, as mobilization for resection may lead to bleeding problem, especially in patients with thrombocytopenia and coagulopathy.

In this study, the median age of the combination group was 65 years, which was 13 years older than the 52-year median of the resection group. Choice of treatment was up to individual surgeons. It turned out that more elderly patients received the combined treatment. This was probably because the combined treatment would require less operation time and induce seemingly less surgical trauma. The resultant shorter operation time, less blood loss and shorter hospital stay have vindicated the postulation.

An ablation rate of 100% was achieved as confirmed by CT scan of the abdomen performed one month after

RFA treatment. The two groups displayed similar recurrence patterns. A margin of 1 cm was sought in all resections and ablations since a 1-cm margin is usually effective in preventing microscopic involvement by the major tumor. However, a clear margin alone is not enough for preventing tumor recurrence, as apart from margin involvement, there are other factors affecting recurrence such as poorly differentiated cell type, lymphovascular permeation, and microsatellite lesion, among which the latter two are the most significant independent risk factors. Unfortunately, we cannot alter these factors even by providing generous margins[24].

The combination group had more bilobar cases than the resection group (73.6% *vs* 7.4%). Theoretically, patients with stage IVa HCC would fare worse[34,35]. The predominance of bilobar disease in the combination group also explains why the group had more, though not significantly, intrahepatic and extrahepatic recurrences. A more advanced stage of HCC probably entails a poorer prognosis in general. Sub-group analysis of overall survival of these patients in the two groups was performed, and the median survival was 53 mo in the combination group and 44.5 mo in the resection group ($P = 0.496$). No significant difference was noted because of the small sample number in the resection group ($n = 3$). In our hospital, the median survival of patients having stage IVa HCC is 10 mo if they undergo no treatment. In the past, bilobar liver disease was considered a contraindication to hepatectomy, but with new tools and techniques, the whole concept of resectability is changing. Liu *et al*[36] pointed out that resection offered better survival outcomes than non-resectional treatments did to HCC patients with stage IVa bilobar disease. For this category of patients, resection in combination with RFA is an attractive choice of treatment. As to survival in our present study, the combination group and the resection group displayed comparable rates of overall survival and disease-free survival.

This study has clearly shown that when complete resection by major hepatectomy is dangerous because of marginal liver function or difficult tumor location, selective use of RFA is helpful. The integration of RFA into resectional surgery contributes to complete removal of tumors with adequate margin, diminishes the extent of parenchymal resection, and improves the resectability rate for patients with stage IVa liver disease. Safe and quick, it is especially handy when unexpected tumor is discovered during laparotomy, allowing complete tumor clearance in an unplanned situation during surgical operation without altering the original plan of treatment procedure too much; this is particularly important to patients having marginal hepatic function.

Fresh hope emerges as tumors previously considered unresectable due to multifocal involvement or poor liver function reserve can now be removed by the combined treatment, a new option in treating HCC. At present, a randomized controlled trial comparing it with surgical resection alone in patients with multifocal HCC is much desirable.

COMMENTS

Background

Management of hepatocellular carcinoma (HCC) in patients with cirrhosis is always a great challenge for clinicians. Prognosis of these patients is poor because many of their tumors are unresectable (with a resectability rate of 20%-37% only). Although resection is regarded as the gold-standard treatment for HCC, it is not applicable to cases with unfavorable anatomical location, major vessel involvement, multifocal involvement, distant metastasis, or poor liver function. On the other hand, radiofrequency ablation (RFA) is a treatment which has been gaining more and more recognition in the management of liver diseases including HCC. Both resection and RFA are good treatment options for HCC. However, they have their own limitations. Resection is hampered by patient's liver function as well as the location of tumor, whilst RFA is limited to smaller tumors only. In reality, only around one-fourth of HCC patients are amenable to surgical intervention, and in this sub-group, around one-fourth develop multiple tumors on presentation. There is no doubt that the combination of resection and RFA can subject more patients to potentially curative surgical intervention. The present study compared the combined treatment of resection and RFA with the treatment of sole resection and investigated the surgical outcomes of the combined treatment in patients with multifocal HCC.

Research frontiers

There is no detailed report on the combined use of resection and RFA in the management of HCC. However, this is an important topic as treating HCC with RFA is getting popular, and combining RFA with resection can definitely extend the operability of surgical intervention to patients with multifocal HCC.

Innovations and breakthroughs

In the management of multifocal HCC, one may argue that multiple resections can achieve what the combined treatment achieves, and thus there is no need to call in RFA. However, in the present study, it has been found that in some situations the combined treatment is easier than resection alone. First of all, since RFA is less traumatic and hence better for liver function preservation, it is preferable to resection when the tumor is small but still requires a large volume of resection for tumor clearance. Secondly, when the tumor is close to an important anatomical structure such as major vessel or bile duct, RFA together with bile duct cooling can achieve complete tumor clearance with lower risk. Thirdly, if dense adhesion is encountered, which is not uncommon in re-operation, RFA is safer as mobilization of the liver for resection may lead to bleeding problem especially in patients with thrombocytopenia and coagulopathy.

Applications

This study has clearly shown that when complete resection by major hepatectomy is dangerous because of marginal liver function or difficult tumor location, selective use of RFA provides the benefit of increased tumor resectability. The integration of RFA into resectional surgery contributes to complete removal of tumors with adequate margin, diminishes the extent of parenchymal resection, and improves the resectability rate for patients with stage IVa liver disease. Being safe and quick, it is especially handy when unexpected tumor is encountered during laparotomy, allowing achievement of complete tumor clearance in an unplanned situation during surgical operation without altering the original plan of treatment procedure too much; this is particularly important to patients with marginal liver function.

Terminology

RFA is a locoregional treatment. RFA treats tumors by inducing coagulative necrosis of the target lesion. During RFA, heat energy generated by high-frequency alternating currents (460-480 kHz) targeted at the lesion through ionic vibration causes protein denature at a temperature of 60℃, which causes coagulative necrosis of tissues.

Peer review

The Hong Kong group describes their experience with surgical treatment of HCC by performing a retrospective analysis of resected-only patients versus resected + RFA patients with HCC. This is important data to present and very clinically relevant as centers all over the world are taking care of rising numbers of patients with HCC.

Abstract

AIM: To demonstrate the optimal surgical procedure for gastroesophageal reflux disease.

METHODS: The electronic databases of Medline, Elsevier, Springerlink and Embase over the last 16 years were searched. All clinical trials involved in the outcomes of laparoscopic Nissen fundoplication (LNF) and laparoscopic Toupet fundoplication (LTF) were identified. The data of assessment in benefits and adverse results of LNF and LTF were extracted and compared using meta-analysis.

RESULTS: We ultimately identified a total of 32 references reporting nine randomized controlled trials, eight prospective cohort trials and 15 retrospective trials. These studies reported a total of 6236 patients, of whom 4252 (68.18%) underwent LNF and 1984 (31.82%) underwent LTF. There were no differences between LNF and LTF in patients' satisfaction, perioperative complications, postoperative heartburn, reflux recurrence and re-operation. Both LNF and LTF enhanced the function of lower esophageal sphincter and improved esophagitis. The postoperative dysphagia, gas-bloating syndrome, inability to belch and the need for dilatation after LNF were more common than after LTF. Subgroup analyses showed that dysphagia after LNF and LTF was similar in patients with normal esophageal peristalsis (EP), but occurred more frequently in patients with weak EP after LNF than after LTF. Furthermore, patients with normal EP after LNF still had a higher risk of developing dysphagia than did patients with abnormal EP after LTF.

CONCLUSION: Compared with LNF, LTF offers equivalent symptom relief and reduces adverse results.

INTRODUCTION

Gastroesophageal reflux disease (GERD) is a chronic acid-peptic disorder characterized by the spontaneous and involuntary retrograde flow of stomach contents into esophagus mainly due to functional defect of the lower esophageal sphincter (LES)[1]. Acid reflux into the esophagus may cause esophagitis, tracheobronchitis,

stricture, Barrett's esophagus and even esophageal cancer, all of which affect a sizeable portion of patients, particularly in the USA and Europe[2-5]. Symptomatic GERD has fundamental effects on the quality-of-life (QOL) of patients. However, the complex pathophysiology of GERD[4] and limitation of the medicine[6] always make it extremely difficult to get a satisfactory efficacy under individual anti-acid medication in the long term.

Surgery is discussed as a very effective treatment for GERD which imparts a mechanical solution[6]. Surgical treatment was initially introduced by Rudolph Nissen[7] in 1956 and subsequently was developed as a safe and effective procedure by Dallemagne in 1991 through a minimal invasive approach[8]. Laparoscopic fundoplication has been established as the "gold standard" in the surgical treatment for GERD because of its immense success. There are two major anti-reflux procedures: 360º total (Nissen) fundoplication and 270º partial (Toupet) fundoplication. The superiority of one over the other is a matter of debate. The supporters of partial fundoplication argue that partial and total wrap construction offer equally effective forms of therapy for GERD[9-11]. To avoid the major postoperative complication, dysphagia, preoperative esophageal motility should be considered, and partial funduplication has the advantage of reducing this complication[12,13]. The proponents of total fundoplication propose that: (1) the 270º wrap provides a weaker anti-reflux barrier, and is therefore insufficient for reflux control[14,15]; (2) the prevalence of postoperative dysphagia after Nissen fundoplication is overestimated; and (3) motility disorders are not correlated with postoperative dysphagia[16], suggesting that the so-called "tailored procedure" should be abandoned[17,18]. Many crucial issues related to the mechanism of GERD, such as whether esophageal dysmotility is a consequence of GERD or just another component (along with LES dysfunction) of a complex foregut motor disease, have not been elucidated[19,20], so the controversy regarding the optimal surgical technique continues[21,22].

Meta-analysis is a powerful tool with an attempt to overcome the problem of reduced statistical power in studies with small sample sizes and to control variations between studies. The goal of surgical treatment for GERD is to provide optimal reflux control while minimizing adverse results. We focused this current systemic review on comparing which procedure was more effective in improving the QOL of patients while producing less adverse results. We attempted to depict a more comprehensive picture of the feature of laparoscopic anti-reflux operation, thus offering guidance for clinical practice.

MATERIALS AND METHODS

Search strategy

The electronic databases of Medline, ScienceDirect (Elsevier), Springerlink and Embase over the last 16 years from January 1994 to November 2009 were searched by two authors (Shan CX and Zhang W) to identify all clinical trials comparing laparoscopic Nissen fundoplication (LNF) with laparoscopic Toupet fundoplication (LTF). A search strategy using disease-specific search terms (e.g. gastroesophageal reflux disease), management-specific terms (e.g. laparoscopic anti-reflux fundoplication) and terms related to surgical procedures (e.g. Nissen, Toupet, partial and total) was adopted. All photocopied abstracts and citations were reviewed. The related articles were used to broaden the searching scope, and references of the articles acquired were also searched.

Selection criteria

Abstracts or full-text articles were initially screened, and then selected or rejected by the two reviewers (Shan CX and Zhang W) on the basis of the inclusion and exclusion criteria described below. A flow chart representing selection of clinical trials is shown in Figure 1.

Inclusion criteria: (1) Comparative clinical trials, including randomized and non-randomized controlled trials, involved in the efficacy and adverse results of different types of laparoscopic anti-reflux surgery (LARS); and (2) The exact data of dichotomous-type information and continuous-type information as well as standard deviation should be provided so as to integrate each single weight in each study.

Exclusion criteria: (1) Comparative trials between total and non-posterior partial fundoplication (e.g. total *vs* anterior partial fundoplication); (2) Fundoplications were carried out with laparotomy; (3) Trials involving children or patients younger than 16 years; and (4) Studies published repeatedly by different journals.

Data extraction

The two reviewers independently extracted details from selected studies which comprised (1) information and quality of the research: first author, year of publication, comparative design, sample capacity, follow-up duration; and (2) outcome analysis, including beneficial and adverse results. The specific rules of data extraction were listed below.

First, the assessment data of repeated trials published in different journals at different phases was extracted based on the latest article. For example, the results in the studies of Strate *et al*[16], Fibbe *et al*[23] and Zornig *et al*[24] were highly homologous, containing identical study objects and design protocol. Thus, the source of data extraction was focused on the latest citation of Zornig *et al*[24].

Second, the assessment data of trials containing multiple groups were initially divided into single groups, and then extracted individually. For example, the research of Mickevicius *et al*[22] included two subgroups of LARS with a 1.5-cm wrap fundoplication and 3.0-cm wrap. We split it into two independent trials according to the wrap length.

And third, the evaluation indices of surgical efficacy and incidence of postoperative morbidities were subject to the final updates based on long-term follow-up results. For example, Chrysos *et al*[25] reported the 3- and 12-mo incidences of postoperative dysphagia in their

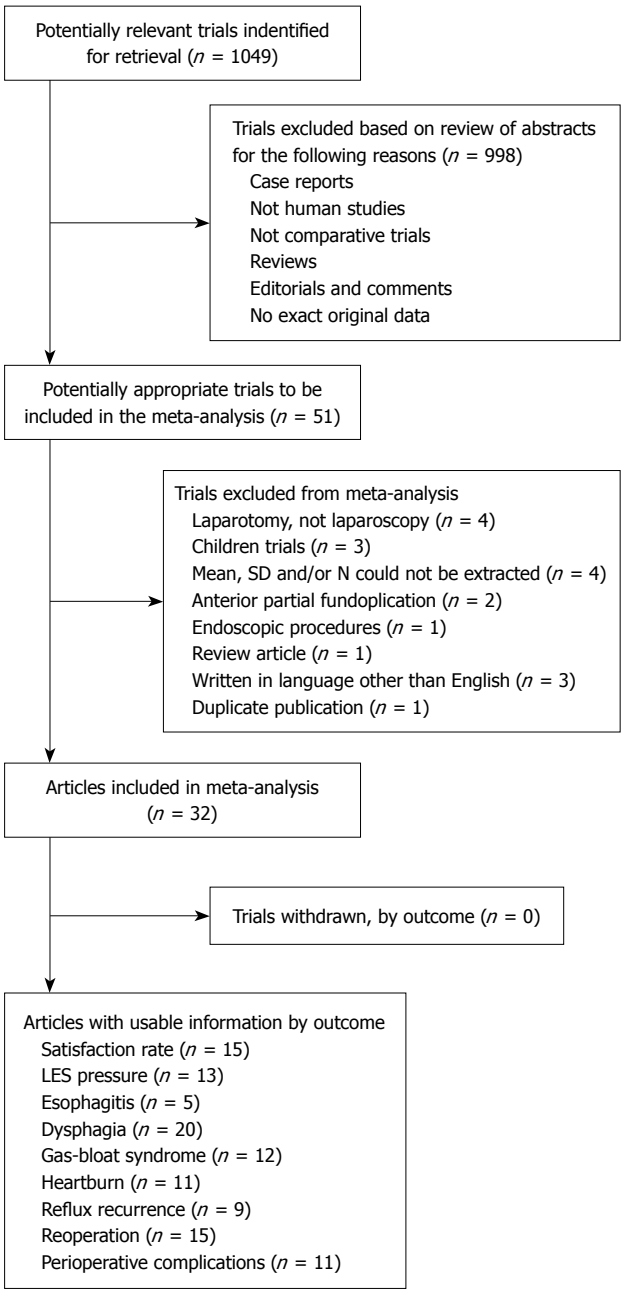

Figure 1 A flow chart showing the progress of trials through the review. LES: Lower esophageal sphincter.

article. We ultimately extracted the information on the 12-mo incidence of dysphagia after LARS and integrated it into the total meta-analysis.

Statistical analysis

All individual outcomes were integrated with the meta-analysis software: Review Manager Software 5.0 (Cochrane Collaborative, Oxford, England). Results were analyzed with the random-effect method if significant heterogeneity ($P < 0.05$ was used to define statistically significant heterogeneity) was detected among studies. Otherwise, a fixed-effect model was adopted. The odds ratio (OR) and the weighted mean difference were calculated for dichotomous data and continuous data, respectively. In addition, subgroup analyses were done to estimate if the results of postoperative dysphagia would change after LARS with respect to preoperative esophageal motility (EM). Thus, three subgroups were established. Subgroup 1: all patients underwent LNF or LTF and had normal esophageal peristalsis (EP); subgroup 2: all patients underwent LNF or LTF and had abnormal EP; and subgroup 3: LNF for patients with normal EP *vs* LTF for patients with abnormal EP.

RESULTS

Identification and characteristics of studies and patients

We ultimately identified 32 references reporting 29 independent controlled studies published between January 1994 and November 2009. Nine randomized controlled trials[10,16,21-27], eight prospective cohort trials[11,17,28-33] and 15 retrospective trials[9,12,20,33-45] met the selection criteria reporting 6236 patients, of whom 4252 (68.18%) underwent LNF and 1984 (31.82%) underwent LTF. Twenty studies provided the sex and 11 trials provided the age of included patients. The percentage of males varied from 39.39% to 70.13% in the LNF group, and from 39.53% to 66.67% in the LTF group. The mean age ranged from 45.2 to 59.2 years in the LNF group and from 44.2 to 61.7 years in the LTF group. The details of these studies are shown in Table 1.

Subjective assessment: Satisfaction rate

Fifteen studies assessed patient satisfaction as the major efficacy of LARS. In addition, patient satisfaction with the outcome of surgery was always expressed by Visick scores evaluating QOL. After follow-up, each single research suggested that > 90% patients were satisfied with postoperative outcomes after LNF or LTF, and 91.78% (1674/1824) of patients in the LNF group and 91.33% (938/1027) in the LTF group reported excellent or good results after LARS. There was no statistically significant difference between the two groups (OR 0.96, 95% CI: 0.72-1.28, $P = 0.77$).

Objective evaluation

LES pressure: The change in LES pressure after LARS was investigated in 13 trials. The mean preoperative LES pressure was 3.1-12.8 mmHg in the LNF group, and about 2.3-13.6 mmHg in the LTF group, and increased significantly to 10.3-26 mmHg after LNF and 11-18 mmHg after LTF, respectively. Moreover, 360° total fundoplication could form a relatively stronger anti-reflux barrier than 270° partial funduplication because the amplitude of LES pressure increase was significantly higher after LNF than after LTF (OR 2.76, 95% CI: 1.57-3.95, $P < 0.05$).

Esophagitis: Five authors outlined the improvement of preoperative esophagitis after LARS by endoscopy. Esophagitis severity was graded according to the Savary-Miller classification in most studies. Remission of moderate-to-severe esophagitis was observed by endoscopic re-examination after anti-reflux procedures; there was a reduction in case number from 87/210 to 12/191 in the

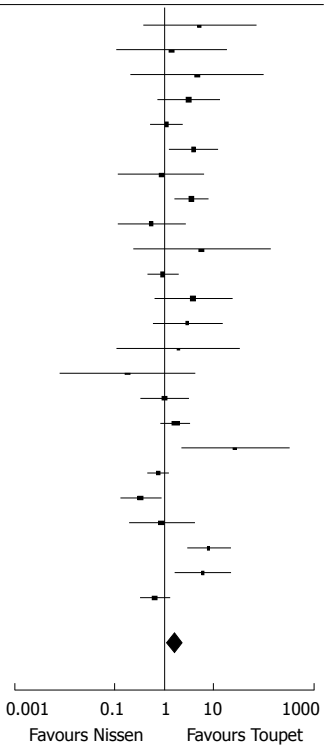
LNF: Laparoscopic Nissen fundoplication; LTF: Laparoscopic Toupet fundoplication; PF: Circumferential degrees of the partial wrap; Subg.: Subgroup; EM: Esophageal motility; RCT: Randomized controlled trial; PCT: Prospective controlled trial; RT: Retrospective trial.

Nissen group, and from 99/218 to 17/197 in the LTF group. There was no significant difference in remission rate between the two groups (6.28% *vs* 8.63%, OR 0.72, 95% CI: 0.59-1.33, $P = 0.42$).

Adverse results: Perioperative complications

Eleven studies reported the surgical complications in 1622 patients with LNF and 836 patients with LTF. Both techniques entailed a low (but definite) risk of surgical morbidity which occurred in 1.30%[26]-14.28%[25] of the population after Nissen fundoplication and in 2.46%[9]-15.63%[12] of the population after Toupet fundoplication. Lacerations of the gastric fundus and spleen, bleeding from the spleen or short gastric blood vessels and pneumothorax were the main disease categories. However, surgical mortality was also a natural sporadic event. Only two patients died: one on the 15th day after LNF due to secondary peritonitis from necrosis of the wrap[40], and the other died of esophageal perforation and mediastinitis[22]. The cumulative prevalence of perioperative complications after LNF and LTF was 4.01% and 5.14%, respectively, with no significant difference between the groups (4.01% *vs* 5.14%, OR 0.73, 95% CI: 0.47-1.12, $P = 0.15$).

Postoperative symptoms



Dysphagia and need for bougie dilatation: Twenty-four studies assessed the outcome of dysphagia after LARS. Various questionnaires were used to define dysphagia severity, ranging from no symptoms to very severe episodes at the end of follow-up. The overall prevalence of dysphagia after LNF was significantly higher than after LTF (14.29% *vs* 11.00%, OR 1.68, 95% CI: 1.12-2.52, $P = 0.01$) (Figure 2A). A similar result was also obtained if only patients with moderate-to-severe dysphagia were included (12.30% *vs* 2.74%, OR 3.11, 95% CI: 1.94-5.00, $P < 0.01$). For patients with severe symptoms needing bougie dilatation, prevalence was still significantly higher after LNF than after LTF (7.91% *vs* 1.44%, OR 3.67, 95% CI: 1.90-7.09, $P < 0.01$). We thought it necessary to carry out subgroup analyses because preoperative EM was an important variable in the choice of surgical procedure and may have an effect on the analyses. Defining esophageal dysmotility was not consistent in the surgical literature. Most surgeons would agree that a distal esophageal amplitude > 40 mmHg and peristaltic contraction of the esophageal body of at least 70% indicate normal motility[18]. As described above, subgroup 1 analysis showed that the surgical procedure had no effect on the occurrence of

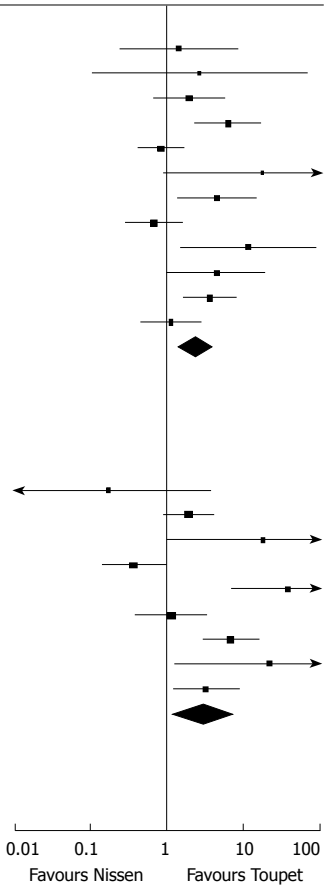

Figure 2 Pooled analysis using the Mantel-Haenszel method and a random-effect model. A: Overall rates of dysphagia after laparoscopic Nissen fundoplication (LNF) and laparoscopic Toupet fundoplication (LTF); B: Subgroup dysphagia depending on preoperative esophageal motility after LNF and LTF; C: Postoperative gas bloating and inability to belch after LNF and LTF.

postoperative dysphagia if preoperative EM was normal (*P* = 0.89). However, in subgroup 2, patients with abnormal EP, the prevalence of dysphagia after LNF was still more common than after LTF (*P* = 0.04). In subgroup 3, even though the surgical choice was in accordance with the so-called "tailored procedure", LNF also led to a significantly higher risk of developing postoperative dysphgia than LTF (*P* = 0.03) (Figure 2B).

Gas-bloat syndrome or gas-related symptoms: Gas-related symptoms ("gas-bloat syndrome") were described in 12 studies involving > 1200 patients. Gas-bloat syndrome included gas bloating, inability to belch, flatulence, postprandial fullness, and epigastric pain. The main objective evaluation of gas-related symptoms was done using a verbal rating scale using the items mentioned above. Overall, 47.39% (327/690) of patients after LNF and 26.09% (138/529) of patients after LTF suffered from gas bloating, whereas 37.22% (220/591) after LNF and 22.24% (109/490) after LTF were unable to belch. Gas bloating and inability to belch were more common in the LNF group and a significant difference between LNF and LTF was also further confirmed to reach a significant level (Figure 2C).

Recurrence and re-operation

Heartburn and reflux recurrence: Eleven studies investigated the incidence of postoperative heartburn (considered to be the cardinal symptom of GERD recurrence). Heartburn occurred in 6.45%[26]-60.29%[43] of the population after LNF, and in 5.26%[25]-55.10%[43] after LTF. No statistically significant difference was found between LNF and LTF concerning the cumulative prevalence of heartburn (32.97%, 331/1004 *vs* 31.09%, 157/505, OR 0.83, 95% CI: 0.52-1.33, *P* = 0.45, respectively).

Nine studies reported the postoperative recurrence of GERD. However, the standard of GERD recurrence was not uniform because some were judged according to symptoms such as reflux, chest pain, and heartburn, whereas others were based on the endoscopic characteristics and 24-h gastric monitoring of pH (e.g. persistent esophagitis, DeMeester score[46]). In our analysis, the cumulative prevalence of reflux recurrence was slightly higher after LTF than after LNF, but this difference was not significant (6.50%, 64/985 *vs* 9.42%, 84/892, OR 0.73, 95% CI: 0.35-1.53, *P* = 0.40).

Re-operation: Re-operation prevalence was described in 15 trials involving > 3800 patients. The main causes

of re-operation were persistent dysphagia, severe reflux symptoms, hiatus hernia recurrence, and other severe treatment failures. Although the re-operation rate after LNF was slightly higher than after Toupet fundoplication, 4.40% (115/2616) *vs* 3.68% (47/1276), the difference was not significant (OR 1.29, 95% CI: 0.73-2.29, $P = 0.38$). The morbidity associated with re-operation after LNF for GERD ranged from 1.56%[21] to 27.27%[41], and in the LTF group the rates varied from 1.00%[28] to 17.5%[22].

DISCUSSION

Lower morbidity and mortality, shorter hospitalization and faster convalescence made LARS so attractive to patients with GERD. Since Nissen procedure was first reported a decade ago, it has been adopted as a tremendously successful procedure for reflux control, and it is therefore more often performed than partial fundoplication. However, numerous recent researches witnessed a strong debate between Nissen and Toupet fundoplications[47], shifting the attention to postoperative failures due to mechanical problems (e.g. dysphagia), rather than worries about the recurrence of disease.

Our analysis is a comprehensive and detailed systematic literature review of 32 articles reporting the surgical outcomes of 6236 patients with GERD after LNF and LTF. It demonstrated that the latter is advantageous over the former, showing similar outcomes of satisfaction rate, endoscopic improvement, perioperative complication occurrence, reflux recurrence and re-operation, but a substantially reduced prevalence of postoperative symptoms (e.g. dysphagia, gas-bloat syndrome).

Patient satisfaction is a reasonable and accurate index for assessing the efficacy of surgical treatment for GERD[11,47]. In our meta-analysis, > 90% of the study populations reported excellent or good results in the LNF and LTF groups. Bearing in mind that the subjective description of patients was not always in accordance with objective findings[48], we further analyzed the alteration of LES pressure and remission of esophagitis after construction of a mechanical anti-reflux barrier. Elevating the resting pressure of the LES played a crucial role in controlling reflux symptoms, blocking the natural history of Barrett's esophagus and reducing the risk of malignancy. We also found that LNF and LTF could increase the LES pressure and improve preoperative esophagitis. Even though the amplitude of elevation of LES pressure was significantly lower after LTF than after LNF, it seemed that it remained sufficiently powerful to resist the reflux of gastric contents. These subjective assessments and objective evaluations supported the point of view that LTF can control reflux symptoms for GERD.

The prevalence of perioperative complications showed no significant difference between groups, indicating that neither procedure was more technically difficult or more demanding of surgical skills. However, the prevalence of postoperative dysphagia and gas-related symptoms was much higher after LNF than after LTF. Even though the mechanism of gas-related symptoms is unclear[29], these results suggest that wrap type and alteration in LES pressure were the underlying causes.

Dysphagia was still the complication of greatest concern and presented in three scenarios: acute total dysphagia immediately after surgery; mild dysphagia within the first postoperative 6-8 wk; and persistent chronic dysphagia after the postoperative 6-8 wk[18,49-51]. Some authors thought that dysphagia converges and the difference normalizes within 12 mo[52-55]. This study analyzed the prevalence of chronic dysphagia at the end of follow-up, and the mean duration of follow-up of most included studies was > 12 mo. A subgroup analysis was also executed to incorporate the variable of EM. It seemed that in normal motility patients (subgroup 1), extent of anti-reflux barrier did not affect the possibility of dysphagia. But in patients with abnormal motility (subgroup 2), the higher dysphagia rate after LNF supported that the tailored approach should be preserved. Even using the tailored approach (subgroup 3), the prevalence of dysphagia after LTF was still significantly lower than after LNF. These results indicated that, irrespective of EM status, LTF would be a safer choice in reducing this complication.

Concerns regarding GERD recurrence made surgeons select the Nissen technique rather than the Toupet technique for a long time. The similar prevalence of reflux recurrence between LNF and LTF groups in our analyses appeared to confirm the effectiveness of the Toupet procedure from another viewpoint. However, the value of this index may be slightly inferior. A DeMeester score > 14.7 was a generally accepted criterion, but the standards of GERD recurrence of selected researches were not uniform. Some were judged based on symptoms, some on endoscopic manometry. Furthermore, even though specific pH changes in the gastric environment were related to symptoms to some extent, inconsistency of poor correlation between postoperative reflux symptoms and reflux abnormal DeMeester scores were noted in many instances[27,45,48].

For re-operation, we did not divide subgroups according to causes such as recurrence of reflux or complications. The reason was that they were a miserable experience for the patients and also indicated the failure of primary surgery. The re-operation prevalence between the two groups was comparable. A remarkable phenomenon discovered in some studies[16,23,24] was that a large proportion of patients needing re-operation after LNF possessed a intact wrap during surgery with herniation of the wraps into the mediastinum. Nevertheless, it was rarely detected and presented after LTF. The technical issue of a suture between the posterior wall of the wrap and the two crura of the diaphragm, or a suture between the upper portion of the wrap and the anterior edge of the hiatus, has been proposed to maintain the wrap in an adequate abdominal position and to avoid its rotation and migration.

In conclusion, the results of the present meta-analysis suggested that LTF might be the current procedure of choice to treat GERD. It should be advocated as a more physiologic alternative for Nissen repair, allowing a reduced morbidity rate with similar efficacy in reflux control

and recurrence. The surgical patterns might be a prior factor to preoperative esophageal motility in affecting the postoperative dysphagia after LARS. More multicenter, randomized controlled trials including objective outcome assessment are required to further confirm the value of LNF and LTF.

COMMENTS

Background

The laparoscopic Nissen fundoplication and the laparoscopic Toupet fundoplication are the two major anti-reflux surgical procedures for gastroesophageal reflux disease (GERD). There has been much debate about the superiority of these two techniques.

Research frontiers

A decade ago, Nissen procedure was first reported, then adopted as a tremendous successful procedure for reflux control, and was therefore more often performed than posterior partial fundoplication. However, numerous recent researches witnessed a strong debate about Nissen and Toupet fundoplication, shifting the attention to postoperative failures due to mechanical problems (e.g. dysphagia), rather than worries about the recurrence of disease.

Innovations and breakthroughs

To the best of the authors' knowledge, the present study was the most comprehensive and detailed systematic literature review to demonstrate the optimal surgical procedure for GERD.

Applications

The research showed that laparoscopic Toupet fundoplication might be the current procedure of choice to treat GERD. It should be advocated as a more physiologic alternative for Nissen repair, allowing a reduced morbidity rate with similar efficacy in reflux control and recurrence.

Abstract

AIM: To develop the simple, rapid and sensitive dual-label time-resolved fluoroimmunoassay for pepsinogens in human serum.

METHODS: Based on two-site sandwich protocol, monoclonal antibodies (McAbs) against pepsinogen Ⅰ (PG Ⅰ) and PG Ⅱ were co-coated in 96 microtitration wells, and tracer McAbs against PG Ⅰ and PG Ⅱ were labeled with europium (Eu) and samarium (Sm) chelate, respectively. Diluted serum samples of Eu^{3+}- and Sm^{3+}-McAbs were added into microtitration wells simultaneously. After washing, fluorescence of bound Sm^{3+} and Eu^{3+} tracers was detected.

RESULTS: The detection limit was 0.2 μg/L for PG Ⅰ and 0.05 μg/L for PG Ⅱ. The assay range was 5.0-320.0 μg/L for PG Ⅰ and 1.0-55.0 μg/L for PG Ⅱ. The average recovery rate was 102.7% for PG Ⅰ and 98.8% for PG Ⅱ. Sera from healthy controls and patients with gastric disease were analyzed. The PG detected by dual-label assay was in good agreement with that detected by single-label assay or by enzyme-linked immunosorbent assay.

CONCLUSION: Dual-label assay can provide high-throughput serological screening for gastric diseases.

INTRODUCTION

There is considerable interest in developing methods to simultaneously quantify two or more analyses of one sample in a single assay[1,2], which is advantageous to the confidence level of results, especially in cases when the ratio of compounds gives important information[3,4]. Dual-label has potential applications in various fields such as microbiology, molecular biology, drug analysis, and clinical research. Fluorescence immunoassay, like other immunoassays involving non-isotopic labeling, has been well accepted as a stable, inexpensive, rapid, and sensitive

method. However, conventional fluorescent labeling has a limited success in assay of multiple analytes because of its high background, short decay time and broad spectrum, which make it difficult to be distinguished between its emission bands[5,6]. Up to now, fluorescent lanthanide is a favorable choice owing to its narrow emission peak at different wavelengths. Its lifetime ranges 50-1000 μs (over four decades longer than the average background duration) depending on the temperature and the solvent presented[7]. These features can be utilized for optimization of the measurement conditions to get the maximal sensitivity and to minimize the signal spillover. The europium ion (Eu^{3+}), is the lanthanide mainly used in time-resolved fluoroimmunoassay (TRFIA)[8]. Eu^{3+} and terbium ion (Tb^{3+}) form the most efficient fluorescent chelates, but Tb^{3+} requires fluorinated aliphatic β-diketone for simultaneous detection[9], rather than β-naphthoyltrifluoroacetone (β-NTA) used in the enhancement solution optimized for Eu^{3+} detection. β-NTA is also applicable to samarium ion (Sm^{3+}) excitation, which has thus been suggested that Sm^{3+} can be used as a counterpart to Eu^{3+} with the same enhancement formulation (enhancement solution or DELFIA inducer) in a dual-label system[10].

Human pepsinogens originating from gastric mucosa can be classified into two immunochemically distinct groups: pepsinogen I (PG I) and PG Ⅱ[11], which are mostly secreted into the gastric lumen and nearly 1% of them are leaked into the blood circulation. Serum PG levels reflect the morphological and functional status of gastric mucosa. Human pepsinogens have a diagnostic value for various gastroduodenal disorders, especially for peptic ulcer and atrophic gastritis, which have been widely discussed[12,13]. The PG I /PG Ⅱ ratio can provide even better information on the extent of chronic gastritis than gastric intubation[14].

Since PG I and PG Ⅱ serve as useful predictors in early diagnosis of gastric cancer and in mass screening of populations at a high risk of gastric cancer[15,16], a reliable and sensitive method is needed to detect PG I and PG Ⅱ in human sera. In our previous study[17], a fast and highly sensitive TRFIA was developed to measure serum PG I and PG Ⅱ. The present study was to evaluate the dual-label TRFIA for simultaneous detection of PG I and PG Ⅱ in human serum.

MATERIALS AND METHODS

Chemicals and instruments

Diethylenetriaminepentaacetate (DTPA), bovine serum albumin (BSA), Tris and Triton X-100 were purchased from Sigma (St. Louis, MO, USA). PD-10 column and sepharoseCL-6B column were from the Pharmacia Company (Chalfont St Giles, UK). Q2 anion exchange chromatography, DEAE-52 chromatography, and gel filtration HPLC were purchased from Bio-Rad Company (Hercules, USA). Pure water was produced by Barnstead Equipment (Dubuque, Iowa, USA). Ninety six -well polystyrene microtitre plates were obtained from Nunc International (Roskilde, Denmark). Eu-labeling reagent 1244-302 and Sm-labeling reagent 1244-303, both including N'-[*p*-isothiocyanatobenzyl]-diethylenetriamine-N^1, N^2, N^3, N^4-tetraacetic acid, were purchased from Perkin-Elmer (Waltham, Massachusetts, USA). β-NTA was synthesized in our laboratory. Two counterparts of monoclonal antibodies (McAbs) to human PG I and PG Ⅱ respectively for capture and detection were obtained from Chinese Institute of Cancer with a purity of over 95% (Beijing, China). Enzyme-linked immunosorbent assay (ELISA) kits for detection of PG I and PG Ⅱ were from Biohit Plc(Helsinki, Finland). AutoDELFIA1235, from Perkin-Elmer (Waltham, Massachusetts, USA), was used to measure Eu^{3+} and Sm^{3+} fluorescence in microtiter wells. All other reagents used were of analytical grade.

Reagent solutions

Labeling buffer contained 50 mmol/L Na_2CO_3-$NaHCO_3$ (pH 8.5), and 0.155 mol/L NaCl. Elution buffer contained 50 mmol/L Tris-HC1 (pH 7.8), 0.9% NaC1, and 0.05% NaN_3. Assay buffer contained 50 mmol/L Tris-HCl (pH 7.8), 0.9% NaC1, 0.2% BSA, 0.05% NaN_3, 20 μmol/L DTPA, and 0.1% Tween-20. Washing solution was a Tris-HCl buffered saline solution (pH 7.8) containing 0.9% NaCl, 0.2% Tween-20, and 0.05% NaN_3. Enhancement solution was a 0.1 mol/L acetate-phthalate buffer (pH 3.2) containing 0.1% triton X-100, 15 μmol /L βNTA, and 50 μmol/L tri-*n*-octylphosphine oxide.

Serum samples

Serum samples, collected from healthy volunteers who had no upper abdominal complaints and evidence of gastroduodenal disorder and liver diseases, were stored at -20℃. Blood samples were collected from patients at endoscopic and histological examinations. This study was conducted with the approval of the Ethics Committee of Jiangyuan Hospital Affiliated to Jiangsu Institute of Nuclear Medicine.

Immobilization of McAbs

Five micrograms of the capture McAbs to PG I and PG Ⅱ in 200 μL of 50 mmol of Na_2CO_3-$NaHCO_3$ buffer (pH 9.6) was co-immobilized in each well and incubated overnight at room temperature. After washing, 200 μL of 1 g/L BSA in 50 mmol of Na_2CO_3-$NaHCO_3$ buffer (pH 9.6) was added to block the coated surface for 2 h. After the blocking solution was removed, the plates were dried in a high vacuum, and then stored at -20℃ in a sealed plastic bag with desiccant.

Labeling of McAbs with Eu^{3+}- and Sm^{3+}-chelates

McAbs to human PG I (PG I McAbs) and PG Ⅱ (PG Ⅱ McAbs) were labeled with Sm^{3+}- and Eu^{3+}-chelates, respectively. The buffer for McAbs was replaced with the labeling buffer. Five hundred micrograms of PG I McAbs was gently mixed in 200 μL of labeling buffer with 250 μg of Sm^{3+}-chelates in 100 μL of the same buffer. After an 18-h incubation with continuous gentle shaking at room

temperature, free Sm^{3+}-chelates and aggregated McAbs were separated from Sm^{3+}-McAbs conjugates using a 1 cm × 40 cm column packed with sepharose CL-6B (lower 20 cm), eluted with a descending elution buffer, and collected with 1.0 mL per fraction. The concentration of Sm^{3+}-conjugates in collected fraction was measured with fluorescence, and diluted with an enhancement solution (1:1000). The fluorescence in microtitration wells (200 μL per well) was detected by comparing the signal of samples to that of stock standards diluted at 1:100 in an enhancement solution. The fractions from the first peak with the highest Sm^{3+} count were pooled and characterized. PG Ⅱ McAbs were labeled with Eu. The labeled McAbs were rapidly lyophilized under high vacuum after dilution with an elution buffer containing 0.2% BSA as a stabilizer, and stored at -20℃. No loss of immunoreactivity was observed during a 6-mo storage period.

Purification of PG and calibrators

Surgically resected stomach tissues were free from the invaded part. PG Ⅰ and PG Ⅱ were purified by DEAE-52 chromatography, gel filtration HPLC, and Q2 anion exchange chromatography, as previously described[18]. The purity of PG Ⅰ was over 98% and that of PG Ⅱ was over 95.0%. Calibrators were prepared by diluting them with the assay buffer containing 0, 5, 10, 50, 100, 300 μg/L of highly purified PG Ⅰ and 0, 5, 10, 20, 30, 50 μg/L of highly purified PG Ⅱ, respectively.

Assay procedure

Dual-label TRFIA was performed to detect PG Ⅰ and PG Ⅱ simultaneously in serum with a one-step "sandwich-type" protocol. In brief, 25 μL of calibrators (samples) and 200 μL of 50-fold diluted Eu^{3+} and Sm^{3+} tracer McAbs solution in assay buffer were pipetted into the coated microtitration wells. The plates were incubated with continuous shaking for 2 h at 25℃. After washed 6 times, 200 μL of enhancement solution was added into each well. The plates were shaken for 5 min before fluorescence reading. All procedures were automatically performed by $_{auto}$DELFIA$_{1235}$ with the software designed in our laboratory. Calibration curve was plotted and concentrations in unknown samples were measured using Multicalc software program, where a spline algorithm on logarithmically transformed data was employed. ELISA was performed with a kit following its instructions.

Statistical analysis

Data about PG Ⅰ or PG Ⅱ were expressed as mean ± SD. The limit of detection was defined by the concentration of PG Ⅰ or PG Ⅱ corresponding to the fluorescence of the zero calibrators plus two SD. The average intra- or inter-assay coefficient of variation (CV) was calculated for the precision of the assay. The recovery rate was evaluated by comparing the measured and theoretical values. Regression analysis was used to display the linearity and correlations. Differences in patients with gastric disease and healthy controls were analyzed using paired *t*-test. $P < 0.05$ was considered statistically significant. Analysis of data was performed using SPSS 13.0 (Chicago, IL, USA).

Table 1 Precision of dual-label assay for PG Ⅰ and PG Ⅱ in serum of controls[1]

	PG Ⅰ (μg/L)		PG Ⅱ (μg/L)	
	mean ± SD	CV (%)	mean ± SD	CV (%)
Serum pool 1				
Within-run (n = 10)	43.2 ± 1.36	3.2	5.23 ± 4.62	4.8
Between-run (n = 6)	42.8 ± 2.28	5.1	5.65 ± 6.45	6.7
Serum pool 2				
Within-run (n = 10)	105.0 ± 1.88	2.3	11.7 ± 3.66	3.9
Between-run (n = 6)	103.8 ± 2.73	3.6	10.5 ± 4.55	5.1
Serum pool 3				
Within-run (n = 10)	198.2 ± 5.31	6.3	22.0 ± 3.88	4.6

[1]Served as controls. PG: Pepsinogen; CV: Coefficient of variation.

RESULTS

Kinetics, detection limits and precision

The calibrators covered a range of 10-300 μg/L of PG Ⅰ and 2-50 μg/L of PG Ⅱ. The serum samples from healthy controls and patients with chronic atrophic gastritis and peptic ulcer were incubated for different periods of time (60, 90, 120, 150 min) at different temperatures (25℃, 37℃). Both calibrators and serum samples reached a plateau value around 120 min at 25℃ and around 60 min at 37℃, respectively. In this study, the incubation time was 120 min and the temperature was 25℃ for the assay on $_{auto}$DELFIA$_{1235}$.

The calibration curves of PG Ⅰ and PG Ⅱ were linear over the concentration. The equation was y = 46.4x + 383.2 for the calibration curve of PG Ⅰ and y = 2198.2x + 5189.1 for the calibration curve of PG Ⅱ, where y indicates the response counts (cps), x indicates the concentration (μg/L). With 25 μL of serum samples, the measurement range of PG Ⅰ, ED_{20}, ED_{50}, and ED_{80} was 5.0-320.0, 19.87 ± 4.3, 64.32 ± 6.2, and 176.0 ± 12.9 μg/L, respectively, and the measurement range of PG Ⅱ, ED_{20}, ED_{50}, and ED_{80} was 1.0-55.0, 3.546 ± 2.2, 9.746 ± 4.7, and 23.79 ± 6.3 μg/L, respectively.

The limit of detection was 0.2 μg/L for PG Ⅰ and 0.05 μg/L for PG Ⅱ. The average intra-assay CV of the calibrators was 4.6% for PG Ⅰ and 5.3% for PG Ⅱ. The intra- and inter-assay CV of serum-based controls was summarized in Table 1. The results showed that the assay had a good precision not only for the calibrators but also for the clinical samples.

The cross-reactivity between anti-PG Ⅰ antibody to PG Ⅱ and anti-PG Ⅱ antibody to PG Ⅰ was detected. No interference between them was found. The result showed that the specificity of the assay was good.

Analysis of samples

The correlations between dual-label and single-label assay are shown in Figure 1. The correlation ratio between

Table 2 Serum PG level and PG Ⅰ/PG Ⅱ ratio in healthy controls and patients with duodenal ulcer, gastric ulcer, atrophic gastritis, superficial gastritis and gastric cancer (mean ± SD)

Diagnosis	*n*	Age (yr)	PG Ⅰ (μg/L)	PG Ⅱ (μg/L)	PG Ⅰ/PG Ⅱ ratio
Healthy controls	500	41.5 ± 18.8	150.3 ± 45.1	10.4 ± 8.4	14.5 ± 4.3
Patients with duodenal ulcer	112	43 ± 14.2	252.9 ± 84.5[d]	18.4 ± 16.0[d]	13.7 ± 8.0
Patients with gastric ulcer	44	37 ± 11.2	221.2 ± 91.7[d]	15.6 ± 12.4[b]	14.2 ± 7.1
Patients with atrophic gastritis	21	48 ± 9.7	89.5 ± 51.2[d]	12.9 ± 9.39	6.9 ± 6.2[b]
Patients with superficial gastritis	76	35 ± 7.4	175.3 ± 45.8[a]	12.7 ± 10.1	13.8 ± 5.3
Patients with gastric cancer	126	55 ± 12.2	157.1 ± 81.9	15.6 ± 14.4[b]	13.4 ± 7.8

[a]$P < 0.05$, [b]$P < 0.01$, [d]$P < 0.001$ *vs* healthy controls.

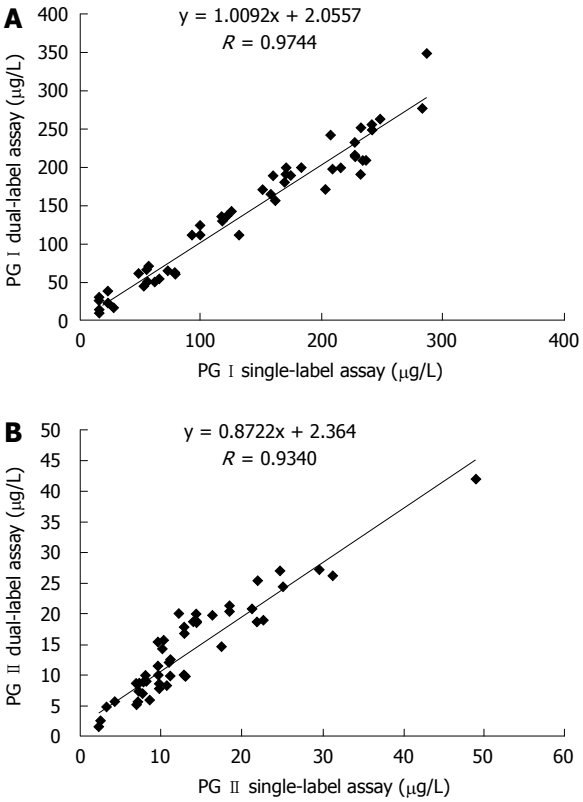

Figure 1 Correlation between single-label and dual-label assay of pepsinogen (PG) Ⅰ (A) and PG Ⅱ (B) in human sera (*n* = 50).

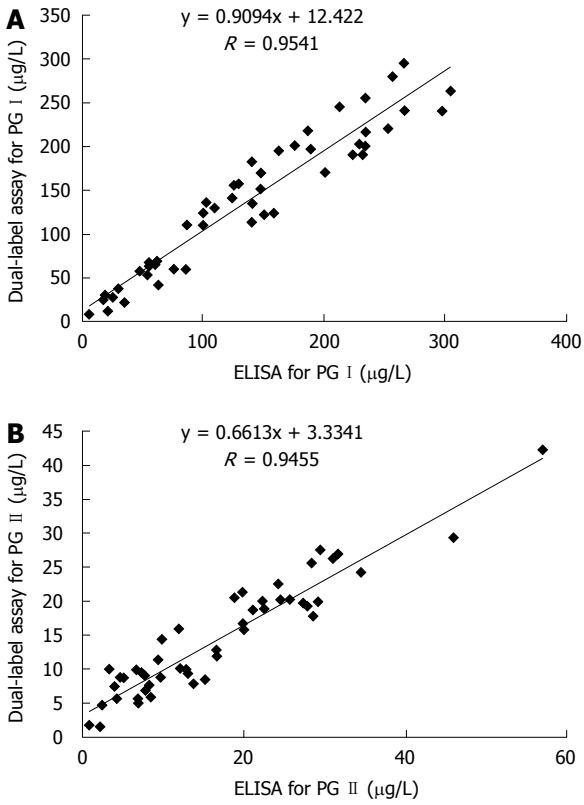

Figure 2 Correlation between enzyme-linked immunosorbent assay (ELISA) and dual-label assay of PG Ⅰ (A) and PG Ⅱ (B) in human sera (*n* = 50).

single-label and dual-label assay for PG Ⅰ and PG Ⅱ was 0.9744 and 0.9340, respectively. The correlations between dual-label assay and ELISA for PG Ⅰ and PG Ⅱ are shown in Figure 2. The correlation ratio between ELISA and dual-label for PG Ⅰ and PG Ⅱ was 0.9541 and 0.94550, respectively. The results indicate that the dual-label assay is in agreement with ELISA or with single-label assay.

The serum samples were analyzed by dual-label assay (Table 2). The normal range of serum PG Ⅰ in healthy controls was 60.1-240.3 μg/L. The range of serum PG Ⅱ was lower than 27.2 μg/L. The cut-off point was 5.9 for the PG Ⅰ/PG Ⅱ ratio.

The serum PG level was lower or higher than its normal range in dyspeptic patients including those with gastric cancer. The distributions of PG Ⅰ and PG Ⅱ value and PG Ⅰ/PG Ⅱ ratio in patients with gastric cancer and in those with duodenal ulcer are shown in Table 3. The difference in PG Ⅰ value was relatively small. The serum PG Ⅰ level was remarkably higher in peptic ulcer patients, especially in those with active duodenal ulcer than in healthy controls. The increased PG Ⅰ level would be a high risk factor for duodenal ulcer, and a remarkably low serum PG Ⅰ level could exclude the diagnosis of peptic ulcer[19].

DISCUSSION

Eu^{3+} chelate is the most commonly used label in time-resolved fluorometry-based analysis because of its higher fluorescence yield and lower background than other lanthanide complexes. Tb^{3+} chelate usually has a longer decay time and a higher fluorescence yield than Sm^{3+} chelate, and their fluorescence is less sensitive to aqueous quench-

Table 3 PG Ⅰ and PG Ⅱ values and PG Ⅰ/PG Ⅱ ratio in patients with gastric carcinoma and duodenal ulcer *n* (%)

	n	PG Ⅰ (μg/L)			PG Ⅱ (μg/L)		PG Ⅰ/PG Ⅱ ratio	
		< 60	60-240	> 240	≤ 27	> 27	≤ 6	> 6
Patients with gastric cancer	126	17 (13.5)	88 (69.8)	21 (16.7)	109 (86.5)	17 (13.5)	25 (19.8)	101 (80.2)
Patients with duodenal ulcer	112	0	69 (61.6)	43 (38.4)	100 (89.2)	12 (10.8)	3 (2.7)	109 (97.3)

ing. However, the relatively shorter emission wavelength of Tb^{3+} chelate (545 nm) makes it more prone to interference (e.g. phosphorescence) derived from plastic or glass materials. Additionally, it is required to use an aliphatic β-diketone to enhance the fluorescence of Tb^{3+} in immunoassay for DELFIA-type of multiple analytes[9]. Considering these factors, we selected Eu^{3+} and Sm^{3+} as labels in the present study.

As the Sm photoluminescence yield is lower than that of Eu, Sm^{3+} is usually used as a tracer in assays not requiring a great sensitivity. The detection limit for PG Ⅰ in dual-label assay is 0.2 μg/L, whereas that of single-label assay is 0.05 μg/L[17]. The sensitivity and precision for PG Ⅰ can be improved significantly by increasing Sm^{3+} label yield. The labeling reaction between PG Ⅰ McAbs and Sm labeling reagent can be prolonged with a suitable excess of the Sm labeling reagents, which may help to get a higher Sm^{3+} label yield. Despite this, the detection sensitivity for PG Ⅰ with a limit of 0.2 μg/L is more than adequate for measuring the PG Ⅰ concentration in clinical samples.

Direct passive absorption of two or more binders is still the routine method for multi-analyte immunoassay (MAIA)[20]. When only the sandwich-type configuration is employed in MAIA, it is necessary to prepare an activated surface binder (e.g. antibody) in order to get a high sensitivity. In this study, the anti-PG Ⅰ and anti-PG Ⅱ antibodies were co-coated simultaneously in a strip well, which was found to be beneficial and economical for a suitable fluorescence by adjusting the concentration of coated antibodies. The total concentration of the co-coated antibodies which can achieve favorable results was no more than 5 μg/mL (1000 ng per well) in this study.

Samples with a relatively high PG Ⅰ or PG Ⅱ were analyzed at various dilutions. The diluting buffer was identical to the calibrator buffer. The percentage of expected value was 96.3%-101.7% for PG Ⅰ and 98.1%-109.6% for PG Ⅱ. No hook effect of dual-label assay was found at a relatively high PG Ⅰ or PG Ⅱ concentration. Recovery was identified by supplementing PG Ⅰ calibrators at 20 μg/L and 100 μg/L, and PG Ⅱ calibrators at 5 μg/L and 50 μg/L. The average recovery rates for PG Ⅰ and PG Ⅱ were 102.7% and 98.8%, respectively, showing that the analytical accuracy is satisfactory for clinical use.

Different analytes (i.e. t-PSA/f-PSA, AFP/CEA) can be detected at present by dual-label TRFIA[3,21] and the corresponding instruments are commercially available. In this study, the human PG detected by dual-label TRFIA was similar to that detected by ELISA and single-label TRFIA. The sensitivity, measurement range and stability of dual-label TRFIA were substantially better than those of ELISA. Unlike radioimmunoassay or ELISA[22,23], dual-label TRFIA can measure the concentration of PG Ⅰ and PG Ⅱ, as well as the ratio of PG Ⅰ/Ⅱ, thus reducing the random handling errors and increasing the clinical confidence level of PG Ⅰ/PG Ⅱ ratio. Direct labeling of immunoreagents with lanthanide chelates and lack of overlapping between Eu^{3+} and Sm^{3+} chelates allow a rapid assay. In addition, 25 μL of samples is enough for the simultaneously detection of PG Ⅰ and PG Ⅱ.

In summary, dual-label TRFIA can serve as a high-throughput tool for the detection of serum PG and has good prospects of clinical application.

COMMENTS

Background

Non-invasive serum pepsinogen (PG) test provides much information on intestinal metaplasia, atrophic gastritis, as well as *Helicobacter pylori* infection and peptide ulcer, which has a significant clinical value for the mass screening of patients at a high risk of gastric cancer. A reliable and effective detection method covering a wide concentration range with good sensitivity for PG is required. Furthermore, simultaneous determination of PG Ⅰ and PG Ⅱ can improve the confidence level of the PG Ⅰ/PG Ⅱ ratio.

Research frontiers

In this study, the authors found that multi-analyte immunoassay could increase the throughput and reduce the overall cost per test. A simple, rapid and sensitive dual-label time-resolved fluoroimmunoassay (TRFIA) for pepsinogens in human serum was developed.

Innovations and breakthroughs

TRFIA is a sensitive technique used in analysis of trace substances. Compared with traditional methods, such as radioimmunoassay or enzyme-linked immunosorbent assay (ELISA), dual-label assay can reduce random handling errors and increase the confidence level of PG Ⅰ and PG Ⅱ (especially for the PG Ⅰ/PG Ⅱ ratio). Only 25 μL of serum samples is enough for each test, which is useful for mass screening.

Applications

The PG detected by dual-label TRFIA was in good agreement with that detected by single-label assay or by ELISA. The analytical accuracy, precision and stability are satisfactory for its use in clinical practice. Dual-label TRFIA may serve as a high-throughput tool for the detection of serum PG and has good prospects of clinical application.

Peer review

The analysis of pepsinogens in serum/plasma of patients is a well established method to identify subjects at a higher risk of developing gastric cancer. The described method for analyzing Pep-Ⅰ and Pep-Ⅱ simultaneously seems to have similar parameters in relation to sensitivity and specificity as EIA or ELISA. The manuscript is well written.

Abstract

AIM: To generate recombinant adenoviral vector containing calreticulin (CRT)-hepatitis B surface antigen (HBsAg) fusion gene for developing a safe, effective and HBsAg-specific therapeutic vaccine.

METHODS: CRT and HBsAg gene were fused using polymerase chain reaction (PCR), endonuclease digestion and ligation methods. The fusion gene was cloned into pENTR/D-TOPO transfer vector after the base pairs of DNA (CACC) sequence was added to the 5′ end. Adenoviral expression vector containing CRT-HBsAg fusion gene was constructed by homologous recombinantion. The human embryo kidney (HEK) 293A cells were transfected with linearized DNA plasmid of the recombinant adenoviral vector to package and amplify recombinant adenovirus. The recombinant adenovirus titer was characterized using the end-dilution assay. The expression of the CRT/HBsAg fusion protein in Ad-CRT/HBsAg infected 293A cells was detected by Western blotting.

RESULTS: The CRT-HBsAg fusion gene was characterized by PCR and sequencing and its length and sequence were confirmed to be accurate. The CRT-HBsAg fusion gene recombinant pENTR/D-TOPO transfer vector was constructed. The recombinant adenoviral vector, Ad-CRT/HBsAg, was generated successfully. The titer of Ad-CRT/HBsAg was characterized as 3.9 × 10^{11} pfu/mL. The CRT-HBsAg fusion protein was expressed by HEK 293A cells correctly.

CONCLUSION: CRT/HBsAg fusion gene recombinant replication-defective adenovirus expression vector is constructed successfully and this study has provided an experimental basis for further studies of Hepatitis B virus gene therapy.

INTRODUCTION

Development of a safe, effective and therapeutic vaccine represents the best hope for treatment of hepatitis B virus (HBV) infection. Recent data have indicated that immunotherapeutic strategies stimulating both cellular and humoral immune responses to HBV antigens are es-

sential to cure chronic HBV infection[1]. In this regard, DNA-based vaccination appears to be a particularly pertinent approach for chronic hepatitis B treatment, since it has been well documented to elicit durable humoral and cell mediated immunity including cytotoxic T lymphocytes and cytokines in normal mice[2,3], ducks[4] and chimpanzees[5]. It is a good candidate for immunization of non-responders to recombinant hepatitis B surface antigen (HBsAg) vaccines and for therapeutic vaccination[2]. However, even at higher doses of DNA, human clinical trials of HBV DNA vaccine have yielded a much lower level of immune responses than that observed in small animals[6,7]. Therefore, the potency of DNA vaccines must be enhanced for successful human application. The use of calreticulin (CRT) represents an innovative and feasible approach for enhancing immune responses and generating an antiangiogenic effect[8]. CRT is an abundant 46 kDa Ca^{2+}-binding protein located in the endoplasmic reticulum (ER)[9]. CRT is considered to be related to the family of heat shock proteins[10,11]. The protein has been shown to associate with peptides delivered into the ER by transporters associated with antigen processing (TAP-1 and TAP-2)[12] and with major histocompatibility complex (MHC) class I -β2 microglobulin molecules to aid in antigen presentation[13].

It is well known that available recombinant HBsAg protein vaccine is effective for preventing HBV infection for healthy persons, but for the infected patients there have been no effective and therapeutic vaccines until now. In this study, CRT-HBsAg fusion gene recombinant adenovirus expression vector was generated to establish the basis for curing chronic HBV infection and HBsAg-positive liver cancer.

MARTERIALS AND METHODS

Plasmids, cells and reagents

ViraPower Adenoviral Expression System including pENTR/D-TOPO Cloning Vector, Adenoviral Expression Vector, HEK293A cells, TOP10 competent cells of *Escherichia coli (E. coli)* were all purchased from Invitrogen Corporation (USA). The pJW4303, plasmid was provided by professor Lu Shan (Umass, USA).

Taq DNA polymerase, *Pfu* DNA polymerase, antibodies marked by HRP, *Pac*I, plasmid DNA purification kit and Gel purification kit were purchased from Tianwei Shidai Corporation (China), New England Corporation (UK), Takara Corporation (China), and Promega Corporation (USA), respectively. Human anti-HBsAg antibody positive serum was collected by our laboratory. Primers were synthesized in Shanghai Invitrogen Corporation (China).

Construction and preparation of CRT/HBsAg fusion gene recombinant plasmid

For the generation of pJW43033-CRT, CRT was amplified with polymerase chain reaction (PCR) using rabbit CRT cDNA as the template[14] and a set of primers, 5'-CCGGAGACTCATGCTGCTCCCTGTGCCGCT-3' and 5'-CCGGGAATTCCAGCTCGTCCTTGGCCTGGC-3'. There is more than 90% homology between rabbit, human, mouse, and rat CRT[14]. The amplified product was then cloned into the *Sac*I/*Eco*RI sites of pJW4303 vector. For the generation of pJW4303-CRT/HBsAg, HBsAg gene was amplified with a set of primers, 5'-GTGGGGAATTCATGGAGAACACAACATCAGG-3' and 5'-GGGGTGGATCCAATTTACATATGGGTTTCTGT-3', and then cloned into the *Eco*RI/*Bam*HI sites of pJW4303-CRT to generate pJW4303-CRT/HBsAg. The accuracy of these constructs was confirmed by endonuclease digestion and DNA sequencing. The sequencing was finished by Shanghai Invitrogen Biological Engineering Corp (China).

Construction of recombinant pENTR/D-TOPO transfer vector containing CRT/HBsAg fusion gene

CRT/HBsAg fusion gene was amplified using pJW4303-CRT/HBsAg plasmid as the template and a set of primers, 5'-CACCATGCTGCTCCCTGTGCCGCT-3' and 5'-AATTTACATATGGGTTTCTGT-3'. In order to construct directional TOPO cloning transfer vector in the desired direction, the CACC sequence was incorporated into the PCR upstream primer at its 5' end. The final optimized conditions of PCR consisted of 94℃ for 5 min, followed by 30 cycles of denaturation at 94℃ for 30 s, annealing at 55℃ for 30 s and extension at 72℃ for 1 min. After PCR, the PCR products of fusion gene were purified for generating the pENTR/D-TOPO transfer vector. The ligated products were transformed into TOP10 chemically competent *E. coli* and incubated overnight at 37℃. Subsequently, extracted and purified plasmids containing CRT/HBsAg fusion gene were characterized by PCR and sequencing, respectively. The sequencing was finished by Shanghai Invitrogen Biological Engineering Corp.

Construction and characterization of CRT/HBsAg fusion gene recombinant adenoviral expression vector, Ad-CRT/HBsAg

Using LR Clonase Mix™ (Invitrogen, US) as catalysis, the purified CRT/HBsAg fusion gene recombinant pENTR/D-TOPO transfer vector was mixed with adenoviral expression vector DNA plasmid to generate the recombinant adenoviral expression vector. The recombinant products were transformed into TOP10 chemically competent *E. coli* and incubated on Luria-Bertani (LB) plates containing 100 μg/mL ampicillin at 37℃ overnight. Subsequently, we selected eight putative positive clones which were ampicillin-resistant to amplify, extract and purify for PCR amplification and electrophoresis detection, respectively. The reason why using LB plates containing 30 μg/mL chloramphenicol to select positive clones is because true expression clones would be ampicillin-resistant and chloramphenicol-sensitive.

Transfecting the HEK 293A cells line with Ad-CRT/HBsAg plasmid

Purified Ad-CRT/HBsAg DNA plasmid was digested with *Pac*I. The day before transfection, the 293A cells were

trysinized, counted, and plated at 5×10^5 cells per well in a 6-well plate. Two milliliter of normally growing Dulbecco's modified Eagle's medium (D-MEM) containing 10% fetal bovine serum (FBS) was plated into each well. Those 293A cells were transfected using Lipofectamine 2000™ (Invitrogen, USA) and Pac I-digested expression plasmid DNA complexes. Culture medium was replaced with refresh complete culture medium every 2-3 d until visible regions of cytopathic effect (CPE) were observed. When approximately 80% of CPE was observed, adenovirus-containing cells and media were harvested.

LacZ gene recombinant adenoviral expression vector plasmid (Ad-LacZ) provided by the manufacturer (Invitrogen, USA) was used as control.

Characterization and titering of Ad-CRT/HBsAg

The titer of Ad-CRT/HBsAg was characterized using the End-Point Dilution Assay. When the 293A cells prepared 24 h before incubated at 37℃ in a CO_2 incubator were at more than 80% confluency in 96-well plates, the recombinant adenovirus stock solution harvested above was diluted to a concentration of 10^{-1}-10^{-12} and 100 μL was added to each well. After cultured for 10 d, the number of wells with CPE was calculated according to the formula of titre (pfu/mL) = $10^{(x + 0.8)}$.

Western blotting analysis

After being cultured for 72 h, the Ad-CRT/HBsAg infected and normal control 293A cells were harvested and frozen to -80℃. Some of them were prepared for Western blotting analysis. Protein samples were fractionated on 5%-12% SDS-PAGE and transferred to PVDF membrane using protein transfer apparatus (Bio-Rad, USA). The membrane was blocked for 1 h with 5% skimmed milk in TBS buffer (50 mmol/L Tris base, 150 mmol/L NaCl, pH 7.5) containing 0.5% Triton X-100. The membrane was probed with human anti-HBsAg antibody positive serum. After washing the membrane, goat anti-human HRP-conjugated antibody was added and incubated. The results were finally revealed using the sensitive substrate of DAB kit (Wuhan Boster, China) for Western blotting detection.

RESULTS

Characterization of CRT/HBsAg fusion gene recombinant plasmid

The CRT/HBsAg fusion gene recombinant plasmid pJW4303-CRT/HBsAg was digested by *Sac*I and *Bam*HI endonucleases. An approximately 2000 bp (1944 bp = 1263 bp + 681 bp) long DNA band was observed using 1.5% agarose gel electrophoresis (Figure 1A).

Characterization of CRT/HBsAg fusion gene recombinant pENTR/D-TOPO transfer vector

Kanamycin-resistant putative positive clones were prepared as template to amplify CRT/HBsAg fusion gene by specific PCR. Approximately 2000 bp long DNA bands were observed in those positive clones using 1.5% agarose gel electrophoresis (Figure 1B). The sequencing results of CRT and HBsAg gene were the same as CRT sequence of NM004343.3 and HBsAg sequence of AF013631 in GenBank.

Lane 1: Negative control; Lane 2: CRT/HBsAg fusion gene recombinant pJW4303 plasmid; Lane M: DNA marker; B: Characterization of CRT/HBsAg fusion gene recombinant pENTR/D-TOPO transfer vector by PCR. Lane 1: Negative control; Lane 2: CRT/HBsAg fusion gene recombinant pENTR/D-TOPO transfer vector amplified by specific PCR; Lane M: DNA marker.

Characterization of CRT/HBsAg fusion gene recombinant adenoviral expression vector, Ad-CRT/HBsAg

All of the selected clones were sensitive for culturing in LB plates containing 30 μg/mL chloramphenicol because those true expression clones would be chloramphenicol-sensitive. After PCR amplification, a nearly 2000 bp long DNA band was observed using 1.5% agarose gel electrophoresis.

Harvest and detection of recombinant adenovirus, Ad-CRT/HBsAg

*Pac*I-digested Ad-CRT/HBsAg DNA plasmid was transfected into 293A cells by Lipofectamine 2000™. About 10 d after transfection, 80% of the cells rounded up and were floating or lightly attached to the tissue culture dish. This indicated that cells were loaded with adenovirus particles (Figure 2A). The shape of normal 293A cells are shown in Figure 2B. The adenovirus-containing cells were harvested and characterized by PCR amplification. A DNA band, which was approximately 2000 bp long, was found with 1.5% agarose gel electrophoresis.

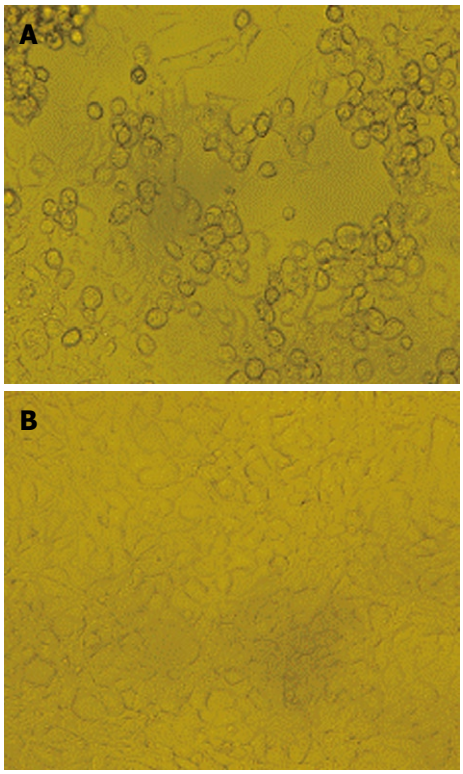

Figure 2 Culture of recombinant adenovirus in HEK293A cells. A: CPE was observed in recombinant adenovirus-containing HEK293A cells; B: Normal HEK293A cells cultured as control.

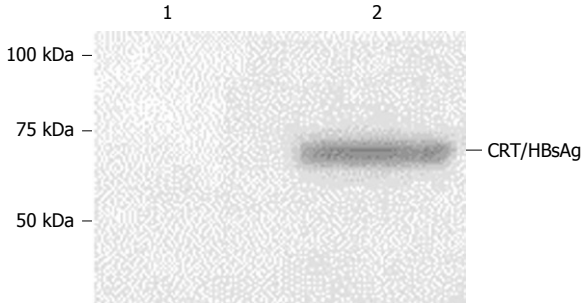

Figure 3 Characterization of CRT/HBsAg fusion protein expression by Western blotting. The expression of CRT/HBsAg fusion protein in 293A cells was determined in 293A cells transfected with Ad-CRT/HBsAg and Ad-LacZ by Western blotting analysis. Human anti-HBsAg positive serum was used at a 1:100 dilution for the detection of CRT/HBsAg fusion protein expression. Lane 1: Lysate from 293 cells transfected with Ad-LacZ; Lane 2: Lysate from 293 cells transfected with Ad-CRT/HBsAg.

Titering of the adenoviral stock, Ad-CRT/HBsAg

After having been amplified, the recombinant adenoviral stock was characterized by the End-Point Dilution Assay. Its titer was calculated as 3.9×10^{11} pfu/mL.

Characterization of CRT/HBsAg fusion protein expression

The expression of CRT/HBsAg fusion protein in Ad-CRT/HBsAg infected 293A cells was detected by Western blotting. Figure 3 shows the 71 kDa CRT/HBsAg fusion protein expression.

DISCUSSION

There are approximately four hundred million chronic hepatitis B patients in the world, and effective therapeutic vaccines are needed urgently. The purpose of this study is to facilitate the development of a new type of therapeutic HBV vaccine. The research hotspot in this field is how to develop an effective therapeutic vaccine by modifying the HBV antigens such as HBsAg, pres1Ag, pres2Ag and HBcAg to induce a high level of humoral and cellular immune responses for clearing the HBV infection. The HBV therapeutic vaccines include protein vaccine, DNA vaccine and virus vector vaccine, but none of them has been developed successfully.

Recently, investigators have performed a head-to-head comparison of linkage of antigen to CRT in a DNA vaccine, and achieved the greatest enhancement of the humoral and T-cell-mediated immune responses in vaccinated mice[15]. Previous studies have shown that adenoviral vectors expressing the fusion of CRT and E7 can effectively be used as a prophylactic and therapeutic vaccine against E7-expressing tumors[16]. In this study, the HBV surface gene was fused with CRT, which can improve immunogenicity by enhancing the MHC class I presentation of linked peptide/protein. CRT-HBsAg fusion gene recombinant adenovirus vector vaccine will be an ideal candidate for HBV therapeutic vaccine, because it can induce HBsAg specific high-level immune responses.

Members of adenovirus family infect a great variety of post-mitotic cells, even those associated with highly differentiated tissues such as skeletal muscle, lung, brain and heart. This characteristic, together with being relatively easy for preparation and purification, has led to their extensive use as gene vectors. Since they deliver their genome to the nucleus and can replicate with high efficiency, they are prime candidates for the expression and delivery of therapeutic genes[17]. The adenovirus vectors used in this study are to be utilized for delivering genes of CRT fused HBsAg to liver tissues to suppress and eliminate chronic inflammation and tumors caused by HBV infection. This is for the first time to construct the CRT-HBsAg gene recombinant adenovirus as a therapeutic vaccine. This study suggested that CRT-HBsAg fusion gene recombinant adenovirus vector may be a potent tool for treating chronic HBV carriers and liver cancer patients.

COMMENTS

Background

The hepatitis B virus (HBV) infection is one of the most widespread viral infections of human and causes acute and chronic hepatitis and hepatocellular carcinoma. Problem of HBV infection has necessitated the development of an effective therapeutic vaccine. Calreticulin (CRT) is a ubiquitously expressed Ca^{2+} binding protein in endoplasmic reticulum of eukaryotic cells. Previous studies have shown that CRT enhances the major histocompatibility complex (MHC) class I presentation of linked peptide/protein and may serve as an effective vaccination strategy for antigen-specific cancer treatment. In this study, CRT-hepatitis B surface antigen (HBsAg) fusion gene recombinant adenovirus

expression vector was generated to establish the basis for curing acute and chronic HBV infection and HBsAg-positive hepatocellular carcinoma.

Research frontiers

There are approximately four hundred million chronic hepatitis B patients in the world, and effective therapeutic vaccines are needed urgently. The research hotspot is how to develop an effective therapeutic vaccine by modifying the HBV antigens such as HBsAg, pres1Ag, pres2Ag and HBcAg to induce a high level of humoral and cellular immune responses for clearing the HBV infection. HBV therapeutic vaccines include protein vaccine, DNA vaccine and virus vector vaccine, but none of them has been developed successfully.

Innovations and breakthroughs

Most of the previous researches about HBV therapeutic vaccines focus on modifying HBsAg to enhance its immunogenicity. In this study, the HBV surface gene was fused with CRT, which can improve immunogenicity by enhancing the MHC class I presentation of linked peptide/protein. CRT-HBsAg fusion gene recombinant adenovirus vector vaccine will be an ideal candidate for HBV therapeutic vaccine, because it can induce HBsAg specific high-level immune responses. Adenovirus can infect a great variety of cell types and tissues in both dividing and non-dividing cells. This characteristic, together with being relatively easy for preparation and purification, has led to their extensive use as gene vectors. The adenovirus vectors used in this study are to be utilized for delivering genes of CRT fused HBsAg to liver tissues to suppress and eliminate tumors and inflammation caused by HBV infection. This is for the first time to construct the CRT-HBsAg gene recombinant adenovirus as a therapeutic vaccine.

Applications

CRT linked HBsAg gene recombinant adenovirus vectors were constructed in this study to develop a new sort of HBV therapeutic vaccine for the purpose of curing chronic hepatitis and hepatocellular carcinoma.

Peer review

It is a nice work to construct CRT/HBsAg fusion gene recombinant replication-defective adenovirus expression vector and it has provided a therapeutic vaccine and an experimental basis for further research of HBV gene therapy.

Abstract

Biliary obstructions can lead to infections of the biliary system, particularly in patients with occluded biliary stents. Fungal organisms are frequently found in biliary aspirates of patients who have been on antibiotics and have stents; however, fungal masses, or "balls", that fully obstruct the biliary system are uncommon and exceedingly difficult to eradicate. We present 4 cases of obstructing fungal cholangitis in patients who had metal biliary stents placed for pancreatic malignancies, and subsequently required aggressive antifungal administration along with endoscopic and radiologic interventions. This report also reviews approaches previously undertaken to manage severe obstructing fungal cholangitis.

INTRODUCTION

Obstructing lesions of the biliary tree include benign and malignant strictures, bile duct stones, stenotic sphincters, and obstructed endoprostheses. Obstructions can lead to infections of the biliary system, particularly in patients with occluded biliary stents. Fungal organisms are frequently found in biliary aspirates of patients who have been on antibiotics and have stents; however, fungal masses, or "balls", that fully obstruct the biliary system are uncommon and exceedingly difficult to eradicate[1-3]. We present 4 cases of obstructing fungal cholangitis in patients who had metal biliary stents placed for pancreatic malignancies and subsequently required aggressive endoscopic and radiologic interventions.

CASE REPORT

Case 1

A 48-year-old male with locally advanced unresectable pancreatic cancer on gemcitabine and docetaxel chemotherapy, presented to our institution with fevers, rigors, jaundice, and epigastric pain 7 d after placement of a metal biliary stent at another institution. Antibiotics were started and endoscopic retrograde cholangiopancreatography (ERCP) showed multiple large filling defects resembling stones (Figure 1). The bile duct was cleared of all defects and the biliary stent was exchanged for a new longer metal biliary stent. Biliary aspirates grew *Candida albicans*. Despite starting 200 mg daily intravenous (iv) fluconazole, the biliary tree rapidly reoccluded within 3 d with large fungal balls. A repeat ERCP in which a plastic

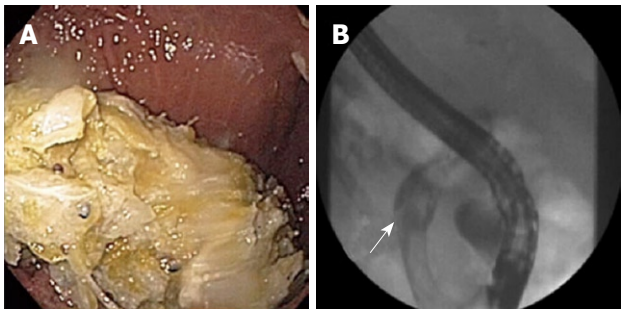

Figure 1 Endoscopic and cholangiographic views of biliary obstruction in patient 1. A: Biliary/fungal debris occluding metal biliary stent; B: "Fungal balls" (arrow) obstructing the bile ducts by cholangiography.

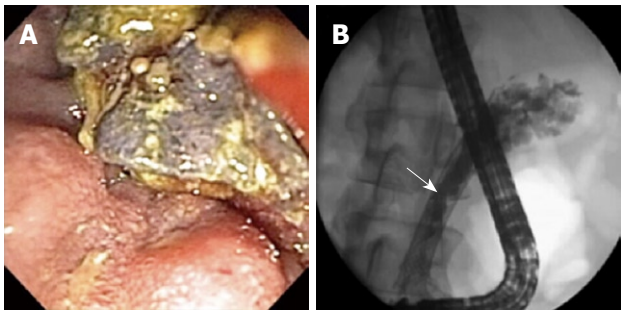

Figure 2 Endoscopic and cholangiographic views of biliary obstruction in patient 2. A: "Fungal ball" visible in the common bile duct; B: Cholangiogram showing fungal debris (arrow) around the metal biliary stent.

endoprosthesis was placed also occluded within 5 d with large fungal balls. A percutaneous transhepatic biliary drain (PTBD) was placed and twice daily 100 mg fluconazole flushes were initiated through the drain. The IV fluconazole was switched to 50 mg daily iv caspofungin, and this antifungal combination resulted in no further obstructions. The patient was discharged home on 200 mg/d oral fluconazole and twice daily 100 mg fluconazole flushes to be continued indefinitely. At 2 mo, repeat biliary cultures through the PTBD identified fluconazole-resistant *Candida*, prompting the patient's oral regimen to be switched to 200 mg twice daily oral voriconazole. The remainder of the patient's clinical course required occasional PTBD catheter exchanges, daily oral voriconazole, and daily intrabiliary flushing of fluconazole until he died 5 mo later secondary to his advanced pancreatic cancer.

Case 2

A 66-year-old female with metastatic pancreatic cancer on gemcitabine chemotherapy underwent metal biliary stent placement and percutaneous cholecystostomy tube placement for obstructive jaundice and acute cholecystitis. Her symptoms improved and 3 mo later, the gallbladder was removed. Shortly after surgery, she was readmitted for fevers, chills, and recurrent jaundice. Antibiotics for presumptive bacterial cholangitis were started and an ERCP was performed revealing caked debris on the proximal edge of her metal biliary stent and multiple soft filling defects within the common hepatic duct (Figure 2). Biliary aspirates grew *Candida glabrata* and *Candida albicans*. Despite clearing the duct of all debris and starting 200 mg twice daily oral voriconazole and 100 mg twice daily fluconazole flushes through the cholecystostomy tube, her biliary tree rapidly reoccluded in 10 d with large fungal balls. A nasobiliary drain was then placed to further facilitate fluconazole flushing into the biliary system. Eradication was finally achieved with daily oral voriconazole and daily fluconazole flushing through both the cholecystostomy tube and the nasobiliary tube. On this regimen indefinitely, the patient remained clear of further obstructions and died from her advanced pancreatic cancer 8 mo later.

Case 3

A 56-year-old male with a Merkel cell lymphoma of his leg and a large metastasis to the pancreatic head, presented to our institution with increasing fevers, abdominal pain, nausea, vomiting, and jaundice. He had been undergoing chemotherapy with irinotecan and carboplatin, and had required duodenal stent placement for tumor overgrowth as well as PTBD and percutaneous metal biliary stent placement 7 mo previously for biliary obstruction. At the time of admission, empiric antibiotic therapy was initiated for presumptive bacterial cholangitis, and an upper endoscopy was performed revealing gastric outlet obstruction with tumor overgrowth of the duodenal stent. A new duodenal stent was placed but the biliary stent could not be visualized, requiring repeat PTBD placement. A PTBD tube check 5 d later revealed multiple soft filling defects within the PTBD catheter consistent with fungal balls (Figure 3). The PTBD catheter was exchanged and after biliary aspirates grew *Candida* spp, 400 mg/d oral fluconazole and 100 mg fluconazole flushes twice daily were initiated through the new PTBD catheter. However, after fluconazole-resistant *Candida glabrata* and *Candida albicans* were isolated from culture, antifungals were switched to 50 mg iv caspofungin once daily and 100 mg amphotericin B flushes once daily through the PTBD catheter. The patient was subsequently discharged from the hospital on a 3-wk course of this antifungal regimen. One month after completion of antifungal therapy, there was no further recurrence of biliary obstruction.

Case 4

A 64-year-old male with metastatic pancreatic cancer on gemcitabine and docetaxel chemotherapy, with an indwelling metal biliary stent in place, presented to an outside facility with biliary obstruction and bacterial cholangitis. Symptoms resolved after a PTBD was placed and antibiotics were administered. However, 2 wk later, the patient re-presented to our institution with recurrent fevers and jaundice. Empiric antibiotic therapy was again initiated for presumptive bacterial cholangitis. Cholangiography performed during ERCP demonstrated obstruction due to migration of the metal biliary stent, tumor overgrowth and multiple soft filling defects consistent with fungal balls. Exchange of the PTBD catheter allowed for external drainage of biliary debris, and the aspirate grew *Candida albicans* in culture. Intravenous fluconazole

	Abd pain, jaundice	Sphincterotomy, nasobiliary drainage, systemic/intrabiliary antifungals	Yes
	Abd pain, jaundice	Sphincterotomy, debridement, nasobiliary drainage, systemic/intrabiliary antifungals	Yes
	Elevated LFTs	Sphincterotomy, debridement, nasobiliary drainage, systemic/intrabiliary antifungals	Yes
	Elevated LFTs	Sphincterotomy, debridement, nasobiliary drainage, systemic/intrabiliary antifungals	No
	Abd pain, jaundice	Sphincterotomy, debridement, nasobiliary drainage, systemic/intrabiliary antifungals	No

200 mg/d was initiated for antifungal coverage. Over the next several days, biliary obstruction persisted due to stent malpositioning, which ultimately was relieved by severing the patient's migrated metal biliary stent. Despite these measures, within 5 d of PTBD catheter exchange and trimming of the metal biliary stent, the patient's bile duct reobstructed with fungal balls visualized on repeat tube check (Figure 4). The PTBD catheter was exchanged and the patient was initiated on an indefinite regimen of 200 mg oral voriconazole daily and 100 mg fluconazole flushes through the PTBD catheter twice daily. Two weeks later, the patient had no further evidence of obstruction.

DISCUSSION

The patients described in this case report highlight the difficulties in treatment of obstructing fungal cholangitis following the placement of metal biliary stents. Clinical improvement was not seen with endoscopic maneuvers alone or in combination with initial systemic antifungals. Ultimately, infection control was only achieved after flushing antifungals through percutaneous intrabiliary or nasobiliary drains and escalating systemic antifungal therapy from fluconazole to voriconazole or caspofungin. All patients remained free of *Candida* infection following optimization of their antifungal regimens.

While the presence of biliary stents likely played a role in the development of fungal cholangitis in our case report, there are several other factors that can contribute to the development of fungal infections. These include immunosuppression secondary to chemotherapy agents, malignant hematologic disease, broad-spectrum antibiotic administration, corticosteroid therapy, diabetes mellitus, improper sterilization of endoscopes or prostheses, previous surgery, or trauma[1-6]. The patients in our case study demonstrated a number of these risk factors; all were

treated with broad-spectrum antibiotics, all were immunocompromised secondary to systemic chemotherapy for their pancreatic malignancies, and all had been given intermittent corticosteroids for chemotherapy administration.

The data regarding optimal treatment strategies for management of obstructing fungal masses is limited. To our knowledge, only 13 cases of obstructing fungal cholangitis have been described in the literature, the majority of which underwent systemic and intrabiliary infusion of antifungals. Several studies support our treatment approach of initiating therapy with fluconazole, given its favorable efficacy toward *Candida albicans* and relatively few side effects[4,6]. The literature further supports the use of escalation of therapy to voriconazole or caspofungin[6] for infection control. Other case studies, prior to the availability of voriconazole, utilized amphotericin B or liposomal amphotericin[5-8]. While the use of systemic amphotericin has been shown to have numerous complications, several case reports demonstrated that local intrabiliary infusion could be effective[5,6,8]. Interestingly, 2 case studies[1,4] reported no further antifungal administration was necessary following bile duct drainage of fungal balls for complete fungal eradication. Further details are shown in Table 1.

Fungal biliary aspirates are frequently positive in patients who have stents and have been on antibiotics[9,10]. However, it is uncommon to find completely obstructed bile ducts caused by large fungal "balls," implying that growth of the organism was rapid in a previously contaminated system due to foreign bodies and antibiotics. The pathogenesis of common bile duct fungal balls is largely unknown; however, 2 possible explanations exist. Firstly, formation of microabscesses in the liver parenchyma from fungal sepsis may allow movement of fungal organisms into the extra-hepatic biliary system[11]. A second hypothesis involves direct invasion of *Candida* into the common bile duct from the duodenum, with "fungal ball" formation resulting from rapid growth of a superficial mat of fungal mycelia on the bile duct surface[7,11]. Fragmented pieces of fungi and mucoid debris become molded to bile duct walls. Subsequent invasion and proliferation of fungal hyphae may be further aided by the presence of metal biliary stents, acting as a scaffold for infection[7,11].

The treatment strategies described herein address both of the above hypotheses. Systemic antifungal administration targets fungal sepsis, preventing further aggregation of fungal organisms. The direct invasion hypothesis is supported by the fact that fungal balls are easily swept out of the biliary system by endoscopic maneuvers. As such, treating the fungal conglomerates directly by flushing antifungal medications through percutaneous or nasobiliary drains may be a more effective treatment strategy than systemic hematologic dissemination of antifungal therapies[8]. The results seen in the 4 cases described in this report further support this idea. While it seems intuitive that intrabiliary antifungal concentrations would be higher with direct flushing than with systemic antifungal administration, both approaches seem to be required to prevent reocclusion of the biliary system. Further studies are needed to expand on these findings.

Abstract

Self-expanding metal stent (SEMS) placement offers safe and effective palliation in patients with upper gastrointestinal obstruction due to a malignancy. Well described complications of SEMS placement include tumor growth, obstruction, and stent migration. SEMS occlusions are treated by SEMS redeployment, argon plasma coagulation application, balloon dilation, and surgical bypass. At our center, we usually place the second SEMS into the first SEMS if there is complete occlusion by the tumor. We discovered an unusual complication during SEMS redeployment. The guidewire passed through the mesh of the first SEMS and caused the second SEMS to become entangled with the first SEMS. This led to the distortion and malfunction of the second SEMS, which worsened the gastric outlet obstruction. For lowering the risk of entanglement, we studied stone extraction balloon-guided repeat SEMS placement. This is the first report of a SEMS entangled by the mesh of the first SEMS and stone extraction balloon-guided repeat SEMS placement for lowering the risk of this complication.

INTRODUCTION

In patients presenting with gastric outlet obstruction, upper gastrointestinal malignancies are the source in up to 39% of cases[1]. Surgical resection is the standard of care in patients who lack significant comorbidities[2]. In unresectable patients, gastrojejunostomy remains the standard of care if a surgical intervention is to be undertaken. In those patients with significant comorbidities, the morbidity rate approaches 40%[3], encouraging alternatives to surgery. In patients who are not surgical candidates, enteral stenting offers an attractive option[4]. Self-expanding metal stent (SEMS) has proven itself to be a safe and relatively cost-effective alternative to surgical palliation allowing the patient to be discharged and start postoperative (PO) intake earlier[5]. Complications related to SEMS placement include stent migration, managed by removal of the original SEMS and replacement with a new SEMS, and obstructions due to local disease progression, treated respectively with repeat SEMS placement, argon plasma coagulation application, balloon dilation, and surgical bypass[2]. We usually perform repeat SEMS placement when there is an obstruction after first stenting. Overlapping the second SEMS into the first SEMS is a safe and easy way for resolving stent obstruction. However, repeat SEMS placement can cause a serious problem if a guidewire transverses the mesh of

the first SEMS and the second SMES is deployed in the mesh of the first SEMS. It must be extremely rare and happens in specific conditions; we experienced just one case of this serious complication. However, once it has happened, this causes irreversible SEMS entanglement leading to further obstruction. Therefore, it is necessary to lower the risk of SEMS entanglement during repeat SEMS placement. To prevent a guidewire from passing through the mesh of the first SEMS, we devised our stone extraction balloon-guided repeat SEMS placement and applied it to one case successfully.

CASE REPORT

A seventy-year-old woman received an 80 mm long SEMS (Niti-S™ Pyloric uncovered stent, Taewoong Medical, Ilsan, Korea) for relieving gastric outlet obstruction due to advanced gastric cancer. Six months later, she presented with vomiting and abdominal distention. Investigation revealed tumor overgrowth distal to the placed SEMS. We decided to deploy another 120 mm long uncovered SEMS (Niti-S™ Pyloric covered stent, Taewoong Medical, Ilsan, Korea), overlapping the previous one. An endoscopy did not pass the existing stent because the proximal part of the existing SEMS was narrow. Thus, we advanced a guidewire from the proximal part of the first SEMS. After performing repeat SEMS placement, we encountered an unusual complication. The newly deployed SEMS was trapped and unexpanded at the entangled site (Figure 1). The guidewire passed through the mesh of the existing stent and caused the second SEMS to be trapped by the mesh of the first one. Because of this complication the gastric outlet obstruction was not improved. This painful experience made us think of stone extraction balloon-guided repeat SEMS placement to avoid SEMS entanglement in specific conditions; the insertion of a guidewire from the proximal or middle part of the first SEMS guided only by fluoroscopy and the acute angulation of duodenum. Several months later, we faced a similar situation. An eighty-four-year-old woman with an 80 mm long SEMS (Niti-S™ Pyloric uncovered stent, Taewoong Medical, Ilsan, Korea) presented with gastric outlet obstruction symptoms. Investigation found that tumor ingrowth had caused SEMS occlusion. We decided to deploy a 100 mm long covered SEMS (Niti-S™ Pyloric covered stent, Taewoong Medical, Ilsan, Korea) into the existing one. Endoscopy was advanced to the middle part of the first SEMS where tumor ingrowth caused near total occlusion. We used a 15 mm stone extraction balloon (ESCORT II™, Willson Cook, Winston-Salem, USA) before advancing a guidewire. An inflated 15 mm stone extraction balloon was passed through from the middle to the distal part of the existing stent without falling into the mesh and led a guidewire to reach the target area safely (Figures 2 and 3). Repeat SEMS placement was successfully performed without the misguidance of a guidewire (Figure 4).

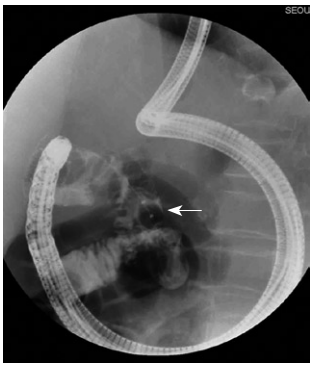

Figure 2 Fluoroscopy. The stone extraction balloon (arrow) was advanced distal to the existing SEMS.

DISCUSSION

The endoscopic placement of enteral SEMS relieves malignant gastroduodenal obstruction in the majority of patients, allowing discharge from hospital and the resumption of enteral nutrition[6]. A multi-center trial of patients with gastric outlet obstruction due to malignancy has concluded that enteral stent insertion allows a purely enteral diet to be maintained in up to 92% of patients, with 73% tolerating solid or semi-solid food[7]. Overall, if migration, fracture, tumor ingrowth, erosion, and perforation are taken into account, the global long-term patency rate obtained is 76%[2]. Stent migration occurs more often with covered stents since tumor ingrowth and subsequent incorporation of the stent into the surrounding tissue is less likely. In contrast, recurrent obstruction is more problematic for uncovered stents[8]. About 9% of total patients who received SEMS developed stent occlusion by local tumor growth with progression of the primary disease process[2]. These were treated, respectively, with repeat SEMS placement, argon plasma coagulation application, balloon dilation, and surgical bypass[2]. At our center, we usually perform repeat SEMS placement when there is a stent occlusion by tumor growth. We have performed repeat SEMS placement through endoscopic-fluoroscopic positioning. An endoscope with a working channel is placed at the distal portion of the first SEMS. Under fluoroscopic guidance, a guidewire pre-loaded through a catheter is used to gently cannulate the stenosis. Once the guidewire has passed through the stenosis, the catheter is advanced over the guidewire through the lesion. As soon as the catheter is passed through the stenosis, the guidewire is

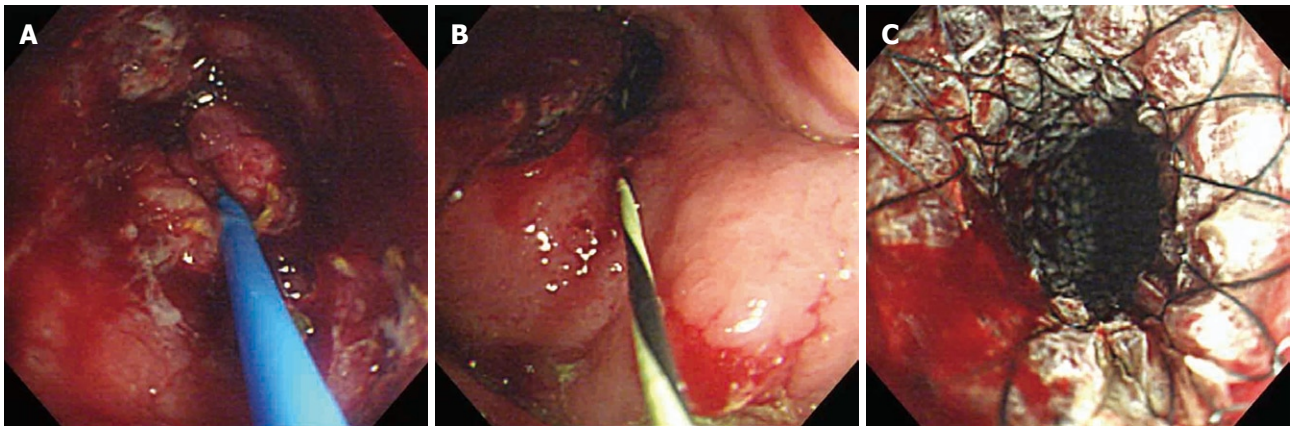

Figure 3 Duodenoscopy. A: The stone extraction balloon advancing over the region of tumor ingrowth; B: The guidewire advancing through the stone extraction balloon; C: The expanded covered SEMS.

removed and water soluble contrast medium is injected to document the characteristics and length of the obstruction and to rule out the occurrence of perforation. At this point, it is very important to push and pull a guidewire through the catheter to find the right position. The stent apparatus is passed through the scope, advanced over the first SEMS under endoscopic and fluoroscopic guidance and deployed so that the middle of the stent covers the first SEMS with 2-2.5 cm extending beyond the proximal and distal margins of the obstructing neoplasm.

Repeat SEMS placement is generally safe and does not cause complications. However, in a specific condition, this procedure can result in irreversible SEMS entanglement. SEMS entanglement can happen by the combination of two conditions: acute angulation of the duodenum and stenosis of the first SEMS that prohibits an endoscope from passing through it. Stenosis of the first SEMS makes practice totally dependent on fluoroscopy, and acute angulation causes a guidewire to touch the duodenal wall. These two conditions make it possible for a guidewire to pass through the mesh of the first SEMS. It is definite that the possibility for a guidewire to transverse the mesh depends more on the angle of a guidewire direction to the mesh wall than on the catheter diameter. Because of the acute angulation of the SEMS in the duodenum, this situation can happen in duodenal obstruction treated by repeat SEMS placement, with frequent misinsertion of the guidewire. Although the acute angulation of an SEMS and the duodenum is the major factor responsible for SEMS entanglement, we thought that a thin guidewire was also responsible for this complication. Because the tip of the guidewire is smaller than the pores of the mesh, it can transverse the mesh and misguide the second SEMS under these specific conditions. When it does occur, the entanglement leads the second SEMS remaining unexpanded and causes further occlusion. For avoiding entanglement of two SEMSs, it is important to push forward and pull back a guidewire repeatedly to ensure the correct position of the guidewire, before starting the insertion of a second SEMS. It is also necessary for the deployment of the new stent to be slow and under careful radiologic control, because most stents can be recovered in their own sheath during the deployment maneuvers, when difficulties are encountered. Adding to these important skills, using a stone extraction balloon can be considered instead of using an ordinary guidewire. When inflated, this system is larger than the pores of the mesh, and therefore, the stone extraction balloon is less likely to pass through the mesh. We used three steps to perform stone extraction balloon-guided repeat SEMS placement in the specific conditions mentioned before. First, we advanced the stone extraction balloon distal to the first SEMS. Second, we inserted the guidewire through the stone extraction balloon so that it was placed at the target area. Finally, we placed the second SEMS within the first one following the guidewire. When there was an acute angulation, and an endoscope was not able to pass through the first SEMS, it seemed easier and safer to perform repeat SEMS placement by the guidance of a stone extraction balloon under careful radiologic control with repeat push and pull of a guidewire.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in tahe field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology

Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
