Abstract

Almost all patients develop postoperative ileus (POI) after abdominal surgery. POI represents the single largest factor influencing length of stay (LOS) after bowel resection, and has great implications for patients and resource utilization in health care. New methods to treat and decrease the length of POI are therefore of great importance. During the past decade, a substantial amount of research has been performed evaluating POI, and great progress has been made in our understanding and treatment of POI. Laparoscopic procedures, enhanced recovery pathways and pharmacologic treatment have been introduced. Each factor has substantially contributed to decreasing the length of POI and thus LOS after bowel resection. This editorial outlines resource utilization of POI, normal physiology of gut motility and pathogenesis of POI. Pharmacological treatment, fast track protocols and laparoscopic surgery can each have significant impact on pathways causing POI. The optimal integration of these treatment options continues to be assessed in prospective studies.

Postoperative ileus: Impact of pharmacological treatment, laparoscopic surgery and enhanced recovery pathways. *World J Gastroenterol* 2010; 16(17): 2067-2074 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i17/2067.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i17.2067

INTRODUCTION

All patients with a bowel resection develop postoperative ileus (POI), an interruption of bowel function after surgery[1-4]. POI is characterized by a transient cessation of bowel function with a variable reduction in motility sufficient to prevent effective transit of intestinal contents[5]. POI is the single most important determinant of length of stay (LOS) after abdominal surgery, and thus has significant implications for individual patients and hospital resource utilization.

POI has been discussed by surgeons for more than two centuries[6,7]. In 1906, Finney divided POI into three subgroups according to pathophysiology: mechanical, septic and adynamic[8]. After a century of debate a conse-

nsus conference in 2006[5] proposed a definition of POI as: "transient cessation of coordinated bowel motility after surgical intervention, which prevents effective transit of intestinal contents or tolerance of oral intake". Primary POI was defined as such cessation occurring in the absence of any precipitating complication, whereas secondary POI was defined as that occurring in the presence of a precipitating complication (infection, anastomotic leak, *etc*.). Patients undergoing major abdominal surgery are at highest risk for developing POI, which is related to the degree and length of manipulation of the intestines. Other surgical procedures may also be associated with POI, such as cardiac surgery, orthopedic surgery and trauma[9-12]. In addition to surgery and trauma, postoperative opioid analgesics that are necessary to manage postoperative pain contribute significantly to the incidence of POI.

Clinically POI is characterized by the inability to tolerate a solid diet, delayed passage of flatus and formed stool, pain and abdominal distention, nausea, vomiting, and accumulation of gas or fluids in the bowel[9,13]. Several pharmacological substances have been introduced to treat or prevent POI[14-26]. There has however been little if any proven success in pharmacologic limitation of POI until the reports investigating selective antagonism of opioid receptors.

In addition to pharmacological treatment, fast track or enhanced recovery pathways (ERP) and laparoscopic surgery have introduced new dimensions in treatment of POI. ERP shorten the postoperative recovery period[27] and laparoscopic surgery shortens the average length of POI[28]. The objective of the present paper is to highlight POI and its consequences for patients and society, and the impact pharmacological treatment, laparoscopic surgery and ERP have upon the pathogenesis and duration of POI.

COST IMPLICATIONS OF POI

POI as a complication of major abdominal surgery can have a substantial clinical and economic impact. POI is associated with increased postoperative morbidity, reduced patient satisfaction, and increased length of hospital stay. Moreover, POI-related increases in LOS and use of resources translated into increased costs for the health care system[29]. It has been estimated that POI accounts for a significant amount of perioperative health care costs in the US[5], with estimated total hospital costs attributable to POI $1.28 billion[5].

A recently published study by Iyer *et al*[30] identified 17 000 patients undergoing colectomy in the US Premier Perspective database. The mean hospital LOS was significantly longer in patients with POI compared with patients without POI (13.8 d *vs* 8.9 d). POI in colectomy patients is a significant predictor of increased hospital resource utilization.

Clearly, reducing the LOS associated with POI has become a health care priority for the surgical community, with interventions reducing the LOS having great implications both for the individual patient and for hospital cost utilization.

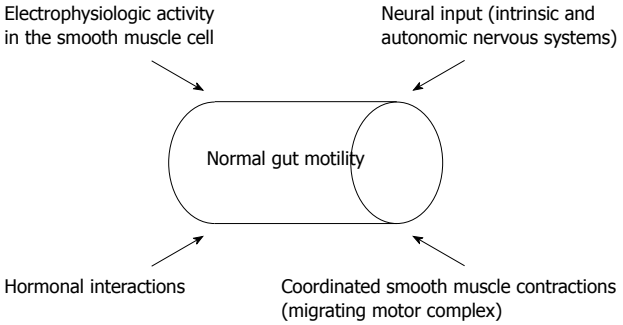

Figure 1 Normal physiology of gut motility.

Bell *et al*[31] recently published a paper, where the economic effect of the use of alvimopan in four randomized controlled trials (RCT) trials was analyzed. This paper used LOS data from the North American alvimopan trials, and calculated cost by extrapolation of cost from the Premier Perspective database, and cost of medication, using mathematical modeling techniques. Compared with placebo, alvimopan was associated with a significantly shorter mean time to gastrointestinal (GI) recovery and a mean hospital LOS of one full day less than placebo. The mean estimated hospital cost was $879-$977 less for patients who received alvimopan compared with placebo. Bell *et al*[31] suggest that use of alvimopan compared with placebo may have a cost-saving effect in the hospital setting. It is however unresolved if alvimopan is more cost effective than optimal use of laparoscopic surgery and ERP protocols, and further research is needed.

PATHOGENESIS OF POI

Normal bowel function is a complex interaction between GI motility, mucosal transport and defecation reflexes. The motility of the intestines is dependent upon the electrophysiological activity in the smooth muscle cells, neural input from the intrinsic and autonomic nervous system, hormonal interactions and coordinated smooth muscle interaction[32] (Figure 1). The migrating motor complex (MMC) has a central position in the normal gut motility[10,33]. The MMC is divided into four phases and regulates the gut motility (contractile pattern) between meals[34] and occurs approximately once every 1-2 h; Phase Ⅰ: Oscillating smooth muscle membrane potentials without actual muscle contractions. Phase Ⅱ: Occurrence of intermittent muscle contractions. Phase Ⅲ: Contractions increase to the maximal contractile frequency (i.e. stomach 3 contractions/min and duodenum 11 contractions/min). Phase Ⅳ: cessation of contractions, and the bowel returns to Phase Ⅰ.

In addition, the nervous system (enteric and central)[35], hormones[36] and smooth muscle activity play roles. Ingestion of food activates these mechanisms and turns off the MMC contractile pattern.

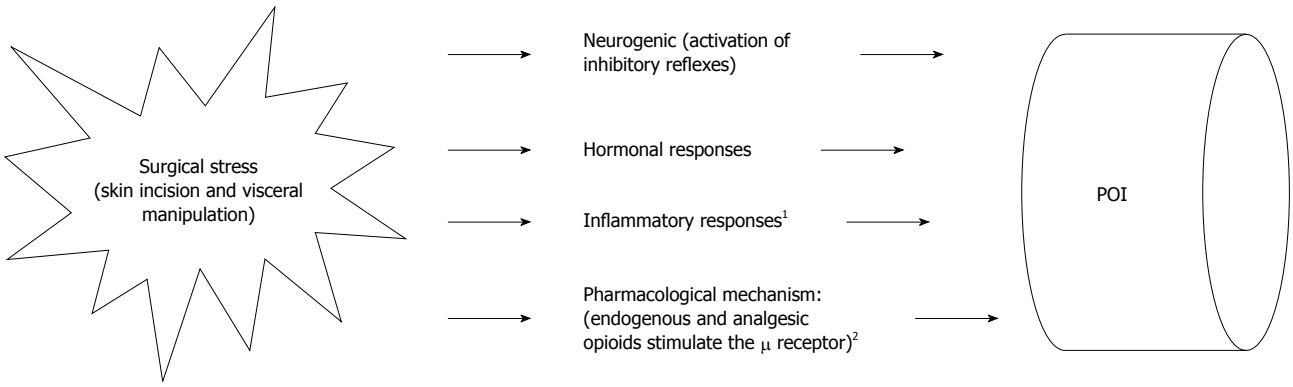

Figure 2 Pathogenesis of postoperative ileus. [1]Laparoscopic surgery decreases the surgical stress and inflammatory response; [2]Primarily exogenous opioids, e.g. morphine, binding to μ-receptors in the GI tract, which results in disorganized and non propulsive motility and, thus, prolongs ileus. In addition, activation of opioid receptors, which occurs following major abdominal surgery, inhibits acetylcholine release, reduces gastrointestinal motility, and has been demonstrated to play a key role in POI regulatory pathways[10,29,36-38]. Alvimopan inhibits this effect by blocking the pheripheral opioid μ receptor.

The interactions between these regulatory components are complex and much is unknown. Contractions in the colon differ from the small intestine, with irregular oscillations and contractile patterns[10,35].

Although multiple factors are thought to contribute to the pathogenesis of POI, four major pathways have been identified (Figure 2): (1) Neurogenic: surgical stress (i.e. skin incision and bowel manipulation) response stimulates inhibitory neural reflexes resulting in decreased bowel motility. This activation of inhibitory reflexes inhibits the normal MMC pattern and is activated as early as at the moment of skin incision (by somatic fibers) and from manipulation of the intestines (by visceral fibers)[37]; (2) Inflammatory: bowel manipulation and resection stimulates normally inactive macrophages and neutrophil recruitment with release of inflammatory mediators that reduce bowel motility; this includes endogenous opioid peptides. Manipulation also causes secretion of proinflammatory cytokines[37]. An increase in the degree of surgical manipulation leads to increased accumulation of neutrophils, macrophages, mast cells, T cells, natural killer cells and dendritic cells which in turn leads to increased inflammation in the intestine and tissue damage[32]. All these factors induce paralysis of the intestine and in turn POI; (3) Hormonal: surgical stress results in elevation of corticotrophin-releasing factor, which stimulates release of inflammatory mediators in the bowel[38]. In addition, a wide variety of local factors, hormones and neurotransmitters may play a role in POI (i.e. Substance P, Nitric Oxide and Calcitonin gene-related peptide CGRP)[10]; and (4) Pharmacologic: primarily exogenous opioids, e.g. morphine, binding to μ-receptors in the GI tract, which results in disorganized and non-propulsive motility and thus prolongs ileus. In addition, activation of opioid receptors, which occurs following major abdominal surgery, inhibits acetylcholine release, reduces GI motility, and has been demonstrated to play a key role in POI regulatory pathways[10,32,39-41].

Opioid-based regimens are the most common treatments to effectively manage post-surgical pain. However, morphine and other μ-opioid receptor agonists can prolong the duration of POI through delayed gastric emptying, reduced GI motility, and disrupted colonic myoelectric activity[42,43]. In addition to exogenous opioids, studies have suggested a role for endogenous opioid peptides in various postoperative responses, including ileus[43-46].

PHARMACOLOGICAL TREATMENT AND POI

Up to the year 2000, several pharmacological agents had been studied in order to prevent POI, however none of these agents was effective enough to become part of routine established practice[14-26].

Chewing sugarless gum following elective intestinal resection is associated with improved outcomes. Gum chewing is thought to promote physiological simulation of the cephalic-vagal axis, thereby increasing bowel motility and GI stimulation[47-49]. There exist two meta-analyses analyzing the effects of chewing gum[50,51], however, all of the included trials in these meta-analyses were small, and only two trials had an adequate sample size calculation.

The meta analysis showed an improvement in first time to bowel movement of 23 h and a reduction in LOS of 1.1 d, and is similar to the effect shown by alvimopan. An adequately powered, methodologically rigorous trial of gum chewing is however required to confirm if there are any benefits[52].

After five RCT, alvimopan represented a novel breakthrough in pharmacological treatment of POI. Alvimopan is a selective peripherally acting μ-opioid antagonist administered orally, blocking the μ-opioid receptor and minimizing the paralytic effect opiates have upon the intestines. The medication blocks the peripheral μ-receptor with high affinity, therefore minimizing the paralytic effect opiates have upon the intestines (Figure 2). This molecule is large and polar and therefore does not cross the blood brain barrier and therefore does not impair analgesia. During the last 5 years five RCTs have been conducted upon alvimopan and its effect upon POI[53-58]. In all these trials

Table 1 Overview of RCT trials 2004-2008 of alvimopan

Author	Number of patients	Primary end point	GI[2] improvement (h)	GI[3] improvement (h)	Hazard ratio	DCO improvement (h)
Wolff *et al*[57]	510	GI[3]	20.0[1]	15.0[1]	1.28[1]	13.0[1]
			28.0[2]	22.0[2]	1.54[2]	20.0[2]
Viscusi *et al*[56]	666	GI[3]	16.4[1]	7.5[1]	1.20[1]	14.2[1]
			13.7[2]	9.9[2]	1.24[2]	15.2[2]
Delaney *et al*[55]	451	GI[3]	15.2[1]	14.1[1]	1.45[1]	14.0[1]
			10.5[2]	7.5[2]	1.28[2]	7.2[2]
Ludwig *et al*[53]	654	GI[2]	20.0[2]	16.0[2]	1.50[2]	17.0[2]
Buchler *et al*[58]	911	GI[3]	14.3[1]	8.5[1]	1.18[1]	8.1[1]
			10.7[2]	4.8[2]	1.37[2]	5.9[2]

[1]6 mg alvimopan; [2]12 mg alvimopan. Hazard ratio: The ratio of two hazard rates. Hazard rate is defined as the probability to failure given survival to date. DCO: Discharge order; GI[2]: The time to recovery of GI function, a composite end points that represent full upper and lower recovery. i.e. time that the patient first tolerated solid food and time that the patient first passed a bowel movement; GI[3]: The time to recovery of GI function, a composite end points that represents full upper and lower recovery. i.e. time that the patient first tolerates solid food, or time that the patient first passes flatus or a bowel movement.

recovery of bowel function was enhanced, except one from Europe when lower opioid doses were used. The primary endpoints in these trials were time to recovery of GI function, measured as either GI[2] or GI[3], composite measures that were developed to track recovery of upper and lower GI function. In these trials GI[2] was defined as "the time that the patient first tolerated solid food and had passed a bowel movement". GI[3] was defined as "the time that the patient first tolerates solid food, and the patient first passes flatus or a bowel movement".

The results from these trials lead to Food and Drug Administration approval in May 2008. A summary of the trial results is shown in Table 1.

The definition of lower GI recovery has been controversial and debated, and up to date there exists no consensus upon this definition. All of the RCTs chose GI[3] as their primary endpoint for GI recovery, except the study by Ludwig *et al*[53], as GI[2] had been noted to be a more robust endpoint by the collaborative study group. GI[3] uses documentation of passage of flatus which can be subject to considerable variability[59], since the patient has to be conscious and willing to report it. In this way it was advocated that GI[2] is a more objective endpoint[53], i.e. a composite end point that was represented by the time the patient first tolerated solid food and time that the patient first passed a bowel movement. In the trial by Ludwig *et al*[53], GI[2] recovery was primarily driven by time to first bowel movement, as this was the later occurring of the two components of GI[2] recovery. In the RCTs there are no obvious dose response curves for alvimopan, and a dose of 12 mg does not give an increased GI recovery, although data were slightly more consistent through the trials (Table 1). This phenomenon is common for new drugs, particularly biologic agents, where effects on a receptor are not directly related to the concentration of the agent. These discrepancies may also be attributed to differing patient populations. However, a pooled analysis has shown that a 12 mg dose provided more consistent benefits across both sexes and all ages[54].

Alvimopan has had fewer side effects than placebo. Treatment adverse events reported in the published RCTs were most commonly nausea and vomiting, but these were less common in the alvimopan treated groups[60]. All studies on alvimopan have been conducted for open abdominal surgery.

Alvimopan will increase pharmacy expenditures; the cost of acquiring gum is substantially lower but more research is needed upon the effect of gum. Whether there is an additive effect upon GI recovery of pharmacological treatment (i.e. alvimopan and/or chewing gum) in combination with laparoscopic surgery and ERP protocols is unresolved.

LAPAROSCOPIC SURGERY AND POI

The greatest advance in limiting POI to date has probably resulted from the expanded use of laparoscopic surgery and the advantage of limiting tissue trauma. Recent studies suggest that laparoscopic surgery causes a lesser degree of mast cell activation and inflammation, and thus prolonged POI[61] (Figure 2). Laparoscopic surgery has many potential advantages over conventional open surgery, including smaller incisions, earlier GI recovery, shorter hospital stay and less pain[62].

Studies of large national databases suggest a higher rate for all commonly identified complications for open compared to laparoscopic colectomy. In a recent published study by Senagore *et al*[63], 4419 cases of open laparotomy were compared to 2728 cases of laparoscopy. All perioperative complications were more frequent in the open laparotomy group. Other database studies, identifying more than 30 000 cases of colectomies, shows superior results of laparoscopic colectomies compared to open cases[64]. Similarly, most other trials have demonstrated significant reductions in time to recovery of GI function after laparoscopic colectomy compared with open techniques, which translate into decreased hospital LOS. In a recent published study[28], mean GI recovery and LOS after laparoscopic colectomy were accelerated compared with those for patients in open laparotomy bowel resection.

Table 2 Effect of interventions to improve gastrointestinal recovery and reduce LOS

Trials	Type of study	Intervention	Improvement passage flatus	Improvement first bowel movement	Decrease in LOS
Noble *et al*[52]	Meta analysis	Chewing gum	14 h	23 h	1.1 d
Delaney *et al*[54]	Pooled analysis	Alvimopan	12 h[1] (6 mg) 15 h[1] (12 mg)	15 h[2] (6 mg) 18 h[2] (12 mg)	18.4 h[3]
Delaney *et al*[28]	Observational multicenter study	Laparoscopic surgery	NA	0.7 d[2]	1.7 d[3]
Walter *et al*[69]	Meta analysis	ERP	NA	NA	3.64 d

[1]Defined as GI[3]; [2]Defined as GI[2]; [3]Discharge order written. Standard elective open colorectal resection is usually associated with LOS of 8-12 d. Pharmacological treatment, laparoscopic surgery and ERP have substantially decreased LOS after surgery. LOS: Length of stay; ERP: Enhanced recovery pathways; NA: Not available.

The primary end points were time to upper and lower GI recovery (GI[2]: toleration of solid food and bowel movement) and postoperative LOS.

Overall POI-related morbidity (postoperative nasogastric tube insertion or investigator-assessed POI resulting in prolonged hospital stay or readmission) was similar between the open bowel resection and laparoscopic colectomy populations, suggesting that POI continues to cause significant morbidity regardless of the surgical approach[28].

Overall, there is substantial evidence that laparoscopic surgery helps accelerate GI recovery after surgery. Although the results in a study by Basse *et al*[65] did not show a benefit with laparoscopy, in our opinion the burden of evidence supports laparoscopic surgery as the standard approach when appropriate.

ERP AND POI

ERP have become part of the standardized postoperative recovery pathway at most hospitals. These protocols include many different elements and interventions, up to 20 elements in a recent published consensus review[66]. The main ERP elements are: avoidance of bowel preparation, preoperative fasting and carbohydrate loading, opioid sparing analgesia and mid thoracic epidural, antibiotic prophylaxis, laparoscopic surgery, small surgical incisions, no nasogastric tubes, normothermia, operative and postoperative fluid restrictions, no abdominal drains, suprapubic urinary drainage, oral diet at will, and early mobilization.

The benefits of fast track protocols (improved recovery, shortening of hospital stay, and earlier recovery of GI function) have been established in several RCTs[67]. Two systematic reviews of controlled and RCT supports the use of fast-track colorectal surgery[68,69]. ERP appear to be safe and shorten hospital stay 1-4 d after elective open colorectal surgery.

During the recent years, old dogmas have been challenged, such as keeping patients fasting after surgery. Allowing patients to eat normal food at will from the first day after major GI surgery does not increase morbidity, including the frequency of POI, when compared with traditional care with nil-by-mouth and enteral feeding[70]. LOS was reduced by approximately 3 d in the group allowed normal food at will. Similarly the use of a nasogastric tube after surgery has been debated. In fact routine nasogastric decompression does not accomplish any of its intended goals (including increased GI recovery) and so should be abandoned in favor of selective use of the nasogastric tube[71].

The best postoperative analgesic regime after surgery has been addressed in several trials, and is still debated. A recent published study advocates the use of thoracic epidural analgesia[72], however this conclusion is contested in a systematic review by Levy *et al*[73]. According to this review there is a paucity of data assessing the benefits of postoperative analgesic regimes following laparoscopic colorectal surgery and none of the protocols were shown to be clearly superior. Low *et al*[74] outlines the concerns of hypotension (increased risk of cardiovascular complications) and splanchnic hypoperfusion (increased risk of anastomotic leak) that are observed in connection with epidural analgesia. The best postoperative analgesic regime is therefore still unresolved; however epidural analgesic regime is included in most published ERP protocols, including a recent published consensus review[66]. Interestingly, while several randomized studies have suggested earlier recovery of GI function with epidurals, this has only been shown for opioid free epidurals, and has never translated into shorter hospital stay.

Over the last decade it has been increasingly realized that the pathophysiology of POI is multifactorial. Thus ideally ERP, and the care provided to colectomy patients should beneficially influence all four pathophysiologic pathways in the pathogenesis of POI (neurogenic, pharmacologic, hormonal, inflammatory, Figure 2)[75]. Although it is not yet clear which pathway is ideal, there is good consensus that fast track, ERP should be used at all modern hospitals, and included in all postoperative care.

FUTURE PERSPECTIVES

Standard elective colorectal resection is usually associated with a complication rate of 20%-30% and a postoperative stay of 8-12 d[67]. The introduction of pharmacological treatment, fast track protocols and laparoscopic surgery has changed this perspective (Table 2).

The introduction of laparoscopy in colorectal surgery improves early postoperative outcome, and randomized

trials have shown promising short term benefits with reduction of LOS by 3-4 d.

Despite rigorous research and several RCT trials during the past decade, the use of alvimopan is still debated, and for unclear reasons its incorporation into practice has been less than might be expected[76,77]. Several important questions remains unresolved, particularly the effect of alvimopan after laparoscopic surgery. After laparoscopic surgery, patients have less pain, lower opioid requirements and a shorter recovery time. It is unclear if alvimopan will have an additive effect upon the duration of POI and consequently LOS for this patient group.

Similarly, all of the alvimopan RCT studies were performed upon patients using a simple and standardized ERP protocol in the treatment and placebo groups. While ERP protocols may include up to 20 different elements, it is unclear which of these elements have the greatest impact upon POI and LOS. Similarly it is unclear what additive effect alvimopan may have upon POI and LOS for patients using ERP protocols. Recent studies[28,78,79] have however included fast track protocols in combination with laparoscopic surgery with promising results upon POI. Future POI research should address fast track protocols, laparoscopic surgery and pharmacological treatment, and the optimal combination of these interventions.

Abstract

The appropriate management of gallstones and gallbladder disease in patients undergoing gastric bypass remains unknown. Several therapeutic modalities are used and include performing cholecystectomy on all patients at the time of gastric bypass, performing concomitant cholecystectomy only when patients have gallstones and performing cholecystectomy only in the presence of both symptoms and gallstones. Some groups administer ursodeoxycholic acid for gallstone prevention in the postoperative period. All treatment modalities are analyzed and their results and rationality are discussed.

INTRODUCTION

Rapid weight loss after bariatric surgery is one of many known risk factors for gallstone development, along with age, female gender, parity, race, obesity, genetics, very-low-calorie diets, short bowel syndrome, gallbladder motor dysfunction, diabetes, drugs and gastrointestinal surgery, among many others[1-25].

Traditionally cholecystectomy was indicated only in the presence of both gallstones and symptoms, but recently some have advocated elective cholecystectomy in selected cases in the absence of symptoms and even in the absence of gallstones[26-29].

Sustained weight loss after gastric bypass is achieved by a combination of gastric restriction and a variable degree of malabsorption[30-32] and has therefore a greater risk for gallstone development than purely restrictive procedures like adjustable gastric banding[33-35]. The appropriate management of gallstones and gallbladder disease in these patients is still under debate and several therapeutic modalities are used[36], including simultaneous cholecystectomy to all patients at the time of gastric bypass, regardless of the presence or absence of gallstones and/or symptoms (prophylactic approach)[37], simultaneous cholecystectomy only to patients with gallstones (elective or selective approach)[38] and expectant management with or without the prophylactic administration of ursodeoxycholic acid until symptoms develop (conventional approach)[39].

The objective of the paper is to discuss the rationale and the results obtained with these therapeutic modalities.

PROPHYLACTIC APPROACH

This consists of performing simultaneous cholecystectomy on all patients at the time of gastric bypass, regardless of the presence or absence of gallstones and/or symptoms.

The rationale behind this approach is based on the elevated incidence of gallstone development after gastric bypass compared to the normal population and the low sensitivity and specificity of ultrasonography for detecting gallstones in patients with morbid obesity[37,40-42]. A minimal morbidity rate with the addition of cholecystectomy is required.

In the series of Fobi *et al*[37] abnormal findings in the gallbladder were found in 75% of surgical specimens despite a negative preoperative ultrasound. Most of these patients had gallstones but other findings include cholesterolosis and cholecystitis. The addition of cholecystectomy to open gastric bypass added only an average of 15 min and the authors report no specific morbidity related to it.

Nougou *et al*[43] found some pathology in nearly 82% of specimens after simultaneous cholecystectomy with laparoscopic gastric bypass. 8.3% of patients did not undergo simultaneous cholecystectomy because it was judged to be dangerous. In the remaining patients, cholecystectomy added only 19 min on average to the procedure, with no extra ports addition. The authors do not report specific morbidity related to cholecystectomy.

Guadalajara *et al*[41] performed simultaneous cholecystectomy on 89 patients undergoing open gastric bypass and found a postoperative incidence of gallstones of 24% while the preoperative ultrasound incidence was only 16%.

Liem *et al*[44] performed simultaneous cholecystectomy on all patients undergoing open gastric bypass and found an incidence of gallbladder pathology of 80%.

A summary of these results is presented in Table 1.

ELECTIVE/SELECTIVE APPROACH

This consists of performing simultaneous cholecystectomy only on patients with asymptomatic gallstones diagnosed pre or intraoperatively.

The rationale behind this approach is based on an assumed higher incidence of symptomatic gallbladder disease in patients with gallstones in comparison to those without them. Some groups administer prophylactic ursodeoxycholic acid to patients without gallstones and therefore not submitted to concomitant cholecystectomy. A low morbidity rate is also required to support this approach.

Hamad *et al*[38] performed simultaneous cholecystectomy on 16.9% of patients at the time of gastric bypass. Operative times were significantly longer for patients undergoing simultaneous cholecystectomy and total hospital stay was almost doubled in comparison to gastric bypass without concomitant cholecystectomy. A significantly higher major morbidity rate was observed for patients undergoing simultaneous cholecystectomy but no specific morbidity was directly related to it. The most common pathological finding in the specimens was cholecystitis (99% of the cases). All patients without simultaneous cholecystectomy received 300 mg of ursodeoxycholic acid twice a day orally for a 6 mo period. During follow up 2.3% of these patients developed symptomatic gallstone disease and required cholecystectomy after an average of 12.4 mo.

Villegas *et al*[45] performed simultaneous cholecystectomy on 14% of patients after intraoperative diagnosis of gallstones or sludge with the aid of laparoscopic ultrasound. The global need for a subsequent cholecystectomy was 7%. Patients completing prophylactic ursodeoxycholic acid treatment had a significantly lower need of subsequent cholecystectomy.

In the series of open gastric bypass of Caruana *et al*[46] the diagnosis of gallstones was made by intraoperative palpation of the gallbladder. The authors did not report significant morbidity related to the addition of cholecystectomy. A subgroup of 125 patients that did not undergo simultaneous cholecystectomy was followed for at least 16 mo, requiring 8% of them to have a subsequent cholecystectomy for symptomatic gallstone disease.

Ahmed *et al*[47] retrospectively analyzed a series of 400 consecutive patients and found only significant differences in terms of operative times, which were 29 min longer for patients undergoing simultaneous elective cholecystectomy. No information about the incidence of symptomatic gallstone disease in the population without simultaneous elective cholecystectomy is given.

The group of the Universidad Católica de Chile reports a rate of simultaneous elective cholecystectomy of 10.9%[48]. The only significant differences were found for operative times, which were higher for the population undergoing simultaneous elective cholecystectomy. No information regarding the incidence of symptomatic gallstones in the population without simultaneous elective cholecystectomy was given.

Taylor *et al*[49] performed simultaneous cholecystectomy on 15% of patients. They reported the lowest need for subsequent cholecystectomy without the administration of prophylactic ursodeoxycholic acid, with only 3% of patients requiring it.

Tucker *et al*[50] performed simultaneous cholecystectomy on 7.2% of patients. A subgroup of patients was not submitted to this approach although they had gallstones present at the time of gastric bypass. The need for subsequent cholecystectomy in these patients was 17.6% whereas for patients without gallstones at the time of gastric bypass it was 6%.

A summary of these results is presented in Table 1.

CONVENTIONAL APPROACH

This consists of performing cholecystectomy only in the presence of both gallstones and symptoms, following the present guidelines for gallstone disease management[51,52]. The rationale behind this approach is to

NA: Not applicable; NR: Not reported.

indicate cholecystectomy only for the patients requiring it and since most of the subsequent cholecystectomies are performed when a significant weight loss is achieved, the operation is done in a leaner and healthier patient.

Swartz *et al*[53] found an incidence of subsequent cholecystectomy of 14.7%, with a significant lower incidence for patients completing prophylactic ursodeoxycholic acid treatment. In Fuller and coworker's experience, the need for subsequent cholecystectomy in patients completing prophylactic ursodeoxycholic acid treatment was 7.69%[54].

Ellner *et al*[55] and Portenier *et al*[56] did not administer prophylactic ursodeoxycholic acid treatment and found an incidence of subsequent cholecystectomy of 9% and 8.1%, respectively.

Papasavas *et al*[39] did an interesting study in which they retrospectively reviewed the records of 644 patients undergoing gastric bypass without simultaneous cholecystectomy. All of them received postoperative prophylactic ursodeoxycholic acid treatment. The need for a subsequent cholecystectomy in patients with gallstones present at the time of gastric bypass was 8.3%, which is similar to the incidence observed for patients without gallstones (6.9%) and to the incidence for patients without preoperative ultrasound screening (8.3%). After obtaining these results, this group no longer screens for gallstones preoperatively. Similarly, Patel *et al*[57] at the UCLA School of Medicine found an incidence of subsequent cholecystectomy without preoperative screening and without postoperative ursodeoxycholic acid administration of 6%. A subsequent analysis by the same group with a longer follow up showed an even lower rate of subsequent cholecystectomy of 4.9%[58].

In our experience at Cosme Argerich Hospital from Buenos Aires, the global need for cholecystectomy after gastric bypass, without prophylactic ursodeoxycholic acid treatment, was 9.84% (unpublished data). For patients with gallstones present at the time of surgery a subsequent cholecystectomy was needed in 5% and for patients without gallstones in 10.71% (*P*: not significant). Based on our own data, the natural history of patients with asymptomatic gallstones undergoing gastric bypass is very much like the natural history of asymptomatic gallstones in the general population[59-61].

A summary of these results is presented in Table 1.

URSODEOXYCHOLIC ACID TREATMENT

The preventive administration of ursodeoxycholic acid proved to be significantly better than placebo in preventing gallstone formation in a double blind, prospective and randomized study conducted by Sugerman *et al*[62]. A daily dose of 600 mg was associated with the lowest rate of gallstone formation and the lowest incidence of adverse events. Patients that developed gallstones showed a lower compliance rate. The effect of the 6 mo treatment seems to last for at least 1 year, since at that moment patients were reevaluated with ultrasonography and the incidence of gallstones was significantly less compared to the placebo arm. Unfortunately, there is no mention in the study regarding how many of those patients that developed gallstones were actually symptomatic and therefore required cholecystectomy, since the actual standard of care for non-obese patients indicates a cholecystectomy only when both symptoms and gallstones are present (SSAT NIH). A true benefit for ursodeoxycholic acid would be a lower rate of delayed cholecystectomy over the placebo group.

Wudel *et al*[63] compared, in a randomized double-blind fashion, a cohort of 60 patients without gallstones at the time of open gastric bypass and prescribed them

a 6-mo course of ursodeoxycholic acid, ibuprofen or placebo. 71% of the patients subsequently developed gallstones and no benefit of the two therapies investigated could be demonstrated because of an extremely low compliance rate of 28%.

A recently published meta-analysis by Uy *et al*[64] concluded that ursodeoxycholic acid administration prevents gallstone formation after bariatric surgery, but no meta-analysis of symptomatic gallstones could be done, since only one paper addressed this topic and unfortunately did not include patients undergoing gastric bypass[65].

CONCLUSION

Prophylactic and selective management can be safely performed and the only significant difference with patients not submitted to concomitant cholecystectomy is mostly observed in operative times that are higher in those who do undergo cholecystectomy. Data obtained from conventional management studies, with or without ursodeoxycholic acid administration, show that most of the patients remain asymptomatic even when they develop gallstones and therefore do not require a subsequent cholecystectomy, so that the risks of performing a concomitant cholecystectomy might be unwarranted. Treatment with ursodeoxycholic acid prevents gallstone formation after gastric bypass but most of the studies conducted show a low compliance rate and do not mention the true benefit of the treatment, which would be a lower cholecystectomy rate.

Abstract

Inflammation is a primary defense process against various extracellular stimuli, such as viruses, pathogens, foods, and environmental pollutants. When cells respond to stimuli for short periods of time, it results in acute or physiological inflammation. However, if the stimulation is sustained for longer time or a pathological state occurs, it is known as chronic or pathological inflammation. Several studies have shown that tumorigenesis in the gastrointestinal (GI) tract is closely associated with chronic inflammation, for which abnormal cellular alterations that accompany chronic inflammation such as oxidative stresses, gene mutations, epigenetic changes, and inflammatory cytokines, are shared with carcinogenic processes, which forms a critical cross-link between chronic inflammation and carcinogenesis. Transforming growth factor (TGF)-β is a multi-potent cytokine that plays an important role in regulation of cell growth, apoptosis and differentiation. Most importantly, TGF-β is a strong anti-inflammatory cytokine that regulates the development of effector cells. TGF-β has a suppressive effect on carcinogenesis under normal conditions by inhibiting abnormal cell growth, but on the other hand, many GI cancers originate from uncontrolled cell growth and differentiation by genetic loss of TGF-β signaling molecules or perturbation of TGF-β adaptors. Once a tumor has developed, TGF-β exerts a promoting effect on the tumor itself and stromal cells to enhance cell growth, alter the responsiveness of tumor cells to stimulate invasion and metastasis, and inhibited immune surveillance. Therefore, novel development of therapeutic agents to inhibit TGF-β-induced progression of tumor and to retain its growth inhibitory activities, in addition to anti-inflammatory actions, could be useful in oncology. In this review, we discuss the role of TGF-β in inflammation and carcinogenesis of the GI tract related to abnormal TGF-β signaling.

TRANSFORMING GROWTH FACTOR-β IN HOMEOSTASIS AND INFLAMMATION OF GASTROINTESTINAL TRACT

The gastrointestinal (GI) tract is composed of the esophagus, stomach, small intestine and large intestine; it is the longest and largest surface among human organs, and is the first contact place for various pathogens and food antigens. Therefore, the GI tract should have many lymphoid organs to control the untoward or harmful immune reactions. The immune system of the GI tract can induce a series of host defensive reactions such as recruitment of immune cells, activation of anti-inflammatory enzymes, and secretion of anti-inflammatory cytokines[1]. To prevent pathological inflammation against various antigens exposed to the GI tract, the human body has developed various regulatory mechanisms: the development of regulatory T (Treg) cells, the maintenance of the gut barrier, and immune reactions. Since the inflammatory process in the GI tract is started by food antigens, extracellular pollutants and pathogenic infections, disruption of the intestinal barrier results in intestinal inflammation by inducing the pro-inflammatory reactions of immune cells[2].

Therefore, in order to maintain homeostasis of the GI tract, tolerance is a prerequisite to maintain the balance between pro-inflammation and anti-inflammation. Although many types of regulatory immune cells perform their suppressive functions in the GI tract to acquire tolerance, this activity is mediated by a relatively small number of materials including interleukin (IL)-10 and transforming growth factor (TGF)-β, which are well known regulators of immune reactions in the GI tract[3,4].

TGF-β is a multifunctional cytokine with critical roles in many cellular pathways including cell growth, apoptosis, differentiation and immune reactions[5,6]. TGF-β is secreted as a latent inactive protein and needs to be activated *via* conformational change or protein cleavage by protease or thrombospondins. Since TGF-β1 knockout mice show a dramatic phenotype and develop severe autoimmunity that leads to death within 2 wk after birth[7,8], and T-cell specific disruption of TGF-β signaling results in serious inflammatory changes through constitutively activated T cells in the gut and lung, as a similar phenotype to whole TGF-β knockout mice[9], TGF-β is thought to be a strong anti-inflammatory cytokine. In the regulation of intestinal inflammation, TGF-β inhibits T-cell proliferation as well as blocking differentiation of $CD4^+$ and $CD8^+$ naïve T cells into helper T cells by inhibiting expression of the transcription factors such as T-bet, STAT4 and GATA-3[10]. Furthermore, TGF-β suppresses immune reactions through the induction of Treg cells. In fact, TGF-β has been shown to be essential for the induction and maintenance of peripheral $CD4^+CD25^+$ Treg cells by activation of Foxp3 expression[11].

However, TGF-β also has pro-inflammatory effects through the differentiation of Th17 cells by induction of retinoic-acid-receptor-related orphan nuclear receptor γt, a Th17-specific transcription factor[12]. Conclusively, cross-talk with surrounding tissues may be important for activity of TGF-β in GI tract inflammation. TGF-β has a critical role in regulation of inflammatory processes, therefore, it should be tightly regulated by various mechanisms. Dysregulated or attenuated TGF-β signaling has been suspected in the pathogenesis of various inflammation-related diseases including chronic inflammatory disorders and cancer. T-cell specific deficiency of furin, which activates latent TGF-β, leads to spontaneous autoimmune disease such as colitis and intestinal inflammation in murine models[13]. Similarily, overexpression of mutant TGF-β, which has a defect in binding activity with integrins, shows similar phenotypes to TGF-β null mice, such as vascular defects, multi-organ inflammation, and lack of Langerhans cells[14].

Disruption of Smad3 in mice also shows defects in mucosal immunity and results in early death after birth. Smad3 mutant mice exhibit large amounts of infiltration of T cells and bacterial abscess formation in the GI tract[15]. Activation of Smad3 in patients with inflammatory bowel disease (IBD) is diminished compared to unaffected persons. Isolated cells from IBD patients do not respond to treatment with TGF-β, and do not activate phosphorylation of Smad3, even in the presence of high concentrations of TGF-β[16,17]. In addition, interaction between Smad3 and Smad4 is markedly decreased in lamina propria mononuclear cells of IBD patients. All of these pathogenic phenotypes seem likely to originate from overexpression of Smad7, which is inhibitory for TGF-β signaling. The anti-inflammatory activity of TGF-β comes from inhibition of nuclear factor (NF)-κB activation, but it is lost in the intestine of IBD patients due to high levels of Smad7[18]. An *in vitro* mouse model of colitis treated with trinitrobenzene sulfonic acid or oxazolone shows similar results to those in humans[19]. When anti-sense oligonucleotide against Smad7 is given to mice to reduce the level of Smad7, TGF-β-induced phosphorylation of Smad3 is markedly increased. Conversely, the inflammatory phenotypes of the colon, such as weight loss and microscopic changes, are recovered to normal states after treatment with Smad7 antisense nucleotides. These data indicate that precise regulation of TGF-β signaling, including activation of Smad3 and level of Smad7, is important for homeostasis during inflammation of the GI tract. In contrast to these data, Smad7 also has anti-inflammatory activity against tumor necrosis factor (TNF) signaling and mediates the suppressive activity of TGF-β in primary macrophages and mouse skin[20]. This discrepancy might originate from

differences in cell lines, mouse strains, and experimental systems.

TGF-β LIGANDS AND THEIR SIGNALS

TGF-β sends signals through the heterodimeric complex formation of type I and type Ⅱ serine/threonine kinase receptors. When the ligands interact with receptor Ⅱ, type I receptor is activated by phosphorylation of serine residues. Activated receptor complexes recruit the adaptor proteins, receptor-activated Smad proteins (R-Smad). For example, Smad2 and Smad3 are R-Smad proteins for TGF-β and Smad1, Smad5 and Smad8 are R-Smad proteins for bone morphogenic protein signaling. R-Smad proteins have two conserved domains that are separated by a middle linker domain. The MH1 domain of the N-terminal region functions as a DNA-binding domain and the C-terminal of the MH2 region regulates the nuclear localization and transcriptional activity of R-Smad proteins. Receptor-mediated phosphorylation of C-terminal serine residues induces activation and nuclear translocation of R-Smad proteins. Activated R-Smad proteins form a complex with common Smad (co-Smad) protein, Smad4. The interaction between R-Smad and co-Smad proteins is mediated through the MH2 domain and induces the translocation into the nucleus of Smad complexes. In the nucleus, Smad complexes interact with Smad binding elements (SBEs) of target genes and regulate the transcriptional activity. TGF-β upregulates or downregulates the expression of target genes, which depend on Smad-interacting partners, coactivators or corepressors[6].

CROSS-LINKING BETWEEN INFLAMMATION AND GI CARCINOGENESIS

Relationship between chronic inflammation and carcinogenesis was originally suggested by Virchow, who first hypothesized in 1893 that the lymphoreticular infiltrate may be the origin of tumor at sites of chronic inflammation. Over 100 years later, his hypothesis was cited as evidenced that chronic inflammatory conditions definitely promote progression of malignant tumors. Inflammatory cells and cytokines act as a tumor promoter that affects cell survival, proliferation, invasion, angiogenesis and chemo-resistance[21-23]. Almost 15% of cancers are reported to occur through chronic inflammation-related processes (Table 1). We have established animal models of GI tumors, all of which were based on the concepts that inflammation leads to tumorigenesis, Barrett's esophagus originates through repeated reflux-induced inflammation in the esophagus, colitic tumors arise from repeated bouts of colitis, and gastric cancer is associated with *Helicobacter pylori* (*H. pylori*) infection.

Reflux esophagitis and esophageal cancer

More than 500 000 patients are diagnosed with esophageal cancer annually, which has the second highest mortality after pancreatic cancer among GI cancers worldwide. The most typical type of esophageal cancer is, in histological terms, squamous epithelial carcinoma, and Asians have a greater prevalence of this histological type of carcinoma than adenocarcinoma. On the other hand, Caucasians have just as many cases of adenocarcinoma as squamous carcinoma[24,25]. Many reasons to explain such differences can be put forward, including lifestyle and genetic factors, but in particular, Barrett's esophagus results in a great discrepancy in incidence between Western and Asian populations. Since the numbers of reflux esophagitis patients are rapidly increasing in Korea, as lifestyle as well as living environment have changed to more western styles, in the near future, it is expected that esophageal adenocarcinoma will be more prevalent among Koreans. Esophageal adenocarcinoma is closely related to Barrett's esophagus, therefore, carcinogenesis has the order of chronic reflux esophagitis followed by Barrett's esophagus and esophageal adenocarcinoma. Reflux esophagitis leads to chronic esophagitis and an increase in Barrett's esophagus, which directly creates a precancerous lesion, for which we have demonstrated that chronic exposure to gastroduodenal contents through duodenoesophageal anastomosis leads to metaplastic changes in the squamous epithelium (Figure 1). Molecular factors related to reflux esophagitis are as follows: increase in cyclooxygenase-2 (COX-2), IL-8, IL-1β, IL-10 and TNF-α; loss of TGF-β signaling; and activation of NF-κB. All of these contribute to development of Barrett's esophagus. This mediates chronic inflammation that increases expression of CDX-like homeobox family genes and the caudal gene family, which results in intestinal metaplasia of squamous epithelial cells. Intestinal metaplasia is the direct cause of esophageal adenocarcinoma and because it shares similar molecular mediators with chronic esophagitis, it is thought to be involved in carcinogenesis[26,27]. Barrett's esophagus is thought to be a precancerous lesion because of the appearance of the following changes: augmentation of the cell cycle and proliferation, increased angiogenesis and aneuploidy, decreased antiproliferative signaling and apoptosis, accompanied by the histological changes involved in the progression from chronic esophagus to Barrett's esophagus.

Table 1 GI tumorigenesis associated with chronic inflammation

	Tumor	Causes
Infection-related		
Chronic gastritis	Gastric cancer	*H. pylori*
Chronic gastritis	Gastric cancer	Cytomegalovirus
Prostate inflammatory atrophy	Prostate cancer	Pathogens
Chronic hepatitis	Hepatocellular cancer	HBV and HCV
Infection-unrelated		
Esophagitis	Esophageal cancer	Gastric acid, alcohol, tobacco
Pancreatitis	Pancreatic cancer	Alcohol, tobacco
IBD	Colorectal cancer	Crohn's disease, UC
Cholecystitis	Gall bladder cancer	Gall bladder stone

GI: Gastrointestinal; *H. pylori*: *Helicobacter pylori*; HBV: Hepatitis B virus; HCV: Hepatitis C virus; UC: Ulcerative colitis; IBD: Inflammatory bowel disease.

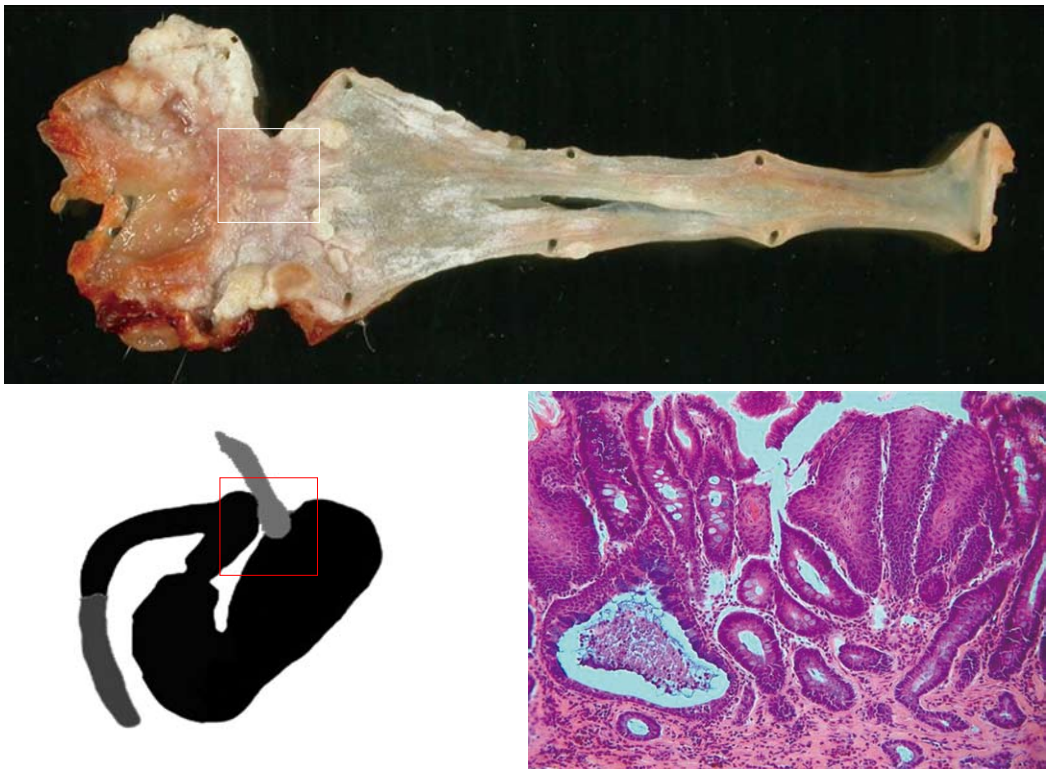

Figure 1 Connection between inflammation and carcinogenesis as demonstrated in a rat model of Barrett's esophagus. With the application of surgical bypass, esophagoduodenostomy (red boxed), overt discolored lesions (white boxed) were noted at the esophagogastric junction, which showed the existence of intestinal metaplasia against a background of squamous epithelium. These animal models provided evidence of the cross-linking between inflammation and premalignant lesions.

Chronic pancreatitis and pancreatic cancer

Pancreatic cancer has the poorest prognosis among GI cancers because patients are diagnosed at a fully progressed stage, and the tumor cells are very aggressive, so that metastasis is very frequent and they do not respond to anti-cancer therapy. Chronic pancreatitis patients have a 3.8-18.5 times higher chance of developing pancreatic cancer[28]. However, severe chronic pancreatitis cannot be discriminated from pancreatic cancer, especially in cases with a history of smoking and alcohol consumption, and a family history. Continuation of chronic pancreatitis for long periods can create a cancer-like molecular environment, such as activation of COX-2, NF-κB and inducible nitric oxide synthetase, production of cytokines such as IL-1, IL-6, IL-8 and TNF-α, and free radical oxygen formation[29,30]. TGF-β plays such an important role in regulating onset of chronic pancreatitis, and we have shown that lack of TGF-β in pancreatic acinar cells leads to increased sensitivity to acute pancreatitis, as well as a favorable environment for chronic pancreatitis.

Chronic atrophic gastritis and gastric cancer

Although there has been a tendency towards a decrease in gastric cancer for the past 80 years, it is still the second highest cause of death following lung cancer. In Korea, about 25-30 people out of every 100 000 develop gastric cancer regardless of their sex, and its mortality rate is ranked as the highest. However, the discovery of a causative pathogen of gastric cancer, *H. pylori*, has raised hopes for preventing gastric cancer through eradication or regulation of the bacterium. The International Agency for Research on Cancer in 1994 defined *H. pylori* as an imminent carcinogenic pathogen, based on epidemiological research and animal studies. This definition is based on epidemiological evidence, and several animal experiments have shown that infection with *H. pylori* causes infiltration of inflammatory cells, oxidative damage and gene mutations. In resected specimens from gastric cancer, the intestinal metaplastic lesions are easily identified around the cancer lesions, with which *H. pylori* infection is closely associated. Although *H. pylori* is a class I carcinogen, gastric cancer is not prevented by *H. pylori* eradication in all patients. This can be explained by the relationship between gastritis, metaplasia and gastric cancer, whereby prevention of *H. pylori*-associated carcinogenesis only benefits those in whom the malignant process has not begun[31]. That is, even though *H. pylori* is completely eradicated, gastric inflammation remains, thus it seems that amelioration of gastric inflammation itself seems to be far more essential in achieving cancer prevention than eradication of the pathogen. This emphasizes that chronic gastritis has a greater chance of causing onset of gastric cancer than the presence of *H. pylori* itself. Furthermore, genetic factors, toxicity of the pathogen, and environmental factors are intertwined in the development of *H. pylori*-induced gastric cancer from inflamma-

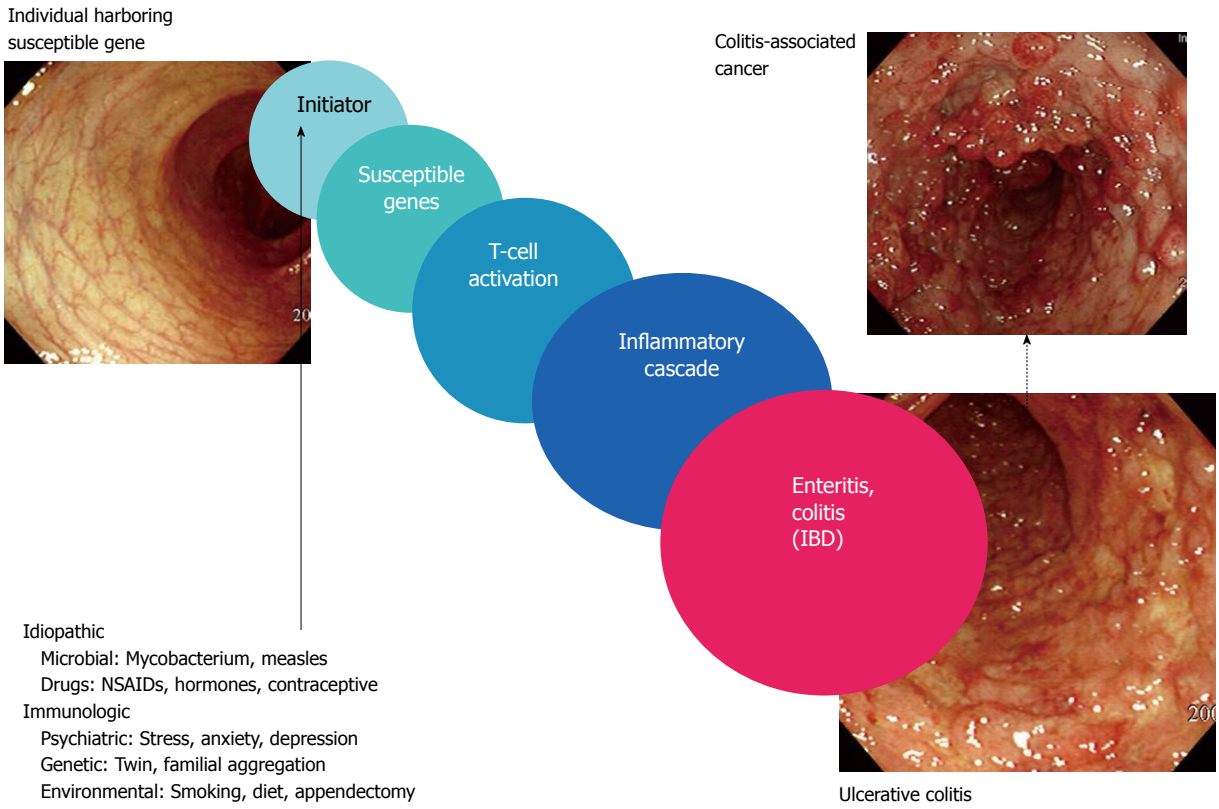

Figure 2 Inflammatory bowel disease (IBD) and colitis-associated cancer. The cause of IBD is idiopathic because several etiologies have been suggested including microorganisms, drugs, psychiatric illness, genetic abnormality, and environmental factors. However, when individuals that harbor IBD susceptibility genes are exposed to the above-mentioned etiological factors, they experience T cell activation, after which perpetual inflammatory cascades lead to enteritis or colitis. Repeated bouts of chronic colitis alone provoke colitis-associated cancer, which emphasizes the cross-linking between inflammation and carcinogenesis. NSAIDs: Nonsteroidal antiinflammatory drugs.

tion, thus alleviation or treatment of inflammation could form the basis of prevention of gastric cancer[32,33]. The contribution of TGF-β to *H. pylori*-associated gastric carcinogenesis has been investigated using pS2-dnR Ⅱ mice, which are defective in TGF-β signaling due to expression of the dominant negative R Ⅱ receptor (TGF-β-dnR Ⅱ) in the stomach, using gastric specific promoter pS2 (gastric trefoil peptide). pS2-dnR Ⅱ mice developed gastric adenocarcinoma with *H. pylori* alone compared to their wild-type littermates, which suggests that the development of gastric cancer after *H. pylori* infection might be influenced by host genetic conditions[34].

IBD and colitis-associated cancer

The most common cause of colorectal cancer is sporadic. However, 10%-15% of these patients continually suffer from chronic IBD for 10 years, which later develops into colitis-associated cancer, namely, colitic cancer. Ulcerative colitis (UC) is a form of chronic IBD that usually has a clinical course of repeated exacerbation and remission, and less commonly presents with an unremitting, fulminating course. Another feature of the clinical course of UC is an increase risk for the development of colitic cancer (Figure 2). Although sporadic colorectal cancer and colitic cancer arise from dysplastic precursor lesions and share several molecular alterations, the nature of the dysplasia and the frequency and timing of several of the key molecular changes differ sufficiently to support our hypothesis that colitic cancer can be prevented by early intervention with strong anti-inflammatory agents or cancer surveillance with strict biomarkers. Etiologically, in the case of sporadic colorectal cancer, most cases are preceded by adenomatous polyps, namely adenoma, followed by the so-called "adenoma-carcinoma" sequence[35]. On the other hand, colitic cancer is contracted at a relatively young age and the crucial factor is the range, extent and period of inflammation, which implies the "inflammation-dysplasia-carcinoma" sequence. Considering the fact that the number of IBD patients is increasing, in the forthcoming 10 years, inflammation-related cancer is expected to increase, thus we should be focusing on cancer prevention through control of inflammation. We have studied colorectal cancer prevention based on an animal model of inflammation-related cancer, and are working on how the control of inflammation itself prevents colorectal cancer. We have performed another similar animal model with repeated bouts of colitic cancer and have shown that potent anti-inflammatory drugs inhibit cancer formation. This suggests that colitis is involved at the beginning as well as the progression of cancer, and control of inflammation is one of the methods for preventing inflammation-related colorectal cancer.

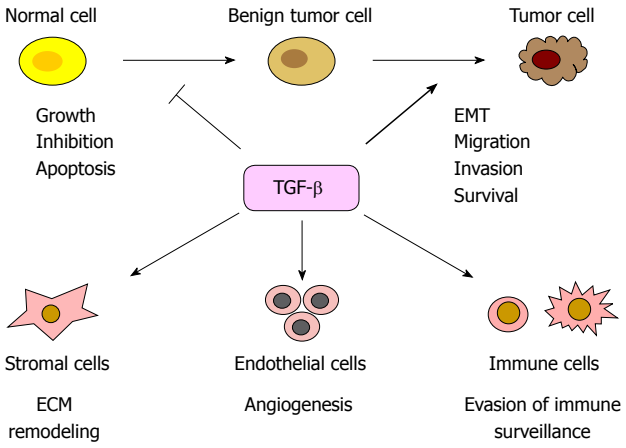

Figure 3 Role of transforming growth factor (TGF)-β in cancer progression. TGF-β is a secreted polypeptide that signals *via* receptor serine/threonine kinases and intracellular Smad effectors. TGF-β inhibits proliferation and induces apoptosis in various cell types. Accumulation of loss-of-function mutations in the TGF-β receptor or Smad genes classifies the pathway as a tumor suppressor in humans. In addition, various oncogenic pathways directly inactivate the TGF-β receptor-Smad pathway, thus favoring tumor growth. On the other hand, all human tumors overproduce TGF-β whose autocrine and paracrine actions promote tumor cell invasiveness and metastasis. Accordingly, TGF-β induces epithelial to mesenchymal transition (EMT).

TGF-β IN GI CARCINOGENESIS

TGF-β signaling is a crucial regulator of intestinal homeostasis and inflammation, therefore, dysregulation of this pathway could be associated with inflammation-related carcinogenesis of the GI tract (Figure 3). Altered signaling pathways can disturb the regulatory mechanism of TGF-β to block chronic inflammation followed by carcinogenesis. As a tumor suppressor gene, TGF-β can inhibit initiation of cell transformation, through growth inhibition and apoptosis in normal epithelium. During changes in the genetic and epigenetic context of transforming cells, the responsiveness of cells to TGF-β is decreased, but the expression and activation of TGF-β are markedly increased[36].

Mouse models have been used to investigate the role of TGF-β in GI inflammation and tumorigenesis. Heterozygotic TGF-β null mice express only 10%-30% of wild-type TGF-β1 protein level, and show increased cell turnover with chemical carcinogens, which results in enhanced tumorigenesis compared with wild-type mice[37]. Furthermore, TGF-β1/Rag2 double knockout mice can live for a long time and develop colon cancer after developing inflammatory lesions[38]. Mutations of TGF-β receptor Ⅱ (TGF-β-RⅡ) are frequently found in colon and gastric cancer with microsatellite instability[39]. Conditional transgenic mice using TGF-β-dnRⅡ with pS2/TFF1 promoter were created and infected with *H. pylori*, and they developed dysplasia as well as adenocarcinoma, which suggests that disruption of TGF-β signaling is related to gastric cancer formation[34]. The findings that TGF-β-dnRⅡ mice have higher levels of gastritis than their wild-type littermates, suggests that TGF-β1 plays an important role in prevention of gastric inflammation as well as cancer. An experiment for inducing IBD was performed on mice that overexpressed TGF-β-dnRⅡ in the small/large intestine using the promoter of ITF (intestinal trefoil factor)/TFF3. TGF-β-dnRⅡ mice showed much more severe colitis than their wild-type littermates when induced with the same concentration of dextran sulfate sodium[40].

Some pancreatic and biliary adenocarcinomas originate from mutation of TGF-β receptor Ⅰ (TGF-β-RⅠ) with very low frequency[41]. In a mouse model, mutation or deletion of bone morphogenetic protein receptor, which is another member of the TGF-β superfamily, also induces chronic inflammatory phenotypes and then precancerous lesions[42].

Deletion of Smad proteins also leads to loss of the regulatory role of immune suppression and induces malignant cell proliferation. Deficiency of Smad4 in mutant mice causes gastric polyps and progression to gastric tumor in old age[43]. In humans, deletion of Smad4 is found in juvenile polyposis syndrome and is a strong risk factor for GI cancer[44]. In addition, T-cell specific deletion of Smad4 results in spontaneous epithelial cancer of the oral cavity, stomach, colon, rectum and duodenum in mice[45]. Smad3 knockout mice also develop metastatic colorectal cancer through dysregulation of cell proliferation. The expression of Smad3 shows low to undetectable levels in 40% of human gastric cancer tissues[46]. Reintroduction of Smad3 into gastric cancer cells restored their responsiveness to TGF-β and blocks tumor formation in nude mice. These data support the suggestion that Smad-mediated TGF-β signaling regulates homeostasis and inflammation in the GI tract.

Mutations in fine tuning of regulatory circuits cause the loss of normal communication within target organs, and defects in regulating stromal and epithelial interactions. In addition to Smad proteins, cofactors of TGF-β signaling can also affect the biological roles of TGF-β and the progress of GI carcinogenesis. Based on mouse model studies, mutations of these cofactors, such as embryonic liver fodrin (ELF), promyelocytic leukemia tumor suppressor, Smad anchor for receptor activation, and filamin lead to malformation of intestinal structures and induce the formation of liver, gastric and colon cancers. In case of ELF, 40%-70% of heterozygotic null mice develop hepatocellular cancer within 15 mo through abnormal angiogenesis or cyclin D1 activation[47,48].

In contrast to its tumor suppressive activity, expression of TGF-β1 is markedly increased in colon, esophageal, gastric, hepatocellular and pancreatic cancer[49]. High levels of TGF-β expression are correlated with tumor progression, metastasis and angiogenesis, which results in poor prognostic outcome. In addition to its oncogenic nature related to TGF-β mutation, TGF-β, which is secreted from tumor cells, can control tumor progression by suppressing cytotoxic immune reactions, stimulating expression of cell survival factors, or regulating autonomous signaling of tumor cells, depending on cell type and context. At the late stage of tumor develop-

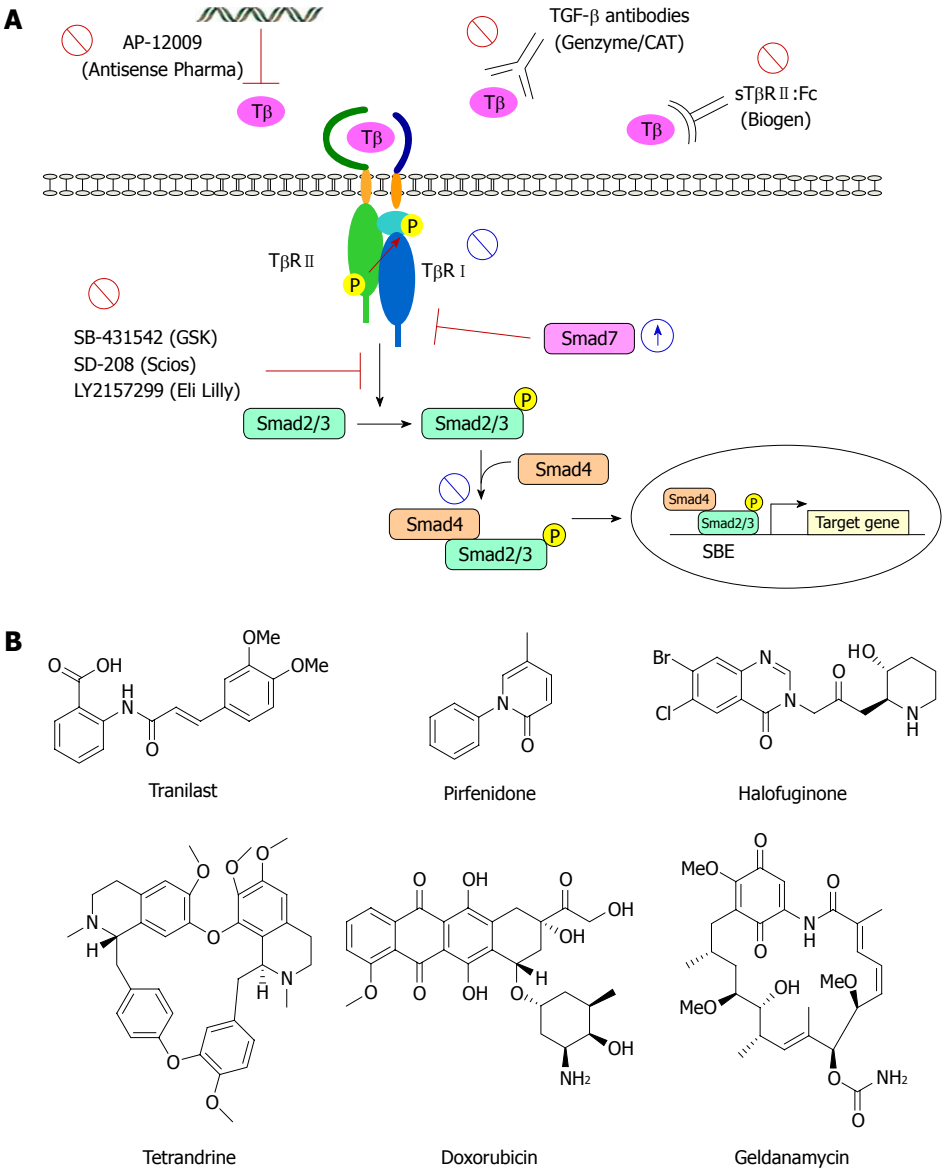

Figure 4 Therapeutic target of TGF-β signaling. A: TGF-β signaling and points of therapeutic intervention; B: Structures of multi-action TGF-β signal inhibitors. SBE: Smad binding element.

ment, invasive and metastatic potentials are important properties, and TGF-β signaling is a crucial pathway for tumor cell invasion and metastasis by inducing epithelial to mesenchymal transition (EMT)[50,51]. EMT progresses by decreasing the expression of E-cadherin to inhibit cell-cell adhesion and by increasing the expression of laminin-5, vimentin, integrins, and fibulin-5 that are involved in cell-extracellular matrix associations[52,53].

THERAPEUTIC TARGET OF TGF-β SIGNALING

Until now, the most successful target-aimed anti-cancer treatment has focused on the suppression of oncogenes that are abnormally activated in cancer cells. As examples, Gleevec® (imatinib), which is a *Bcr-abl* kinase inhibitors, and Herceptin (trastuzumab), which is a monoclonal antibody that interferes with the *Erb*B2/*Neu* receptor, are good examples of target-aimed molecular cancer treatments[54]. However, regarding TGF-β, the development of TGF-β inhibitors for the purpose of cancer treatment has shown no apparent progress so far in spite of TGF-β being known as a potent growth inhibitory factor against epithelial and blood cells. Instead, TGF-β signal transduction has been recognized as one of the representative targets of cancer treatment, aided by recent clinical results and cancer biology with regard to TGF-β. TGF-β ligands, as well as various downstream signal transducers can be a target in the therapeutic regulation of TGF-β signaling (Figure 4A). For instance, a potential target for the therapeutic intervention can be unveiled by inhibiting TGF-β synthesis, suppressing TGF-β activity at the cell surface, removing or neutralizing synthesized TGF-β, or regulating receptors and Smads involved in intracellular signaling pathways. By using EMT6 murine mammary tumor cell line that stably expresses antisense TGF-β transduced with a retroviral vector, it has been

demonstrated that the decreased production of TGF-β inhibited tumor growth[55]. In particular, the decreased secretion level of TGF-β by cancer cells induced tumor regression by increasing the activity of anti-tumor cytotoxic T cells. Currently, the inhibition of TGF-β production by using anti-sense oligonucleotides is one of the most potent methods in clinical cancer treatment. For example, AP-12009, which is synthesized by Antisense Pharma and is especially selective for TGF-β2, has prominent clinical effects on malignant neuroglial tumor patients[56,57]. It is now in phase Ⅱ clinical trials for the treatment of neuroglioma and pancreatic and skin cancer. The suppression of latent TGF-β activation can also be useful for regulating TGF-β activity. It has been reported that the furin protease inhibitor, decanoyl-Arg-Val-Lys-Arg-chloromethylketone (*dec-RVKR-cmk*), participates in TGF-β activity and inhibits the release of mature bioactive TGF-β molecules *in vitro*[58]. However, furin is not considered as a good selective inhibitor for TGF-β signaling because it is known to be involved in the activity of other growth factors, growth factor receptors, integrin, and matrix metalloproteinase.

Agents that promote TGF-β signaling

Restoration or augmentation of TGF-β signal transduction can be a good strategy for cancer prevention and treatment. For instance, chemical compounds such as retinoid and deltanoid (vitamin D), which are related to the expression or regulation of TGF-β signaling, have been used for chemoprevention of cancer[59,60]. Based on tumor suppressor activity of TGF-β, various attempts have been made to screen compounds that may activate TGF-β signaling. The first attempt, which was made by Seto's group, was to screen small molecular chemical compounds that have similar activities to TGF-β[61,62]. By searching for agents that increased the transcriptional activity of plasminogen activator inhibitor-1 (PAI-1), which is one of target genes of TGF-β, they finally isolated diheteropeptin and spiruchostatin A and B from microbial metabolites. These compounds turned out to increase the expression of PAI-1 and p21 and suppress the growth of lung epithelial cells in nanomolar concentrations. In addition, they had an inhibitory activity against histone deacetylase (HDAC). Lee *et al*[63] have isolated onnamide A and theopederin B from marine sponge, which promotes the transcriptional activity of TGF-β.

Onnamide A and theopederin B induce expression of PAI-1 gene and apoptosis through activation of mitogen-activated protein kinases (MAPKs) such as p38 and JNK, which suggests that they have strong anti-tumor activity. Moses's group[64] identified one TGF-β mimicking agent, A-161906, by performing high-throughput screening using mink lung epithelial cells stably transfected with PAI-1 promoter reporter. As an HDAC inhibitor, A-161906 demonstrated cellular effects similar to those of TGF-β. A-161906 not only inhibited cell proliferation, but also induced growth arrest at the G1-S checkpoint, and expression of the cyclin-dependent kinase inhibitor p21. In addition, based on the fact that Smad4 (DPC4) mutation, which is frequently found in pancreatic cancer, plays a crucial role in the loss of TGF-β-mediated growth inhibition, Sohn's group[65] performed high-throughput screening. Using a stably transfected reporter gene that has six copies of SBE (p6SBE-Luc) in a pancreatic cancer cell line, PANC-1, they screened a library of approximately 16000 compounds from ChemBridge DIVERSet, and finally identified scriptaid compound, which increased Smad transcriptional activity.

It is well known that expression of TGF-β receptors plays an important role in TGF-β-mediated cell growth inhibition. Therefore, increasing expression levels of TGF-β receptors in cancer cell lines, in which TGF-β receptors are mutated or their expression levels are attenuated, may be a good therapeutic target in cancer treatment. In fact, it has been reported that HDAC inhibitors, such as MS-275 and suberoylanilide hydroxamic acid (SAHA), increase response to TGF-β by inducing the expression of TGF-β-RⅡ and TGF-β-RⅠ, respectively, in breast cancer cell lines[66,67]. Besides, it has been found that the expression level of TGF-β-RⅡ is increased by captopril (angiotensin-converting enzyme inhibitor), FTI-27742 (farnesyl transferase inhibitor), and 5-aza-2'-deoxycytidine (DNA methyltransferase inhibitor)[68-70]. Thus, these compounds may be used as anti-cancer drugs or for combination treatments when treating colon or small cell lung cancer that commonly displays decreased expression levels of TGF-β-RⅡ.

Intriguingly, the screened chemical compounds including A-161906 and scriptaid that were identified by high-throughput screening, diheteropeptin, and spiruchostatins are strong HDAC inhibitors. This indicates that the activity of HDAC may play a key role in the regulation of TGF-β signaling. Recently, the FDA has approved SAHA (Vorinostat® Zoniza) as a treatment for cutaneous T-cell lymphoma (CTCL). It has been reported that SAHA activates p21 and induces apoptosis of T cells in CTCL patients[71].

Many transport molecules of TGF-β signaling as well as TGF-β receptors are regulated by epigenetic mechanisms. Therefore, even though HDAC inhibitors do not induce selective activation during TGF-β signal transduction, it is considered that HDAC inhibitors and various chemical compounds similar to or increasing TGF-β activity can be good targets in the prevention and treatment of cancer. Since the most frequent genetic alteration found in cancer is the loss-of-function in tumor suppressor genes, this alteration is very specific to cancer cells and it may be a good therapeutic target in the development of anti-cancer drugs. In order to identify the agents selectively targeting cancer cells with loss-of-function mutations, Wang *et al*[72] have demonstrated a novel screening technique, named pharmacologic synthetic lethal screening, and have identified UA62001, which shows selectivity against DPC4-deficient cell line BxPC-3, and by investigation of

downstream target genes of UA62001, they have found that UA62001 arrests cells in G2/M phase by inhibiting cyclin B/CDC2 expression. In addition, Park *et al*[73] have screened the Maybridge Diversity Set chemical library using a cell-based assay to measure nuclear translocation of Smad proteins. Through high-throughput screening, DAM-1976, which enhances TGF-β signaling, has been identified. DAM-1976 increases sensitivity to TGF-β by prolonging Smad2/3 activation in the nucleus in a TGF-β-independent manner.

Professor Sporn MB, who discovered TGF-β and has been in the vanguard of cancer chemoprevention research, and his colleagues[74] have made many modifications of triterpenoids that possess anti-inflammatory and anti-tumor activity. They have screened derivatives of two known triterpenoids, oleanolic acid, and ursolic acid, and synthesized 2-cyano-3,12-dioxooleana-1, 9-dien-29-oic acid (CDDO), which has the most potent anti-inflammatory activity and low toxicity. It has been reported also that CDDO not only promotes Smad signal transduction, but also displays various biological activities similar to that of TGF-β[75]. Moreover, CDDO is currently in phase Ⅱ clinical trials for the treatment of leukemia and solid tumors, based on its anti-inflammatory and anti-tumor activities, cellular protection, and suppression of tumorigenesis. Therefore, CDDO is considered to be a promising chemopreventive and chemotherapeutic agent in cancer treatment.

TGF-β antibody and soluble TGF-β receptors

The monoclonal antibody that neutralizes TGF-β ligand is one of most developed inhibitors for the clinical application of suppressing TGF-β activity. The human monoclonal antibodies CAT-152 (lerdelimumab), CAT-192 (metelimumab) and GC1008, and the mouse monoclonal antibodies 1D11 and 2G7 against TGF-β have been generated to date. CAT-152 and CAT-192 are the human IgG4 monoclonal antibodies that neutralize TGF-β2 and TGF-β1, respectively. CAT-152 and CAT-192 (Cambridge Antibody Technology) have entered phase Ⅲ and Ⅱ clinical trials for the treatment of wounds after glaucoma filtration surgery and pachyderma, respectively. However, the trials were discontinued in 2004 due to problems concerning their effectiveness[76]. GC1008, developed by Genzyme Corporation, is a pan-TGF-β selective monoclonal antibody that works against all TGF-β isomers. Clinical trials for GC1008 were conducted in idiopathic pulmonary fibrosis patients. Also, it is currently in a clinical trial for the treatment of metastatic skin cancer and renal cancer. The anti-tumor effectiveness of 1D11 and 2G7 has been studied in various animal tumor models. According to the report of Arteaga *et al*[77], intraperitoneal injection of 2G7 suppresses not only tumor growth of MDA-MB-231 breast cancer cell lines, but also lung metastasis. Moreover, 2G7 partially inhibits angiogenesis by reducing the levels of vascular endothelial growth factor in blood plasma. On the other hand, suppression of TGF-β activity can be achieved by using macromolecular proteins such as soluble TGF-β receptors that are able to inhibit competitively interactions between the ligand and the receptor. In particular, soluble TGF-β-RⅡ has been extensively studied in preclinical tumor models. A soluble chimeric protein, composed of the extracellular domains of the TGF-β-RⅡ and the Fc portion of IgG1, has been shown to block TGF-β activity[78]. When tested in a transgenic mouse model that expressed a soluble TGF-β-RⅡ receptor: Fc fusion protein (Fc:TGF-β-RⅡ), metastatic capacity was suppressed without any increase of tumor growth, which indicated that this fusion protein selectively inhibited metastasis-associated TGF-β activity[79]. In addition to soluble TGF-β-RⅡ, soluble TGF-β-RⅢ also suppressed tumor growth and lung metastasis in an MDA-MB-231 xenograft tumor model by antagonizing the tumor-promoting activity of TGF-β[80].

TGF-β receptor kinase inhibitors

TGF-β receptor kinases are not only key molecules in intracellular TGF-β signal transduction, but potential therapeutic targets that can be easily regulated by small molecular compounds. Owing to the success of Gleevec®, many projects, focused on TGF-β receptor kinases, have been carried out along with large pharmaceutical companies. In particular, numerous studies concerning TGF-β-R Ⅰ have been performed to elucidate the domain structures, biochemical activity, and biological functions of TGF-β-R Ⅰ [81]. Thus, TGF-β-R Ⅰ serves as an attractive target for drug development. The development of protein kinase inhibitors can be achieved in several ways, such as target hopping, novel screening and virtual screening.

TGF-β-R Ⅰ kinase inhibitors with various structures have been developed by drug companies. Their various effects including anti-tumor activity confirmed in animal models, relations with TGF-β-induced Smad phosphorylation, activation of reporter genes, cell cycle arrest, and EMT, have been reported. SB-431542, SB-505124 (Glaxo Smith Kline; GSK), LY364947, LY2157299 (Eli Lilly), SD-208 (Scios), and IN-1130 (In2gen) are well known TGF-β-R Ⅰ kinase inhibitors. SB-431542 and SB-505124 compounds from GSK were developed by target hopping based on the structures of the kinases. Phosphorylation of TGF-β-R Ⅰ is inhibited by SB203580, a p38 kinase inhibitor, because TGF-β-R Ⅰ has a gatekeeper residue equivalent to that of p38 kinase, which results in structural similarity to p38 kinase[82]. SB-431542 was synthesized having SB-203580 as a lead compound. It has shown greater selectivity for TGF-β-R Ⅰ compared with other serine/threonine kinases (protein kinase C, extracellular signal-regulated kinase, JNK, p38 MAPK). However, it also has displayed strong inhibitory activity against activin receptor (ALK4) and nodal receptor (ALK7)[83]. In addition, SB-431542 inhibits proliferation of glioma, TGF-β-mediated morphological changes, and cell motility, which suggests that small molecule inhibitors of TGF-β receptor kinases have potential to suppress tumor progression[84].

Based on the growth inhibitory characteristics of TGF-β in epithelial cells, researchers at Eli Lilly (Indianapolis, MN, USA) have identified the heteroarylpyrazole structure of LY364947 through high-throughput screening[85]. After they confirmed that TGF-β-R I and TGF-β-R Ⅱ kinase were the molecular targets of LY364947, the latter became a lead compound in the development of inducers. LY364947 also turned out to be identical to HTS-466274, which was identified by Biogen Inc. through computer modeling of a compound database that contained over 200 000 compounds. The result suggested shape-based virtual screening as a powerful tool to discover and develop new TGF-β-R I kinase antagonists. Furthermore, studies on the relationship between structure and activation, as well as optimization of lead compounds have led to the development of more advanced compounds, such as LY2157299. In particular, LY2157299 entered a phase I clinical trial for the first time as a TGF-β-R I kinase antagonist. Also, studies on its pharmacotoxicity, pharmacokinetics, and pharmacodynamics are currently in progress[86].

Oral bioavailability of SD-208, another type of TGF-β-R I kinase inhibitor under development by Scios Inc., has been verified by demonstrating its ability to inhibit infiltration of glioma cells and metastasis of a highly metastatic breast cancer cell line[87]. Besides, A-83-01 has been found to be more potent in the inhibition of TGF-β-R I than SB-431542, and GW788388 can be administered orally, with improved pharmacokinetics[88,89]. IN-1130, recently developed in Korea as a small molecular inhibitor of TGF-β-R I , has shown kinase selectivity similar to that of SB-431542. IN-1130 also inhibits tumor growth and promotes activation of cytotoxic T cells in xenograft prostate tumor models, which suggests that it might restore TGF-β-induced immunosuppression in cancer cells[90].

Non-selective agents that suppress TGF-β signaling

Besides the selective inhibitory substances, including antibodies against the ligand and receptor kinase inhibitors, non-selective chemical compounds may provide strategies for the regulation of TGF-β signaling. Such agents include compounds that suppress the expression level of TGF-β, increase the expression level of Smad7, an endogenous inhibitory protein, or regulate the stability of TGF-β receptors (Figure 4B). Natural or synthesized agents that suppress TGF-β signaling through these mechanisms generally demonstrate anti-inflammatory, anti-fibrosis, and various biological activities. Among these, tranilast (Rizaben®) has been used as an anti-allergic drug for the treatment of asthma and atopy. Also, it has been known that tranilast has anti-fibrosis and anti-tumor effects. According to animal experiments recently carried out with the highly metastatic murine 4T1 breast cancer cell line, tranilast effectively suppressed metastasis by activating Smad proteins, inhibiting EMT, and strongly suppressing the production of TGF-β and IL-17 that were secreted by immune cells[91]. The suppressive effect of tranilast on metastasis turned out to be greater than that of TGF-β antibody 1D11 or paclitaxel.

In addition, pirfenidone, which is in a clinical trial for idiopathic pulmonary fibrosis, due to its anti-fibrosis effects, suppresses proliferation of neuroglioma by inhibiting expression and activation of TGF-β[92]. Halofuginone, a plant alkaloid and inducer of febrifugine, is a representative small molecular weight molecule in the suppression of collagen synthesis. It was first isolated from *Dichroa febrifuga*, approved by the FDA, and has been used for the treatment of scleroderma. Recently, clinical trials have been conducted on Kaposi's sarcoma to examine its inflammatory activity. Halofuginone has been reported to inhibit TGF-β signaling by decreasing TGF-β-R Ⅱ expression and elevating inhibitory Smad7 expression[93].

Moreover, tetrandrine, another plant alkaloid, and doxorubicin have demonstrated increased expression of Smad7[94,95]. While screening for agents that suppress TGF-β signal transduction, geldanamycin, which is also known as a heat shock protein 90 (Hsp90) inhibitor, was identified. Geldanamycin inhibits TGF-β-induced target gene expression and Smad phosphorylation even at the subnanomolar concentrations. Analysis of its mechanism of action revealed that geldanamycin suppresses TGF-β signaling *via* complex processes. For instance, geldanamycin regulates Hsp90 chaperone-associated stability of TGF-β receptors, suppresses receptor complex formation between TGF-β-R Ⅱ and TGF-β-R I , and induces interaction between Hsp70 and its receptors[96]. In general, Hsp90 inhibitors are widely recognized as a promising therapeutic target for anti-cancer drug development because of their ability to suppress tumor growth by inactivating various proteins that are related to tumorigenesis, such as Bcr-abl, ErbB2 and Raf-1. Various Hsp90 inhibitors, including geldanamycin inducer and 17-(allylamino)-17-demethoxygeldanamycin (17-AGG) are currently undergoing clinical trials. In fact, 17-AGG has completed a phase Ⅲ clinical trial for the treatment of multiple myeloma[97].

CONCLUSION AND FUTURE DIRECTIONS

Although TGF-β signaling has been shown to have some paradoxical actions in tumorigenesis, many factors activate TGF-β signaling for tumor suppression, such as HDAC inhibitor, SAHA, synthetic terpenoid, CDDO, in addition to inhibitors of TGF-β signaling. It is a good strategy to block the initiation of inflammation-associated tumorigenesis through the development of TGF-β mimics in order to achieve chemoprevention. Activators of TGF-β signaling inhibit initiation of tumorigenesis and invasion and metastasis of advanced-stage tumors. This sort of approach will be very helpful for TGF-β-responsive tumor therapy, so-called tumor vaccination. In terms of chemoprevention, the difficulty in applying TGF-β activators to normal people is due to immunosuppressive action and difficulty in detecting the tumor

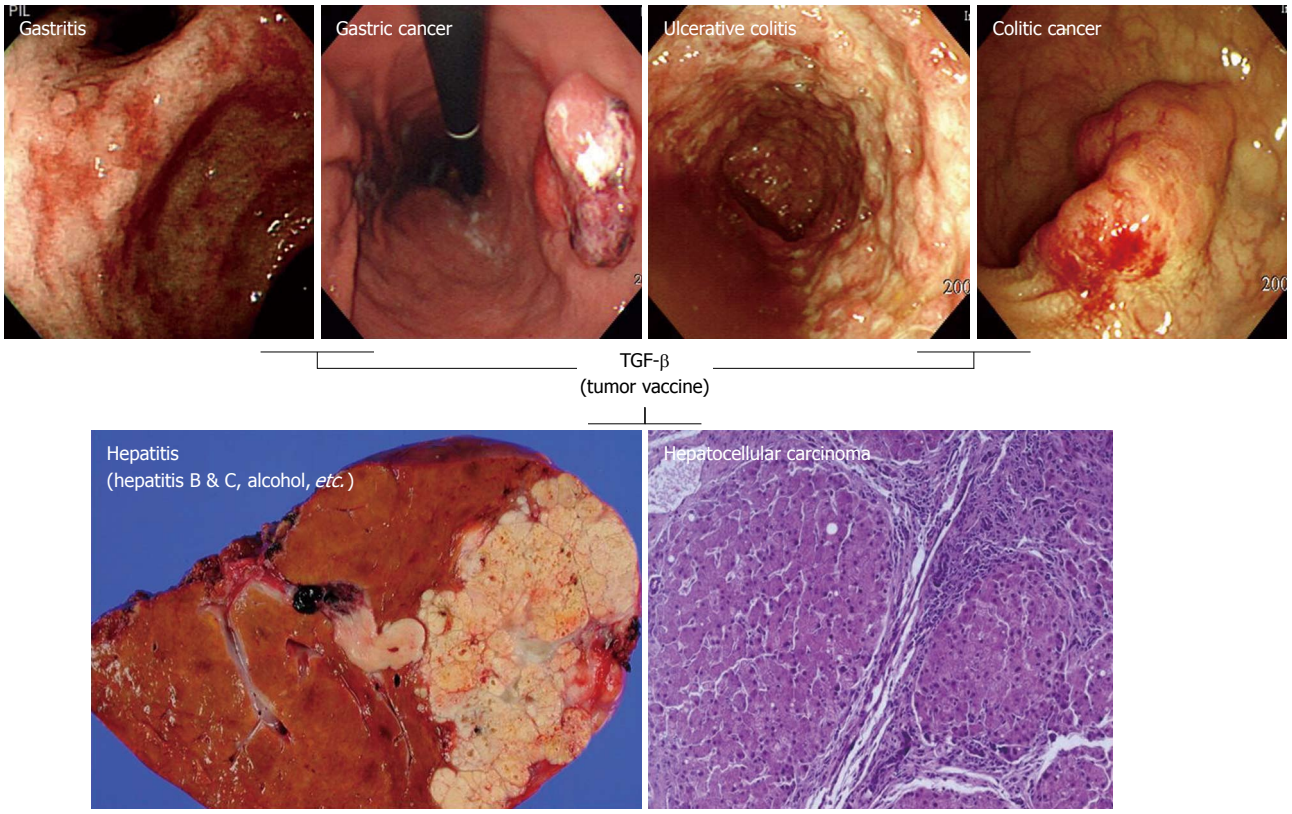

Figure 5 TGF-β1 as pivotal tumor vaccine based on anti-inflammatory actions that block progression from inflammatory lesions to precancerous lesions/cancer. Chronic inflammation induced by biological, chemical, microbial and physical factors is associated with increased risk of human cancer at various sites. Inflammation facilitates initiation of normal cell transformation, growth, and progression to malignancy through production of pro-inflammatory cytokines and diverse reactive oxygen species. In this pathway, TGF-β plays a key role in chemoprevention through anti-inflammatory and anti-mutagenic actions.

at an early stage. Blocking inflammation-associated carcinogenesis with the anti-inflammatory activity of TGF-β signaling can be used as a chemopreventive strategy in patients at high risk of cancer (Figure 5). Even though TGF-β may regulate the inflammatory process by modulating the differentiation of many kinds of T cells, we still do not know the exact role of TGF-β in T-cell biology. Further study of the role of TGF-β in development of GI tract immune cells can lead to future therapeutic approaches for inflammation and tumorigenesis. To date, tumor chemotherapy by suppression of TGF-β signaling has been tried, to enhance the tumor-specific immune reaction, inhibit angiogenesis of the tumor microenvironment, and block invasion and metastasis of tumor cells. However, TGF-β has different effects depending on the type or context of the tumor, and has an anti-inflammatory effect on various immune cells. For these reasons, it is important to select the right patients, time of intervention, therapeutic reagents to combine, and exact targets, to minimize the side effects and maximize successful treatment. Recently, many low molecular size inhibitors of TGF-β receptor kinase have been tested in clinical trials of tumor chemotherapy. Also, cross-talk between TGF-β signaling and other signaling pathways has been studied in detail, and new candidates have been screened and developed to regulate these signaling pathways. Based on results of cooperative activity of TGF-β with oncogenes, combination therapy with conventional anti-tumor reagents and TGF-β signaling inhibitors can enhance the therapeutic effects. Since inflammation-associated carcinogenesis is caused by complex cross-talk between many different cytokine signaling pathways, by collaboration with systems biologists, we can understand in more detail the mechanisms and networks of signaling pathways for inflammation and tumorigenesis. Through this approach, we can design and develop more efficient therapeutic drugs for treatment of GI cancer based on the biological action of TGF-β.

Abstract

Acute lung injury (ALI) and acute respiratory distress syndrome (ARDS) in acute pancreatitis still represents a substantial problem, with a mortality rate in the range of 30%-40%. The present review evaluates underlying pathophysiological mechanisms in both ALI and ARDS and potential clinical implications. Several mediators and pathophysiological pathways are involved during the different phases of ALI and ARDS. The initial exudative phase is characterized by diffuse alveolar damage, microvascular injury and influx of inflammatory cells. This phase is followed by a fibro-proliferative phase with lung repair, type Ⅱ pneumocyte hypoplasia and proliferation of fibroblasts. Proteases derived from polymorphonuclear neutrophils, various pro-inflammatory mediators, and phospholipases are all involved, among others. Contributing factors that promote pancreatitis-associated ALI may be found in the gut and mesenteric lymphatics. There is a lack of complete understanding of the underlying mechanisms, and by improving our knowledge, novel tools for prevention and intervention may be developed, thus contributing to improved outcome.

INTRODUCTION

The incidence of acute pancreatitis is in the range of 300 or more patients per million annually[1,2]. Using the Atlanta classification on severity, about 10% of acute pancreatitis patients are classified as severe[3]. About one-third of all deaths from acute pancreatitis has been reported to occur prior to admission to hospital, and in most cases, is associated with acute lung injury (ALI)[4]. Hospital deaths occur within the first week after admission in 35%-50%[1,5,6] and the cause of death is related to single or multiple organ failure in a majority of cases[7]. In elderly patients, up to 60% of all deaths within the first week are considered to be caused by pancreatitis-

associated ALI and acute respiratory distress syndrome (ARDS)[8]. Independently, ALI is a consequence of a pronounced systemic inflammatory response with increased endothelial and epithelial barrier permeability, with leakage of a protein-rich exudate into the alveolar space and interstitial tissues, thus compromising oxygenation and gas exchange[9]. The magnitude of the systemic inflammatory response determines the concomitant clinical course and outcome[10,11] and this also is true for the severity of the acute-pancreatitis-associated ALI[12] (Figure 1). Respiratory complications are frequent in acute pancreatitis, and respiratory dysfunction, presenting as ALI or ARDS, is a major component of multiple organ dysfunction syndrome (MODS), with a frequent need for ventilatory support[8,13], which contributes to early death in severe acute pancreatitis[14] (Figure 2).

The mortality in ALI has been reported as 30%-60%, and is higher in elderly patients[15,16]. In those who survive, the quality of life is impaired[17]. Overall, ALI and ARDS represent the most common and earliest organ dysfunction in the development of MODS, in which mortality is related to the number of involved organs[18]. This type of secondary ALI, a dominant part of MODS, is also found in severe acute pancreatitis, in which lung injury has been reported to account for a high percentage of deaths.

Acute respiratory failure, including ALI and the more severe form, ARDS, has radiological findings with bilateral pulmonary infiltrates and physiological changes, normal cardiac filling pressures, and a ratio of arterial oxygen pressure and inspiratory oxygen concentration (PaO_2/FiO_2 < 300 mmHg for ALI and < 200 mmHg for ARDS, which reflects pronounced morphological changes)[19]. ALI and ARDS frequently occur in critically ill patients, although the exact incidence in acute pancreatitis has not been stated. If we extrapolate Scandinavian data on ALI and ARDS patients, mortality in the United States is about 36 000 patients per year[20]. More recent mortality rates have also been reported to be 30%-40% and higher in elderly patients[21].

MECHANISMS

Two different phases in ALI and ARDS have been described. Initially, an exudative phase during the first days with diffuse alveolar damage, microvascular injury, type I pneumocyte necrosis, and influx of inflammatory cells and fluid to the pulmonary interstitium has been seen, followed by a fibro-proliferative phase during days 3-7, during which type II pneumocyte hyperplasia, proliferation of fibroblasts and lung repair occur[22]. As a consequence of a pronounced and complex systemic net pro-inflammatory response, both endothelial and epithelial injury is involved in ALI and ARDS (Figure 3). Mediators are several, including cytokines and chemokines, pro-inflammatory mediators and a variety of cells, which regulate the migration and pulmonary infiltration of neutrophils into the interstitial tissue, where they cause injury and breakdown of the pulmonary parenchyma[23]. In order to give a sense of the significance of acute pancreatitis as an etiological factor for ARDS in ICU patients,

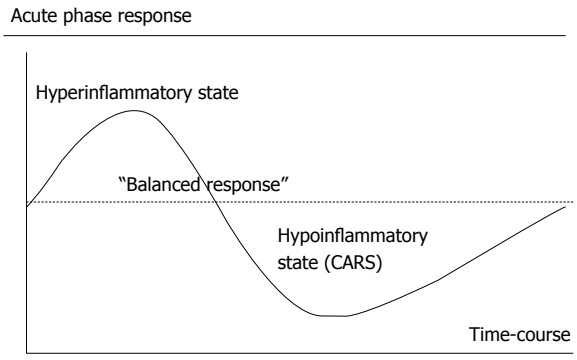

Figure 1 The acute phase response as seen in critical illness, e.g. severe acute pancreatitis.

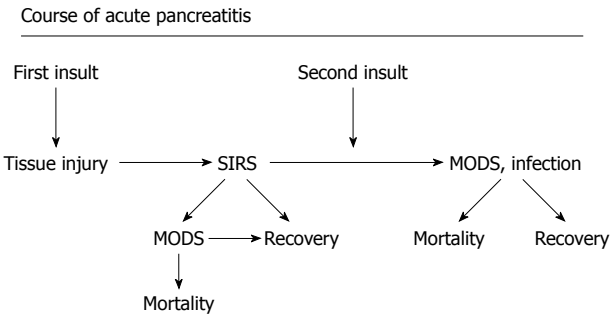

Figure 2 Course of acute pancreatitis. A potential development in severe acute pancreatitis with the first "insult" resulting in a pronounce systemic inflammatory response and potential development of organ dysfunction, and in the worst scenario early mortality. Later during the course, combination of organ dysfunction and infection, potentially pronounced after the second "insult" (translocation from the gut, burst of proinflammatory cytokines, surgery, *etc.*) may result in late mortality. MODS: Multiple organ dysfunction syndrome.

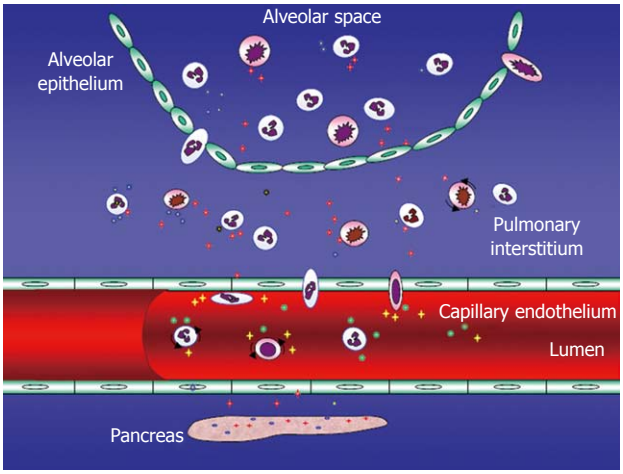

Figure 3 Acute pancreatitis-associated acute lung injury (ALI) - potential mechanisms including endothelial barrier dysfunction. Several adhesion molecules [selectins, intercellular adhesion molecule-1 (ICAM-1), platelet endothelial cell adhesion molecule-1 (PECAM-1) among others] involved in the extravasation of not at least polymorphonuclear neutrophils (PMNs). Tissue injury by not at least these PMNs.

almost one out of seven patients have acute pancreatitis as a primary cause[24].

PATHOPHYSIOLOGICAL MECHANISMS IN SECONDARY ALI

ALI and ARDS may occur secondary to acute pancreatitis, with similar appearances. In general, controlling the source of what is actually fuelling the ALI is important. The features of secondary ALI/ARDS thus involve an initial exudative phase with diffuse alveolar damage, microvascular injury, type- I pneumocyte necrosis and influx of inflammatory cells, followed by a fibro-proliferative phase with lung repair and type- Ⅱ pneumocyte hyperplasia and proliferation of fibroblasts[13]. Both endothelial and epithelial injury is involved. These changes in ALI, which involve endothelial barrier dysfunction, neutrophil and monocyte/macrophage activation, adhesion molecule expression and intracellular signaling, can to a great extent be executed by proteases derived from polymorphonuclear neutrophils (PMNs), and the process seems driven by tumor necrosis factor (TNF)-α and monocyte chemoattractant protein (MCP)-1, with involvement of mast cells, at least during the initiation of leukocyte activation[25-27]. These complex mechanisms that underlie the ALI associated with acute pancreatitis, and the variety of cells involved, which contribute to neutrophil recruitment, adhesion and activation, as well as signal transduction pathways such as tyrosine kinase activation, local transcription of nuclear factor-κB, and expression of multiple inflammatory genes, have been described in a number of experimental studies and reviews[9,13,28,29]. It thus seems well established that inflammatory mediators play a key role in the pathogenesis of ALI and ARDS. These mediators include TNF-α, interleukins-1β, -6, and -10, transforming growth factor-β, granulocyte-macrophage colony-stimulating factor, platelet-activating factor (PAF), selectin and adhesion molecules, complement component C5a, neuropeptide substance P, and chemokines such as MCP-1, and macrophage inflammatory protein-1α. Moreover, one of the results seems to be the production of reactive oxygen and nitrogen species with potential deleterious effects on pulmonary endothelial and epithelial functions[12,29,30]. The neuropeptide substance P possesses pro-inflammatory action that increases vascular permeability, evidently acting through neurokinin-1 receptors. The complement component C5a is a pro-inflammatory chemoattractant that, at least in the experimental setting, seems to increase lung injury, as does the CD40 receptor found on lymphocytes, monocytes and dendritic cells[30]. All of these represent potential targets for future intervention. It is thus the net magnitude of the pro-inflammatory response and the ratio between pro- and anti-inflammatory activity during the process that ultimately determine the outcome of pancreatitis-associated ALI/ARDS. The means of activating leukocytes may be complex and different, and also involve mast cells during the initiation of leukocyte activation. Pulmonary macrophages are likely to be involved in pancreatitis-induced endothelial barrier dysfunction, compromise of type Ⅱ pneumocytes, and tissue injury, and furthermore, the release of matrix metalloproteinases seems essential, not at least, that derived from mast cells[31,32].

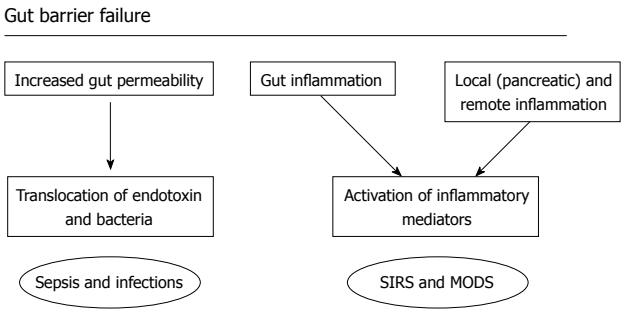

Figure 4 Gut barrier failure. The increase in permeability of the gut barrier from the intestinal lumen may allow translocation of endotoxin and bacteria and there is also activation of immunocompetent cells in the gut wall and gut associated lymphoid tissue, contributing to the inflammatory response, infection, and potentially the development of organ dysfunction.

Pancreatitis-associated ALI has been reported to be related to the effects of pancreatic enzymes, and in particular, phospholipase A_2 is thought to play a role in ALI by damaging pulmonary surfactant, which is a substrate for phospholipase A_2[33]. Furthermore, patients with severe acute pancreatitis have been found to have elevated serum concentrations of phospholipase A_2, which are correlated with the extent of pulmonary complications[34], and a correlation between lung injury score and serum concentration of phospholipase A_2 has been identified[35]. It should be mentioned that the increased systemic levels of phospolipase A_2 that have been reported in this study may be derived not only from the pancreas, but also be of non-pancreatic origin[35]. With all these mechanisms involved, including a variety of different mediators and cells, there have been high expectations on the use of various types of pancreatic protease inhibitors.

DOES THE GUT PLAY A ROLE IN ALI?

The gut barrier not only represents a mechanical line of defense, i.e. a border between the gut lumen and its contents and the rest of the body, but also includes a variety of immunocompetent cells both within the intestinal wall and in associated lymph nodes, which are represented as mucosa-associated lymphoid tissue and gut-associated lymphoid tissue. Preserving an intact gut barrier is thus a complex and meticulous process that is impaired in critical illness such as severe acute pancreatitis, in which the compromised barrier allows for increased intestinal permeability and translocation of bacteria derived from the intestinal lumen and toxins, as well as a gut inflammatory state[10,36-39] (Figure 4).

Mesenteric lymphatics have been found to carry gut-derived factors that contribute to ALI in various

experimental models[40-42]. Interruption of the flow of mesenteric lymph leads to amelioration of ALI, but still we have not identified the exact factors derived from the gastrointestinal tract that are responsible for the pulmonary and systemic effects. This observation represents one potential tool to achieve control of the systemic response and decrease pulmonary injury by modulating factors derived from the gut[43,44].

OUTCOME OF EXPERIMENTAL STUDIES AND POTENTIAL CLINICAL IMPLICATIONS

Our improved understanding of the underlying pathophysiological mechanisms involved in ALI in critical illness has led to a corresponding expectation about potential clinical interventions. This concerns the role of the inflammatory response and signaling mechanisms, such as the protein kinase C pathway[30-32]. Pretreatment and early treatment in experimental acute pancreatitis with, for example, a PAF antagonist and monoclonal antibodies against adhesion molecules such as intercellular adhesion molecule-1 (ICAM-1) and platelet endothelial cell adhesion molecule-1 (PECAM-1) have been successful[26,27,45]. When evaluating clinical trials with a variety of non-antibiotic interventions in acute pancreatitis, outcome has been less favorable with contradictory results for octreotide and its analogs, as well as the use of the intracellular protease inhibitor gabexate[46]. High expectations have been raised for the use of the highly specific PAF antagonist lexipafant, which has been shown to reduce organ failure and the inflammatory response in patients with predicted severe acute pancreatitis, when administered early[47,48]. A concomitant major study was less convincing, although it did report decreased organ failure inflammatory mediators[49].

FUTURE ASPECTS

Cross-talk between coagulation and inflammation evidently seems to exist, as exemplified by treatment with recombinant human activated protein C in patients with severe acute pancreatitis, in whom a reduction in mortality has been reported[50]. Other components of the coagulation cascade seem to possess inflammatory properties to various degrees. For example, blockers of tissue factor or factor VIIa in experimental severe acute pancreatitis have been shown to ameliorate the associated ALI and decrease neutrophil influx, both when administered as pretreatment and as early treatment[51]. The role of anticoagulants as anti-inflammatory agents in ALI may represent a novel therapeutic option and should be further investigated[52].

The epithelium is involved early in the development of ALI, and produces pro-inflammatory chemokines and triggers neutrophil migration. Furthermore, the epithelium interacts with pulmonary macrophages, which may exacerbate production of pro-inflammatory mediators, thereby increasing recruitment of PMNs from the circulation to the pulmonary interstitial tissue and alveolar lumen. The blocking of chemokines, for example, MCP-1, may thus represent an interesting mode of intervention[53].

Gram-negative infections may be an important predisposing factor for ARDS in acute pancreatitis and endotoxin might potentiate ALI[54]. This emphasizes translocation from the gastrointestinal tract to the systemic circulation and remote organs, as well as the role of the gut-lymph-lung axis. Toll-like receptor 4 (TLR4) compromises the innate immune response and initiates complex signaling pathways when interacting with lipopolysaccharide, which ultimately results in a pro-inflammatory response. Amelioration of the severity of acute pancreatitis and reduced lung injury has been noted in mice that lack TLR4[55], and the lung injury decreases in severity in experimental severe acute pancreatitis treated with nitric oxide, which affects TLR4 gene expression[56]. Therefore, TLR4 has been emphasized as a potential future therapeutic target against inflammatory processes[57].

Heparan sulfate derived from the extracellular matrix or the surface of epithelial cells induces a pro-inflammatory response and has, in its soluble form, been suggested to activate TLR4, thus triggering an endogenous pathway to initiate cytokine production[58]. In experimental acute pancreatitis, heparan sulfate aggravates pancreatic inflammation, and promotes the progression from a local to a systemic inflammatory response, which implies that blocking of heparan sulfate is a potential route of intervention[59]. It has also been suggested that heparan sulfate is important during the initiation of acute pancreatitis, by aggravating the local inflammatory response within the pancreas and thereby potentially promoting the development of a more pronounced systemic inflammatory response, in which heparan sulfate is cleaved off from the epithelial lining of the pancreatic ducts[60]. The role of heparan sulfate and its inhibition thus represents an interesting future line of research, both for the initiation of acute pancreatitis, as well as the development of a systemic inflammatory response.

CONCLUSION

ALI and ARDS in acute pancreatitis remains a major challenge that requires substantial resources. Presently, there is a lack of interventions directed at the underlying pathophysiological mechanisms, although improved understanding may provide us with novel tools for prevention and intervention. Ongoing research on acute pancreatitis and acute respiratory injury gives hope of improvement in the management of this severe and resource-demanding complication, that is still associated with substantial mortality.

Abstract

AIM: To examine the effect of hepatitis C virus (HCV) structural mimics of regulatory regions of the genome on HCV replication.

METHODS: HCV RNA structural mimics were constructed and tested in a HCV genotype 1b aBB7 replicon, and a Japanese fulminant hepatitis-1 (JFH-1) HCV genotype 2a infection model. All sequences were computer-predicted to adopt stem-loop structures identical to the corresponding elements in full-length viral RNA. Huh7.5 cells bearing the BB7 replicon or infected with JFH-1 virus were transfected with expression vectors generating HCV mimics and controls. Cellular HCV RNA and protein levels were quantified by real-time polymerase chain reaction and Western blotting, respectively. To evaluate possible antisense effects, complementary RNAs spanning a mimic were prepared.

RESULTS: In the BB7 genotype 1b replicon system, mimics of the polymerase (NS-5B), X and BA regions inhibited replication by more than 90%, 50%, and 60%, respectively. In the JFH-1 genotype 2 infection system, mimics that were only 74% and 46% identical in sequence relative to the corresponding region in JFH-1 inhibited HCV replication by 91.5% and 91.2%, respectively, as effectively as a mimic with complete identity to HCV genotype 2a. The inhibitory effects were confirmed by NS3 protein levels. Antisense RNA molecules spanning the 74% identical mimic had no significant effects.

CONCLUSION: HCV RNA structural mimics can inhibit HCV RNA replication in replicon and infectious HCV systems and do so independent of close sequence identity with the target.

INTRODUCTION

Chronic hepatitis C virus (HCV) infection is a leading cause of chronic hepatitis, liver cirrhosis and hepatocellular

carcinoma[1-3]. Current therapeutic options are limited and associated with significant adverse effects[4,5]. Accordingly, there is a strong impetus to develop novel therapeutic options. Because HCV replicates through the interaction of its RNA-dependent RNA polymerase and its RNA template to generate progeny RNA, physical contact between the enzyme and genomic RNA is required[6-8]. We hypothesized that mimics could be created with sufficient resemblance to the natural genomic structure to compete with the HCV genome, resulting in inhibition of replication. HCV RNA has a number of cis-acting replication elements (CREs) whose function could potentially be inhibited by structural RNA mimics[9]. For example, structural mimics based on the HCV internal ribosome entry site (IRES) were recently shown to inhibit HCV translation *in vitro* and in replicon cell culture[10]. Synthesis of (+)-strand RNA molecules was inhibited by RNA aptamers specific for the (-)-strand IRES domain corresponding to the 3'-terminal end of the negative strand of HCV RNA[11,12]. In addition to the IRES[13-15], HCV RNA bears CREs in the positive-strand NS5B[6,8,16,17] and X region[18,19] as well as in the negative strand 3'-terminal region[13,20]. The function of each CRE is assumed to depend on the ability of these structures to bind host factors[21-24] and viral non-structural proteins[8,14,15,25,26]. The objective of the current study was to determine to what extent computer-predicted single-stranded HCV RNA structures could inhibit HCV replication.

MATERIALS AND METHODS

Cloning of HCV RNA structural mimics

For replicon studies, structural mimics were constructed based on RNA sequences of the HCV 1b subgenomic replicon, BB7[27,28] (Table 1). Table 1 shows the regions and the nucleotides from which the mimic sequences were derived. Mimics 5B and X were designed to be identical to the (+) strand of the NS5B and X regions (Figure 1A and D, respectively). Mimics BA (Figure 1B) and EC (Figure 1C) were designed to be identical to the (-) strand of the 3'-terminus. The HCV RNA structural mimic sequences were predicted to adopt stem-loop structures identical to the corresponding CRE in full-length viral RNA, as determined by the Mfold ver 3.2 web server[29,30]. For Japanese fulminant hepatitis virus (JFH-1) infection studies, mimic sequence identities corresponding to HCV JFH-1 genotype 2a were designed to vary from 100% (5B-100), 74% (5B-74) and 46% (5B-46), the latter achieved by changes in the stem regions. The 5B-74 mimic was identical to the mimic (NS5B) used in genotype 1b replicon studies. To construct 5B-46, base-pair exchanges were made at positions 2-15, 18, 30-43, 49-53, 57-60, 75-78, 89-94 in 5B-74 (Figure 2). Regions in the stems or loops in which changes were predicted by Mfold ver 3.2 to alter the secondary structure were left intact. DNA fragments containing each mimic sequence flanked by *Bam*H I and *Hin*dⅢ sites were generated by polymerase chain reaction (PCR) amplification of sequences from pHCV rep1bBB7 (Apath, LLC, St. Louis, MO, USA). As a negative control, an unrelated [hepatitis B virus (HBV) encapsidation signal] was amplified by PCR from plasmid adwR9 (from Dr. T Jake Liang, NIH, Bethesda, MD, USA). The region cloned included HBV sequences flanking a 60 nucleotide (nt) element, so that the total insert length approximated that of the HCV RNA structural mimics. Each insert was cloned into a T7 transcription vector, pENT7 by *Bam*H I /*Hin*dⅢ digestion and ligation. pENT7 is a derivative of pENTR4 (Invitrogen Co., Carlsbad, CA), in which a T7 expression cassette (*Bam*H I and *Hin*dⅢ sites downstream of the consensus T7 RNA polymerase promoter) had been inserted in the multiple cloning site.

For expression of HCV RNA structural mimics as polymerase Ⅱ transcripts in mammalian cells, each insert was subcloned into pSilencer 4.1-CMV puro (Ambion) by *Bam*H I /*Hin*dⅢ digestion and ligation. To confirm fidelity, clones containing pSilencer 4.1-CMV puro with HCV RNA structural mimics were sequenced with primers as recommended by the manufacturer: 5'-AGGCGATTAAGTTGGGTA-3', 5'-CGGTAGGCGTGTACGGTG-3'.

Cloning of a 5B-100 structural mimic

As a positive control for HCV JFH-1 genotype 2a inhibition, a 5B-100 mimic was constructed to be 100% identical to the HCV JFH-1 genotype 2a NS5B coding region (Table 1). This mimic was also predicted using web server Mfold ver. 3.2 to adopt stem-loop structures identical to the corresponding CRE in full-length viral RNA.

Cells

Huh7.5 cells, a human hepatoma cell line, bearing the BB7 HCV genotype 1b replicon were obtained from Apath (St. Louis, MO). Huh7.5 cells, which support JFH-1 replication, were obtained from Dr. Charles M. Rice, Rockefeller University, NY, USA[16,31,32]. Cells were maintained in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% fetal bovine serum (FBS) and 1X antibiotic/antimycotic solution (Invitrogen). Cells were passaged every 3-4 d to maintain 75% confluence.

Transfection of plasmids for in situ generation of HCV structural mimics

Huh-7.5 cells containing the BB7 replicon, or cells carrying persistent infection with JFH-1 HCV RNA were seeded at a density of 10^5 cells in 2 mL of growth medium per well in 6-well plates, 6 d before transfection. For transfection, 25 μg of each plasmid encoding a structural mimic were transfected into Huh7.5 cells, 95% confluent, with 15 μL Lipofectamine 2000 (Invitrogen) according to the manufacturer's instructions. Plasmid DNA was diluted in 250 μL of Opti-MEM I Reduced Serum Medium (Invitrogen) without serum. Lipofectamine 2000 was diluted to the appropriate amount in 250 μL of Opti-MEM I medium. After 5 min incubation, diluted

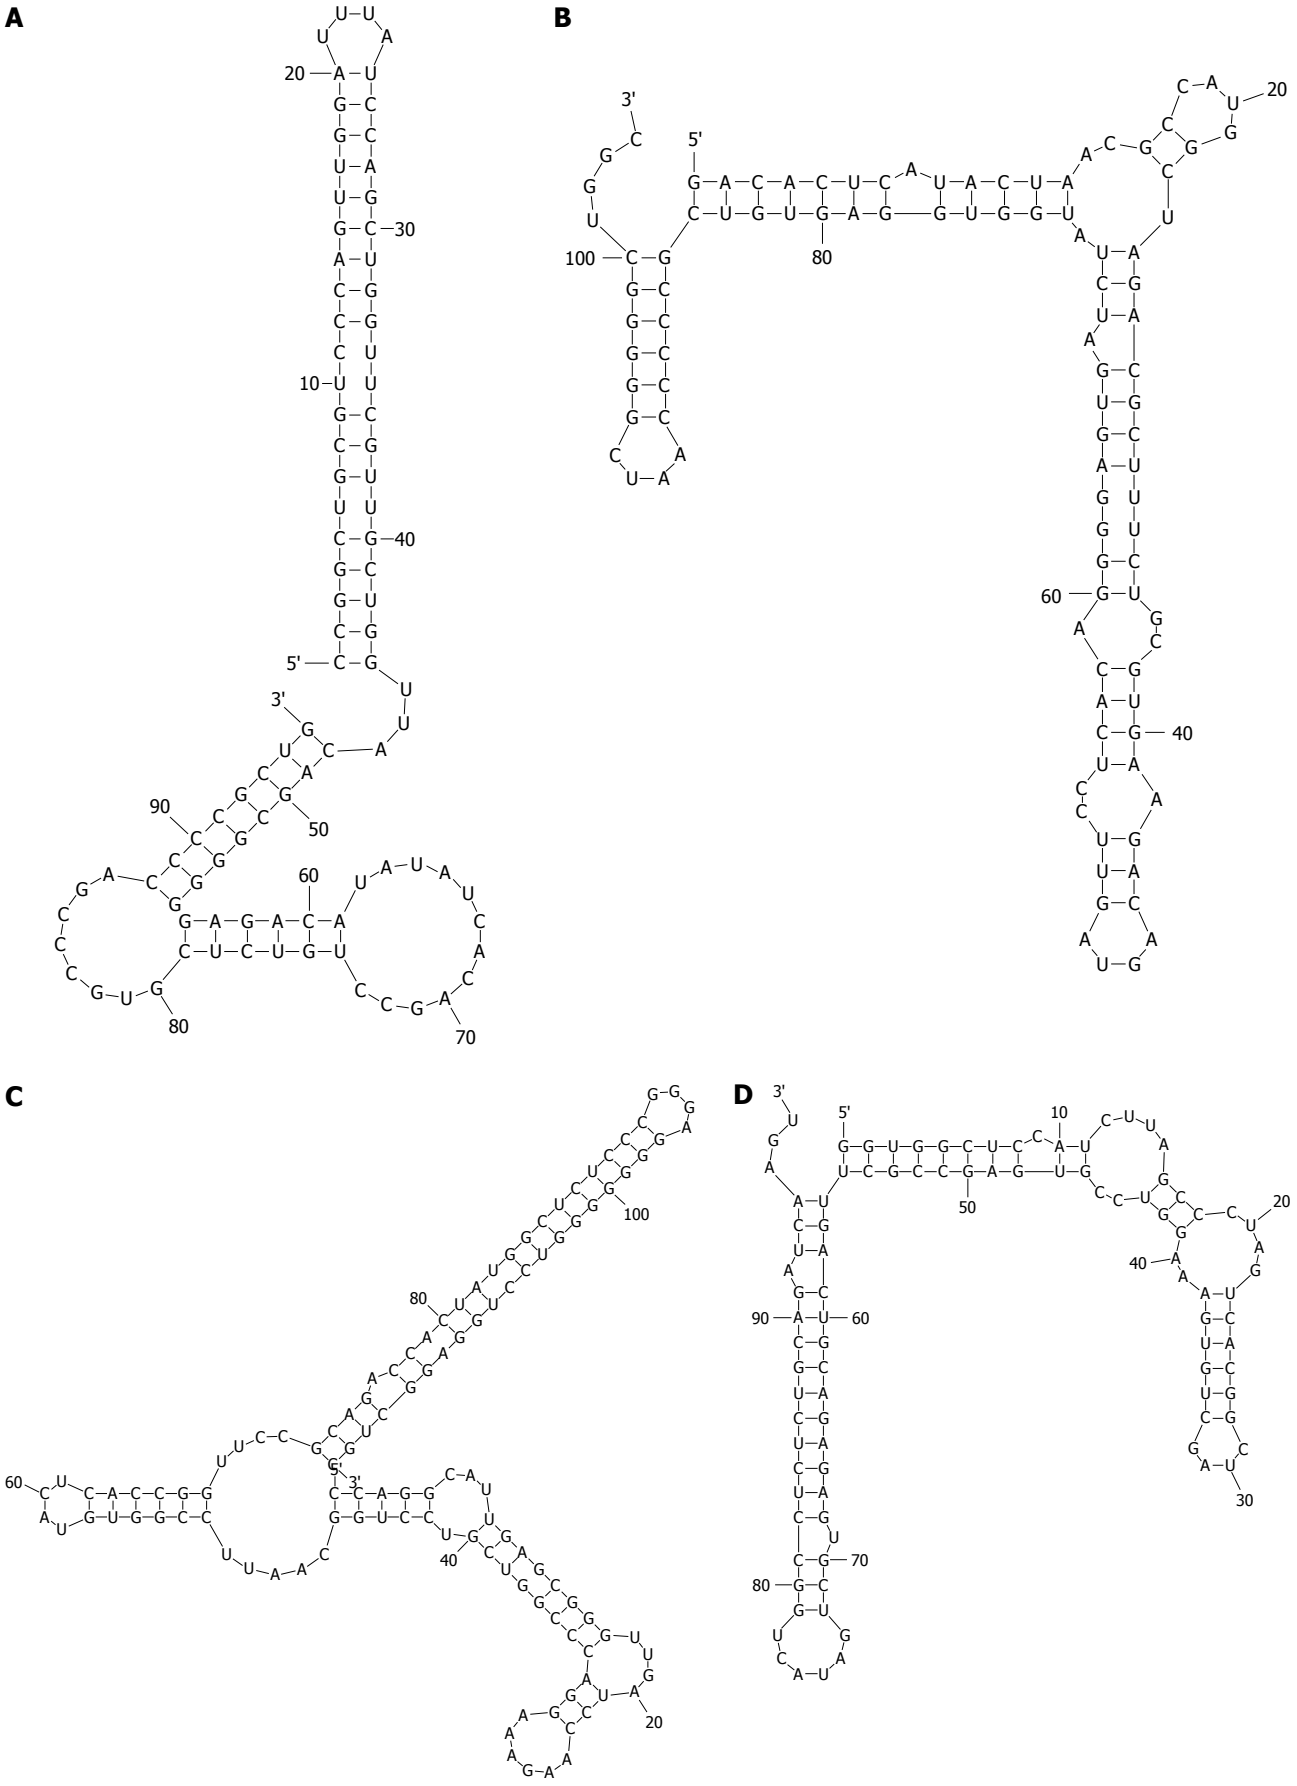

Figure 1 Predicted folding of RNA sequences designed as mimics of hepatitis C virus (HCV) genotype 1b regions. HCV RNA sequences were predicted by Mfold ver 3.2 to adopt stem-loop structures identical to the corresponding sequences in full-length viral RNA. A: 5B-74 corresponding to NS-5B (+) strand; B: BA region 3'-terminus of (-) strand; C: EC region 3'-terminus of (-) strand; D: X region of (+) strand.

Table 1 HCV RNA structural mimics

Structural analogs	Source BB7 sequence (nt)	Source JFH sequence (nt)	Replicon strand	JFH strand	Stem-loop domains
NS-5B (5B-74)	9216-9310		(+) strand		NS5B coding region
X	9508-9605		(+) strand		X region
EC	107-222		(-) strand		3'-terminus
BA	1-104		(-) strand		3'-terminus
5B-100		9284-9378		(+) strand	NS5B coding region

HCV: Hepatitis C virus; JFH: Japanese fulminant hepatitis.

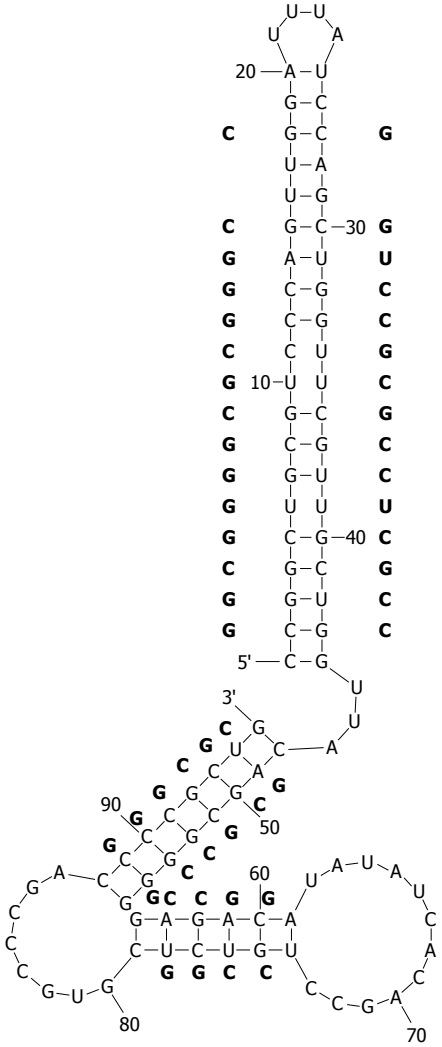

Figure 2 Diagram showing the nucleotide replacements (in bold) in 5B-74 made to create the 5B-46 structural mimic and predicted stem-loop structures identical to the corresponding sequences in 5B-74.

DNA was combined with diluted Lipofectamine 2000, mixed and incubated for 20 min at 25℃. Complexes in 500 μL medium were added. After 6 h of incubation at 37℃ under 50 mL/L CO_2, 1.5 mL of DMEM with 15% FBS were added to each well, and cells were incubated at 37℃ under CO_2 for 48 and 72 h. Cells were harvested and lysates assayed for NS3 protein levels by Western blotting. Total RNA was isolated and HCV RNA levels were determined by real-time reverse transcriptase PCR (RT-PCR).

HCV infection system

A cDNA from hepatitis C genotype 2a virus, JFH-1 strain (from Dr. Takaji Wakita, National Institute of Infectious Diseases, Tokyo, Japan)[33] has been shown to replicate autonomously without drug selection or adaptive mutations[34-37]. This cDNA was used to transfect the full-length JFH-1 genome into Huh7.5 cells to produce infectious HCV[38].

Real-time RT-PCR

RNA was isolated from BB7 replicon cells with Trizol (Invitrogen), and treated with RNase-free DNase (Promega). One microgram of DNase-treated total RNA was reverse transcribed using an iScript cDNA Synthesis Kit (BioRad Laboratories, Hercules, CA, USA). After incubation at 25℃ for 5 min, at 42℃ for 30 min and at 85℃ for 5 min, the resulting cDNA was quantified by real-time RT-PCR with SYBR GREEN according to the manufacturer's protocol (Roche Applied Science, Indianapolis, IN, USA) using HCV genotype 1b specific primers: forward primer: 5'-CTGTCTTCACGCAGAAAGCG-3' and reverse primer: 5'-CACTCGCAAGCACCCTATCA-3'. *Homo sapiens* lactate dehydrogenase A (LDHA) mRNA levels in each sample were simultaneously quantified to normalize values of HCV RNA. The primer sequence for LDHA forward primer was: 5'-TAATGAAGGACTTGGCAGATGAACT-3' and reverse primer: 5'-ACGGCTTTCTCCCTCTTGCT-3'. Assays were performed in triplicate and results expressed as mean ± SD of HCV replication as a percent of unrelated control.

For the JFH infection system, RNA replication in transfected cells was quantified by RT-PCR using HCV genotype 2a specific forward primer: 5'-TAGGAGGGCCCATGTTCAAC-3', reverse primer 5'-CCCCTGGCTTTCTGAGATGAC-3'. The PCR conditions were: 2 min at 50℃, 10 min at 95℃ and 15 s at 95℃. After 40 cycles, final extension was performed at 60℃ for 1 min. Assays were performed in triplicate and results expressed as mean ± SD of HCV replication as a percent of unrelated control.

Western blotting analyses

Total protein lysates of Huh7.5 cells stably infected with JFH-1 were evaluated by Western blotting. Cells were harvested in RIPA buffer (50 mmol/L Tris-HCl, pH 7.4, 1% NP-40, 0.25% Na-deoxycholate, 150 mmol/L NaCl, 1 mmol/L EDTA) supplemented with protease inhibitors

(Roche). Protein concentrations were determined with Bio-Rad assay as described by the manufacturer. Forty micrograms of protein was resolved by SDS-PAGE, and transferred to Hybond nitrocellulose membranes (Amersham Pharmacia, Piscataway, NJ, USA). Membranes were blocked with 5% nonfat milk in PBS, incubated with a 1:1000 dilution of the monoclonal mouse HCV NS3 antibody (Biodesign International, Saco, ME, USA), washed with PBS/0.05% Tween 20 and incubated with horseradish peroxidase (HRP)-conjugated goat anti-mouse antibody (Pierce, Rockford, IL, USA) at 1:20 000 dilution. Bound antibodies were detected with SuperSignal chemiluminescent substrate (Pierce) and quantified by Gel Imaging software GeneTools (SynGene, Frederick, MD, USA). To ensure comparable loading of samples, blots were incubated with a 1:1000 dilution of a polyclonal rabbit α-tubulin antibody (Abcam Inc., Cambridge, MA, USA), and detected by HRP-conjugated goat anti-rabbit secondary antibody using procedures as described above.

Evaluation of possible antisense effects

Because the 5B-74 structural mimic was single-stranded, and retained significant (74%) sequence identity to JFH-1 genotype 2a sequence, it was possible that the observed inhibition of replication was a result of antisense effects. To assess this possibility, 4 complementary RNAs 21-28 nt long, spanning the 5B-74 mimic were synthesized (IDT-Integrated DNA Technologies, Inc., Coralville, IA, USA). The antisense sequences were: 5B-C1 (nt 5-21), 5'-CCGGCUGCGUCCCAGUUGGAU-3', 5B-C2 (nt 22-43), 5'-UUAUCCAGCUGGUUCGUUGCUG-3', 5B-C3 (nt 44-71), 5'-GUUACAGCGGGGGAGACAUAUAUCACAG-3' and 5B-C4 (nt 72-95), 5'-CCUGUCUCGUGCCCGACCCCGCUG-3'.

One day before transfection, JFH-1-infected Huh7.5 cells were plated in growth medium without antibiotics, to be 95% confluent at transfection. Oligomer-Lipofectamine 2000 complexes were prepared by dilution of 50 pmol or 500 pmol RNA oligomer in 250 μL of Opti-MEM I without serum. Five microliters of Lipofectamine 2000 was diluted in 250 μL Opti-MEM mixed gently and incubated for 5 min at 25℃. The diluted oligomer was combined with diluted Lipofectamine 2000, mixed and incubated for 20 min at 25℃. Complexes were added to each well containing cells and medium. After 6 h, 1.5 mL of 15% FBS diluted in DMEM was added and the cells were incubated at 37℃ in a CO_2 incubator for 48 h. HCV RNA replication was determined by real-time RT-PCR using HCV specific primers. Assays were performed in triplicate and results expressed as mean ± SD of HCV replication as a percent of unrelated control.

RESULTS

For replicon studies, structural RNA mimics were constructed based on sequences of the HCV 1b subgenomic replicon, BB7. Because HCV RNA replication involves generation of both positive and negative strands, structural mimics were designed for both strands. These targets were selected based on previous reports that HCV RNA bears CREs in the positive-strand NS5B coding region[6,8,16,17] and X region[18,19] as well as in the negative strand 3'-terminal region[13,39].

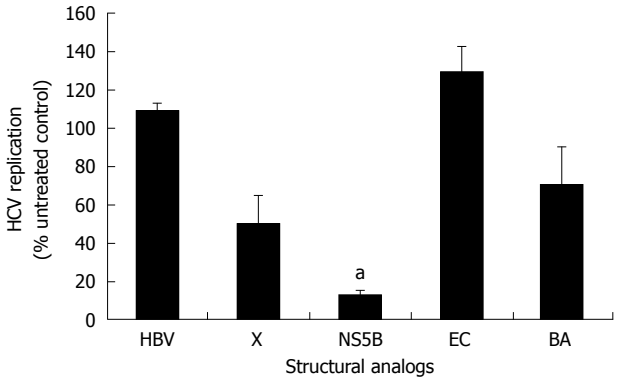

Figure 3 HCV RNA levels in the BB7 replicon cell lysates at 48 h post-transfection with structural mimics. BB7 replicon cells were transfected with plasmids generating structural mimics, and HCV RNA levels were assayed by real-time reverse transcriptase polymerase chain reaction (RT-PCR). The columns and bars represent the mean ± SD, respectively of 3 independent triplicate transfections. Statistically significant differences relative to controls are indicated by ($^aP < 0.05$).

The results of transfection of RNA mimics into BB7 replicon cells quantified by real time RT-PCR are shown in Figure 3. The 5B mimic inhibited HCV replication by more than 90%. Mimics to X and BA regions decreased replication by 50%, and 60%, respectively. The EC mimic actually had no inhibitory effect, and in fact appeared to increase replication, but the effect was not statistically significant. The fact that this sequence, also identical to the natural HCV sequence, failed to inhibit replication indicates that the observed inhibition by the NS5B mimic did not result from a nonspecific effect of HCV RNA. The inhibition by the NS5B plasmid was found to be dose-dependent up to 25 μg (data not shown).

Because the NS5B structural mimic appeared to be the most effective, further experiments were performed to determine whether this mimic might be effective against a different genotype in JFH-1-infected Huh-7.5 cells. It was found that the NS5B, now named 5B-74, mimic which was only 74% identical to the genotype 2a sequences of NS5B was as effective in suppression of HCV replication of JFH-1 genotype 2a as 5B-100 which was 100% identical to the genotype 2a (Figure 4).

The intent of the design of the structural mimics was to create single-stranded versions of the natural structure to compete for protein interactions. However, it is possible that the observed inhibitory effects could have been simply the result of non-specific effects. To explore this possibility, the mimic 5B-46 was prepared in which bases were changed at positions 2-15, 18, 30-43, 49-54, 57-60, 75-78, and 89-94 (Figure 2), with a sequence identity of the stems of only 27.5%, and overall

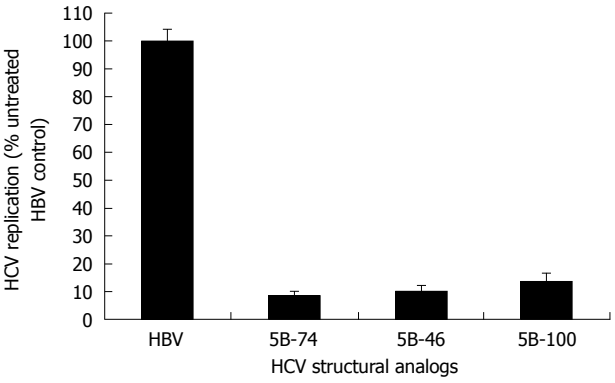

Figure 4 Effects of transfection of NS5B mimics 5B-74, 5B-46 and 5B-100 on Japanese fulminant hepatitis-1 (JFH-1) genotype 2a viral infection in Huh7.5 cells. Cells stably infected with JFH-1 genotype 2a virus were transfected with plasmids generating structural mimics, and HCV RNA levels were assayed by real-time RT-PCR. Assays were performed in triplicate and results expressed as mean ± SD of HCV replication percents of unrelated hepatitis B virus (HBV) control.

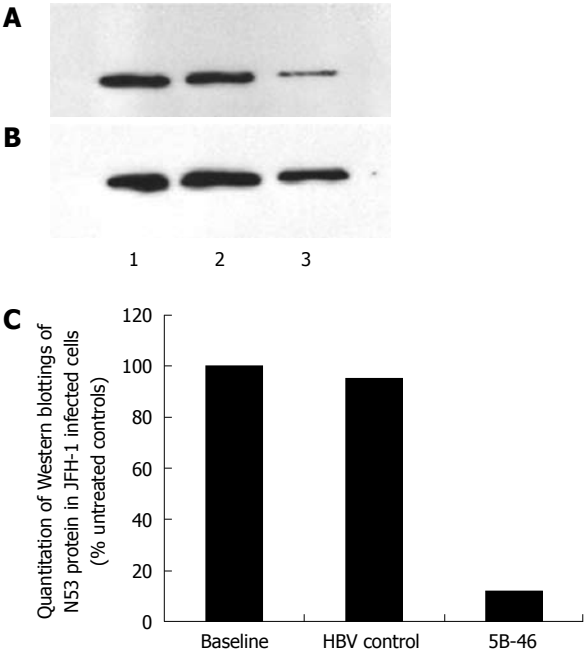

Figure 5 Western blotting analysis of NS3 protease gene expression in JFH-1 infected Huh7.5 cells after transfection of 5B-74 mimic and controls. A: HCV NS3; B: Tubulin, 72 h after transfection. Lane 1: Levels prior to addition of mimic; Lane 2: HBV (unrelated) control; Lane 3: 5B-46 mimic; C: Quantification of Western blottings of NS3 protein in JFH-1-infected cells at baseline, after 72 h exposure to 5B-46, and to HBV unrelated control. Bound NS3 antibodies were detected with SuperSignal chemiluminescent substrate and quantitated by Gel Imaging software GeneTools.

identity of 46%, relative to JFH-1 (genotype 2a) NS5B. The 5B-74 mimic decreased HCV replication by 91%. Furthermore, in spite of a sequence identity of only 46%, the novel mimic 5B-46, decreased HCV replication in JFH-1-infected cells by 90%, not significantly different from the mimic 5B-74 with 74% identity, or the mimic 5B-100 with complete identity to the HCV genotype 2a (Figure 4).

To assess viral protein levels, Western blottings of

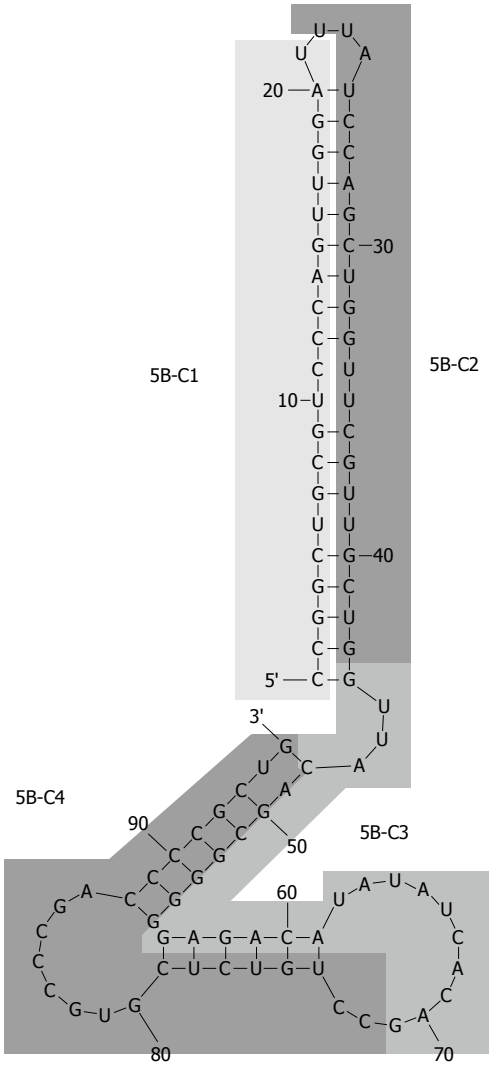

Figure 6 Diagram of single-stranded fragments spanning the entire length of the 5B-74 mimic used as antisense controls.

the NS3 protease were performed. Levels of neither the housekeeping protein tubulin (lane 2, Figure 5B) nor the NS3 protease (lane 2, Figure 5A) were affected by the unrelated HBV control mimic. However, the 5B-74 mimic decreased NS3 protease levels by 90% (lane 3, Figure 5A), while tubulin levels remained unchanged (lane 3, Figure 5B), the latter arguing against a non-specific effect or toxicity by the mimics. Quantification of the Western blottings confirmed the strong inhibitory effects of the 5B-46 mimic as shown in Figure 5C.

In the 5B-46 mimic, although most of the stem regions were altered, the sequences in the loops were left unchanged in order to retain secondary structure. Therefore, an antisense effect of the loop regions was still possible. To evaluate this possibility, short single-stranded fragments were prepared spanning the 5B-74 mimic (Figure 6). Analysis by Mfold ver 3.2 did not generate any stem-loop structures corresponding to regions in the native 5B-74 (data not shown). None of these sequences had any significant effects on HCV RNA levels compared to control (Figure 7), supporting the

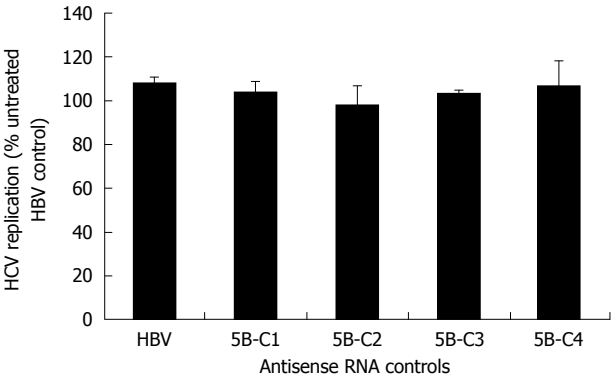

Figure 7 HCV replication after transfection of single-stranded RNA fragments corresponding to specific regions of the 5B-74 mimic in JFH-1-infected Huh7.5 cells. Cells stably infected with JFH-1 HCV were transfected separately with single-stranded fragments spanning the entire length of the 5B-74 mimic. HCV RNA levels were assayed by real-time RT-PCR. Assays were performed in triplicate and results expressed as mean ± SD of HCV replication as percent of unrelated (HBV) control.

conclusion that the 5B-74 and 5B-46 mimics inhibited HCV replication not by sequence complementarity, but by conformational attributes.

DISCUSSION

Previous studies have shown that overexpression of RNA analogs in infected cells can result in sequestration of essential factors. For example, suppression of human immunodeficiency virus-1 replication in cell models has been demonstrated by expression of structural mimics of the TAR element[40], RRE structure[41], and primer binding sequence[42]. HCV RNA has a number of CREs that could potentially be inhibited by structural RNA mimics. Structural mimics based on the HCV IRES were recently shown to inhibit HCV translation *in vitro* and in replicon models[10]. However, no effect on RNA replication was observed in the latter, possibly because of the bicistronic nature of the replicon.

It has been shown previously that double-stranded RNA can induce synthesis of cytokines including interferons which have antiviral effects. However, stimulation of interferon production has been reported to be dependent on the length of the RNA, with duplexes greater than 30 bp having been found to be most efficient[43]. Many studies have shown that smaller siRNAs of 20-21 base pairs (bp) have purely RNAi activity. In the current study, for the 5B-74, 5B-46, and 5B-100 mimics, the longest double-stranded regions were only 9 bp, followed by 8, 6 and 3 bp. Furthermore, the EC mimic was also predicted to have 9, 8, 6 and 3 bp regions. Yet, EC had essentially no significant inhibitory activity. Therefore, while double-stranded RNA stimulation of interferon production cannot be entirely excluded, if it occurs, it is not likely to account for the observed inhibitory effects of the 5B mimics.

Recently, cell culture systems for *in vitro* replication and infectious virus production have been established based on full-length HCV genotype 2a RNA[36,38,44,45]. This infectious HCV possesses 21% differences compared to the HCV 1b subgenomic replicon, BB7. Nucleotide sequences involved in the kissing-loop interaction are conserved between JFH-1 and BB7. However, mutations in other regions may affect this interaction by disrupting the RNA secondary structure[46]. It is interesting to note that small RNAs corresponding to 2 domains of HCV 2a, which differed from those in HCV 1b in 13 of 44 nucleotides and 6 of 48 nucleotides, respectively, inhibited the replication of replicon RNA from pLMH14 (HCV 1b) by 48.3% and 37.1%, respectively indicating that HCV 2a-derived RNAs could cross-interact with HCV 1b components despite the sequence differences between the elements of the 2 viruses[47]. Based on this finding, and the fact that most of the nucleotide substitutions in one domain from HCV 2a were compensatory bp changes, Zhang *et al*[47] hypothesized that the structure rather than the primary sequence was important for its function.

Viral replication has been shown to require the interaction of host factors with viral RNA and/or proteins. For HCV, several RNA-binding proteins, including L autoantigen[48], NS1-associated protein 1[49], polypyrimidine tract binding protein[50] and cyclophilin B[22] have been shown to bind to HCV RNA. Therefore, while we have focused on effects of mimics on HCV replication, because other vital HCV activities also depend on protein-RNA interactions, it is possible that the strategy for inhibition of replication by structural mimicry could be extended to other targets.

ACKNOWLEDGMENTS

The authors thank Dr. Charles Rice (Rockefeller University, NY) for providing Huh7.5 cells, Dr. Takaji Wakita (National Institute of Infectious Diseases, Tokyo) for providing HCV JFH-1 cDNA, and Amy Pallotti for secretarial assistance.

COMMENTS

Background

Chronic hepatitis C virus (HCV) infection is a leading cause of chronic hepatitis, liver cirrhosis and hepatocellular carcinoma. Current therapeutic options are limited and associated with significant adverse effects. Accordingly, there is a strong impetus to develop novel therapeutic options. Because HCV replicates through the interaction of its RNA-dependent RNA polymerase and its RNA template to generate progeny RNA, physical contact between the enzyme and genomic RNA is required. The authors hypothesized that mimics could be created with sufficient resemblance to the natural genomic structure to compete with the HCV genome, resulting in inhibition of replication.

Research frontiers

Previous studies have shown that overexpression of RNA analogs in infected cells can result in sequestration of essential factors. For example, suppression of human immunodeficiency virus-1 replication in cell models has been demonstrated by expression of structural mimics of the TAR element, RRE structure, and primer binding sequence. HCV RNA has a number of cis-acting replication elements that could potentially be inhibited by structural RNA mimics. Structural mimics based on the HCV internal ribosome entry site were recently shown to inhibit HCV translation *in vitro* and in replicon models.

Innovations and breakthroughs

The novel feature of this research is the discovery that stretches of RNA can

be made that have little sequence similarity to HCV. However, because of the retention of the predicted structure, they have been found to be highly potent and specific agents for inhibition of HCV replication.

Applications

Specific sequences inhibiting HCV replication without substantial HCV sequence identity may be a novel therapeutic option to circumvent the appearance of resistance arising from mutation of the viral genome.

Terminology

Single-stranded RNA structural mimics are a class of polynucleotides that can inhibit replication of the HCV and are designed to mimic the shape of natural viral nucleic acids, without requiring the matching of nucleic acid sequences.

Peer review

The study of Smolic *et al* described the antiviral effect of HCV structural mimics in replicon and infectious models. It is a very straightforward and concise paper. The results provided clear evidence of the inhibition of viral replication by these mimics, likely *via* conformational attributes. However, several issues regarding the mechanism of action should be addressed to further strengthen this study.

Abstract

AIM: To differentiate focal liver lesions based on enhancement patterns using three-dimensional ultrasonography (3D US) with perflubutane-based contrast agent.

METHODS: Two hundred and eighty two patients with focal liver lesions, including 168 hepatocellular carcinomas (HCCs), 63 metastases, 40 hemangiomas and 11 focal nodular hyperplasias (FNHs), were examined by 3D US with perflubutane-based contrast agent. Tomographic ultrasound images and sonographic angiograms were reconstructed. Among 282 lesions, enhancement patterns of 163 lesions between January 2007 and October 2007 were analyzed retrospectively. Then from November 2007 to May 2008, compared with contrast-enhanced (CE) 2D US, CE 3D US was performed on 119 lesions for prospective differential diagnosis. Sensitivity, specificity, area under receiver operating characteristic curve (A_z) and inter-reader agreement were assessed.

RESULTS: With the tridimensional view, dominant enhancement patterns were revealed as diffuse enhancement or peripheral ring-like enhancement, followed with washout change for HCCs or metastases, respectively, and peripheral nodular enhancement or diffuse enhancement with spoke-wheel arteries, followed by persistent enhancement for hemangiomas or FNHs, respectively. At CE 3D US, the prospective differentiation of lesions showed sensitivity 92% (mean for two readers), specificity 91% and A_z value 0.95 for HCCs, 84%, 97%, and 0.95 for metastases, 91%, 98%, and 0.98 for hemangiomas and 80%, 99%, and 0.99 for FNHs, respectively, while good to excellent inter-reader agreement was achieved. No significant difference exists between prospective diagnosis accuracy at CE 3D US and that at CE 2D US.

CONCLUSION: CE 3D US provides a spatial perspective for liver tumor enhancement, and could help in differentiating focal liver lesions.

INTRODUCTION

Focal liver lesions are increasingly being discovered with the widespread use of diagnostic imaging modalities, and differentiation of various liver lesions is considered to be critical for determining treatment options. Tremendous advancements in imaging techniques, including ultrasonography (US), computed tomography (CT), and magnetic resonance imaging (MRI) have resulted in these modalities being accepted as effective and thus widely used to characterize focal liver lesions[1-5]. This reduces the necessity of invasive histopathological examination.

With the advantages of non-invasiveness, no radiation and flexible operation, contrast-enhanced (CE) US has become increasingly important in the detection and characterization of focal liver tumors over the past several years[6-13]. Microbubbles of ultrasound contrast agent approximately the same size as red blood cells move into vessels but not through the vascular endothelium into the interstitium, which provides exact information about vascularity by reflecting specific signals, while some contrast agents present a postvascular hepato-specific phase probably due to reticuloendothelial system phagocytosis or the adherence of microbubbles to hepatic sinusoids[14-17]. Sonazoid (Daiichi Sankyo, Tokyo, Japan), a newly-developed second-generation ultrasound contrast agent, which consists of microbubbles (mean diameter 2-3 μm) of a perfluorobutane gas stabilized by a phospholipid monolayer shell, allows continuous real-time CE imaging for more than 10 min, and improves the reproducibility and durability of CE US examination[18-20].

Recently, the advent of CE three-dimensional (3D) US, facilitating demonstration of the desired regions with dynamic information in spatial volume, has led to new applications of CE US imaging[21-24]. Different from the 2D images, CE 3D US acquires the data in a volume of interest (VOI) by automatically scanning with a desired angle and allows reconstruction of tomographic images in three orthogonal planes and rendered angiogram-like images. With the feature of illustration in three dimensions, CE 3D US has been proven to offer accurate and detailed visualization of the vascular characteristics of various focal liver tumors[25,26].

To our knowledge, although many studies on differentiation among various focal liver lesions have been conducted using CE 2D US[27-29] and recently a few using CE 2D US with Sonazoid[30], the exact value of CE 3D US with Sonazoid in the differential diagnosis of various focal liver lesions has not yet been clarified. Thus, in this study, in order to examine the potential role of CE 3D US in characterizing focal liver lesions, we retrospectively evaluated the enhancement patterns and the diagnostic criteria established using dominant enhancement patterns were then applied to differentiation among focal liver lesions in a prospective study.

MATERIALS AND METHODS

Patients

Institutional Review Board approval was obtained for this retrospective and prospective study and informed consent was obtained from all patients. The reference standards for focal liver lesions in this study were described as follows: hepatocellular carcinomas (HCCs) with diameters exceeding 2 cm were confirmed by typical findings on both dynamic multi-detector CT and CE MRI[31]; HCCs exceeding 2 cm in diameter without typical radiological findings and those less than 2 cm in diameter, as well as all the liver metastases, were confirmed using histopathological results from percutaneous biopsy or surgery; benign tumors were confirmed by typical appearance on either dynamic multi-detector CT or CE MRI with at least 6-mo follow-up by dynamic multi-detector CT or CE MRI, and those without typical findings were confirmed histopathologically.

Between January 2007 and October 2007, 183 consecutive patients known or suspected to have focal liver lesions were examined using CE 3D US. Among these, 163 patients (90 men and 73 women) with 163 focal liver tumors were retrospectively identified, based on the following enrollment criteria: satisfactory CE 3D US images were acquired without artifacts from the cardiac and respiratory motion, shadows of costal bones, and abdominal gas; the definitive diagnosis of lesions was confirmed according to reference standards; the lesions had not been treated previously. Twenty patients were excluded: 6 with HCCs and 6 with hepatic metastasis lesions lacking a histological diagnosis; 3 HCCs and 3 hemangiomas with serious artifacts on the images; 2 benign lesions suspected on clinical information and imaging follow-up, without typical radiological findings and histological results. For 58 patients with multiple lesions, only the largest one with CE 3D US images and confirmed diagnosis was selected for evaluation. These 163 lesions were reviewed in the retrospective study to summarize the dominant enhancement patterns, which would be the diagnostic criteria in the prospective study.

From November 2007 to May 2008, the prospective study was conducted using CE 3D US on 124 consecutive patients with suspicious focal liver lesions detected by prior conventional US or CT and after that, CE 2D US was performed on each patient. For 40 patients with multiple lesions, CE 3D US examination was performed on the largest one, and if the largest lesion was not suitable for scanning due to its location, the next largest lesion was selected. CE 2D US was performed on the same lesion scanned by CE 3D US. In the prospective study, the exclusion criteria were: patients unable to hold breath; lesions with inappropriate locations for acquiring CE 3D

Table 1 Clinical characteristics of patients and focal liver lesions in retrospective and prospective studies (mean ± SD)

HCC: Hepatocellular carcinoma; FNH: Focal nodular hyperplasia.

US images due to artifacts from costal bone shadows, heart motion or abdominal gas; patients with lesions requiring histopathological diagnosis according to a reference standard but in whom surgery or biopsy was not possible due to poor liver function or lack of consent. Finally, 119 patients (67 men and 52 women) with 119 liver lesions were enrolled, while 2 patients with HCCs less than 2 cm in diameter and one with metastases were excluded for lack of consent on biopsy, and one patient with HCC and one with hemangioma were excluded for the obstruction of costal bone shadow.

Final diagnosis and clinical characteristics are shown in Table 1. The metastases in the retrospective study included 17 from colon carcinomas, 6 from pancreatic carcinomas, 5 from intrahepatic cholangiocellular carcinomas (ICC), 4 from rectal carcinomas, 1 from an ileum carcinoma, 1 from a gallbladder carcinoma and 1 from an ovarian carcinoma. Metastases in the prospective study comprised 15 from colon carcinomas, 4 from pancreatic carcinomas, 4 ICCs, 2 from rectal carcinomas, 1 from an ileum carcinoma, 1 from an ovarian carcinoma, and 1 from a gastric carcinoma. In this study, we classified the ICCs as hepatic metastasis because differentiation of ICCs from metastasis is difficult using only radiological imaging enhancement patterns.

Data acquisition

In the retrospective study, using the LOGIQ 7 ultrasound imaging system and 4D3CL volume probe (GE Healthcare, Milwaukee, WI) with a 2.0-5.5 MHz frequency, CE 3D US was performed by one sonographer with 10 years experience in using abdominal CE US. In the prospective study, CE 3D US was performed by the same sonographer in the retrospective study. After 1 or 2 d using the LOGIQ 7 ultrasound imaging system and 3.5 CS convex probe (GE Healthcare, Milwaukee, WI), CE 2D US was performed on each lesion by the same sonographer at CE 3D US. In this study, the acquisition of 3D images was performed with a convex volume 4D3C-L probe which scans automatically with internal sectorial mechanical tilt movement to obtain the data. The scanning angle could be selected from 15° to 84°. In this study we used 30-70° depending on different tumor sizes and the duration for one scanning process varied from 4.5 to 21.3 s (mean time, 12 s).

Prior to both CE 2D US and CE 3D US scanning, all patients received an intravenous bolus injection of 0.2 mL Sonazoid followed by a 2 mL 5% glucose solution and subsequent infusion of 5% glucose solution at 10 mL/min. The coded harmonic angio (CHA) mode (mechanical index = 0.5-0.9) at 8 to 13 frames per second was used for both CE 2D US and CE 3D US scanning. The contrast sonography process included three phases, that is, an early phase (10-40 s after contrast medium injection), a middle phase (80-120 s after contrast medium injection) and a late phase (more than 5 min after contrast medium injection). During each phase, the CE US scanning was performed when the characteristic enhancement of focal liver lesions appeared.

Static 3D and Autosweep 3D functionalities, with which the LOGIQ 7 ultrasound imaging system is equipped, were used for image acquisition. Employing the different engineering features of these two functionalities, in the early phase, both Static 3D and Autosweep 3D were used to acquire 3D data, while in the two other phases only the Autosweep 3D functionality was used. A VOI with an adjustable scanning angle and size was determined before scanning to contain the desired region. The data acquired were stored as cineloops in the hard disk of the ultrasound imaging system.

Image reconstruction

3D image reconstruction was performed using the functionalities with which the LOGIQ 7 ultrasound system was equipped. In the VOI which was presented in an isotropic rectangular coordinate frame, the three orthogonal planes were referred to as plane A which could migrate from front to rear through the VOI, plane B from left to right and plane C from up to down. Tomographic ultrasound images (TUI) with presentation of several parallel slices in three orthogonal planes were reconstructed in three phases, while the number of slices that could be selected was 2, 4, or 6 for images obtained using Autosweep 3D, and 2, 4, or 9 for Static 3D. In

order to show the desired images, the range of distance between two slices in TUI could be adjusted if required. The mean times of these procedures were about 20 s. Sonographic angiogram images were reconstructed in an angio-like view during the early phase by using various rendering modes. The maximum intensity mode displaying the maximum grey values in the VOI, mixed with surface mode displaying the grey value on the surface of objects, was used to visualize tumor vessels and early tumor enhancement, while the average intensity mode displaying the average grey values in the VOI, mixed with surface mode, was employed to describe the tumor based on the predominantly unenhanced areas. The mean times of these procedures were about 45 s. TUI in three dimensions and sonographic angiogram images were stored with volume data in the hard disk of the ultrasound imaging system. In both the retrospective study and the prospective study, the reconstruction of all the images was completed by one operator with 10 years of experience in abdominal US and 1 year in CE 3D US, blinded to the final diagnosis and other related information on patients.

Image evaluation

Before the 3D image evaluations in both the retrospective and prospective studies, all readers were given training in the assessment of various enhancement patterns. Image evaluation was divided into two sections: in the first section, TUI in early, middle and late phases and sonographic angiograms in the early phase were reviewed separately in random order for all the lesions and the enhancement patterns in each phase were classified; in the second section, all images in three phases for each lesion were read consecutively to observe enhancement changes over time. In the prospective study, 2D images were read 2 wk after the 3D image review. All the images were reviewed on the ultrasound imaging system. The zoom function and arbitrary rotation of images are available in both TUI and sonographic angiograms.

In the retrospective study, images were reviewed independently by two readers (Numata K and Morimoto M) with 10 years of experience in liver US and 1.5 years of experience in CE 3D US imaging, who were blinded to final diagnosis and clinical and other radiological information. The readers were asked to classify the enhancement patterns in three phases and enhancement changes over time. In the early phase, the enhancement patterns consisted of tumor enhancement and tumor vessels: four tumor enhancement patterns including diffuse enhancement defined as homogeneous or heterogeneous tumor enhancement, peripheral ring-like enhancement defined as enhancement in the tumor periphery with a ring shape, peripheral nodular enhancement defined as enhancement in the tumor periphery with a nodular shape, and absence of tumor enhancement; four tumor vessel patterns including intratumoral vessels in the central portion of the tumor, peritumoral vessels at the periphery of the tumor, spoke-wheel arteries defined as a centrally located artery with centrifugal stellate branching, and absence of vessels. In the middle phase, four patterns were classified based on tumor enhancement: diffuse enhancement, peripheral ring-like enhancement, peripheral nodular enhancement and perfusion defect. In the late phase, the hypoechoic pattern was defined as all or part of the lesion having low echogenicity as compared to the surrounding liver parenchyma, and the isoechoic pattern as the entire lesion having echogenicity equal to that of the surrounding liver parenchyma. The enhancement changes over time were assessed: washout, early enhancement greater than that of the liver parenchyma and enhancement in the middle or late phase less than that of the liver parenchyma; persistence, whatever the enhancement pattern in the early phase was, enhancement of the lesion in the middle and late phases was at least equal to that of the liver parenchyma; absence of washout and persistence, no distinct enhancement was detected in any of the three phases.

Evaluations of 153 lesions by two readers were in concordance. For 10 lesions, enhancement patterns evaluated by two readers were different but a consensus was finally reached. After the pattern classification, the combination of enhancement patterns in the three phases was summarized and the positive predictive value (PPV) was calculated. The combined enhancement patterns with PPV more than 50% served as diagnostic criteria for the analysis in the prospective study.

In the prospective study, two readers (Nozaki A and Luo W) with 8 and 5 years of experience in CE US of the liver and 1 year of experience in CE 3D US imaging, blinded to the final diagnosis and clinical and other radiological information, read CE 3D US images and differentiated focal liver lesions according to the diagnostic criteria established in the retrospective study. After reading 2D images, these two readers also made a diagnosis of each lesion according to the criteria previously established (Table 2)[27,28,32,33].

On 3D images and 2D images, for each diagnosis, i.e. HCC, metastasis, hemangioma, and focal nodular hyperplasia (FNH), a four-point scale was used to grade diagnostic confidence. For instance, in HCCs, grade 1 was defined as "probably not a HCC lesion", grade 2 as "possibly not a HCC lesion", grade 3 as "possibly a HCC lesion" and grade 4 as "probably a HCC lesion". The confidence level of each reader was compared in consideration of the final diagnosis by two physicians (Kondo M and Tanaka K). True-positive (TP) cases were considered to be those assigned as grade 3 to 4 and verified by reference standards as actually being positive diagnoses. False-positive (FP) cases were considered to be those assigned as grade 3 to 4 but verified as actually being negative diagnoses. True-negative (TN) cases were considered to be those assigned as grade 1 to 2 by the reader, and verified as actually being negative diagnoses. False-negative (FN) cases were considered to be those assigned as grade 1 to 2 but verified as actually being positive diagnoses.

Table 2 Diagnostic criteria for focal liver lesions depicted by CE 2D US

Lesion	Enhancement patterns		
	Early phase	Middle phase	Late phase
HCC	Intratumoral vessels with early homogeneous or heterogeneous enhancement, or intratumoral vessels alone	Homogeneous or heterogeneous enhancement	Hypoechoic lesion
Metastasis	Peritumoral vessels with early peripheral ring like enhancement	Peripheral ring like enhancement or perfusion defect	Hypoechoic lesion
Hemangioma	Peripheral nodular enhancement	Peripheral nodular enhancement, with centripetal progression	Isoechoic lesion, with centripetal progression
FNH	Spoke-wheel arteries with early homogeneous enhancement	Homogeneous enhancement	Isoechoic lesion with central scar

CE: Contrast-enhanced; 2D US: Two-dimensional ultrasonography.

Statistical analysis

The data analysis was performed by using SPSS software (version 11.0; SPSS, Tokyo, Japan). In the retrospective study, SE was defined as the probability of the given enhancement pattern appearing in a reference disease, while SP indicated the probability of the absence of a given enhancement pattern for negative diagnoses. Prior probability was calculated by dividing the numbers of HCCs, metastases, hemangiomas and FNHs by the total number of tumors (163 tumors). According to Bayes theorem, the PPV of the combination of enhancement patterns for each tumor category was calculated based on sensitivity (SE), specificity (SP), and prior probability (PP) using the formula: PPV = SE × PP/[SE × PP + (1 - SP)× (1 - PP)].

In the prospective study, SE was calculated as TP/(TP + FN) and SP was calculated as TN/(FP + TN). The ROC curve was fitted to each reader's confidence level by using a maximum likelihood estimation program (ROCKIT 0.9B; http://www-radiology.uchicago.edu/krl/KRL_ROC). Area under the ROC curve (A_z) with the 95% confidential interval was calculated for each modality to measure the overall diagnostic performance. κ values were used to assess inter-reader agreement in characterizing focal liver tumors. Agreement was graded as poor (< 0.20), moderate (0.20 to 0.40), fair (0.40 to 0.60), good (0.60 to 0.80), or excellent (0.80 to 1.00).

RESULTS

Retrospective study

The enhancement patterns of 163 focal liver lesions are summarized in Table 3. In the early phase, 90% (88 of 98) of HCCs showed diffuse enhancement with intratumoral vessels (Figure 1A and B), 60% (21 of 35) of liver metastases peripheral ring-like enhancement with intratumoral or peritumoral vessels (Figure 2A), 79% (19 of 24) of hemangiomas peripheral nodular enhancement with peritumoral vessels or absence of vessels (Figure 3A and B), and 100% (6 of 6) of FNHs diffuse enhancement with spoke-wheel arteries (Figure 4A-C). In the middle phase, 93% (91 of 98) of HCCs showed diffuse enhancement (Figure 1C) and 69% (24 of 35) of metastases peripheral ring-like enhancement (Figure 2B), 75% (18 of 24) of hemangiomas peripheral nodular enhancement (Figure 3C) and 25% (6 of 24) diffuse enhancement, and 100% (6 of 6) of FNHs diffuse enhancement. In the late phase, 137 of 163 lesions were hypoechoic (Figures 1D, 2C, 2D and 3D), while the others were isoechoic (Figure 4D). Washout of enhancement was detected mainly in 121 of 133 malignant lesions (Figures 1 and 2), while enhancement persistence was detected mainly in 29 of 30 benign lesions (Figures 3 and 4). One HCC and two metastasis lesions were not enhanced from the early to the late phase and were assessed as showing absence of washout and persistence. The combination of enhancement patterns in three phases with PPV above 50% were summarized for each tumor category in Table 4 as the dominant enhancement patterns for establishing diagnostic criteria on 3D images in prospective study.

Prospective study

For CE 3D US, the diagnostic criteria for HCCs resulted in a SE of 93% (mean for two readers), SP of 91% and A_z value of 0.95, while those for metastases showed a SE of 84%, SP of 97% and A_z value of 0.95 in the prospective study. The combined enhancement patterns for hemangiomas as diagnostic criteria resulted in a SE of 91%, SP of 98% and A_z value of 0.98, while the dominant enhancement patterns for FNHs as diagnostic criteria resulted in a SE of 80%, SP of 99%, and A_z value of 0.99. Good to excellent inter-reader agreement was thus achieved for HCCs (κ = 0.86), metastases (κ = 0.83), hemangiomas (κ = 0.79) and FNHs (κ = 0.76).

For CE 2D US, sensitivity, specificity and A_z value of differential diagnosis were shown in Table 5. There were no significant differences between sensitivity, specificity and A_z value on CE 2D US and those on CE 3D US ($P > 0.05$). For HCCs, there was an SE of 92%, SP of 87% and A_z value of 0.95 (mean of two readers), while an SE of 84%, SP of 97% and A_z value of 0.94 were recorded for metastasis. For hemangioma, there was an SE of 84.5%, SP of 98% and A_z value of 0.95. For FNH, an SE of 70%, SP of 98% and A_z value of 0.98 were presented. SE, SP and A_z value of hemangioma and FNH on CE 2D US appeared lower than those on CE 3D US.

Table 3 Enhancement patterns using CE 3D US in three phases: positive predictive value in retrospective study

No.	Enhancement patterns					Positive predictive value			
	Early phase		Middle phase	Late phase	Enhancement changes	HCC	Metastasis	Hemangioma	FNH
	Tumor enhancement	Tumoral vessels	Tumor enhancement	Tumor echogenicity					
1	Diffuse	Intratumoral	Diffuse	Hypoechoic	Washout	0.98 (81)	0.01 (1)	0.01 (1)	0.00 (0)
2	Diffuse	Intratumoral	Diffuse	Isoechoic	Persistence	0.60 (3)	0.00 (0)	0.40 (2)	0.00 (0)
3	Diffuse	Intratumoral	Peripheral ring-like	Hypoechoic	Washout	0.33 (2)	0.67 (4)	0.00 (0)	0.00 (0)
4	Diffuse	Intratumoral	Perfusion defect	Hypoechoic	Washout	0.67 (2)	0.33 (1)	0.00 (0)	0.00 (0)

Sensitivity and specificity data are presented as percentages with numbers of tumors in parentheses.

DISCUSSION

Our study explored the potential role of CE 3D US, a newly-developed imaging modality, in presenting various tumor enhancement patterns and further characterizing different types of focal liver lesions. In this study, we used Sonazoid with CHA mode and high mechanical index contrast conditions, which allowed sensitive observation of vessels in the early phase by eliminating microbubbles in microvessels but not those in relatively large vessels, such as tumor vessels and portal veins[19].

In a previous study, we explored the visualization methods of CE 3D US for demonstrating focal liver lesions[24]. Moreover, in a retrospective study, according to the diagnostic criteria based on our experience and that described in the literatures, we assessed the diagnostic value of CE 3D US for characterization of focal liver lesions, in comparison with that of CE 3D CT[22]. Further, in the present study, we performed a retrospective study to clarify the enhanced patterns of focal liver lesions on CE 3D US, and the combined enhancement patterns with PPV more than 50% served as diagnostic criteria. According to these diagnostic criteria, we prospectively evaluated CE 3D US for characterizing liver lesions.

On CE 3D US, sonographic angiograms rendered using maximum intensity mode could be used to delineate tumor enhancement and present the spatial distribution of tumor vessels. Spoke-wheel arteries were regarded as a typical characteristic of FNHs on CE imaging in previous studies[34-36]. CE 3D US facilitated categorization of spoke-wheel arteries and provided a tridimensional view of the stellate branches. With consensus of the two readers, all 6 FNHs in the retrospective study were detected based on spoke-wheel arteries followed by persistent enhancement. In the prospective study, except for one FNH without distinctly detectable of spoke-wheel arteries, 4 of the other 5

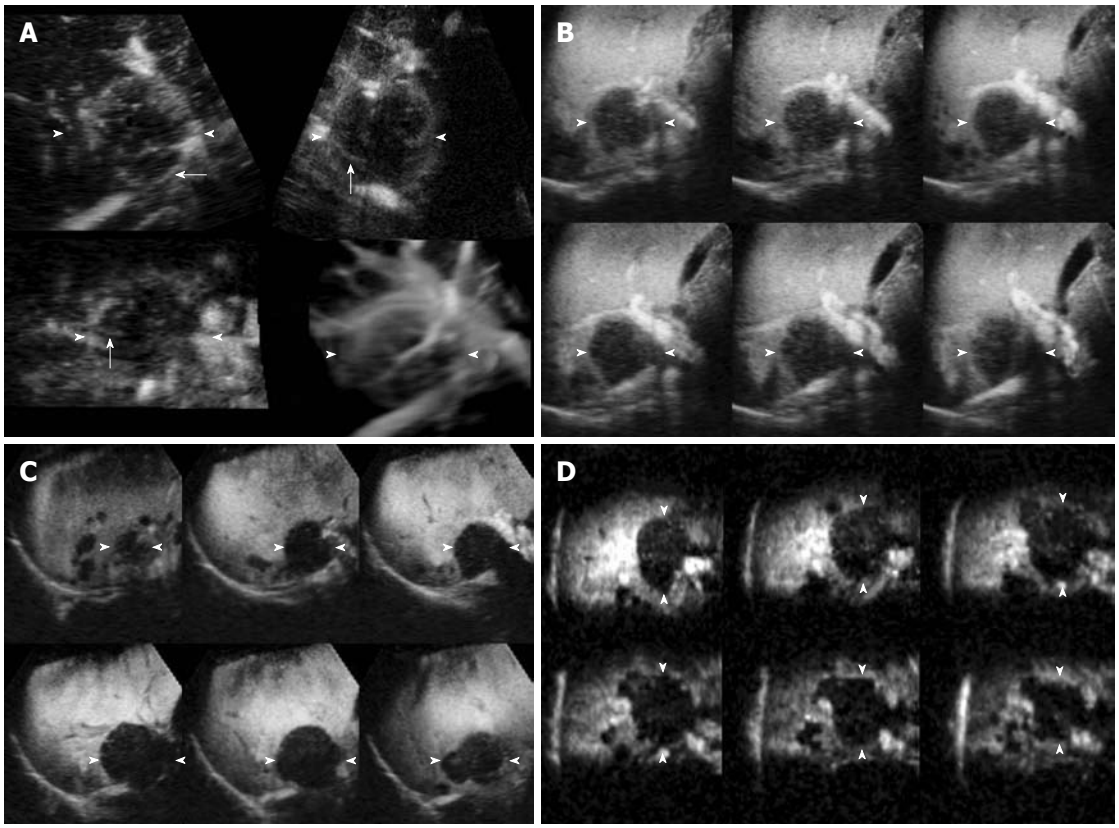

Figure 2 CE 3D US images of the liver in a 64-year-old woman with metastases from pancreatic carcinoma in the anterior superior segment of the right lobe. A: Images in the early phase show peripheral ring-like enhancement with peritumoral vessels (arrows) in plane A (upper left), plane B (upper right), plane C (lower left) and the sonographic angiogram rendered by average intensity with surface mode (lower right); B: Tomographic ultrasound image with slice distance 2.0 mm in plane A shows peripheral ring-like enhancement in the middle phase; C, D: Tomographic ultrasound images (TUI) in plane A with slice distance 2.5 mm (C) and that in plane C with slice distance 2.0 mm (D) show hypoechoic pattern in the late phase. Enhancement change of washout was detected in this lesion. Arrowheads indicate the tumor margin.

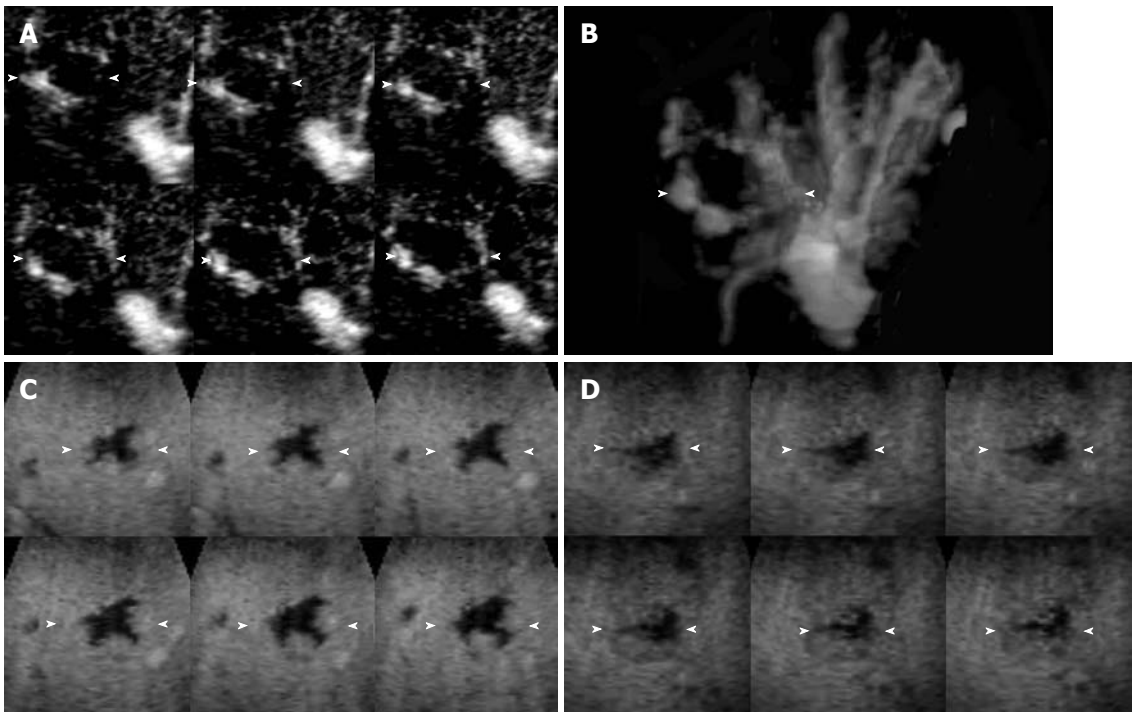

Figure 3 CE 3D US images of the liver in a 59-year-old woman with a hemangioma in the anterior inferior segment of the right lobe. A, B: Tomographic ultrasound image in plane A with slice distance 1.0 mm (A) and sonographic angiogram rendered by average intensity with surface mode (B) show peripheral nodular enhancement without distinct tumor vessels in the early phase; C: Tomographic ultrasound image in plane B with slice distance 1.0 mm shows peripheral nodular enhancement in the middle phase; D: Tomographic ultrasound image with slice distance 1.0 mm in plane B with slice distance 1.0 mm shows hypoechoic pattern in the late phase. Persistent enhancement over time was detected in this lesion. Arrowheads indicate the tumor margin.

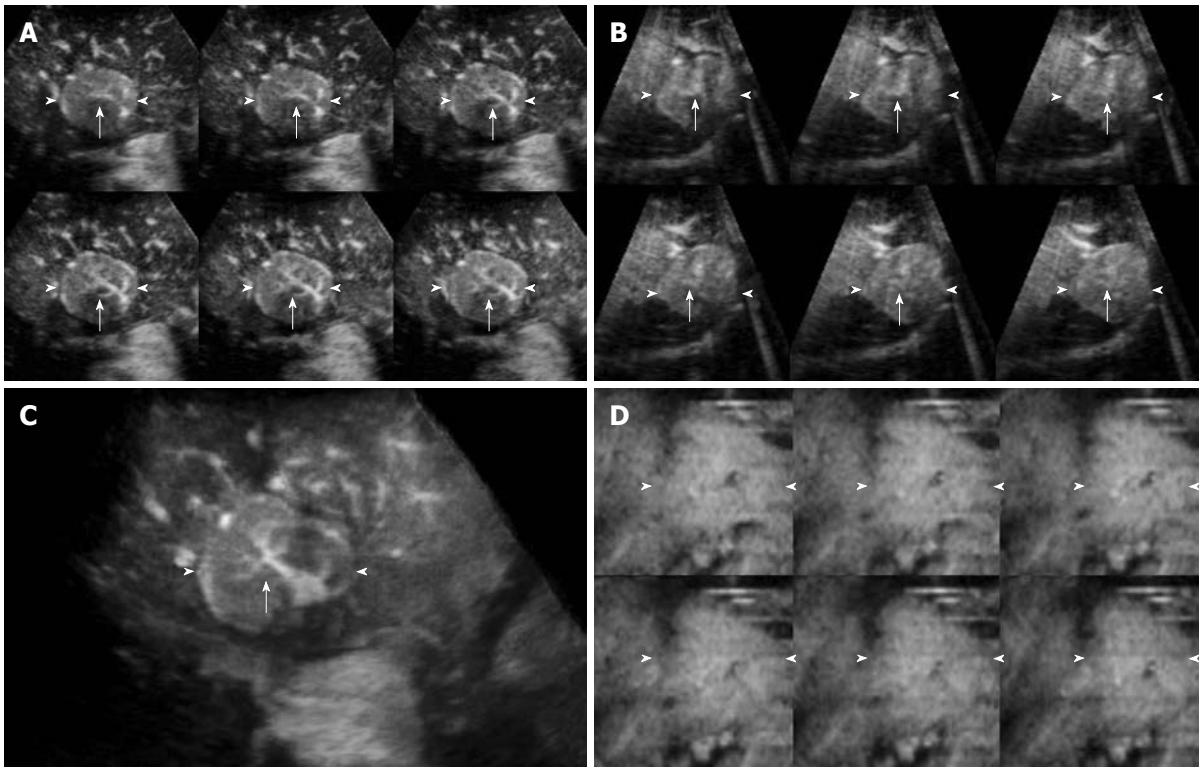

Figure 4 CE 3D US images of the liver in a 77-year-old man with FNH in the medial segment of the left lobe. A-C: TUI in plane A with slice distance 1.5 mm (A) and plane B with slice distance 1.5 mm (B), and the sonographic angiogram rendered by maximum intensity with surface mode (C) show diffuse enhancement with spoke-wheel arteries (arrows) in the early phase; D: TUI in plane C with slice distance 2.5 mm show isoechoic pattern in the late phase and hypoechoic regions within the tumor indicate central scars. Persistent enhancement over time was detected in this lesion. Arrowheads indicate the tumor margin.

lesions were diagnosed correctly. For the lesions with peripheral enhancement, sonographic angiograms rendered using average intensity modes delineated unenhanced portions in the lesions with hypoechoic appearance to make the tumor distinguishable from the surrounding liver parenchyma. Another feature of CE 3D US was the application of tomographic images presented in several parallel slices to multiplanar reconstruction, which allowed the reader to evaluate enhancement patterns in different portions of the lesion simultaneously. In this study, although there were no significant differences between the prospective diagnosis at CE 3D US and that at CE 2D US, CE 3D US created a spatial and easily understood view for both hemodynamic and morphologic evaluation of focal liver tumors, which were formed only in the doctors' imagination by 2D imaging using complex acquisition methods. The good to excellent inter-reader agreement in our previous study about CE 3D US as a means of presenting characteristic enhancement of HCCs has indicated CE 3D US can exhibit the characteristic enhancement of HCC tumors objectively[34].

In the present study, with analysis of combination of the enhancement in three phases at CE 3D US, the dominant patterns were used as the diagnostic criteria for individual category, and prospective differentiation yielded a good sensitivity, specificity, high A_z value, and good to excellent inter-reader agreement, which revealed the potential usage of CE 3D US in differentiating various focal liver lesions.

In the late phase in the retrospective study, 91% of malignant tumors (88 HCCs and 33 metastases) with washout changes appeared hypoechoic, while 53% of benign tumors (10 hemangiomas and 6 FNHs) with persistent enhancement appeared isoechoic. Neither isoechoic metastases nor hypoechoic FNHs were found in the late phase. There were 13 hemangiomas exhibiting hypoechoic findings in the late phase, and 12 of these 13 lesions were detected with incomplete fill-in and persistent enhancement, while one hemangioma was detected with early diffuse enhancement and washout change and was confirmed by the histological results on surgery. Vascularity in the early and middle phases appeared to be important for differentiation of focal liver lesions, and enhancement in the late phase with enhancement changes over time also facilitated characterizing the benign and malignant lesions[28,37].

This study has some limitations. First, CE 3D US on focal liver lesions has shortcomings including artifacts from the heart or respiratory motion, shadows of costal bones, and interference from abdominal gas, and so on. We minimized the influence of artifacts by requiring patients to hold their breath during the scanning procedure, selecting the location of the volume transducer, mediating the size and position of VOI, adjusting the scanning angle, and reconstructing the sonographic angiogram with appropriate rendering modes. Nevertheless, in some cases, artifacts on CE 3D US images might impact the readers' judgments and these lesions were thus excluded.

Second, in each case, only one lesion was evaluated and we did not assess the diagnostic capability and detectability of multiple lesions with CE 3D US. Third, the FNH cases in this study were few because FNHs have a relatively low prevalence and Sonazoid has been available in Japan for less than 2 years. More cases need to be examined in a future investigation.

In summary, our present results indicate CE 3D US with the contrast agent Sonazoid to offer a novel and useful means of presenting the vascularity characteristics three-dimensionally and differentiation of focal liver lesions with good diagnostic capability. These features of CE 3D US are anticipated to be of benefit in clinical diagnosis.

COMMENTS

Background

Recently, contrast-enhanced (CE) ultrasound (US) appeared as an important modality to show the vascularity in the areas of interest, and has been used widely in clinical diagnosis of liver lesions. Three dimensional ultrasonography (3D US) allows three orthogonal planes to spatially demonstrate the features of subjects, which has been frequently used in fetal US. Different from the 2D images, CE 3D US acquires the data in a volume of interest (VOI) by automatically scanning with a desired angle and allows reconstruction of tomographic images in three orthogonal planes and renders angiogram-like images. The combination of 3D US and CE US can present the enhancement of lesions in three dimensions and also in parallel slices by multiple- planar visualization.

Research frontiers

With the advantages of non-invasiveness, no radiation and flexible operation, CE US has become increasingly important in the detection and characterization of focal liver tumors over the past several years. Sonazoid (Daiichi Sankyo, Tokyo, Japan), a newly-developed second-generation US contrast agent, which consists of microbubbles (mean diameter 2-3 μm) of a perfluorobutane gas stabilized by a phospholipid monolayer shell, allows continuous real-time CE imaging for more than 10 min, and improves the reproducibility and durability of CE US examination.

Innovations and breakthroughs

To the authors' knowledge, although many studies on differentiation among various focal liver tumors have been conducted using CE 2D US and recently a few using CE 2D US with Sonazoid, the exact value of CE 3D US with Sonazoid in the differential diagnosis of various focal liver tumors has not yet been clarified. Thus, in this study, in order to examine the potential role of CE 3D US in characterizing focal liver tumors, the authors retrospectively evaluated tumor enhancement patterns, and the diagnostic criteria established using dominant enhancement patterns were then applied to differentiation among focal liver tumors in a prospective study.

Applications

The study's results suggest that CE 3D ultrasound provides a spatial perspective for liver tumor enhancement, and could help in differentiating focal liver tumors.

Terminology

Contrast enhanced ultrasound: the imaging modality of using US scanning while microbubbles serving as contrast agent are injected into vessels in order to improve the signals of red blood cells. Using this modality, the vascularity of VOI was depicted exactly and hemodynamics was demonstrated clearly.

Peer review

The aim of this study is to differentiate focal liver lesions based on enhancement patterns using 3D US with perflubutane-based contrast agent. The paper is written in a good English form, and is properly structured.

Abstract

AIM: To explore the distribution and metabolism of ^{131}I-gelatin microspheres (^{131}I-GMSs) in rabbits after direct injection into rabbits' livers.

METHODS: Twenty-eight healthy New Zealand rabbits were divided into seven groups, with four rabbits per group. Each rabbit's hepatic lobes were directly injected with 41.336 ± 5.106 MBq ^{131}I-GMSs. Each day after ^{131}I-GMSs administration, 4 rabbits were randomly selected, and 250 μL of serum was collected for γ count. Hepatic and thyroid functions were tested on days 1, 4, 8, 16, 24, 32, 48 and 64 after ^{131}I-GMSs administration. Single-photon emission computed tomography (SPECT) was taken for each group on days 0, 1, 4, 8, 16, 24, 32, 48, 64 after ^{131}I-GMSs administration. A group of rabbits were sacrificed respectively on days 1, 4, 16, 24, 32, 48, 64 after ^{131}I-GMSs administration. Their livers were taken out for histological examination.

RESULTS: After ^{131}I-GMSs administration, the nuclide was collected in the hepatic area with microspheres. The radiation could be detected on day 48 after ^{131}I-GMSs administration, and radiography could be seen in thyroid areas in SPECT on days 4, 8, 16 and 24. One day after ^{131}I-GMSs administration, the liver function was damaged but recovered 4 d later. Eight days after ^{131}I-GMSs administration, the levels of free triiodothyronine and free thyroxin were reduced, which restored to normal levels on day 16. Histological examination showed that the microspheres were degraded to different degrees at 24, 32 and 48 d after ^{131}I-GMSs administration. The surrounding parts of injection points were in fibrous sheathing. No microspheres were detected in histological examination on day 64 after ^{131}I-GMSs administration.

CONCLUSION: Direct *in vivo* injection of ^{131}I-GMSs is safe in rabbits. It may be a promising method for treatment of malignant tumors.

Direct *in vivo* injection of ^{131}I-GMS and its distribution and excretion in rabbit. *World J Gastroenterol* 2010; 16(17): 2120-2128 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i17/2120.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i17.2120

INTRODUCTION

The treatment of malignant tumors in hepatic, biliary and pancreatic systems has been and will always be a tough and key part of general surgery[1-3]. Surgical removal has been considered a positive approach for most of malignant tumors in these systems[4]. But the success rate of surgical removal is very low and the prognosis after operation is unsatisfactory[5-8]. For example, the number of cases of primary hepatic carcinoma in China was around 384 119 in 2005[9-12] and the number of deaths was 357 624[13-15], only 10%-30% are related to surgical removal, and 25% of them survived over 5 years[16]. The number of cases of pancreatic cancer in America was around 42 470 and the number of death was around 35 240 in 2009[17]. Surgical procedure has much limitations for treatment of malignant cancers. Many patients with malignant tumors in the three systems at middle to advanced stages are in the urgent need of new and effective non-surgical treatment.

Radionuclide labeled microspheres and seeds are the new progress made in the area of tumor therapy and interventional radiotherapy. It has now become a fast developing sub-field of medicine combining nuclear medicine and oncotherapy. Nuclide microspheres under study over recent years include ^{90}Y glass and resin microsphere[18-20], ^{188}Re glass microsphere[21], ^{32}P glass microsphere[22,23] and ^{166}Ho glass microsphere[24]. The ^{90}Y glass microsphere is being increasingly recognized by the medical community as an important strategy for the treatment of primary and secondary neoplasm, which was officially approved in 1999 in America and Canada for treatment of malignant tumors. Now hundreds of publications have described the treatment of ^{90}Y glass microsphere[25]. The therapeutic practices in thousands of patients with liver cancer in about 80 medical centers around the globe show that hepatic arterial injection of ^{90}Y glass microsphere is a safe and effective method for liver cancer treatment. Carr reports a group of clinical control study involving 65 cases of primary liver cancer. Forty-two cases are Okuda stage 1 with a median survival of 649 d (244 d for the control group), 23 are Okuda stage 2 with a median survival of 302 d (64 d for the control group)[26]. Salem reports another clinical study involving 49 cases of liver cancer with a median survival of 85.9 mo. Twenty-eight patients reached the condition for tumor removal after the treatment and had their tumors removed, and 13 patients had tumor necrosis after the treatment. Their survival rate for 1, 3 and 5 years are 98%, 64% and 57%, respectively[27]. Intratumoral injection of ^{90}Y glass microsphere has also been studied. Tian reported that the tumor was reduced by 92% in 27 cases of primary liver cancer and 6 cases of metastatic liver cancer. α-fetoprotein in 13 cases recovered entirely after intratumoral injection[28]. These studies showed similar clinical therapeutic efficacy of ^{90}Y glass microsphere to that of surgical procedure. The ^{125}I-seeds used for prostate cancer in Europe and America has been tried in intratumoral implantation in China to treat advanced pancreatic carcinoma, which has demonstrated effects in alleviating pains and prolonging life[29-31]. In conclusion, directional radiotherapy using nuclide microsphere or nuclide particle is a potential alternative to treat malignant tumors in hepatic, biliary and pancreatic systems.

China is a country with a large population in the world and has the highest incidence and death rate of primary liver cancer. And the incidence of biliary and pancreatic malignant tumors is increasing. However, most of the patients with middle to advanced stage cancers of the three systems cannot be treated with surgery. Therefore, directional radiotherapy using nuclide microsphere will significantly improve the prognosis of patients with middle to advanced stage cancers. Since ^{90}Y glass microspheres have to be activated in an accelerator to get radioactivity, and when they are activated, they have relatively short half-life. We have been studying the nuclide microspheres for local brachytherapy for hepatic, biliary and pancreatic malignant tumors. In the 1990s, we developed the ^{32}P glass microsphere with relatively long half-life, and treated 40 patients with advanced liver cancer from 1992 to 1994 after the completion of the metabolism tests *in vivo* in tumor-carrying animals[32]. In recent years, we have developed the gelatin microspheres (GMSs) with a diameter of 50-70 μm carrying a high concentration of ^{131}I to treat patients with advanced liver cancer with hepatic arterial transfusion and embolotherapy. Since its half-life is 8.04 d and free ^{131}I in the body is either collected in thyroid tissue or discharged out of the body quickly, ^{131}I is safe and has relatively weak influence on other tissues[33-35]. And the GMS is one of the degradable biomaterials with good biocompatibility, which can also bind ^{131}I nuclide at a high concentration[36]. So in this study, we prepared ^{131}I-GMSs with a diameter of 10-30 μm for intratumoral implantation, which is expected to be easily applied for the hepatic, biliary, pancreatic and other malignant tumors that cannot be removed. Healthy rabbits are used as models to observe the metabolism of ^{131}I-GMSs *in vivo* and the tissue reaction in their livers.

MATERIALS AND METHODS

Materials

Lime-processed gelatin (sigma G-9382) with an isoelectric point of 4.8-5.2 was purchased from Sigma Co. Ltd., USA; ^{131}I-sodium-iodine solution (37 GBq/mL) was purchased from China Nuclear Group Chengdu Gaotong Isotope Co. Ltd., Chengdu, China. All other chemicals were of the highest commercially available purity.

Laboratory animals

This study was approved by the Animal Ethics Committee of Sichuan University. Twenty-eight healthy New Zealand rabbits weighing 1.8-2.5 kg were supplied by the animal experimental center of the Medical School of

Sichuan University and were divided into seven groups (groups 1-7), with four rabbits per group. Half of the rabbits were female and half were male. The rabbits were fed with a particulate (3-5 mm) chow and housed in a layered stainless steel coop. Rabbits had *ad libitum* access to running water. The air humidity and temperature were maintained at 50%-70% and 20-29℃, respectively. Eight days before the operation, four rabbits were randomly selected as control animals to collect serum from their hearts for the measurement of the liver and thyroid function.

Preparation of GMSs

GMSs were produced according to the modified method of Tabata *et al*[37]. Briefly, 10 mL of 10% lime-processed gelatin solution was added dropwise while stirring, to 80 mL of liquid paraffin (Kelong Chemical Reagent Co. Ltd., Chengdu, China), which was preheated to 55℃ with 0.8 mL span-80 (Shenyu Chemical Reagent Co. Ltd., Chongqing, China). The mixture was then stirred at 550 r/min at 55℃ for 15 min to yield a water-in-oil emulsion. The stirring was then continued for 30 min at 4℃. Next, 3 mL of glutaraldehyde (25%, Kermel Chemical Reagent Co. Ltd., Tianjin, China) was added to the mixture after it cooled for 5 min to induce crosslinking and solidification of the microspheres. The resulting microspheres were removed by suction filtration and washed three times with acetone (Changlian Chemical Reagent Industries, Ltd., Chengdu, China) after dehydration by immersion in 30 mL of acetone for 15 min. After air-drying, the GMSs were examined by the Analyzing and Testing Center of Sichuan University and imaged under a scanning electron microscope.

Preparation of ^{131}I-GMS

The ^{131}I was labeled by a modification of the chloramine-T method. Briefly, 50 mg of GMSs were placed in test tubes, rehydrated with 190 μL of phosphate-buffered saline (pH 7.0) for 10 min. Next, 3.4 μL of ^{131}I-sodium-iodine solution (37 GBq/mL) and 200 μL of chloramine-T solution (Bodi Chemical Reagent Co. Ltd., Tianjin, China) (20 mg/mL) were added to each test tube. After the reaction mixture had been incubated for 5-15 min at room temperature, with agitation, 200 μL of sodium pyrosulfite solution (Jiangbei Chemical Reagent Industries, Ltd., Wuhan, China) (15 mg/mL) was added to stop the reaction. The mixture was centrifuged (Eppendorf® 5702R refrigerated centrifuge, Eppendorf Co. Ltd., Hamburg, Germany) at 4400 r/min for 4 min to separate the ^{131}I-GMSs. Finally, the products were washed seven times with normal saline and sterilized by Co60 irradiation.

Implantation of ^{131}I-GMS in the liver

Each rabbit was injected intramuscularly with 0.1-0.2 mL/kg SuMianXin® (Veterinary Institute of the Chinese Military Academy of Medicine, Changchun, China) veterinary injection for anesthesia and placed on an animal operation table. The epigastrium was shaved, disinfected, and covered with a drape. The abdomen was opened with a 5-cm incision along the median line, and the left middle lobe or right middle lobe of the liver was fixed by the left index finger and thumb of the operator. Then, the mixture of 41.336 ± 5.106 MBq of the ^{131}I-GMSs, as measured in a Capintec® CRC-15R (Capintec, Inc., New Jersey, USA) dose calibrator, and 1 mL of 25% glucose solution (Kelun Pharmaceutical Industries, Ltd., Chengdu, China) drawn by a 1 mL syringe with a 4-G needle was slowly injected into the liver, after checking the needle was not inserted into a capillary. Two or three injections of 0.3-0.5 mL of the mixture were administered. When the injection points were not observed to be bleeding after being pressed for approximately 1 min after withdrawing the needle, the abdomen was closed and the operation was finished. The rabbit was immediately administered intramuscularly with 40 000 U gentamycin sulfate (Tianjin Pharmaceutical Co. Ltd., Tianjin, China).

Radioassay of rabbit serum

Four rabbits were chosen randomly for collecting 1 mL of blood from the ear veins between 0 and 24, then at 28, 32, 48 and 64 d after the administration of the GMSs. Those blood were centrifuged at 4400 r/min, and 250-μL aliquots of serum were used for γ counting in a γ counter (No. 262 Industry, Ltd., Xi'an, China).

Single-photon emission computed tomography, hepatic and thyroid functions examinations

The single-photon emission computed tomography (SPECT) scan (Skylight SPECT Camera, Philips Co. Ltd., Amsterdam, Netherlands) was conducted by the Nuclear Medicine Department of West China Hospital at 4 h, and at 1, 4, 8, 16, 24, 32, 48 and 64 d after administration. The animals in group 1, 2, 3, 4, 5, 6 and 7 were sacrificed at 1, 4, 16, 24, 32, 48 and 64 d after the surgery, respectively. Eight milliliters of blood was collected from each deceased animal. On day 8, four rabbits were randomly selected, and a further 8 mL of blood was collected from the heart of each rabbit on this day. Blood samples were used to assess hepatic and thyroid functions, which was conducted at the Biochemical Laboratory and the Hormonal Laboratory of the Experimental Medicine Department of West China Hospital.

Histological examination

Liver samples were fixed in 10% formalin solution (Kelong Chemical Reagent Co. Ltd., Chengdu, China) for 48 h. Liver samples were then embedded in paraffin, sectioned, and stained with hematoxylin and eosin (HE) for histological examination.

Statistical analysis

Results were expressed as mean ± SD and were analyzed by *t* tests using SPSS 11.5 software. The level of significance was regarded at a P value of < 0.05.

Day 48	162.875 ± 7.955

RESULTS

Morphology of the microspheres

The GMSs were uniform in appearance, with a diameter of 10-30 μm, and a good divergence (Figure 1).

Effect of washing on GMS ^{131}I content

The GMSs labeled with ^{131}I were washed seven times to inhibit physical adsorption. Then, 50 mg of the GMSs labeled with ^{131}I showed decreased radioactivity levels with increasing number of washes. The slope for the relative ^{131}I content decreased gradually until it nearly reached a straight line (Table 1 and Figure 2).

Findings of SPECT imaging

The rabbits showed normal behaviors after the operation. SPECT imaging showed that the radioactive nuclide was concentrated in the liver, in regions surrounding the site of injection at 4 h and at 1, 4, 8, 16, 24, 32 and 48 d after ^{131}I-GMSs administration. However, SPECT did not reveal any nuclide labeling on day 64. The thyroid also showed low levels of nuclide accumulation on days 4, 8, 16 and 24. Furthermore, there was faint nuclide labeling in the bladder of four rabbits before day 24, although this disappeared by day 32. SPECT imaging showed no accumulation of nuclide in other tissues, including the lung, heart, stomach, intestines and kidney in any rabbits for the entire observation period (Figure 3). The radioactive ratios between the injected parts of liver and thyroids was assessed by region of interest analysis and increased with time, from 15.91 ± 0.74 at 4 h after ^{131}I-GMSs administration to 162.875 ± 7.955 at day 48 (Table 2).

Radioactive changes in serum

According to the serum γ counts, the radioactivity level decreased markedly over the first 2 d after ^{131}I-GMSs administration. The decline in radioactivity continued to decline thereafter, but at a slower rate until day 24. At this time, there was no difference in relative radioactivity level compared with the background level (Figure 4).

Hepatic and thyroid function

The levels of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) increased rapidly, particularly that of ALT, within 1 d after ^{131}I-GMSs administration. The levels of these enzymes then decreased gradually, reverting to the normal level by day 4. The values of alkaline phosphatase and γ-glutamyltransferase were relatively stable. Similarly, the total protein, albumin and globulin did not change markedly during the study period (Table 3 and Figure 5).

The levels of free triiodothyronine (FT3) and free thyroxin (FT4) were significantly decreased on day 8 (P < 0.05), but returned to normal levels at day 16, and remained at the normal level until day 64 (Table 4 and Figure 6). The level of thyrotropic-stimulating hormone (TSH) remained < 0.005 mU/L throughout the study.

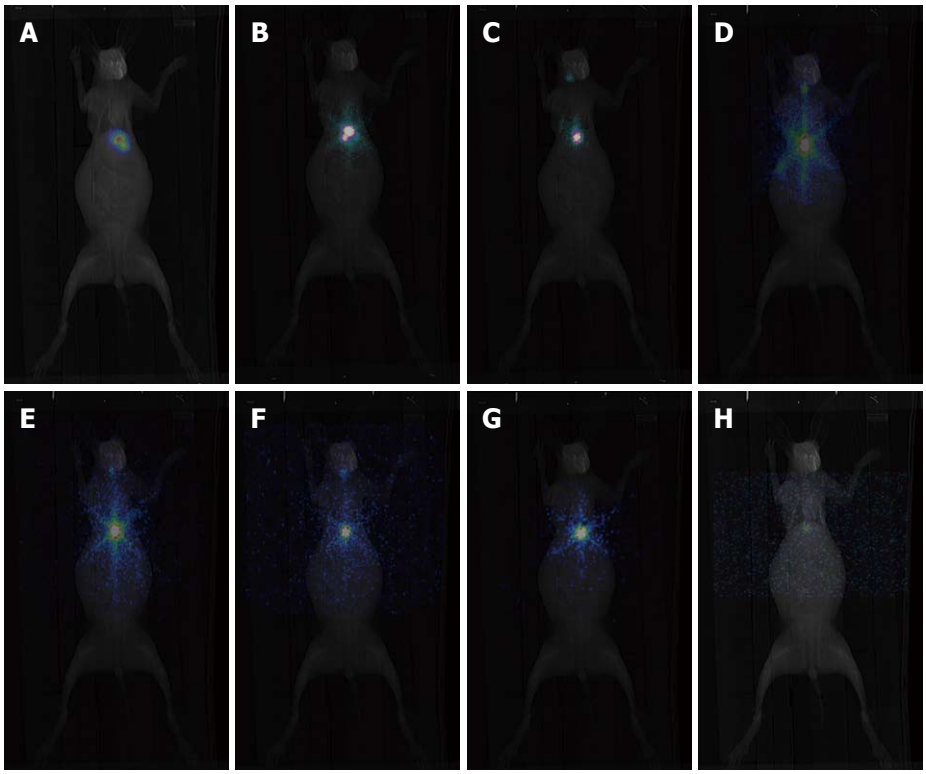

Figure 3 Single-photon emission computed tomography (SPECT) imaging performed at 4 h (A) and 1 (B), 4 (C), 8 (D), 16 (E), 24 (F), 32 (G) and 48 (H) d after the administration of ^{131}I-labeled gelatin microspheres.

Histological findings

The histological specimens showed that the ^{131}I-GMSs were quite concentrated, with a few inflammatory cells surrounding the injection sites on day 1 (Figure 7A) and some hepatic cells had died by day 4 (Figure 7B). Fibrous sheaths coating the ^{131}I-GMSs and sequential degradation of the ^{131}I-GMS were observed on days 16, 24 and 32. Most of the hepatic cells around and within the

sheaths died, leaving the hepatic cell cords on days 24 and 32. By day 24, the ^{131}I-GMSs had started to degrade and had an irregular shape (Figure 7C-E). However, the remnant ^{131}I-GMSs could still be histologically identified on day 48 (Figure 7F). No microspheres were found on day 64.

DISCUSSION

In recent years, many radioactive nuclide microspheres and nuclide particles have been successfully developed to target malignant tumors. However, because of the potential toxicity and side-effects associated with ^{90}Y, ^{32}P and other radioactive nuclides on marrow and other tissues, nonbiodegradable glass is often used as a carrier for most nuclides to avoid causing unwanted damage to normal tissues. However, glass has some limitations, including a protracted bioavailability due to its nonbiodegradable characteristics. Furthermore, its high specific gravity may adversely affect its injection and distribution. In this study, we generated degradable GMSs carrying the ^{131}I nuclide. Gelatin has a similar specific gravity to blood, and could be conjugated to many other drugs and nuclides *via* physical adsorption or chemical keys. Gelatin also shows good histocompatibility and degrades gradually *in vivo*[38-40]. Therefore, as a carrier for slow release of drugs, GMSs have been widely used by the medical community[41,42]. Meanwhile, ^{131}I is the most widely used radioactive nuclide in clinical settings, and has shown good anti-tumor effects in many clinical cases[43]. *In vivo*, dissociative ^{131}I mainly accumulates in the thyroid and is excreted *via* the kidney[44-46]. Therefore, ^{131}I that is released by the degradation of ^{131}I-GMS into the serum could result in tissue damage, particularly the thyroid gland. Therefore, detailed evaluation of the metabolic characteristics of ^{131}I-GMS, including its release, distribution and excretion *in vivo*, and the potential damage to the body should be evaluated to comprehensively appraise its safety. The study has provided some insight into these concerns.

The initial labeling rate of ^{131}I includes chemical binding and physical adsorption. When radionuclide-labeled microspheres are injected into the body, the nuclides conjugated to the microspheres *via* physical adsorption are more likely to dissociate. This has been reported to cause a severe de-iodinated state *in vivo*. In this study, we washed the microspheres seven times after the initial labeling, until the dissociative curve flattened, indicating that most of the ^{131}I conjugated *via* physical adsorption had been eluted and the ^{131}I-GMSs mainly exist *via* chemical combination. Although this reduces the labeling index, the *in vivo* de-iodination process is also attenuated, protecting against unwanted de-iodination effects.

Some studies have shown that injecting the microspheres at multiple sites could provide a more even distribution of the microspheres in the tumor tissues[47]. Therefore, in this study, we injected the microspheres in several sites in the liver. SPECT imaging revealed that the nuclides were principally localized to the injection sites at 4 h and at 1, 4, 8, 16, 24, 32 and 48 d after administration. The extrahepatic labeling with ^{131}I was mainly found in the thyroid gland between days 4 and 24 after administration, without any accumulation in other tissues, including the lung, heart, kidney, brain, stomach and intestines. Radioactivity of the serum could be detected for 24 d after the operation; after this time, the serum radioactivity level was not different to that of the background level. Because the thyroid gland is the

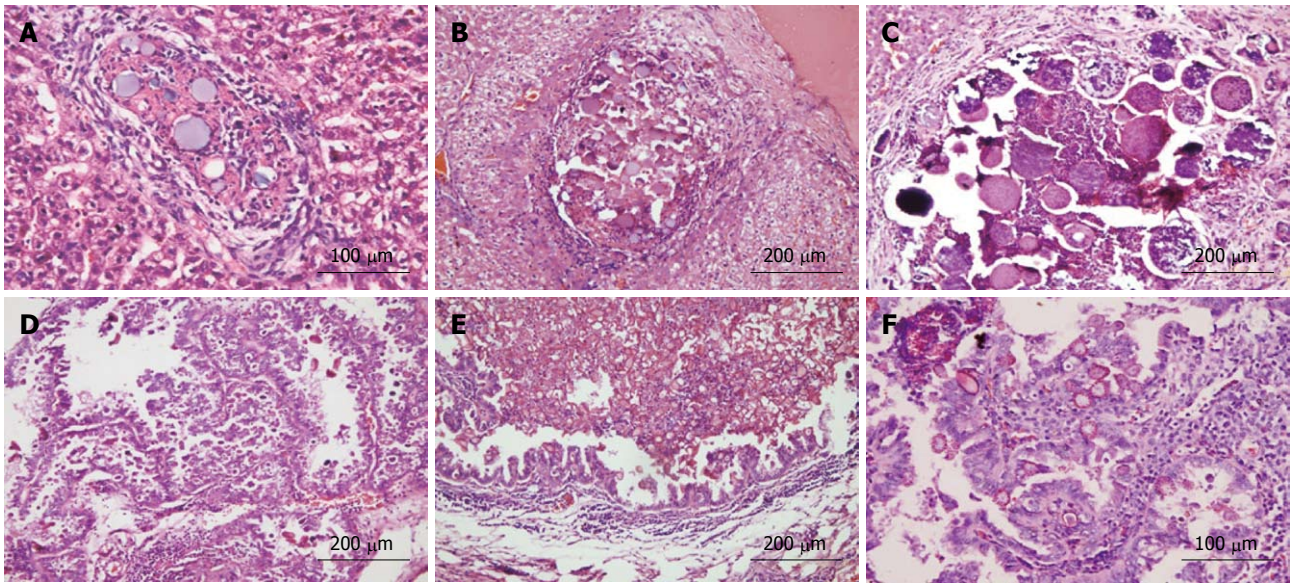

Figure 7 Pathological examination at 1 (A), 4 (B), 16 (C), 24 (D), 32 (E) and 48 (F) d after the administration of ^{131}I-labeled gelatin microspheres (HE stain; original magnification, × 200 in B, C, D and E, and × 400 in A and F).

principle site of iodine absorption and accumulation, it can absorb ^{131}I from the serum into thyroid follicles, which is shown on the SPECT scan. Based on the radioactivity ratio between the site of injection in the liver and the thyroid, it is clear that only a small amount of ^{131}I is absorbed by the thyroid.

SPECT imaging before day 24 revealed low radioactivity levels in the bladder, but not thereafter. This may be related to the full state of the rabbits' bladders when they were scanned, with full bladders showing some radioactivity as a result of excretion *via* the urinary system. Therefore, we believe that the release of ^{131}I from the microspheres mainly occurs within 24 d after administration, but only very small amounts are released.

Assessment of thyroid function revealed that the TSH level was consistently below 0.005 mU/L, while FT3 and FT4 declined on day 8, but returned to normal levels after day 16. This suggests that the thyroid is only subject to transient damage. Because the thyroid has its own repair mechanisms, the damage caused by some radiation doses can be repaired, without causing hypothyroidism[48]. In this study, a small amount of radioactive nuclides released into the blood was absorbed by the thyroid gland, but did not cause permanent damage or long-lasting hypothyroidism.

The assessment of hepatic function revealed that the ALT and AST increased rapidly compared with the normal level within 1 d after ^{131}I-GMSs administration. However, these parameters returned to the normal level 4 d later. This suggests that the administration of 41.336 MBq of ^{131}I caused notable liver damage in these experimental animals; however, because of the liver's capacity for self-repair and compensation, these impairments were transient and resolved within 4 d. This demonstrates the safety profile of radionuclide microspheres in the treatment of liver cancers.

From the pathological examination, we could conclude that the microspheres were gradually surrounded by fibroblasts to form fibrotic sheaths between days 16 and 24. This seemed to delay the degradation of the GMSs and reduced the rate of radionuclide release. This may explain the absence of thyroid radiolabelling from day 24 after surgery. Ohta reported that, after injecting GMSs into the renal artery of rabbits for 2 wk, the microspheres became wrapped with fibrous tissue and the GMSs in the embolism were completely biodegraded within 1 mo[49,50]. However, in this experiment, we used the intra-tissue implantation method, which differs from the arterial embolism method. Indeed, over four half-lives of ^{131}I decay (i.e. 32 d), the GMSs had degraded to varying degrees, but there was no sign of disappearance, with a large number of fiber-coated GMSs present, even by day 48. This difference may be due to the different methods of administering the GMSs. Previous studies have shown that gelatin is degraded in the body by degrading enzymes[51]. In this study, the ^{131}I-GMSs administered into the liver are, on the one hand, treated as a foreign body and induce foreign body reactions, with the activation of inflammatory cells, fibrotic cells and Kupffer cells to encapsulate and phagocytose the GMSs. On the other hand, the radiation will cause cells surrounding the GMSs to die to prevent phagocytosis by macrophages. This may explain why, in this experiment, the GMSs degrade slowly than that in the arterial embolism.

In conclusion, the hepatic administration of ^{131}I-GMSs in rabbits caused marked hepatic damage. Furthermore, there was some ^{131}I accumulation in thyroid tissue, causing slight, but only transient damage to the thyroid tissue. Other tissues showed no radioactive accumulation. Fibrous sheaths formed around the injected GMSs, which likely hampered the degradation of the

GMSs and protracted the release of ^{131}I. Taken together, we believe that it is safe to inject ^{131}I-GMSs into tissues *in vivo*, and these are likely to be effective against malignant tumors.

COMMENTS

Background

Malignant tumors in hepatic, biliary and pancreatic systems are very commonly encountered and treated surgically worldwide. In recent years, the incidence of malignant tumors in these three systems was reported to be rising worldwide. However, the rate of surgical removal of the malignant tumors of the three systems is very low and the prognosis after surgery is very unsatisfactory.

Research frontiers

Internal radiotherapy has become an important facet of clinical therapy for malignant tumors. ^{90}Y, ^{188}Re and ^{166}Ho microspheres have already been shown to be safe and are frequently used to therapy malignant tumors. However, their vehicle material is usually glass, which cannot degrade in the body. Unfortunately, once the nuclides have decayed completely, the vitreous carriers become foreign bodies that persist in the patient's body, and trigger foreign body reactions.

Innovations and breakthroughs

Nuclide microspheres and nuclide particles represent a new generation of tumor therapies and interventional radiotherapies. The authors used gelatin microspheres (GMSs) that can be easily produced to carry radionuclides, and can degrade *in vivo*. This study provides a foundation to show how nuclides attached to GMSs are distributed and metabolized *in vivo*. Healthy rabbits were used as a model to observe the metabolism of ^{131}I-GMSs. Overall, ^{131}I-GMSs were found safe for administration in rabbits.

Applications

By understanding the distribution and metabolism of ^{131}I-GMSs administered in the livers of rabbits, this study supports the use of ^{131}I-GMSs in directional internal radiotherapy for the treatment of hepatic malignant tumors. This approach could be applied to pancreatic, hepatic, biliary and other material malignant tumors that cannot be removed by surgery. This approach could also be considered to treat osteoarthritis.

Terminology

^{131}I-GMSs are protein microspheres containing the radionuclide ^{131}I. The half life of ^{131}I is 8.04 d and free ^{131}I either in the body or accumulates in the thyroid is quickly excreted *via* the urinary system. Compared with glass microspheres, the gelatin microsphere is a biodegradable material with good biocompatibility. In recent years, the authors have developed 50-70 μm nuclide protein microspheres that can be labeled with high concentrations of ^{131}I. These microspheres can be applied for hepatic arterial transfusion and embolotherapy for patients with advanced liver cancer.

Peer review

This is an interesting experimental study.The technique used in this study can be an effective method for treatment of maling tumors in the patients.

Abstract

AIM: To examine body fluids such as ascitic fluid (AF), saliva, bile and pleural effusions for the presence of hepcidin using a novel radioimmunoassay (RIA).

METHODS: Serum samples were collected from 25 healthy volunteers (mean age: 36 ± 11.9 years, 11 males, 14 females). In addition bile was obtained from 12 patients undergoing endoscopic retrograde cholangiopancreatography (mean age: 66.9 ± 16.7 years, M:F = 5:7). Saliva was collected from 17 healthy volunteers (mean age: 35 ± 9.9 years, M:F = 8:9). Pleural and AF were collected from 11 and 16 patients [(mean age: 72 ± 20.5 years, M:F = 7:4) and (mean age: 67.32 ± 15.2 years, M:F = 12:4)], respectively. All biological fluid samples (serum, exudative and transudative fluids) were tested for the presence of hepcidin-25 molecule using RIA.

RESULTS: Hepcidin-25 was detected in all biological fluids tested. The mean ± SD hepcidin-25 in serum was 15.68 ± 15.7 ng/mL, bile 7.37 ± 7.4 ng/mL, saliva 3.4 ± 2.8 ng/mL, exudative fluid 65.64 ± 96.82 ng/mL and transudative fluid 14.1 ± 17.8 ng/mL.

CONCLUSION: We provide clear evidence that hepcidin-25 is present in bile, saliva, pleural and ascitic fluids. Hepcidin is likely to play a role here in innate immunity.

INTRODUCTION

Hepcidin-25 is a cysteine-rich circulating bioactive peptide that is predominantly secreted from the liver and excreted in the urine[1]. It is synthesized as preprohepcidin and undergoes posttranslational processing before release into circulation in an active form[2]. It is a central iron regulator with *in-vitro* evidence of antimicrobial properties. Hepcidin exerts its regulatory effect by preventing the efflux of intracellular iron by binding to ferroportin channels[3]. These ferroportin channels are present on the basal surface of the intestinal enterocytes as well as hepatocytes, macrophages and placental cells and are predominantly involved in the export of iron from these cells[4]. Despite a considerable body of literature on this novel peptide, research has been impeded by the lack of a reliable assay. Initially a semi quantitative assay (immunodot) was described but more recently quantitative assays have been developed using surface-enhanced laser desorption/ionization time-of-flight mass spectrometry (SELDI-TOF-MS)[5] and liquid chromatography tandem MS (LC-MS/MS)[6,7].

We developed and validated a radioimmunoassay (RIA) for hepcidin-25 and measured serum levels of hepcidin-25 in various patient groups[8]. In this manuscript, we describe the use of RIA to demonstrate and measure hepcidin-25 in various biological fluids.

MATERIALS AND METHODS

This was a prospective study performed with approval of our Regional Ethics Committee and written consent was obtained from all patients and healthy volunteers in accordance with the Declaration of Helsinki. Patients and healthy volunteers were recruited from a single hospital with mixed ethnicity mainly comprising Caucasians and South Asians living in West London.

Healthy controls

The serum study comprised of 25 healthy controls (HC); 14 were females, mean age was 36 ± 11.9 years (age range: 21-62 years), were hospital colleagues recruited to measure serum hepcidin-25, ferritin and serum prohepcidin. HC with systemic illness (acute or chronic) or any history of regular use of medication including supplemental vitamins were excluded. A fasting venous blood sample was obtained between 08:30-09:00 h. Serum was separated and stored at -20℃ for analysis.

Bile

Bile was collected from 12 patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) for proven or suspected choledocholithiasis, mean age 66.9 ± 16.7 years, M:F = 5:7 (age range: 40-88 years). All patients had ultrasonography (USG) of the abdomen to identify choledocholithiasis, or cholelithiasis. Ten out of 12 patients recruited had cholelithiasis confirmed on USG. Two patients had a dilated common bile duct (CBD) without choledocholithiasis. During ERCP, CBD was cannulated and 2 mL of bile was aspirated before injecting contrast medium for CBD visualisation. Stone extraction or biliary sludge removal including sphincterotomy was done after bile collection to avoid contamination. Bile obtained was stored at -20℃.

Saliva

Saliva was obtained from a separate cohort of 17 healthy volunteers, mean age of 35 ± 9.9 years (age range: 23-60 years), M:F = 8:9. A history of systemic illness or dental or pharyngeal pathology was excluded. Participants were not allowed to eat or drink 30 min before the collection of saliva. Ten minutes before collection, participants had to rinse their mouth with plain water. They had to chew on a cotton swab and return the same with saliva in sterile tube (Salivette, Sarstedt, UK) and stored at -20℃.

Pleural fluid

Eleven patients, mean age 72 ± 20.5 years (age range: 26-95 years), M:F = 7:4 were recruited for pleural fluid (PF) analysis. PF was collected by diagnostic thoracocentesis under sterile conditions and stored in a sterile container at -20℃. PF was analysed and divided into a transudate and exudate by comparing the total protein concentrations in fluid to that in blood as per Light's Criteria[9]. Three patients had transudative fluid (PF-T) (M:F = 2:1). The underlying cause for fluid accumulation in this group was congestive heart failure secondary to ischemic heart disease. Eight patients had exudative fluid (PF-E) (M:F = 5:3). The underlying cause for fluid accumulation in this cohort was parapneumonic (5 cases) and neoplastic [3 cases (1 breast and 2 lung malignancies)].

Ascitic fluid

Ascitic fluid (AF) was collected from 16 patients, mean age 67.32 ± 15.2 years (age range: 42-85 years), M:F = 12:4 under sterile conditions by diagnostic paracentesis as further differentiated by serum/ascites albumin gradient (SAAG)[10]. Twelve patients were identified as having transudative ascites (AF-T) (M:F = 8:4). Alcohol induced liver cirrhosis was the aetiology and comprised majority with 10 patients. The remaining 2 patients had chronic hepatitis B and chronic hepatitis C as etiology. The exudative ascites cohort comprised 2 patients (AF-E) (M:F = 2:0), with aetiology being congestive heart failure secondary to ischemic heart disease and idiopathic.

One patient had transudative AF with spontaneous bacterial peritonitis (SBP) (M:F = 1:0) analysed for presence of hepcidin-25. The cause of ascites was cirrhosis of the liver secondary to alcohol misuse. The AF white cell count was 350/mm^3 (90% polymorphs, 10% lymphocytes) and AF culture had grown *Escherichia coli* (*E. coli*).

On the basis of above, 2 cohorts were obtained, those with Transudative Fluid and those with Exudative Fluid, comprising both pleural and AFs in each respective category. One patient with SBP-ascites was excluded from the transudative fluid group. Thus, there were 10 patients

in the total exudative fluid cohort (M:F = 7:3) and 15 patients in the total transudative fluid cohort (M:F = 10:5).

Assay

Hepcidin-25 was measured using a novel competitive RIA. This was produced in our laboratory and has been described in our previous manuscript (Busbridge *et al*[8]).

The specificity of the antibody was also confirmed by Western blotting analysis of the precipitated proteins, where a single band of < 6 kDa was detected. Western blotting analysis was carried out by using 10 mL normal human plasma, which was first centrifuged and filtered through a 0.22 mm filter (Millipore, MA). After addition of 10-mL dithiothreitol, plasma was again filtered through a 30 kDa filter (Millipore) and the filtrate precipitated using 25% TCA. The precipitated proteins were resuspended in loading buffer and subjected to SDS electrophoresis on a 4%-16% NuPAGE Novex Bis/Tris gel (Invitrogen, UK). Western blotting was performed using an XCell Ⅱ blot module (Invitrogen) and a 0.1 mm pore size nitrocellulose membrane (Sigma Aldrich). Non-specific sites were blocked with 5% BSA in PBS and the membrane probed with purified rabbit anti-hepcidin antibody (1 in 2000 dilution in blocking buffer), followed by incubation with a secondary anti-rabbit antibody conjugated with horseradish peroxidase (Sigma Aldrich). Specific signals were detected with 3,3', 5,5' tetramethylbenzidine liquid substrate (Sigma Aldrich) (Figure 1).

Serum prohepcidin was measured by enzyme linked immunosorbent assay (ELISA) (DRG Diagnostics, UK) as per manufacturer's guidelines. Ferritin, iron and C-reactive protein were measured using Abbott Architect *i*8000 system (Abbott Diagnostics, Ireland).

Statistical analysis

Values are expressed as mean ± SD as indicated. Quantitative variables were compared using unpaired *t*-test; Pearson's rank correlation was used for calculating correlation between the hepcidin-25 and other variables. A value of $P < 0.05$ was considered significant. All statistical analyses were carried out using the statistical package GraphPad Prism version 5.0 for Windows, (GraphPad Software, San Diego California USA, http://www.graphpad.com).

RESULTS

HC

Serum hepcidin in HC was 15.30 ± 15.71 ng/mL with a range of 1.1-55.0 ng/mL. The mean prohepcidin was 236.88 ± 83.68 ng/mL and the mean ferritin was 110.00 ± 128.08 μg/L. There was no correlation between serum prohepcidin and ferritin in healthy volunteers. However, serum hepcidin showed a weak correlation with ferritin ($r = 0.174$, $P < 0.05$).

Bile and saliva cohort

Hepcidin-25 was detected in all bile samples ($n = 12$) and was measured at a mean of 7.37 ± 7.39 ng/mL with a range of < 1.0-23 ng/mL. Hepcidin-25 was detected in saliva with a mean of 3.39 ± 2.83 ng/mL, range of < 0.9-11.8 ng/mL.

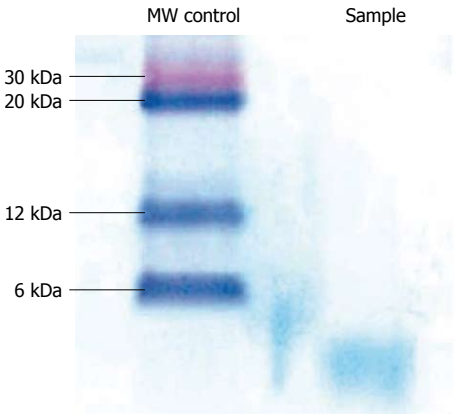

Figure 1 Western blotting analysis of serum proteins using rabbit anti-hepcidin antibody demonstrating the presence of a protein band at < 6 kDa.

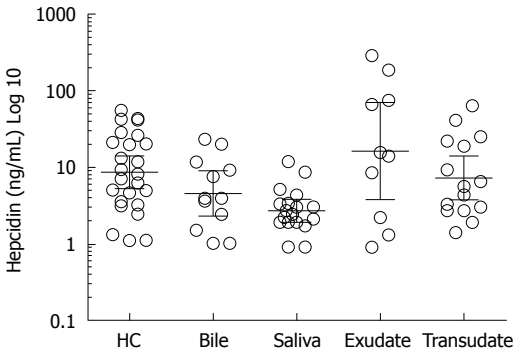

Figure 2 Scatter-dot plot of hepcidin data from healthy control sera (HC) and various body fluids, bile, saliva and pleural fluid both exudates and transudate in nature. Data is presented with geometric mean and 95% CI levels.

Exudative and transudative fluid

Hepcidin-25 level was 65.64 ± 96.82 ng/mL in exudative fluid. The mean total protein level in the fluid was 43.69 g/L. The hepcidin-25 level was 14.10 ± 17.88 ng/mL in transudative fluid. Hepcidin-25 concentration in exudative fluid was higher than in transudative but did not reach statistical significance ($P = 0.05$, student *t*-test). This could be due to the small number of patients involved in the study. We demonstrated hepcidin-25 in all bodily fluids analysed using RIA. To our knowledge this is the first report confirming the presence of hepcidin-25 in these bodily fluids (Figure 2).

DISCUSSION

Hepcidin, as an antimicrobial peptide, was first described as a liver expressed antimicrobial peptide 1[11].

Hepcidin is a novel peptide due to its dual role as an 'iron-hormone' and 'antimicrobial peptide'. However, previous research studies have been hampered due to lack

of a reliable quantitative assay for hepcidin-25. Several factors have been cited for this difficulty including presence of non-biologically active iso-forms of hepcidin-20, hepcidin-22, and the fact that hepcidin-25 is conserved over evolution thus making an immunological response in host species difficult to determine[12]. Several semi quantitative and quantitative assays have recently been developed for hepcidin-25 measurement. The quantitative assays include ELISA[13] and MS. MS methods includes TOF-MS, LC-MS, matrix-assisted laser desorption ionization MS, and SELDI-MS[14,15]. Although very successful, the availability of the MS assay is limited to specialist laboratories as they require strict internal standards and specialised equipment. Two quantitative assays have been described using ELISA techniques. Ganz *et al*[13] have described a competitive quantitative ELISA assay using functional synthetic peptide hepcidin-25 while the method described by Koliaraki *et al*[16] detects hepcidin-25 using a recombinant functional hepcidin-25 peptide. Thus, although a number of methods are available to measure hepcidin-25, there does not appear to be a standardisation amongst various methods. The results of the first international round robin for the quantification of urinary and plasma hepcidin assays were published in an attempt to help standardisation issues[17].

Until recently, hepcidin-25 was shown to be present in urine and serum. However, its expression by various organs such as salivary glands, tonsils, trachea, lung and prostate have also been reported[18]. The exact nature and function of hepcidin expression in these organs remains unclear.

Hepcidin in saliva

This study confirms the presence of hepcidin-25 in saliva. Its exact role in saliva is still uncertain but could contribute to the broad spectrum defence of the oral cavity along with peptides such as cathelicidins[19].

Hepcidin in bile

The presence of hepcidin-25 in bile may be a mechanism of hepcidin-25 excretion apart from urine. It may act along with α-defensins against gut microflora[20]. Further studies are needed to fully understand its role in bile.

Hepcidin in PF and AF

We were able to demonstrate the presence of hepcidin in pleural and AF where its iron regulator function is hard to explain. Hepcidin present in these fluids has unknown biological activity. Hepcidin-25 is a cationic peptide with 4 disulfide bridges[21]. The connection between hepcidin and infection/inflammation became clearer after the initial discovery in 2000. Shike *et al*[22], in 2002 showed that in white bass liver, infection with the fish pathogen *Streptococcus iniae* increased hepcidin mRNA expression 4500-fold. In another study by Nicolas *et al*[23] in 2002 injections of turpentine, a standard inflammatory stimulus, into mice induced hepcidin mRNA 4-fold and led to a 2-fold decrease in serum iron.

Hepcidin maintains a role in host defence by acting as a bridge between immunity and iron metabolism, as indicated by markedly induced hepcidin by infection and inflammation[24-26]. Park *et al*[1] have shown that hepcidin has antimicrobial activity against *E. coli*, *Staphylococcus aureus*, *Staphylococcus epidermidis* and group B *Streptococcus*. Hepcidin also exhibits antifungal activity against *Candida albicans, Aspergillus niger* and *Aspergillus fumigatus*.

Our study on the presence of hepcidin in bile, saliva and various other biological fluids provides further confirmatory evidence that hepcidin has evolved from being an antimicrobial peptide. Hepcidin may form part of human innate immunity and complement other antimicrobial peptides to provide a wide spectrum of mucosal immunity against pathogens.

ACKNOWLEDGMENTS

We thank Mr. Kamran Qureshi for his valuable help in collecting bile samples. We are indebted to Dr. Amar Sharif for advice and assistance.

COMMENTS

Background

Until recently iron metabolism had been extensively studied but poorly understood. With the discovery of hepcidin as an iron regulator in the body, there has been a significant growth in the knowledge related to iron metabolism. Crucial research has been done to explore the role of hepcidin in iron deficiency anaemia, anaemia of chronic disease and iron excess disorders.

Research frontiers

Hepcidin is a 25 amino-acid peptide predominantly formed in the liver and is a key component in iron homeostasis. Its major role is to prevent iron export by binding to iron export channels, ferroportin, leading to internalisation and lysosomal degradation of the hepcidin-ferroportin complex. Interestingly, hepcidin is found throughout evolution and in amphibian species has possible antimicrobial properties while in humans its major action is iron metabolism. Prior research showed hepcidin expression in various human organs like heart, intestine and salivary glands. In this study, the authors demonstrate clear evidence that hepcidin is present in various bodily fluids with higher levels found in exudative fluids and could be a potential mechanism for innate immunity preserved over evolution.

Innovations and breakthroughs

Recent studies have highlighted the importance of hepcidin in iron metabolism, particularly anaemia of chronic disease and iron overload. There have also been reports of its expression in various proinflammatory disorders and various organs, linking it to innate immunity and iron metabolism. This is the first study to report that hepcidin is found in various biological fluids. Furthermore, *in-vitro* studies have suggested that hepcidin has antimicrobial activity.

Applications

By understanding how hepcidin is expressed and by blocking its expression, there may be a therapeutic potential in patients with anaemia of chronic inflammation. Further application could be that secondary infection of pleural and ascitic fluid complicating underlying diseases may be better understood by studying hepcidin levels in infected and non-infected patients.

Terminology

Hepcidin is a protein involved in iron metabolism. Hepcidin is formed predominantly in the liver and is released in the circulation where its major function is hypoferremia by binding to iron export channel ferroportin. Hepcidin is expressed by various organs and thus it was conceivable that hepcidin would be found in various biological fluids. The exact role of hepcidin in these fluids remains uncertain and more studies are needed.

Peer review

The authors present a nicely conceived and analysed study. It is well written and offers new information about the presence of hepcidin in human biological fluids.

Abstract

AIM: To evaluate the *in vitro* immunomodulation capacity of various non-pathogenic yeast strains and to investigate the ability of some of these food grade yeasts to prevent experimental colitis in mice.

METHODS: *In vitro* immunomodulation was assessed by measuring cytokines [interleukin (IL)-12p70, IL-10, tumor necrosis factor and interferon γ] released by human peripheral blood mononuclear cells after 24 h stimulation with 6 live yeast strains (*Saccharomyces ssp.*) and with bacterial reference strains. A murine model of acute 2-4-6-trinitrobenzene sulfonic acid (TNBS)-colitis was next used to evaluate the distinct prophylactic protective capacities of three yeast strains compared with the performance of prednisolone treatment.

RESULTS: The six yeast strains all showed similar non-discriminating anti-inflammatory potential when tested on immunocompetent cells *in vitro*. However, although they exhibited similar colonization patterns *in vivo*, some yeast strains showed significant anti-inflammatory activities in the TNBS-induced colitis model, whereas others had weaker or no preventive effect at all, as evidenced by colitis markers (body-weight loss, macroscopic and histological scores, myeloperoxidase activities and blood inflammatory markers).

CONCLUSION: A careful selection of strains is required among the biodiversity of yeasts for specific clinical studies, including applications in inflammatory bowel disease and other therapeutic uses.

INTRODUCTION

Yeasts, as an inevitable part of the microflora of various fermented foods and beverages, are found in a wide range of foods from plant or animal origin, where they have a significant impact on food safety and organoleptic properties. Both baker's and brewer's yeasts [*Saccharomyces cerevisiae* (*S. cerevisiae*)] have been available for the last

decades as dietary supplements because of their high contents of vitamin B, proteins, peptides, amino-acids and trace minerals. Regardless of their non-human origin, such non-pathogenic yeasts fulfill the major criteria for probiotic definition[1]. Interest in probiotic yeasts has increased, especially in relation to animal feed but also for human applications. Hence, yeasts are rarely (if ever) associated with outbreaks or cases of food-borne illness and, through their history, many yeast species are recognized as safe, as confirmed by their Qualified Presumption of Safety status, assigned by the European Food Safety Authority (http://www.efsa.europa.eu). However, some rare cases of *Saccharomyces boulardii* (*S. boulardii*) fungemia have been reported, although they are essentially restricted to immunocompromised patients or associated with patients being contaminated through a central venous catheter[2]. Also, identification of the contaminating yeast strains in some cases could be questioned, as it was often based on cross-reacting anti-yeast mannan circulating antibodies, shared with *Candida* species.

Although *S. boulardii* was originally selected using rather empiric methods, this yeast species has many proven benefits in various gastrointestinal diseases[3-5] and is well recognized as the non-bacterial prototype of a probiotic. Multiple mechanisms have been suggested that explain the broad health-promoting effects of consuming food grade yeasts, ranging from local general trophic effects to action on both innate and/or adaptive immunity[6,7]. The yeast-induced probiotic signals might be either prophylactic or therapeutic in a defined pathologic context or in a specific application.

Most reported effects of yeasts as probiotic organisms in clinical trials stand for alleviation of (1) antibiotic-associated diarrhea; (2) infectious diarrhea [including recurrent *Clostridium difficile* (*C. difficile)* related diseases, CDAD]; (3) irritable bowel syndrome; and (4) inflammatory bowel diseases (IBD). Focusing on IBD, *S. boulardii* efficacy was both observed in Crohn's disease[8] and by favoring remission of ulcerative colitis[9]. Most of the therapeutic approaches in IBD were also using anti-inflammatory drugs such as mesalamine concomitantly and the exclusive use of yeast as possible ecological treatment has not been tested, most probably for ethical reasons. The anti-inflammatory potential of yeasts has been addressed by many *in vitro* studies elaborating on multiple mechanisms[4,7]. Surprisingly, data using yeasts in animal models of colitis are very scarce and the precise mechanism(s) of action by which such intervention may exert its beneficial effects *in vivo* is consequently poorly documented. Dalmasso *et al*[10] have reported a beneficial action of secreted yeast molecules on T cell migration in the chronic model of CD4+CD45RB^{hi} T-lymphocytes transfer into SCID mice. The same authors have also reported the preventive effect of *S. boulardii* in an acute murine 2-4-6-trinitrobenzene sulfonic acid (TNBS) model, characterized by a strong inhibitory activation of NFκB and the reduction of mRNA for pro-inflammatory cytokines together with decreased histological scores of inflammation[11,12]. Consistently, a similar TNBS-induced model of colitis, although developed for a more therapeutic approach in rats, also showed appreciable reduction of histological scores and pro-inflammatory colonic markers by *S. boulardii* (including cytokines but also metabolites of pro-oxidative pathways such as iNOS). The proposed mechanism depended on PPAR activation by the probiotic yeast[13], a regulator previously demonstrated to reduce intestinal inflammation[14]. Finally, yeast-driven therapy in a DSS-induced colitis model was also successfully demonstrated in mice[15], even when this chemically induced colitis was amplified by *Candida albicans* colonization. Because the model is known to affect epithelial crypt cells and destroy barrier integrity without intervention of the adaptive immune system[16], it was suggested that the contribution of yeast-mediated protection was restricted to the switching off of the innate mechanisms of colitis and/or to the enhancement of the mucosal barrier integrity.

Very few yeast strains have been studied as possible biotherapeutics agents and, at the moment, *S. boulardii* is the only yeast commercialized for human use, and consequently the single preparation formally recognized as probiotic. However, other *Saccharomyces spp.* or members of other yeast genera with similar or possibly better therapeutic properties will certainly be isolated in the future[17,18]. Hence, distinct non pathogenic yeast strains may have their own impact on gut homeostasis, sharing some of the common mechanisms of *S. boulardii,* but also other more specific consequences or even novel prophylactic or therapeutic effects.

Considering the widespread use of lactic acid bacteria and bifidobacteria as probiotics, it is now well accepted that all strains are not equally beneficial, that each may have individual mechanisms of action. Furthermore, host characteristics (e.g. flora composition or immune status) may determine which probiotic species or strains may be optimal[19]. Peran *et al*[19] conclude that it would be interesting to compare different probiotics in the same experimental model, in order to establish the best profile in a given setting. Likewise, this reasoning can be extent towards "friendly yeasts" as far as evaluation is conducted for a specific use without generalizations about probiotic effects[20,21].

In this paper, we compared yeast strains in their ability to induce cytokines on human peripheral blood mononuclear cells (PBMC). Our results also demonstrated that some yeast strains exhibit significant anti-inflammatory activities *in vivo*; whereas other may have weaker inflammation lowering effects or no anti-inflammatory effect at all. Thus, as for probiotic bacteria[20], strain-specific differences were seen for yeasts, suggesting that careful selection of strains for therapeutic use is required for preclinical and further clinical studies, including for applications in IBD.

MATERIALS AND METHODS

Microbial strain preparation and growth conditions

All *Saccharomyces* strains used in this study and listed (Table 1), including baker's yeast *S. boulardii* and wine-

related strains, were originally isolated from a proprietary germoplasm bank of *S. cerevisiae* (Societe Industrielle Lesaffre 147 Rue Gabriel Peri, BP 6027, 59700 Marcq-en-Baroeul Cedex, France). They were all provided by Lesaffre as a similar dry form with a cell concentration near to 1×10^{10} colony-forming units (CFU)/g. The different dried yeast products were processed and enumerated as follows. For both *in vitro* and *in vivo* assays, yeast was rehydrated with phosphate buffered saline (PBS) (pH 7.2) 1:10 (w/v) at room temperature, and adjusted to an appropriate concentration in CFU/mL. For this purpose, cellular counts together with viability, expressed in %, were routinely performed using a hematimeter (type Thoma) combined with a Trypan blue exclusion method. More than 95% viability was preserved following rehydration. Enumeration was also confirmed *a posteriori* by plating on *YPD-agar* and allowing growth during 2 d at 30℃ and 37℃.

Some bacterial strains were used as reference strains for immune cell stimulation as previously described[24], also listed (Table 1). *Lactobacillus* strains were grown under limited aeration at 37℃ in MRS medium (Difco) and a *Bifidobacterium* strain was grown anaerobically in MRS supplemented with 0.05% L-cysteine-hydrochloride (Sigma). *Lactococcus lactis* MG1363 was grown at 30℃ in M17 medium supplemented with 0.5% glucose. *Escherichia coli* (*E. coli*) was grown at 37℃ in LB medium (Difco). Bacterial cells were grown until stationary phase, washed and resuspended at 1×10^9 CFU/mL in PBS containing 20% glycerol and stored at -80℃ until required for later assays. Some routine analyses were also performed using a portable photometer (Densimat bioMerieux)[25]. Cells were adjusted to McFarland 3 and stored at -80℃.

In vivo resistance to gastrointestinal tract

Groups contained 10 mice. When needed, fecal samples from 5 mice were collected, pooled, weighed and mechanically homogenized in sterile neutral and isotonic buffer at 50 mg/mL of feces. Dilutions were plated onto the "yeast-selective" tetracycline (150 μg/mL) *YPD-agar* (Yeast extract, Peptone, Dextrose, as described elsewhere[26]. No tetracycline-resistant microorganisms (bacteria or fungi) were detected in non-inoculated mice, indicating no or negligible basal colonization of mice gastrointestinal tract (GIT) by non-pathogenic yeast nor *Candida* species.

PBMC isolation

PBMCs were isolated from peripheral blood of healthy donors as previously described[24]. Briefly, after a Ficoll gradient centrifugation (Pharmacia, Uppsala, Sweden), mononuclear cells were collected, washed in RPMI 1640 medium (Live technologies, Paisley, Scotland) and adjusted to 2×10^6 cells/mL supplemented with gentamicin (150 g/mL), L-glutamine (2 mmol/L), and 10% foetal calf serum (Gibco-BRL) supplementation.

Induction of cytokine release

PBMC (2×10^6 cells/mL) were seeded in 24-well tissue culture plates (Corning, NY). Twenty microliters of the thawed bacterial or yeast suspensions at 10^9 CFU/mL in PBS containing 20% glycerol (bacteria:cell or yeast: cell ratio of 10:1) or standardized at homogeneous cell density, were added. PBS containing 20% glycerol was used as a negative (non-stimulated) control. On the basis of preliminary time-course studies, 24 h stimulation corresponded to the best time point for cytokine responses of bacteria stimulated-PBMCs. After 24 h stimulation at 37℃ in an atmosphere of air with 5% CO_2, culture supernatants were collected, clarified by centrifugation and stored at -20℃ until cytokine analysis. Concerning yeast stimulation, freshly rehydrated powders were used at distinct yeast:cell ratios (from 0.1:1 to 5:1), with or without the presence of fungizone (amphotericin B, 10 μg/mL). Neither medium acidification nor bacterial or fungal proliferation was observed. Cytokines were measured by enzyme-linked immunosorbent assay (ELISA) using BD Pharmingen antibody pairs (BD Biosciences, San Jose, Ca, USA) for interleukin (IL)-10, interferon γ (IFNγ) and IL-12p70, and R&D systems (Minneapolis, Mn, USA) for human tumor necrosis factor (TNF), according to the manufacturer's recommendations.

Induction of colitis and inflammation scoring

BALB/c mice (female, 7 to 8 wk old) were obtained from Charles River (St Germain sur l'Arbresle, France). A standardized murine TNBS colitis model was used in which moderate levels of inflammation were induced[27]. Briefly, a 50 μL solution of 100 mg/kg TNBS (Sigma) in 50 % ethanol was slowly administered in the colon *via* a 3.5 F catheter. Freshly rehydrated yeast suspensions (100 μL), containing 1×10^9 CFU/mL in $NaHCO_3$ buffer were administered intragastrically to mice each day, starting 4 d before until the day of TNBS administration while control mice received the corresponding buffer. Mice were weighed, bled from the retro-orbital venous

plexus and killed 72 h after TNBS administration. Cleared sera were frozen and stored until cytokine assays at -20℃. Colons were removed, washed and opened longitudinally. Inflammation grading was performed by two blinded observers, using the Wallace scoring method[28]. Results are expressed as % protection, corresponding to the reduction of the mean macroscopic inflammation score of treated mice (n = 10) in comparison to the mean score of TNBS-treated control mice ($NaHCO_3$ buffer-treated mice, n = 10)[27]. Histological analysis was performed on May Grünwald-Giemsa stained 5 μm tissue sections from colon samples fixed in 10% formalin and embedded in paraffin and tissue lesions were scored according to the Ameho criteria[29]. Additionally, the degree of polymorphonuclear neutrophil infiltration of the distal colon was assessed by quantifying myeloperoxidase (MPO) - a neutrophil granule enzyme - as reported earlier[30]. A commercial preparation of prednisone (Cortancyl, Sanofi Aventis, France) was used as a positive control of protection and was orally administered for 2 subsequent days at 10 mg/kg starting at the day before TNBS administration. When needed, heparinized whole blood was collected by retro-orbital puncture and, after separation, mice sera samples were stored at -20℃ for subsequent analysis.

Cytokine and serum amyloid A protein assays

Murine IL-6 and serum amyloid A (SAA) protein levels were measured by ELISA using commercial antibodies from Pharmingen antibody pairs (BD Biosciences, San Jose, Ca, USA), and Biosource International (Camarillo, Ca, USA), respectively, with a lower limit of sensitivity of 15 pg/mL for IL-6 and 30 ng/mL for SAA.

Statistical analysis

All analyses were performed as comparison of experimental groups with respective controls by the non-parametric one-way analysis of variance Mann-Whitney U-testing, or by Student-T testing where appropriate. Differences were judged to be statistically significant when the P value was < 0.05. Data are presented as mean ± SE.

Ethical considerations

All experiments were performed in an accredited establishment (number 59-35009; Institut Pasteur de Lille, France) and using approved guidelines according to French Ethical Committee and European Union Normatives (number 86/609/CEE).

RESULTS

Production of cytokines by human PBMCs in response to food-grade yeast strains

To determine the optimal dose of yeast that can induce cytokine production in human PBMCs, immuno-competent cells were first stimulated with three different multiplicity levels of infection (0.1:1, 1:1 and 5:1) of three live yeast strains and compared with immuno-stimulatory effects of reference bacteria (ranging from weak to strong inducers). Substantial amounts of IL-10, and to a lesser extent for TNF were dose-dependently induced by yeast cells (Figure 1A and B, respectively) while no or very low levels of the pro-inflammatory indicators IL-12 p70 and IFNγ could be detected following yeast stimulation (Figure 1C and D). Following these results, the yeast: host cell ratio of 1:1 was retained for further comparative analyses between strains in order to mimic physiological interactions between cells but without saturating the stimulatory capacity. In addition, the variable responsiveness due to individual blood donors was highly minimized by expressing data as % of a reference strain instead of in pg/mL, as shown (Figure 2, panel A and B). PBMCs from 5 donors were stimulated with each of the six yeast strains covering distinct subspecies and origins (Table 1).

All individual strains of yeast induced relatively high levels of the anti-inflammatory IL-10, reaching the values generally obtained with lactobacilli (mean/max values 535/2300 pg/mL). However, in contrast to bacteria, no significant strain-specificity was observed among different strains of yeasts, which all induced similar levels of cytokines (Figure 3A). Analysis of the cell culture supernatants revealed moderate induction of TNF after yeast stimulation, as compared with bacterial stimulation, again without a clear strain dependency (Figure 3B). Yeasts induced extremely low levels of the pro-inflammatory signals IL-12 and IFNγ as compared to some bacteria such as *Lactococcus lactis* MG1363 or *Lactobacillus acidophilus* NCFM (Figure 3C and D). Concerning the intrinsic immunostimulatory capacity of yeast cells *in vitro*, we can conclude that no specific stimulation pattern could be discriminated among the six strains, while all strains favored anti-inflammatory profiles with a high IL-10/IL-12 ratio, low induction of TNF and negligible levels of IFNγ.

Resistance of various yeasts strains to the GIT passage

Next to the effect of yeasts on cytokine induction on PBMCs *in vitro*, we compared the ability of the 3 strains LV01, LV02 and LV09 to survive the digestive tract of mice. Following 0, 1 and 5 consecutive days of intragastric feeding of 10^8 CFU of each of the yeasts; faecal enumeration showed equivalent survival counts for all the strains with a progressive increase with the duration of the treatment (Figure 4). The systematic increase by 2 log units between day 1 and day 5 suggests that proliferation occurs in the gut, rather than simple transit and shedding. Although we cannot speculate on the long term persistence and colonization of the yeast species, a 5-d-treatment clearly leads to a noticeable presence of living yeasts in the colon lumen (up to 10^8 CFU/g for the 3 strains). A significant faecal recovery of yeast colonies from healthy mice was still detectable 10 d after the last feeding (more than 10^5 CFU/g, data not shown). It is noteworthy to mention that neither diarrhoea nor slight changes in faecal character, nor weight disturbance or other deleterious signs were observed in mice treated with those food-grade yeasts.

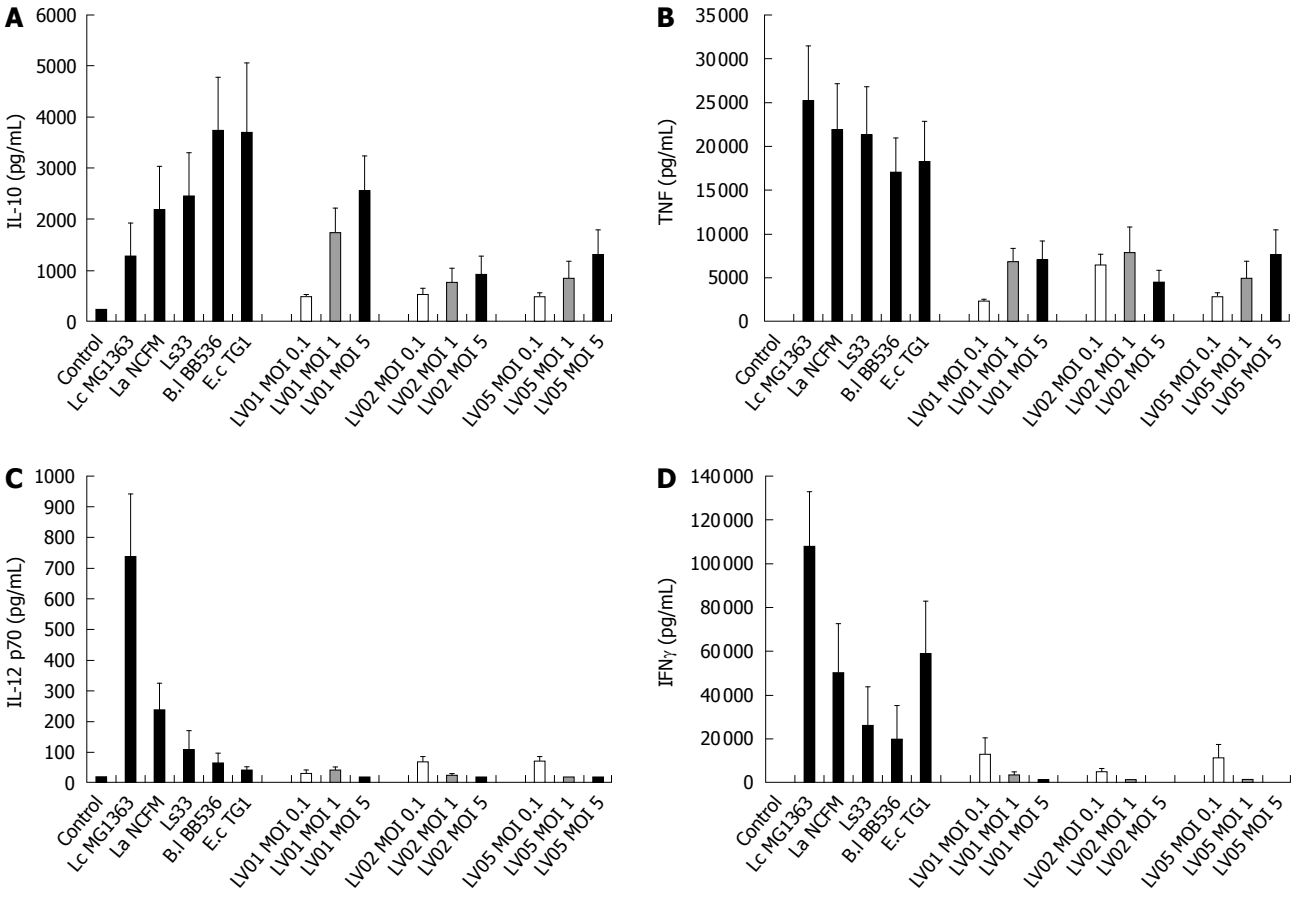

Figure 1 Dose-dependent cytokine production in human peripheral blood mononuclear cells (PBMCs), stimulated with bacterial reference strains and 3 yeast strains at distinct multiplicity levels of infection [multiplicity levels of infection (MOI) 0.1, 1 and 5 yeasts/cells] for 24 h. Cytokine levels were analyzed in supernatants by enzyme-linked immunosorbent assay (ELISA). Panels A, B, C and D respectively show results for interleukin (IL)-10, tumor necrosis factor (TNF), IL-12 p70 and interferon γ (IFNγ), respectively. Results are expressed in pg/mL, mean ± SE, *n* = 3 distinct donors.

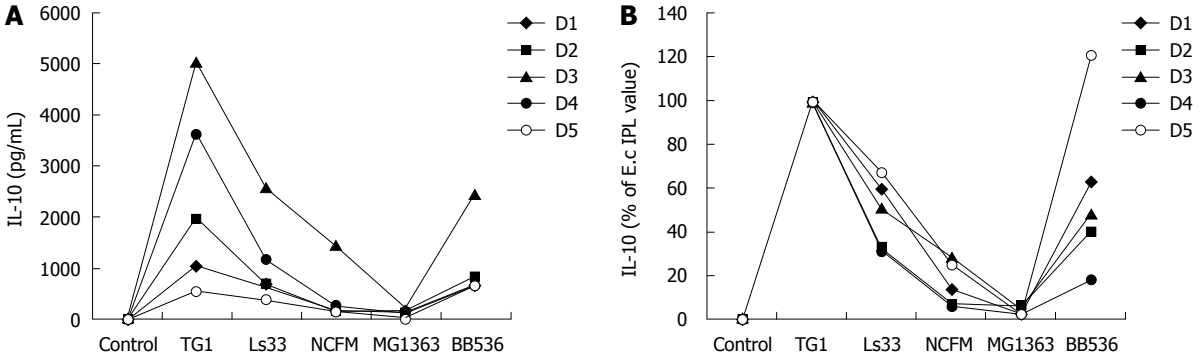

Figure 2 Standardized assessment of cytokine production in human PBMCs from distinct donors. Immuno-competent cells are stimulated with 5 bacterial reference strains for 24 h and cytokine levels were analyzed in supernatants by ELISA. A: IL-10 release for 5 individual donors. Results are expressed in pg/mL; B: Standardized IL-10 release with values expressed as % of *Escherichia coli* (*E. coli*) value for each of the 5 donors.

Comparative preventive capacity of yeasts in alleviating experimental colitis

In order to evaluate whether the administration of distinct yeast strains equally impacted on TNBS-induced colitis, we compared the performance of the three strains LV01, LV02 and LV09 with the anti-inflammatory corticoid drug (prednisone) which we and others previously used in this experimental setting[31,32]. Since some anti-inflammatory effects of lactobacilli were observed both after oral and systemic administration[33,34], we assessed whether intraperitoneal administration of the yeast LV01 could also rescue mice from colitis.

Rectal administration of TNBS causes progressive weight loss in vehicle-treated mice, reaching up to 22.5% of the initial weight 72 h after induction of colitis (Figure 5A and B). As expected, prednisone prevented body weight loss associated with experimental colitis (-3.3%, $P < 0.001$). The oral treatments by the 3 yeast

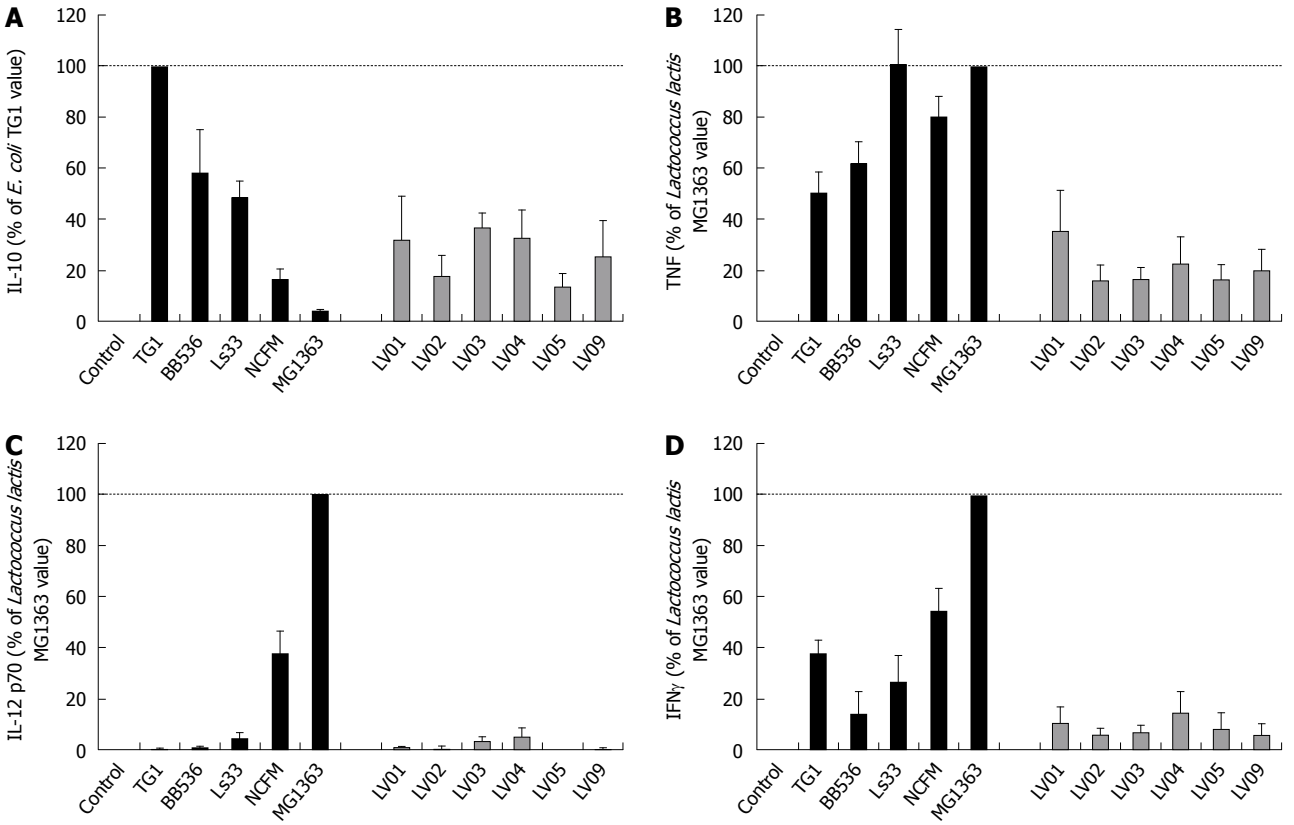

Figure 3 Cytokine production in human PBMCs, stimulated with bacterial reference strains and 6 yeast strains for 24 h. Cytokine levels were analyzed in supernatants by ELISA. A: IL-10; B: TNF; C: IL-12 p70; D: IFNγ. Results are expressed in % of *E. coli* TG1 value for panel A and in % of *Lactococcus lactis* MG1363 for B, C and D, including mean ± SE; *n* = 5.

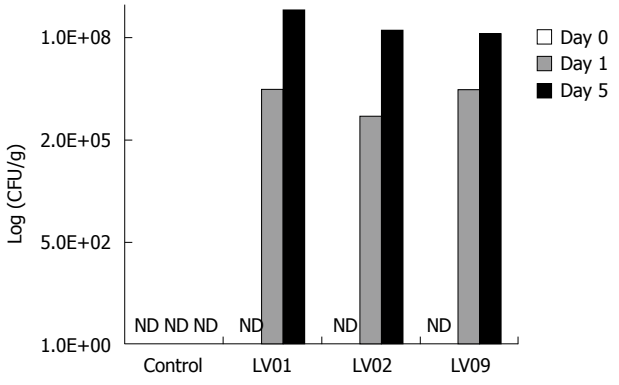

Figure 4 Fecal recovery of the 3 distinct yeast strains in yeast-fed mice, at days 0, 1 and 5. Data were obtained by counting dilutions of stools on appropriate "yeast-selective"-tetracycline agar plates. Results are expressed in Log CFU/g of stools. Results are representative for 2 separate experiments, SD are not represented for clarity reasons. ND: Not detected; CFU: Colony-forming units.

strains also significantly attenuated the deleterious weight changes for the LV01 (-9.9%, $P < 0.01$), and to a lesser extent for LV02 and LV09 (18%, $P < 0.05$). In contrast, the systemic administration of the strain LV01 (LV01-IP) had no additional effect on weight.

After the onset of colitis, anti-inflammatory effects were measured macroscopically for the prednisone-treated as well as for the LV01-treated mice (66% and 27% reduction of macroscopic damage, respectively, $P < 0.01$, Figure 6A). More moderately LV02 reduced the colonic insult (18% of control, $P < 0.05$) while intra-peritoneal injection of LV01 failed to influence the macroscopic scores.

Considering the histological assessment of colitis in various conditions (Figure 6B), both the prophylactic treatment by prednisone and LV01 significantly reduced the microscopic scores of inflammation (by 60.3% and 35%, respectively, $P < 0.05$), while neither LV02 nor LV09 treament could be associated with a significant reduction of the histopathological features observed during active colitis (mucosal erosions, oedema, ulcerations areas and even necrosis). These observations, including thickening of the submucosa and inflammatory infiltrates, were correlated with the colonic myeloperoxidase activities measured (MPO, Figure 6C) and with similar reductions for the steroid drug and LV01 ($P < 0.01$). In contrast, no improvement, and even some aggravation, was depicted for strain LV01 provided by the systemic route, as supported by massive neutrophil infiltrates. Representative aspects of the corresponding colon sections are given (Figure 7). Mouse colons with vehicle-treated TNBS-induced colitis exhibited massive goblet cell depletion and showed disorganized mucosal architecture, including muscle layer necrosis (Figure 7B). By contrast, corticoid-treated animals showed a well-conserved appearance, more similar to normal structures despite a slight thickening of the submucosa. Only minor thickening of submucosa and superficial lesions, mainly

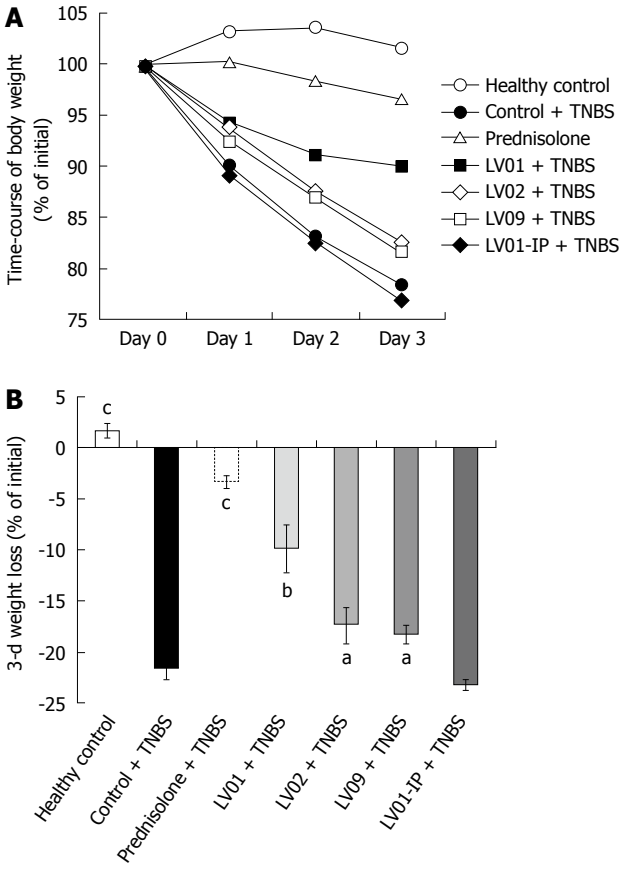

Figure 5 Changes in body weight during the preventive interventional study on experimental colitis. A: Time-course changes of weight for control mice and 2-4-6-trinitrobenzene sulfonic acid (TNBS)-treated mice, covering saline vehicle, prednisone and yeast pre-treated animals. Results are expressed as % of initial weight; SDs are not represented for clarity; B: Final weight loss 3 d after colitis. Results are expressed as mean ± SE (n = 10 per group), $^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$ *vs* TNBS-saline.

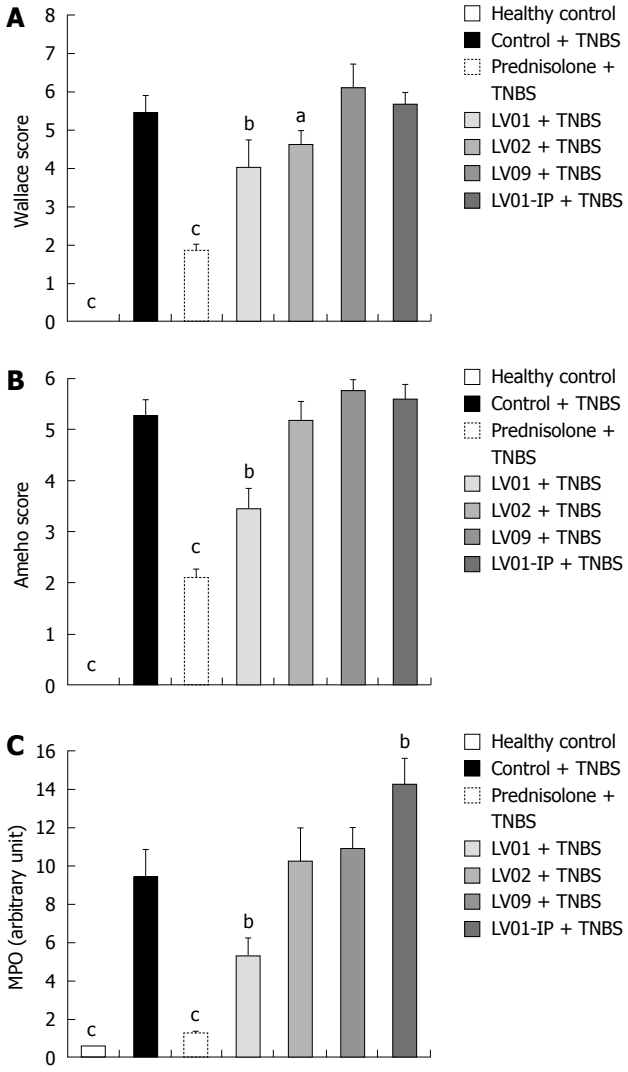

Figure 6 Effects of the various treatments 3 d after the TNBS-induced colitis on colonic macroscopic damage (Wallace) (A), histology scores (Ameho) (B) and myeloperoxidase (MPO) activity (C). Mice received intrarectally either saline or TNBS following oral pre-treatment by prednisone (10 mg/kg, 2 d), by various yeast strains for 5 d or after intra-peritoneal administration (IP) of the yeast at the onset of colitis. Results are expressed as mean ± SE (n = 10 per group), $^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$ *vs* TNBS-saline.

oedema, were seen in mice treated with the yeast LV01, in complete absence of necrosis. Erosions were more important in LV02-pretreatment, although necrosis was restricted to the upper luminal compartment and the crypt's architecture was still identifiable. Treatment with strain LV09 given orally and strain LV01 after intraperitoneal administration were characterized by prominent inflammatory infiltrates and transmural inflammation with necrosis reaching the deeper muscle layers.

The levels of the blood markers of inflammation SAA and IL-6, while significantly increased after TNBS administration, were strikingly reduced by prednisone and LV01 treatments, approaching baseline values ($P <$ 0.01). LV02 strain also minimized the pro-inflammatory cytokine IL-6 in the serum ($P < 0.05$), with a similar trend observed for SAA ($P = 0.055$, Figure 8).

In conclusion, TNBS caused increases in mucosal and systemic inflammatory symptoms that can be prevented by an orally administered anti-inflammatory drug (prednisone) as well as the food-grade yeast LV01. This was substantiated on the basis of reduction of body-weight loss, macroscopic damage, histological scores, colonic inflammatory infiltrates and serum markers. The yeast strain LV02 showed an intermediate protection capacity with sometimes partial and borderline effects in the degree of attenuation, depending on the marker considered. LV09 only lowered the weight loss with no improvement of other colitis-related symptoms. These results support the relevance of yeast for colitis protection, but distinct performance of various strains highly suggests strain-dependent mechanisms.

DISCUSSION

Evidence that yeasts can be used as a probiotic with therapeutic potential in IBD has emerged from clinical trials and experimental models of colitis in animals. However, these studies remained scarce and essentially used the strain *S. boulardii,* formerly *S. cerevisiae* var *boulardii*. In this study we aimed at questioning the differential anti-inflam-

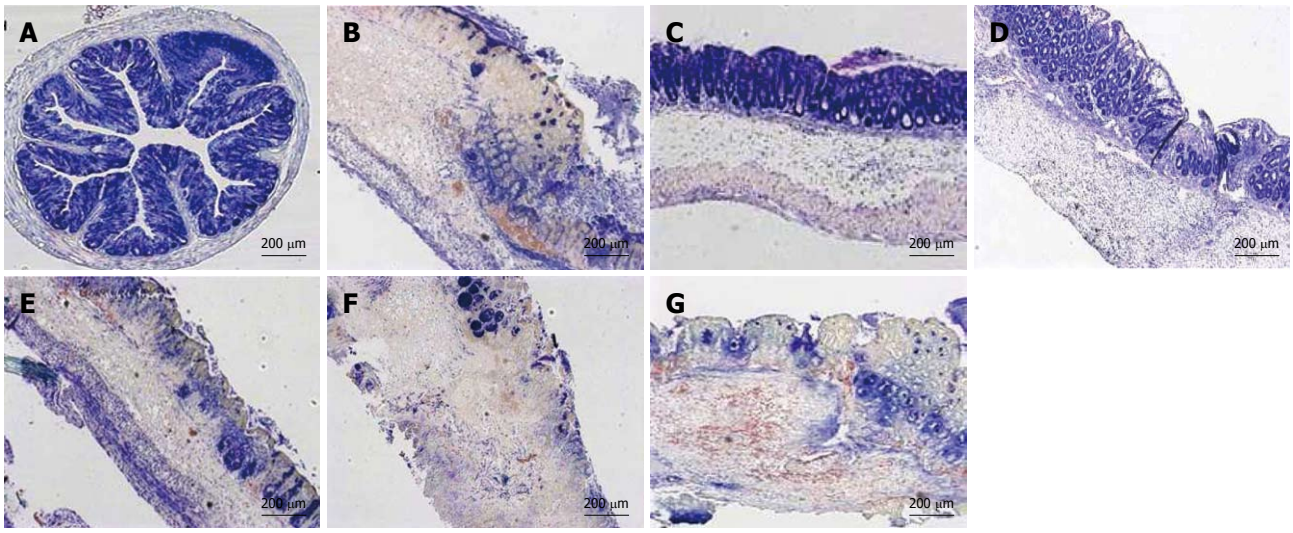

Figure 7 Histological features of yeast-mediated protection. The figure shows representative May-Grünwald and Giemsa-strained colon sections of control healthy mice (A) or day 3 after instillation of TNBS in Balb/c mice pre-treated with either vehicle (B), prednisone (C), LV01 (D), LV02 (E), LV09 (F) and LV01-IP (G). Figure 8 Effects of the various treatments 3 d after the TNBS-induced colitis on blood markers. A: Serum amyloid A protein (SAA); B: IL-6. Mice received intra-rectally either saline or TNBS following oral pre-treatment by prednisone (10 mg/kg, 2 d), by various yeast strains for 5 d or after intra-peritoneal administration (IP) of the yeast at the onset of colitis. Results are expressed as mean ± SE (n = 10 per group), $^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$, $0.05 < {}^{d}P < 0.1$ *vs* TNBS-saline.

matory potential of other yeast strains. Whether food-borne strains of *S. cerevisiae* or other yeast species possess probiotic properties is of fundamental importance in developing, understanding and handling of new potential biotherapeutic agents, both concerning the pharmaceutical and the (functional) food industry. Attempts for such a screening of yeast biodiversity were already carried out *in vitro*[17,35,36], mainly by studying selection criteria such survival at low acid pH and tolerance to bile salts or adhesion on epithelial cells. The predictability for the *in vivo* situation, however, is limited, as the importance of colonization in strain efficacy remains to be determined *in vivo*[37]. An example was recently given with a *Lactobacillus* strain that fulfilled adhesion and survival criteria *in vitro* but was unable to persist in mice, although exerting immunomodulatory effects[38]. To our knowledge, the comparison of distinct yeast strains based on their ability to induce cytokine secretions by immunocompetent cells was never reported.

Results obtained in this study showed that, in contrast to bacteria[22,39,40], *in vitro* immunomodulation did not discriminate among various strains. This can be attributed to the more conserved cell-wall structure of the yeasts. However, yeast cells are not inert from an immunological point of view and substantial induction of IL-10, on PBMCs, associated with weak TNF and no release of IFNγ and IL-12, favor, in general, a more anti-inflammatory profile than bacteria. This is in agreement with very recent studies using germ-free mice[41].

The three strains used in the murine TNBS-induced colitis exhibited similar colonization patterns *in vivo*, thus allowing accurate comparisons. Standardization of experimental settings for all evaluations and, as far as possible into the same study, is highly recommended[42]. The

present work confirms that a yeast strain (*S. boulardii*) is able to significantly prevent symptoms in an acute experimental colitis in mice. The 30% protection observed, lower than the protection obtained by a traditional anti-inflammatory drug, is consistent with previous reports using the same yeast strain in a rat model of TNBS[13]. By contrast, in another study in rats, TNBS-induced inflammation was only weakly lowered with *S. boulardii* with the 18% trend, which did not passed the statistics test, while conventional IBD drugs and other probiotic preparations did show significance[43,44]. Such differences between studies may depend on experimental design including distinct outcomes when considering preventive *vs* therapeutic applications, as reported e.g. for bacteria in the TNBS colitis model[45], in the experimental DSS model[46] or even in clinical studies[47]. Hence, these observations emphasize the necessity to compare distinct treatments and strains in a single study. We enlightened here for the first time that, like probiotic bacteria, probiotic yeasts are not equivalent in their capacity to alleviate colitis, despite a similar colonization profile.

The "main contribution" of yeast-mediated anti-inflammatory effects is suggested to more address the intestinal barrier properties and epithelial cells rather than an immunocompetent cell-based immunity, because (1) protection triggered by yeasts *in vivo* is strain-dependent, whereas together with the immune screening *in vitro*, was poorly discriminating; and (2) the failure of *S. boulardii* to induce protection by the systemic route, in contrast to the oral route. Indeed, in contrast to some beneficial bacteria which are able to exert effects distantly from the inflammation site[33,34,48], emphasizing a possible role of migratory cells such as dendritic cells (DC)[31], yeast-mediated protection seems to take place predominantly in the intestinal mucosa. An intestinal barrier dysfunction in IBD is obvious, although it is not clear yet whether this is a cause or a consequence of the disease[49]. Prophylactic reinforcement and therapeutic restoration of barrier function by changing the luminal environment may successfully stimulate the mucosal barrier. Probiotics are elements of choice to normalize the barrier function, stabilize tight junction components[50] and limit translocation[51]. Trophic effects[52] as well as enhancement of epithelial integrity mediated by yeasts have been extensively described[4,7]. Reduction of bacterial translocation by oral treatment with yeasts in various models of sepsis also confirmed this functional aspect of probiotic-yeasts[53-55].

However, other mechanisms including direct yeast-DC interactions were also evoked to explain how *S. boulardii* exhibits its anti-inflammatory properties[56]. Stimulation may occur in Peyer's patches or in the lamina propria. This mechanism did not seem to be very strain specific and, paradoxically, even *Candida albicans* was recently reported to induce tolerogenic DC and to positively balance inflammation after adoptive transfer in a mice colitis model[57]. Similarly, soluble β-glucans derived from *C. albicans* were able to suppress the production of pro-inflammatory cytokines by PBMCs[58] while mannan from *S. cerevisiae* impaired the ability of macrophages to kill phagocytosed pathogens[59]. On the other hand, colonization of mice by *C. albicans* exacerbated DSS-colitis[60] and delayed healing of TNBS colitis[61]. Finally, intraperitoneal injection of zymosan, a polysaccharide cell wall component from *S. cerevisiae* has been widely used as a (self-resolving) model of acute inflammation[62]. By contrast, yeast extracts administered to mice *per os* resulted in a significant reduction of the *C. difficile*-toxin A-mediated COX-2 increase and in the toxin-mediated disruption of epithelial cells[63]. Whether yeast or yeast-derived molecules will have a pro- or anti-inflammatory role may thus greatly depend on the route of administration and consequently on the target cells and tissues.

Nevertheless, we can speculate that oral yeast-induced immunomodulation predominantly addresses intestinal permeability and, based on published data, the immune function of intestinal cells. This is consistent with clinical findings indicating that *S. boulardii* has a positive effect on the maturation of enterocytes, but only a minor influence on lymphocytes[64]. Our results suggest that further screening for probiotic yeasts may favor the use of epithelial cell or mucosa-integrated models, rather than immune-cell based approaches. This will help us to select yeast or fungal strains with important potential in inflammatory conditions or in a context where inflammation is concomitant with enteropathogens such *C. difficile* and *E. coli*[65]. Understanding how various strains perform *in vivo* will allow us to trace specific mechanisms and select or design optimal strains for specific infectious or inflammatory diseases, or even consider new probiotic applications[66]. As some of the yeast-based probiotic mechanisms seem to be distinct from the bacterial ones, possible synergy might be expected from mixing both types of probiotics[67]. This was previously shown in a preclinical study on traveler's diarrhea, where the combination of yeast and bacteria was found to be more effective than each probiotic alone[68]. Using probiotic *Saccharomyces spp.* alone or in combination with lactic acid bacteria will thus enhance and extend the actual biotherapeutic/probiotic approach in IBD together with conventional anti-inflammatory treatments. Lastly, the strain-specific differences seen in the anti-inflammatory capacity of yeasts may also be extended for clinical use against *Salmonella ssp.*, *C. difficile* and *Candida species*, requiring an optimal and controlled formulation of the probiotic product[69].

COMMENTS

Background

As for probiotic bacteria, probiotic yeast such *Saccharomyces boulardii*

(*S. boulardii*) can be effective in gastrointestinal pathologies such as inflammatory bowel disease (IBD) and bacterial- or enterotoxin-mediated diarrhea and inflammation. However, very few yeast strains have been studied as possible biotherapeutics agents. The underlying mechanisms of action of probiotics are not fully understood but there is some evidence that they exert their beneficial effect by multiple and specific modes of action depending on the type of the probiotic (bacteria, yeast), the species and strain.

Innovations and breakthroughs

The yeast-mediated capacity to lower inflammation is suggested to mainly involve epithelial cells and barrier function, as demonstrated by (1) the weakness of specific immunomodulatory response *in vitro*; and (2) the lack of protection by *S. boulardii* when administered by the systemic but not the oral route. In contrast with the performance of some probiotic bacteria which the authors previously showed to be directly correlated with their *in vitro* anti-inflammatory potential, the immunoregulatory mechanism of probiotic yeasts fails to directly act on the cytokine level.

Applications

As for probiotic bacteria, strain specificity also matters for yeast as for probiotics, but mechanisms, and consequently screening methods, partly differ between yeast and bacteria. A careful and appropriate selection of strains is then required to screen the biodiversity of yeasts for specific clinical studies including applications in IBD as well as for other dedicated therapeutic uses. This will impact on future product composition to enhance or synergize gastrointestinal related disorders by using probiotics.

Terminology

Probiotics are defined as living microorganisms that may have beneficial effects on health, including mainly food-grade bacteria and non-pathogenic yeasts.

Peer review

The paper by Benoit Foligné and co-workers investigated the anti-inflammatory effects of various yeasts strains in experimental colitis in mice. The overall design of the study is fair and the results are stimulating for future research.

Abstract

AIM: To assess the safety and effectiveness of prophylaxis for venous thromboembolism (VTE) in a large population of patients with hepatocellular carcinoma (HCC) on cirrhosis.

METHODS: Two hundred and twenty nine consecutive cirrhotic patients with HCC who underwent hepatic resection were retrospectively evaluated to assess whether there was any difference in the incidence of thrombotic or hemorrhagic complications between those who received and those who did not receive prophylaxis with low-molecular weight heparin. Differences and possible effects of the following parameters were investigated: age, sex, Child-Pugh and model for end-stage liver disease (MELD) score, platelet count, presence of esophageal varices, type of hepatic resection, duration of surgery, intraoperative transfusion of blood and fresh frozen plasma (FFP), body mass index, diabetes and previous cardiovascular disease.

RESULTS: One hundred and fifty seven of 229 (68.5%) patients received antithromboembolic prophylaxis (group A) while the remaining 72 (31.5%) patients did not (group B). Patients in group B had higher Child-Pugh and MELD scores, lower platelet counts, a higher prevalence of esophageal varices and higher requirements for intraoperative transfusion of FFP. The incidence of VTE and postoperative hemorrhage was 0.63% and 3.18% in group A and 1.38% and 1.38% in group B, respectively; these differences were not significant. None of the variables analyzed including prophylaxis proved to be risk factors for VTE, and only the presence of esophageal varices was associated with an increased risk of bleeding.

CONCLUSION: Prophylaxis is safe in cirrhotic patients without esophageal varices; the real need for prophylaxis should be better assessed.

INTRODUCTION

Venous thromboembolism (VTE) is a significant cause of morbidity and mortality in patients who have undergone open gastrointestinal surgery, particularly if they were operated on due to malignancy[1,2].

Hepatocellular carcinoma (HCC) is the most frequent primary neoplasm of the liver and often develops as a consequence of chronic liver disease[3]. It is well known that several hemostatic alterations are present in patients with liver disease: primary hemostasis is often impaired due to piastrinopenia and secondary hemostasis can be hampered by the reduced synthesis of coagulation factors that normally takes place in the liver[4]. These alterations can be worsened by the decrease in hepatic volume caused by hepatic resection. A historical series of cirrhotic patients undergoing liver resection reported an 8.4% incidence of hemorrhagic complications following surgery[5].

While there is currently agreement on the need for pharmacological prophylaxis of VTE in surgical patients in general, little is know about the effect of this prophylaxis in patients with chronic liver disease who undergo hepatic resection due to the presence of HCC.

Studies on the coagulative pattern have shown that in patients with chronic liver disease there is decreased production of natural anticoagulant proteins that could result in an increase in the risk of thrombotic events; however, in clinical studies the incidence of VTE in cirrhotic patients seems to be lower than in the general medicine population[6].

Although great advances have taken place in the field of hepatobiliary surgery, resection of a cirrhotic liver remains a challenging procedure and hepatic surgeons may not feel confident in administering antithromboembolic prophylaxis to patients who have an increased risk of bleeding.

In our centre, where a large number of hepatic resections are performed, we have more and more frequently adopted a scheme of prophylaxis with low-molecular-weight heparin, however, we have no clear-cut parameters to refer to when deciding whether to administer prophylaxis or not and a significant number of patients are not given prophylaxis due to the risk of bleeding.

The aim of the present study was to assess the possible effect of different prophylactic strategies in the prevention of venous thrombosis in a large series of cirrhotic patients who underwent hepatic resection for HCC.

MATERIALS AND METHODS

The records of 229 consecutive patients with chronic liver disease who underwent hepatic resection due to the presence of HCC between January 1999 and December 2008 were retrospectively reviewed to ascertain whether there was any difference in the incidence of venous thromboembolic or hemorrhagic complications between those patients who received venous thrombosis prophylaxis and those who did not.

Table 1 Baseline characteristics of the study population (mean ± SD) *n* (%)

Variables	All patients (*n* = 229)	Group A (*n* = 157)	Group B (*n* = 72)	*P* value
Age (yr)	65.0 ± 9.3	65.0 ± 9.8	63.0 ± 9.5	0.080
Gender (M/F)	171 (74.7)/ 58 (25.3)	119 (76.0)/ 38 (24.0)	52 (72.0)/ 20 (28.0)	0.330
Etiology of cirrhosis				0.200
Hepatitis C	148 (64.6)	106 (67.0)	42 (58.3)	
Hepatitis B	37 (16.2)	21 (14.0)	16 (22.2)	
Hepatitis B + C	15 (6.6)	7 (5.0)	8 (11.1)	
Non-viral	29 (12.7)	23 (14.0)	6 (8.3)	
Child-Pugh score				0.005
A	218 (95.2)	154 (98.0)	64 (89.0)	
B	11 (4.8)	3 (2.0)	8 (11.0)	
C	0			
MELD score	8.8 ± 1.5	8.5 ± 1.2	9.3 ± 1.9	0.001
Platelet count (× 10^3)	139 ± 60	150 ± 60	115 ± 51	0.001
Esophageal varices	63 (28.0)	34 (22.0)	29 (40.3)	0.003

MELD: Model for end-stage liver disease.

All patients in the present series had the diagnosis of chronic liver disease confirmed by histology which was carried out on the resected specimen. Etiology of liver disease was predominantly viral (87.3% of cases) (Table 1).

Preoperative Child-Pugh-Turcotte score[7] and model for end-stage liver disease (MELD)[8] score were available for all patients; other parameters that were taken into account to determine the severity of portal hypertension were platelet count and presence of esophageal varices. Two hundred and eighteen patients (95.2%) had class A liver disease according to the Child-Pugh scoring system, while 11 (4.8%) had class B and none had class C disease; the mean MELD score of the patients was 8.8 ± 1.5.

Body mass index (BMI), diabetes mellitus and clinical history of cardiovascular disease were recorded as possible risk factors for thromboembolism. Type of surgical resection (minor when one or less and major when more than one hepatic segment was resected), duration of surgery, intraoperative transfusion of blood and fresh frozen plasma (FFP) were also recorded (Tables 2 and 3). Minor hepatic resection was carried out in 219 cases (95%), while major hepatic resection was performed in 10 cases (5%).

A protocol for general surgical procedures for the prevention of venous thrombosis using low-molecular-weight heparin prophylaxis was always observed in the period considered here. In the case of hepatic resection in cirrhotic patients the decision on whether to use prophylaxis was left to the judgment of the surgeon who performed the resection based on preoperative coagulation tests and intraoperative findings. For those patients

Table 2 Details of surgery performed in the two groups

Variables	All patients (*n* = 229)	Group A (*n* = 157)	Group B (*n* = 72)	*P* value
Type of resection *n* (%)				0.610
Minor	219 (95.0)	150 (95.5)	69 (95.8)	
Major	10 (5.0)	7 (4.5)	3 (4.2)	
Duration of surgery (mean ± SD)	266 ± 99	261 ± 106	275 ± 83	0.320

i.o. FFP transfusion [mL, median (range)]	175.7 (0-1200)	139.5 (0-1200)	266.6 (0-1200)	0.003

i.o.: Intraoperative; FFP: Fresh frozen plasma.

who were administered anticoagulant prophylaxis, this consisted of nadroparin calcium 0.3 mL or enoxaparin sodium 0.4 mL subcutaneously, starting from the day of surgery and continued for at least 7 d or until the patient was actively ambulant.

Prophylaxis was stopped when hemorrhagic complications developed.

Independent of the use of low-molecular-weight heparin, all patients had mechanical prophylaxis by means of anti-embolism stockings.

Patient follow-up included evaluation at the outpatient clinic on days 7 and 30 and months 3, 6, 9 and 12 after discharge from the Hospital.

VTE was defined as the symptomatic or asymptomatic occurrence of deep vein thrombosis confirmed by Doppler ultrasonography or venography; pulmonary embolism was confirmed by helical computed tomography.

Hemorrhagic complications were defined as follows: (1) Blood loss from surgical drainage associated with a significant drop in hemoglobin levels (> 1.5 g/dL from the last control); (2) Intraabdominal fluid collection with density at CT compatible with blood of diameter > 3 cm; and (3) Bleeding from the upper or lower gastrointestinal tract.

The analysis of risk factors for VTE included the following parameters: (1) age; (2) sex; (3) etiology of chronic liver disease; (4) Child-Pugh score; (5) MELD score; (6) presence of esophageal varices; (7) platelet count; (8) BMI; (9) chronic heart disease; (10) diabetes; (11) extent of surgical resection (major when more than 1 hepatic segment was resected); (12) duration of surgery; (13) intraoperative requirement for blood or FFP transfusion; and (14) prophylaxis with low-molecular weight heparin.

Statistical analysis

Continuous variables are reported as mean ± SD or in median and range on the basis of parametric assumption; differences between subgroups were investigated with Levene's test for equality of variances and compared with the Student *t*-test or Mann-Whitney test as appropriate. Categorical variables were reported in a number of cases and prevalence and differences in subgroups were compared using the χ^2 test with Yates correction. Univariate logistic regression analysis was applied in order to investigate risk factors for thrombosis or hemorrhage. *P*-values less than 0.05 were considered statistically significant in all the analyses. Statistical analysis was performed using the SPSS for Windows package (Version 10.0).

Table 3 Specific risk factors for venous thromboembolism in the two groups *n* (%)

Variables	All patients (*n* = 229)	Group A (*n* = 157)	Group B (*n* = 72)	*P* value
BMI > 30 kg/m^2	36 (17.1)	26 (17.8)	10 (15.4)	0.410
Diabetes	47 (20.5)	33 (21.0)	14 (19.4)	0.460
Cardiovascular disease	56 (24.5)	43 (27.0)	13 (18.1)	0.080

BMI: Body mass index.

RESULTS

One hundred and fifty-seven of the 229 (68.5%) patients received antithromboembolic prophylaxis (Group A) while the remaining 72 (31.5%) patients did not (Group B). The proportion of patients who received prophylaxis significantly varied with time: prophylaxis was given to 48 of 99 (48.4%) patients in the period 1999-2003 and to 109 of 130 (83.8%) patients in the period 2004-2008 (*P* = 0.001).

There was no difference in age, gender and etiology of liver disease between the 2 groups, while patients in group B had higher Child-Pugh and MELD scores, lower platelet counts and a higher prevalence of esophageal varices (Table 1).

Extent and duration of the hepatic resection and intraoperative blood transfusions were similar in the 2 groups, while in group B there was a significantly higher requirement for intraoperative transfusion of FFP (Table 2). This latter finding might indicate a higher bleeding tendency observed by the surgeon in the operative field, which resulted in the administration of greater amounts of FFP.

As regards the specific risk factors for venous embolism that were considered, there was no difference between the 2 groups (Table 3).

Two cases (0.87%) of deep venous thrombosis were observed: these were one case of pulmonary embolism secondary to a deep vein thrombosis of the leg in a patient who was receiving prophylaxis and one case of total portal vein thrombosis in a patient who did not receive prophylaxis: this latter patient had a Child score of A6, a MELD score of 13 with a low platelet count (113.000/mL) an INR = 1.3 and no esophageal varices, and underwent wedge resection and died of hepatic failure. The incidence of VTE was therefore 1.38% in patients who did not receive prophylaxis and 0.63% in those patients who were treated with low-molecular-weight heparin (*P* = 0.530).

Six cases of hemorrhagic complications were observed (2.62%); 5 of these cases occurred in those 157

VTE: Venous thromboembolism.

patients who received prophylaxis (prevalence: 3.18%) and one in patients who did not receive prophylaxis (prevalence: 1.38%); the difference was not significant ($P = 0.380$). The hemorrhagic complications consisted of prolonged blood leakage from the surgical drains requiring blood transfusion (3 cases), intraperitoneal blood collection (2 cases) and gastric bleeding (1 case). Only 1 of the above-mentioned cases required invasive intervention (CT-guided percutaneous drainage of intraperitoneal collection).

None of the considered risk factors proved to be significantly associated with VTE in the univariate analysis, and only the presence of esophageal varices was linked to an increased risk of hemorrhagic complications (Tables 4 and 5).

DISCUSSION

Despite the clinical relevance of this topic, to our knowledge no reports have been published to date on the use of venous thrombosis prophylaxis in cirrhotic patients undergoing hepatic resection for HCC. The absence of clear guidelines for prophylaxis of thromboembolism in the specific setting of hepatic surgery in patients such as those with chronic liver disease who are known to have imbalances in coagulative function may induce those surgeons with less experience in hepatobiliary surgery to avoid prophylaxis for fear of hemorrhagic complications; on the other hand, administering prophylaxis to patients with severe coagulative impairment and severe portal hypertension possibly following an extensive liver resection should be done on more solid grounds than simple adherence to existing guidelines that were drawn up for open abdominal surgery. In both cases, should thromboembolic or hemorrhagic complications develop, then the possibility of a malpractice accusation would be consistent[9].

In our experience, we found a particularly low incidence of deep vein thrombosis in cirrhotic patients who underwent liver resection, which could be partially justified by the absence of specific postoperative screening; however, at our center, HCC patients are always closely monitored with follow-up after resection and we can therefore exclude the fact that major thrombotic complications took place after hospital discharge which do not show up in the clinical records. Of note, all the patients in this report received prophylaxis with a mechanical method (anti-embolism stockings) which, together with the peculiarities of the study population, may have played a role in keeping the rate of VTE particularly low.

Hemorrhagic complications after liver resection are often poorly defined in specific reports, and the impression is that only those that require invasive maneuvers are usually reported; nevertheless, the incidence of these complications after resection in cirrhotic patients ranges between 1% and 8%[5,10,11]. The hemorrhagic complications reported in the present study were mainly represented by prolonged blood leakage from the surgical drains requiring blood transfusion. Although a trend towards a higher incidence of hemorrhage following resection was observed in those patients who received prophylaxis, the difference between the 2 groups was not significant.

Prophylaxis was withheld mainly in those patients who had a higher Child-Pugh or MELD score, lower platelet count and higher prevalence of esophageal varices; however, the overall increase in prophylaxis administration over time reflects an increase in confidence in handling it.

The surgeon performing the hepatic resection can assess some elements such as the bleeding tendency observed in the operative field and the degree of portal hypertension as revealed by the number and size of hepatofugal collateral veins, which can provide information that goes beyond what can be assessed with laboratory and imaging screening. However, the categorization of these elements largely depends on the degree of experience and confidence of the surgeon, and their effective relationship with the risk of bleeding in the postoperative period is difficult to demonstrate.

Similarly, in the cirrhotic patient, the common coagulative tests such as prothrombin time or INR poorly predict the effective risk of bleeding: in fact, these tests

only measure the activity of procoagulant factors while they ignore possible changes in the activity of anticoagulant factors that, in liver disease, are also deficient[12].

In our study, a greater amount of FFP was administered to those patients who did not receive prophylaxis, which might reflect a bleeding tendency that was observed at surgery. We believe that, unless clear guidelines are validated by large clinical trials, antithromboembolic prophylaxis should probably be avoided in those patients who are judged at high risk of bleeding by the surgeon.

Despite their low incidence in this series, the thromboembolic complications seen after surgery were life-threatening, however, we did not experience similar serious hemorrhagic complications. In the absence of more reliable tools to quantify the probability of bleeding it seems reasonable to avoid prophylaxis when portal hypertension is present or significant bleeding is observed at surgery.

Further prospective studies are necessary to establish guidelines for application in this specific setting.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the most common primary neoplasm of the liver and often arises in the context of a chronic liver disease that impairs coagulative function. Surgical resection is the best option to cure HCC, however, surgery on cirrhotic liver may increase the risk of bleeding. Despite the clinical relevance of the matter, no guidelines are available on the administration of antithromboembolic prophylaxis in cirrhotic patients undergoing hepatic resection.

Innovations and breakthroughs

The study shows that the risk of venous thromboembolism after hepatic resection in cirrhotic patients is low. A trend towards an increased incidence of postoperative hemorrhage was observed in patients who received prophylaxis. Portal hypertension, as demonstrated by the presence of esophageal varices, is significantly associated with the risk of bleeding.

Applications

The absence of guidelines for prophylaxis of thromboembolism specifically aimed at patients with chronic liver disease undergoing hepatic surgery can lead to the generalized application of prophylactic schemes which are used in the setting of open abdominal surgery, thus increasing the risk of bleeding. Conversely, to withold prophylaxis might increase the risk of thromboembolism. Both these policies can be dangerous and lead to malpractise accusations. Prospective studies are necessary to establish specific guidelines.

Peer review

This is a good manuscript to get published but needs some more information. The manuscript is well written and would be helpful in the field of hepatic surgery.

Abstract

AIM: To assess the impact of bolus volume on the characteristics of small intestinal (SI) impedance signals.

METHODS: Concurrent SI manometry-impedance measurements were performed on 12 healthy volunteers to assess the pattern of proximal jejunal fluid bolus movement over a 14 cm-segment. Each subject was given 34 boluses of normal saline (volume from 1 to 30 mL) *via* the feeding tube placed immediately above the proximal margin of the studied segment. A bolus-induced impedance event occurred if there was > 12% impedance drop from baseline, over ⩾ 3 consecutive segments within 10 s of bolus injection. A minor or major impedance event was defined as a duration of impedance drop < 60 s or ⩾ 60 s, respectively.

RESULTS: The minimum volume required for a detectable SI impedance event was 2 mL. A direct linear relationship between the SI bolus volume and the occurrence of impedance events was noted until SI bolus volume reached 10 mL, a volume which always produced an impedance flow event. There was a moderate correlation between the bolus volume and the duration of impedance drop (r = 0.63, P < 0.0001) and the number of propagated channels (r = 0.50, P < 0.0001). High volume boluses were associated with more major impedance events (⩾ 10 mL boluses = 63%, 3 mL boluses = 17%, and < 3 mL boluses = 0%, P = 0.02).

CONCLUSION: Bolus volume had an impact on the type and length of propagation of SI impedance events and a threshold of 2 mL is required to produce an event.

INTRODUCTION

Absorption of nutrients is the main function of the

small intestine and requires not only normal mucosal integrity but also normal motor function[1-4]. Adequate mixing and proper transit of chyme are important in ensuring optimal absorption[3,4]. Accurate assessment of small bowel motor function is important for understanding the physiology of the gastrointestinal tract, as well as assessment of clinical disorders of the intestine[1,5-7]. Currently, several tests are available for the assessment of intestinal motility and transit. Although intra-luminal manometry detects contractile patterns, it provides only indirect data regarding flow[5]. Similarly, although intestinal transit can be measured by conventional scintigraphy and more recently by breath tests, these methods detect only total transit time and not patterns of flow; transit can be affected by gastric emptying rate and conditions such as bacterial overgrowth[5]. Fluoroscopic studies, on the other hand, are able to assess overall intestinal motility and bolus transit, but are greatly limited by the exposure of patients to radiation[5].

In combination with manometry, multiple intra-luminal impedance (MII) has been introduced as a technique to assess motility and bolus transit concurrently[8-10]. Although this combined technique has been validated and applied extensively in the study of oesophageal physiology and disease[11-14], few data are available regarding its use in the evaluation of small bowel motor function[15-17]. Recently, detailed analysis from a study using combined video-fluoroscopy, manometry and MII showed that an impedance drop of > 12% from the baseline which propagated over 5 cm is associated with a flow event as seen on fluoroscopy[17]. Furthermore, various patterns of impedance flow events during fasting and in the postprandial state have been reported in the proximal intestine of healthy subjects[16]. This study, however, did not have concurrent manometric assessment and it is unclear whether the variation in impedance patterns of flow was influenced by intestinal motor activity or volume of the transported bolus or chyme. Knowledge on the relationship between bolus volume and impedance changes in the oesophagus[18] allows investigators to use intra-luminal impedance to assess oesophageal flow and clearance, without the need for radiological assessment. Corresponding data for the small intestine, however, are lacking. The aim of the current study was to assess the impact of bolus volume on the characteristics of small intestinal (SI) impedance signals in healthy humans.

MATERIALS AND METHODS

Subjects

Studies were performed in 12 healthy subjects (6 males; age: 53 ± 6 years; body mass index: 24.5 ± 1.1 kg/m^2) at the Department of Gastroenterology and Hepatology, Royal Adelaide Hospital. Exclusion criteria included previous or current gastrointestinal symptoms or surgery, evidence of acute or chronic illness and medications known to influence gastrointestinal motor function. The protocol was approved by the Research Ethics Committee of the Royal Adelaide Hospital and all subjects gave written informed consent.

SI manometry and impedance recording

SI motility and intraluminal electrical impedance were recorded concurrently using (1) a 110-cm perfused multilumen manometric assembly (DentSleeve Pty Ltd., Wayville, Australia); and (2) an impedance catheter (Sandhill Scientific, Highland Ranch, CO, USA).

Intestinal motility was recorded using an assembly comprising 11 pressure recording side holes: eight spaced at 2 cm intervals and the following three at 10 cm intervals, from the catheter tip. All manometric lumina were perfused with degassed distilled water at a rate of 0.15 mL/min, by a pneumo-hydraulic capillary perfusion pump (Dentsleeve).

SI luminal flow was recorded using an electrode with eight impedance rings (4 mm in length) spaced 2 cm apart, enabling 7 consecutive recording segments over a distance of 14 cm (Z1 to Z7; proximal to distal, respectively). Each segment straddled a corresponding manometric side hole and was activated by a high frequency (1 kHz) low amplitude (< 6 μA) alternating current.

Manometric and impedance signals were recorded simultaneously using a specialised computer system (Insight Acquisition, Sandhill Scientific) and displayed and stored on a personal computer for subsequent display and analysis.

Duodenal feeding tube

An 18F feeding tube was used to deliver the liquid boluses. The tube was attached to the manometry-impedance assembly and was positioned so that its tip was 1-cm above the most proximal impedance recording segment, Z1. The assembly configuration is outlined in Figure 1.

Protocol

All subjects were studied after an overnight fast. The assembly was passed into the stomach to a distance of 65 cm, through an anaesthetized nostril. The assembly was then allowed to migrate naturally into the duodenum *via* peristalsis, which was monitored continuously by measurements of the antro-duodenal trans-mucosal potential difference (TMPD). The final catheter position was achieved when the most proximal manometric side-hole was located in the duodenum, confirmed by a TMPD reading ⩾ -15 mV[19]. In this position, the combined manometry-impedance recording segment would be expected to lie in the proximal jejunum and at least 20 cm distal to the pylorus. Radiological confirmation of the catheter position was not performed due to the concern of unnecessary radiation exposure to healthy subjects.

Once the assembly was positioned in the proximal jejunum, subjects were positioned in a 30 degree head-up, supine position. During phase I of the interdigestive migrating motor complex (MMC), a total of 34 boluses of saline (0.9%) were given to each subject *via* the feeding tube. Five boluses for each volume of 1, 2 and 3 mL

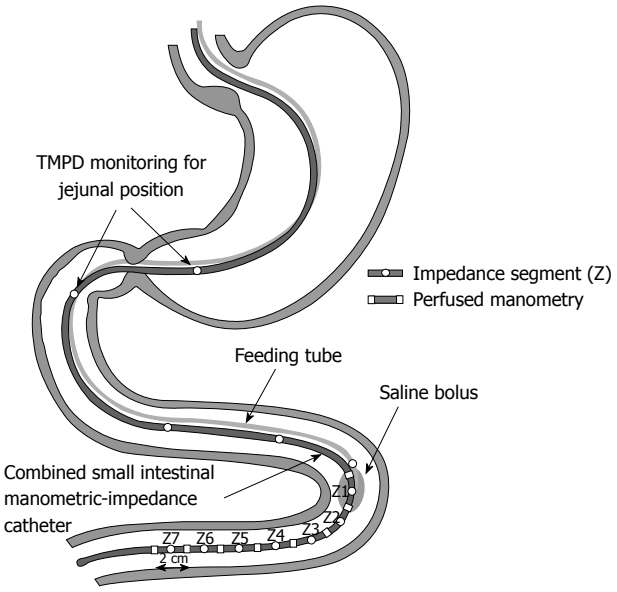

Figure 1 Outline of recording assembly, consisting of combined manometry and impedance catheters and feeding tube, positioned within the proximal small intestine.

were given at 2-min intervals. Five boluses for each volume of 5, 10 and 15 mL were given at 5-min intervals. Two boluses for each volume of 20 and 30 mL were given at 10-min interval. Each bolus was infused at the maximal rate allowed by the assembly lumen.

Data analysis

Manometry: Phase I of MMC was defined as a quiescent period without any intestinal motor activity, and phase II as a period of irregular intestinal motor activity[5,19]. A SI pressure wave was defined as a pressure rise ≥ 6 mmHg from baseline and lasting between 0.8 and 7 s[19]. Pressure waves in adjacent channels were regarded as temporally related if their onsets were within 3 s, and "propagated" if there were ≥ 3 temporally-related sequential pressure waves[19].

Impedance: The recordings were analysed manually using the impedance analysis software (Bioview Analysis, Sandhill Scientific). An impedance event judged to be associated with flow was defined as having an impedance drop of > 12% below the baseline and propagated over 3 or more impedance segments[17]. The impedance baseline for which the percentage drop was based on was the average impedance value over the 5 s immediately before the impedance drop. For each impedance event, the following variables were characterized: (1) the baseline impedance value (5 s) before injection of the bolus; (2) the magnitude of impedance drop, including minimum, average and maximum values; (3) the number of propagated channels; and (4) total bolus clearance time (TBCT), which was defined as the time taken (in seconds) for the bolus to traverse the whole recording segment in the intestine. TBCT was measured from the time the bolus entered the most proximal intestinal recording segment (Z1) until it cleared the most distal recording segment (Z7). Impedance events with TBCT greater than 60 s were classified as 'major' events (Figure 2). For each tested bolus, an impedance event was deemed to be associated with the tested bolus if the event occurred within 10 s from the administration of the bolus and an absence of corresponding motility. Boluses that had the associated impedance signal interfered by movement artefacts, or that coincided with intestinal contractions at the time of bolus administration were excluded from the final analysis as it was not possible to confidently determine whether the impedance changes in these events were related to the bolus administration, the movement artefact or coincident intestinal contractions.

Statistical analysis

Data are presented as mean ± SE. Categorical data were compared by chi-square test with Yates' correction and continuous data by Student's *t*-test, using GraphPad Prism 4 (v 4.02, San Diego, CA, USA) statistical software. The relationships between bolus volume and impedance flow events, magnitude of impedance drop, number of propagated channels and TBCT were determined by repeated measures ANOVA and Pearson's linear regression analysis. Significance was accepted at a P value < 0.05.

RESULTS

Relationship between bolus volume and impedance events

Injection of a saline bolus at the proximal end of the recording segment induced a prompt impedance drop that propagated distally. A minimum volume of 2 mL was required to induce a recognizable intestinal impedance flow event (Figure 3). As the bolus volume increased from 2 to 10 mL, the proportion of detectable intestinal impedance events increased in a linear relationship. A bolus volume of ≥ 10 mL always produced an impedance event.

Relationship between bolus volume and magnitude of impedance drop

The mean baseline impedance value was 389 ± 58 ohms. There were no significant differences in the baseline impedance values among the different bolus volumes. The mean impedance drop for a detectable flow event was 151 ± 4 ohms. The median impedance drop from baseline associated with a detectable flow event was 27% (IQR: 12%-53%). There was a weak relationship between the bolus volumes and the magnitude of impedance drop (mean: $r = 0.33$, $P < 0.0001$; minimum: $r = 0.28$, $P < 0.000$; maximum: $r = 0.30$, $P < 0.01$) (Figure 4A).

Relationship between bolus volume and number of propagated channels

Boluses with a volume of ≥ 5 mL propagated over a longer distance than those with a volume < 5 mL. Once the bolus volume was ≥ 10 mL, an impedance drop always propagated over at least 7 channels (i.e. 14 cm) (Figure 3). Up to a bolus volume of 10 mL, there was

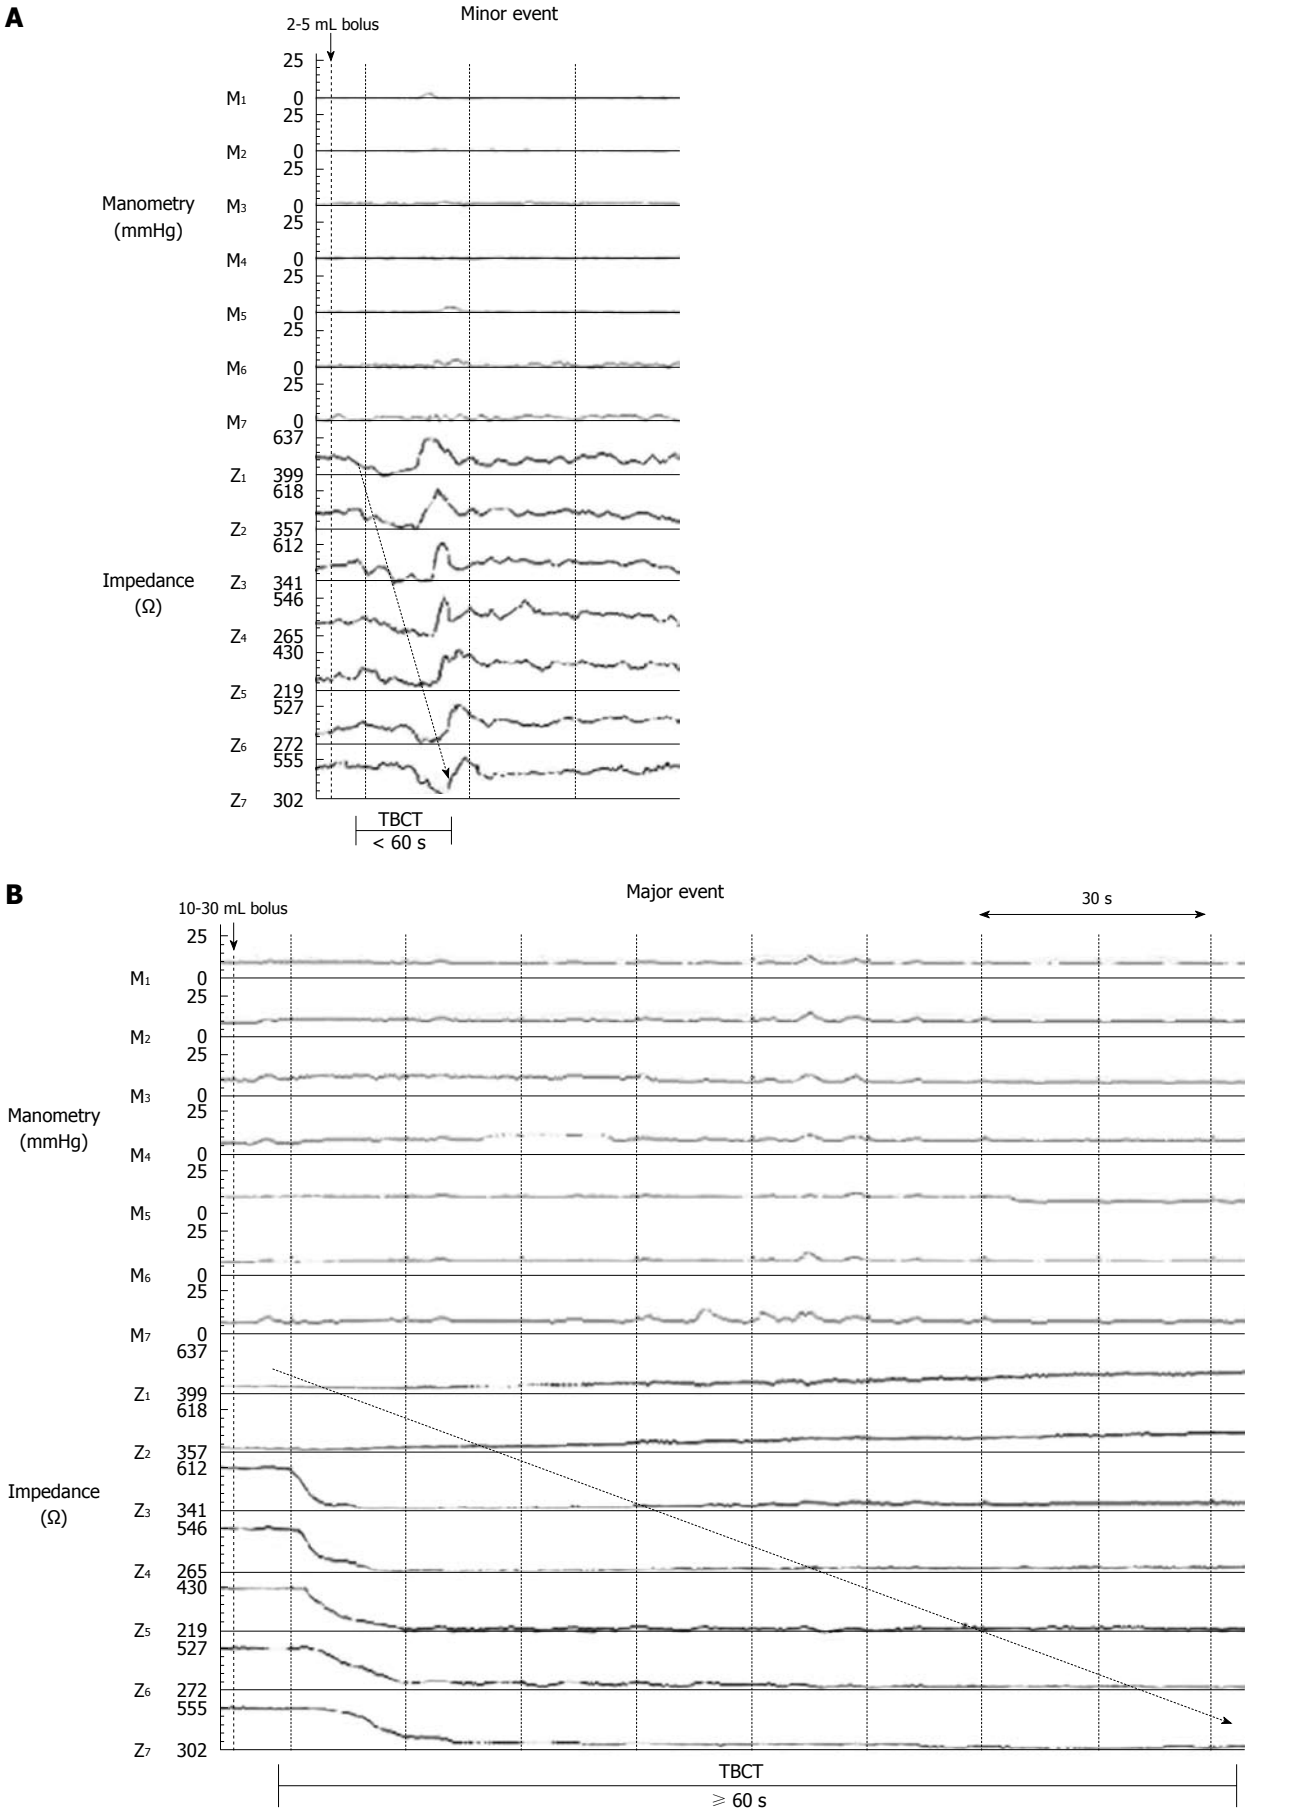

Figure 2 An example of combined manometry-impedance recording, demonstrating the patterns and the definition of total bolus clearance time (TBCT) for minor and major flow events.

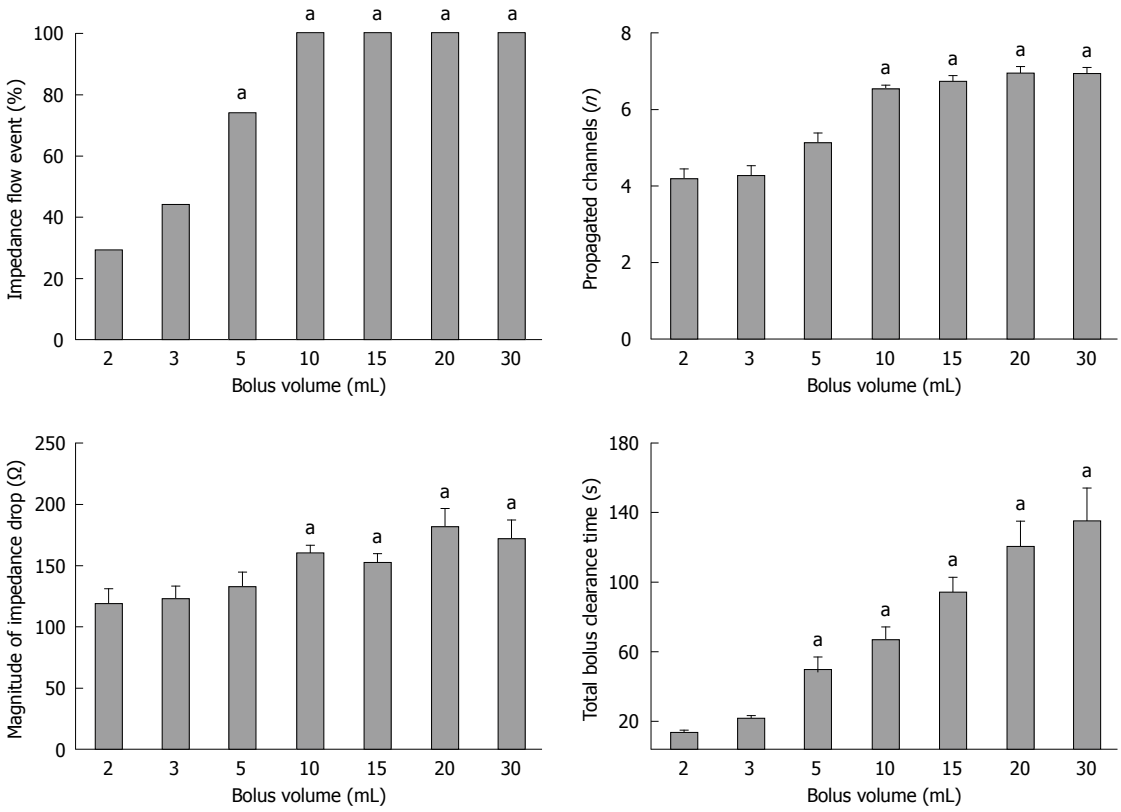

Figure 3 Relationship between bolus volume and characteristics of the associated impedance changes. [a]*P* < 0.05 *vs* 2 mL boluses.

a strong correlation between the bolus volume and the number of channels in which an impedance drop occurred ($r = 0.71$, $P < 0.00001$).

Of the administered test boluses, 48% ± 5% were followed by an intestinal pressure wave that propagated over 6.0 ± 0.1 channels. The duration between the bolus administration and the initiation of the propagated pressure wave was 20 ± 2 s. There was a positive correlation between the bolus volume and proportion of boluses followed by a propagated pressure wave ($r = 0.54$, $P < 0.0001$), which was significantly greater for bolus volumes ⩾ 15 mL (66% ± 12% *vs* 30% ± 11%, $P = 0.04$; *vs* 2 mL, respectively, Figure 4B). The bolus volume was also positively correlated with the duration between the bolus administration and the initiation of the propagated pressure wave ($r = 0.53$, $P < 0.001$).

Relationship between bolus volume and TBCT

The baseline impedance level was recovered after all bolus-induced drops, indicating bolus clearance from the impedance segment. For the majority of boluses ⩽ 5 mL, the impedance drop recovered spontaneously without an intestinal clearance pressure wave, with a TBCT of < 60 s (Figure 3). In contrast, for the majority of boluses ⩾ 10 mL, the recovery of impedance signal was more likely to require the assistance of an intestinal clearance pressure wave. Overall, there was a direct relationship between bolus volume and TBCT ($r = 0.63$, $P < 0.0001$). With increasing bolus volume, the proportion of boluses with a TBCT > 60 s also significantly increased ($P < 0.01$, Figure 4C).

DISCUSSION

This is the first methodological study to examine the relationship between bolus volume and impedance changes in the proximal small intestine. In particular, the study examined the limit of detection, and thus sensitivity, of impedance changes for identifying bolus volume. These data will enable the application of impedance as a technique to assess intestinal flow, without radiology. The main findings were (1) a bolus volume of at least 2 mL is required to generate an impedance event; (2) there is a linear relationship between bolus volume (between 2 and 10 mL) and impedance signal; (3) volumes of 10 mL or greater always generate an impedance event; and (4) bolus volume positively correlates with the magnitude of impedance drop, distance of propagation and clearance time. This modest relationship between bolus volume and intestinal impedance signals may explain, at least in part, the various patterns of flow events associated with chyme transport in the small intestine.

The threshold volume for bolus detection by impedance appears to be higher in the small intestine compared with that previously reported in the oesophagus[18]. However, the relationship between volume of liquid boluses and impedance signal observed in the proximal intestine does not exist in the oesophagus[18]. These differences

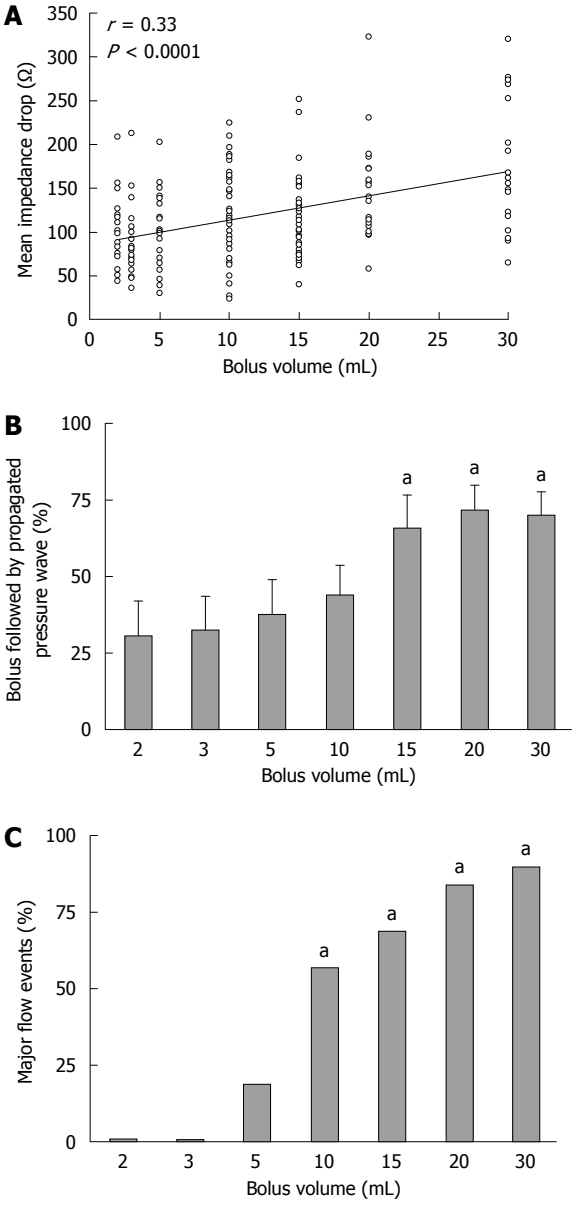

Figure 4 Relationship between bolus volume and the magnitude of impedance drop (A), the proportion of boluses followed by a propagated pressure wave (B) and the occurrence of major flow events (C). $^{a}P < 0.05$ *vs* 2 mL boluses.

may reflect structural and functional differences between the two organs[1-4,17]. The absence of mucosal secretion and possibly a more complete clearance from stronger contraction amplitudes of the oesophagus are likely to explain the higher baseline level of intra-luminal impedance in the oesophagus (approximately 1000 Ω), compared to the intestine (approximately 400 Ω)[16-18]. With a higher baseline signal, liquid boluses of 1 mL or less can induce significant and readily identifiable impedance drops in the oesophagus[18]. In contrast, with a lower baseline impedance signal, possibly caused by a relatively 'wet' lumen from constant intestinal secretions, impedance drops detected in the small intestine are proportionately smaller, and larger volumes are required to induce an identifiable impedance signal. This is supported by the current study, in which a volume threshold of 2 mL was required to induce an intestinal impedance drop. Even with this volume, impedance flow events were only observed in approximately one third of boluses, and were not observed consistently until the volume was at least 10 mL.

The characteristics of impedance changes associated with liquid transit in the small intestine were also influenced by the bolus volume. In the current study, transit of liquid boluses with a volume between 2 and 5 mL was typically associated with a shorter clearance time (less than 60 s) and propagation distance (less than 10 cm). This pattern of flow has been reported to occur during the postprandial period and possibly phase 2 of the MMC[16,17]. In contrast, transit of larger volumes (> 20 mL) were predominantly associated with clearance times greater than 60 s and propagating over 14 cm. The signals of these 'major' impedance events did not spontaneously recover to baseline level until the bolus was cleared by intestinal contraction(s). This pattern of luminal flow is typically seen at the end of phase 3 activity, which may be consistent with the clearance function of the MMC[16,17]. Characteristics of impedance events induced by liquid boluses between 10 and 20 mL varied considerably, particularly in clearance duration. This appears to depend on the timing of intestinal contraction(s) which occur after the bolus is delivered. However, there was also a direct linear relationship between the clearance time and bolus volume. The understanding of the relationship and characteristics between bolus volume and impedance changes will aid the interpretation of various patterns of luminal flow events in the small intestine.

In the current study, impedance changes associated with bolus transit were assessed in the quiescent phase of the MMC cycle, in order to avoid interference from intestinal contraction(s)[17]. Consequently, this relationship is applicable only to bolus transit within a relatively inactive small intestine. However, under normal physiological conditions of digestion, frequent intestinal contractions would be expected and may shorten the clearance time, but not propagation distance.

Furthermore, the current study used saline as a test medium, rather than chyme, which may not reflect the true transit of intestinal contents during normal digestion in humans. Nevertheless, although there are no human data that have evaluated spontaneous flow events in the small intestine, the bolus volumes used in the present study are similar to those reported during the pulsatile flow of gastric emptying in pigs[20]. However, chyme or digested food in the small intestine is typically more viscous than saline, and it is well known that viscosity significantly influences the characteristics of impedance flow events in the oesophagus[21]. Further investigation is required to assess the flow volume of chyme and its relationship with impedance signals. Due to the small diameter of the feeding tube, evaluation of a viscous medium was not possible in the current study.

A potential limitation of this study is the lack of fluoroscopic confirmation of bolus flow. However, fluoroscopy would have exposed the volunteers to excessive

radiation exposure due to the prolonged recording period. More importantly, the criteria used in this study to define an impedance "flow event" in the small intestine has already been established and validated against fluoroscopy[17]. Flow could thus be reasonably inferred from the pattern of impedance changes with evidence of propagated clearance from successive impedance segments.

In conclusion, there is a strong relationship between bolus volume and changes in impedance signals within the small intestine. Bolus volume has an impact on both the type and length of propagation of flow events and a threshold volume of 2 mL is required to produce a flow event.

COMMENTS

Background

Fluoroscopy and scintigraphy are the currently available techniques to assess intestinal motility and bolus transit, but their utilities are greatly limited by radiation exposure. Although combined intraluminal manometry and impedance has been recently used to assess flow in the small intestine, the relationship between bolus volume and impedance changes has not been assessed.

Research frontiers

The ability to use a combined intraluminal manometry-impedance technique to assess bolus transit in the small intestine will not only improve the safety of the procedure, but also its utilization in clinical practice.

Innovations and breakthroughs

This is the first methodological study to demonstrate a linear relationship between bolus volume and impedance changes in the proximal small intestine. Bolus volumes of at least 2 mL are required to generate an impedance signal that can be recognised as a flow event. Volumes of 10 mL or greater will always generate an impedance drop. These findings may explain the various patterns of flow that are associated with chyme transport in the small intestine.

Applications

These findings assist the interpretation of various patterns of bolus transit or flow of chyme in the small intestine assessed by a manometry-impedance technique, without the need for fluoroscopy or scintigraphy.

Terminology

Intra-luminal impedance is a new technique designed to detect intraluminal flow without the use of radiation. The impedance technique measures changes in resistance (in Ohms) to alternating electrical current when a bolus passes a pair of metallic rings mounted on a catheter. In an empty tubular organ (i.e. small intestine), the electrical current is conducted by the few ions present in and on the intestinal mucosa. Liquid boluses with an increased number of ions have a higher conductivity and when entering the measurement segment will lower the impedance to a nadir value. Measurement of flow at multiple sites allows for determination of bolus direction based upon temporal differences in bolus entry and exit.

Peer review

This is a high quality manuscript, presenting a series of experimental results which demonstrates, for the first time, the relationship between bolus volume and impedance changes in the proximal small intestine.

Abstract

AIM: To investigate treatment outcome of *Helicobacter pylori* (*H. pylori*)-negative low-grade gastric mucosa-associated lymphoid tissue (MALT) lymphoma.

METHODS: In this study, we retrospectively reviewed the clinical outcome and clinicopathologic factors of stage I E *H. pylori*-negative low-grade gastric MALT lymphoma cases from August 1998 to June 2009.

RESULTS: A total of eleven patients with *H. pylori*-negative low-grade gastric MALT lymphoma were enrolled in the study and received anti-*H. pylori* eradication treatment and/or radiotherapy or excisional therapy. Complete remission (CR) of gastric MALT lymphoma was achieved in all patients. The time to CR was 1-66 mo (median, 1 mo).

CONCLUSION: Eradication therapy may be offered as an initial treatment option even in cases of localized *H. pylori*-negative gastric MALT lymphoma.

Treatment outcome of localized *Helicobacter pylori*-negative low-grade gastric MALT lymphoma. *World J Gastroenterol* 2010; 16(17): 2158-2162 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i17/2158.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i17.2158

INTRODUCTION

Mucosa-associated lymphoid tissue (MALT) lymphoma, first described in 1983 by Isaacson and Wright[1], has been recently re-classified as extranodal marginal zone lymphoma of MALT-type, in the Revised European-American Classification of Lymphoid Neoplasms (REAL)/World Health Organization (WHO) Classification of Lymphoid Neoplasms. An important feature of MALT lymphoma is the presence of lymphoepithelial lesions formed by the invasion of individual glands by aggregates of lymphoma cells[2].

In previous studies, *Helicobacter pylori* (*H. pylori*) infection was suggested to be causally associated with primary gastric MALT lymphoma[3,4]. Indeed, *H. pylori* provides the antigenic stimulus, which is mediated by mucosal T cells, for sustaining the growth of gastric MALT lymphoma[5]. The regression of gastric MALT lymphoma after the eradication of *H. pylori* was first reported in 1993 by Wotherspoon *et al*[3]. *H. pylori* eradication led to complete remission in 80% of stage I E, low-grade gastric MALT lymphoma patients, with a yearly recurrence rate of approximately 5%[6]. Curr-

ently, eradication of *H. pylori* is considered the accepted initial therapy in cases of localized, stage I E low-grade gastric MALT lymphoma[7].

However, there are no treatment guidelines for the management of patients who are unresponsive to antibiotic treatment or for the subset of patients who present with stage I E low-grade gastric MALT lymphoma but are *H. pylori*-negative and understandably do not respond to antibiotic treatment[8]. In these cases, treatment choices include the known, conventional therapeutic approaches such as surgery, chemotherapy or radiotherapy[9]. Because of the ambiguity of treatment in *H. pylori*-negative patients, further studies are required to clarify a treatment strategy for *H. pylori*-negative MALT lymphoma. In this study, we evaluated the treatment outcome of eleven *H. pylori*-negative low-grade gastric MALT lymphoma patients to offer therapeutic guidelines for treating *H. pylori*-negative low-grade gastric MALT lymphoma.

MATERIALS AND METHODS

Patients

We retrospectively studied eleven patients with *H. pylori*-negative low-grade gastric MALT lymphoma diagnosed at the Severance Hospital from August 1998 to June 2009. All patients were confirmed by pathology to have low-grade gastric MALT lymphoma without a diffuse large B-cell lymphoma (DLBCL) component. Histological diagnosis of MALT lymphoma was performed according to the criteria outlined in the WHO classification, and histological assessment was performed by a reference pathologist (Yang WI). Immunological phenotyping of paraffin sections was performed to demonstrate light chain restriction and the $CD20^{+}CD5^{-}CD10^{-}cyclinD1^{-}$ phenotype which was microscopically consistent with the presence of low-grade MALT lymphoma. The study was approved by our institutional review board, and informed consent was not required.

Examination of H. pylori infection and endoscopic findings

None of the patients had evidence of *H. pylori* infection as judged by histology, a urea breath test, a rapid urease test (CLO™, Delta West, Bentley, Western Austria) and serological testing. The gross phenotype for each patient was classified into five types according to endoscopic features: (1) ulcerative: one or more ulcerations; (2) protruding: elevated or polypoid; (3) granular: small nodules on the lesion; (4) infiltrative: mucosal infiltration; and (5) mixed.

Staging work-up

Determination of the stage of disease included a detailed physical examination, chest X-ray, abdominal computed tomography (CT), endoscopic ultrasonography (EUS), bilateral bone marrow examination, and ^{18}F-FDG PET scan.

Therapeutic approach

Treatment modalities included anti-*H. pylori* eradication therapy, radiotherapy, and excisional therapy (one endoscopic mucosal resection and one subtotal gastrectomy). The most common treatment was radiotherapy (six patients), followed by anti-*H. pylori* eradication only (three patients). Prior to radiotherapy, three of the six radiotherapy patients received anti-*H. pylori* eradication therapy which consisted of amoxicillin (2 × 1000 mg/d), clarithromycin (2 × 500 mg/d), and esomeprazole (2 × 40 mg/d) or pantoprazole (2 × 20 mg/d) for 7 or 14 d. Radiotherapy was performed at a total dose ranging from 30 Gy to 36 Gy on an outpatient basis. Two patients underwent local excision therapy, including one subtotal gastrectomy and one endoscopic mucosal resection (EMR).

Response assessment

The median time for follow-up after remission was 25 mo (range: 5-76 mo). Complete remission (CR) was defined as the total disappearance of clinical evidence for lymphoma and an absence of histologic evidence for lymphoma on biopsy specimens. Partial remission (PR) was defined as a tumor reduction of at least 50%, and stable disease (SD) was defined as variation within either a 50% decrease or 25% increase in tumor size. In cases with complete remission, endoscopic examinations and biopsies were performed at regular intervals.

RESULTS

Baseline characteristics

The male to female patient ratio in this study was 1:1.2. The mean age of the patients was 55.7 (36-73) years. Four patients were symptomatic at presentation indicating abdominal pain (two cases), abdominal discomfort (one case), and GI bleeding (one case). Lymphoma was most often localized in the body and the antrum in 36% of the patients. Endoscopic lesions were characterized as ulcerative (five cases), infiltrative (one case), protruding (two cases), granular (one case) and mixed (two cases). Initial endoscopic findings are summarized in Table 1. Initial clinical staging with EUS and/or CT scans and BM examinations revealed all the cases to be stage I E.

Treatment outcome

Complete remission (CR) of gastric MALT lymphoma was achieved in all patients (Table 2). The time to CR ranged from one to 66 mo (median, 1 mo). Anti-*H. pylori* eradication therapy was performed in six of the eleven patients. Three of six patients, who completed the follow-up endoscopic examination 1 or 2 mo later, had complete remission of gastric MALT lymphoma. However, two patients refused to wait for the treatment response evaluation and subsequently underwent radiotherapy for definitive treatment. The remaining patient had stable disease for 2 mo before being referred for radiotherapy. All three of these patients showed complete remission of gastric MALT lymphoma 1 mo after the cessation of radiotherapy based on histological evidence. None of the 11 patients showed

local or distant recurrence after a median follow-up time of 25 mo (range: 5-76 mo).

DISCUSSION

The prevalence of *H. pylori* in patients with low-grade gastric MALT lymphoma is variable[10]. It is possible that a reduced number of *H. pylori* organisms present in the infection may account for the negative *H. pylori* diagnostic test result in some cases, and false-negative results may also be obtained when only one diagnostic method is employed[11]. The European Guidelines generally take the gold standard to be represented by at least two tests[12]. When appropriate diagnostic methods are used, the prevalence of *H. pylori* infection in low-grade MALT lymphoma is high, at nearly 90%[10]. In our study, four diagnostic tests were performed and showed that true *H. pylori*-negative patients were included. However, additional tests, such as culture with polymerase chain reaction, would allow the detection and identification of other infective organism[13].

Due to the excellent clinical outcome of *H. pylori* eradication treatment, the eradication of *H. pylori* with antibiotics should be employed as the sole initial treatment in the localized form (confined to the stomach) of gastric MALT lymphoma[14]. However, in advanced stages with *H. pylori*-positive gastric MALT lymphoma and in *H. pylori*-negative lymphoma, definitive treatment guidelines are not yet available despite the numerous published clinical research papers[8,14,15].

Antibiotic treatment for *H. pylori*-negative gastric MALT lymphoma has been described in a limited number of patients. We collectively reviewed a series of four published studies including patients treated solely with the anti-*H. pylori* antibiotic regimen as the initial treatment for *H. pylori*-negative stage I E gastric MALT lymphoma (Table 3). A total of 31 patients were included in these studies, and ten patients (32%) were shown to respond to this treatment alone. Raderer *et al*[16] reported that five of six patients with *H. pylori*-negative gastric MALT lymphoma responded to antibiotic treatment (one partial remission and four complete remissions). However, Steinbach *et al*[17] and Ye *et al*[18] experienced a 0% response rate. In other words, marked variation in treatment response rate was noted. Nevertheless, instituting anti-*H. pylori* treatment showed satisfactory clinical outcomes and allowed for gastric preservation in a significant number of cases with *H. pylori*-negative gastric MALT lymphoma. Although seemingly contradictory, anti-*H. pylori* treatment may be advised as the first-line therapy in *H. pylori*-negative localized gastric MALT lymphoma. Unfortunately, the effectiveness of anti-*H. pylori* treatment could not be confirmed in this study, as only four out of the six patients who received the anti-*H. pylori* eradication regimen waited long enough to receive the follow-up endoscopic examination which was used to confirm the complete remission status of MALT lymphoma. The other two patients proceeded to radiation therapy due to various clinical and psychosocial issues. In addition, previous studies also included patients with advanced stages of disease, including ⅡE$_1$ (Table 3). However, it was not possible from the available data to categorize lymphoma regression according to tumor stage (I E *vs* ⅡE$_1$). Therefore, additional studies are needed to define the role of anti-*H. pylori* eradication therapy in advanced stages of gastric MALT lymphoma such as stages ⅡE, ⅢE or Ⅳ.

There is still no explanation for the effectiveness of anti-*H. pylori* treatment in *H. pylori*-negative gastric MALT lymphoma[16]. However, it has been speculated that another infective organism, *Helicobacter heilmannii*[19], might be involved in the development of gastric MALT lymphoma. Also, one cannot rule out the possibility that unknown bacterial agents capable of surviving in the stomach might play a role in the development of rare *H. pylori*-negative

[1]Failure of anti-*H. pylori* treatment as the initial therapy.

gastric MALT lymphomas[16]. Another possibility is that low bacterial counts[20] and urease-negative *H. pylori* mutant strains may escape detection by the diagnostic tests that are currently available. If this assumption is correct, one might expect the noted *H. pylori*-negative gastric MALT lymphoma patient response to broad-spectrum antibiotic therapy. Also, MALT lymphoma is to some extent an immunologically driven disease, therefore an additional hypothesis may involve the potential immunomodulatory effects of the antibiotic agents used[16].

Disease control using radiotherapy alone has been previously reported in the literature, which supports the use of a modest dose of involved-field radiotherapy for patients with stages I E-II E MALT lymphoma of the stomach without evidence of *H. pylori* infection[14]. Table 4 summarizes these previously reported cases. Including our cases, 35 of 35 cases responded to radiotherapy. One of the 35 patients reported by Akamatsu *et al*[21] had a partial remission, while the others all had a complete remission. Based on these results, it is prudent to say that radiotherapy is suitable in early stage (I E or II E) *H. pylori*-negative gastric MALT lymphoma. In addition, excisional treatments such as endoscopic mucosal resection or laparoscopic gastric resection may represent another therapeutic option in the case of localized forms of gastric MALT lymphoma in individuals who are not suitable for, or who refuse, standard therapeutic approaches[15,20,22]. In the past, surgical treatment has often been advocated to establish accurate diagnosis, staging, and management of early-stage gastric lymphoma, which has about a 90% 5-year survival rate, but leads to significant morbidity[22]. In our study, two patients received endoscopic mucosal resection and subtotal gastrectomy, respectively. There has been no local or distant recurrence during the follow-up period of 54 to 69 mo.

In our series, therapeutic measures such as anti-*H. pylori* eradication, radiotherapy and excisional therapy achieved complete remission in all cases. Nevertheless, antibiotic treatment is simple, inexpensive, less harmful and *H. pylori* negative low grade MALT lymphoma shows a favorable long-term outcome[22]. Therefore we suggest that *H. pylori* eradication therapy may be an initial treatment option for localized *H. pylori*-negative gastric MALT lymphoma. In addition, further studies on eradication therapy are required to help in the establishment of strategies for patients with localized *H. pylori*-negative gastric MALT lymphoma.

COMMENTS

Background

Eradication of *Helicobacter pylori* (*H. pylori*) is a well-accepted initial therapy in cases of localized (stage I E) low-grade gastric mucosa-associated lymphoid tissue (MALT) lymphoma associated with *H. pylori* infection. However, there are no treatment guidelines for the management of *H. pylori*-negative low-grade gastric MALT lymphoma.

Research frontiers

Previous studies revealed the effectiveness of radiotherapy for localized *H. pylori*-negative low grade gastric MALT lymphoma. However, *H. pylori* eradication therapy is still a controversial treatment modality, although this treatment is simple and less harmful than other treatments.

Innovations and breakthroughs

With the exception of this study, only 31 *H. pylori*-negative patients have received eradication therapy (response rate 32%). However, treatment response was variable. The authors' study enrolled a small number of patients, but they all had complete remission.

Applications

The findings from this study suggest that *H. pylori* eradication therapy may be an initial treatment option for localized *H. pylori*-negative gastric MALT lymphoma. Their study adds information which helps in the establishment of strategies for patients with localized *H. pylori*-negative gastric MALT lymphoma.

Peer review

This is an interesting paper that may be beneficial for patients with *H.pylori*-negative gastric MALT lymphoma.

Abstract

AIM: To explore if vascular endothelial growth factor receptor-3 (VEGFR-3) and carcinoembryonic antigen (CEA) can predict overall survival in advanced gastric cancer.

METHODS: VEGFR-3 level was assessed by enzyme-linked immunosorbent assay, and CEA was assessed by chemiluminescence immunoassay in the sera of 81 advanced gastric cancer patients before treatment with oxaliplatin plus 5-fluorouracil and folinic acid.

RESULTS: Median survival time in patients with a low serum VEGFR-3 level was significantly longer than in those with a higher VEGFR-3 level (15.4 mo *vs* 7.7 mo, $P < 0.001$). Patients with a low CEA level had a longer survival than those with a higher CEA level (15.8 mo *vs* 8.6 mo, $P < 0.001$). Thirty-nine patients with low VEGFR-3 and low CEA levels had a median survival of 19.7 mo ($P = 0.0006$). The hazard ratio for patients with a high VEGFR-3 level was 2.443 ($P = 0.002$).

CONCLUSION: High serum VEGFR-3 level is correlated significantly with poor survival. In patients with a high serum level of VEGFR-3, alternative chemotherapy regimens should be considered.

INTRODUCTION

According to global estimates, gastric cancer is the second most frequent cancer-related cause of death. The incidence of gastric cancer is estimated to be 934 000 cases, with 56% of the new cases occurring in East Asia, 41% in China and 11% in Japan[1]. In 2005, there were approximately 400 000 new cases and 300 000 deaths from gastric cancer in China[2].

Great efforts are being made to develop serological markers that are noninvasive and can easily reflect the dynamic status of the tumor. Among these, carcinoembryonic antigen (CEA) has been used widely as a serological marker in patients with gastrointestinal malignancies[3-5]. CEA was first described by Gold and Freedman in 1965 as an antigen that is expressed by gastrointestinal carcinoma cells, which is secreted in blood or body fluids. Several studies have focused on the utility of CEA and carbohydrate antigen 19-9 (CA19-9) measurement in cancer progression, recurrence, and prognosis in patients with gastric carcinoma[4,6,7].

There has been a dramatic increase in the number of studies of the mechanisms of associated lymphangio-

genesis and lymphatic metastasis. It has been recognized that lymphangiogenic growth factors promote the spread of cancer cells to regional lymph nodes[8-10], and one of the most important ones is vascular endothelial growth factor receptors (VEGFR).

Regional lymph node metastasis is an important indicator of tumor aggressiveness, as well as a known prognostic factor[11]. Therefore, it is important to estimate the degree of lymphatic system invasion and lymphangiogenesis in the evaluation of biological tumor aggressiveness and patient outcome. VEGFRs1, 2 and 3 are endothelial-specific receptor tyrosine kinases that are regulated by members of the VEGF family. VEGFR-3 expression has been demonstrated in a variety of human malignancies[12]. The role of the VEGF-C, D and/or VEGFR-3 axis in various types of cancer has been investigated by many research groups[12]. In clinical studies, a negative correlation between VEGF-C, D and/or VEGFR-3 and patient survival time has been reported in non-small cell lung cancer, colorectal carcinoma, endometrial carcinoma, epithelial ovarian carcinoma and primary breast cancer[13-17].

Advanced gastric cancer patients need chemotherapy, but there is currently no established standard regimen; oxaliplatin plus 5-fluorouracil and folinic acid (FOLFOX) is well tolerated. Recently, several phase Ⅱ studies have yielded a median time to progression (TTP) of 5.4-6.5 mo and a median overall survival (OS) of 9.8-12.6 mo[18-21].

A reliable factor is necessary to predict objectively the effectiveness of some special chemotherapy protocols. Recently, two studies have investigated if gene polymorphisms and mRNA can predict the TTP and OS in advanced gastric cancer treated with FOLFOX[22,23]. For oxaliplatin-associated chemotherapy of advanced gastric cancer, seeking more reliable predictive values for chemotherapy is of great importance in research and clinical settings.

We hypothesized that secreted CEA reflects the tumor burden, and VEGFR-3 is associated with poor survival. The purpose of this study is to find out the prognostic value of serum levels of VEGFR-3 and CEA in gastric cancer patients receiving FOLFOX chemotherapy.

MATERIALS AND METHODS

Patients

Patients with histologically proven locally advanced or metastatic gastric cancer and Eastern Cooperative Oncology Group (ECOG) performance status (PS) $\leqslant 2$ were included in the study. Clinical stage and histological type of gastric cancer were evaluated according to AJCC criteria (the sixth edition). All patients received FOLFOX chemotherapy after resection of primary tumors as follows: oxaliplatin 130 mg/m^2 on day 1, plus folinic acid 200 mg/m^2 as a 2-h infusion, followed by a 22-h infusion of 5-fluorouracil (5-FU) 450 mg/m^2 on days 1-5, every 3 wk. Survival was calculated from the date of diagnosis to the date of last follow-up or death from any cause.

All patients gave their signed informed consent, and the study was approved by the Institutional Ethics Review Boards.

Quantitative detection of VEGFR-3 and CEA

Sera from 40 healthy volunteers (20 females and 20 males ranging in age from 25 to 60 years) and gastric cancer patients were collected using a serum separator tube and kept frozen at -80℃ until assay.

Enzyme-linked immunosorbent assay for serum VEGFR-3 and CEA

Serum was collected before chemotherapy. VEGFR-3 was analyzed with enzyme-linked immunosorbent assay (ELISA) kits (R&D Systems, Minneapolis, MN, USA). An ELISA component kit that measures the extracellular (soluble) domain of VEGFR-3 was employed. Serum VEGFR-3 assays were calibrated against recombinant proteins that consisted of the full-length extracellular domain of the respective receptors. A 96-well microplate was coated with diluted capture antibody, and incubated overnight. After washing, the plate was blocked by adding diluent reagent. Plate preparation was finished. Samples or standards were added, then the plates were washed, detection antibody was added, and washing was repeated. Streptavidin-horseradish peroxidase was added to each well. After washing, substrate solution was added to each well. Finally, stop solution was added to each well. The plate was tapped gently. The optical densities of each well were quantified within 30 min at dual wavelengths of 450 nm corrected to 540 nm using a micro-plate reader.

CEA level of all serum samples was analyzed by chemiluminescence immunoassay (CEA Regent Kit, Abbott Diagnostics). Assays were carried out according to the manufacturer's instructions using the machine of ARCHITECT i2000 SR.

Statistical analysis

Spearman's Rho method was used to correlate levels of VEGFR-3 and CEA. The maximal χ^2 method of Miller *et al*[24] and Halpern[25] was adapted to determine which cutoff value can best dichotomize the patients into low- and high-expression CEA and VEGFR-3 subgroups; the Tree method[26] was then applied to optimize these cutoff values. The final cutoff values were confirmed by recursive partitioning and amalgamation using S-Plus software, version 6.1 (Statistical Sciences, Seattle, WA, USA). Cumulative survival rates were determined using the Kaplan-Meier method, and the difference between each group was evaluated by the log-rank method. The cases lost to follow-up were treated as censored data for the analysis of survival rates. A univariate Cox model with overall survival as the dependent variable was constructed and categorized with two factors levels as independent variables, and the factors that were significant in the univariate analysis were included in a multivariate Cox proportional hazards model for survival. Differences were considered significant at $P < 0.05$. All statistical calculations were performed using the Statistical Package for the Social Sciences, version 13 (SPSS Inc., Chicago, IL, USA).

RESULTS

Patient characteristics

A total of 81 advanced gastric adenocarcinoma patients were included in the study. The median age was 59 years; 55 patients were male and 64 patients had ECOG PS 0-1; and 13 patients had no lymph node involvement. Thirty-eight (46.9%) patients had stage Ⅲ, and 43 (53.1%) had stage Ⅳ disease at the time of diagnosis. Patient characteristics are summarized in Table 1.

Levels of VEGFR-3 and CEA

Serum VEGFR-3 and CEA levels were detected in all the patients and healthy donors. Serum VEGFR-3 level varied in healthy donors, and the median level was 24.5 ng/mL [range: 0.3-40.3 ng/mL, 95% confidence interval (CI): 19.2-31.7]. In gastric cancer, the median VEGFR-3 level was 41.8 ng/mL (range: 17.2-385.5 ng/mL, 95% CI: 52.5-114.6). A highly significant difference was found in the median VEGFR-3 level between gastric cancer patients ($P < 0.01$) and healthy donors.

Serum CEA level was variable in healthy donors, and median level was 2.3 ng/mL (range: 0.1-6.2 ng/mL, 95% CI: 1.7-3.9). In gastric cancer, the median CEA level was 13.7 ng/mL (range: 2.2-301.7 ng/mL, 95% CI: 18.3-57.8). A highly significant difference was found in the median CEA level between gastric cancer patients ($P < 0.01$) and healthy donors.

Using a cutoff value of 70.6, 52 (64.2%) patients had low VEGFR-3 expression levels and 29 (35.8%) patients had higher VEGFR-3 levels. Using a cutoff value of 23.5, 57 (70.4%) patients had low CEA expression levels and 24 (29.6%) had higher levels. There was no significant association between VEGFR-3 and CEA levels ($P = -0.136$, $P = 0.227$). No significant association was detected between VEGFR-3 or CEA and clinical parameters.

Table 2 Serum VEGFR-3 and CEA levels and survival in advanced gastric cancer patients

Factors	*n*	MST (mo) (95% CI)	*P*[1]
VEGFR-3 (ng/mL)			
Low ⩽ 70.6	52	15.400 (11.799-19.001)	< 0.001
High > 70.6	29	7.700 (5.691-9.709)	
CEA (ng/mL)			
Low ⩽ 23.5	57	15.800 (11.223-20.377)	< 0.001
High > 23.5	24	8.600 (7.219-9.981)	

[1]Adjusted *P*-value based on log-rank statistics after 1000 bootstrap simulations. VEGFR-3: Vascular endothelial growth factor receptor-3; CEA: Carcinoembryonic antigen; CI: Confidence interval.

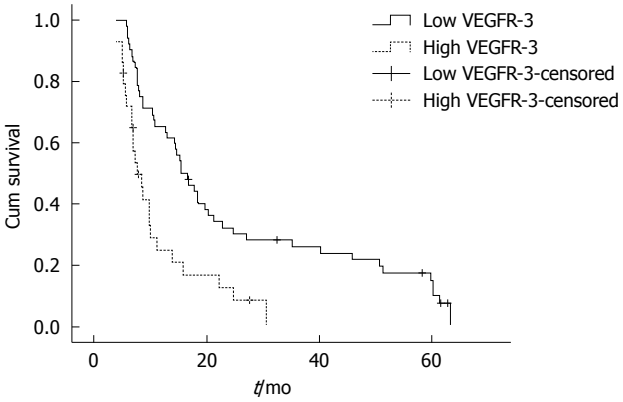

Figure 1 Kaplan-Meier estimates of overall survival by vascular endothelial growth factor receptor-3 (VEGFR-3) levels (*n* = 81, low VEGFR-3: 52; high VEGFR-3: 29).

Survival time

The median survival time for all patients was 13.0 mo (95% CI: 8.820-17.180). A significant association was observed between survival and ECOG PS ($P = 0.034$), lymph node involvement ($P = 0.004$) and initial staging ($P = 0.017$). No other association between clinical characteristics and survival was found (Table 1).

A significant association was also observed between survival and levels of VEGFR-3 ($P < 0.05$) and CEA ($P < 0.05$). Median survival for patients with low VEGFR-3 levels was 15.4 mo (95% CI: 11.799-19.001) compared with 7.7 mo (95% CI: 5.691-9.709) for those with higher VEGFR-3 levels ($P < 0.001$) (Table 2 and Figure 1). Median survival for patients with low CEA levels was 15.8 mo (95% CI: 11.223-20.377) compared with 8.6 mo (95% CI: 7.219-9.981) for those with higher CEA levels ($P < 0.001$, Table 2).

Among the 24 patients with high CEA levels, 13 patients with low VEGFR-3 levels had a median survival of 13.0 mo (95% CI: 5.954-20.046) while 11 patients with higher VEGFR-3 levels had a median survival of 7.2 mo (95% CI: 4.622-9.778) ($P = 0.003$, Figure 2A).

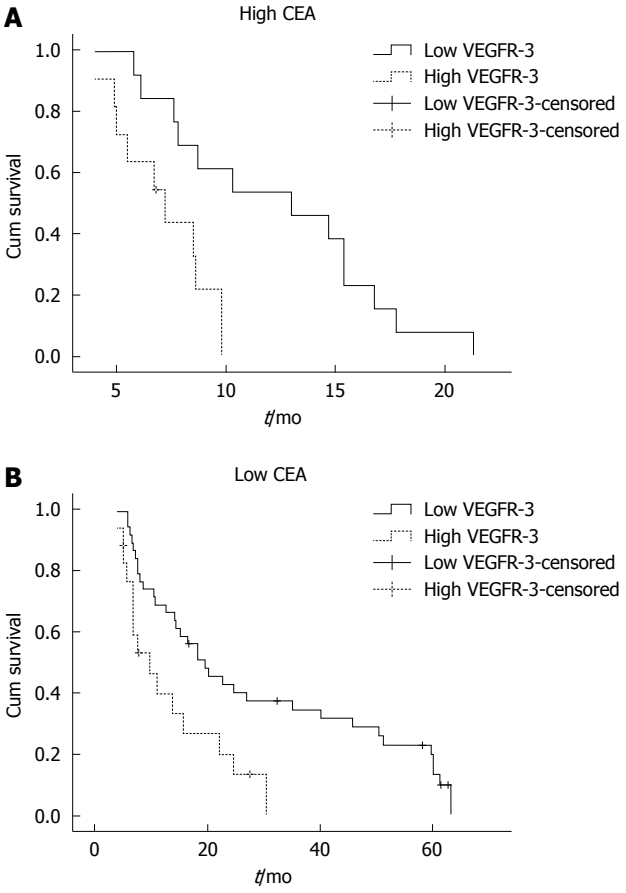

Figure 2 Kaplan-Meier estimates of overall survival according to VEGFR-3 levels in patients. A: Patients with high carcinoembryonic antigen (CEA) levels (n = 24, high CEA and low VEGFR-3: 13, high CEA and high VEGFR-3: 11); B: Patients with low CEA levels (n = 57; low CEA and low VEGFR-3: 39; low CEA and high VEGFR-3: 18).

Among the 57 patients with low CEA levels, 39 patients with low VEGFR-3 levels had a median survival of 19.7 mo (95% CI: 12.53-26.87) while 18 patients with higher VEGFR-3 levels had a median survival of 9.9 mo (95% CI: 4.651-15.149) (P = 0.006, Figure 2B).

Multivariate analysis identified VEGFR-3 levels [hazard ratio (HR) = 2.443, P = 0.002], initial staging (HR = 1.844, P = 0.018), and ECOG PS (HR = 2.396, P = 0.011) as independent markers for survival (Table 3), whereas CEA levels (HR = 1.255, 95% CI: 0.721-2.184, P = 0.121) were not an independent marker for survival.

DISCUSSION

In this study of serum levels of VEGFR-3 and CEA in advanced gastric cancer, multivariate analysis identified VEGFR-3 levels, initial staging, and ECOG PS as independent markers for the survival of the patients who received the FOLFOX regimen. CEA was not an independent marker for survival.

VEGF-C and VEGFR-3 are associated with lymphatic metastasis, mainly *via* tumor lymphangiogenesis in animal models and human tumors[9,27]. Many previous studies have investigated the association between expression of VEGFR-3 and tumor histology. VEGFR-3 is an independent prognostic factor for survival; the expression of VEGFR-3 is correlated with lymphatic invasion, lymph node metastasis, and poor prognosis for survival[28-30]. In the present study, the median survival time in patients with low serum VEGFR-3 levels was significantly longer than in those with higher VEGFR-3 levels (15.4 mo *vs* 7.7 mo, $P < 0.001$). Patients with low VEGFR-3 and CEA levels had a median survival of 19.7 mo (P = 0.0006). The HR for patients with a high VEGFR-3 level was 2.443 (P = 0.002).

PS: Performance status.

Although great efforts have been devoted to improve early detection of gastric cancer, the majority of patients are diagnosed at an advanced stage. The median OS has been shown to be 9.8-12.6 mo after FOLFOX chemotherapy[18-21]. Identification of patients with potentially poor prognosis after FOLFOX chemotherapy would help us to optimize another treatment protocol for patients with advanced gastric cancer.

These findings are similar to those with metastatic malignant melanoma, for which, a high pretreatment serum VEGFR-3 level is correlated significantly with poor prognosis. Patients with a low serum VEGFR-3 level had a higher median disease-free survival than those with a high serum VEGFR-3 level (16.2 mo *vs* 10.8 mo, χ^2 = 3.85, P = 0.022). Median serum VEGFR-3 levels were significantly higher in patients with a high tumor burden than those with a low tumor burden (P = 0.013)[31].

There are few reports on biomarkers with a high and reliable predictive value for chemotherapy. Recently, two studies have investigated predictive factors for FOLFOX chemotherapy in advanced gastric cancer. In one study of genetic polymorphism, the glutathione S-transferase M1 positive genotype showed a significantly longer survival time compared with negative genotype in advanced gastric cancer treated with FOLFOX[22]. In a study of mRNA, the median survival time in patients with low levels of mammalian excision repair *via* complementing protein ERCC1 was significantly longer than in those with higher levels (15.8 mo *vs* 6.2 mo, $P < 0.0001$) in advanced gastric cancer treated with FOLFOX chemotherapy[23].

However, in the present study, the difference in the survival of the patients with a low level and a high level of VEGFR-3 was much more striking (15.4 mo *vs* 7.7 mo, $P < 0.001$), with an HR of 2.443. The determination of relative serum VEGFR levels by ELISA and electrochemiluminescence is considered currently to be easier than by immunohistochemistry and quantitative PCR.

It has been shown that VEGFR-3 is expressed not only in lymphatic endothelial cells, but also in tumor cells, and it has been seen in the cytoplasm, along the nuclear and cell membranes, which underlines its potential role in tumor growth[15,32,33]. Despite vast amounts of literature on VEGFR-3 expression in tissues (quantitative PCR and immunohistology)[32,34-37], there are few data about serum levels of VEGFR-3, which is the major axis specific for lymphangiogenesis.

To address the biological and clinical significance of pre-chemotherapeutic serum VEGFR-3 levels in advanced gastric cancer, we compared serum VEGFR-3 levels with clinicopathological parameters. A significant association was observed between survival and ECOG PS, lymph node involvement and initial staging. We found a significant association between the pre-chemotherapeutic serum level of VEGFR-3 and lymph node status. In contrast, there was no correlation between survival and age, sex, tumor grading, or tumor site.

In a recent study of anti-angiogenic treatment, DePrimo *et al*[38] found that the decrease in the soluble variant of VEGFR-3 could be a marker of sunitinib activity in patients with metastatic renal cell carcinoma. Similar to our results, Rini *et al*[39] have shown that a high baseline VEGFR-3 level is related to non-response to treatment and shorter progression-free survival in renal cell cancer that is refractory to bevacizumab, when the patients are treated with sunitinib. The presence of high levels of circulating VEGFR-3 in advanced gastric cancer patients might prospectively identify high-risk patients undergoing FOLFOX chemotherapy with a worse prognosis and shorter survival, and special target medicine is needed for therapy.

It is also not known in which way VEGFR-3 contributes to tumor angiogenesis, lymphangiogenesis, tumor progression and metastasis[40,41]. However, our results were from serum, and further investigations are necessary to confirm our observations.

A high CEA level has been shown to be a negative factor for survival in breast, gastric and colorectal cancer[42-47]. In patients with metastatic colorectal cancer receiving cetuximab plus FOLFIRI or FOLFOX-4 chemotherapy, serum CEA could predict progression-free survival time. Survival time in responders assessed by changes in serum CEA was significantly longer than that in non-responders ($P = 0.0091$)[48].

In another study, a preoperative CEA level was an independent prognostic factor in patients with node-positive Dukes' C colorectal cancer treated with 5-FU-based adjuvant chemotherapy[49]. However, the role of CEA in predicting chemosensitivity remains controversial. In a prospective study, by multivariate analysis, serum CA19-9 level ($P < 0.001$) was found to be an independent prognostic factor, whereas pretreatment serum CEA level was not considered to be a significant prognostic indicator in patients with metastatic colorectal cancer treated with 5-FU-based chemotherapy[50].

In the present study, patients with lower CEA levels had a longer survival than those with higher CEA levels, especially in patients with higher VEGFR-3 levels. VEGFR-3 over-expression increases proliferation of MCF7 cells, but proliferation of BT474 cells is reduced drastically when endogenous VEGFR-3 is down-regulated[51]. Producing a plausible explanation of why a meaningful number of patients with low VEGFR-3 and CEA levels had the longest survival is one of the aims of the present study.

Irinotecan and taxane-based regimens have been used in the treatment of advanced gastric cancer patients, with a similar survival to those attained with FOLFOX[52-54]. Irinotecan or taxane-based regimens could be the better alternative for patients with high VEGFR-3 levels. A randomized customized trial is warranted in this setting.

Targeting the VEGF-C/VEGFR-3 axis may be therapeutically significant for certain types of tumors. Thus, the continued discovery and characterization of factors that regulate VEGF-C or VEGFR-3 are essential for developing new therapies that limit the spread of cancer. In a recent study of gastric tumors, the target drug Ki23057 inhibited the phosphorylation of VEGFR-3 in lymphatic endothelial cells. The degree of lymphatic invasion and lymphangiogenesis was significantly ($P < 0.05$) lower in the gastric tumors treated by Ki23057[55]. Therefore, the target medicine is required to be developed in the future. In particular, new drugs that block the VEGFC/VEGFR-3 signaling pathway may provide useful anticancer therapeutics by mechanisms other than the blockage of lymphangiogenesis.

In conclusion, the data from our study indicate that serum VEGFR-3 level is the most significant prognostic indicator of patients with advanced gastric cancer. It is recommended that stratification for further clinical trials of patients with advanced gastric cancer should be carried out according to serum VEGFR-3 levels. Combined analysis of the VEGF-C/VEGF-D/VEGFR-3 system might be useful for identifying patients with an unfavorable clinical outcome, thereby helping refine therapeutic decisions in gastric cancer.

In our study, we only detected the levels of VEGFR-3 and CEA before chemotherapy. Changes in these levels after chemotherapy, especially with regard to differences between the responding and non-responding groups, need further researches.

COMMENTS

Background

Carcinoembryonic antigen (CEA) has been used widely as a serological marker in patients with gastrointestinal malignancies. Several reports have focused on the utility of CEA measurements in cancer progression, recurrence, and prognosis in patients with gastric carcinoma. Vascular endothelial growth factor

receptor-3 (VEGFR-3) expression has been demonstrated in a variety of human malignancies. CEA reflects the tumor burden, and VEGFR-3 is associated with tumor progression. For oxaliplatin-associated chemotherapy of advanced gastric cancer, seeking a more reliable predictive marker for chemotherapy has been of great interest in research and clinical settings.

Research frontiers

In this study, serum VEGFR-3 and CEA levels were assessed in advanced gastric cancer. The authors observed that VEGFR-3 and CEA could help predict survival in advanced gastric cancer patients treated with oxaliplatin plus 5-fluorouracil and folinic acid (FOLFOX).

Innovations and breakthroughs

High serum VEGFR-3 levels are correlated significantly with poorer survival. In patients with a higher serum VEGFR-3 level, alternative chemotherapy regimens should be considered.

Applications

The results of this study will help predict survival in advanced gastric cancer patients treated with FOLFOX chemotherapy.

Peer review

In this paper, the authors analyzed the clinicopathological parameters, serum CEA, serum VEGFR-3 levels and survival of advanced gastric cancer patients treated with FOLFOX. Based on the results of the study, the authors concluded that a high serum VEGFR-3 level is significantly correlated to poorer survival of the patients.

Abstract

AIM: To investigate the association between peroxisome proliferator-activated receptor-γ (*PPAR-γ*) gene polymorphism 34 C>G and colorectal cancer (CRC), a meta-analysis review was performed in this report.

METHODS: A systematic literature search and selection of eligible relevant studies were carried out. Nine independent studies with a total number of 4533 cases and 6483 controls were included in the meta-analysis on the association between polymorphism 34 C>G and CRC.

RESULTS: There was no evidence for the association between PPAR-γ 34 C>G and CRC if all of the subjects in the nine studies were included. However, CG + GG showed a marginally significant difference from CC (OR = 0.84, 95% CI: 0.69-1.01, *P* = 0.07) in random-effect model. Stratified meta-analysis indicated that PPAR-γ 34 C>G was associated with colon cancer (OR = 0.8, 95% CI: 0.65-0.99, *P* = 0.04) in random-effect model, and the G allele decreased colon cancer risk. No significant association was observed between PPAR-γ 34 C>G and rectal cancer.

CONCLUSION: PPAR-γ 34 C>G is associated with colon cancer risk, but not associated with CRC and rectal cancer risk.

INTRODUCTION

Colorectal cancer (CRC) is one of the major causes of cancer death in developed countries, with over 9500 new cases in Netherlands in 2002 alone, for instance[1]. In 2003, it was estimated that about 147 500 new cancer cases and 57 100 deaths were caused by CRC in the USA[2]. With more than 71 000 new occurrences per year, the incidence and mortality rate of CRC in Germany is almost the highest all over the world[3]. Epidemiological and experimental evidences attributed CRC to both genetic and experimental factors were involved. Accumulating evidences suggested that the peroxisome

proliferator-activated receptor-γ (*PPAR-γ*) gene is related to CRC, which has been implicated in the pathogenesis of CRC in animal models and clinical studies. PPAR-γ is a member of the nuclear hormone receptor super-family, and plays a pivotal role in regulating adipocyte differentiation, glucose and lipid metabolism, insulin sensitivity, atherogenesis and immune[4]. A proline to alanine substitution has been detected in the *PPAR-γ* gene which is a common structural polymorphism (34 C>G, rs1801282) located at codon 12 (Pro12Ala) of PPAR-γ2-specific exon B. Although many studies were performed to investigate the relationship between the polymorphism 34 C>G of *PPAR-γ* gene and CRC, results were contradictory. Our study aims to confirm the former data of the association between *PPAR-γ* gene 34 C>G and CRC.

MATERIALS AND METHODS

Identification and eligibility of relevant studies

A systematic literature search in PubMed and Google was carried out in January 2010 using '*PPAR* gene', 'association' and 'CRC' with restriction to 'human' or 'homo sapiens'. Additional articles were identified through references cited in retrieved articles. Publications containing the same or overlapping data from the same authors were excluded. Studies were considered as eligible for the meta-analysis if the frequency of relevant genotypes was reported in both CRC cases and CRC-free controls, or in both colon cancer cases and CRC-free controls, as well as in both rectal cancer cases and CRC-free controls. Moreover, all of them were case-control studies or cohort studies. Nine articles reported on the analysis of the association between PPAR-γ Pro12Ala and CRC[1,2,4-10], four of which focused on the association between the polymorphism PPAR-γ Pro12Ala and colon cancer risk or rectal cancer risk[4-7].

Data extraction and statistical analysis

For each study, information was gathered about the first author, year of publication, country where the study was conducted and the distribution of each PPAR-γ 34 C>G genotype in cases and controls (Table 1). Some calculated data collected from the original data of the articles were applied in the subsequent meta-analysis.

Percentage of GG genotype in controls of each study was calculated, followed by Hardy-Weinberg Equilibrium (HWE) test in controls to determine the reliability of data, using a Chi-squared Goodness-of-fit Test by SPSS 13.0. Analysis was also conducted on inter-ethnicity difference in minor allele frequency. One-way ANOVA was used to compare more than two independent groups, while two-tailed *t* test was used to compare two independent groups by SPSS 13.0 software.

To investigate the effect of each allele, the ORs of G allele were calculated, referenced by C. Subsequently, pairwised combinations of genotypes were used to determine the hereditary models, including GG *vs* CC, CG *vs* CC, and GG *vs* CG, CG *vs* CC + GG, GG *vs* CC + CG and CG *vs* GG + GC, and the later genotype was used as a reference in each pair.

We also conducted meta-analyses for a combination of CG and GG genotypes *vs* CC genotype in each subgroups (European and USA population). In addition, stratified analyses were performed based on the case collection, including meta-analyses on the association between PPAR-γ 34 C>G and colon cancer risk and rectal cancer risk.

Heterogeneity among studies was tested to estimate which effect model, the fixed-effect one or the random-effect one, should be used. With a $P > 0.05$, the included studies were considered homogeneous and the fixed-effect model should be selected, otherwise, random-effect model should be used.

All of the meta-analyses above were conducted using Review Manager 4.2 software. The two-sided $P < 0.05$ was considered statistically significant.

RESULTS

Nine studies published from 2003-2007 were about the analysis on the relationship between PPAR-γ 34 C>G polymorphism and CRC risk, with a total number of 4533 cases and 6483 controls (Table 1). Seven studies (3870 cases/5028 controls) were conducted in Western countries, including 4 in Europe[1,5,9,10] and 3 in the USA[2,6,8]. Another two studies were performed in Asian countries[4,7]. There were four studies concerning colon cancer or rectal cancer with a total number of 2073 cases/3735 controls and 1321 cases/2765 controls, respectively[4-7].

The genotype distribution in the control groups in each study did not depart from the HWE with $P > 0.05$, except for two studies, in which HWE test could not be performed because of the incomplete data (Table 1).

The G allele frequency of PPAR-γ 34 C>G was 0.13 in the control group (626 cases/4694 controls) and 0.12 in the case group (424 cases/3600 controls), respectively. No statistical significance was found between case group and control group ($P = 0.381$). The G allele frequency of PPAR-γ 34 C>G in the Western controls (seven studies) was 0.14, the same as in the European controls (four studies). And in USA controls of three studies, G allele frequency of PPAR-γ 34 C>G was 0.13. In conclusion, there is no inter-ethnicity difference in minor allele frequency ($P = 0.968$).

Overall and subgroup-specific summary ORs and 95% CIs for the relationship between PPAR-γ 34 C>G and CRC risk are summarized in Table 2. For G *vs* C allele, GG *vs* CC, CG *vs* CC, GG *vs* CG, CG *vs* CC + GG, GG *vs* CC + CG and CG + GG *vs* CC genotypes of the overall study population, the fixed-effect and the random-effect ORs (95% CIs) were listed, respectively. Test for heterogeneity indicated that studies in the analyses for G *vs* C allele, CG *vs* CC, CG *vs* CC + GG, CG + GG *vs* CC genotypes, respectively were heterogeneous with $P < 0.05$. Hence, random-effect models were selected. And

Europe	4	CG + GG *vs* CC	0.002	0.84 (0.70, 1.00), 0.060	0.79 (0.52, 1.19), 0.260
Colon cancer	4	CG + GG *vs* CC	0.030	0.83 (0.72, 0.96), 0.010	0.80 (0.65, 0.99), 0.040
Rectal cancer	4	CG + GG *vs* CC	0.050	0.98 (0.82, 1.18), 0.860	0.84 (0.58, 1.22), 0.370

[1]*P* value for test for heterogeneity; [2]*P* value for fixed-effect model; [3]*P* value for random-effect mode.

for the rest ones with $P > 0.05$, fixed-effect model was used. As a result, no statistical significance was observed among the above analyses. However, the data of CG + GG *vs* CC genotypes was marginally significant with OR = 0.84 (95% CI: 0.69-1.01, $P = 0.07$).

Limited results in studies from Western countries, the fixed-effect and random-effect ORs (95% CIs) for G *vs* C allele, GG *vs* CC, CG *vs* CC, GG *vs* CG, CG *vs* CC + GG, GG *vs* CC + CG and CG + GG *vs* CC genotypes are listed in Table 2, respectively. Same to the former analyses of the total study population, there was no evidence for the association between PPAR-γ 34 C>G and CRC risk.

Further subgroup-specific analyses were performed in the European and USA studies. In studies from European countries, summary ORs (95% CIs) for CG + GG *vs* CC genotypes in fixed-effect model and random-effect model were 0.84 (0.70, 1.00) and 0.94 (0.80, 1.11), respectively. In studies from the USA, the corresponding ORs (95% CIs) were 0.79 (0.52, 1.19) and 0.95 (0.84, 1.07), respectively. No evidence was found for the association between PPAR-γ 34 C>G and CRC risk in each of the two study populations.

However, when stratified analyses were performed, the results were different. As shown in Table 2, four studies were involved in the meta-analyses for the association of PPAR-γ 34 C>G with colon cancer risk and rectal cancer risk. In the four studies, only the data for CG + GG *vs* CC genotypes was sufficient enough for the analyses. As *P* values of the heterogeneity test in the two meta-analyses were less than 0.05, random-effect model was used. Summary ORs (95% CIs) for CG + GG *vs* CC genotypes in colon cancer studies and rectal cancer studies were 0.80 (0.65, 0.99) and 0.84 (0.58, 1.22),

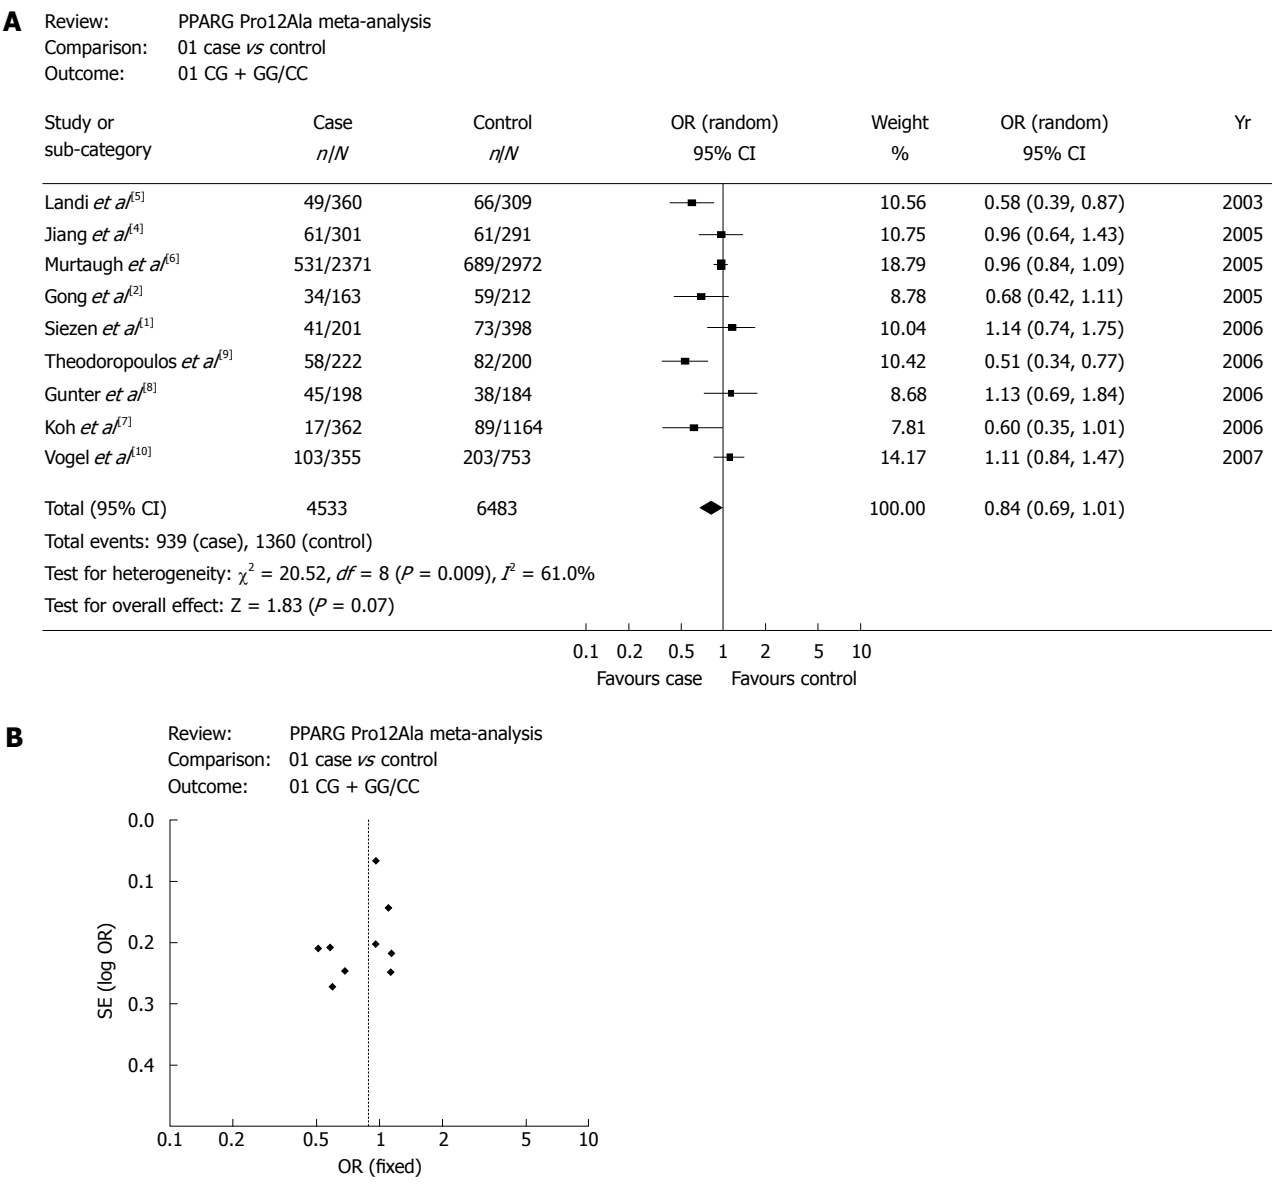

Figure 1 Association between peroxisome proliferator-activated receptor-γ (PPAR-γ) 34 C>G and colorectal cancer risk (CG + GG *vs* CC). A: Forest plot-studies are sorted in order of publication year; B: Funnel plots for the associations.

respectively. Statistical significance was observed in the association meta-analysis between PPAR-γ 34 C>G and colon cancer risk (P = 0.04), indicating that PPAR-γ 34 C>G was associated with colon cancer risk, and G allele decreased the colon cancer risk. However, there was no evidence for the association between PPAR-γ 34 C>G and rectal cancer risk (P = 0.37).

Figure 1A shows the forest plots of meta-analysis for CG + GG *vs* CC genotypes to confirm the association between PPAR-γ 34 C>G and CRC risk in the overall study population. The association between PPAR-γ 34 C>G and CRC risk had a marginally statistical significance. Figure 1B is the funnel plot, suggesting that there was no publication bias in the studies.

Figure 2A displays the forest plots of the study on the association between PPAR-γ 34 C>G and colon cancer risk. Obviously, there was a significant association of PPAR-γ 34 C>G with colon cancer risk. Publication bias was not found in this study as shown in Figure 2B. Other forest plots and funnel plots of meta-analyses on the association between PPAR-γ 34 C>G and CRC risk, colon cancer risk and rectal cancer risk were not shown. However, the results are presented in Table 2.

DISCUSSION

CRC is one of the leading causes of cancer death in the developed countries[11,12]. Both sporadic and hereditary CRC is caused by a set of molecular events[13]. Accumulated evidences indicate that lipid metabolism, especially the one involved in the arachidonic acid (AA)-pathway, appears to play a critical role in the development of colorectal tumor[14]. *PPARγ* gene, one of the most important components of the AA-pathway, has been veri-

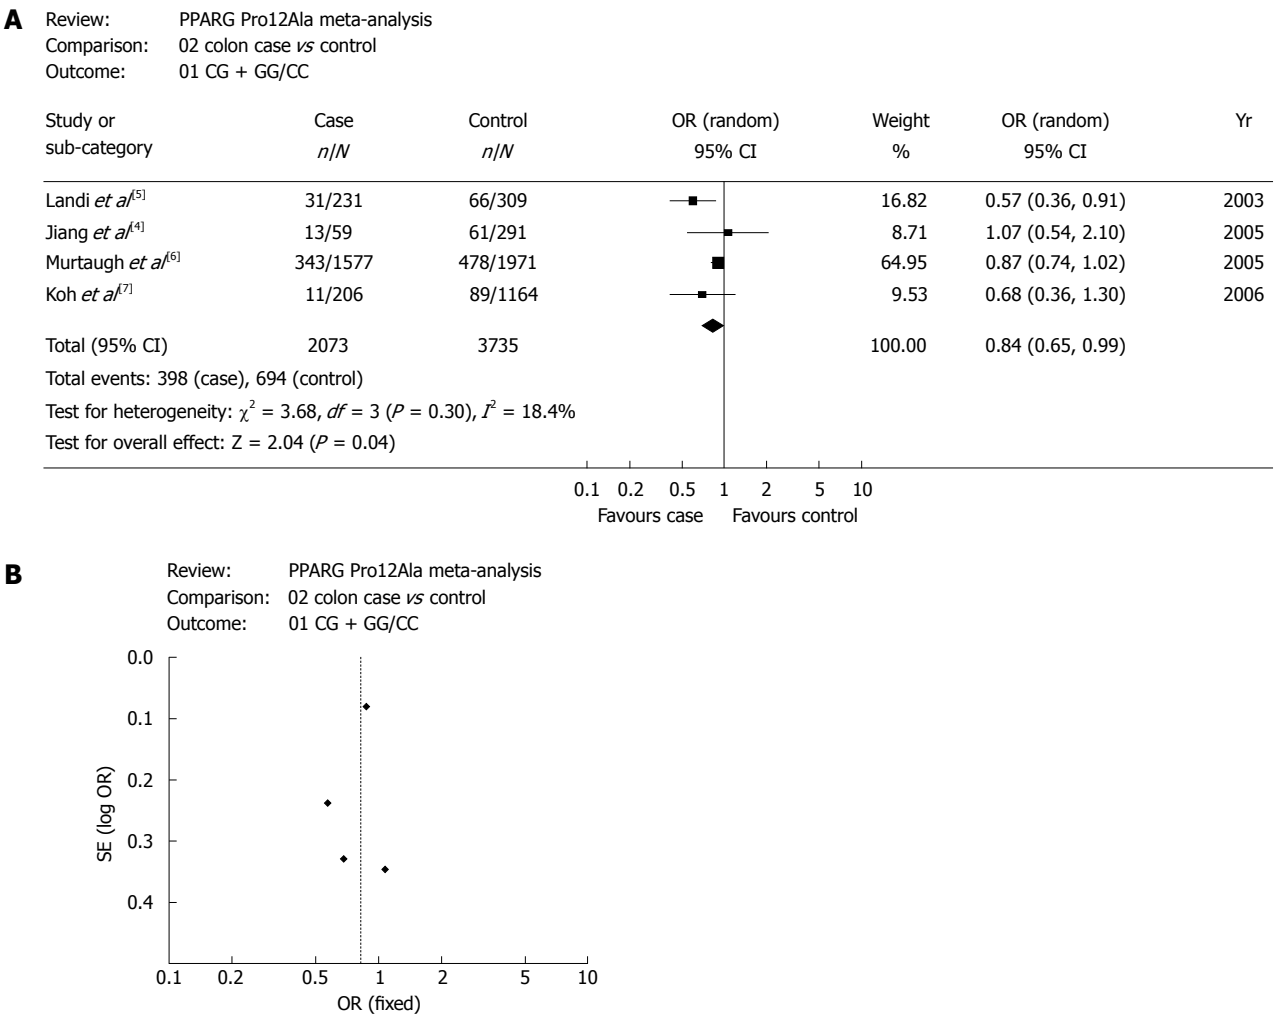

Figure 2 Association between PPAR-γ 34 C>G and colon cancer risk (CG + GG *vs* CC). A: Forest plot-studies are sorted in order of publication year; B: Funnel plots for the associations.

fied to express in a variety of tumor cells. And it will lead to either inhibition of cell proliferation or induction of apoptosis after bonding with ligands[15,16]. Many studies reported that PPAR-γ was also expressed in colon tumors, normal colon mucosa and colon cancer cell lines[17-19]. Genomics research showed that there was a polymorphism in the coding region 34 C>G in PPAR-γ which resulted in the amino acid change of Pro12 Ala[20]. So far, many studies have been performed on the association between PPAR-γ 34 C>G polymorphism and CRC risk, but produced controversial results.

According to our search of references, no systematic review has been published on the analysis of the association between PPAR-γ 34 C>G and CRC. In order to confirm the data on the associations between *PPAR-γ* gene polymorphism and CRC, we did a meta-analysis based on nine studies from Europe, Asia and the USA.

Our results showed that there was no evidence for the association between PPAR-γ 34C>G and CRC if all of the subjects in the nine studies were included. Subgroup-specific meta-analyses also indicated that there was no association between PPAR-γ 34C>G and CRC in European, Asian and the USA studies. As shown in our analysis, G allele might decrease CRC risk, although statistical difference was not significant in these meta-analyses.

Many studies have indicated that both genetic and environmental factors are involved in the development of colorectal tumor[21]. Environmental factors include ethnicity, gender, diet, age, NSAIDS use, BMI, smoking, drinking, family history of disease and so on. It was inferred that there must be interaction between the environmental factors and *PPAR-γ* gene, which had been proved in many researches, including the nine studies. Therefore, interaction is one of the factors of the meta-analyses. Further analysis should be conducted to confirm the influence of PPAR-γ 34 C>G on CRC risk.

Stratified meta-analysis indicated that PPAR-γ 34 C>G was associated with colon cancer, and the G allele decreased the colon cancer risk. No evidence was observed for the association between PPAR-γ 34 C>G and rectal cancer.

In conclusion, no evidence was observed for the association between PPAR-γ 34 C>G and CRC risk and rectal cancer risk. However, PPAR-γ 34 C>G is associated with colon cancer risk, which is meaningful to early

diagnosis, prevention and individual-based treatment of colon cancer. Furthermore, 34 C>G of *PPAR-γ* gene might be a potential therapeutic target for colon cancer.

COMMENTS

Background

Colorectal cancer (CRC) is one of the major causes of cancer death in the developed countries. Accumulated evidences suggest that the peroxisome proliferator-activated receptor-γ (*PPAR-γ*) gene is related to CRC.

Research frontiers

Accumulated evidences indicate that lipid metabolism, especially the one in the arachidonic acid (AA)-pathway, appears to play a critical role in the development of CRC. *PPAR-γ* gene, one of the most important components of the AA-pathway, has been verified to express in a variety of tumor cells. A proline to alanine substitution in the *PPAR-γ* gene was detected, which might be associated with CRC.

Innovations and breakthroughs

Many studies have been performed about the association between the polymorphism 34 C>G of *PPAR-γ* gene and CRC, but got conflicting results. In order to confirm the data, meta-analyses, as a better statistical analysis technique, were performed in this report.

Applications

In this report, the association between *PPAR-γ* gene polymorphism 34 C>G and colon cancer risk was observed, and the G allele decreased the colon cancer risk, which is meaningful to early diagnosis, prevention and individual-based treatment of colon cancer. Furthermore, 34 C>G of *PPAR-γ* gene might be a potential therapeutic target for colon cancer.

Terminology

Susceptibility to colon cancer differs according to genotype of PPAR-γ 34 C>G, and people with G allele might have a lower colon cancer risk.

Peer review

This is an interesting meta-analysis on the association between PPAR-γ 34C>G polymorphism and CRC risk. The main finding of the paper was that PPAR-γ 34 C>G was weakly associated with colon cancer risk, but was not associated with CRC and rectal cancer risk. The methods are properly used; authors report a high quality meta-analysis.

Abstract

AIM: To investigate the aberrant expression of nuclear matrix proteins in human gastric cancer cells before and after hexamethylene bisacetamide (HMBA) treatment.

METHODS: Proteomics analysis of differential nuclear matrix proteins was performed by two dimensional electrophoresis polyacrylamide gel electrophoresis and matrix-assisted laser desorption/ionization time-of-flight mass spectrometry. The expression levels of three nuclear matrix proteins were further confirmed by Western blotting and their locations in nuclear matrix filament were observed by quantum dots-based immunofluorescence.

RESULTS: Proteomics analysis showed that 43 protein spots were significantly changed due to HMBA treatment. Fifteen proteins were identified in the HMBA-induced differentiation of gastric tumor cells. Eight proteins spots were down-regulated while seven were up-regulated. Among these proteins, prohibitin, nucleophosmin and hnRNP A2/B1 were significantly decreased in HMBA-treated human gastric cancer cells, and their locations in nuclear matrix were altered by HMBA. Our results proved the alteration of specific nuclear matrix proteins during the differentiation of human gastric cancer cells. And the aberrant expressions of nuclear matrix proteins were of significance in revealing the regulatory mechanism of tumor cell proliferation and differentiation.

CONCLUSION: The aberrant expressions and intracellular redistributions of nuclear matrix proteins before and after HMBA treatment indicated that nuclear matrix proteins play a pivotal role in the differentiation of gastric cancer cells.

INTRODUCTION

Gastric cancer is the most common malignant gastrointestinal cancer, which accounts for 25% of cancer

deaths[1]. Researches on gastric cancer cell differentiation will not only contribute to the diagnosis of gastric cancer, but also the regulatory mechanism of tumor cell differentiation. Studies have been carried out on the mechanism of induced differentiation of gastric cancer cells. But reports about the proteins related to the differentiation and proliferation of gastric cancer are rare. It is important to elucidate the regulatory mechanism of gastric cancer cell differentiation. Nuclear matrix is a filamentous protein framework for eukaryotic cell chromatin. Nuclear matrix proteins closely relate to DNA duplication and transcription[2]. Some regulatory proteins or enzymes are nuclear matrix proteins or nuclear matrix-binding proteins[3], and they regulate cell differentiation. Protein components of nuclear matrix are dynamic throughout cell proliferation and differentiation. Protein composition of nuclear matrix in tumor cells differ from normal tissue-derived cells[4]. In our previous study we found that the protein compositions of nuclear matrix were changed during the induced-differentiation of various tumor cells[5,6], suggesting that analysis on the aberrant expression of nuclear matrix proteins was of great importance for an in-depth investigation in the mechanism of cell carcinogenesis and reversal. Hexamethylene bisacetamide (HMBA) is a hybrid bipolar compound and originally developed as a potent inducer of cell differentiation[7]. Hereby, based on the induced effects of HMBA on the differentiation of human gastric cancer cells[8,9], we extended our study to determine the aberrant expression of nuclear matrix proteins in HMBA-treated human gastric adenocarcinoma BGC-823 cells. We aimed to identify specific nuclear matrix proteins related to gastric cancer cells and provide further scientific evidences for the mechanism of gastric cancer cell proliferation and differentiation.

MATERIALS AND METHODS

Cell culture

BGC-823 cells, obtained from China Center for Type Culture Collection, were routinely cultured in RPMI 1640 (Gibco) supplemented with 10% heat-inactivated fetal bovine serum (FBS; Hyclone) and 100 U/mL penicillin, 100 μg/mL streptomycin and 50 μg/mL kanamycin at 37℃ in a humidified atmosphere containing 5% CO_2.

Whole cell and nuclear matrix lysates preparation

To prepare the whole cell extracts, cells were washed in phosphate buffered saline (PBS) and then lysed in ice-cold lysis buffer {7 mol/L urea, 2 mol/L thiourea, 4% 3-[(3-Cholanidopropyl)dimethylammonio]-1-propanesulfonate (CHAPS), 1.5% Triton X-100, 1% pharmalyte (pH 3-10 Bio-rad), 65 mmol/L DL-Dithiothreitol (DTT), 40 mmol/L Tris, 5 mg/mL aprotinin, 1 mg/mL leupeptin, 1 mg/mL pepstatin, 2 mmol/L phenylmethanesulfonyl fluoride (PMSF), and 5 mmol/L ethylenediaminetetraacetic acid (EDTA)}. The suspension was then sonicated for 20 min at 0℃ and centrifuged at 8000 × *g* for 30 min.

Nuclear matrix proteins were prepared using a method described by Michishita *et al*[10]. After washed in ice-cold PBS twice, BGC-823 cells were suspended in cytoskeleton (CSK) buffer [100 mmol/L KCl, 3 mmol/L $MgCl_2$, 5 mmol/L ethylene glycol tetraacetic acid, 10 mmol/L piperazine-N,N'-bis(2-ethanesulfonic acid), 300 mmol/L sucrose, 0.5% Triton X-100, and 2 mmol/L PMSF, pH 6.8] for 10 min at 0℃. After being centrifuged at 1000 × *g* for 5 min, the pellet was resuspended in digestion buffer (identical to CSK buffer except for 50 mmol/L NaCl instead of KCl) containing 400 mg/mL DNase I for 30 min at room temperature and centrifuged at 1000 × *g* twice. Cold ammonium sulfate at a final concentration of 0.25 mol/L was used to precipitate proteins. After centrifugation, the pellet was dissolved in lysis buffer [7 mol/L urea, 2 mol/L thiourea, 4% CHAPS, 1.5% Triton X-100, 1% Pharmalyte (pH 3-10 Bio-rad), 65 mmol/L DTT, 40 mmol/L Tris, 5 mg/mL aprotinin, 1 mg/mL leupeptin, 1 mg/mL pepstatin, 2 mmol/L PMSF, and 5 mmol/L EDTA] and then sonicated at 0℃ for 20 min. Finally, the suspension was centrifuged at 10000 × *g* at 4℃ for 30 min and the supernatants were used as nuclear matrix extracts.

Protein concentrations were determined by BCA assay.

Two dimensional electrophoresis, matrix-assisted laser desorption/ionization time-of-flight mass spectrometry analysis and protein identification

2-D polyacrylamide gel electrophoresis (PAGE) was performed as follows. Protein lysates were diluted in sample buffer with 2% Immobiline™ DryStrip gel (IPG) buffer, pH 3-10, nonlinear (GE Heathcare). The samples were applied to 18 cm, immobilized pH gradient strips of pH 3-10 (IPG Drystrips, GE Healthcare). After isoelectric focusing was completed, the strips were equilibrated and the second dimensional electrophoresis was carried out overnight at 3 W/gel at 20℃. The triplicate sets of silver-stained gels were scanned using a UMAX POWER LOOK Ⅲ photometer and analyzed with the PD Quest 8.0 software (Bio-rad). The digitalized two dimensional electrophoresis (2-DE) gel images were compared by matching method. Differentially expressed spots were analyzed and annotated.

The spots were cut and digested using 12.5 ng/μL trypsin (Promega, Madison, WI, USA) in 50 mmol/L ammounium bicarbonate (pH 8.0, Sigma). After that the samples were eluted with 2 μL of matrix solution containing 10 mg/mL α cyano-4-hydroxy cinnamic acid (CHCA, Sigma) and were submitted to Bruker Ⅲ matrix-assisted laser desorption/ionization time-of-flight mass spectrometer. The spectra were internally calibrated using the trypsin autolysis products [842.51 (M + H) and 2211.11 (M + H)] by Flex Analysis software and searched against Swiss-prot and NCBI database using the Mascot tool from matrix science. All the searches were analyzed with a 50 ppm mass tolerance.

Western blotting

For Western blotting experiments, 20 μg cell lysates were

loaded and separated on polyacrylamide gles and then transferred to positively-charged nylon membranes (Millipore, Bedford, MA) according to standard protocol. These blots were blocked for 1 h at room temperature in 5% skim milk. The target proteins were probed with primary antibodies and horseradish peroxidase-labeled secondary antibodies (Santa Cruz). β-actin was used as an indicator for equality of lane loading. Antibody positive bands were visualized using ECL Western blotting detection reagents (Pierce). The X-ray film was scanned and the band density was calculated using the ImageJ software[11].

Quantum dots-based sample preparation for fluorescence microscopy

The NM-IF system was prepared according the methods described by Liang *et al*[12]. After being prefixed with 4% paraformaldehyde at room temperature for 10 min, the cover slips were blocked with 3% bovine serum albumin for 1 h and then incubated with nucleophosmin (NPM), prohibitin (PHB) and hnRNP A2/B1 primary antibodies at 37℃ for 1 h. After washing, the cover slips were rinsed in biotin-labeled secondary antibodies for 45 min at 37℃, washed with tris-buffered saline Tween-20, and incubated with streptavidin-conjugated quantum dots (size scale, 605 nm) for 1 h at 37℃. After that, the cover slips were enveloped with 90% glycerol and observed under fluorescence microscope.

RESULTS

Proteomics analysis of BGC-823 cells before and after HMBA treatment

For proteomics analysis, cell lysates from control and HMBA-treated cells were submitted to 2D-PAGE followed by silver-staining of the gel. The procedures were independently repeated three times and the representative gel images are shown in Figure 1A. And Figure 1B displayed the enlarged maps of changed expression of nuclear matrix proteins from BGC-823 cells. PD Quest 8.0 software (Bio-rad) detected about 342 ± 10 proteins spots on the silver-stained gels of control group while 280 ± 13 protein spots of HMBA-treated group, suggesting that the result of 2-DE PAGE had a high repeatability. Forty-three changed spots were excised and digested with trypsin, and were identified by mass spectrometry. Fifteen proteins were identified in the HMBA-induced differentiation of gastric tumor cells. The identified proteins are listed in Table 1. The expressions of Zinc finger protein 268, calcium-binding protein CaBP5, MAGUK p55 subfamily member 3, vacuolar protein sorting 33B, and Ras-related protein Rab-30, Vimentin, Calnexin (Precursor) were up-regulated while peroxiredoxin 2, transcriptional repressor CTCFL, PHB, Keratin 1 type Ⅱ cytoskeletal, PACAP protein, hnRNP A2/B1, C-type lectin and NPM were down-regulated. Another 28 protein spots were not identified for their low abundances. We next focused on PHB, NPM and hnRNP A2/B1, which were also identified as aberrantly expressed proteins in our previously studies[12-15].

Immunoblotting confirmation of differentially expressed nuclear matrix proteins

To further verify the aberrant changes of PHB, NPM and hnRNP A2/B1, Western immunoblotting was employed to confirm the expression levels of these proteins in cells before and after HMBA treatment, and the intensities of protein bands were densitometrically quantified as described by Sheffield JB[11]. Results showed that signals of PHB, NPM and hnRNP A2/B1 in HMBA-treated cells were much lower than that in control cells, suggesting that the expressions of these three proteins at 7 d of treatment were significantly inhibited by HMBA (Figure 2). All the Western blotting results were consistent with the proteomic analysis.

Localization of PHB, NPM and hnRNP A2/B1 in NM-IF system before and after HMBA treatment

Proteomics analysis showed that PHB, NPM and hnRNP

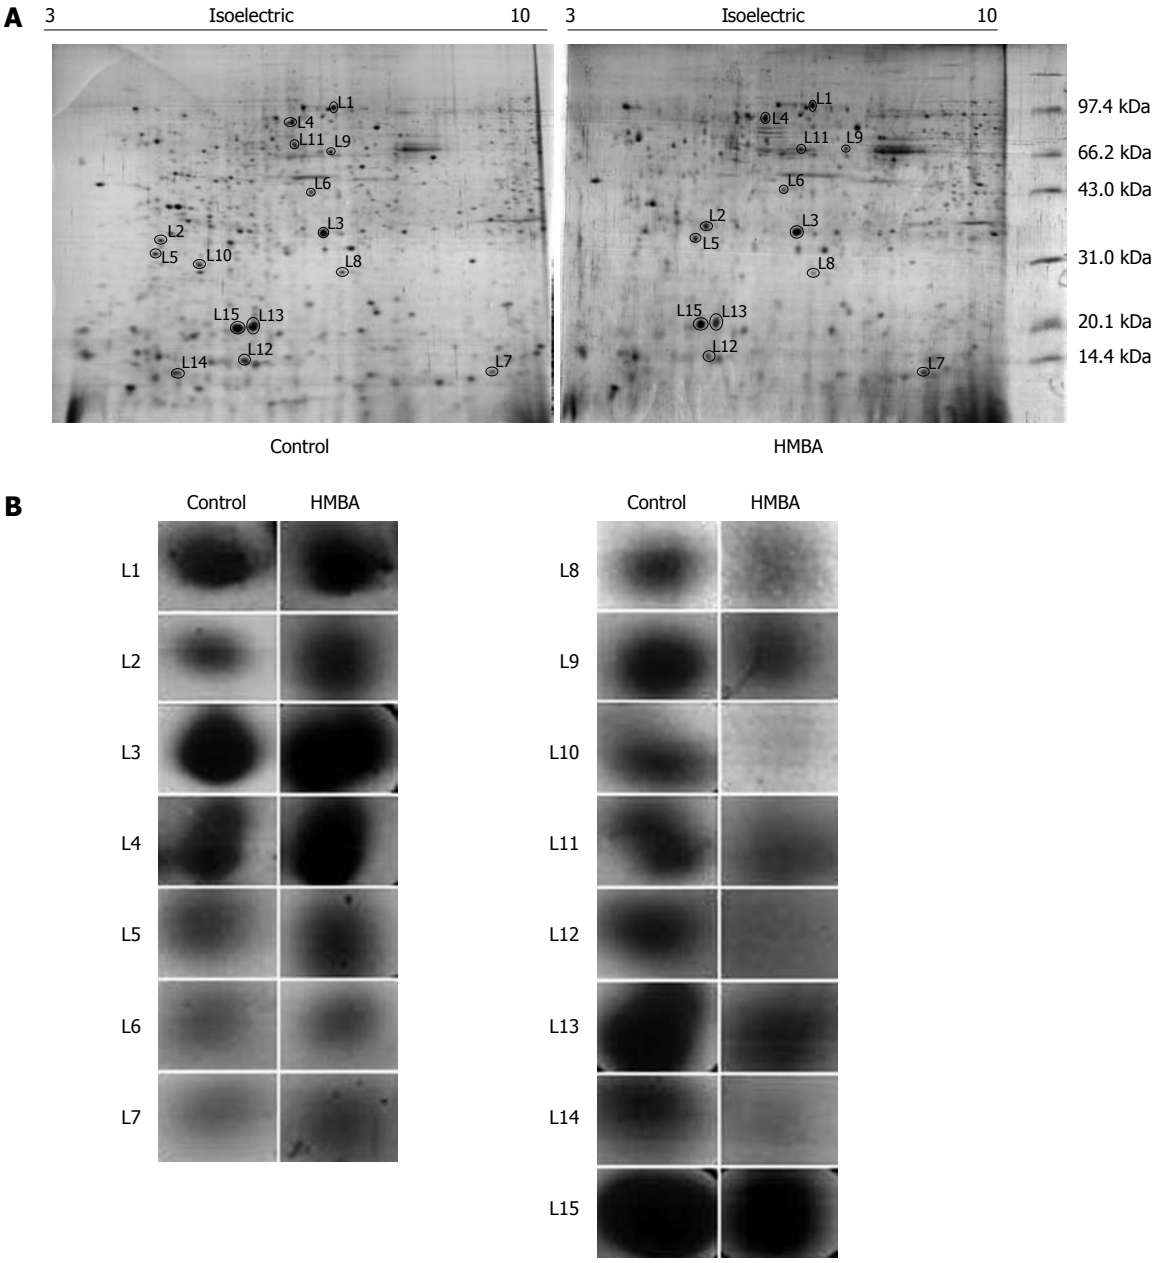

Figure 1 Two-dimensional protein profiles from the nuclear matrix of BGC-823 cells. A: Representative two-dimensional protein profiles from the nuclear matrix of BGC-823 cells before and after hexamethylene bisacetamide (HMBA) treatment. The differentially expressed proteins are marked with circular symbols on the gels. L1-L7 spots indicate the up-regulated proteins while L8-L15 indicates the down-regulated proteins; B: Enlarged portions from 2-DE gels.

A2/B1 were nuclear matrix proteins. QDs-based location experiments were conducted to corroborate the alteration of the physical distribution of these three proteins in nuclear matrix-intermediate system. Clearly altered distribution patterns for NPM and hnRNP A2/B1 were observed in the nucleus while PHB in at the cytoplasm. The red fluorescence representing PHB mainly accumulated at the nucleus periphery in control cells (Figure 3C), while PHB was uniformly distributed in the whole cytoplasm after HMBA treatment, suggesting that HMBA obviously altered the location of PHB (Figure 3D). Highly intensified NPM fluorescence mainly localized in the residue of nucleoli in correspondence with the fact that NPM was an established marker for the granular components[16], with very subtle expression in the cytoplasm (Figure 3A). HMBA treatment resulted in the low intensity of fluorescence in nucleolus and faint fluorescence in cytoplasm derived from NPM, suggesting that NPM had a tendency of translocation from nucleoli regions to nuclear matrix (Figure 3B). When referred to hnRNP A2/B1, a similar distribution pattern to NPM was observed. In control cells, the fluorescence representing hnRNP A2/B1 was mainly detected in nuclear region with subtle signals in cytoplasm region (Figure 3E), whereas after HMBA treatment, a clear translocation appeared from nuclear to cytoplasm region, and hnRNP A2/B1was uniformly distributed in the cytoplasm but not in the nucleus (Figure 3F).

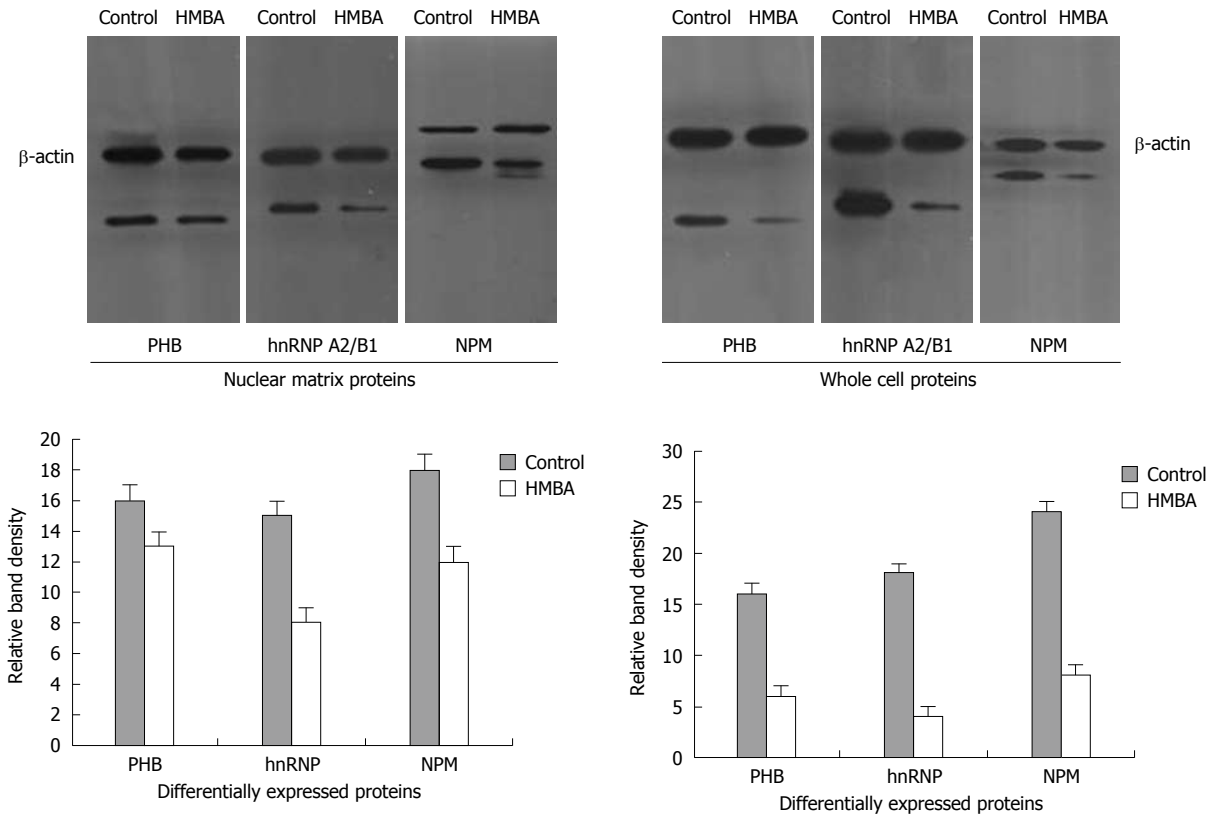

Figure 2 Determination of prohibitin (PHB), nucleophosmin (NPM) and hnRNP A2/B1 at nuclear matrix proteins and whole cell proteins by Western immunoblotting. All of these three protein signals were found to be down-regulated at whole cell level and nuclear matrix level after HMBA treatment.

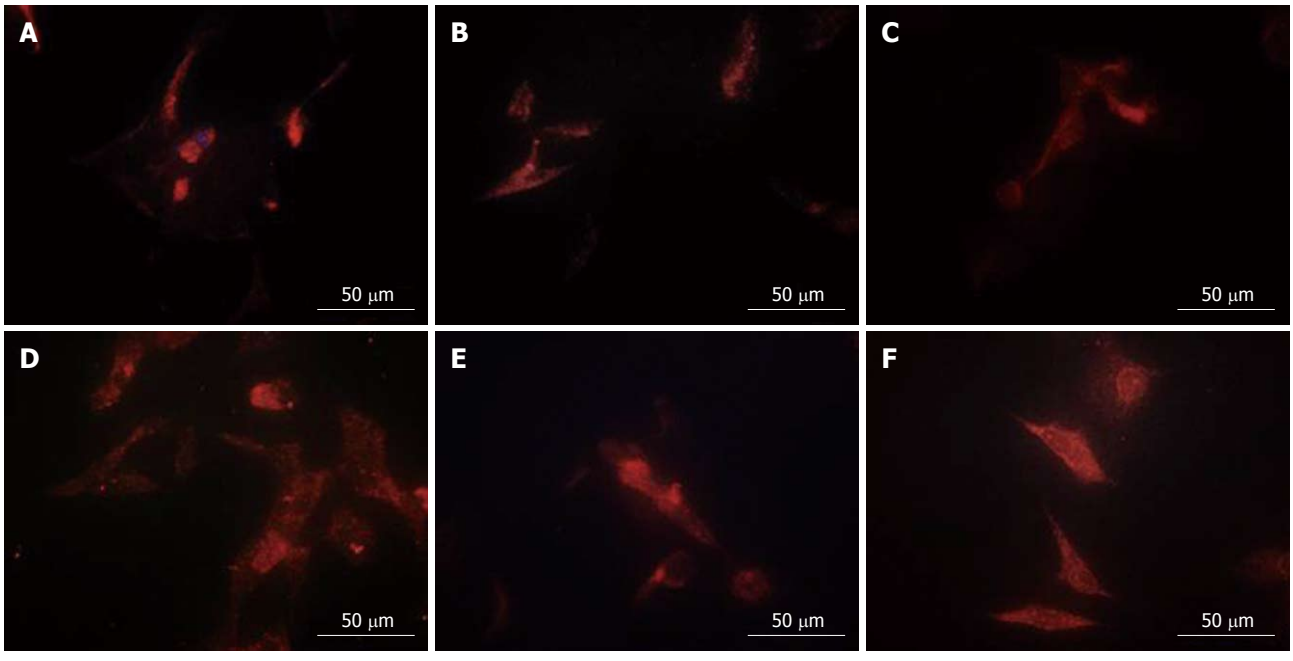

Figure 3 Effects of HMBA treatment on the localization of differentially expressed nuclear matrix proteins in NM-IF system as shown by a quantum dots-based immnuofluorescence. Typical changes of localization of NPM (A, B), PHB (C, D) and hnRNP A2/B1 (E, F) are observed after treatment with 5 mmol/L HMBA. The figure is composed of representative pictures taken from three independent experiments. A, C, E: Control; B, D, F: HMBA.

DISCUSSION

The alteration of nuclear matrix components is closely related to cell carcinogenesis. Configuration and protein composition of nuclear matrix in tumor cells differ from normal tissue-derived cells. For further investigating the effects of HMBA on the protein components of nuclear matrix of human gastric cancer cells, proteomics

analysis was employed to screen the aberrant nuclear matrix proteins of human gastric cancer cells before and after HMBA treatment. And 15 differentially expressed proteins were identified, seven of which, including Zinc finger protein 268, nebulin, *etc.* were up-regulated while the other eight proteins, including PHB, KeHMBAtin 1 type Ⅱ, cytoskeletal, hnRNP A2/B1, NPM, *etc.* were down-regulated. Getzenberg *et al*[17] reported that nuclear matrix profiles of bladder cancer, liver cancer and colon cancer were significantly altered in comparison with that of the normal tissues; moreover, differential nuclear matrix proteins were tumor-specific[17-19]. In our previous studies, we found variational nuclear matrix profiles of tumor cells[5,6]. HMBA could change protein compositions of gastric cancer cell nuclear matrix. The alteration of nuclear matrix protein expressions during the differentiation of gastric cancer cells was closely related to their functional transformation.

In this article we focused on the aberrant expression of nuclear matrix proteins in the induced-differentiation of gastric cancer cells. Among all the differentially expressed proteins, the down-regulated proteins, PHB, NPM and hnRNP A2/B1, were also identified in our previous studies on the induced differentiation of gastric cancer MGC80-3 cells, suggesting that PHB, NPM and hnRNP A2/B1 were common aberrantly expressed nuclear matrix-specific proteins in different tumor cell lines[8,12-15]. Proteomics analysis showed that expressions of PHB, NPM and hnRNP A2/B1 were down-regulated both in the whole cell lysates and nuclear matrix lysates, and the expression changes were further confirmed by Western blotting. Quantum dots-based immunofluorescent assay was performed to investigate the localization of specific nuclear matrix proteins in nuclear matrix-intermediate filament system. And results displayed that PHB, NPM and hnRNP A2/B1 were localized in nuclear matrix fibers, and their locations were altered by HMBA treatment. Our data further proved that PHB, NPM and hnRNP A2/B1 were common differential nuclear matrix proteins. And the aberrant expression and relocation of these three proteins were closely related to their regulatory roles in the process of tumor cell differentiation.

The importance of differentially expressed nuclear matrix proteins was embodied not only by their locations in nuclear matrix fibers but also their regulations on cell differentiation and apoptosis. For example, PHB presented anti-proliferation activities by inhibiting the activity of nuclear estrogen receptors, and it was usually over-expressed in tumor tissues[20]. PHB was also a biomarker protein for differentiating benign prostate hyperplasia from prostate cancer[21]. NPM was an abundant nucleolar phosphoprotein, and it could cause the suppression of cell differentiation and anti-apoptosis in human carcinogenesis. Inhibiting the activity of NPM led to the over-expression of P53[22]. Cell proliferation could be inhibited by blocking the shuttle of NPM from nuclear to cytoplasm[23]. hnRNP A2/B1 played a pivotal role in DNA damage repair[24]. The expression and location of PHB, NPM and hnRNP A2/B1 were changed in gastric tumor cells before and after HMBA treatment, suggesting their pivotal biological functions in the differentiation of gastric tumor cells. Continued investigation on specific nuclear matrix proteins will contribute to better understanding the regulatory mechanisms of nuclear matrix proteins in gastric carcinogenesis and reversal.

COMMENTS

Background

Gastric cancer is the most common malignant gastrointestinal cancer and accounts for 25% of cancer deaths. Nuclear matrix proteins are closely related to DNA duplication and transcription. Researches on nuclear matrix proteins of gastric tumor cells will contribute to the diagnosis and prevention of gastric cancer.

Research frontiers

It is important to identify specific nuclear matrix proteins related to gastric cancer cells and provide further scientific evidences for the mechanism of gastric cancer cell proliferation and differentiation.

Innovations and breakthroughs

Forty-three protein expressions were significantly changed in hexamethylene bisacetamide (HMBA)-treated human gastric cancer cells. Moreover, the locations of three proteins in nuclear matrix fibers were obviously altered after HMBA treatment.

Applications

The differentially expressed nuclear matrix proteins might be intracellular target proteins of HMBA and the tumor markers for gastric cancer.

Peer review

This study examined the effects of HMBA on nuclear matrix protein expression in gastric cancer cell BGC-823. Forty-three proteins were affected significantly by the treatment, among them 15 were identified including 7 up-regulated and 8 down-regulated ones. The study is neatly designed and the figures are presented with good quality. The manuscript is highly interesting, well-written and valuable.

Abstract

We describe a 77-year-old man with refractory gastric ulcer that worsened after *Helicobacter pylori* eradication therapy. Pathology showed marked infiltration of IgG4-positive plasma cells in the gastric lesions, which led us to suspect IgG4-related sclerosing disease. To the best of our knowledge, this is the first report of IgG4-related gastric ulcer without the main manifestation of autoimmune pancreatitis.

INTRODUCTION

Gastric ulcer is now recognized as an infectious disease that results from infection with *Helicobacter pylori* (*H. pylori*). *H. pylori* causes continuous gastric inflammation with abundant neutrophil infiltration, and eradication therapy is standard treatment in gastric ulcer[1]. We encountered a 77-year-old man with gastric ulcer of 5 years' duration, which worsened after *H. pylori* eradication therapy. Pathologically, gastric lesions show marked infiltration of plasma cells, and immunohistochemical study revealed frank IgG4-positive plasma cell infiltration. This clinical picture suggested refractory gastric ulcer that was suspected of being IgG4-related sclerosing disease.

CASE REPORT

A 72-year-old man visited the gastroenterology department of our hospital in June 2004 complaining of abdominal discomfort and appetite loss. He had been well until 1 mo earlier, when he experienced discomfort in the upper abdomen and decreased appetite. He had no abdominal pain, diarrhea, fevers, night sweats or body weight loss. He had no allergies, and was not taking any medication. He had undergone appendectomy at age 21 years. He had no history of tobacco smoking and drank alcohol socially. There was no family history of cancer or autoimmune disease. On examination, he appeared comfortable, with a temperature of 37.3℃, blood

pressure 110/70 mm Hg, and pulse 128 beats/min. The abdomen was soft, without tenderness or distension. The remainder of the examination was normal.

Esophagogastroduodenoscopy (EGD) revealed multiple ulcers in the stomach, while the rapid urease test (RUT) was negative (Figure 1A). Biopsy specimens revealed no malignant cells. Treatment with famotidine was initiated at a single daily dose of 20 mg, which resulted in the gradual resolution of symptoms. EGD at 2 mo revealed multiple gastric ulcer scars. At 14 mo, he remained well, and EGD revealed multiple gastric ulcer scars and biopsy revealed gastritis.

At 26 mo, he remained well, and again EGD revealed multiple gastric ulcer scars and biopsy specimens revealed gastritis (Figure 1B). However, urea breath testing was positive for *H. pylori* infection. Elimination with lansoprazole (30 mg twice daily), amoxicillin (750 mg twice daily) and clarithromycin (200 mg twice daily) for 7 d was successful, and was maintained with rabeprazole (10 mg daily).

At 37 mo, he remained well, but EGD revealed severe active inflammation (edematous mucosa with exudates, multiple ulcers and stricture) at the body of the stomach (Figure 1C). Biopsy revealed no neoplastic infiltrate and RUT was negative. Laboratory results in serum included lactate dehydrogenase 122 IU/L (reference range: 124-226 IU/L), soluble interleukin 2 receptor 325 U/mL (reference range: 190-650 U/mL), carcinoembryonic antigen 3.3 ng/mL (normal value: ≤ 5.0) and amylase 181 IU/L (reference range: 58-167 IU/L). Serum Epstein-Barr antiviral-capsid-antigen IgG titer was 160. Cytomegalovirus (CMV) antigenemia assay and the *Treponema pallidum* hemagglutination test were negative. Additional investigation on reference to other facilities precluded the presence of malignant tumor and inflammatory bowel disease, whereas ultrasonography of the abdomen showed slight enlargement of the pancreatic head. Serum IgG4 at this time was 165 mg/dL (reference range: 4.8-105 mg/dL). The presence of autoimmune pancreatitis (AIP) was suspected.

At 49 mo, he remained well on maintenance treatment with rabeprazole. EGD revealed multiple ulcers and ulcer scars, and worsening of the stricture of the upper stomach (Figure 1D). At 54 mo, in February 2009, he remained well and completely asymptomatic. Repeated EDG disclosed multiple ulcer scars with stenosis of the upper body and well-defined ulcers at the lesser curvature (Figure 2). Pathological examination of gastric lesion biopsies revealed intense infiltration of plasma cells that contained IgG4 (Figure 3). Serum IgG was 1909 mg/dL (reference range: 870-1700 mg/dL); IgG4 was 203 mg/dL (reference range: 4-108 mg/dL); complement component C3 was 114 mg/dL (reference range: 80-140 mg/dL); complement component C4 was 25.9 mg/dL (reference range: 11.0-34.0 mg/dL); and amylase was 167 IU/L (reference range: 58-167 IU/L). Antinuclear antibody, rheumatoid factor, anti SS-A antibody, and anti SS-B antibody were negative. Computed tomography scanning of the abdomen showed that the pancreas was normal, with no evidence of enlargement. Magnetic resonance imaging of the abdomen with magnetic resonance cholangiopancreatography revealed normal biliary and pancreatic ducts, and confirmed the lack of pancreatic enlargement.

Although the high serum IgG4 level strongly suggested AIP, the clinical imaging studies showed no pancreatic enlargement. Corticosteroid therapy and the management of side effects were discussed, but the patient, who was asymptomatic, declined this option. At 64 mo (December 2009), he remains well and stable under maintenance therapy with a proton-pump inhibitor.

DISCUSSION

AIP is a specific type of pancreatitis that is thought to have an autoimmune etiology, and typically shows infiltration of IgG4-positive plasma cells and increased levels of serum IgG4[2,3]. IgG4-positive plasma cells may involve not only the pancreas, but also other organs including the bile duct, gallbladder, salivary gland, thyroid gland, lungs, stomach, colon, liver, retroperitoneum, kidney, prostate and lymph nodes. In 2003, Kamisawa *et al*[4,5] proposed a new clinicopathological entity, IgG4-related sclerosing disease, and suggested that AIP is a pancreatic lesion that reflects this systemic disease. Shinji *et al*[6] described a relationship between gastric ulcer and AIP in 2004, and detected gastric ulcer in eight of 23 AIP patients, and significantly more abundant IgG4-positive plasma cell infiltration in the gastric lesions of AIP patients. They have concluded that AIP is closely associated with gastric ulcer with abundant IgG4-bearing plasma cell infiltration.

A common cause of gastric ulcer is *H. pylori* infection. However, the gastric lesions in the present patient worsened after successful eradication of *H. pylori* with triple therapy. He had no history of non-steroidal anti-inflammatory drug use, which is another important cause of gastric ulcer. Pathological and serological findings precluded the possibility of gastric cancer of the scirrhous type, malignant lymphoma arising from mucosa-associated lymphoid tissue, Crohn's disease, reactivation of CMV infection, chronic active EBV infection, and syphilis. Given his elevated serum levels of IgG4 and abundant infiltration of IgG4-positive plasma cells, we consider that the gastric lesions in this patient were associated with infiltration of IgG4-positive plasma cells, and that the most likely diagnosis is IgG4-related sclerosing disease. Since some IgG4-related sclerosing disease patients relapse and improve spontaneously, worsening of this gastric lesion after *H. pylori* eradication was assumed to be independent of *H. pylori* infection. From recent reports that suggest that IgG4-related sclerosing disease is associated with cancer, our treatment goals in this asymptomatic 77-year-old man are the prevention of gastric cancer and gastric obstruction[7,8]. Since corti-

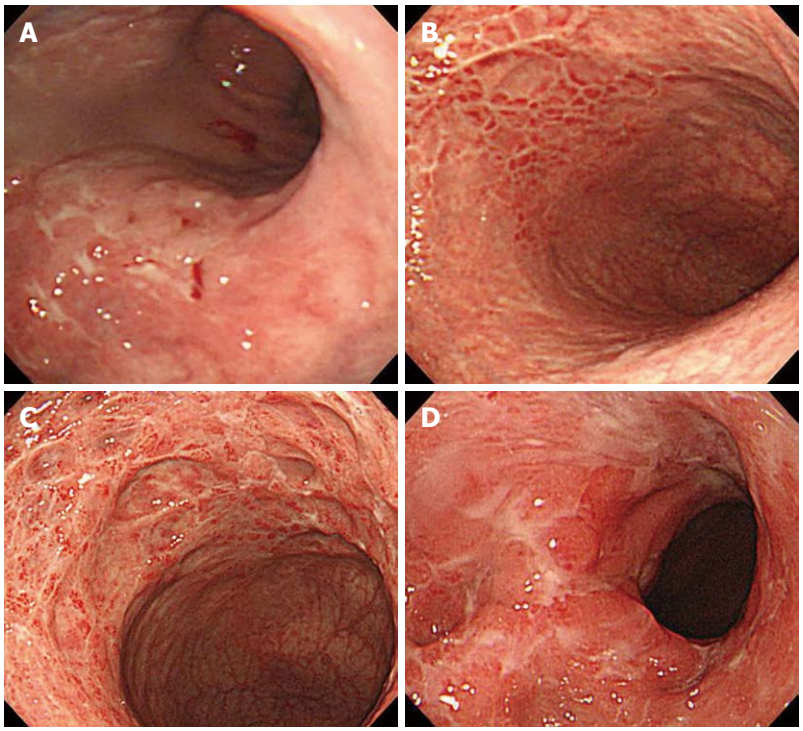

Figure 1 Endoscopic findings show chronic persistent inflammation of the stomach. costeroid therapy is effective in IgG4-related sclerosing disease, it may be considered the first treatment option, albeit with consideration to its many side effects, particularly in elderly patients, and uncertainty over optimal dosages. This patient, who was asymptomatic, declined this option and was placed instead on maintenance therapy with a proton-pump inhibitor. Treatment of this

rare gastric ulcer will be advanced by multicenter trials in patients with gastric ulcer and IgG4-related sclerosing disease.

Abstract

Hepatocellular carcinoma (HCC) is an aggressive tumor with poor long-term prognosis. Here, we present an unusual patient with a solitary recurrence of HCC in the right kidney 12 years after the initial diagnosis. This illustrates the importance of considering late recurrence in patients with a history of HCC and the management of these metastases.

INTRODUCTION

Hepatocellular carcinoma (HCC) is an aggressive tumor with poor long-term prognosis. The reported 5-year recurrence rate ranges from 75% to 100%[1]. Therefore, extrahepatic metastasis of HCC is uncommon due to the highly malignant nature of the primary tumor. However, with advances in different treatment modalities for HCC, the incidence of extrahepatic metastasis appears to be increasing[2]. Nevertheless, most recurrences occur relatively early after the initial diagnosis and treatment. Here, we report a patient who presented with a renal tumor 12 years after the initial treatment of primary HCC, which turned out to be a solitary recurrence of the initial HCC. The management of these distant metastases is also highlighted.

CASE REPORT

A 61-year-old man who was a chronic hepatitis B carrier with Child's A liver cirrhosis, first presented 12 years ago with hemoperitoneum secondary to ruptured HCC. Emergency laparotomy for hemostasis was performed. Non-anatomical resection of the liver tumor was subsequently performed 1 mo later after his condition was optimized. Pathology showed an 8 cm × 6 cm × 4 cm, moderately differentiated HCC with a clear resection

Figure 1 Computed tomography showing the contrast-enhanced mass in the right kidney.

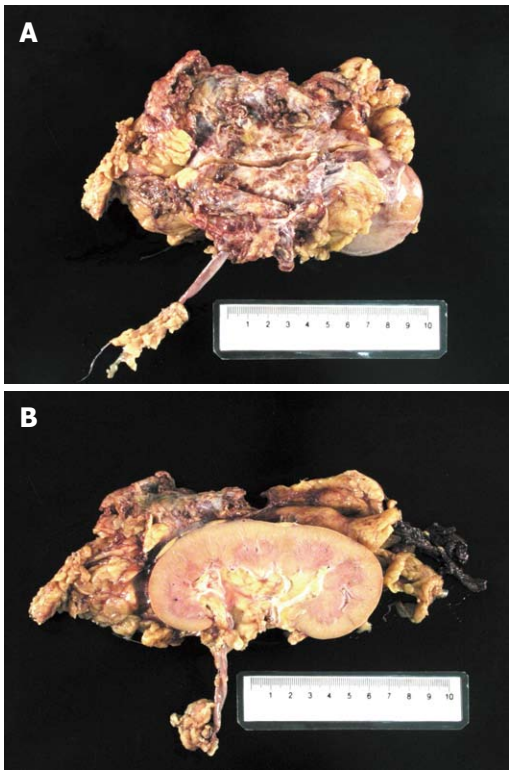

Figure 2 Gross specimen of tumor showing its relationship with the right kidney. A: External appearance; B: From cut section of kidney.

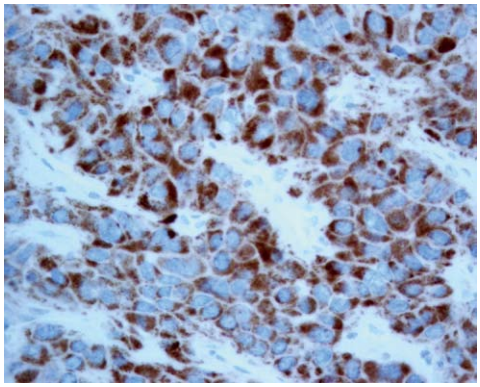

Figure 3 Immunological stain of the tumor with HepPar, confirmed the tumor as hepatocellular carcinoma.

margin. The postoperative serum α fetoprotein (AFP) level dropped from 1500 to 2 ng/mL.

He was followed up regularly, 3-monthly for the first 2 years, followed by half-yearly follow-up. Serum AFP was measured during each follow-up and abdominal ultrasound was also performed during each follow-up for the first 5 years and then yearly during subsequent follow-up. There was no evidence of recurrence and the patient remained well clinically until 12 years later, when surveillance ultrasound revealed a right renal mass. Subsequent computed tomography showed a 5.3 cm pedunculated, well-circumscribed, contrast-enhanced soft tissue tumor in the right kidney, suspicious of renal cell carcinoma (RCC) (Figure 1). There was no space-occupying lesion in the liver or ascites. The tumor was asymptomatic and was not found on the last ultrasound performed 1 year ago. Serum AFP level was also increased from 3 (6 mo previously) to 27 ng/mL. However, in view of the long recurrence-free period and no evidence of local recurrence, the treatment plan was to closely monitor the raised AFP level and proceed to treatment of the renal mass.

With the past history of laparotomy and hepatectomy, retroperitoscopic nephrectomy was planned. During the operation, a large vascular, friable and exophytic tumor was found to have developed in the right kidney. However, the tumor was quite adhesive to the surrounding tissue, such that it inadvertently ruptured despite careful dissection. The surgery was then converted to an open procedure. The operation lasted 195 min with an estimated blood loss of 3 L. The post-operative course was uneventful and he was discharged 7 d after the operation.

However, the subsequent unexpected pathology was found to be extra-hepatic metastasis of HCC at Gerota's fascia. Macroscopically, the tumor was in the perinephric fat with no invasion to the renal capsule (Figure 2). Microscopic examination showed trabeculae of polygonal eosinophilic tumor cells, with epithelial cohesion, marked pleomorphism, associated with sinusoidal-type vascular channels and bile canaliculi were also identified. The kidney and pelvi-calyceal system were intact. When compared with the previously resected HCC 12 years ago, they both demonstrated similar microscopic characteristics and both were immunoreactive to polyclonal carcinoembryonic antigen and HepPar (Figure 3), but not to markers for RCC. Both the primary and recurrent HCC demonstrated the same TP53 mutation in exon 7 (R249S AGG > AGC). This result by itself was not confirmatory, but supported the clonal relationship of the primary and recurrent HCC in this case.

After nephrectomy, the patient's serum AFP level dropped to 1 ng/mL, i.e. normal. As there was no evidence of other systemic recurrence, no adjuvant chemotherapy was administered. The patient remained well 18 mo after the nephrectomy and serum AFP remained normal. The latest positron-emission tomography per-

formed at 1 year after nephrectomy showed no evidence of recurrence.

DISCUSSION

In the past, extrahepatic metastasis of HCC was considered a relatively uncommon phenomenon, owing to the highly malignant nature of the primary tumor. Nonetheless, with advances in treatment for HCC, its overall prognosis is improving and the incidence of extrahepatic metastasis appears to be increasing[3]. The commonest sites of extrahepatic metastases are lung, lymph node and bone followed by adrenal glands[4-6]. Extrahepatic metastasis can occur *via* three routes: hematogenous (56%), lymphogenous (27%) and direct invasion (22%) and more than one mode of spread can occur[7]. It is uncommon for HCC to spread to kidney and most believe that tumor spread to the kidneys is *via* the hematogenous route[8]. In our patient, the metastasis spread to the perinephric tissue without direct invasion of kidney parenchyma. It was postulated that the initial rupture of the primary liver tumor resulted in some seeding of tumor cells in the retroperitoneal region giving rise to subsequent tumor recurrence.

However, it is still extremely rare to have recurrent HCC 12 years after the initial diagnosis and treatment. The reported median duration between initial treatment for HCC to extrahepatic spread is 23.2 mo[1]. While there was a report suggesting that HCC can recur more than 6 years after initial management[9], there are no reports of recurrence occurring 10 years after initial treatment. It is difficult to explain the exceptionally long time lapse between treatment of the primary tumor and the current recurrence in our patient. It can not be explained even by shed cells belonging to a very low malignant clone of tumor cells.

Although there is no standard management protocol for patients with extrahepatic metastasis of HCC, it is generally believed that aggressive treatment for extrahepatic metastasis can prolong survival in selected patients with good performance status and limited volume of recurrence. In a review of patients with both intrahepatic and extrahepatic recurrent HCC, patients who received an aggressive combination of metastatectomy and locoregional therapy, with or without systemic therapy, had a better survival rate compared to those who received only non-surgical treatment (median survival after recurrence was 44.0 mo in the aggressive treatment group *vs* 10.6 mo in the non-surgically treated group)[2]. For patients with lung metastasis, it was also shown that a longer disease-free interval from primary treatment and a smaller number of metastasis (less than three) were associated with better prognosis[10]. In our patient, the solitary nature and long disease-free interval were relatively good prognostic factors.

Certainly, a more frequent follow-up protocol, especially imaging, may help to detect the lesion at an earlier stage. However, a careful balance between the yield and medical cost is needed, as late recurrence of HCC after a disease-free period of 5 years is still a very rare condition.

Our case illustrates that, in managing patients with a past history of HCC who present with new mass lesions, the diagnosis of extra-hepatic metastasis should always be suspected. Although the final treatment might not be altered, the diagnosis of metastatic HCC would allow better surgical planning and counseling for the patient.

Abstract

Lipoma within jejunal duplication presenting as abdominal bloating and partial intestinal obstruction is an exceptional clinical entity. We report a case of 68-year-old man complaining of abdominal bloating for 10 d due to multiple lipomas arising from jejunal duplication cysts. Only a few cases of a single lipoma within a Meckel's diverticulum giving rise to this clinical scenario have been reported in the English language literature. However, no case of multiple lipomas within jejunal duplication cysts has been reported. We present a case in which double-balloon endoscopy revealed a small intestinal structure changed into Meckel's diverticulum-like cavities containing several lipomas. This case highlights intestinal lipoma as an uncommon cause of adult intussusceptions, which should be included in the differential diagnosis of small intestinal obstruction and appropriate examinations should be chosen.

INTRODUCTION

Lipoma of the small intestine is a benign tumor of mesenchymal origin which is mostly found by chance during gastrointestinal investigation. Invaginations account for 2/3 of small bowel occlusion caused by up to 80% of tumors and the lipoma is the most frequent benign tumor that causes invagination in its submucous polypoid and it is in more or less scissile form[1].

However, multiple lipomas within the intestinal duplication canal as a predominant cause of partial intestinal obstruction is an exceptional clinical scenario. We report a case of a 68-year-old man with a 10-d history of abdominal bloating after meals caused by intussusception due to a small intestine lipomatous lesion located in the jejunal duplication cyst. Although the same complications such as intestinal obstruction and intussusception may crop up in the duplication patients, we still consider the multiple lipomas as the main cause of the symptom.

CASE REPORT

A 68-year-old man was referred to our department complaining of gradual abdominal bloating after meals for the last 10 d, but without abdominal pain and vomiting. He had a bowel movement every 2 d despite a history of chronic constipation for 6 years. The patient refused eating for 2 d and lost approximately 5 kg. There was no

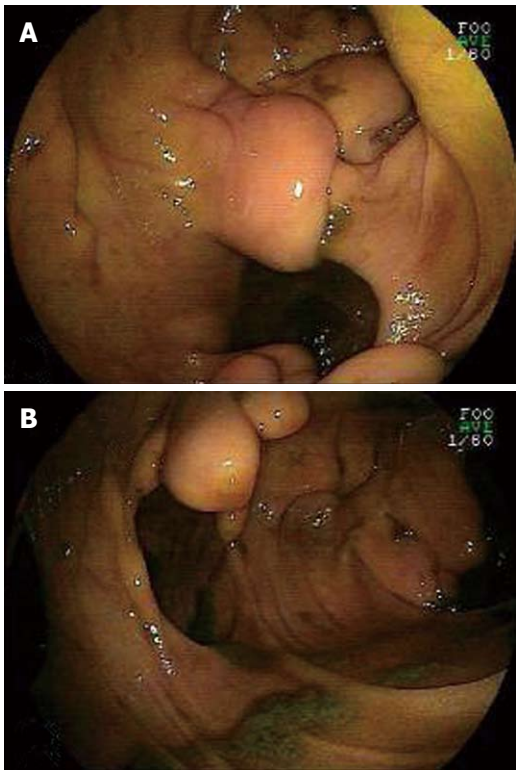

Figure 1 Double-balloon endoscopy (DBE) by the oral approach revealing several rounded protuberances in the jejunum (B) and a diverticulum-like hole (A).

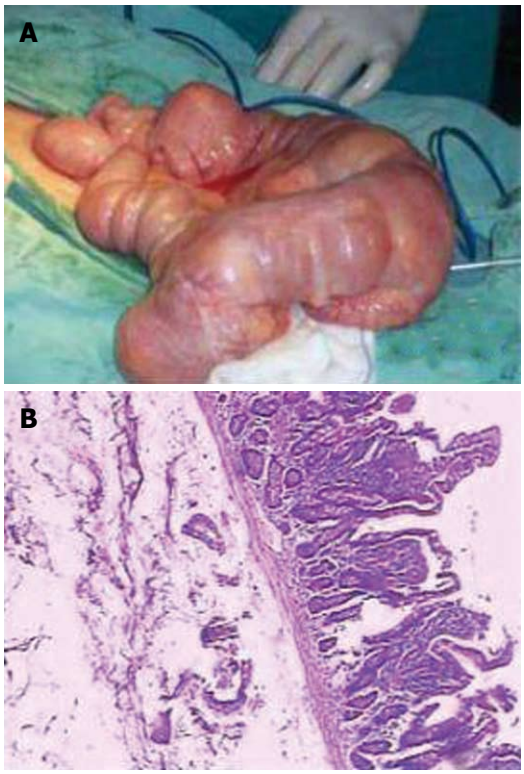

Figure 2 Resected specimen of jejunal tissue. A: Macroscopic appearance of the resected specimen with seven remarkably dilated cysts; B: Microscopic appearance of resected tissue showing multiple lipomas lining within intestinal wall (HE, × 20).

more relevant past medical, family or surgical histories. Physical examination revealed abdominal bulge with visible intestinal peristalsis, and active bowel sounds. Abdominal palpation revealed a firm, round and fixed mass of 7 cm × 4 cm over the left umbilical region. Examination of other systems was unremarkable with insignificant laboratory results.

Abdominal plain X-ray film showed air-fluid levels while colonoscopy failed to reveal any lesions which might be responsible for the symptoms. However, double-balloon endoscopy (DBE) revealed small intestinal structures which changed into Meckel's diverticulum-like cavities at 30 cm beyond the ligament of Treitz from the oral route (Figure 1A). Several yellow spherical or stalactite-like protuberances of unequal size rose into the jejunal cavity in these cystic formations with smooth surface (Figure 1B). We also found scar tissues in the partial jejunal cavity (Figure 1A). A possible diagnosis of jejunal duplication with multiple lipomas was established and the patient underwent exploratory laparotomy. One remarkably dilated intestinal canal with seven duplication cysts of about 7.5 cm × 6 cm on the mesenteric aspect of the jejunum of around 55 cm was found intraoperatively (Figure 2A). All the cyst-like dilatation had independent vascular supply, some of them were connected to the intestinal cavity while some did not. The end of intestinal tract invaginating into the low intestinal canal appeared dark red and edematous, while the upper segment was dilated significantly. Excision of the cystic lesion and an end-to-end anastomosis of the jejunum were performed. Pathological examination of the resected specimen revealed jejunal duplications having seven cysts ranging from 5.5 cm × 6 cm to 8.5 cm × 7.5 cm, with multiple submucosal lipomas lining on its wall (Figure 2B). The biggest lipoma was 32 mm in diameter. The patient had an uneventful postoperative recovery and was discharged on the seventh post-operative day. He remained well 14 mo after surgery without any symptoms of recurrence.

DISCUSSION

Alimentary tract duplications are rare congenital malformations, which in most of cases are diagnosed in infancy and childhood, although they can remain undetected until older age[2]. In contrast to Meckel's diverticulum, duplication cysts are located on the mesenteric aspect and share a common smooth muscle wall and vascular supply[2,3]. Most of the patients are asymptomatic and remain undiagnosed for years. When symptomatic, they manifest as bleeding, constipation and obstruction as a result of direct compression, volvulus or intussusception[4,5]. Our patient had a history of chronic constipation as a presenting symptom of jejunal duplication. Although it seemed to be the complication of duplication cyst, the right diagnosis was only made after 6 years.

Lipoma is a benign tumor of mesenchymal origin which is uncommon to be localized in the small bowel.

It is mostly encountered incidentally during the investigation of the gastrointestinal tract for other reasons, since they are usually asymptomatic[6]. Generally, lipoma is defined to originate in the submucosal layer and usually solitary (85%-90%), with variable sizes ranging from 1 to 30 cm[7]. Zografos *et al*[8] reported that lesions smaller than 1 cm are generally unable to cause symptoms, while 75% of those > 4 cm might give rise to gastrointestinal symptoms. Intestinal occlusion is one of the major results, which is caused by direct pressure by the lipoma or due to intestinal intussusception. Duplication cysts and lipomas can both lead to intussusception or obstruction, but in this case, we speculated that the small bowel lipomas should be the main reason. Firstly, more than 60% of the gastrointestinal duplications are diagnosed prenatally or in the first 2 years of life[9], making it rare to be symptomatic in adults. Ileocecal valve makes cystic duplications easier to cause obstruction of the colon than jejunal duplication. Secondly, several lipomas in the lesion are greater than 3 cm in diameter which might be the cause of intussusception and partial intestinal obstruction in our patient. Direct compression of cystic duplication led to intestinal stenosis, prolonging the time for chyme passage. Consequently, jejunal lipomas continued to be under progressive inflammatory stimulation.

Preoperative diagnosis of duplication cyst or small intestinal lipoma is difficult. Data from our hospital shows that, from 1998 to 2008, only 14.3% of duplication cysts have been correctly diagnosed before surgery. Abdominal computed tomography and ultrasonography were helpful in identifying large lesions but not in small intestinal lesions. However, the availability of DBE[10] and wireless capsule endoscopy made it possible to directly examine the whole digestive tract. In this case, we found multiple small intestinal lipomas arising from the spherical type duplication cysts of the jejunum using DBE. From April 2007 to May 2009, 214 enteroscopic studies were carried out, and 165 patients underwent entire digestive tract examinations. We found other two cases of tubular duplications of the ileum.

Although it is a rare entity, malignant transformation has been reported, mostly to adenocarcinoma[11]. From our patient, we have found out that jejunal duplication may induce the growth of lipoma, hence causing symptoms of intestinal obstruction. We consider that surgical removal of the lesion in asymptomatic cases is necessary because of the risk of malignant degeneration.

Multiple lipomas within jejunal duplication cysts are rare and difficult to diagnose before surgery. This case highlights intestinal lipoma as an uncommon cause of adult intussusceptions, which should be included in the differential diagnosis of small intestinal obstruction. Such a case found by DBE is an example to remind doctors to be vigilant in diagnosing patients with intestinal obstruction and in choosing appropriate examinations.

Abstract

The exact cause of rectal prolapse is not well addressed, but it is often associated with long standing constipation, advanced age, chronic obstructive pulmonary disease and some neurological disorders. Rectal prolapse is usually only a symptom, which needs a focus on discovery of the underlying pathology or disorder. Three different clinical presentations are often combined and called rectal prolapse. Rectal prolapse can be divided into full thickness rectal prolapse where the entire rectum protrudes beyond the anus, mucosal prolapse where only the rectal mucosa (not the entire wall) prolapses, and internal intussuception wherein the rectum collapses but does not exit the anus. Although constipation and straining may contribute to the development of rectal prolapse, simply correcting these problems may not improve the prolapse once it has developed. There are many different approaches to surgical correction of rectal prolapse.

INTRODUCTION

Rectal prolapse, or procidentia or "complete prolapse", defined as a protrusion of the rectum beyond the anus[1], occurs at the extremes of age. In the pediatric population, the condition is usually diagnosed by the age of 3 years, with an equal sex distribution. In the adult population, the peak incidence is after the fifth decade and women are more commonly affected, representing 80%-90% of patients with rectal prolapse[2].

Complete rectal prolapse is a disabling condition that has been reported even since the Egyptian and Greek civilizations[3]. Throughout the history of medicine, multiple approaches to the treatment of rectal prolapse have been described. In the past century, its management has evolved a great deal due to accumulation of knowledge obtained from physiologic investigations and follow up of surgical series[4].

The surgical landscape for rectal prolapse has expanded to include new treatment modalities such as the STARR and EXPRESS procedures. However, technical details, indications, and outcomes of these new techniques are not widely understood. The richness and variety of choices for treating rectal prolapse may become confusing, and controversial. These are some reasons why many surgeons feel the need for one articulate and comprehensive volume that present an all inclusive understanding of the pathophysiology of rectal prolapse and state of the art surgical treatment for it.

BOOK REVIEW

The book "Rectal Prolapse: Diagnosis and Clinical Management, edited by Altmomare and Filippo Pucciani (PP 206), illustrated, Springer Publisher (2008), ISBN:

978-88-470-0688-6" offers a body of information encompassing all aspects of rectal prolapse. It deals comprehensively with the various forms of prolapse, including external prolapse, rectal intussusception and genital prolapse. The chapters on etiology and investigation set out in detail the present position regarding the value of the advancements in clinical practice. Beside the classic operations, new treatment modalities such as the STARR and EXPRESS procedures are dealt with, and their indications are considered in relation to the clinical presentation and the various other options. Function following surgery receives considerable attention and the difficult problems that may be posed by recurrence after surgery are dealt with. Non surgical treatment and rehabilitation are also described in this book.

The book, is beautifully laid out with very clear illustrations including high quality operative color photographs and line drawings. It is important not only to surgeons but also to gastroenterologists, physiologists and radiologists.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in tahe field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Contents

Weekly Volume 16 Number 18 May 14, 2010

EDITORIAL

2195 Serum response factor: Look into the gut
Modak C, Chai J

2202 Systematic review and meta-analysis of *Saccharomyces boulardii* in adult patients
McFarland LV

TOPIC HIGHLIGHT

2223 Understanding mechanisms of the pathogenesis of nonalcoholic fatty liver disease
Basaranoglu M, Kayacetin S, Yilmaz N, Kayacetin E, Tarcin O, Sonsuz A

ORIGINAL ARTICLE

2227 Cost-utility of molecular adsorbent recirculating system treatment in acute liver failure
Kantola T, Mäklin S, Koivusalo AM, Räsänen P, Rissanen A, Roine R, Sintonen H, Höckerstedt K, Isoniemi H

2235 Apoptotic activity of caged xanthones from *Garcinia hanburyi* in cholangiocarcinoma cell lines
Hahnvajanawong C, Boonyanugomol W, Nasomyon T, Loilome W, Namwat N, Anantachoke N, Tassaneeyakul W, Sripa B, Namwat W, Reutrakul V

2244 Roux-en-Y gastric bypass promotes expression of PDX-1 and regeneration of β-cells in Goto-Kakizaki rats
Li Z, Zhang HY, Lv LX, Li DF, Dai JX, Sha O, Li WQ, Bai Y, Yuan L

2252 Expression of interleukin 6 in brain and colon of rats with TNBS-induced colitis
Wang K, Yuan CP, Wang W, Yang ZQ, Cui W, Mu LZ, Yue ZP, Yin XL, Hu ZM, Liu JX

BRIEF ARTICLE

2260 Covered nitinol stents for the treatment of esophageal strictures and leaks
Bona D, Laface L, Bonavina L, Abate E, Schaffer M, Ugenti I, Siboni S, Carrinola R

2265 Insulin resistance is associated with hepatocellular carcinoma in chronic hepatitis C infection
Hung CH, Wang JH, Hu TH, Chen CH, Chang KC, Yen YH, Kuo YH, Tsai MC, Lu SN, Lee CM

Contents

World Journal of Gastroenterology

AIM AND SCOPE		
FLYLEAF	I-VII	Editorial Board

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

Serum response factor (SRF) is a transcription factor that regulates many genes involved in cellular activities such as proliferation, migration, differentiation, angiogenesis, and apoptosis. Although it has only been known for about two decades, SRF has been studied extensively. To date, over a thousand SRF studies have been published, but it still remains a hot topic. Due to its critical role in mesoderm-derived tissues, most of the SRF studies focused on muscle structure/function, cardiovascular development/maintenance, and smooth muscle generation/repair. Recently, SRF has received more attention in the digestive field and several important discoveries have been made. This review will summarize what we have learned about SRF in the gastrointestinal tract and provide insights into possible future directions in this area.

INTRODUCTION

Although serum response factor (SRF) has only 25-year history, its studies have been exponentially grown in several fields including smooth muscle structures, cardiac functions, cellular stress responses and cell motility. SRF is a ubiquitously expressed transcription factor, therefore, its role should be far beyond these areas. When the new millennial dawn broke, we opened a new field for SRF research-digestive system. Several important discoveries have been made in different parts of the system ever since, which foresee a bright and fruitful future for this area. This article is to provide you an update in this line of study and hopefully point you to the right direction.

HISTORY OF SRF

SRF was first identified by Treisman[1] in 1986 based on a previous observation in Greenberg's lab that resting cells responded to serum addition with a rapid activation of *c-fos*[2]. He discovered that it is SRF that initiates the immediate response of c-fos to serum or any other growth factors by binding to a short DNA sequence-serum response element (SRE), which is located about 300 bp upstream of the *c-fos* gene transcription initiation site. Since then, SRE has been identified in as many as 300 human genes, accounting for 1% of our entire genome[3,4]. Although it has only been known for a little over two decades, studies on SRF have been populated exponentially. Last year, more than a hundred SRF studies were documented in PubMed; and ten papers have already been published within the first 3 wk of this

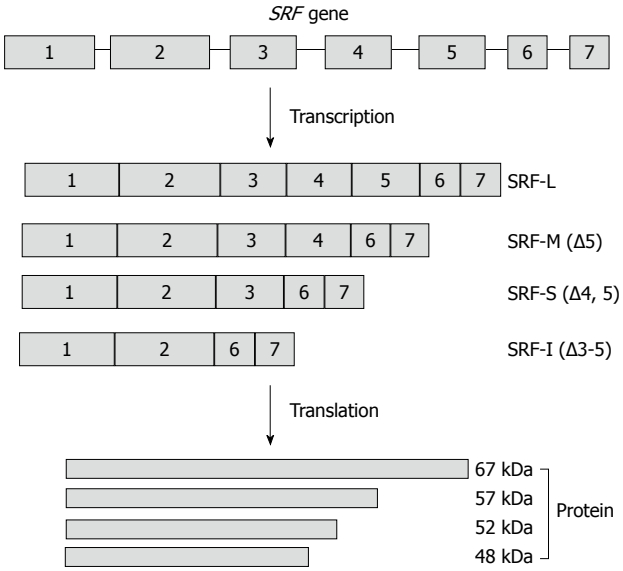

Figure 1 Serum response factor (SRF) splice variants (adapted from Chai and Tarnawski 2002).

year. Most of the published SRF studies deal with its functions in muscle structures or in the regulation of immediate early genes. However, SRF is a ubiquitously expressed protein and thus its role must be far beyond these areas. A few years ago, we started to look for SRF in the gastrointestinal (GI) tract[5,6]. After that, several other groups have expanded our mission. Today, there have been over 20 studies published dealing with SRF in the digestive system.

BIOCHEMISTRY OF SRF

The human *SRF* gene was mapped to chromosome 6p21.1. It is 10607 bp long and contains 7 exons. In both humans and mice, SRF can be expressed in different isoforms due to alternative splicing and some of them appear to display tissue specificity[7]. For instance, SRF-S, which lacks both exon 4 and 5 (Δ4, 5), has only been detected in the aorta, while SRF-I, which is the shortest isoform (missing exon 3, 4 and 5), is specific to embryonic tissues. On the other hand, SRF-M, which lacks only exon 5, has been shown to be a dominant negative mutant (Figure 1).

Full length SRF protein, which is approximately 67 kDa, was shown to contain three distinct domains: a SRE DNA binding domain, a transactivation domain and multiple phosphorylation sites[8]. The DNA binding domain, which also serves for dimerization and interaction with accessory factors, has been highly conserved throughout evolution, showing a 93% homology between fruit flies and humans[9]. Phosphorylation at Serine 103, which is immediately adjacent to the DNA binding domain, was shown to greatly enhance SRF activity[10]. Since its initial discovery in response to serum, SRF has also been shown to be activated by several other agents, including mitogens, cytokines, specific oncogenes and extracellular stimuli, such as antioxidants, UV light and microgravity, to name a few[7].

FUNCTIONS OF SRF

SRF is a master regulator of many cellular activities including cell growth and differentiation, cell migration, and apoptosis. To date, approximately 300 human genes have been estimated to contain an SRE element and be activated by SRF, accounting for 1% of our entire genome[3,4]. Early transgenic data provided important clues to some of the biological functions of SRF, best elucidated through its role in the myocardium, which is of mesodermal origin, and to the different optimal expression requirements during embryogenesis and adulthood[7]. More specifically, mice with complete SRF knockout (*srf* -/-) failed to develop the mesoderm and died in the uterus between E8.5 and E12.5[11], indicating that SRF is required for early embryonic development. For this reason, we generated a mouse model with overexpression of a dominant mutant SRF in cardiac-specific tissue and found that SRF is required for myofiber generation as the transgenic mice died within the first week after birth due to heart dysfunction[12]. For comparison, we also developed a mouse model with overexpression of functional SRF in the heart and demonstrated that too much SRF can cause hypertrophic cardiomyopathy as the mice died of heart failure within 6 mo[13]. From these initial studies, SRF emerged as a key factor in muscle development and maintenance. In addition, modulation of SRF expression levels seems to play an important role in its different functions, where high expression levels of SRF are required for proper embryonic development, while lower levels may be more beneficial in adulthood[7].

IMPLICATIONS IN GI

Even though SRF had been studied extensively in other tissues since its discovery, its role in the GI system was not examined for at least another decade. The earliest record that can be found was in 1997, and this study showed that SRF binding activity is elevated in the liver of Long-Evans Cinnamon rats (animal model of Wilson's disease) compared to Wistar rats[14]. In addition, several other studies used GI-derived cell lines purely as tools to investigate the molecular properties of SRF[15-17]. However, the role of SRF in the GI system was not studied directly until eight years ago, when our group found that SRF is not only expressed in smooth muscle structures, such as muscularis mucosa and muscularis propria, which are of mesoderm origin, but it is also found at intermediate expression levels in the mucosal epithelium, which is of endoderm origin[5]. Since then, work from our group and others has provided important information about the role of SRF in both normal and pathological processes in the digestive system (Table 1).

Esophagus

Esophageal ulcers occur with a great geographical variation, from 5%-10% in the United States to approximately 80% in some Iranian regions. Its causes are also different with locations. While gastroesophageal reflux is its main cause in

Table 1 Identified roles of SRF in the GI tract

GI system	Process involved	Molecules associated	GI disorder associated
Esophagus	Myofibroblast differentiation[19]	TGFβ, ILK	Ulcer
Stomach	Angiogenesis[20]	VEGF, Rho-actin, MEK-ERK	Ulcer
Stomach	Re-epithelialization, muscular structure restoration[6]	Actin, immediate-early genes	Ulcer
Stomach	*H. pylori* activates SRF[21,22]	CagA, villin	Intestinal metaplasia
Intestine	Smooth muscle contraction[23,24]	Smooth muscle actin, smooth muscle myosin, smoothelin, F/G actin	Intestinal obstruction, CIPO
Colon	Alternative splicing, cell survival[26]	SRFΔ5, K-ras	Colon cancer
Liver	Cell cycle; hepatocyte proliferation/survival[29,30]	IGF-1	Liver injury
Liver	Cell proliferation, cell cycle, apoptosis[33]	E2F1	Hepatocellular carcinoma
Liver	Cell invasion[31]	E-cadherin, β-catenin	Liver metastasis
Pancreas	Cell proliferation[32]	Pro-inflammatory cytokines	Pancreatitis

SRF: Serum response factor; GI: Gastrointestinal; TGF: Transforming growth factor; VEGF: Vascular endothelial growth factor; MEK: Mitogen-activated protein kinase kinase; ERK: Extracellular regulated kinase; *H. pylori*: *Helicobacter pylori*; IGF: Insulin-like growth factors; CIPO: Chronic intestinal pseudo-obstruction.

the United States, in Europe it is alcohol consumption and in the Middle East it is the diet[18]. Healing of esophageal ulcers proceeds *via* a series of overlapping events[19], and among them myofibroblasts make a significant contribution to the wound closure. Our study[20] showed that when the connective tissue has been damaged and denuded of its epithelium during gastrointestinal ulceration, fibroblasts next to the ulcer area are activated to become myofibroblasts and participate in restoration of new epithelial continuity and extracellular matrix. Over-expression of SRF promotes myofibroblast differentiation both *in vitro* and *in vivo*, and knockdown of SRF was sufficient to prevent TGFβ-induced myofibroblast differentiation.

Stomach

While there are nearly 50 thousand publications dealing with stomach ulcers, we are the only researchers to have investigated the role of SRF in this common gastric disorder. SRF is a master regulator of cytoskeleton dynamics and cell motility. We showed that injury-activated SRF is critical to gastric ulcer healing, as local knockdown of SRF severely impairs angiogenesis[21], an essential process for any wound healing. Without SRF, VEGF, the most powerful activator of angiogenesis, loses its power. Since angiogenesis is a key step in tumor progression by providing growing tumors with oxygen and nutrient supplies through generation of new blood vessels, these findings may have potentially important therapeutic implications for blocking cancer progression. We also demonstrated[6] that over-expression of SRF in gastric epithelial cells or in smooth muscle cells (*in vitro*) as well as in gastric tissue (*in vivo*) can promote cell proliferation/migration, and thereby promotes re-epithelialization and restoration of smooth muscle structures damaged by ulcers. These findings show great potential for therapeutic applications of SRF.

While the normal processes of angiogenesis and wound healing have been indirectly associated with promoting cancer when inappropriately activated, therefore making SRF a potential oncogenic factor through its regulation of these processes and a promising target for cancer therapy as elucidated before, more direct evidence that SRF can indeed promote cancer progression has come from different sources. First, two different groups linked SRF to *Helicobacter pylori* (*H. pylori*), a gram-negative bacterium that colonizes the human gastric mucosa, resulting in stomach disorders such as chronic gastritis, peptic ulcers and gastric adenocarcinoma. Of the two *H. pylori* strains, the type one strain contains the cag pathogenicity island (PAI), which confers greater virulence compared to the type two strain lacking PAI. Hirata *et al*[22] showed that transfection of the *CagA* gene into gastric epithelial cells greatly increases *in vitro* binding activity of SRF to SRE. Up to that point, CagA protein had only been linked to cellular cytoskeletal rearrangements, after activation through tyrosine phosphorylation. Therefore, aside from linking SRE and SRF to *H. pylori* pathogenesis, their findings are important for understanding *H. pylori* infection mechanisms by identifying a novel, phospho-tyrosine-independent, mode of action of CagA protein. Rieder and co-workers later built on the story by identifying villin as a new target of SRF and showing that SRF mediates Helicobacter-induced intestinal metaplasia in the stomach through villin[23]. Intestinal metaplasia is a premalignant precursor lesion to several organs of the GI tract, including stomach, gall bladder and pancreas, and it is defined by the presence of intestine-like cells expressing enterocyte-specific markers, such as villin.

Intestine

The importance of SRF in the GI tract was further strengthened by the work from Angstenberger and collaborators on smooth muscle contraction[24], which is a key feature of proper GI function. They developed an inducible mouse model where SRF was conditionally knocked out only in the smooth muscle cells of adult mice. The mutant mice developed symptoms of ileus paralyticus due to impaired contraction of intestinal smooth muscle and died 2 wk after the induction. Through more detailed phenotypic and gene expression analysis of the same model system in collaboration with Feil, Mericskay and co-workers confirmed[25] that SRF plays a central role in maintaining proper smooth muscle function and they provide an inducible mouse model that could have potential implications for studying chronic intestinal pseudo-obstruction

(CIPO). The mutant mice displayed cachexia and autopsy showed severe dilation of the intestinal tract associated with food stasis, indicating impairment of GI motility due to smooth muscle deficiency. Defects in GI contractile function can lead to a variety of different disorders, from common and relatively benign, to more rare but potentially life-threatening. CIPO falls in the latter category, sharing similarities with chronic heart failure in the way that the "intestinal pump" is no longer able to effectively maintain tone and coordinate transit of intestinal contents through the luminal cavity, resulting in intestinal pseudo-obstruction[26]. Several different mechanisms have been associated with CIPO, with both genetic and environmental causes, surely making CIPO a multifactorial condition. Nonetheless, these two studies clearly show that SRF plays a central role in proper smooth muscle contraction and that it could be an important model system to shed new light on CIPO. In their editorial commentary, De Giorgio *et al*[26] propose three different models by which SRF ablation could affect intestinal contractility: "(1) loss of smooth muscle cell (SMC) contractile phenotype due to an impairment of the contractile apparatus; (2) degeneration of SMCs with synthetic phenotype; and (3) derangements of pathways (including neuronal ones) implicated in smooth muscle contraction"[26]. Even though results from Angstenberger and Merickskay made it possible to define these models of potential SRF involvement in CIPO, there is definitely room for additional work, especially in regard to the latter model, which is only briefly touched upon by Merickskay and co-workers.

Colon

As we mentioned earlier, SRF can be expressed in different isoforms in a tissue-specific manner due to alternative splicing of mRNA. Patten and co-workers[27] found that the predominant SRF isoform expressed in colon cancer cell lines derived from poorly differentiated tumors (WiDr, HCT116, LoVo, and SW480) is SRFΔ5, the dominant negative isoform lacking the transactivation domain (Figure 1). SRFΔ5 is normally expressed at high levels in terminally differentiated tissues, such as brain, heart, skeletal muscle, testes and liver. However, aberrant elevated expression of SRFΔ5 in other tissues has been associated with medical conditions. For instance, while normal lungs express very low levels of SRFΔ5, hypoplastic lungs, in which stretching is compromised, express elevated levels of this isoform[28]. Similarly, over-expression of another isoform (SRFΔ4,5), which was shown to inhibit transcription of SRF-dependent cardiac muscle genes, was detected in failing hearts[29]. Patten and co-workers also showed that stable expression of SRFΔ5 in rat intestinal epithelial cells (IEC-6) significantly increased cell survival rates, possibly by preventing apoptosis, as cell proliferation was improved only after day 11 and mRNA levels of pro-apoptotic caspase 3 and Fas were significantly reduced.

Liver

It is known that the liver has a remarkable capacity to regenerate after injury. Latasa *et al*[30] found that SRF and its targeted immediate early genes are rapidly activated after partial hepatectomy in rodents. When they knocked down SRF in the liver, this regeneration capacity was severely damaged. Following up on this idea, Sun and co-workers showed that liver-specific SRF knockout in mice led to a lower survival rate, where surviving animals were generally smaller with smaller and poorly functioning livers[31]. Through gene array analysis of SRF deficient liver fragments, they also showed that loss of SRF prevents activation of a wide array of genes, particularly those involved in IGF-1-mediated cell cycle control, consistent with impaired normal growth, as well as several genes specific to hepatocyte function, suggesting that adequate amounts of SRF are indispensable for proper liver development and function. These findings highlight the different expression requirements for SRF in tissue development and proper function/maintenance, stressing the importance of optimal SRF expression. While cell culture and animal models on the mechanistic action of SRF are quite informative, correlation with cancer progression in patients is often determined based on differential expression between normal and tumor tissue, which implies that up- or down-regulation of a particular gene (or aberrant expression of a different variant of the gene) confers more tumorigenic potential to the cell and is therefore maintained. In this respect, Choi *et al*[32] recently reported that nuclear SRF staining, which was not detected in normal colon tissue, was found in 37% of primary colon cancers and 60% of metastatic liver cancer. A similar trend was observed with loss of E-cadherin expression (14% and 33%, respectively), while nuclear expression of β-catenin was significantly higher in primary tumors (56%) compared to normal tissue but did not change much in metastatic tumors. Loss of E-cadherin expression and translocation of β-catenin from the membrane to the nucleus are fundamental steps in disruption of epithelial cell junctions and acquisition of more migratory potential, which are at the basis of tumor metastasis. Therefore, to follow up on these observations, Choi and co-workers showed that over-expression of SRF in colorectal carcinoma cells enhanced cell motility and invasiveness, paralleled by loss of E-cadherin protein expression and increase in non-phosphorylated (nuclear) β-catenin expression, suggesting that SRF promotes liver metastasis through its action on membrane E-cadherin and β-catenin[32]. The oncogenic potential of SRF overexpression in the liver was further confirmed a few weeks ago by Farra and co-workers. Building on recent advances in the field mentioned above, they decided to test the effectiveness of SRF depletion in highly and poorly differentiated hepatocellular carcinoma (HCC) cell lines[33]. Their studies, which highlight differences in response to SRF depletion among different grades, also support a therapeutic role for SRF depletion against HCC, for which there are currently no effective treatment options[33].

Pancreas

The importance of SRF to the early phase of liver regeneration is well established by the studies above, however, they also noticed that the liver without SRF can still

Table 2 Tools and models available to study SRF functions in GI

Tool	Purpose	Model
SRF in pcDNA3.1, His[6,21]	SRF over-expression	Gene therapy
SRF antisense sequence[21,33]	SRF down-regulation (siRNA)	Gene depletion
Srf Flex1 mice[35]	Conditional *in vivo* SRF deletion	Gene depletion
Srf loxP mice[30]	Conditional *in vivo* SRF deletion	Gene depletion
CreER T2 mice[36]	SMS tissue expression	CIPO
AlfpCre mice[31]	Hepatocyte tissue expression	Liver function
K5-Cre mice[37]	Squamous epithelial expression	Esophagus, foregut
Fabp/Cre mice[38]	Conditional gut tissue expression	Small/large intestine
H. pylori[23]	*H. pylori* infection in human cell lines (*in vitro*) or mice (*in vivo*)	*H. pylori* gastric diseases

develop. A similar situation was also observed in the pancreas. Miralles and co-workers[34] found that mice with conditional inactivation of SRF in the pancreas had normal development of both the exocrine and endocrine pancreas. However, after weaning, these mice developed profound morphological alterations of the exocrine pancreas, which were reminiscent of severe pancreatitis. In these mice, massive acinar injury and pro-inflammatory cytokines release led to complete destruction of the exocrine pancreas and its replacement by adipose tissue.

SRF-related tools and models

Over the last decade, work on SRF in GI tissues has been very productive not only in establishing that SRF plays very important roles in both normal and pathological processes, but also in generating good *in vivo* model systems and validated tools to further study the role of SRF in both normal development and function as well as in related pathologies of the GI tract. Here we provide a detailed list of SRF-related models and tools (Table 2), which will be very useful for further exploration of the role of SRF in the GI tract. These include His-tagged SRF cDNA in the pcDNA3.1 mammalian expression vector under the control of the cytomegalovirus (CMV) promoter[6,21] for SRF over-expression in cell culture and gene therapy *in vivo*; validated antisense SRF oligonucleotide sequences to knock down SRF protein expression[21,33]. Two different conditional SRF knockout mice[30,35], are also available to generate temporally and spatially controlled SRF deletion in any desired tissue through the use of tissue-specific Cre mice. Currently, these have been combined with SMS[36]- and hepatocyte[31]-specific Cre mice to generate the CIPO model[24] and the liver model[30] of SRF, respectively. However, they hold unlimited potential for selectively knocking out SRF in any desired tissue or subpopulation of the GI tract to further study the role of SRF in GI. For instance, crossing either the SRF knockout line to the previously described K5-Cre transgenic mice[37] would allow SRF deletion in the basal cell layers of various squamous epithelial cells, including esophagus and foregut. Moreover, the Gordon group also generated two different Cre model systems (Fabp), which allow for intestinal-specific deletion, which could also be temporally controlled in a doxycycline inducible manner by combining Fabp-rtTA and tetO-Cre with the desired gene knockout[38].

FUTURE DIRECTIONS IN GI

Results summarized here clearly show that SRF is an important factor in mediating both normal and pathological conditions in the GI tract and that different optimal expression levels are associated with its various functions, while deviations from those levels can result in more or less severe pathological conditions. The flip side of that is that SRF could also lend itself to favorable manipulation, if we only know what it is. While providing initial clues and identifying several factors involved in SRF-mediated functions (Table 1), the findings above still leave the door wide open for additional exciting work in these areas of research, with particular focus on the finer details of SRF signaling in the individual processes, which would also help us understand how and when SRF could be a good therapeutic target.

Role of SRF in gastrointestinal ulcers

For instance, we show that SRF is critical for mediating the wound healing process in both gastric[6] and esophageal[21] ulcers, primarily through its role in VEGF-induced angiogenesis in a Rho A/actin- and ERK pathway-dependent manner[21]. However, while both Rho A and ERK have been linked to SRF induction[6], little is known about how they may interact with each other, and more studies along those lines would be extremely helpful in defining the role of SRF in this process and its potential as a therapeutic agent.

Role of SRF in gastrointestinal motility disorders

Similarly, preliminary work by Angstenberger and Merickskay established a very useful model for studying CIPO and trying to find possible treatment options for this very serious condition. Insights for new avenues into this area of research can be found in the three models proposed by de Giorgio[26]. In addition, given the emerging central role of SRF in the contractile function of the intestine, findings in this area of research may also be useful for less severe but more common dysfunctions of the intestine, with wider applications.

Role of SRF in *H. pylori* and related pathologies

H. pylori infection appears to be another major new area of research for SRF function in GI pathogenesis, which definitely deserves more attention. Here too, Hirata[22] and

Rieder[23] outline initial important connections between SRF and *H. pylori* infection and premalignant transformation, however, more work is needed to fill in the gaps. For instance, SRF activation appears to be involved in a new mode of CagA-mediated infection, which, given its more virulent nature, deserves more attention. In addition, work from Rieder and co-workers provide a preliminary molecular framework to further study the signaling components involved in SRF-mediated metaplasia[23]. A better understanding of the signaling cascades downstream and upstream of SRF in this process would be very useful for both diagnosis and more informed development of therapeutic options. For this purpose, the different *H. pylori* strains optimized for either *in vivo* mouse studies or human cell culture studies[23] (Table 2) will be particularly useful.

Role of SRF in gastrointestinal cancers

Overall, several lines of evidence seem to point to a positive role of SRF in various GI cancers, such as its role in driving angiogenesis[21], in mediating *H. pylori* infection[22] and metaplasia[23], which is strongly associated with gastric cancer, and in promoting cell proliferation in HCC[33] and liver metastasis by weakening cell adhesion[32]. Findings by Patten and co-workers that an SRF variant is also over-expressed in colon cancer in response to a very prevalent colon cancer mutation[27] further highlight the potential importance of SRF in cancer. However, the fact that the variant is a known dominant negative form of SRF makes its role in cancer progression not as straight forward. This is particularly true given findings by Choi and co-workers, which clearly correlate SRF over-expression with colon cancer progression[32]. However, since Patten and co-workers never examined actual tumor tissues and, while SRFΔ5 expression was indeed elevated in response to K-ras activation, full-length SRF was also elevated and generally showed much stronger expression than SRFΔ5 itself, more work may be required to better understand the actual prevalence of this variant in colon cancer and, most importantly, its role in cancer progression. More solid evidence to support the conclusions by Patten and co-workers could have important implications for diagnosis, identifying the SRFΔ5 variant as a possible marker for colon cancer. Since it is much easier to routinely collect small biopsies from colon tissue than from some other tissues, this could potentially be an effective way for better risk assessment.

Role of SRF in normal and abnormal liver function

Recent findings reported here suggest an interesting role for SRF in liver function. While Sun and co-workers show that not enough SRF is bad for proper liver function and regeneration after injury[31], studies from Ferra and co-workers raise hopes for effective HCC therapy through SRF depletion[33]. Clearly, this is just the tip of the iceberg and more data is needed in this area of research, where SRF is once again taking a leading role.

CONCLUSION

The last decade has been very prolific in shifting the focus of SRF from its role in the myocardium to a central role in the gastrointestinal tract as well. As summarized here, SRF is critical for proper development and function of most GI tissues in what appears to be a dose-dependent manner, as changes in its expression pattern have been implicated in various GI pathologies from intestinal motility disorders to cancer. In addition, both SRF gene therapy and SRF antisense expression to either elevate or inhibit normal SRF expression have been shown to hold great promise as potential therapeutic agents to either promote ulcer healing or inhibit cancer-related angiogenesis, respectively. Therefore, while great advances have already been made in this field, more in depth studies are warranted to fully understand its various roles and optimal expression requirements in all these processes, with particular attention to the potential therapeutic efficacy of SRF gene therapy and antisense expression where modulation of SRF expression may prove beneficial. For instance, SRF gene therapy could promote wound healing and liver regeneration, while its antisense expression could be more beneficial in slowing down cancer progression, where its effect on VEGF-mediated angiogenesis may play a central role in its dual applications.

Abstract

This article reviews the evidence for efficacy and safety of *Saccharomyces boulardii* (*S. boulardii*) for various disease indications in adults based on the peer-reviewed, randomized clinical trials and pre-clinical studies from the published medical literature (Medline, Clinical Trial websites and meeting abstracts) between 1976 and 2009. For meta-analysis, only randomized, blinded controlled trials unrestricted by language were included. Pre-clinical studies, volunteer studies and uncontrolled studies were excluded from the review of efficacy and meta-analysis, but included in the systematic review. Of 31 randomized, placebo-controlled treatment arms in 27 trials (encompassing 5029 study patients), *S. boulardii* was found to be significantly efficacious and safe in 84% of those treatment arms. A meta-analysis found a significant therapeutic efficacy for *S. boulardii* in the prevention of antibiotic-associated diarrhea (AAD) (RR = 0.47, 95% CI: 0.35-0.63, $P < 0.001$). In adults, *S. boulardii* can be strongly recommended for the prevention of AAD and the traveler's diarrhea. Randomized trials also support the use of this yeast probiotic for prevention of enteral nutrition-related diarrhea and reduction of *Heliobacter pylori* treatment-related symptoms. *S. boulardii* shows promise for the prevention of *C. difficile* disease recurrences; treatment of irritable bowel syndrome, acute adult diarrhea, Crohn's disease, giardiasis, human immunodeficiency virus-related diarrhea; but more supporting evidence is recommended for these indications. The use of *S. boulardii* as a therapeutic probiotic is evidence-based for both efficacy and safety for several types of diarrhea.

INTRODUCTION

Probiotics have become increasingly popular in the US and are rapidly reaching levels of use in Europe and Asia, which have a longer history of use compared with the US[1-3]. Probiotics are "live microorganisms, which when administered in adequate amounts, confer a health benefit on the host"[4,5]. In one survey, of 435 users of dietary supplements, 50% of women and 33% of men reported use of probiotics[6].

Probiotics are generally recommended to help strengthen host systems and assist in recovery from certain diseases. However, the general public and many health care providers are still confused about how best to utilize probiotics and which ones are effective for specific diseases. There are several challenges in choosing the appro-

priate probiotic; including the wide diversity of probiotic strains, quality control of commercially-available probiotic products and the degree of evidence-based trials for each disease and probiotic. The ability of an organism to be an effective probiotic has been found to be strain-specific and microbial organisms are defined by their genus, species and strain. For example, *Lactobacillus rhamnosus* (*L. rhamnosus*) GG is a specific bacterial strain, which has been shown to be an effective probiotic for several diarrheal diseases, but other strains within the *L. rhamnosus* species may not be an effective probiotic. Similarly, other species under the same genus (*Lactobacillus*) may not be effective probiotics[7]. To add to this confusion, probiotic products are available in diverse forms: capsules of freeze-dried or lyophilized cultures, heat-dried culture supernatants, mixed in diary food (such as yogurts, cheese, milks, or ice cream) or other food (kefir, chocolate, wafers)[8-10]. The variety of probiotic products are also regulated under different guidelines according to the ways of use (food, dietary supplement, over-the-counter use or prescription). Different standards of quality assurance also vary with the type of product, indication for use and country.

Despite these challenges, the awareness of probiotics as a therapeutic modality has increased dramatically and the frequency of peer-reviewed randomized clinical trials have kept abreast with the global interest in this innovative method of therapy. Numerous probiotic strains have been investigated for clinical efficacy, including multiple bacterial strains: *Lactobacilli*, *Bifidobacteria*, *Streptococci*, Clostridia and fungal strains: *Saccharomyces boulardii (S. boulardii), S. cerevisiae*, and *Monascus purpureus*[11-13]. This review examines evidences for Saccharomyces probiotics and focuses on *S. boulardii* for the efficacy and safety of different diseases in adult patients. The two goals of this study were: (1) to provide guidance for clinicians and patients on how to appropriately use *S. boulardii* as a therapeutic probiotic and (2) to review the evidence for efficacy and safety of *S. boulardii* for various disease indications in adults.

SEARCH STRATEGY FOR SYSTEMATIC REVIEW

PubMed, Medline and Google Scholar were searched for articles unrestricted by language from 1976 to 2009. Three on-line clinical trial registers were searched: Cochrane Central Register of Controlled Trials (www.cochrane.org), metaRegister of Controlled Trials (www.controlled-trials.com/mrct) and National Institutes of Health (www.clinicaltrials.gov). Secondary and hand searches of reference lists, other studies cross-indexed by authors, reviews, commentaries, books and meeting abstracts also were performed. Search terms included: *Saccharomyces boulardii*, probiotics, yeast, diarrhea, risk factors, randomized controlled trials, placebo-controlled, and associated author names. Search strategies were broad-based initially, then narrowed to the disease of interest to increase the search network[14].

META-ANALYSIS

If sufficient numbers of clinical trials (> 5) were found on one type of disease indication, a meta-analysis for the efficacy of *S. boulardii* was performed; otherwise a systematic review was done. The procedure for the meta-analysis followed standard meta-analysis methodology with clearly delineated parameters, *a priori* inclusion and exclusion criteria and standardized data extraction[15,16]. Abstracts of all citations and retrieved studies were reviewed and rated for inclusion. In some cases, only published abstracts from meetings were available. Published abstracts from meetings were included to lessen the potential for publication bias due to failure to publish negative findings. Information on study design, methods, interventions, outcomes, adverse effects and treatments was extracted from each article using a standardized extraction table. When necessary, authors were contacted for data not reported in the original article.

The primary objective of the meta-analysis was to determine the overall efficacy of *S. boulardii* within one specific type of disease indications (antibiotic-associated diarrhea, *Clostridium difficile* disease, traveller's diarrhea, irritable bowel syndrome, inflammatory bowel disease or other types of diarrhea). Inclusion criteria were: randomized, controlled, blinded efficacy trials in humans published as full articles or meeting abstracts in peer-reviewed journals. Exclusion criteria included: use of other strains of Saccharomyces (such as *Saccharomyces cerevisiae*) or other strains of probiotics, pre-clinical studies, safety studies, case reports or case series, phase I studies in volunteers, reviews, duplicate reports, trials of unspecified treatments, uncontrolled studies, prebiotic treatments only (no living organisms) or insufficient data in article.

To estimate pooled relative risks across studies, heterogeneity between and within trials was evaluated using the Cochrane Q and I^2 tests[17]. Relative risks (RR) and 95% confidence intervals (CI) were calculated using the Mantel-Haenszel method. The relative risks of responding to *S. boulardii* therapy were pooled using a random-effect model if significant heterogeneity was found or a fixed-effect model if the studies were homogenous. P values less than 0.05 were considered significant. Analyses were performed using Stata software version 9.2 (Stata Corporation, College Station, Texas). A funnel scatterplot and Begg's test were used to assess publication bias[18].

HISTORY

Saccharomyces cerevisiae strains have a long history of use in baking and brewing preparation, but have only infrequently been investigated for probiotic properties[19,20]. Another closely related strain, *S. boulardii*, was discovered by a French microbiologist, Henri Boulard in 1920 when he was in IndoChina searching for new strains of yeast that could be used in fermenting processes. He was a visitor during a cholera outbreak and noticed that some people who did not develop cholera were drinking a special tea. This tea was

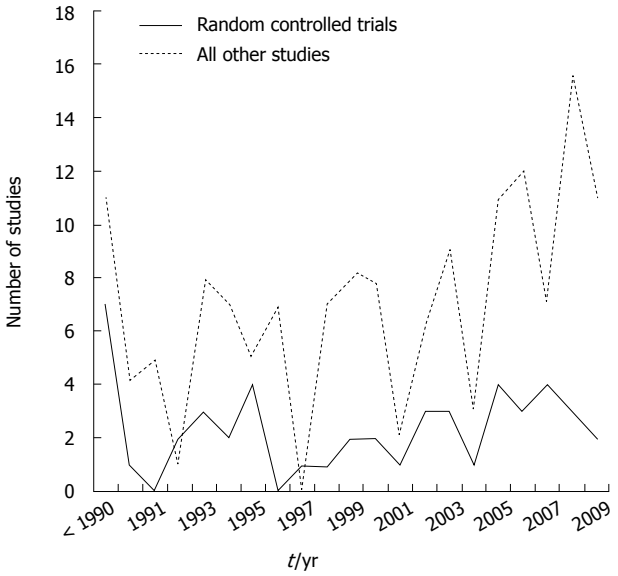

Figure 1 Frequency of peer-reviewed publications on *Saccharomyces boulardii* from 1976 to 2009.

made by taking the outer skin from a tropical fruit (lychee and mangosteens) and cooking them down to make tea. He succeeded in isolating the agent responsible. It was a special strain of yeast he named "*Saccharomyces boulardii*". The patent for this yeast was bought by Laboratories Biocodex in 1947, which began researching and manufacturing protocols. As shown in Figure 1, interest in this strain has increased, as reflected by the increasing number of scientific publications, encompassing both pre-clinical papers in mechanisms of action, animal models of efficacy, pharmacokinetics, early studies in safety and dose-ranging. In addition, there are currently 53 randomized controlled clinical trials, encompassing 8475 subjects, investigating the safety and efficacy of *S. boulardii* in pediatric and adult patients spanning several disease indications, of which 43 (81%) found significant efficacy for *S. boulardii*. As a recent review article on the efficacy of *S. boulardii* was published for pediatric indications[21], this study will focus on *S. boulardii* use in adult patients. There have been 27 randomized controlled trials, with 31 treatment arms testing *S. boulardii* in adult patients for a variety of diseases and most (84%) found a significantly protective efficacy of this probiotic. There have been only a few randomized clinical trials using other strains of Saccharomyces probiotics, which will be discussed later in this paper.

TAXONOMY

Probiotics may be either bacterial or yeast microbes. Yeast probiotics, such as *S. boulardii*, are different from bacterial probiotics (different physiologic structures, large in size, do not acquire antibiotic-resistant genes and are not affected by antibiotics)[12]. Not only is there a confusing array of probiotic products on the global market, but the taxonomy of Saccharomyces strains has been debated[22]. One strain has received considerable discussion about its valid nomenclature[23,24]. It was originally named *S. boulardii* in the 1950's. Advances in typing methods opened a debate as to whether this strain should be reclassified as a strain of *S. cerevisiae* or remain a separate species. Early work using PCR electrophoretic karotyping or rRNA sequencing methods reported that *S. boulardii* was indistinguishable from other strains of *S. cerevisiae*[24,25]. Newer metabolomic tools (microsatellite polymorphism analysis and retrotransposon hybridization analyses) show that *S. boulardii* has a unique clustering different from other strains of *S. cerevisiae*[26-28]. In addition, *S. boulardii* differs from other strains of *S. cerevisiae* by several metabolic and genetic characteristics[29,30]. *S. boulardii* persists longer in gnotobiotic mice models (10 d) compared with rapid clearance of other strains of *S. cerevisiae* (< 1 d)[31]. *S. boulardii* is also different physiologically and metabolically and its optimum growth temperature is 37℃ and it is resistant to low pH and is tolerant to bile acids; whereas other strains of *S. cerevisiae* prefer cooler temperatures (30-33℃) and do not survive well in acid pH ranges[32-34]. *S. boulardii* can be distinguished from other strains of *S. cerevisiae* by advanced typing methods, by differences in metabolism and physiology and by the ability to have anti-pathogen effects (as discussed in the mechanisms of action section).

GUIDELINES FOR CHOOSING APPROPRIATE PROBIOTICS

Challenges in providing guidance to patients regarding the appropriate choice of probiotic include the wide diversity of available products on the market, variances in quality control, stability and formulations in those products, and the requirement to match the type of probiotic with the disease indication. The efficacy of probiotics have been shown to be both strain-specific and disease-specific[11,35,36].

Product to product variation

There are many different Saccharomyces products available commercially. Table 1 lists some examples of products that contain *S. boulardii*, sold as probiotics either as lyophilized or heat-dried powders in capsules, or as one of several strains in a probiotic mixture in capsules or in liquid beverages[12,13,21,37-66]. The quality of these products from different sources have been found to vary. Choosing a probiotic product from a manufacturer with a regulated quality control program is a sound policy. Unfortunately, many of the products available commercially may lack regulated quality control programs. Studies of other probiotics have found a wide diversity in both quality and contamination in products available on the Internet[67]. Marcobal *et al*[68] tested 14 commercial probiotics in the US and found 93% were incorrectly labeled (57% had contaminants and 36% did not list strains on the label). Masco *et al*[69] tested 58 different probiotic products from Europe, UK, Asia, Japan and Canada and found only 38% had the dose stated on the label and 29% did not contain strains listed on the label. Not all products were found to have high standards of manufacture and quality control, as only some conform to Good Manufacturing Practices.

Table 1 Examples of commercially available probiotics containing "*Saccharomyces boulardii*"

Product name	Probiotic strain	Manufacturer	Stable at room temp[1]	Facility certified	Strain confirmed	Colony forming unit (cfu) per mg capsule or mL	Original strain-specific studies	Degree of clinical evidence[2]
Single strain								
Florastor® (US) Perenterol® (Germany) Reflor® (Turkey) Ultra-Levure® (Asia)[3]	*S. boulardii* lyo	Biocodex (France)	Yes	EU GMP	Microsatellite sequency polymorphism [28,29]	5×10^9/ 250 mg	Multiple [37-62]	A
SB+MOS	*S. boulardii*	Jarrow Formulas (Los Angeles, CA) and Gnosis (Italy)	No	EU GMP	Not stated	1.5×10^9	One study[63]	C
Saccharomyces boulardii	*S. boulardii*	Kirkman (Oregon)	No	GMP	DNA fingerprint	3×10^9/ 150 mg	None	F

Saccharomyces boulardii	*S. boulardii*	Klaire Labs (Reno Nevada)	No	GMP ISO 9001	Ribotyping	3×10^9/ 150 mg	None	F
In mixtures of probiotics								
Protecflor® (Canada) Erce Flora® (Belgium)	*S. cerevisiae boulardii* CNCM I-1077) + *L. rhamnosus* + *L. acidophilus* + Bifido. strain	Institut Rosell-Lallemand (Quebec, Canada)	Not stated	Canadian GMP	Not stated	10^9/2 mL	Two studies [64,65]	D
MitoMix®	*S. boulardii* and *Pediococcus acidilactici*	Imagilin Technology (Maryland)	Yes	Not stated	Not stated	2.3×10^9/ capsule	One study[66]	D
Primal Defense™	*S. boulardii* with 13 other strains[4]	Garden of Life (FL)	Yes	Not stated	No (only certified "organic")	Total 1×10^9 per 410 mg	None	F
Pro-Bio Defense™	*S. boulardii* + 7 other strains[5]	Kirkman (OR)	No	GMP	DNA fingerprint	Total: 2×10^{10}/cap, no data on SB cfu	None	F
ABX Support™	*S. boulardii* + *L. rhamnosus* + *Bifido. bifidum* + *Bifido. breve*	Klaire Labs (NEV)	No	GMP ISO 9001	Ribotyping	5×10^9/ 300 mg	None	F
Kombucha fermented tea	*S. boulardii* + *L. bacterium* + blue-green algae	Millennium Products, Inc.	No	No	Not stated	1×10^9 per 16 oz.	None	F

[1]Products not stable at room temperature require refrigeration, probably heat-dried. Products stable at room temperature are typically packaged in blister packs and are lyophilized; [2]Degree of evidence: A = at least two randomized, controlled clinical trials in patients; B = one randomized controlled clinical trial in patients, C = case reports, uncontrolled randomized trials or open safety/kinetic studies in patients or volunteers, D = *in vivo* animal model or *in vitro* studies only, E = expert opinion only, F = no direct evidence; [3]A few examples, Biocodex has over 40 brand names worldwide; [4]Other strains in Primal Defense include: 11 strains of *Lactobacilli* (*L. acidophilus, L. bulgaricus, L. lactis, L. plantarum, L. casei, L. lactis, L. leichmannii, L. brevis, L. caucasicus, L. fermenti*, *L. helveticus* and 1 strain each: *Bifidobacterium bifidum, Bacillus subtilis, Bacillus lichenformis*); [5]Other strains in Pro-Bio Defense include: 5 strains of *Lactobacilli* (*L. plantarum, L. rhamnosus, L. acidophilus, L. casei, L. bulgaricus*) and *Bifidobacterium lactis* and *Streptococcus thermophilus*. GMP: Good manufacturing practices.

Although most products state they contain at least 1×10^9 *S. boulardii*/mg, independent assays have determined 50% of the products contained a dose less than on the label. In one study comparing six *S. boulardii* products, all had identical PCR typing profiles, but only 50% [Floratil (Merck), Flomicin (NeoChemical), and Florazin (Herald's)], had the same concentration identified on their label. One product [Lactipan (Sigma Pharm)] had 2×10^4 fewer *S. boulardii* than stated on its label. One product [Floratil (Merck)], had the highest concentration (1×10^9/100 mL) and maintained high levels (9.5×10^8) six months later[70]. Even if the label states it contains *S. boulardii*, a variation in efficacy may occur due to lower than stated dose or inaccurate strain composition. Four *S. boulardii* products were tested (along with one *S. cerevisiae* product) in Brazil. Only two (50%) of the *S. boulardii* products were protective in a *Salmonella typhimurum* mouse model (two *S. boulardii* products were ineffective, as well as the one *S. cerevisiae* product)[71]. Without access to specific quality control assays for commercially available probiotic products, the choice of a high quality product can be difficult. One method of selecting a probiotic product is to find a product in which the manufacturing company has sponsored original clinical trials, as this indicates a degree of commitment that may not be present in companies that do not sponsor original research. As shown in Table 1, only a few *S. boulardii* probiotic products are supported by original research. Although at present, most probiotic clinical trials are sponsored by private companies, as more national funding becomes available, this situation may change.

Stability

How the probiotic product is manufactured may significantly affect its potency over time (shelf-life). Probiotics may be available as lyophilized preparations, heat-dried preparations or contained in diary or drink food products.

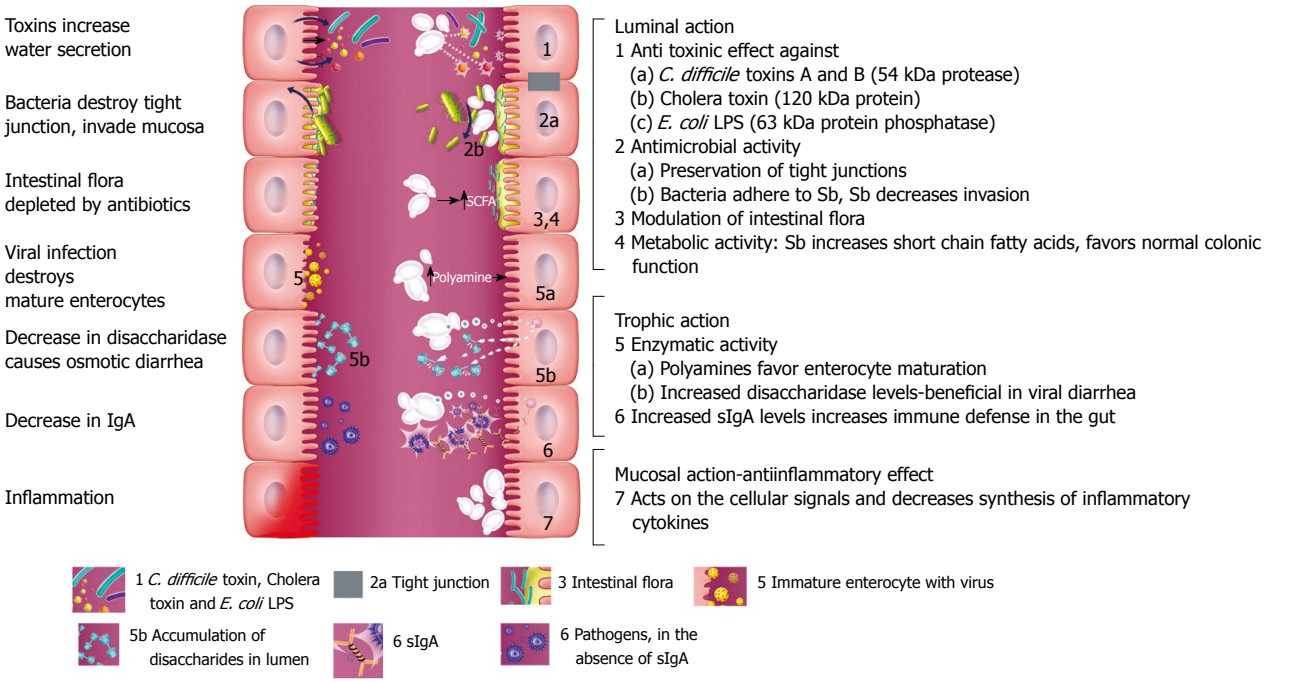

Figure 2 Schematic of intestinal tract, illustrating the different potential mechanisms of action of *Saccharomyces boulardii* (Sb). On the left, effects of different pathogenic microbes are depicted. On the right, seven different protective effects of *S. boulardii* are depicted. Within the lumin of the intestine, *S. boulardii* may degrade toxins of pathogens, interfere with pathogenic adherence, modulate normal microbiota and preserve normal intestinal physiology. *S. boulardii* may also indirectly restore normal short chain fatty acid (SCFA) balance. *S. boulardii* may also increase secretory IgA (sIgA) levels or act as an immune regulator by influencing cytokine levels.

S. boulardii is usually available in capsules of either lyophilized or heat-dried preparations. Heat-dried capsule products may be identified by their labels, which usually state that the products should be refrigerated after opening and they lose their potency rapidly. Lyophilized preparations of *S. boulardii* are stable over one year at room temperature, as long as it is protected from moisture[72]. Lyophilized products are stable at room temperature and have the advantage of portability and convenience and maintain high viability counts over prolonged periods. Heat-dried preparations are not stable at room temperature and must be refrigerated. A study of four *S. boulardii* products in Germany found a lyophilized product [Perenterol Forte (Thiemann)] outperformed three heat-killed *S. boulardii* preparations in terms of higher viable cells and quicker start-up times[73].

Single strain or probiotic "cocktails"

As shown in this review, all the randomized controlled trials using *S. boulardii* probiotics have utilized a single strain preparation. Although mixtures of probiotics, which may contain *S. boulardii*, are available on the market, no randomized controlled trials have been done showing that these mixtures are superior to the single stain preparations. Pre-clinical studies in animal models have found promising results in a probiotic mixture (*L. rhamnosus*, *L. acidophilus, Bifidobacterium* and *S. boulardii*) for reducing *E. coli* diarrhea in rats, but no human clinical trials have been performed with this mixture[65]. Another potential limitation to probiotic mixtures is antagonism between the different probiotic strains and conflicting mechanisms of actions that may tend to attenuate the therapeutic responses of the probiotic strains[74].

Mechanisms of action

An advantage of probiotics is that they are living organisms incorporating a delivery system (most probiotics survive to the target organ) bringing an arsenal of anti-pathogenic strategies into play. *S. boulardii* has several different types of mechanisms of action (Figure 2) which may be classified into three main areas: luminal action, trophic action and mucosal-anti-inflammatory signaling effects[8,75-77]. Within the intestinal lumen, *S. boulardii* may interfere with pathogenic toxins, preserve cellular physiology, interfere with pathogen attachment, interact with normal microbiota or assist in reestablishing short chain fatty acid levels. *S. boulardii* also may act as an immune regulator, both within the lumen and systemically.

Anti-toxin effects: *S. boulardii* may interfere with pathogenesis within the intestinal lumen by several mechanisms: either by blocking pathogen toxin receptor sites[78], or acting as a decoy receptor for the pathogenic toxin[79] or by direct destruction of the pathogenic toxin. Castagliuolo *et al*[80] found a 54 kDa serine protease produced by *S. boulardii* directly degrades *C. difficile* toxin A and B. The efficacy of other strains of Saccharomyces has also been investigated. Only *S. boulardii* produces a protease capable of degrading *Clostridium difficile* toxins and receptors sites on the enterocyte cell surface, unlike other strains of Saccharomyces[78,81]. Buts *et al*[82] found a 63 kDa phosphatase produced by *S. boulardii* destroys the endotoxin of pathogenic *E. coli*. Several investigators showed that *S. boulardii* could reduce the effects of cholera toxin and this may be due to a 120 kDa protein produced by *S. boulardii*[83,84].

Antimicrobial activity: *S. boulardii* is capable of directly or indirectly interfering with intestinal pathogens. *S. boulardii* may directly inhibit the growth of pathogens (such as *Candida albicans*, *Salmonella typhimurum*, *Yersinia enterocolitium*, *Aeromonas hemolysin*[43,85,86]). In animal models testing for the ability to inhibit pathogen growth, several studies using non-*S. boulardii* strains of *S. cerevisiae* did not find any effect unlike the protective effects of *S. boulardii*[31,70]. A few studies have tested other strains of *S. cerevisiae* and found promising results. Brandao *et al*[79] tested *S. cerevisiae* strain W303 in rats and found less histologic damage due to cholera toxin compared with saline controls, but no clinical trials have been done using this strain. *S. boulardii* may also act by enhancing the integrity of the tight junction between enterocytes, thus preserving intestinal integrity and function[87,88]. Wu *et al*[88] found less crypt hyperplasia and cell damage in a *Citrobacter rodentium*-induced mice model of colitis when mice were treated with 1×10^9 *S. boulardii* per day for 7 d. Garcia Vilela *et al*[62] found decreased intestinal permeability when patients with Crohn's disease were given *S. boulardii* (1.6×10^9/d for 4 mo) compared with placebo. *S. boulardii* has also been shown to reduce the translocation of pathogens in rat and pig animal models[64,89,90]. *S. boulardii* can also interfere with pathogenic attachment to intestinal receptor sites[88,91,92]. Gedek *et al*[93] also found that *S. boulardii* acts as a decoy by causing EPEC cells to directly bind to the surface of *S. boulardii* cells rather than enterocytes.

Cross-talk with normal microbiota: Newer techniques, including metagenomics and PCR probes have documented that a typical human may carry over 40 000 bacterial species in the collective intestinal microbiome[94]. The normal intestinal flora has many functions, including digestion of food, but the one that is most germane for this discussion is called "colonization resistance"[77,95,96]. This involves the interaction of many bacterial microflora and results in a barrier effect against colonization of pathogenic organisms. Normal microflora may act by competitive exclusion of nutrients or attachment sites, produce bacteriocins, or produce enzymes detrimental to pathogenic growth. Factors that disrupt this protective barrier, for example antibiotic use or surgery, results in host susceptibility to pathogen colonization until such time as the normal microflora can become re-established. Typically, it takes six to eight weeks for normal microbiota to recover after antibiotic exposure or disease resolution[97]. Probiotics are uniquely qualified to fit into this window of susceptibility and may act as surrogate normal microflora until recovery is achieved. *S. boulardii* has no effect on normal microbiota in healthy human controls[98,99]. In contrast, when *S. boulardii* is given to antibiotic-shocked mice or patients with diarrhea, normal microbiota is re-established rapidly[99,100].

Restoration of metabolic activities: *S. boulardii* has been shown to be able to increase short chain fatty acids (SCFA), which are depressed during disease, indicating altered colonic fermentation[98,101,102].

Trophic effects: *S. boulardii* can reduce mucositis[103], restore fluid transport pathways[84,101,104], stimulate protein and energy production[105], or act through a trophic effect by releasing spermine and spermidine or other brush border enzymes that aid in the maturation of enterocytes[106,107].

Immune response: *S. boulardii* may also regulate immune responses, either acting as an immune stimulant or by reducing pro-inflammatory responses. *S. boulardii* may cause an increase in secretory IgA levels in the intestine[56,108-110]. It has also been found associated with higher levels of serum IgG to *C. difficile* toxins A and B[111]. *S. boulardii* may also interfere with NF-κB-mediated signal transduction pathways, which stimulate pro-inflammatory cytokine production[76,112,113]. Chen *et al*[114] found that *S. boulardii* blocks activation of ERK1/2 and MAP kinases, which typically stimulate IL-8 production and cell necrosis in mice ileal loop models and in *in vitro* models. *S. boulardii* has also been shown to cause the trapping of T helper cells into mesenteric lymph nodes, thereby reducing inflammation[115].

Properties of *S. boulardii*

To be an effective probiotic, it must survive passage to its target organ (most commonly the colon). Organisms need to survive at body temperature (37℃), be resistant to stomach acids and bile acids, and exist in the competitive milieu of the intestinal tract. Probiotic strains of Saccharomyces have been shown to have these abilities. Although the optimal temperature for most strains of Saccharomyces range from 22-30℃, *S. boulardii* survives best at 37℃, giving it a unique advantage of being one of the few yeasts that do best at human body temperatures.

Survival to target sites: Although much of the oral dose is destroyed (usually stool levels are 100-1000 times lower than the oral dose), surviving oral doses have been found to be effective (usually at levels over 10^8 organisms/g stool)[116]. *S. boulardii* is resistant to antibacterial agents and survives gastric acidity[34,117]. In human volunteers, the concentration in the colon was found to be dose-dependent[118]. When *S. boulardii* was given to healthy volunteers at doses typically used therapeutically ($1\text{-}2 \times 10^{10}$/d), colonic levels were 2×10^8/g stool[118]. Few clinical trials using probiotics have documented the level of organisms present in the terminal site (colonic lumen in their study subjects). However, in one trial of patients with recurrent *C. difficile* infection (CDI) given *S. boulardii* (2×10^{10}/d) for 28 d, patients who had a subsequent CDI recurrence were found to have significantly lower numbers of *S. boulardii* (2×10^4/g stool) compared with those without recurrence (1×10^6/g stool)[119].

Pharmocokinetics: *S. boulardii*, when given orally, achieves steady-state concentrations within three days and is cleared within 3-5 d after it is discontinued[34,119,120]. Blehaut *et al*[120] gave eight healthy human volunteers *S. boulardii* (oral dose

of 5×10^9) for six days and followed them for time-to-clearance. They determined *S. boulardii* has half-life of 6 h, fecal steady-state concentrations (2×10^7/g) were reached by day 3 and the yeast was cleared after four days after administration. Klein *et al*[118] confirmed these findings in their studies of human volunteers and also found *S. boulardii* levels were 23 times higher in volunteers with disturbed intestinal microbiota (due to ampicillin exposure) than volunteers who were not given ampicillin. Elmer *et al*[121] found that some types of fiber (psyllium) increased *S. boulardii* levels by 22%, while other types of fiber (pectin) showed no effect.

CLINICAL EFFICACY: ACUTE DISEASES

S. boulardii probiotics have been tested for clinical efficacy in several types of acute diseases including antibiotic-associated diarrhea, *C. difficile* infections, *Helicobacter pylori* (*H. pylori*) disease, acute adult diarrhea, enteral nutrition-related diarrhea, and traveler's diarrhea.

Antibiotic-associated diarrhea

Epidemiology of antibiotic-associated diarrhea: The reported incidence of antibiotic-associated diarrhea (AAD) ranges from 12/100 000 to 34/100[122] depending upon the type of antibiotic, host factors (age, health status, *etc.*), etiology, hospitalization status and presence of a nosocomial outbreak. The highest frequency of AAD is found (26%-60%) during healthcare associated outbreaks, when susceptible patients are clustered by time, exposure and proximity[123]. Healthcare associated (hospital, long-term care facilities, nursing homes) outbreaks of AAD are to be expected because inciting agents (antibiotics), infectious agents and a susceptible patient population are intermixed. Historically, most cases of AAD were reported in hospitalized patients[122]. More recently, although AAD still occurs in hospital settings, rates of 6-33/100 have been reported in outpatient populations[124,125] and lower rates (12/100 000 to 14/100) in non-hospitalized adults[126,127]. Lower rates observed in outpatients may be due to their generally higher health status compared with hospitalized patients and also to the lack of exposure to nosocomial pathogens that commonly contaminate hospital environments. Higher incidences are still found in healthcare associated pediatric and adult patients (ranging from 5-34/100 patients)[128-130].

The clinical presentation of AAD may be mild (uncomplicated diarrhea) or more severe (colitis), or result in toxic megacolon or death[122]. The onset of AAD may occur while the patient is on antibiotics, but delayed-onset AAD is more common[122]. In addition, the onset of AAD may vary according to the type of antibiotic. Elmer *et al*[131] found a variable time of onset using the hamster model of AAD and different types of antibiotics. Early onset of AAD was associated with clindamycin, amoxicillin and ampicillin, while delayed-onset AAD was associated with erythromycin, ciprofloxacin and clarithromycin. Consequences of AAD may result in extended hospital stays, increased medical care costs and increased diagnostic procedures[122,132]. Prevention of AAD has rested on discontinuing the inciting antibiotic or switching to an antibiotic with a narrower spectrum of action, but there are no other current effective preventive measures for AAD.

Efficacy evidence for AAD: There have been ten randomized controlled trials in adults using *S. boulardii* for the prevention of AAD (Table 2)[37,42,44,54,55,58,133-136]. These studies have used a variety of daily doses, durations of treatment, length of follow-up and types of patient population. Of the ten controlled trials, 8 (80%) showed significant efficacy for the prevention of AAD compared with controls. One of the earliest trials by Adam *et al*[37], randomized 388 hospitalized patients to 200 mg of *S. boulardii* [4×10^9 cfu (colony forming units)/d] or placebo for seven days and found a significant reduction in AAD in the *S. boulardii group* (4.5%) compared with the controls (17.5%, $P < 0.05$). The protective effect of *S. boulardii* was confirmed in later studies. Monteiro *et al*[55] enrolled 240 patients receiving oral antibiotics and found significantly fewer patients randomized to *S. boulardii* developed AAD (15.7%) compared with placebo (27.7%, $P < 0.05$). McFarland *et al*[54] enrolled 193 hospitalized patients receiving beta-lactam antibiotics and randomized them to either 1 g of *S. boulardii* or placebo for the duration of the antibiotic treatment plus three additional days. Significantly fewer patients developed AAD while on the beta-lactam antibiotics or in the seven week follow-up period when given *S. boulardii* (7.2%, $P < 0.05$) compared with 14.6% of those given placebo. This study confirmed an earlier study by Surawicz *et al*[58] of 180 hospitalized adults randomized to either *S. boulardii* or placebo for the duration of their antibiotic treatment plus an additional two weeks. Of the 23% patients who were contacted 2-3 wk after the study, only one patient given placebo developed delayed-onset AAD. Only 9.5% of those randomized to *S. boulardii* developed AAD compared with 21.8% of those on placebo ($P < 0.05$). Can *et al*[135] enrolled 151 adult inpatients receiving various types of antibiotics, who were then randomized to *S. boulardii* or placebo for the duration of the antibiotic treatment. Significantly fewer patients (1.4%, $P < 0.05$) of those given *S. boulardii* developed AAD compared with the control group (9.0%). Three trials have been in conducted in patients with *H. pylori* infections receiving triple therapy (usually two antibiotics and an acid suppressor), which is associated with a high rate of AAD development. Duman *et al*[44] enrolled 389 patients with peptic ulcer or non-ulcer dyspepsia in nine hospitals in Turkey to observe if lower rates of side-effects could be achieved. This study compared 204 patients who received 1 g of *S. boulardii* (2×10^{10}/d for 2 wk) and triple therapy with 185 controls, who received only the triple therapy. Of the 389 patients, 376 completed the treatment phase and the four-week follow-up. Significantly fewer patients given *S. boulardii* (6.9%) developed AAD compared with the control group (15.6%, $P = 0.007$). Two other randomized controlled trials in adult patients receiving triple therapy for *H. pylori* infections were conducted and both showed a significant reduction in AAD for those treated with *S. boulardii*. Cremonini *et al*[134] randomized 85 *H. pylori* carriers to placebo, *L. rhamnosus* GG, *S. boulardii* or a mix of

[a]$P < 0.05$, probiotic *vs* controls. cfu: Colony forming unit; nr: Not reported; abx: Antibiotics.

L. acidophilus and *Bifidobacterium lactis* and found significantly fewer patients developed AAD in only the *S. boulardii* group (5%, $P = 0.05$) compared with placebo (30%). Cindoruk *et al*[42] also found a significant reduction in AAD in adult patients treated with triple therapy for *H. pylori* infections for those randomized to *S. boulardii* (14.5%, $P < 0.05$) compared with placebo (30.6%). None of these trials reported any adverse reactions associated with *S. boulardii*.

It is important to have a sufficiently long follow-up period (usually 4-6 wk after cessation of antibiotics) to capture delayed-onset AAD. Several studies have shown that AAD may occur in patients on antibiotics, but AAD may also be delayed for up to two months (in up to 38% of patients) after antibiotics are discontinued[54,129]. Most studies of AAD followed patients for 4-6 wk after antibiotic treatment to document delayed-onset AAD[42,44,135]. In contrast, Lewis *et al*[133] found no significant reduction in AAD in a study of 69 elderly patients randomized to 226 mg of *S. boulardii* (4.5×10^9 cfu/d) or placebo for 14 d. This failure may have been due to a flawed study design, in that patients were only followed while on antibiotics and no follow-up was done after antibiotics were discontinued. The study by Lewis *et al*[133] therefore, may have missed a significant number of AAD cases due to a too short follow-up period. Short or no follow-up after antibiotic exposure may explain why some studies[133,136] did not find a significant protective effect of *S. boulardii*[137]. No adverse reactions associated with *S. boulardii* were noted in any of these studies. No other strains of Saccharomyces have been found to be effective to prevent AAD.

Meta-analyses for AAD: The literature search yielded 322 unique citations on *S. boulardii*, of which 278 were excluded: non-*S. boulardii* studies ($n = 19$), reviews ($n = 84$), pre-clinical studies including animal models of efficacy, mechanism of action, *in vitro* assays or strain characterization ($n = 130$), case reports or case series ($n = 15$), and phase Ⅱ safety or pharmacokinetic studies ($n = 30$). Of the 44 randomized controlled trials with *S. boulardii* screened, 34 were excluded (pediatric populations, $n = 17$; or non-AAD indications in adults, $n = 17$) and 10 were included (AAD in adult populations). As significant heterogeneity was found among studies, a random effect model was used. The random effect model gave a $\chi^2 = 10.8$, $P = 0.29$, indicating that the heterogeneity was well controlled. A meta-analysis of the ten randomized, controlled trials in adults presented in this review found that *S. boulardii* was significantly protective for AAD (Figure 3), with a pooled relative risk of 0.47 (95% confidence interval 0.35-0.63, $P < 0.001$). Begg's test did not find any significant publication bias ($P = 0.93$), nor did the funnel plot (data not shown). The number needed-to-treat (NTT) to prevent one case of AAD was 10.2.

In the established medical literature, meta-analysis has been used to combine different probiotic strains and studies to obtain a pooled estimate of the efficacy of probiotics for the prevention of AAD. A note of caution, however, while most meta-analyses have concluded that probiotics are effective for preventing AAD[123,138], it is inappropriate to conclude that all probiotic strains are effective. The effectiveness of probiotics is strain-specific and disease-specific, so each probiotic strain must be linked to the disease. Most probiotic meta-analyses have focused on one type of disease indication with a variety of probiotic strains (e.g. antibiotic associated diarrhea)[123,138,139]. When there are sufficient numbers of clinical trials, a meta-analysis limited to one disease indication and one type of probiotic strain may reduce the heterogeneity of studies[140]. Szajewska *et al*[141] limited her meta-analysis to randomized controlled trials of one type of probiotic (*S. boulardii*) in adults and children.

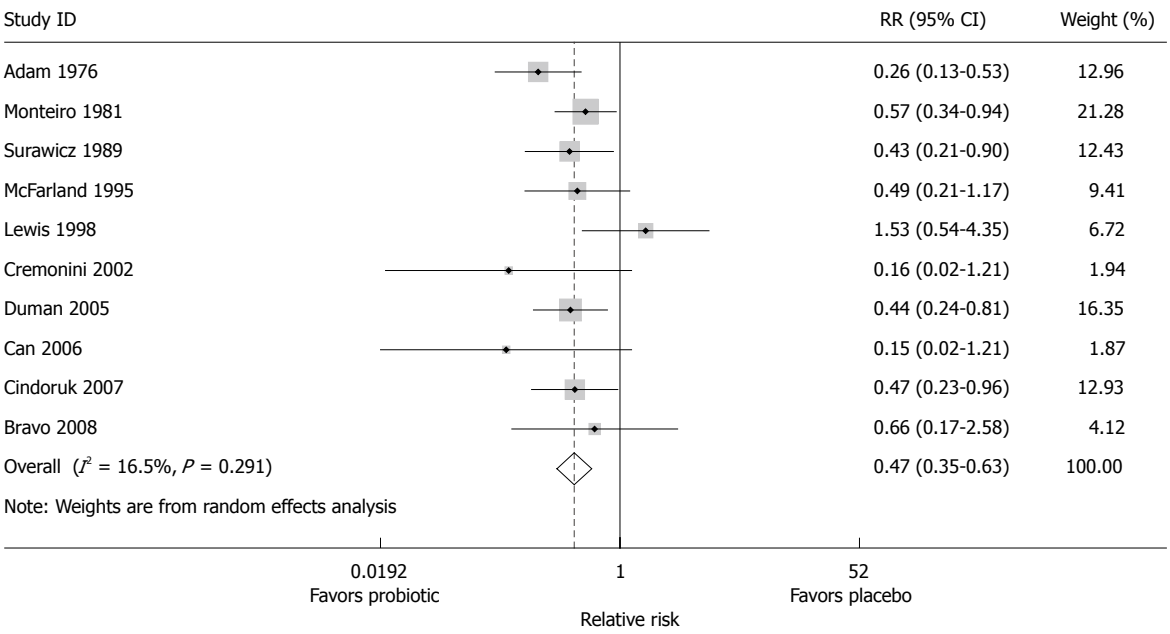

Figure 3 Forest plot of meta-analysis of ten randomized controlled trials measuring protective effect after treatment with *S. boulardii* or placebo for the prevention of antibiotic-associated diarrhea in adult patients. The x-axis depicts effect size, with black dot denoting the relative risk and the line indicating 95% CI, with the size of the grey box proportional to the study size. Relative risks to the left of RR = 1 denote study favored the probiotic, RR to the right denotes the study favors the placebo. Overall, pooled RR was 0.47 (0.35-0.63).

Pooling the results from five trials (involving 1076 subjects), a significantly protective effect of *S. boulardii* was found (pooled RR = 0.43, 95% CI: 0.23-0.78). As an alternative, some meta-analyses have done sensitivity analysis, separating out sub-groups by patient type (e.g. just adults or just children) or by type of probiotic strain[123,142]. One sensitivity analysis found with sufficient evidence that only two probiotic strains had significant efficacy for the prevention of AAD, i.e. *S. boulardii* and *L. rhamnosus* GG. However, *L. rhamnosus* GG probiotics may be contraindicated that this strain is susceptible when the patient is prescribed a type of antibiotic[123]. Although many meta-analyses have been done, pooling studies must be performed with these limitations in mind.

CDI

Epidemiology of *C. difficile* disease: For over two decades, *Clostridium difficile* infections continue to persist as a leading cause of nosocomial gastrointestinal illness[143-146]. The incidence rates of CDI have been increasing globally. In the US, CDI doubled to 301 200 cases from 2001 to 2005[147]. It is estimated that 450 000-750 000 CDI cases will occur per year by 2010 in the US[148,149]. Outbreaks of an emergent strain, BI/NAP1/027, caused large outbreaks of severe CDI with a high mortality rate in Canada between 2003-2005[150]. Studies have documented that CDI extends patients' hospital stays from 4 to 36 d[151-154]. In a study of 1034 CDI cases in Massachusetts in 2000, the average cost ranged from $10 212-$13 675/patient[155], leading to a nation-wide cost of $3.2 billion/year for CDI. There are only two standard antibiotics for CDI (vancomycin and metronidazole) and the response rate of metronidazole has been declining[152]. In addition, 20%-60% of patients may develop recurrent episodes of CDI despite additional antibiotic treatment. Although other investigational antibiotics are under development, no new antibiotics are superior to the two standard antibiotics.

Efficacy evidence for *C. difficile* disease: Probiotics may offer promise as an adjunctive therapy (given along with standard antibiotics vancomycin or metronidazole) for CDI. A meta-analysis of six randomized controlled trials of different probiotics (*S. boulardii*, *Lactobacillus rhamnosus* GG, *L. planatarum* 299v, and a mix of *L. acidophilus* and *Bifidobacterium bifidum* showed probiotics, in general, had a overall significant efficacy to prevent subsequent recurrences of *C. difficile* disease (RR = 0.59, 95% CI: 0.41-0.85, P = 0.005)[123]. However, due to limited number of trials, no meta-analysis was conducted for one probiotic strain.

S. boulardii shows promise for *C. difficile* infection control at several levels: it produces a 54-kDa serine protease that directly degrades *Clostridium difficile* toxins and also directly destroys the colonic receptor site for *C. difficile*[76], *S. boulardii* increases the immune response to *Clostridium difficile* toxins A and B[108], and animal models of *C. difficile* disease respond to this yeast. In addition, case reports or small case series of patients with recurrent *C. difficile* diarrhea treated with *S. boulardii* showed improvement. Toothaker and Elmer found that significantly fewer (51%) hamsters challenged with *C. difficile* died if given *S. boulardii* (5% solution) compared with the saline controls (80%)[156]. Subsequent studies confirmed this efficacy in other animal models: gnotobiotic mice[41,157,158], rats[89,103], and turkeys[159]. Since 1989, case reports or small case series have reported that patients with recurrent CDAD were either cured or improved by *S. boulardii* treatment[40,59, 160,161].

Table 3 Randomized controlled trials for the treatment of *C. difficile* disease using *S. boulardii*

Ref.	Treatment groups	Study population	Daily dose: cfu/d (mg/d)	Duration of treatment (wk)	Follow-up (wk)	*C. difficile* recurrence in probiotic group	*C. difficile* recurrence in placebo group
McFarland *et al*[53]	*S. boulardii vs* placebo	124 adult patients on varied doses of vancomycin or metronidazole; recurrent and initial CDAD cases; 3 referral sites, US	3×10^{10} (1000 mg)	4	4	15/57 (26.3%)[a]	30/67 (44.8%)
Surawicz *et al*[60]	*S. boulardii vs* placebo	168 adult patients recurrent CDAD; on vancomycin (2 g/d, $n = 32$) or V (500 mg/d, $n = 83$) or M (1 g/d, $n = 53$); 4 referral sites, US	2×10^{10} (1000 mg)	4	4	V (2 g/d) 3/18 (17%)[a]; V (500 mg/d) 23/45 (51%); M (1 g/d) 13/27 (48.1%)	V (2 g/d) 7/14 (50%); V (500 mg/d) 17/38 (44.7%); M (1 g/d) 13/26 (50%)

[a]$P < 0.05$, probiotic *vs* controls. V: Vancomycin; M: Metronidazole.

There was a case report[162] and two small case series with 3-4 patients[163,164] with recurrent *C. difficile* disease who seemed to have responded to *S. cerevisiae* administration. However, since no comparison groups or controls were used, there is no foundation to claim the efficacy of other strains of Saccharomyces for *C. difficile* disease.

There have been two randomized, double blinded, controlled trials for the use of *S. boulardii* and antibiotics for patients with recurrent *C. difficile* disease (Table 3)[53,60]. In a multisite, randomized, double-blinded, placebo-controlled trial of 168 patients with recurrent *C. difficile* disease, standard antibiotics were combined with *Saccharomyces boulardii* or placebo[60]. Three antibiotic regimens were used for 10 d: either high-dose vancomycin (2 g/d), low-dose vancomycin (500 mg/d) or metronidazole (1 g/d). Then either *S. boulardii* or placebo (1 g/d for 28 d) was added to the antibiotic treatment. The patients were followed up for two months for subsequent *Clostridium difficile* recurrences. A significant decrease in recurrences was observed only in patients treated with the high-dose vancomycin and *S. boulardii* treatment (16.7%) compared with patients who received high-dose vancomycin and placebo (50%, $P = 0.05$). There were no significant reductions in recurrence rates in either the low-dose vancomycin or metronidazole treatment group, regardless if *S. boulardii* was used. No serious adverse reactions were noted in any of these patients. By the end of the antibiotic treatment, only high-dose vancomycin completely cleared *C. difficile* toxin from the colon, low-dose vancomycin and metronidazole could not clear the toxin. A subsequent investigation of 163 patients with recurrent CDI confirmed this finding[165]. In this study, stool samples were assayed at the end of antibiotic treatment to determine if there was a difference in toxin clearance by the type or dose of antibiotic. Treatment with high-dose (2 g/d) of vancomycin completely cleared *C. difficile* toxin, but 11% of those treated with lower doses of vancomycin and 41% treated with metronidazole were positive for *C. difficile* at the end of antibiotic treatment. *S. boulardii* may be more effective if complete *C. difficile* toxin clearance is achieved before sole reliance upon the yeast probiotic is required.

An earlier randomized, controlled double-blinded study had also found efficacy of the combination treatment using a standard antibiotic (vancomycin or metronidazole) and *S. boulardii* for patients with *C. difficile* disease[53]. This study did not control the dose or duration of either vancomycin or metronidazole (it was under the physician's discretion), but randomized patients to either *S. boulardii* (1 g/d) or placebo for 28 d. All patients were followed up for two months for subsequent recurrences. Approximately half of the enrolled patients had their first episode and half had recurrent *C. difficile* disease. Twenty-six percent of the 57 patients given *S. boulardii* had a recurrence of *C. difficile* disease, which was significantly fewer as compared with 45% of the 67 given placebo ($P < 0.05$). The strongest effect was found in the 60 patients with recurrent *C. difficile* disease; significantly fewer patients (35%) given *S. boulardii* had a recurrence compared with 65% of patients given placebo ($P = 0.04$). Two adverse reactions were associated with *S. boulardii* (thirst and constipation). No randomized controlled trials using stains of *S. cerevisiae* for this disease were found in the literature.

H. pylori

Epidemiology of *H. pylori*: *H. pylori* colonizes the gastric mucosa and usually induces a chronic, asymptomatic carrier state, but some people may develop gastroduodenal ulcers as a result. Carriage of *H. pylori* is a risk factor for developing gastric lymphoma or adenocarcinoma in later life. The prevalence of *H. pylori* carriage is 50%-80% worldwide[166,167]. Standard treatment for *H. pylori* involves a two-week course of triple therapy (usually clarithromycin, amoxicillin and an acid suppressor such as lansoprazole or omeprazole), that also has gastrointestinal side effects.

Efficacy for *H. pylori*: *S. boulardii* induces morphologic changes in *H. pylori* cells consistant with cellular damage[21] and was shown to reduce 12% of *H. pylori* colonization in infected children in one trial[46]. Of four randomized controlled trials testing *S. boulardii* in *H. pylori* infections, two were in children[46,168] and two (Table 4) were in adults[42,134]. Cremonini *et al*[134] first explored the efficacy of probiotics to eradicate *H. pylori* in 85 asymptomatic carriers. They

[a]$P < 0.05$, probiotic *vs* controls; [1]Strain currently known as *S. boulardii*.

randomized patients to one of three probiotic treatments (*S. boulardii*, *L. rhamnosus* GG or a mixture of *L. acidophius* and *Bifidobacterium lactis*) or placebo for 14 d. All patients were treated with the triple therapy for the first week. By the end of the second week, eradication rates were similar for all groups (81% for *S. boulardii vs* 80% of placebo). A promising result of this study was a lower rate of antibiotic-associated diarrhea (5%) in all the probiotic groups compared with 30% of the placebo group. A subsequent study by Cindoruk *et al*[42] assessed *S. boulardii* for both eradication of *H. pylori* and the reduction of side-effects of the standard triple treatment. This study enrolled 124 adults with *H. pylori* dyspepsia in Turkey who were receiving the triple therapy and randomized to either 1 g of *S. boulardii* (2×10^{10}/d for 2 wk) or placebo. Patients were followed up for six weeks for side-effects and *H. pylori* clearance. Although there was no significant difference in *H. pylori* eradication (71% in *S. boulardii vs* 60% in placebo), significantly fewer patients randomized to *S. boulardii* reported epigastric distress (14.5%, $P < 0.05$) compared with placebo (43.5%), as well as lower global dyspepsia symptom scores. The frequency of AAD was also significantly reduced in those receiving *S. boulardii* (14.5%) compared with the placebo group (30.6%). These studies indicate that *S. boulardii* may not be effective in eradicating *H. pylori* itself, but it is effective in reducing the side-effects of the standard triple therapy.

Acute adult diarrheas

Epidemiology of acute adult diarrhea: Acute adult diarrhea is a broad classification for diarrhea that includes illnesses that may develop quickly, but are typically short-lived and are sporadic. The etiologies of acute adult diarrhea may include infectious agents (*Entamoeba histolytica*, *E. coli*, or Salmonella) or may be idiopathic. Diarrhea in adults occurring in outbreaks or due to other situations (antibiotic-associated diarrhea, *C. difficile*-associated diarrhea, traveler's diarrhea, inflammatory bowel disease or irritable bowel disease) are not included in this classification.

Clinical efficacy for acute adult diarrhea: Two randomized controlled trials using *S. boulardii* showed that this probiotic may be effective in treating acute diarrhea due to a variety of causes. Hochter *et al*[169] enrolled 92 German

adult outpatients with acute diarrhea and randomized them to *S. boulardii* (8×10^9/d) or placebo for eight days. By the third day, the 43 given *S. boulardii* had a significantly lower diarrhea severity score (5.5 ± 6.8, $P = 0.04$) compared with the 49 given placebo (6.7 ± 8.7). Mansour-Ghanaei *et al*[51] enrolled 57 patients with acute *Entamoeba histolytic* dysentery and treated them with *S. boulardii* (1.5×10^{10}/d for 10 d) or nothing (control). Both groups also received metronidazole and iodoquinol for 10 d. At the end of four weeks, all the patients given *S. boulardii* were cured compared with 19% of those not given the yeast. Unfortunately, the number of trials in this area is small and the etiologies were different in the two trials, so conclusions are limited. No randomized controlled trials using stains of *S. cerevisiae* for this disease were found in the literature.

Enteral nutrition-related diarrhea

Epidemiology of enteral nutrition-related diarrhea: Diarrhea is a common complication associated with enteral tube feeding and may result in a loss of nutrition in an already seriously ill patient. The frequency of diarrhea in enteral tube fed patients has been reported as high as 50%-60%[170] and complications may include life-threatening acidosis, increased morbidity and mortality and increased healthcare costs. Schneider *et al*[102] reported a significant increase in short-chain fatty acids in 10 enteral-fed patients receiving *S. boulardii* (1 g/d for 6 d) compared with 15 healthy controls.

Clinical efficacy for enteral nutrition related diarrhea: Three randomized, controlled trials have assessed the ability of *S. boulardii* to reduce diarrhea in patients receiving this type of nutritional intake (Table 4). Tempe *et al*[61] compared 40 enteral-fed patients randomized to either *S. boulardii* (1×10^{10}/d) or placebo for 11-21 d and found significantly fewer patients (8.7%) given *S. boulardii* developed diarrhea compared with placebo (16.9%). Schlotterer *et al*[171] randomized 18 patients with burns who were receiving enteral nutrition to *S. boulardii* (4×10^{10}/d) or placebo for 8-28 d. Those given *S. boulardii* suffered fewer diarrhea days (3/204 d, 1.5%) than those given placebo (19/208 d, 9.1%, $P < 0.001$). The efficacy of *S. boulardii* was confirmed in a later study of 128 intensive care unit (ICU) patients randomized to either *S. boulardii* (4×10^{10}/d) or placebo for 21 d[39]. Those given *S. boulardii* reported significantly fewer diarrheal days (7.7%) than those given placebo (12.7%). No adverse reactions associated with *S. boulardii* were reported in any of these three trials.

Traveler's diarrhea

Epidemiology of traveler's diarrhea: Traveler's diarrhea (TD) is a common health complaint among travelers; globally 12 million cases are reported every year[172]. Rates of TD range from 5% to 50%, depending upon the destination, with equatorial countries having the highest rates of TD. TD usually occurs as sporadic cases, but outbreaks of TD may occur in large groups traveling or located together (tourists on cruise ships, group tours, military personnel, disaster-relief groups). The etiologies of TD vary widely, but commonly include enterotoxigenic and entroaggregative *E. coli*, *Campylobacter jejuni*, *Salmonella typhimurum*, viruses (Norwalk or Rotavirus) or parasites (*Entamoeba histolytica*, *Giardia lamblia*). Traditional preventive measures including frequent handwashing, avoiding high-risk foods and water and ingestion of bismuth subsalicyclate showed only modest protection[173].

Clinical efficacy for TD: A meta-analysis of 12 randomized, controlled trials of various probiotics (including *S. boulardii*, *Lactobacilli* and mixtures of different probiotic strains) for the prevention of TD found a significant reduction in the risk of TD if probiotics were used (RR = 0.85, 95% confidence interval 0.79-0.91)[174]. Two randomized controlled trials have been done with *S. boulardii* that included a total of four different probiotic treatment arms (Table 4). Kollaritsch *et al*[175] enrolled 1231 Austrian tourists traveling to hot climates and randomized travelers to either of two doses of *S. boulardii* (250 or 500 mg/d) or placebo for 3 wk. The treatment was started 5 d prior to the trip and continued through the duration of the trip. Traveler's diarrhea developed in 43% given placebo and significantly fewer in those given the low-dose *S. boulardii* (34%) and the higher dose *S. boulardii* (32%). A second study by Kollaritsch *et al*[49] was done with 3000 Austrian tourists traveling to northern African, the Middle East and the Far East. Travelers were randomized to either 250 mg/d (5×10^9) *S. boulardii*, 1000 mg/d (2×10^{10}) *S. boulardii* or placebo, starting five days before leaving and throughout the duration of their trip (median of 3 wk). Only 1016 (34%) completed the study, but *S. boulardii* significantly reduced the incidence of traveler's diarrhea in a dose-dependent manner. Of the travelers given placebo, 39% developed diarrhea whereas only 34% of those given the lower dose and 29% of those given the higher dose of *S. boulardii* developed traveler's diarrhea ($P < 0.05$). No adverse reaction was noted by the travelers in either of these studies.

Bruns *et al*[176] tested *S. cerevisiae* Hansen CBS 5926 (Perenterol®, Germany) to treat travelers who had developed TD in Tunisia. Travelers with TD were randomized to 600 mg of *S. cerevisiae* (1×10^{10}/d) for five days or an active control treatment and the duration of their TD tracked. Of 60 enrolled, 43 completed the trial, but the duration of diarrhea was not significantly different between those given *S. cerevisiae* (2.1 d) and those given ethacridine-lactate and tannalbuminate (1.4 d). This strain is known as *S. boulardii* outside of Germany. No other randomized controlled trials have been done for the treatment of TD using *S. boulardii*. These limited numbers of studies indicate that probiotics may be more effective in preventing TD, rather than treating the diarrhea once it becomes symptomatic.

CLINICAL EFFICACY: CHRONIC DISEASES

S. boulardii has been tested for clinical efficacy in several types of chronic diseases including Crohn's disease, irri-

table bowel syndrome, giardiasis and human immunodeficiency virus (HIV)-related diarrhea.

Inflammatory bowel disease

Epidemiology of inflammatory bowel disease: inflammatory bowel diseases (IBDs) are chronic, immune-related inflammatory diarrheas, which include ulcerative colitis, pouchitis and Crohn's disease. The incidence of Crohn's disease varies by countries, with the highest incidences (8-66/100 000) found in Wales, New Zealand, Canada, Scotland, France, Netherlands, intermediate rates (4-7/100 000) in UK, USA, Europe, Australia, and the lowest rates (0.2-3/100 000) in South America, China, Korea, Japan[177]. In Crohn's disease, typically the lower small intestine and colon are the most affected organs. Symptoms include diarrhea, abdominal pain or cramping and loss of appetite. Unlike ulcerative colitis, lesions of Crohn's disease are deep and patchy and often involve thickened areas resulting in intestinal obstruction, which can be life threatening. Disruption of the intestinal wall also allows intestinal bacteria to translocate and incite the immune system. Complications of Crohn's disease are common, in that 40% of Crohn's patients report lower GI bleeding, intestinal obstruction, or perforation[178]. Lifetime risk for surgery in Crohn's patients is extremely high (70%-80%)[179]. Unfortunately, the cause of Crohn's disease is not known, so current therapies are directed at symptom relief. But 10%-60% suffer recurrences of Crohn's disease after treatment is completed[180].

Clinical efficacy for IBD: Guslandi *et al*[48] enrolled 25 adults with mild to moderate ulcerative colitis in a pilot study and treated them with a combination of mesalazine (3 g/d) and *S. boulardii* (1.5×10^{10}/d) for 4 wk. All of these patients had histories of poorly tolerated steroid courses. Most (68%) of the patients responded to the probiotic treatment. This study had a promising result, but the implications were uncertain as patients treated for only a short time, were not followed up for subsequent flare-ups of their disease and there was no control group in this pilot study. Garcia Vilelea *et al*[62] enrolled 31 patients with Crohn's disease in remission (at the time of enrollment). All patients continued their maintenance medications during the trial (mesalamine, azathioprine or others). Patients were randomized to either *S. boulardii* (2×10^{9}/d) for three months or placebo. Those treated with *S. boulardii* were found to have a significant reduction in colonic permeability compared with those given placebo, thus reducing the risk of translocation in these patients.

Two randomized controlled clinical trials have been done testing *S. boulardii* for patients with Crohn's disease (Table 5)[47,57]. Plein *et al*[57] randomized 20 patients with Crohn's disease to either 750 mg of *S. boulardii* (1.5×10^{10}/d) or placebo for seven weeks. All patients continued their maintenance medications during the trial. At the end of seven weeks, patients treated with *S. boulardii* were significantly improved (mean = 3.3 ± 1.2 stools/d, $P < 0.05$) compared with the placebo group (mean = 4.6 ± 1.9 stools/d). Guslandi *et al*[47] studied the effect of *S. boulardii* on the rate of Crohn's disease relapses in a study of 32 patients with Crohn's disease in Italy. Adults (23-49 years old) who were in remission were randomized to either 1 g of *S. boulardii* (2×10^{10}/d) and mesalamine (2 g/d) or mesalamine alone (3 g/d) for 6 mo. Significantly fewer patients treated with *S. boulardii* (6%, $P = 0.04$) relapsed than the control group (38%). No adverse reactions associated with *S. boulardii* were reported in any of these trials.

Crohn's disease is a challenging condition for clinical trials in that it is sporadic, has no defined etiology, has multiple measurable disease outcome and requires lengthy treatment and follow-up period. *S. boulardii* offers promise to this group of patients who are in need of a safe and effective therapy for this chronic condition. The probiotic protection seems to be strain specific. A study tested another strain of *S. cerevisiae* (Baker's yeast) in 19 adults with Crohn's disease, but found the disease was worse in those receiving this strain than in controls[181].

Irritable bowel syndrome

Epidemiology of irritable bowel syndrome: Irritable bowel syndrome (IBS) is a frequent disorder characterized by a triad of symptoms (bloating, abdominal pain, and intestinal transit disturbances). The prevalence of IBS is high (3%-20%) in the general population and IBS may account for 25%-50% of gastroenterologist practice[182]. Consequences of IBS include worse quality of life[183], higher health care costs ($1.7 billion in health care costs)[184], and higher incidences of depression[185].

Clinical efficacy for IBS: Standard treatments target symptom relief, but have not been more effective than placebo. IBS is a recent focus of probiotic clinical trials. A meta-analysis of 20 randomized, controlled trials (with 23 treatment arms) including 1404 subjects found a pooled relative risk (RR) for improvement in global IBS symptoms in 14 probiotic treatment arms (RR = 0.77, 95% CI: 0.62-0.94)[36]. One of those trials (Table 5) randomized 34 patients with IBS to *S. boulardii* (9×10^{9}/d) or placebo for four weeks[52]. A significant decrease in the daily number of stools was found in the *S. boulardii* group and 87.5% of this group reported their IBS had improved compared with 72% of the placebo group ($P < 0.05$). No adverse reactions were noted in this trial. More trials using *S. boulardii* for IBS are required.

Giardiasis

Epidemiology of giardiasis: This condition is characterized by long lasting diarrhea with symptoms ranging from mild to severe diarrhea, weight loss, abdominal pain and weakness. The incidence may be high in developing countries such as Colombia (13%) and lower in developed countries such as Germany (12/100 000)[186,187]. It is also found in people enjoying outdoor hiking and camping who drink contaminated untreated water that appears clean.

Clinical efficacy for giardiasis: Besirbellioglu *et al*[38] randomized 65 adults with giardiasis in Turkey to either *S. boulardii* (1×10^{10}/d) or placebo for 10 d. Both groups

Table 5 Randomized, controlled trials for chronic disease conditions using *S. boulardii*

Ref.	Treatment groups	Study population	Daily dose: cfu/d (mg/d)	Duration of treatment and follow-up	Outcome in probiotic	Outcome in controls

also received metronidazole for the same duration. Two weeks later, both groups reported a resolution of their diarrhea, but none of those on *S. boulardii* had detectable giardia cysts, while significantly more (17%) on placebo still carried giardia cysts.

HIV diarrhea

Epidemiology of HIV-related diarrhea: Patients infected with HIV are susceptible to a variety of diseases and may also develop chronic life-threatening diarrhea. The prevalence of diarrhea in HIV patients ranges from 50%-60% in developed countries and nearly 100% in developing countries[188].

Clinical efficacy for HIV-related diarrhea: A blinded, placebo-controlled dose-ranging study was done in 11 HIV positive patients who had chronic diarrhea[45]. *S. boulardii* was given at 1-3 g/d and six patients reported diarrhea was controlled while taking 3 g/d after one month, while lower doses of *S. boulardii* were not as effective. Patients with HIV-associated diarrhea seem to be one group that requires a higher than typical dose of *S. boulardii*. Saint-Marc *et al*[189] randomized 35 Stage IV AIDS adult patients with chronic diarrhea to either *S. boulardii* (3 g/d or 6×10^{10}/d) or placebo for one week (Table 5). Significantly more of those given *S. boulardii* (61%, $P = 0.002$) had their diarrhea resolved compared with placebo (12%) patients. *S. boulardii* was well tolerated by all HIV patients even treated with high doses of 3 g/d in these two studies.

SAFETY OF *S. BOULARDII*

The use of a living organism as therapy increases the potential risk in four general areas: transfer of antibiotic-resistance genes, translocation of the living organism from the intestine to other areas of the body, persistence in the intestines and the development of adverse reactions. The first three theorical concerns are of minimal impact on *S. boulardii*. Unlike other bacterial strains of probiotics, such as *Enterococcus faecium* and *Lactobacillus rhamnosus*, which have been shown to acquire antibiotic-resistance genes, *S. boulardii* has not developed any antibiotic or antifungal resistance[190,191]. Data from animal models shows reduced translocation with *S. boulardii* treatment[64,89], unlike other strains of *S. cerevisiae*[192]. As pharmacokinetic studies indicate, *S. boulardii* does not persist 3-5 d after oral ingestion is discontinued, so persistence is not a concern for this probiotic[118].

S. boulardii has been used as a probiotic since the 1950s in Europe and has been investigated in clinical trials worldwide. Safety and adverse event data collected during clinical trials, when patients are closely monitored for problems associated with the investigational treatment, has documented a remarkable safety profile of *S. boulardii* in adults. A wide diversity of adult patients have been followed up who were either randomized to *S. boulardii* as part of a clinical trial or were documented in case series or case reports for various disease indications (TD, $n = 1596$; AAD, $n = 958$; adult acute diarrhea, 156; enteral tube feeding, $n = 103$; IBD, $n = 66$; IBS, $n = 16$, HIV-related diarrhea, $n = 18$ and giardia infections, $n = 50$). These studies provide safety data for a total of 2963 adult patients and the only adverse reactions associated with *S. boulardii* was thirst (in 5 patients) and constipation (in 8 patients) in a trial of patients with *C. difficile* infections[53]. No case of *S. boulardii* fungemia has been reported in these diverse patient populations enrolled in clinical trials.

Infrequent cases of fungemia have been reported in case reports or case series in the literature. Most of the adult cases of *S. boulardii* fungemia are with serious co-

Table 6 Summary of recommendations for clinical use of *S. boulardii* in adults

Use for disease	Dose (mg/d)	Duration	Adjunct to	Strength of evidence[1]
Prevention of antibiotic associated diarrhea	500-1000	During antibiotics with additional 3 d to 2 wk after	Nothing	++++
Prevention of Traveler's diarrhea	250-1000	Duration of trip (3 wk)	Nothing	+++
Enteral nutrition-related diarrhea	2000	8-28 d	Nothing	++
H. pylori symptoms	1000	2 wk	Standard triple therapy	++
Treatment of *Clostridium difficile* infections	1000	4 wk	Vancomycin or metronidazole	+
Acute adult diarrhea	500-750	8-10 d	Nothing	+
Inflammatory bowel disease	750-1000	7 wk to 6 mo	Mesalamine	+
Irritable bowel syndrome	500	4 wk	Nothing	+
Giardiasis	500	4 wk	Metronidazole	+
HIV-related diarrhea	3000	7 d	Nothing	+

[1]Strength of evidence, + (weak, needs more randomized controlled trials) to ++++ (strong, efficacy and safety are evidence based from numerous large randomized controlled trials).

morbidities and have central venous catheters. Most cases responded well to treatment with fluconazole or amphotericin B[193]. Some cases developed fungemia, not from the direct ingestion of *S. boulardii* probiotics, but acquired the yeast from contaminated environmental fomites[194]. Fungemia from *S. cerevisiae* (non-boulardii strains) have also been reported and are similar to *S. boulardii* cases, but have poorer prognosis[195,196]. A challenge to determining valid incidence of fungemia is the lack of available advanced yeast identification assays which can distinguish *S. cerevisiae* from *S. boulardii*.

CONTRAINDICATIONS/PRECAUTIONS

Even though fungemia with *S. boulardii* is infrequent, it may be prudent to closely follow up the adult inpatients who are severely ill or in intensive care units and have central catheter for episodes of unexplained fever. Some studies have recommended not to give *S. boulardii* to immunosuppressed patients or those with central catheters to reduce this risk[108].

Unlike many bacterial probiotics, there are few drug or antibiotic interactions with *S. boulardii*. However, if patients are on anti-fungal medications, a staggered dose regime (at least 4 h apart) is suggested[45].

CONCLUSION

The use of *S. boulardii* as a therapeutic probiotic is supported by its mechanisms of action, pharmacokinetics, and efficacy from animal models and clinical trials. The overall safety profile for *S. boulardii* is beneficial. *S. boulardii* can be recommended for several diseases. Other strains of Saccharomyces may have probiotic properties, but clinical efficacy evidence for other strains are still deficient. Guidelines for the most effective use of *S. boulardii* are given in Table 6 and generally, the daily dose is typically $> 10^9$/d, the duration of treatment can vary from 7 d to 6 mo and it may be given alone or as an adjunctive treatment, depending upon the disease indication. *S. boulardii* is significantly effective for the prevention of AAD and prevention of TD. Trials also show evidence for *S. boulardii* in the reduction of side-effects of *H. pylori* treatment and the prevention of enteral nutrition-related diarrhea. More clinical trials are encouraged for the treatment of chronic diseases (Crohn's disease, irritable bowel syndrome and HIV-related diarrhea) and the prevention of *C. difficile* disease recurrences.

Abstract

A central issue in the understanding of the pathogenesis of nonalcoholic fatty liver disease is the problem of the underlying mechanisms which are not fully understood. In the setting of excessive central adiposity, insulin resistance is the major underlying cause of fat accumulation in hepatocytes. Because of the difficulties with human trials, several animal models have been developed for this purpose mainly characterized as follows: genetically disturbed or murine fatty liver, methionine-choline deficient diet fed or murine steatohepatitis, and high-fat or sucrose diet fed models. Although these animal models have provided useful information, none of them accurately reflect genetic, metabolic and biochemical characteristics of the human disease.

OBESITY AND NONALCOHOLIC FATTY LIVER DISEASE

Nonalcoholic fatty liver disease (NAFLD) is one of the most prevalent forms of chronic liver disease[1-4]. The reported prevalence of NAFLD in developed countries is 30% and 13% in adults and children, respectively. It is likely that in type 2 diabetes mellitus, NAFLD is one of the consequences of obesity. The prevalence of NAFLD in the obese population is nearly 95%. Factors contributing to NAFLD include sedentary life style, and increased consumption of foods with high-fat and high fructose corn syrup content. A cafeteria style diet which includes both high fat and fructose corn syrup is the

leading cause of obesity in the population. Furthermore, in the setting of excessive central adiposity, insulin resistance is the major underlying cause of fat accumulation in the liver[5-11]. NAFLD is characterized by hepatic fat accumulation in hepatocytes (> 5% of liver weight).

NONALCOHOLIC STEATOHEPATITIS

Nonalcoholic steatohepatitis (NASH), as a subgroup of NAFLD, is characterized by chronic, progressive liver pathology which has the ability to lead to advanced fibrosis, cirrhosis, hepatocellular carcinoma, and liver-related death[1,2,4,5]. The prevalence of NASH is 3% among adults. The mechanisms underlying NASH pathogenesis are not fully understood. One of the hypotheses has been termed the "two-hit" theory[5,6]. According to this paradigm, NAFLD is a result of inappropriate fat storage or ectopic fat accumulation and the primary abnormality is most likely insulin resistance which leads to the accumulation of triglycerides (TGs) within the hepatocytes. After the first hit of steatosis, the second hit of oxidative stress leads to hepatocyte injury and inflammation.

Animal models

There are several types of animal model used for NAFLD studies, and these are mainly characterized as follows: genetically disturbed or murine fatty liver, methionine-choline deficient (MCD) diet fed mice or murine steatohepatitis model and feeding high-fat and/or sucrose diets with or without high caloric intake model[12-24]. Manipulation of the mouse genome and production of new animal models, such as leptin-deficient ob/ob mice, leptin-resistant db/db rats or knockout mice regarding a special character, have given us great opportunities for research[12-16]. However, it is not possible to extrapolate all the information gained from these animal models into knowledge on the human species as there are some fundamental differences regarding their genetics, mediators, and the mechanisms of the events. For example, although obese patients have higher circulating leptin levels, ob/ob mice exhibit complete leptin deficiency. Additionally, leptin has some immunologic functions, besides its metabolic regulatory capacity. Secondly, although insulin resistance is a universal feature of patients with NASH, the MCD model is not insulin-resistant and not obese[15]. MCD mice have increased insulin hypersensitivity, and their serum has both insulin and glucose levels lower than mice fed a standard diet.

High caloric intake models

With regard to the problems mentioned above, it is reasonable to try to find a suitable model for investigating the mechanism behind human NASH. Actually, there have been several attempts to mimic human species by feeding mice with high fat and/or sucrose diets with or without high caloric intake in order to produce obesity, insulin resistance, and NASH[16-23]. The type and amount of fat, and total daily caloric intake on these diets are very important and there has been no standardized diet reported by study groups. In this regard, Lieber *et al*[25] fed Sprague-Dawley rats with a high-fat, liquid diet (71% of energy from fat which included corn, olive, and safflower oil) for 3 wk and developed a steatohepatitis model in murines which resembled human NASH. These mice displayed obesity and insulin resistance together with increased hepatic tumor necrosis factor (TNF)-α, TNF-α messenger RNA, cytochrome 2E1, cytochrome 2E1 mRNA, increased oxidative stress and lipid peroxidation, fatty liver histopathology, mononuclear cell infiltration, abnormal mitochondria and increased collagen in the liver. Bruce *et al*[26] used a high fat diet (45% kcal from fat, 20% kcal protein, 35% kcal carbohydrate) and Tetri *et al*[27] fed mice with 45% calories in the chow from fat and 30% of the fat in the form of partially hydrogenated vegetable oil (28% saturated, 57% monounsaturated fatty acids, 13% polyunsaturated fatty acids). Both research groups developed mice displaying obesity, insulin resistance and NASH.

There is substantial diversity within and between mouse strains resembling phenotypic variations in human populations. C57 BL6J mice have usually been chosen by NASH researchers because of their predisposition to develop insulin resistance by means of diet and the availability of genetically manipulated mice[14,27-29]. These features of the strain are explained by a strong influence of the genetic background on the susceptibility to diet-induced obesity and insulin resistance[14].

WHAT WE KNOW ABOUT THE MECHANISMS UNDERLYING NASH PATHOGENESIS?

For NASH pathogenesis, it is a prerequisite firstly to develop fatty liver which is then unusually vulnerable to various second hits or injury[5,6]. Although insulin resistance is a universal finding for both simple steatosis and NASH, only a small group of insulin-resistant patients develop NASH, even in patients with metabolic syndrome (MS). MS is the most severe form of insulin resistance and might instigate more advanced NASH. It is believed that oxidative stress and lipid peroxidation might play a central role in the transition of simple steatosis to NASH[30].

Increased production of ROS and lipid peroxidation of hepatocyte membranes and organelles promote necroinflammation, satellite cell activation and fibrosis in the liver. In this context, elevated free fatty acids (FFAs) in both circulation and the liver, mitochondrial abnormalities (dysfunction and structural abnormalities such as mega mitochondria with true crystalline inclusions), gut-derived endotoxins, ethanol secondary to gut and liver interaction, and disturbed production of adipokines should be major concerns in the development of steatohepatitis in an animal model.

Insulin resistance and peripheral lipolysis cause an

increased FFA pool in the circulation[7,21,30]. This pool is one of the major sources of hepatic TGs. FFAs are also the major source of hepatic mitochondrial, peroxisomal and microsomal ROS production. It has been reported that increased hepatic and serum FFA concentrations promote hepatic and systemic insulin resistance by the activation of PKCθ and serine phosphorylation of insulin receptor substrates. Feldstein *et al*[30] reported that FFAs promote lysosomal permeabilization, release cathepsin B which is a lysosomal protease within hepatocytes, and cause hepatocyte apoptosis and injury. In addition to these aspects, increased serum concentrations of FFAs due to obesity were found to be correlated with the severity of fibrosis in patients with NASH[31]. FFAs play a major role in the transition from simple steatosis to NASH.

High-fat diet-induced obesity and insulin resistance have been reported in Wistar rats[32,33], Sprague-Dawley rats[34,35], F344 rats[36], and in Long-Evans rats[37]. Additionally, prolonged feeding periods with high fat (59% fat), such as a 3 mo duration, promoted a greater degree of insulin resistance in Wistar rats[33]. Borst and Conover induced obesity and developed an insulin-resistant animal model by feeding them for 39 d with a high-fat (50%) inclusive diet[38]. In this model, daily caloric intake was not increased, and it was even slightly less than for the normal rat chow (12.4% fat). These mice developed increased visceral and subcutaneous fat mass, insulin resistance, elevated fasting serum insulin, decreased insulin-stimulated glucose transport in skeletal muscle, increased TNF-α expression on visceral adipose tissue, and an undetectable serum TNF-α concentration. Most importantly, serum FFA concentration was not increased significantly in both mice fed high-fat diet and controls, while liver TNF-α expression was not affected. This observation is interesting, as obesity is strongly associated with increased concentration of FFAs in the circulation.

It was previously reported that a five-fold increase of plasma FFAs caused up to 100-fold increase in plasma insulin concentrations[26,30]. Thus, FFAs are more important than TNF-α for inducing insulin resistance. TNF-α expressed in visceral adipose tissue macrophages, and maybe TNF-α in muscle, appears the major cause of systemic insulin resistance in these animal models, since FFA levels were not increased. Oxidative stress is one of the most popular proposed mechanisms of hepatocellular injury in NASH in both animal experiments and human trials. It has been reported that obesity correlates with systemic oxidative stress. Obese adults with MS have a higher plasma concentration of oxidative stress biomarkers than obese adults without MS[2,6,7]. Increased ROS production has been selectively shown in adipose tissue of obese mice. There is also some indirect evidence as to the benefit of antioxidants such as vitamin E, S-adenosylmethionine and betaine, phlebotomy to remove iron, and N-acetylcysteine for treating NAFLD. However, a causal relationship or a pathogenic link between NASH and oxidative stress has so far not been established.

Hepatocyte mitochondria are the main site of β-oxidation of FFAs and adenosine triphosphate (ATP) production is one of the crucial issues in the understanding of NASH pathogenesis. It was previously reported that mitochondrial structural abnormalities, depletion of mitochondrial DNA and ATP, and mitochondrial dysfunction are characteristics of NASH patients as well as of diet-induced and animal models[39-41]. Increased oxidative stress and lipid peroxidation products are integral components of the pathway progressing to NASH from fatty liver. Specifically, rats fed a high-fat diet have been shown to have reduced electron transport chain capacity and increased oxidative stress in liver mitochondria[39,41].

Excessive fatty acids might be used as an alternative pathway to produce mitochondrial injury rather than the mitochondrial β-oxidation pathway. These possible routes of injury include the peroxisomal and microsomal oxidation systems[42]. Alternative fatty acid oxidation systems produce more hydrogen peroxide and thus may contribute to oxidant stress. Increased cytochrome P450 2E1 expression and induction have been well-established previously in both murine SH and human NASH studies.

In a very recent study, researchers developed a novel model which suggested maternal fat intake contributes toward the NAFLD progression in adult offspring; mediated through impaired hepatic mitochondrial metabolism and up-regulated hepatic lipogenesis[26]. Large-scale gene expression study, particularly a whole genome array analysis, is a very powerful technique which was used to measure the differences between the samples in this model[26]. This technique was able to measure the mRNA expressed in the tissue analyzed, assessing parameters such as relative expression of genes involved in inflammation, oxidative stress, lipogenesis, and beta-oxidation.

CONCLUSION

One of the areas for ongoing research is the understanding of how much calorie intake and composition of the diet affect the development of NASH. In conclusion, although these animal NAFLD models are already in use and further improve our knowledge, the underlying mechanisms in NAFLD pathogenesis need further research.

Abstract

AIM: To determine the short-term cost-utility of molecular adsorbent recirculating system (MARS) treatment in acute liver failure (ALF).

METHODS: A controlled retrospective study was conducted with 90 ALF patients treated with MARS from 2001 to 2005. Comparisons were made with a historical control group of 17 ALF patients treated from 2000 to 2001 in the same intensive care unit (ICU) specializing in liver diseases. The 3-year outcomes and number of liver transplantations were recorded. All direct liver disease-related medical expenses from 6 mo before to 3 years after ICU treatment were determined for 31 MARS patients and 16 control patients. The health-related quality of life (HRQoL) before MARS treatment was estimated by a panel of ICU doctors and after MARS using a mailed 15D (15-dimensional generic health-related quality of life instrument) questionnaire. The HRQoL, cost, and survival data were combined and the incremental cost/quality-adjusted life years (QALYs) was calculated.

RESULTS: In surviving ALF patients, the health-related quality of life after treatmeant was generally high and comparable to the age- and gender-matched general Finnish population. Compared to the controls, the average cost per QALY was considerably lower in the MARS group (64732€ *vs* 133858€) within a timeframe of 3.5 years. The incremental cost of standard medical treatment alone compared to MARS was 10928€, and the incremental number of QALYs gained by MARS was 0.66.

CONCLUSION: MARS treatment combined with standard medical treatment for ALF in an ICU setting is more cost-effective than standard medical treatment alone.

INTRODUCTION

Since its introduction in 1993[1,2], the molecular adsorbent recirculating system (MARS) has been used in the treatment of both acute liver failure (ALF) and acute-on-chronic liver failure (AOCLF). The MARS device is an extracorporeal albumin dialysis apparatus that removes both albumin-bound and water-soluble toxins from the patient's blood, enabling native liver regeneration and allowing time to locate a suitable organ for liver transplantation (Ltx)[3-5].

Numerous studies have documented the favorable effects of MARS treatment on clinical and laboratory parameters[4,6-9] and survival[10-13]. However, only three small non-randomized studies[14-16] have focused on the cost-utility of MARS treatment in AOCLF and the health-related quality of life (HRQoL) of MARS-treated AOCLF patients. Currently, there are no studies on the HRQoL or cost-utility of MARS treatment in ALF patients.

In assessing therapy utility, the subjective feelings of the patient should be taken into account in addition to health benefits (e.g. survival) and cost. To ensure that limited resources are utilized in an ethical manner, the impact of a given treatment on the future HRQoL of the patient must be considered[17]. The effectiveness of a given treatment should be assessed by considering the treatment's impact on both the length and quality of life, which can be combined into the measure quality-adjusted life years (QALYs). In the cost-utility analysis, the QALYs gained by a given treatment are used as the measuring units of efficacy. Thus, the QALYs and cost/QALY-ratios can be used to compare the different treatments in terms of length of life and quality of life. Currently, there is no consensus as to how much a QALY gained can cost, but a 50 000€ threshold has been suggested[17].

The aim of this study was to determine the short-term (3.5 years) cost-utility of MARS treatment in ALF patients.

MATERIALS AND METHODS

Patients

This study included 90 ALF patients treated with MARS from May 2001 to October 2005 and a historical control group of 17 consecutive ALF patients treated from March 2000 to April 2001. ALF was defined as a rapid deterioration of hepatic synthetic function with or without encephalopathy and no previous history of liver disease[18].

All patients were treated in the same intensive care unit (ICU) specializing in liver disease at the Helsinki University Hospital and according to the same main principles of standard medical therapy (SMT). The SMT in our ICU and the operational principles of the MARS device were reported previously[3-5]. Our liver ICU is the only Ltx center in Finland, and all critical ALF patients are referred to our unit for treatment and transplantation evaluation. The indications for MARS treatment and the treatment protocols are summarized in Table 1. The 3-year survival and the need for Ltx were determined in all patients.

Economic evaluation

In the cost-utility analysis, effectiveness was measured as QALYs gained. The costs and outcomes of MARS treatment were compared with those of SMT in the control group over a 3-year time horizon from the perspective of the health care provider. For this comparison, a deterministic decision model was developed using TreeAge Pro HealthCare software (TreeAge, Williamstown, MA, USA). The model was used to combine the data on costs and effectiveness and to incorporate data variability and uncertainty into the analysis (Figure 1). The pathways presented in Figure 1 are mutually exclusive sequences of events, and the expected values are based on the pathway values weighted by the pathway probabilities. The probabilities show the proportion of the patient cohort that is expected to experience the event at any particular point in the tree.

The incremental cost-effectiveness ratio (ICER) was determined by dividing the difference in costs by the difference in QALYs. Both costs and QALYs were discounted 5% as currently recommended in the Finnish guidelines for pharmacoeconomic evaluation. The base-case analysis estimated the cost-effectiveness based on the mean values from the data in the simplified model structure. The effect of model input parameter uncertainty on the results was tested in a one-way and probabilistic sensitivity analysis.

Direct costs

From the year 2000 onwards, the Helsinki University Central Hospital district began to use the clinical patient-administration database Ecomed® for registering all treatment costs. In this study all direct medical costs were obtained from the Ecomed®-database (Datawell Ltd., Espoo, Finland). The total costs included all relevant liver disease-related expenses incurred at the Helsinki University Hospital. All costs incurred between 6 mo before the first MARS treatment (or liver ICU admission in the control group) and 3 years after the treatment were included. Complete cost data were available only for those patients who were living (31 MARS and 16 control patients) and received all hospital care in the catchment area of the Helsinki and Uusimaa Hospital District. Therefore, patients referred from outside the catchment were excluded from the cost analysis. Direct non-medical costs (transportation, domestic help, productivity costs due to absences from work, *etc.*) were not included. The mean total cost within the specified time period was used in the base-case analysis. All costs in Euros were inflated to the 2006 price level.

Table 1 MARS treatment protocols for acute liver failure in Finland

Etiology	MARS treatment initiation criteria	Treatment protocol
Acute liver failure	Rapid deterioration of hepatic synthetic function and clinical condition despite conservative standard medical therapy And one of the following criteria: (1) Ingestion of a lethal dose of a known hepatotoxin (e.g. *Amanita*, paracetamol) (2) The patient fulfills the criteria for highly urgent liver transplantation	22-h sessions daily until: (1) Native liver recovers (2) Suitable transplant organ is found (3) Irreversible multi-organ damage occurs

MARS: Molecular adsorbent recirculating system.

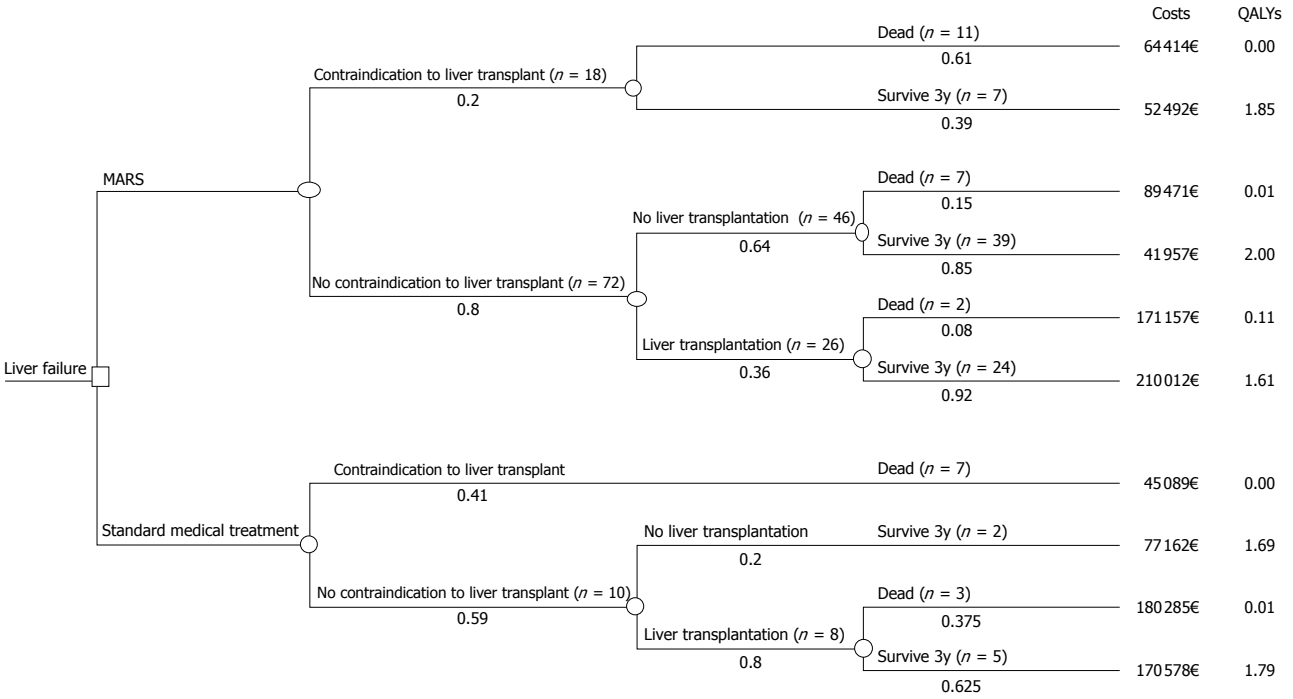

Figure 1 A deterministic decision model. In both treatment arms, the patient cohort was divided based on contraindication *vs* no contraindication to liver transplantation (Ltx) and then on the basis of Ltx *vs* no-Ltx. The "survive 3y" branches include all patients who survived at least three years after the first treatment, and the "death" branches include all patients who died within those three years. The pathway probabilities i.e. the proportion of the cohort that is expected to experience the event, are shown under each branch and were calculated based on real patient data. MARS: Molecular adsorbent recirculating system; QALY: Quality-adjusted life year.

HRQoL

The HRQoL was measured by the 15D (15-dimensional generic health-related quality of life instrument)[19-21], which is a generic, self-administered questionnaire for adults using criteria related to 15 dimensions: moving, seeing, hearing, breathing, sleeping, eating, speech, eliminating, usual activities, mental function, discomfort and symptoms, depression, distress, vitality, and sexual activity. For each dimension, the patient chooses one of five levels that best describes his/her current state of health. A set of utility weights is used to generate a single index number, the 15D score, which ranges from 0 to 1 (1 = full health, 0 = dead)[22]. For most of the important properties (i.e. reliability, content validity, discriminatory power, and responsiveness to change), the 15D is at least equal to other similar HRQoL instruments, such as the EQ-5D, SF-6D, HUI3, and AqoL[19-21,23-25].

Most ALF patients admitted to our liver ICU are seriously ill and encephalopathic, if not unconscious, and thus unable to fill out the HRQoL questionnaires. Therefore, we used expert opinion to assess the pre-treatment HRQoL. Three ICU doctors separately and retrospectively estimated the HRQoL of 30 ALF patients using the 15D instrument and the patients' clinical documents. All patients were divided into five groups according to their pre-treatment encephalopathy grade, which was represented as a number from 0 to 4. The HRQoL was assessed in all patients who were conscious and not intubated. The HRQoL was evaluated for six randomly selected non-intubated patients from each encephalopathy grade 0-3, and their average 15D score was assumed to represent the approximate HRQoL of the entire group (Table 2). Unconscious and intubated patients, which included some encephalopathy grade 3 patients and all encephalopathy grade 4 patients, received a 15D score of 0.0162[22].

In July 2007, the 15D questionnaire was sent to the 68 MARS-treated ALF patients who were still alive (one patient was not found). Two reminder letters were sent to those who did not return the first questionnaire. In total, 79% (54/68) completed the post-treatment 15D questionnaire; 37% of these patients (20/54) had undergone Ltx. At the time of the survey, the time elapsed after the first MARS treatment varied among individual patients

Table 2 Mean pre-treatment 15D scores in different encephalopathy grade groups (mean ± SD)

Pre-treatment encephalopathy grade	15D score
0	0.532 ± 0.151
1	0.461 ± 0.188
2	0.403 ± 0.177
3	0.079 ± 0.077
4	0.016

The average age-matched 15D score of the Finnish population is 0.92, and the standardized 15D score for unconscious/intubated patients is 0.016[22].

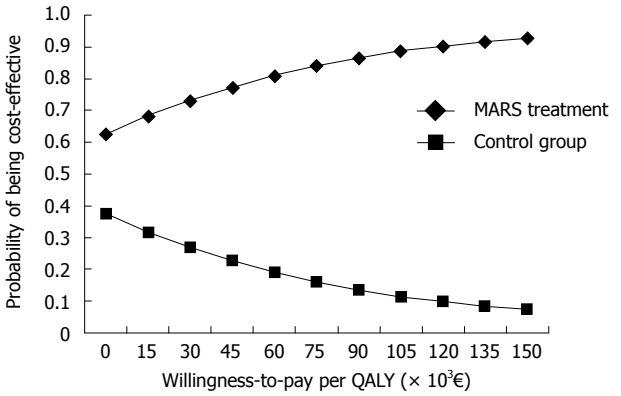

Figure 2 The cost-effectiveness acceptability curve for MARS *vs* standard medical therapy in the historical control group in acute liver failure.

(median 49 mo, range 22-72 mo). Thus, a 15D score 3 years after the first MARS treatment was individually estimated for each patient using linear regression analysis with the patient's age, time since MARS treatment, and the etiology of liver failure as explanatory variables.

The mean 15D scores and resulting QALYs were calculated separately for each pathway in the decision tree (Figure 1). For patients who died within the time horizon, QALYs were calculated based on survival, assuming the 15D score declined linearly from the baseline value to zero at the time of death.

Sensitivity analysis

The effect that model parameter uncertainty had on the results was examined first in a one-way analysis and further in a probabilistic sensitivity analysis. In the one-way sensitivity analysis, the discount rate, the mean cost and QALYs of both the MARS and control groups, the probability of Ltx, and survival rates varied. For the probabilistic sensitivity analysis, probability distributions for tree probabilities, cost, and utility input parameters were estimated. The results of the probabilistic sensitivity analysis are presented as a cost-effectiveness acceptability curve (Figure 2). Probability and utility values are represented by beta distributions (limiting values between 0 and 1 for utility values), the parameters of which were estimated from the patient data. For cost estimates, a gamma distribution was determined. Because the actual patient level cost data were limited, regression analysis was used to estimate costs for all patients. Sex, Ltx and its contraindication, and the number of MARS treatments received were used as explanatory variables in the regression analysis.

Table 3 Baseline data for the MARS and control groups

	MARS group	Historical control group	*P* value
Pre-treatment demographic & clinical data			
Number of patients	90	17	
Age (yr)	45 (14-81)	42 (21-72)	0.714
Sex (male)	37 (41%)	7 (41%)	0.996
Body mass index (kg/m^2)	26 (17-40)	26 (21-37)	0.372
MARS sessions/patient	2 (1-9)	0	
Mechanically ventilated	30 (33%)	6 (35%)	0.875
Vasoactive infusion used	27 (30%)	9 (56%)	0.041

Creatinine (μmol/L)	75 (35-1318)	78 (38-275)	0.946
FV (%)	32 (5-142)	38 (7-71)	0.865

All values are expressed as median (range) or as number of patients (%). Hepatic encephalopathy grade is presented as mean ± SD. MELD score: Mean end-stage liver disease score; Ltx: Liver transplantation; FV: Coagulation factor V.

Statistical analysis

All data were analyzed using SPSS for Windows version 15.0 (SPSS, Inc., Chicago, IL, USA). The Wilcoxon signed-rank test, the Mann-Whitney *U*-test, Pearson's χ^2, and Fisher's exact tests were used when appropriate. $P \leqslant 0.05$ was considered significant, and a $\geqslant 0.03$ (absolute value) difference in the HRQoL scores was considered clinically important[26].

RESULTS

Characteristics of the study population

The demographic and clinical characteristics of the MARS-treated and control ALF patients did not differ significantly, with the exception of a need for vasoactive infusion (Table 3). The grade of encephalopathy before treatment was also comparable between the two groups. The etiological distribution of ALF patients differed between the groups ($P = 0.002$). Control patients had mostly ALF of unknown etiology (65%), whereas the majority of MARS-treated patients (57%) had ALF due to known toxicity (e.g. paracetamol or other drugs).

Outcome and 3-year survival

The percentage of transplanted patients was lower (29% *vs* 47%, $P = 0.14$), and the percentage of patients who survived 3 years after treatment was higher (78% *vs* 41%, $P = 0.002$) in the MARS-treated group compared to controls.

Table 4 The survival, cost, and HRQoL data of MARS-treated and control patients

	Subgroups according to outcome	3-yr survival			Cost (€)				HRQoL		
		n	%	Mean (d)	*n*	Mean	Min	Max	*n*	Pre-treatment mean	Post-treatment mean

HRQoL: Health-related quality of life; ALF: Acute liver failure.

Table 5 Base case results for MARS

	Cost (€)	Incremental cost (€)	QALYs	Incremental QALYs	Cost per QALY (€)	Incremental cost per QALY
MARS	93214		1.44	0.66	64732	MARS dominates SMT
Control group (SMT only)	104142	10928	0.78		133858	

SMT: Standard medical therapy; QALY: Quality-adjusted life year.

A similar survival benefit favoring MARS treatment compared to controls was noted in both transplanted (92% *vs* 63%, $P = 0.072$) and non-transplanted patients (72% *vs* 22%, $P = 0.006$).

Costs

The total mean direct medical costs related to liver disease were 79745€ for the MARS group and 105820€ for the controls (Table 4). The total mean direct medical costs for transplanted and non-transplanted MARS and control patients are shown in Figure 3 and the expected costs weighted by the pathway probabilities are shown in Table 5.

In all patient groups, most of the costs were incurred within a year of the first MARS or standard medical treatment. The costs during the second and third years were negligible. In all groups, the highest costs were observed in transplanted patients.

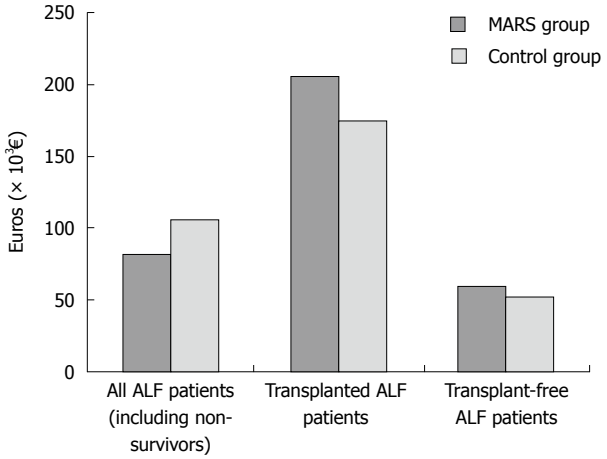

Figure 3 The 3.5-year mean overall direct medical costs per patient in the MARS and control groups. ALF: Acute liver failure.

HRQoL and QALYs

The pre- and post-treatment 15D scores are shown in Figure 4 and Table 4. The estimated HRQoL for all patients prior to treatment was very low compared to an age-standardized reference population in Finland (0.30 *vs* 0.92)[27]. The highest post-treatment 15D scores were observed in MARS-treated patients who did not have a contraindication to Ltx and recovered without transplantation. The same patients also experienced the highest mean number of QALYs (2.00, within the 3-year follow-up). The groups with the smallest mean number of QALYs were patients with a contraindication to Ltx and those who died within 3 years of treatment.

Cost-utility analysis

In the base-case analysis, the MARS group strongly domi-

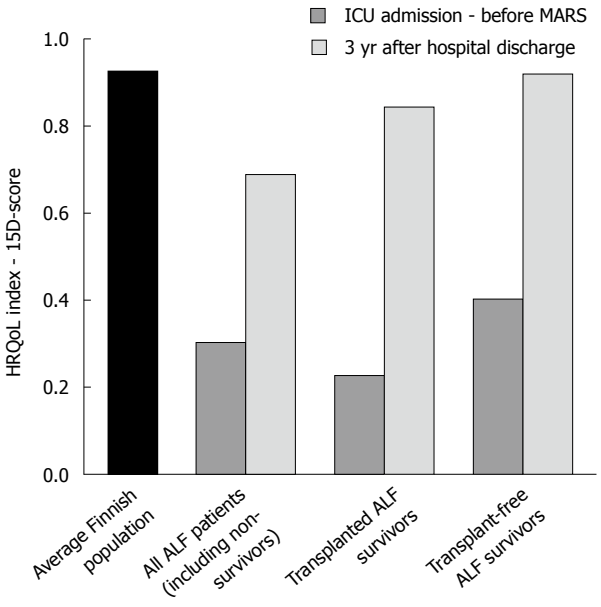

Figure 4 The 15D-score before and 3 years after MARS treatment. HRQoL: Health-related quality of life.

nated the control group receiving only SMT; MARS treatment was both less costly and more effective than SMT in ALF patients (Table 5). Using the 3-year time horizon, the expected outcome of MARS patients was 1.44 QALYs and the expected costs were 93 214€. The corresponding figures for the controls were 0.78 and 104 142€, respectively. Compared to MARS, the incremental cost of SMT in the control group was 10 928€. The incremental number of QALYs gained by MARS was 0.66.

Sensitivity analysis

MARS remained the dominant strategy throughout most of the one-way sensitivity analyses. Neither increasing the proportion of patients with a contraindication to Ltx in the MARS group nor varying the survival rates of patients after Ltx or MARS-treated patients with a contraindication, mitigated the dominance of MARS treatment. MARS also remained the dominant strategy throughout QALY estimate variation in the one-way sensitivity analysis. Using a discount rate of 0%, 3%, or 5% did not eliminate the dominance.

The results were more sensitive to variation in the cost estimates. In the one-way sensitivity analysis, increasing the costs for MARS-treated patients who had no contraindication and survived three years with Ltx removed the dominance of MARS and resulted in an ICER of 63 206€ per QALY gained.

The proportion of liver disease with unknown etiology was significantly higher in the control group (P = 0.002), which can lead to a higher probability of Ltx. We varied the probability of Ltx in the MARS group from 0.89 (observed in controls) to 0.36 (observed in the MARS-treated group); throughout which, MARS remained the more effective alternative. However, when the probability of Ltx in the MARS group was increased to 0.42 or higher, the expected cost of MARS exceeded that of the control group receiving SMT, and its dominance was eliminated. When the probability of Ltx in the MARS group was set to the same level as the control group (0.89), the ICER was 98 686€ per QALY gained.

The cost-effectiveness acceptability curve (Figure 2) of MARS *vs* controls showed the probability that MARS is cost-effective given a range of willingness-to-pay thresholds per QALY gained. If the decision-maker is willing to pay 50 000€ per QALY, the probability of MARS being cost-effective is 78%. Furthermore, the probability of MARS being cost-effective is 95% if the willingness-to-pay threshold is 200 000€ per QALY.

DISCUSSION

To our knowledge, there are no previous studies evaluating the cost-utility of MARS treatment in ALF patients. We found that MARS treatment was both less costly and more effective than SMT in ALF. Compared to the controls, the average cost per QALY was significantly lower in the MARS group (64 732€ *vs* 133 858€), mainly due to the significantly higher 3-year overall survival rate and fewer transplantations in the MARS group.

The average overall 3.5-year costs associated with the treatment of ALF were substantial with or without MARS treatment due to the long ICU stay and, in some cases, Ltx costs. The fewer Ltx in the MARS group resulted in reduced overall average costs compared to conservative treatment. Because the costs associated with the Ltx procedure are high, any intervention that decreases the number of transplantations is bound to have a profound effect on the total expense.

As reported previously[28,29], we found that, even though the HRQoL of surviving transplanted patients was generally very good, it was still somewhat lower than that of a person in the age-standardized general population (0.84 *vs* 0.92)[27]. In ALF patients who recovered without Ltx, the HRQoL after treatment was similar to that of the age-standardized Finnish reference population (0.93 *vs* 0.92)[27].

Only a handful of HRQoL and cost-effectiveness studies have been completed on MARS patients, and all have been limited to AOCLF patients treated in the same center[14-16]. Until now, MARS-treated ALF patients have not been evaluated in terms of total cost and QALYs, possibly owing to the rarity of the condition, which makes it difficult to enroll enough patients for statistical analysis. Furthermore, comparing results from different studies can be difficult because transplant organ availability varies, and centers may have different criteria for MARS treatment. In addition, the heterogeneity of the etiology of ALF in different countries markedly affects survival rates and the percentage of patients who may experience native liver recovery[30,31].

The most recent cost-utility evaluation of MARS treatment included 79 alcohol-related AOCLF patients[14]; their 3-year survival was 52% with mean direct medical costs of 40 032€ and an ICER of 31 448€ per life-year gained. However, transplanted patients and those with serious co-

morbidities were excluded from this analysis, which had a huge impact on the total costs. Another study focused on the impact of MARS treatment on the hospitalization costs and 1-year survival of cirrhotic AOCLF patients[32]; the in-hospital cost for surviving MARS-treated patients was $32 036, $4000 less than in the control group.

The main limitation of this study was the nonrandomized design. Also, due to patient incapacitation, the pretreatment HRQoL was retrospectively assessed by an expert panel rather than by the patients themselves. Studies have shown that the subjective feelings of a patient, such as pain or HRQoL, are usually misjudged or underestimated by the attending doctors, other treatment staff, or even close relatives[33,34]. Another factor affecting the positive outcomes of MARS-treated ALF patients in this study was the uneven distribution of liver failure etiologies between treatment groups. The prognosis and need for Ltx is strongly related to the underlying cause of ALF[30]; the MARS treatment group was at an advantage in that it included many patients with a good prognosis compared to controls. This predisposition must be taken into account when interpreting the results of this study. The sensitivity analysis was used to estimate the effect of this bias, and it seems that even if both the MARS and control groups had a similar distribution of etiologies, MARS treatment would remain the more effective strategy, although more expensive in terms of total cost.

One must bear in mind that this study dealt with a 3.5-year time window, thus severely underestimating the QALYs to be gained over the remaining lifetime. Alternatively, we could have extrapolated the expected lifetime costs and outcomes; however, this would have necessitated further assumptions and resulted in greater uncertainty.

In conclusion, cost-utility analysis found that MARS treatment plus SMT is both less costly and more effective than SMT alone in ALF patients. Although some uncertainty exists in the model input parameters, probabilistic sensitivity analysis showed that the probability of MARS being cost-effective is higher than that of SMT alone.

COMMENTS

Background

The molecular adsorbent recirculating system (MARS) device is an extracorporeal albumin dialysis apparatus which can be used to treat liver failure patients. MARS removes both albumin-bound and water-soluble toxins from the patient's blood, enabling native liver regeneration and allowing time to locate a suitable organ for liver transplantation. Numerous studies have documented the favorable effects of MARS treatment on clinical and laboratory parameters and survival. However, only a few small non-randomized studies have focused on the cost-utility of MARS treatment in patients with acute-on-chronic liver failure.

Research frontiers

The cost-utility of the MARS treatment and its impact on the health-related quality of life in acute liver failure patients has never been investigated previously.

Innovations and breakthroughs

The results from the current study suggest that MARS treatment is both less costly and more effective than standard medical therapy in the treatment of acute liver failure patients. Compared to the controls, the average cost per quality-adjusted life year (QALY) was significantly lower in the MARS group, mainly due to the significantly higher 3-year overall survival rate and fewer transplantations in the MARS group. The authors also found that in MARS-treated acute liver failure patients who recovered without liver transplantation, the health-related quality of life after treatment was similar to that of the age-standardized Finnish reference population.

Applications

The cost-utility analysis suggests that MARS treatment plus standard medical therapy is both less costly and more effective than standard medical therapy alone in acute liver failure patients. Therefore, the additional costs which are associated with the use of the MARS machine seem justifiable in this patient group.

Peer review

This paper deals with the important topic of the cost-utility of molecular adsorbent recirculating system treatment in acute liver failure. The report is concise and informative.

Abstract

AIM: To investigate the growth inhibitory mechanism of four caged xanthones from *Garcinia hanburyi* in cholangiocarcinoma (CCA) KKU-100 and KKU-M156 cells.

METHODS: Four caged xanthones, selected on the basis of their anticancer potency and chemical structure diversities (i.e. isomorellin, isomorellinol, forbesione and gambogic acid) were used in this study. Growth inhibition of these caged xanthones was determined using the sulforhodamine B assay. Induction of apoptosis was assessed by observing cell morphology, ethidium bromide and acridine orange staining and DNA fragmentation assay. Levels of apoptotic-related gene and protein expressions were determined by a real-time reverse transcriptase polymerase chain reaction and Western blotting analysis, respectively.

RESULTS: The compounds were found to inhibit growth of both cell lines in a dose-dependent manner and also showed selective cytotoxicity against the cancer cells when compared with normal peripheral blood mononuclear cells. Growth suppression by these compounds was due to apoptosis, as evidenced by the cell morphological changes, chromatin condensation, nuclear fragmentation, and DNA ladder formation. At the molecular level, these compounds induced down-regulation of Bcl-2 and survivin proteins with up-regulation of Bax and apoptosis-inducing factor proteins, leading to the activation of caspase-9 and -3 and DNA fragmentation. The functional group variations did not appear to affect the anticancer activity with regard to the two CCA cell lines; however, at a mechanistic level, isomorellinol exhibited the highest potency in increasing the Bax/Bcl-2 protein expression ratio (120 and 41.4 for KKU-100 and KKU-M156, respectively) and in decreasing survivin protein expression (0.01 fold as compared to control cells in both cell lines). Other activities at the molecular level indicate that functional groups on the prenyl side chain may be important.

CONCLUSION: Our findings for the first time demonstrate that four caged xanthones induce apoptosis in

CCA cells which is mediated through a mitochondria-dependent signaling pathway.

INTRODUCTION

Cholangiocarcinoma (CCA) is a malignant tumor arising from bile duct epithelial cells[1], characterized by a poor prognosis and unresponsive to conventional chemotherapeutic agents. The increasing global incidence of this tumor underscores the need for novel and effective therapeutic agents for CCA[2,3].

Much attention has been focused on natural products as potential sources of novel anticancer drugs over the decades[4]. An emerging class of compounds, being potent antiproliferatives as well as having anticancer and anti-tumor activities against mammalian cancer cell lines, is caged xanthones. Recent work by our and other research groups has identified a tropical plant, *Garcinia hanburyi* (*G. hanburyi*) Hook.f. (family Guttiferae), used as a purgative and externally for infected wounds in Thai traditional medicine[5], as a rich source of these compounds[6-11]. In addition, gambogic acid, derived from the gamboges resin of *G. hanburyi,* has been shown to induce apoptosis in human gastric carcinoma cells[9]. These data suggest that these caged xanthones might be effective as chemotherapeutic agents and that they warrant further study of the underlying mechanisms of their anticancer activities.

Our interest in searching for agents for the effective treatment of CCA led us to test a series of caged xanthones from *G. hanburyi*[10] against two human CCA cell lines. Among the compounds tested, isomorellin, isomorellinol, forbesione and gambogic acid (Figure 1) exhibit promising IC_{50} values against both cell lines in comparison with the standard drug doxorubicin. In view of their anticancer potency and chemical structure diversity, these four caged xanthones were selected for a more in-depth study. In order to further delineate the underlying mechanisms, the apoptotic action of these compounds was investigated in detail. The results are the main focus of this communication.

MATERIALS AND METHODS

Reagents and cell culture

Four caged xanthones, i.e. isomorellin, isomorellinol, forbesione and gambogic acid, were isolated from *G. hanburyi* Hook.f. (family Guttiferae) using bioassay-directed fractionation[10]. The KKU-100 and KKU-M156 cells were isolated from Thai CCA patients and the original characterization of these cell lines has been described previously[12,13]. Human peripheral blood mononuclear cells (PBMCs) were freshly isolated using the standard Ficoll-hypaque gradient centrifugation method and used as normal control cells[14]. Cells were grown in RPMI 1640 (GIBCO BRL, Grand Island, NY) supplemented with 10% heat-inactivated fetal bovine serum (FBS), 100 units/mL of penicillin and 100 μg/mL streptomycin (GIBCO BRL) at 37℃ in a humidified incubator containing 5% CO_2.

Cell proliferation assay

For the cell proliferation assay, 1.9×10^4 cells/well were seeded in 96-well microtitre plates and incubated for 24 h. After treatment for 72 h with 0-8.8 × 10^4 μmol/L per well for the caged xanthones, 0.04, 0.4, 4, 40 and 400 μmol/L for doxorubicin (Boryung Pharmaceutic Co. LTD, Korea) as a reference compound and DMSO as the solvent-control cells, cell growth was measured using the sulforhodamine B (SRB) assay[15].

Morphological examination

KKU-100 and KKU-M156 cells (1×10^6) were grown in a 25 cm^2 flask at 37℃ for 24 h, and treated with 2 × IC_{50} concentration of each caged xanthone for 48 h. Morphological changes occurring in the cells were observed under bright field inverted Nikon microscope. For nuclear staining, cells (1.9×10^3 cells/well) were grown in 96-well microtitre plates at 37℃ for 24 h, and treated with 2 × IC_{50} concentration of each caged xanthone for 24, 36 and 48 h. The treated cells were stained with 14 μL of 100 μg/mL ethidium bromide/acridine orange (EB/AO) mixture (Sigma Chemical, St. Louis, MO) and observed under a Nikon fluorescent microscope. Apoptotic cells with condensed chromatin or fragmented chromatin were counted and expressed as a percentage from a total of 500 cells each[16].

DNA fragmentation assay

The isolation of fragmented DNA was carried out according to the procedure of Herrmann *et al*[17] with some modifications. Briefly, after culturing for 24 h and starving in medium containing 0.5% FBS for 24 h, cells (1×10^6) were treated with DMSO or 2 × IC_{50} concentrations of the caged xanthones for 24 and 36 h. After extraction, DNA in cell lysate was purified by QIAamp DNA Blood Mini Kit (QIAGEN, Germany) according to the manufacturer's protocol. The DNA fragments were precipitated with ethanol, re-suspended in 50 μL of TE buffer, and analyzed by electrophoresis.

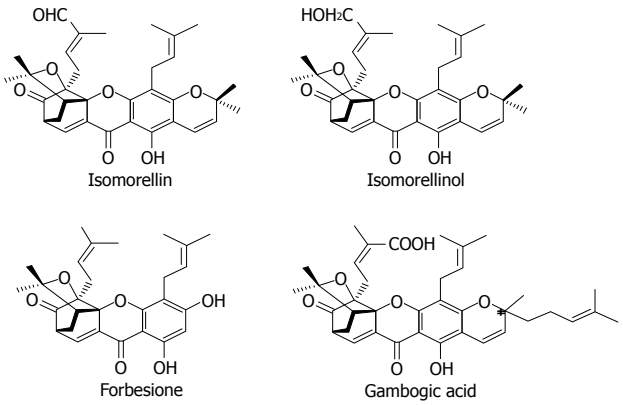

Figure 1 Chemical structure of four caged xanthones.

RNA extraction, reverse transcription and quantitative real-time polymerase chain reaction

Cells were treated with 2 × IC_{50} concentrations of the caged xanthones for 0, 6, 12, 24 and 48 h. Total RNA was isolated from the treated and control cells using TRIzol reagent (Invitrogen, Carlsbad, CA), according to the manufacturer's instructions. The reverse transcription reaction was performed as described[18].

Real-time polymerase chain reaction (PCR) was performed according to the procedure of Namwat *et al*[18]. Real-time PCR of Bcl-2, Bax, survivin and GAPDH were performed in a 20 μL PCR reaction mixture containing first strand cDNA, 5 pmol of each primer, and 10 μL of 2 × SYBR Green PCR Master Mix (Gene Systems Co., Ltd, USA), employing an ABI 7500 Real-time PCR system (Applied Biosystems, Foster City, CA). The PCR primers (Bioservice Unit, Bangkok, Thailand) are shown in Table 1. The sequences of these PCR products were obtained by direct sequencing. Each amplicon was then cloned into the pGEM®-T vector (Promega, Madison, WI, USA) in order to generate standard curves for target cDNA. The mRNA level is reported as the ratios of the copy numbers of target cDNA to GAPDH cDNA. The ratio of fold change in gene expression level between the treated and control cells was determined to identify the up- or down-regulation of gene expression.

Protein extraction and Western blotting analysis

After treatment with DMSO or 2 × IC_{50} concentrations of the caged xanthones for 0, 12, 24 and 48 h, protein extraction and Western blotting were performed as described previously[19]. After blocking, the membranes were incubated at 4℃ overnight with the following antibodies: Bcl-2, Bax, survivin, apoptosis-inducing factor (AIF) (Santa Cruz Biotechnology, CA) or procaspase-9 and -3, activated caspase-9 (Cell Signaling, Beverly, MA) or activated caspase-3, β-actin (Sigma Chemical, St. Louis, MO). The secondary antibodies were horseradish peroxidase-conjugated goat anti-mouse IgG and goat anti-rabbit IgG antibodies (Santa Cruz Biotechnology). Protein bands were detected by an enhanced chemiluminescence kit (Pierce Biotechnology, Rockford). The intensity of the protein bands was quantified using Scion Image software.

Statistical analysis

Data were expressed as mean ± SE. Comparisons between untreated control cells and the caged xanthone-treated cells were made using Student's *t* test. Differences were considered significant at $P < 0.05$. All analyses were performed using SPSS version 10.0 (SPSS Inc., USA).

RESULTS

Anti-proliferative effects of four caged xanthones on CCA cell lines

The treatment of KKU-100 and KKU-M156 cells with four caged xanthones markedly inhibited cell growth in a dose-dependent manner (Figure 2). The IC_{50} values of these caged xanthones and doxorubicin are shown in Table 2. The anticancer potencies of these compounds are comparable to doxorubicin in both cell lines. These caged xanthones induced growth inhibition in the CCA cell lines about 4 to > 8 × 10^6 times greater than that for normal PBMCs (Table 2). These results indicate that these compounds possess considerable potential for further development.

Apoptosis induction by four caged xanthones in CCA cell lines

In both cell lines, treatment with four caged xanthones resulted in cell shrinkage, rounding and membrane blebbing, thus taking on the typical characteristics of apoptotic cells (Figure 3C and D); whereas no effect was observed with the vehicle control cells (Figure 3A and B). Using EB/AO staining, both cell lines showed nuclei with homogeneous chromatin distribution under vehicle-control conditions (Figure 3E and F). In the treated cells, characteristic apoptotic features such as chromatin condensation and nuclear fragmentation were observed (Figure 3G and H). The number of apoptotic cells in both cell lines treated with four caged xanthones was significantly increased in a time-dependent manner (Table 3). Using an agarose gel electrophoresis, a typical ladder pattern of internucleosomal DNA fragmentation, a hallmark of apoptotic cell death[20], was observed in the treated cells (Figure 3I and J).

Effect of four caged xanthones on the expression of apoptosis-related genes and proteins

In both CCA cell lines treated with isomorellinol there was a significant increase in both mRNA (Figure 4A) and protein (Figure 5) of pro-apoptotic Bax, but a marked decrease in the anti-apoptotic Bcl-2 (Figure 4A and Figure 5) in a time-dependent manner leading to an enhanced Bax/Bcl-2 ratio (Figure 4B and Table 4). The same results were obtained when both CCA cell lines were treated with the other three compounds (Figure 4B and Table 4). Using Western blotting, isomorellinol was found to have the highest potency in increasing Bax/Bcl-2 ratio. At 48 h of treatment, isomorellinol increased the Bax/Bcl-2 ratio up to 120 and 41.4 in the KKU-100 and KKU-M156 cells, respectively (Table 4).

Western blotting analysis revealed that treatment of

both cell lines with isomorellinol resulted in a significant reduction of procaspase-3 and -9 while increasing activated caspase-3 and -9 in a time-dependent manner (Figure 5). The treatment of both CCA cell lines with the other three compounds also showed the same results (data not shown). When the relative intensities of activated caspase-3 and -9 to β-actin of treated cells were compared to control cells (0 h), there was a multi-fold increase in the activated caspase-3 and -9 (Table 5). The high degree of multi-fold increase in activated caspase-9 was detected in the isomorellinol-treated KKU-100 and KKU-M156 cells (56 × and 58 ×, respectively), in gambogic acid-treated KKU-100 cells (78 ×) and in isomorellin-treated KKU-M156 cells (34 ×) (Table 5). All four compounds were also shown to increase the activated caspase-3 level in treated KKU-M156 cells, from 10 × to 46 × compared with the control cells (0 h), with a high degree of activated caspase-3 for isomorellinol-treated (33 ×) and gambogic acid-treated KKU-M156 cells (46.7 ×) (Table 5).

The real-time PCR and Western blotting analysis exhibited a significant time-dependent decrease in *survivin* gene (Figure 4A) and protein (Figure 5) expression in the isomorellinol-treated KKU-100 and KKU-M156 cell lines. The same results were obtained when these cell lines were treated with the three other compounds (data not shown). The multi-fold decreases in *survivin* gene and protein expression are shown in Figure 4C and Table 5, respectively. Using Western blotting, isomorellinol showed the highest potency in suppression of survivin protein expression (0.01 ×) (Table 5).

Western blotting analysis revealed that cells treated with isomorellinol resulted in a significant increase of AIF protein (Figure 5). Similar results were obtained for both CCA cell lines treated with the other three compounds (data not shown). Similar multi-fold increases in AIF protein expression were found for the four compound-treated cells as compared to controls (Table 5).

DISCUSSION

The present study demonstrated that the four caged xanthones; isomorellinol, forbesione, gambogic acid and isomorellin, exerted strong growth inhibition with different IC_{50} values in both CCA cell lines in a dose-dependent manner (Table 2 and Figure 2). The results indicate that these two CCA cell lines responded differently to different compounds. However, the potencies of these four compounds were very high, indicating their broad spec-

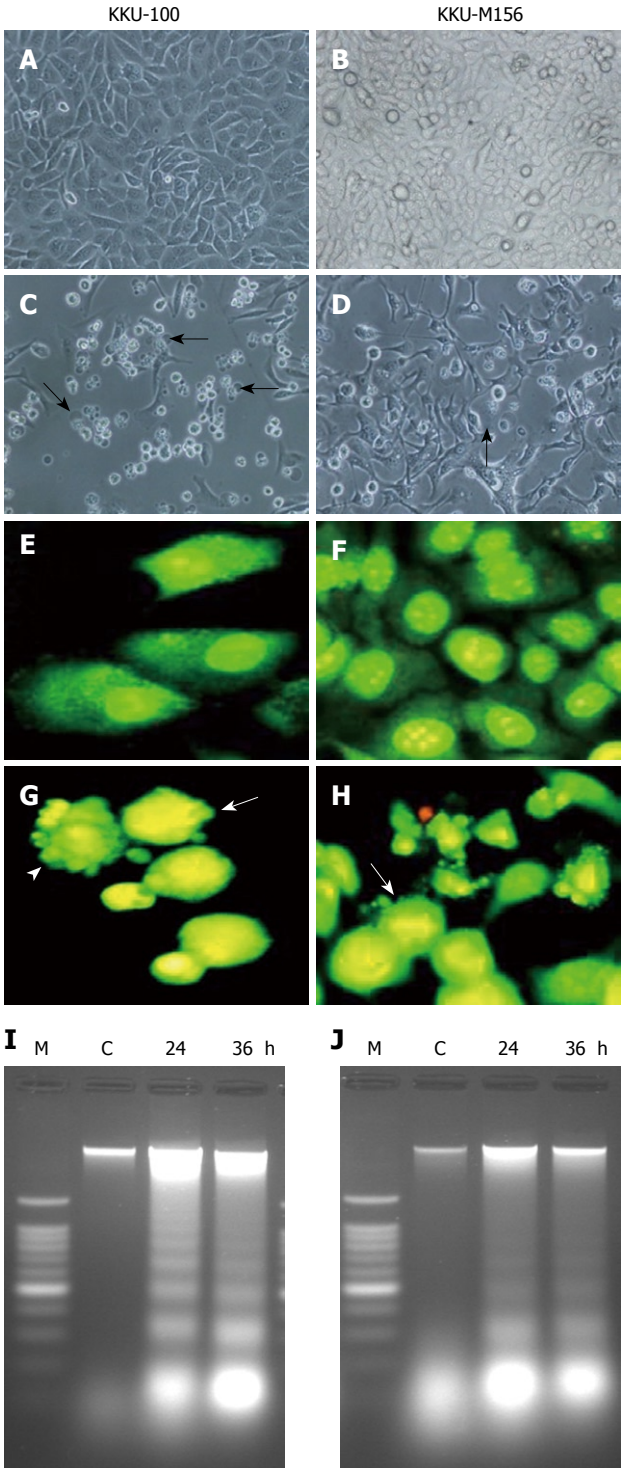

Figure 3 Induction of apoptosis in cholangiocarcinoma (CCA) cell lines by four caged xanthones. trum of anti-CCA effects. In addition, the selectivity of these compounds toward cancer cell lines compared to normal PBMCs was demonstrated (Table 2). Previously, these four caged xanthones have been shown to inhibit the growth of various mammalian cancer cell lines[10]. Gambogic acid was reported to be an effective telomerase inhibitor, displaying potent anticancer activity both *in vitro* and *in vivo*[8-11], and was shown to kill cancer cells selectively with no influence on normal cells[9]. The anticancer potencies of these caged xanthones were comparable to doxorubicin. Due to their potencies, the anticancer mechanisms of these four compounds deserve further investigation.

The growth inhibitory effect of these caged xanthones in both CCA cell lines was modulated through apoptosis which was evidenced by the typical morphological characteristics of apoptosis, such as cell shrinkage, membrane blebbing, chromatin condensation, nuclear fragmentation and DNA ladder formation (Figure 3). Cleavage of DNA at the inter-nucleosomal linker sites yielding DNA fragments has been used as a hallmark of apoptosis[20]. Consistent with our study, the apoptotic effects of gambogic acid in human breast tumor cells T47D[21] and human gastric carcinoma cells MGC-803[9] have been reported.

Apoptosis is regulated by several different genes in response to various stimuli. The Bcl-2 family of proteins plays major roles in apoptotic regulation through the mitochondrial pathway[22]. Our results show that these caged xanthones down-regulated the expression of the Bcl-2

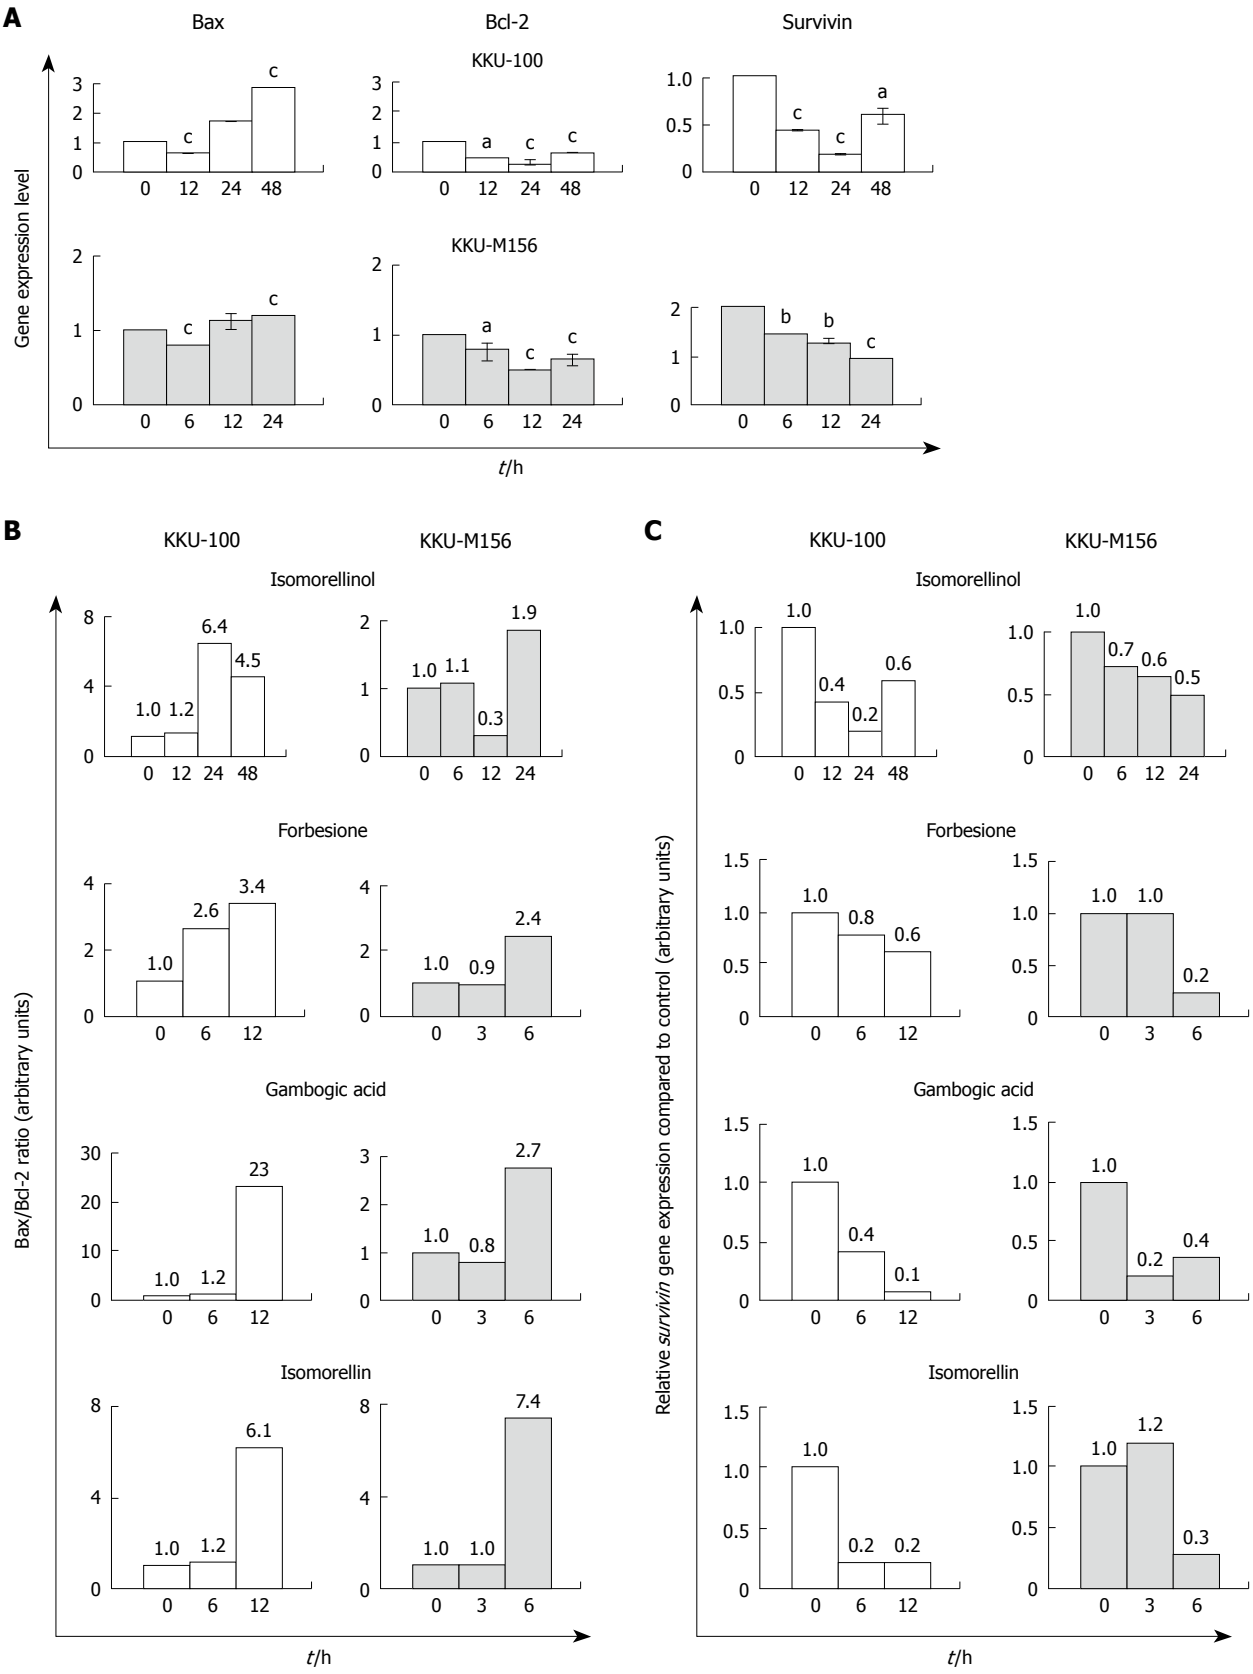

Figure 4 The four caged xanthones induce up-regulation of Bax with down-regulation of *Bcl-2* and *survivin* gene expressions in CCA cell lines. KKU-100 and KKU-M156 cells were treated with DMSO or the four caged xanthones for the indicated times. Real-time polymerase chain reaction for each gene was performed as described in Materials and Methods. Data were expressed as mean ± SE fold increase/decrease in mRNA expression compared to control, normalized with GAPDH (n = 3). $^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$ *vs* control. All four compounds showed the same result. A: The histograms of the isomorellinol-treated cells were used as a representative; B: Bax/Bcl-2 ratio; C: Relative *survivin* gene expression compared to control.

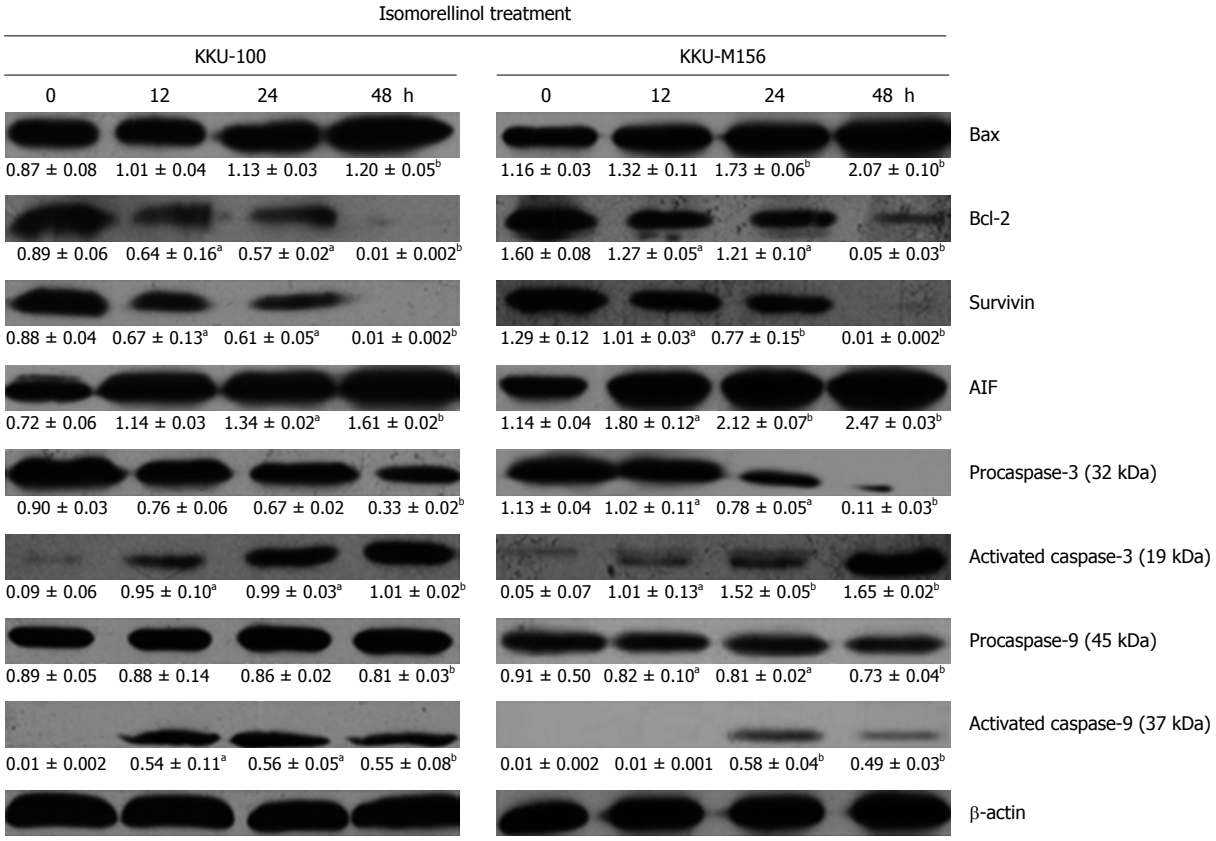

Figure 5 The four caged xanthones induce increase of Bax, AIF, activated caspase-3 and -9 while decreasing Bcl-2, survivin, procaspase-3 and -9 protein levels in CCA cell lines. KKU-100 and KKU-M156 cell lines were treated with DMSO or the four caged xanthones for the indicated times. Western blottings for each protein were performed as described in Materials and Methods. The mean ± SE of density reading of target protein normalized to β-actin was expressed in the respective box (n = 3). $^aP < 0.05$, $^bP < 0.01$ *vs* control. All four compounds showed the same result. The protein bands of the isomorellinol-treated cells were used as a representative.

gene and protein while up-regulating the expression of Bax gene and protein, leading to an increase in the Bax/Bcl-2 ratio (Figure 4B and Table 4). In agreement with our study, gambogic acid-induced apoptosis by regulation of the expression of Bax and Bcl-2 proteins in the human gastric carcinoma cell line MGC-803 has been reported[9]. Bax protein has previously been reported to induce the intrinsic apoptosis pathway by inhibiting the function of

Bcl-2[23], and by increasing the release of death-mediated proteins such as cytochrome C, Smac/DIABLO and AIF from the inter-membrane space to the cytosol[24,25]. Our results show a significant increase in the level of AIF protein in response to the four caged xanthone treatments (Figure 5 and Table 5). This result suggests that the AIF, caspase-independent mitochondrial pathway[25] may be involved in apoptosis induction in the caged xanthone-treated cells.

In the intrinsic apoptotic pathway, the release of cytochrome C from mitochondria triggers caspase-9 and -3 activation through formation of the apoptosome complex. Then the activated caspase-3 is able to cleave multiple cellular substrates leading to DNA fragmentation[24]. Our results show that caspase-9 and -3 were activated by the caged xanthones (Figure 5 and Table 5), suggesting that these caged xanthones induced apoptosis in both CCA cell lines through caspase-9 and -3 activation. Previously, mitochondrial destabilization and caspase-3 activation were reportedly involved in the apoptosis of Jurkat cells induced by gaudichaudione A, a cytotoxic xanthone[26]. Gambogic acid reportedly induced apoptosis and activated caspases in T47D cells[21].

The family of human inhibitor of apoptosis proteins (IAP), including XIAP, c-IAP1, c-IAP2, NAIP and survivin, have been reported to be direct inhibitors of activated caspase-3 and -7[27,28]. Our data show that *survivin* gene and protein expressions were decreased by the four caged xanthones (Figure 4A and C, and Table 5). Since these compounds were found to induce apoptosis in both CCA cell lines by activation of caspase-3, the factor contributing to caspase-3 activation in these treated cells may be a decreased survivin expression. Previously, gambogic acid has been reported to down-regulate IAP, IAP1 and IAP2 in human myeloid leukemia cells[29].

Using Western blotting, isomorellinol was found to have the highest potency in increasing the Bax/Bcl-2 ratio (Table 4) and in decreasing survivin protein expression (Figure 5 and Table 5). This result was also confirmed by the greatly increased amount of activated caspase-3 and -9 in both isomorellinol-treated CCA cell lines (Table 5). Gambogic acid was shown to have lower potency in increasing the Bax/Bcl-2 ratio (Table 4) and decreasing survivin protein expression (Table 5); whereas the increased level of activated caspase-3 was similar to that of isomorellinol (Table 5). These results suggest that the activation of caspase-3 might be stimulated by caspase-12 through endoplasmic reticulum stress-induced apoptosis[30]. Comparing these two CCA cell lines, both isomorellinol and gambogic acid showed higher potency in increasing activated caspase-3 in KKU-M156 cells than KKU-100 cells (Table 5). This may be due to the different histological type of the CCA cell lines. KKU-100 is a poorly differentiated adenocarcinoma which has a higher resistance to chemotherapeutic drugs than KKU-M156, a moderately differentiated adenocarcinoma[13]; whereas forbesione and isomorellin showed the same potency against both CCA cell lines. The latter result may be due to the different functional groups present in these four caged xanthones.

The chemical structure diversity of the four compounds reflects the biological activities. The common feature of all four compounds is the presence of the novel caged structure, which is believed to be a prerequisite for potent anticancer activity in comparison with normal xanthones and chromyl xanthones. The chromene ring is absent in forbesione compared with the other three compounds. Forbesione has only two non-functionalized prenyl side-chains, whereas isomorellin, isomorellinol and gambogic acid are highly prenylated with one of the prenyl methyl groups functionalized as an aldehyde, a primary alcohol and a carboxylic acid functional group, respectively. The functional group variations do not appear to affect the anticancer activity against the two CCA cell lines; however, at a mechanistic level, isomorellinol exhibited the highest potency in increasing the Bax/Bcl-2 ratio and in decreasing survivin protein expression. Other activities at the molecular level indicate that functional groups on the prenyl side chain may be important. It is premature to conclude what the definite structure-activity relationship may be but this preliminary insight provides a basis for further medicinal chemistry studies.

In conclusion, our findings demonstrate for the first time that the four caged xanthones, isolated from *G. hanburyi,* are capable of inhibiting proliferation and inducing apoptosis in CCA cell lines. This is also the first report which shows the molecular mechanism of the growth inhibitory effects of isomorellinol, forbesione and isomorellin. These compounds induce down-regulation of Bcl-2 protein while up-regulating the Bax and AIF proteins, leading to the activation of caspase-9 and -3 and DNA fragmentation. Moreover, the down-regulation of survivin protein thus maintains caspase-3 in an active state and stimulates the molecular cascade of apoptosis. Based on these results, we conclude that these four caged xanthones stimulate both caspase- and non-caspase mitochondrial-dependent apoptosis in KKU-100 and KKU-M156 cells. Furthermore, it appears the mitochondrial apoptosis pathway is induced by the upstream receptor-ligand mediated apoptosis pathway. The precise target of action of these four caged xanthones therefore remains to be elucidated. There is a potential role for these caged xanthones in cancer therapy.

COMMENTS

Background

Cholangiocarcinoma (CCA) is a malignant tumor, characterized by a poor prognosis and unresponsive to conventional chemotherapeutic agents. Therefore, searching for novel and effective therapeutic agents for CCA is necessary. Several caged xanthones from *Garcinia hanburyi* (*G. hanburyi*) have been reported to be potent antiproliferatives, as well as having anticancer and anti-tumor activities, and induce apoptosis in various cancer cell lines.

Research frontiers

The four caged xanthones from *G. hanburyi*; isomorellin, isomorellinol, forbesione and gambogic acid, exerted strong growth inhibition in both KKU-100 and KKU-M156 cells, indicating their broad spectrum of anti-CCA effects. These compounds were shown to kill cancer cells selectively with no influence on normal peripheral blood mononuclear cells (PBMCs). Growth suppression by these compounds was due to apoptosis which correlated with an increase in Bax/Bcl-2 ratio and apoptosis-inducing factor, activation of caspase-9 and -3, and a decrease in survivin expression. At mechanistic level, isomorellinol exhibited the highest potency.

Innovations and breakthroughs

This is the first report which shows the growth inhibitory effect and molecular mechanisms of the four caged xanthones isolated from *G. hanburyi* in CCA cell lines. The results suggest that these compounds stimulate both a caspase- and non-caspase mitochondrial-dependent signaling pathway in CCA cell lines.

Applications

The chemical structure diversity of the four compounds reflects the biological activities. At the molecular level, isomorellinol exhibited the highest potency, indicating that functional groups on the prenyl side chain may be important. It is premature to conclude what the definite structure-activity relationship may be, but this preliminary insight provides a basis for further medicinal chemistry studies. Based on these results, The authors suggest that these four caged xanthones are compounds with great promise and may serve as a potential source and lead-structure for the development of a drug for the treatment of CCA.

Peer review

The manuscript by Hahnvajanawong *et al* evaluates the mechanism by which various caged xanthones exert their antiproliferative activity on cholangiocarcinoma cell lines. The data presented are convincing and the manuscript well written.

Abstract

AIM: To study the effects of Roux-en-Y gastric bypass (RYGB) on the expression of pancreatic duodenal homeobox-1 (PDX-1) and pancreatic β-cell regeneration/neogenesis, and their possible mechanisms in diabetics.

METHODS: Three groups of randomly selected non-obese diabetic Goto-Kakizaki (GK) rats were subjected to RYGB, sham-RYGB and sham-operation (sham-op) surgery, respectively. The rats were euthanized at post-operative 1, 2, 4 and 12 wk. Their pancreases were resected and analyzed using reverse transcription polymerase chain reaction to detect the mRNA of PDX-1. Anti-PDX-1 immunohistochemical (IHC) staining and Western blotting were used to detect the protein of PDX-1. Double IHC staining of anti-Brdu and -insulin was performed to detect regenerated β-cells. The index of double Brdu and insulin positive cells was calculated.

RESULTS: In comparison with sham-RYGB and sham-op groups, a significant increase in the expressions of PDX-1 mRNA in RYGB group was observed at all experimental time points (1 wk: 0.378 ± 0.013 *vs* 0.120 ± 0.010, 0.100 ± 0.010, $F = 727.717$, $P < 0.001$; 2 wk: 0.318 ± 0.013 *vs* 0.110 ± 0.010, 0.143 ± 0.015, $F = 301.509$, $P < 0.001$; 4 wk: 0.172 ± 0.011 *vs* 0.107 ± 0.012, 0.090 ± 0.010, $F = 64.297$, $P < 0.001$; 12 wk: 0.140 ± 0.007 *vs* 0.120 ± 0.010, 0.097 ± 0.015, $F = 16.392$, $P < 0.001$); PDX-1 protein in RYGB group was also increased significantly (1 wk: 0.61 ± 0.01 *vs* 0.21 ± 0.01, 0.15 ± 0.01, $F = 3031.127$, $P < 0.001$; 2 wk: 0.55 ± 0.00 *vs* 0.15 ± 0.01, 0.17 ± 0.01, $F = 3426.455$, $P < 0.001$; 4 wk: 0.39 ± 0.01 *vs* 0.18 ± 0.01, 0.22 ± 0.01, $F = 882.909$, $P < 0.001$; 12 wk: 0.41 ± 0.01 *vs* 0.20 ± 0.01, 0.18 ± 0.01, $F = 515.833$, $P < 0.001$). PDX-1 mRNA and PDX-1 protein production showed no statistical significance between the two sham groups. Many PDX-1 positive cells could be found in the pancreatic islets of the rats in RYGB group at all time points. In addition, the percentage of Brdu-insulin double staining positive cells was higher in RYGB group than in the other two groups (1 wk: 0.22 ± 0.13 *vs* 0.03 ± 0.06, 0.03 ± 0.06, $P < 0.05$; 2 wk: 0.28 ± 0.08 *vs* 0.00 ± 0.00, 0.03 ± 0.06, $P < 0.05$; 4 wk: 0.24 ± 0.11 *vs* 0.07 ± 0.06, 0.00 ± 0.00, $P < 0.001$; 12 wk: 0.20 ± 0.07 *vs* 0.03 ± 0.06, 0.00 ± 0.00, $P < 0.05$).

CONCLUSION: RYGB can increase the expression of pancreatic PDX-1 and induce the regeneration of β-cells in GK rats. The associated regeneration of islet cells may be a possible mechanism that how RYGB could improve type 2 diabetes mellitus.

INTRODUCTION

Type 2 diabetes mellitus (T2DM) is a chronic metabolic disease characterized by insulin resistance and progressive deterioration of islet functions[1]. The apoptosis of β-cells may be a major contributor to the failure of these cells at the late stages of T2DM[2]. An effective treatment for diabetes can improve the functions of β-cells and increase their numbers. Roux-en-Y gastric bypass (RYGB) is a commonly used surgical treatment for patients with morbid obesity. It could not only significantly and persistently reduce patients' body weight, but also lower the serum levels of glucose, and glycosylated hemoglobin in 80%-100% of T2DM patients[2,3]. Furthermore, this treatment could also prevent impaired glucose intolerance from developing into diabetes among these patients[3]. Animal experiments have shown that RYGB treatment can improve the functions of pancreatic islets and the metabolism of glucose in both obese and non-obese diabetic rats[4]. These results suggest that RYGB surgery is effective in the treatment of diabetes.

Efforts have been made to understand the mechanism of RYGB treatment on T2DM patients, however, the exact mechanism still remains elusive[5,6]. RYGB treatment may be correlated to the changes of gastrointestinal hormones, which then influence the enteroinsular axis to regulate the endocrine function of the pancreas[7]. One of the most important intestinal hormones involved in this mechanism is glucagon-like peptide 1 (GLP-1). It has been found that RYGB surgery can increase GLP-1 levels in the sera of T2DM patients and in the experimental animals. This effect may last 1 year and in some cases, even up to 20 years after RYGB surgery[5,8]. This may be one of the reasons why the post-operative diabetes is well controlled in both human beings and experimental rodents.

Recently, it has also been reported that after RYGB surgery, some patients developed nesidioblastosis, a serious life-threatening postprandial hyperinsulinism with hypoglycemia[9-12]. These symptoms may be alleviated, after part of the pancreas is removed. Hypertrophy and hyperplasia pancreatic islets are common features seen in the resected specimens, and even multiple islet tumors detected in some specimens. Since the hyperplasia of islet cells are rarely found in the normal population[9,12,13], the above data suggest that RYGB may be associated with the regeneration and neogenesis of the pancreatic islets. Thus, RYGB surgery may occasionally cause the pathological overgrowth and hyperplasia of β-cells in the islets[14]. However, this hypothesis has not been supported by any animal experiments.

Pancreatic duodenal homeobox-1 (PDX-1) is known as the first and most important transcription factor expressed during the embryonic development of the pancreas in experimental animals. All pancreatic cells are derived from the precursor cells with expression of PDX-1[15]. The embryonic pancreas failed to develop in the PDX-1 knockout mice[16]. The mice with heterozygous mutations of *PDX-1* gene could develop a normal pancreas, but may show abnormal glucose tolerance and diabetes in adulthood[17]. If PDX-1 is removed from mature β-cells by Cre-recombinase-mediated deletion, the expression of these genes is impaired and the loss of β-cells is accelerated[18]. The expression level of PDX-1 in the pancreas reach the peak in the first 10.5 d during the development of mouse embryos, and decline gradually afterwards. After the birth and in the adulthood, the expression of PDX-1 becomes very weak, which is specifically found only in 90% of β-cells and 10% of δ-cells in the islets[19].

PDX-1 is significantly re-expressed in proliferating cells in the ducts[20,21] and islets[22] during pancreas regeneration[23] and may serve as a marker of cells that regain their pluripotency to differentiate into all types of pancreatic cells. Subtotal pancreatectomy promoted the PDX-1 expression of duct epithelial cells in Sprague-Dawley rats[21], and the PDX-1 positive cells were also obvious in mouse model with pancreas injury[24]. PDX-1 has significant effect on cell proliferation and could induce a dramatic cell proliferation, which is similar to the formation of the pancreas during embryonic development[25]. Studies of animal models suggested that the down-regulation of PDX-1 expression in the β-cells may underlie the pathogenesis of β-cell failure and the onset of T2DM[26]. Therefore, the regeneration of islet β-cells requires the activation and expression of PDX-1. PDX-1 expression is the basis of regeneration of the pancreas.

Goto-Kakizaki (GK) rats are used in a genetically non-overweight type 2 diabetes model, which has the features of slightly elevated blood glucose, impaired secretion of glucose-stimulated insulin and reduced mass of pancreatic β-cells[1]. It is similar to those in T2DM patients. Therefore, GK rats have been widely used in an experimental animal model for T2DM studies. The aim of this study was to investigate the effects of RYGB surgery on the expression of PDX-1 as well as on the regeneration of pancreatic β-cells in non-obese diabetic GK rats, and the possible mechanisms.

MATERIALS AND METHODS

Animals

Sixty male GK rats weighing 200-230 g, at age of 10-12 wk, were provided by Shanghai Laboratory Animal Center,

Chinese Academy of Sciences, and kept in the animal facility at the Henan Key Lab of Biological Psychiatry, China. The rats were randomly divided into 3 groups with 20 rats in each group: RYGB group, sham-RYGB group and sham-operation (sham-op) group.

Abdominal surgeries

For experiments, GK rats in the RYGB group were fasted overnight and anesthetized with 4% chloral hydrate (Wako Co., Japan). Upper abdomen was cut open with midline incision and then the stomach was sutured bisecting it to produce two separate gastric cavities, distal one and a proximal one. The jejunum was cut off about 8 cm from the Tretiz ligaments. The proximal part of the stomach was opened and anastomosed with the distal jejunum. The proximal jejunum was anastomosed with the side of distal jejunum at the site about 10 cm away from the above stomach-jejunum anastomosis. The abdominal incisions were closed with absorbable sutures. For controls, the stomachs of rats were transected across the pylorus followed by discontinuously suturing back the two gastric stumps in the sham-RYGB group, and in the sham-op group there was only an anterior abdominal wall incision which was immediately sutured without disturbing the internal organs. After surgery, all rats were fasted and only fed with water on the same day of the operation (day 0). They were fed with food starting from day one. Animals were administered with the antibiotics, cefradine powder (Bright Future Pharmaceuticals Factory, Hong Kong), at a dose of 100-150 mg/kg body weight, once every 24 h, for a total of 3 d to prevent infections. Animals were euthanized on the 1st, 2nd, 4th and 12th wk after operation, with five rats from each group at each time-point, separately.

Reverse transcription polymerase chain reaction

On the sacrifice day, each rat was first intraperitoneally injected with 5-bromo-2-deoxyuridine (Brdu, from Sigma, USA) at 50 mg/kg and two hours later, the rats were euthanized with overdose anesthesia. The pancreatic tissues were isolated and rinsed with 0.01 mol/L phosphate buffered saline (PBS). Eighty mg of pancreatic tissues from each rat was homogenized using Trizol reagent (Sigma, USA), and the total RNA was extracted according to the manufacturers' protocol. The optical density of RNA was read with the spectrophotometry at the wavelength of 260 nm (A_{260}). The cDNAs were synthesized by adding 1-2 μg DNA-free RNA to the RT mixture. Glyceraldehyde phosphate dehydrogenase (GAPDH) was used as an internal control. PCR was performed with the following primers: GAPDH (forward: 5'-ACCACAGTCCATGCCATCAC-3'; reverse: 5'-TCCACCACCCTGTTGCTGTA-3'), PDX-1 (forward: 5'-CCAAAACCGTCGCATGAAGTG-3', reverse: 5'-TCTGGGTCCCAGACCCG-3'). The combination of the DNA primers produced single PCR products of 550 and 208 bp in length, respectively. PCR was carried out in a DNA thermal cycler (Biometra, Goettingen, Germany) after denaturation at 95℃ for 5 min. The number of total PCR cycles was 35 for PDX-1 and 30 for GAPDH, and each cycle consisted of denaturation at 94℃ for 15 s, annealing at 65℃ (GAPDH at 62℃) for 30 s, and extension at 72℃ for 90 s. For semiquantitative analysis, 25 μL of each PCR product was examined by electrophoresis in 1.8% agarose gel containing 0.5 μg/mL of ethidium bromide. DM 1000 (LEICA, Germany) was used as a molecular marker. OD readings of PDX-1 mRNA were normalized to those of GAPDH mRNA, and the ratios were analyzed.

Paraffin sectioning

The pancreatic tissues obtained from the above rats were also immediately fixed with 4% paraformaldehyde at 4℃ overnight. The tissues were then dehydrated in graded ethanol, cleared in xylene and finally embedded in paraffin. The tissues were sectioned to produce 4 μm-thick sections, which were mounted onto slides for further staining.

Immunohistochemical staining

In brief, the pancreatic sections were deparaffined in xylene and rehydrated in graded ethanol. The sections were blocked in H_2O_2 and sequentially incubated with goat anti-PDX-1 polyclonal primary antibody (1:50 dilution; Santa Cruz, USA) overnight and anti-goat secondary antibody (1:100 dilution; Santa Cruz, USA) for 2 h. For negative control, the primary antibody was replaced with 0.01 mol/L PBS.

Western blotting

Total protein was obtained from the pancreatic tissues, that were lysed in the buffer containing 50 mmol/L Tris, pH 7.5, 0.3 mol/L NaCl, 0.5% Triton X-100 and 0.1% sodium azide, and protease inhibitor cocktail CLAP (chymostatin, leupeptin, aprotinin and pepstatin, 100 μmol of each, Sigma Aldrich, USA). Then protein samples (50 μg) were separated in 10% sodium dodecyl sulphate polyamide gel electrophoresis (SDS-PAGE) and transferred to a nitrocellulose membrane (Amersham, UK). The membranes were then blocked in 0.01 mol/L PBS containing 5% dry milk and 0.3% Tween 20 for 1 h. The membranes were then incubated with goat anti-PDX-1 antibody (1:10000 dilution) at room temperature for 2 h and horseradish peroxidase-labelled secondary antibody (1:5000 dilution; Amersham, Japan) at room temperature for 1 h, respectively. Finally, the proteins were visualized on enhanced chemiluminescence hyperfilm (Amersham, Japan) by application of Amershem's Enhanced Chemiluminescence Western blotting Detection System. The band intensity was quantitated with GelAnalysis software (GreyStone-Iconix).

Double immunohistochemical staining

Briefly, the pancreatic sections were sequentially incubated with guinea pig anti-insulin polyclonal antibody (1:50 dilution; Santa Cruz, USA), biotinylated rabbit anti-guinea pig antibody (1:50 dilution; Santa Cruz, USA), and streptavidin-alkaline phosphatase complex (Santa Cruz, USA), for a period of 45 min each. The alkaline phosphatase activity was identified using new fuchsin under light microscope. The sections were counterstained with Harris hematoxylin.

To detect the second antigen Brdu, the sections were placed in 2 N hydrochloric acid and kept at 70℃ for 15 min for antigen retrieval. The reaction was stopped by 0.1 mol/L sodium borate and left in 0.01 mol/L PBS for 20 min. Tissue sections were incubated with hydrogen peroxide for 45 min, mouse anti-Brdu monoclonal antibody for 3 h, biotinylated goat anti-mouse antibody for 45 min, and streptavidin-peroxidase complex for 45 min, respectively. Finally, the peroxidase activity was visualized with diaminobenzidine under light microscope, and the reaction was stopped by rinsing with PBS. Avidin and biotin were then applied to the sections for 45 min each.

Cell count

The images of the above double-stained sections were captured at 100 × magnifications. In each rat, a total of 1000 nuclei from five sections were counted, and the sections were randomly selected from tail (3 sections), body (1 section) and head (1 section). The index of Brdu-labeling was calculated as follows: The index of Brdu labeling = (The number of double-stained cells/1000) × 100%.

Statistical analysis

All data were presented as mean ± SD (n = 5). The data were analyzed using SPSS13.0 statistical package. The differences were analyzed by factorial design of variance. The comparison of variance between two groups was analyzed by LSD method. Missing variance was analyzed using Dunnett T3. Non-normal data were analyzed non-parametrically using a number of independent samples and tested by Kruskal-Wallis method. $P < 0.05$ was considered to indicate statistical significance of the test results.

RESULTS

Reverse transcription polymerase chain reaction

Compared with internal control, GAPDH, the data of relative mRNA expression of PDX-1 at weeks 1, 2, 4 and 12 after surgery were 0.378 ± 0.013, 0.318 ± 0.013, 0.172 ± 0.011 and 0.140 ± 0.007 in the rat pancreas of RYGB group, 0.120 ± 0.010, 0.110 ± 0.010, 0.107 ± 0.012 and 0.120 ± 0.010 in sham-RYGB group, and 0.100 ± 0.010, 0.110 ± 0.010, 0.090 ± 0010 and 0.097 ± 0.015 in sham-op group, respectively. The above data were plotted as shown in Figure 1B. The F values of the relative expression level of PDX-1 mRNA in the rat pancreas at 1, 2, 4 and 12 wk after surgery in the three groups were 727.717, 301.509, 64.297 and 16.392, respectively, all $P < 0.05$. There was statistically significance at each time point. In addition, the relative mRNA expression level of PDX-1 in the RYGB group showed statistical significance (F = 512.105, $P < 0.05$), being higher at 1 and 2 wk after surgery. In contrast, there was no significant difference at different time points between sham-RYGB and sham-op groups (F = 0.750, both $P > 0.05$).

Immunohistochemical staining

Anti-PDX-1 immunohistochemical (IHC) staining showed that there were many PDX-1 positive cells with brown nuclei in the rat pancreas in the RYGB group. These cells were mainly located in the islets. A few PDX-1 positive cells could be observed in the ducts and acini (Figure 2A and B). In contrast, few PDX-1 positive cells were found in the islets of rat pancreas at each time point in both sham-RYGB and sham-op groups (Figure 2C).

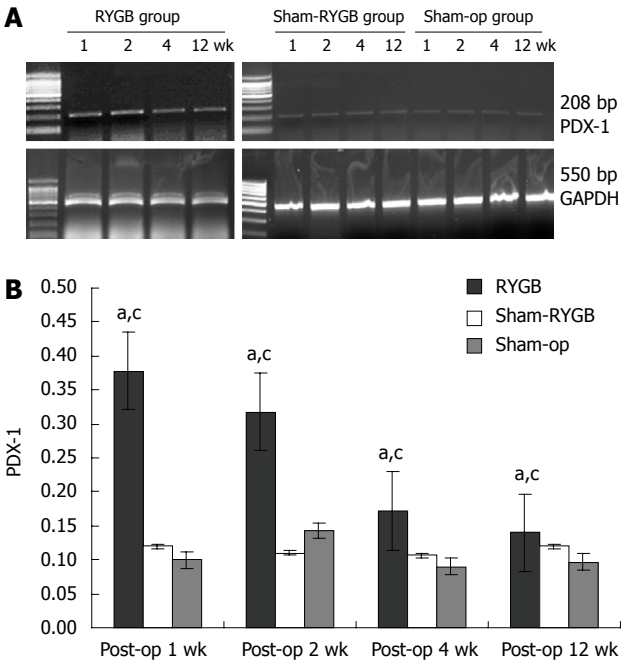

Figure 1 The expression of PDX-1 mRNA in the pancreas of GK rats. A: Representative gel from RT-PCR with primers to PDX-1 (208 bp) and GAPDH (550 bp); B: The intensities of PDX-1 mRNA bands relative to those of GAPDH bands. $^{a}P < 0.05$ *vs* sham-RYGB; $^{c}P < 0.05$ *vs* sham-op group.

Western blotting

The data of the expressions of PDX-1 protein in the rat pancreas are plotted in Figure 3A. Compared with the internal control, GAPDH, the relative expressions of PDX-1 protein in the rat pancreas are shown in Figure 3B. The F values of the relative expression of PDX-1 protein in the rat pancreas at 1, 2, 4 and 12 wk after surgery in the three groups were 3031.127, 3426.455, 882.909 and 515.833, respectively (all $P < 0.05$). In addition, there was statistical significance at each time point among the three groups. The relative expression levels of PDX-1 protein in the rat pancreas of RYGB group showed statistical significance (F = 676.157, $P < 0.05$), being highest at 1 and 2 wk after surgery.

Double IHC staining

Anti-Brdu and anti-insulin double stained cells could be found in the rat pancreas in the RYGB group at each time point (Figure 4A-C). The Brdu and insulin double positive cells were found primarily in the islets and occasionally in the ducts (Figure 4C). Single insulin positive cells could be observed in the acini (Figure 4B) and there were many single Brdu positive cells in the acini of the pancreas (Figure 4A-D). However, few Brdu and insulin double positive cells could be found in the rat pancreas in both sham-RYGB

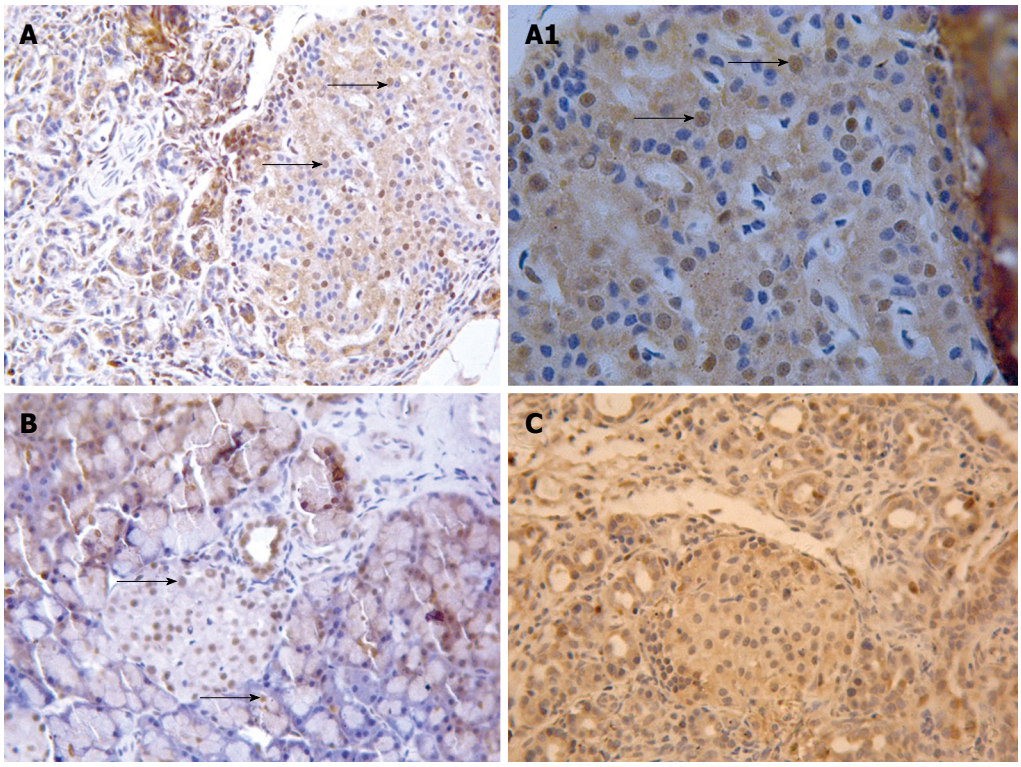

Figure 2 The expression of PDX-1 protein in the pancreas of GK rats. PDX-1 positive signals were stained in dark brown color (arrows), and mainly located the islets. Occasionally, they were found in the duct and acinar cells. A, B and A1 in RYGB group; C in sham-op group. (Hematoxylin & anti-PDX-1 IHC stain. A, B and C at 200 × magnifications; A1, at 400 × magnifications).

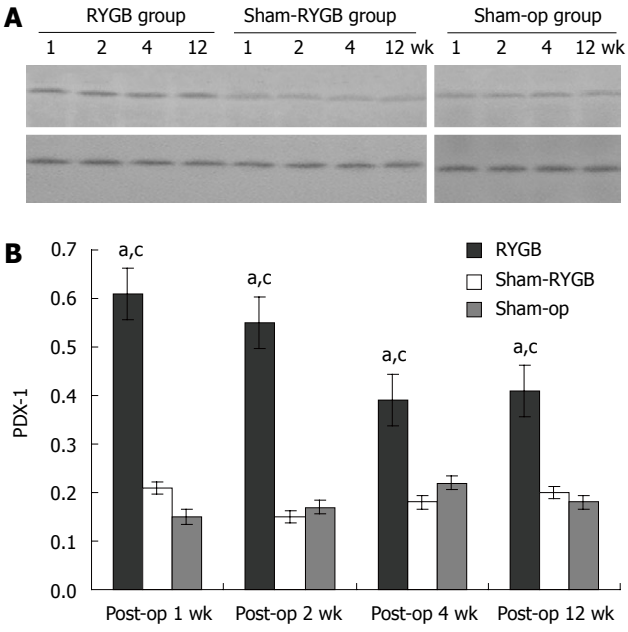

Figure 3 Western blotting analysis of PDX-1. A: Representative Western blotting analysis of PDX-1 protein; B: The relative expression level of PDX-1 protein. $^{a}P < 0.05$ *vs* sham-RYGB; $^{c}P < 0.05$ *vs* sham-op group.

and sham-op groups at each time point after surgery. The percentage of both Brdu and insulin positive cells showed a significant increase at 1, 2, 4 and 12 wk after surgery as compared with the other two groups (Figure 4E). The χ^2 values were 6.197, 8.485, 7.808 and 8.166, respectively; the corresponding *P* values were 0.045, 0.014, 0.020 and 0.017. The rank of RYGB group was the highest at each time point. In addition, there were more single Brdu positive cells in RYGB group than in the other two groups.

DISCUSSION

In this study, the expression levels of PDX-1 mRNA in the RYGB group were significantly higher than those in the sham-RYGB and sham-op groups at all time points of 1, 2, 4 and 12 wk after surgery. It suggests that RYGB surgery may result in an increase in the expression of pancreatic PDX-1 mRNA in GK rats. In other words, RYGB surgery may promote the expression of PDX-1 mRNA, which may last at least 12 wk. The expression of PDX-1 mRNA in RYGB group peaked at the first two weeks and decreased afterwards, which may suggest that RYGB surgery played a role in promoting the expression of PDX-1 mRNA primarily at the early stage after the surgery.

Similarly, the protein expressions of PDX-1 in RYGB group were also significantly higher than those in the other two groups at all time points. The protein expression level of pancreatic PDX-1 in RYGB group also peaked at the first two weeks after surgery, and decreased afterward. Furthermore, the results of anti-PDX-1 IHC staining also showed that PDX-1 positive cells in the pancreas of GK rats increased significantly in RYGB group when compared with those in both sham-RYGB and sham-op groups. The PDX-1 positive cells were mainly located in the islets, but not in the acinus and ducts.

It is important to increase the number of β-cells in the pancreatic islets in the treatment of diabetes. The regenerated β-cells in the islets may be double labeled by anti-Brdu and anti-insulin double IHC staining. In this experiment, Brdu and insulin double positive cells were visible in the pancreas in all GK rats at all time points. In addition, the percentages of Brdu and insulin double positive cells in RYGB group were significantly higher than those in both sham-RYGB and sham-op groups. The results also suggest

(A and C at 400 × magnifications; B and E at 200 × magnifications; D at 1000 × magnifications). $^{a}P < 0.05$ *vs* sham-RYGB; $^{c}P < 0.05$ *vs* sham-op group.

that RYGB surgery may promote the regeneration of islet β-cells in GK rats, which is likely another mechanism why RYGB surgery may decrease the blood glucose in diabetes patients.

The results in this study have shown that RYGB surgery may result in an increase in expressions of PDX-1 mRNA and PDX-1 protein, the number of PDX-1 positive cells and the percentage of Brdu and insulin double positive cells in GK rats. All these suggest a regeneration of islet β-cells, which may be related to persistent elevations of serum GLP-1 after RYGB surgery. It is reported that GLP-1 and its long-acting analog exendin-4 (Ex-4) enhance the expression of pancreatic PDX-1 and regeneration of islet β-cells, and inhibit the apoptosis of β-cells[27,28]. GLP-1 can stimulate the differentiation and proliferation of β cells in GK rats[29]. GLP-1 increases the number of β cells by inducing the differentiation and neogenesis of ductal progenitor cells into islet endocrine cells. Koizumi *et al*[27], have found that Ex-4 can significantly stimulate β-cell proliferation in PDX-$1^{+/+}$ mice, but not obviously influence the apoptosis of β-cells. However, in PDX-$1^{-/-}$ mice, the proliferation of β-cells showed no significant change, whereas the apoptosis of β-cells increased significantly in number. Therefore, functions of GLP-1 may rely on the *PDX-1* gene activation and expression[24,30]. Ex-4 has been approved by the Food and Drug Administration for the clinical treatment of diabetes[31]. GLP-1 is decomposed *in vivo* by enzyme dipeptidyl peptidase-Ⅳ (DPP-Ⅳ)[31], whose inhibitor, vildagliptin, has been applied in the treatment of diabetes and is at the stage of advanced clinical trials[30]. This compound may increase the mass of β-cells, and slow or even reverse the progressive islet-cell deterioration in diabetes. It is possible that the effect of GLP-1 on increasing β-cells is partly mediated by an increase in the circulating insulin, which may act as a

growth factor. But, long-term over-stimulation of GLP-1 signaling may cause pathologic hypertrophy and hyperactivity of β-cells, resulting in hypoglycemia.

New pancreatic β-cells are formed in two ways: proliferation of preexisting β-cells, which is called regeneration, and transdifferentiation of non-β-cells from either duct or acinar cells to new β-cells, which is called neogenesis. Dor *et al*[32], have found that the removal of most of the pancreas in mice led to hyperplasia of the pancreas, and suggested that the new β-cells came from the proliferation of pre-existing β cells in the adult pancreas. Injury in the mouse model caused by pancreatic duct ligation has shown that the progenitors of β-cells exist in adult mouse pancreas, which could be activated and then produced new functional β-cells by differentiation and proliferation[33]. It has been reported that new β-cells in adult pancreas were transdifferentiated from epithelial cells in pancreatic ducts whose characteristics as duct cells were lost either in normal or injured pancreas[27,33-37]. Stem cells also existed in adult human pancreatic ducts, which not only expressed nestin and PDX-1, but also exhibited the markers of mesenchymal stem cells[38]. These data suggest that the new β-cells in pancreas may be formed through a variety of channels and derived from different cells.

Similarly, *in vitro* cultured stem cells from adult bone marrows[35] and adipose-derived mesenchymal stem cells[36] can be induced to differentiate into insulin-like cells which produce insulin. This indicates that the stem cells from the mesoderm may cross over the embryonic layer and differentiate into insulin-like cells in the endoderm. In other words, the mesenchymal stem or progenitor cells have a strong reserving function in the body. Yuan *et al*[39] and Kodama *et al*[40] have also proposed similar hypothesis, in which progenitor cells exist in the adult pancreas and may transform to endocrine cells under pathological conditions. In Streptozotocin-treated mice, regeneration of β-cells seemed to occur mainly from intra-islet stem/progenitor cells[40].

In this study, the regeneration of β-cells was mainly located within the islets, which is consistent with the experimental results of Kodama *et al*[40]. In addition, in this experiment, Brdu and insulin double positive cells were mainly found in the pancreatic duct and single insulin positive cells were mainly in the acini. These results suggest that the duct epithelial cells and acinar cells can be transdifferentiated into insulin-like cells, which are consistent with the experimental results of De Haro-Hernández *et al*[41]. Single Brdu positive cells were found within the pancreatic acini in RYGB rats, which suggests that RYGB promotes not only regeneration/neogenesis of pancreatic β-cells, but also regeneration/neogenesis of other cells. However, the emergence of these new cells depends on the PDX-1 activation and expression.

COMMENTS

Background

Roux-en-Y gastric bypass (RYGB) is a commonly used surgical treatment for patients with morbid obesity. It significantly and persistently decreases the levels of blood glucose and glycosylated hemoglobin in 80%-100% of type 2 diabetes mellitus (T2DM) patients. Efforts have been made to understand the mechanism of RYGB treatment in T2DM patients, however, the exact mechanism is still elusive.

Research frontiers

Some patients who underwent RYGB surgery developed nesidioblastosis, a serious life-threatening postprandial hyperinsulinism with hypoglycemia, which is rarely found in the normal population. The article suggests that RYGB may be associated with the regeneration and neogenesis of the pancreatic islets. However, this hypothesis has not been supported by any animal experiment.

Innovations and breakthroughs

This study showed that RYGB could increase the expression of pancreatic PDX-1, which is the first and most important transcription factor found during the embryonic development of the pancreas and pancreas regeneration, and induce the regeneration of β-cells in GK rats used in a model of genetic non-overweight type 2 diabetes. The regeneration of islet cells is a possible mechanism how RYGB can treat T2DM.

Applications

T2DM is one of the most common chronic metabolic diseases that is characterized by insulin resistance and progressive deterioration of islet cell functions. Findings of this study explain the possible mechanism of treating T2DM with RYGB surgery. This study has provided a new basis for surgery to treat T2DM and explained why the post-surgical nesidioblastosis occurs in RYGB patients.

Peer review

This is a very important paper since it is dealing with an issue of high relevance, nevertheless not properly addressed in most of the publications at present. Moreover, an extensive literature review is reported and examined.

Abstract

AIM: To characterise expression of interleukin 6 (IL-6), a potent proinflammatory cytokine, in the occurrence and development of inflammatory bowel disease (IBD) and investigate its effect on neuroimmunomodulation and immune homeostasis regulation.

METHODS: In this study, rats with colitis induced by trinitrobenzene sulfonic acid (TNBS) were sacrificed on days 3, 7, 14, 21 and 28 after induction. In the controls, the TNBS was just replaced by equivalent amount of phosphate buffered solution (PBS, 0.01 mol/L). IL-6 mRNA expression in brain and colon tissues in each phase was evaluated by real-time reverse transcription-polymerase chain reaction, and cellular localisation and protein level of IL-6 was determined by immunohistochemistry.

RESULTS: At day 7, mRNA expression of IL-6 was significantly higher in the colon and brain of IBD rats than that of the controls. The protein level was also significantly higher in colon, hypothalamus and cerebral cortex of IBD rats compared with the controls. So there are similar temporal trends in IL-6 mRNA expression and protein levels in all positions with a persistent increase to a peak at day 7, followed by a decline and gradual return to normal levels.

CONCLUSION: These results revealed that changes in IL-6 expression in brain and colon tissues occur in different phases of IBD. Therefore, we propose that the nerve centre regulates and controls the occurrence and development of IBD *via* IL-6.

INTRODUCTION

Inflammatory bowel disease (IBD) includes two chronic pathologies characterised by alternating phases of active inflammation and quiescence: ulcerative colitis (UC) and Crohn's disease (CD)[1]. Although the pathogenesis of IBD has not been well established, it has been suggested that some frequently observed clinical manifestations such as abdominal pain, nausea, vomiting, ileus, or diarrhoea, can be attributed to deranged gastrointestinal motility associated with inflammation[2]. The hypothesis that immune abnormalities induced by Th1/Th2 imbalances play a core role in the pathogenesis of IBD has been widely accepted[3,4]. Th1 cells predominantly secrete interferon-γ (IFN-γ), interleukin 2 (IL-2) and tumor necrosis factor α (TNF-α), while Th2 cells secrete interleukins 4, 5 and 10 (IL-4, IL-5, IL-10). Cytokines can be divided into pro-inflammatory and anti-inflammatory cytokines and growth factors. Pro-inflammatory cytokines such as IL-1, IL-2, IL-8, IL-12, TNF-α, TNF-β and IFN-γ are produced by monocytes and macrophages and are involved in cell-mediated immune responses. Anti-inflammatory cytokines such as IL-4, IL-5, IL-10 and IL-13 are produced mainly by T cells and are involved in the humoral immune response.

Communication between the periphery and the brain takes place *via* neural and humoral pathways. Cytokines released by activated immune cells are mediators of inter- and intra-cellular communication[5-11] and are part of a chemical signalling system that regulates development, tissue repair, haemopoiesis, inflammation and specific and nonspecific immune responses. Potent cytokine polypeptides (such as interleukins 1, 6, 8 and TNF-α) have pleiotropic activities and functional redundancy and exist in a complex, intermingled network in which one cytokine can influence the production of and response to many other cytokines[12]. Of note, modulation of cytokines and their antagonists also exhibits therapeutic potential in several chronic and acute diseases[10,11]. The immune system is regulated in part by the central nervous system (CNS), acting principally *via* the hypothalamic-pituitary-adrenal (HPA) axis and the sympathetic nervous system (SNS)[13-15]. IL-6 is a pleiotropic cytokine whose expression in physiological conditions is important for host responses to a number of infections; in addition, it exerts antigen-specific immune responses and has both pro- and anti-inflammatory effects[16,17]. In CD, IL-6 is present at high levels in both serum and intestinal tissues[18]. Increased levels of IL-6 receptor (IL-6R) and gp130 expression have been also demonstrated in peripheral lymphocytes of Crohn's patients, along with increased serum soluble IL-6R[19].

To explore the role of IL-6 in the initiation and development of IBD with respect to the neuroimmunomodulation and regulation of immunological homeostasis at the organismic level, we used real-time reverse transcription polymerase chain reaction (RT-PCR) and immunohistochemistry (IHC) to evaluate the mRNA expression and cellular localisation of IL-6 in brain and colon tissues in the inflammatory and quiescent phases of IBD in an animal model with trinitrobenzene sulfonic acid (TNBS)-induced IBD.

MATERIALS AND METHODS

Reagents

All chemicals were purchased from Sigma Chemical, unless otherwise stated.

Animals

Eighty female Wistar rats (Laboratory Animal Service of Jilin University, Changchun, China), 8-10 wk old and weighing 180-200 g, were maintained under specific pathogen-free conditions according to our institutional guidelines for animal care. This study was carried out in accordance with guidelines established by a consensus statement entitled the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes.

Experimental model

After a seven-day acclimation period, 80 rats were divided randomly into 8 cages (one cage for 10) and fed in the same condition. Among them, 4 cages were experimental group and the others were controls. Rats were fasted overnight, and colitis was induced in the TNBS group by the method originally described by Morris *et al*[20], with some modifications made by our group. Briefly, rats were anaesthetised with ethylether and given a 5% TNBS (Sigma, R&D, USA) and ethanol mixture (2:1) at a dose of 0.3 mL/100 g inserted through the anus to a distance of 8 cm. Rats from the non-colitis group were given an intracolonic dose of 0.25 mL phosphate buffered saline (PBS) instead of TNBS. Animals were maintained in a vertical position for 30 s and returned to their cages.

Assessment of experimental model

Macroscopic scoring: At 3, 7, 14, 21, and 28 d after induction of colitis, rats were exsanguinated under ether anaesthesia, and the small and large intestines and the brain were excised. Samples of the descending colon were obtained for paraffin section and measurement of myeloperoxidase activity (see below). The remaining descending colon, sigmoid colon, and rectum were opened longitudinally and fixed onto a board with pins, and the macroscopic appearance was scored by two blinded investigators on a 0-4 scale similar to the original scoring system of Morris and colleagues[20]; briefly, 0 = no evidence of inflammation, 1 = erythema only, 2 = erythema with slight oedema and small erosions, 3 = two or more bleeding ulcers and/or inflammation and/or moderate adhesions, and 4 = severe ulceration and/or stenosis with prestenotic dilations with or without severe adhesions.

Determination of myeloperoxidase activity: Colonic myeloperoxidase activity was measured as previously described by Grisham *et al*[21] and Suzuki *et al*[22]. Briefly, tissue was homogenised in approximately 10 mL 50 mmol/L

KPO_4 at pH 7.4 and centrifuged for 20 min at 20 000 *g*. The pellet was homogenised in 10 mL 50 mmol/L KPO_4, and 10 mmol/L EDTA at pH 6.0 with 0.5% hexadecyltrimethylammonium bromide (wt/vol). After one freeze-thaw cycle, the homogenate was sonicated, and myeloperoxidase activity was determined by measuring H_2O_2-dependent oxidation of 3,3',5,5'-tetramethylbenzidine and expressed as units per gram of tissue.

Microscopic scoring: Specimens were fixed in PBS containing 4% formaldehyde and embedded in paraffin. Multiple sections (5 μm thick) were stained with haematoxylin and eosin using standard techniques. The degree of inflammation was assessed by two blinded investigators using the 0-4 scoring system described by Neurath *et al*[23] (0 = no signs of inflammation, 1 = low levels of leucocyte infiltration, 2 = moderate levels of leucocyte infiltration, 3 = high levels of leucocyte infiltration, high vascular density, thickening of bowel wall, and 4 = transmural infiltrations, loss of goblet cells, high vascular density, significant bowel wall thickening).

Isolation of mRNA and analysis of mRNA expression by real-time RT-PCR

A total of 80 rats (normal and IBD model) were used for real-time RT-PCR analysis. The proximal part of the colon (the area with macroscopically visible mucosal folds) and the brain were stored in RNAlater (Ambion, Austin, TX) at -80℃ for use in RNA extraction. RNA was extracted using the Trizol reagent (Invitrogen) according to the manufacturer's protocol. The integrity and quality of the isolated RNA was examined by quantifying the A260/280 ratio (BioPhotometer, Eppendorf, Hamburg, Germany) and resolving the RNA on a 1% agarose gel. The cDNA was prepared from 1.0 μg RNA (OD = 1.9-2.0) in the presence of 2.5 μmol/L oligo (dT) primer and 200 U Moloney murine leukemia virus reverse transcriptase (M-MLV; Promega, Madison, WI) in a total volume of 20 μL. The reaction mixture was incubated for 1 h at 42℃ and stopped by heating at 90℃ for 5 min. The primers and FAM-labelled probes were designed with Primer Express v1.5 software (Applied Biosystems). For IL-6, the forward primer was 5'-GCCCTTCAGGAACAGCTATGA-3', the reverse was 5'-TGTCAACAACATCAGTCCCAAGA-3', and the probe was 5'-CTCTCCGCAAGAGACTTCCAGCCAGTT-3'. For the housekeeping gene beta-actin, the forward primer was 5'-GTCAGGTCATCACTATCGGCAAT-3', the reverse was 5'- AGAGGTCTTTACGGATGTCAACGT-3', and the probe was 5'-CCTTCCTTCCTGGGTATGGAATCCTGTG-3'. All the primers and probes were obtained from Applied Biosystems. PCR was performed in the ABI PRISM 7000 Sequence Detection operated by Sequence Detector v1.3 software (Applied Biosystems), using TaqMan Real-time PCR Master Mix (Toyobo, Japan). A threshold was set at the linear part of the amplification curve, and the number of cycles needed to reach it were calculated. Relative mRNA levels were determined by using a standard curve and by further normalisation to the housekeeping gene beta-actin. The annealing temperatures were both set to 60℃.

Immunohistochemistry

IHC for detection of IL-6 was performed on paraffin sections of rat brain and colon samples; female rats were perfused under chloral hydrate anaesthesia *via* the abdominal aorta. After a 30 s rinse with physiological saline, a fixative containing 4% freshly prepared paraformaldehyde in 0.01 mol/L PBS buffer (pH 6.0) was perfused for 5 min. The brains and colons were cut into 1-2 mm frontal or sagittal slices and were embedded in paraffin using an automated vacuum tissue processor (Leica ASP300, Germany). For experiments, 4 μm sections were cut and mounted on specific slides. For antigen retrieval, the protocol recently described by Pizarro *et al*[24] and Strober *et al*[25] was used. Briefly, the deparaffinised and rehydrated sections were subjected to a 5 min digestion with 0.01% trypsin (Sigma) in PBS and an additional microwave treatment in 10 mmol/L citrate buffer (pH 6.0) for 15 min at 720 W, followed by a 20 min cooling period in the same buffer. After pretreatment, sections were treated for 15 min with 3% hydrogen peroxidase to block endogenous peroxidase activity and were blocked with 0.5% blocking reagent for 30 min to reduce non-specific reactions. The sections were incubated for 36 h at 4℃ with rabbit anti-rat-IL-6 IgG (Biozol, Eching, Germany; diluted 1:400) in blocking buffer. Sections were washed in PBS, and biotinylated linking antibody solution (Biozol, Eching, Germany) was applied (100 μL/section) for 20 min at 37℃. Sections were then washed in PBS before application of HRP conjugated streptavidin (100 μL/section, 15 min) at 37℃. Slides were stained with DAB (IBL, Germany) after being washed in PBS for 5 min, washed in PBS and DAB (BIOS) for 5 min and counterstained with hematoxylin. For negative controls, the primary antibody was replaced with the corresponding affinity-purified preimmune IgG.

Statistical analysis

Data are expressed as mean ± SE. Statistical analysis was performed using SPSS 17.0. Differences were considered to be statistically significant when $P < 0.05$ by analysis of variance (ANOVA).

RESULTS

Effects of TNBS-induced colitis on clinical and macroscopic appearance

After administration of TNBS, we found that Wistar rats regularly developed colitis with severe diarrhoea, losing 15% of their body weight and suffering rectal prolapse and extensive wasting. Gross blood adhesion to the anus was noted in some rats. Macroscopically, colitis was characterised by bowel wall thickening, adhesions and necrotic foci (Figure 1). As these severe inflammatory changes covered 2-4 cm of the distal colonic mucosa, this resulted in a higher median macroscopic damage score in TNBS-treated rats compared to controls (Figure 2A, $P < 0.01$), especially by day 7.

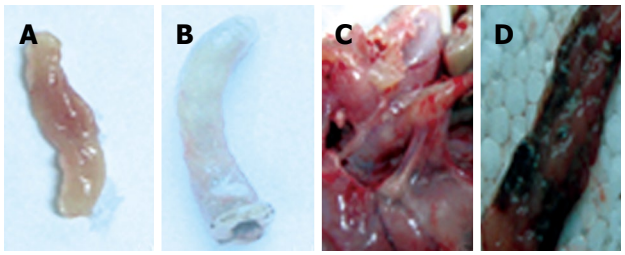

Figure 1 The macroscopic appearance of colon tissue in trinitrobenzene sulfonic acid (TNBS)-treated *vs* control rats. A: The colon of control rats, with macroscopic damage score = 0; B-D depict colonic tissue of TNBS-treated rats: B: Significant swelling and distension, with macroscopic damage score = 5; C: Extensive adhesions around the colon, with macroscopic damage score = 7; D: Necrotic foci in colon, with macroscopic damage score = 8.5.

Effects of TNBS-induced colitis on colonic myeloperoxidase activity

Myeloperoxidase (MPO) activity was determined by using accumulation of polymorphonuclear leucocytes as an indicator. Compared with the control rats, MPO activity increased gradually, peaked by day 7, and decreased to nearly the baseline value (Figure 2B).

Effects of TNBS-induced colitis on colonic histology

The degree of inflammation was assessed using the scoring system at 3, 7, 14, 21, and 28 d after TNBS induction. The score reached a peak at day 7, and then decreased gradually to nearly the normal value (Figure 2C). Microscopic evaluation of colons from control rats showed normal colonic histological features (Figure 3A). Histological evaluation of the colon at each period after TNBS induction is shown in Figure 3B-F. TNBS caused the inflammatory features typical of colitis in the rats' colonic architecture: severe oedema and haemorrhage at the muscular layer of the mucosa, ulceration, goblet cell depletion, and a mixed cell infiltration that was mainly composed of mononuclear cells such as macrophages, lymphocytes and plasmocytes.

Analysis of IL-6 mRNA expression

We used real-time RT-PCR to measure expression of IL-6 mRNA in the brain and colon at various time points after induction of colitis. Our results demonstrated a remarkable difference ($P < 0.01$) in colon and brain tissues in the experimental *vs* the control group. IL-6 mRNA expression levels increased by day 3 and returned to near baseline levels by day 28, reaching their highest point at day 7. Thus, there is similarity on the increasing trend (Figure 4A).

IHC

IHC was performed to determine IL-6 localisation in the colon, cerebral cortex and hypothalamus. The distribution, cellular localisation, and intensity of staining were assessed using light microscopy. The distribution and relative abundance of IL-6 in the parts of the colon, cerebral cortex and hypothalamus examined in this study are presented in Figure 4B; representative sections are shown in Figure 5. Control sections immunolabeled with the preimmune serum were devoid of immunolabeling for IL-6. We found that

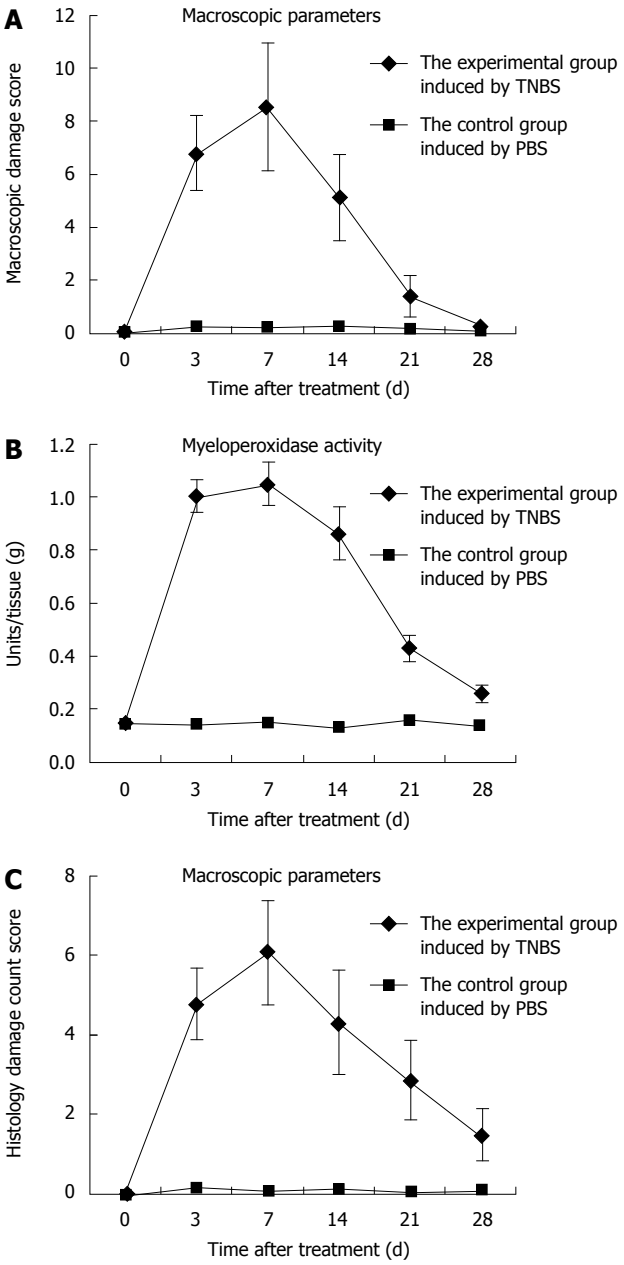

Figure 2 Assessment of TNBS-induced colitis rats by time points. As these severe inflammatory changes covered 2-4 cm of the distal colonic mucosa, this resulted in a higher median macroscopic damage score in TNBS-treated rats compared to controls (A, $P < 0.01$), especially by day 7; compared with the control rats, MPO activity increased gradually, peaked by day 7, and decreased to nearly the baseline value (B); The score reached a peak at day 7, and decreased gradually to nearly the normal value (C).

immunostaining was clearly increased in the colon, cerebral cortex and hypothalamus after induction of colitis, reaching a peak at day 7 and decreasing thereafter. Morphologically, analyses showed that the number of IL-6 immunopositive cells was significantly increased ($P < 0.01$) in the colon, cerebral cortex and hypothalamus after induction compared to control animals.

DISCUSSION

Over the past several years, a variety of IBD animal mod-

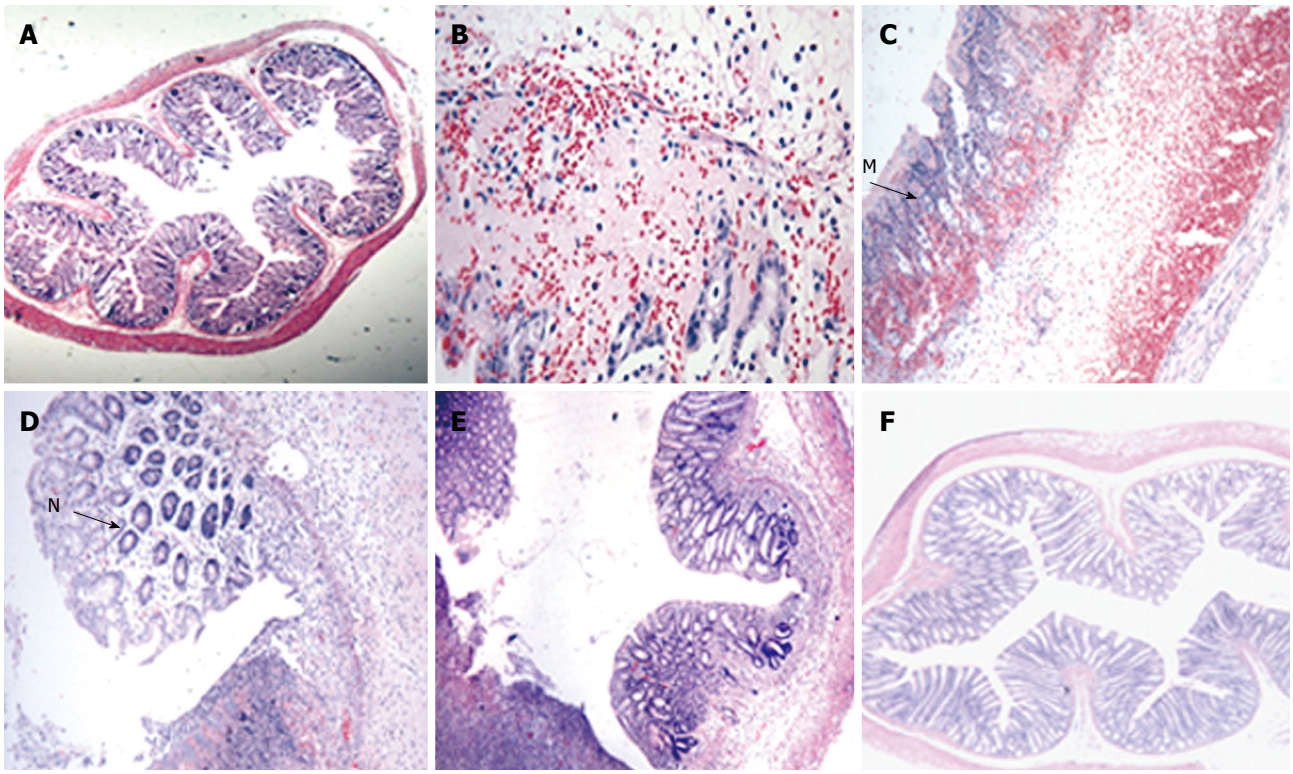

Figure 3 Light photomicrograph of colon tissues from TNBS-induced colitis rats. In control rats, normal histological colon morphology is evident (A, × 4). At day 3, oedema and haemorrhage at the mucosa with goblet cell depletion were seen (B, × 20). At day 7, severe transmural infiltration of the colon wall developed, with submucosal oedema and haemorrhage, lymphocytic and neutrophilic infiltration (M) and coagulative necrosis (C, × 10). At day 14, goblet cell regeneration (N), oedema and haemorrhage regressed by degrees (D, × 20). At day 21, abundant goblet cells and crypts developed (E, × 10). At day 28, oedema and haemorrhage had almost entirely disappeared, the structure of the muscular layer became compact and the intestinal glands developed highly (F, × 4).

The results were determined by ANOVA.

els have been developed and investigated, with the ultimate goal of understanding the causes of CD and UC[24,25]. To study the inflammatory pathways and pathogenesis of IBD, we have established models of colitis after chemical induction (TNBS) of hapten-induced gut inflammation; with this model, we have detected mRNA expression and cellular localisation of IL-6 using RT-PCR and IHC in brain and colonic tissues.

Our IHC and RT-PCR analysis of the colon demonstrate an important role for IL-6 in the development of IBD. The induction-related changes in IL-6 described here are not limited to our animal models and are seen in human IBD as well[26,27]. Although the pathogenesis of IBD is unclear, many earlier experiments have proved that IL-6

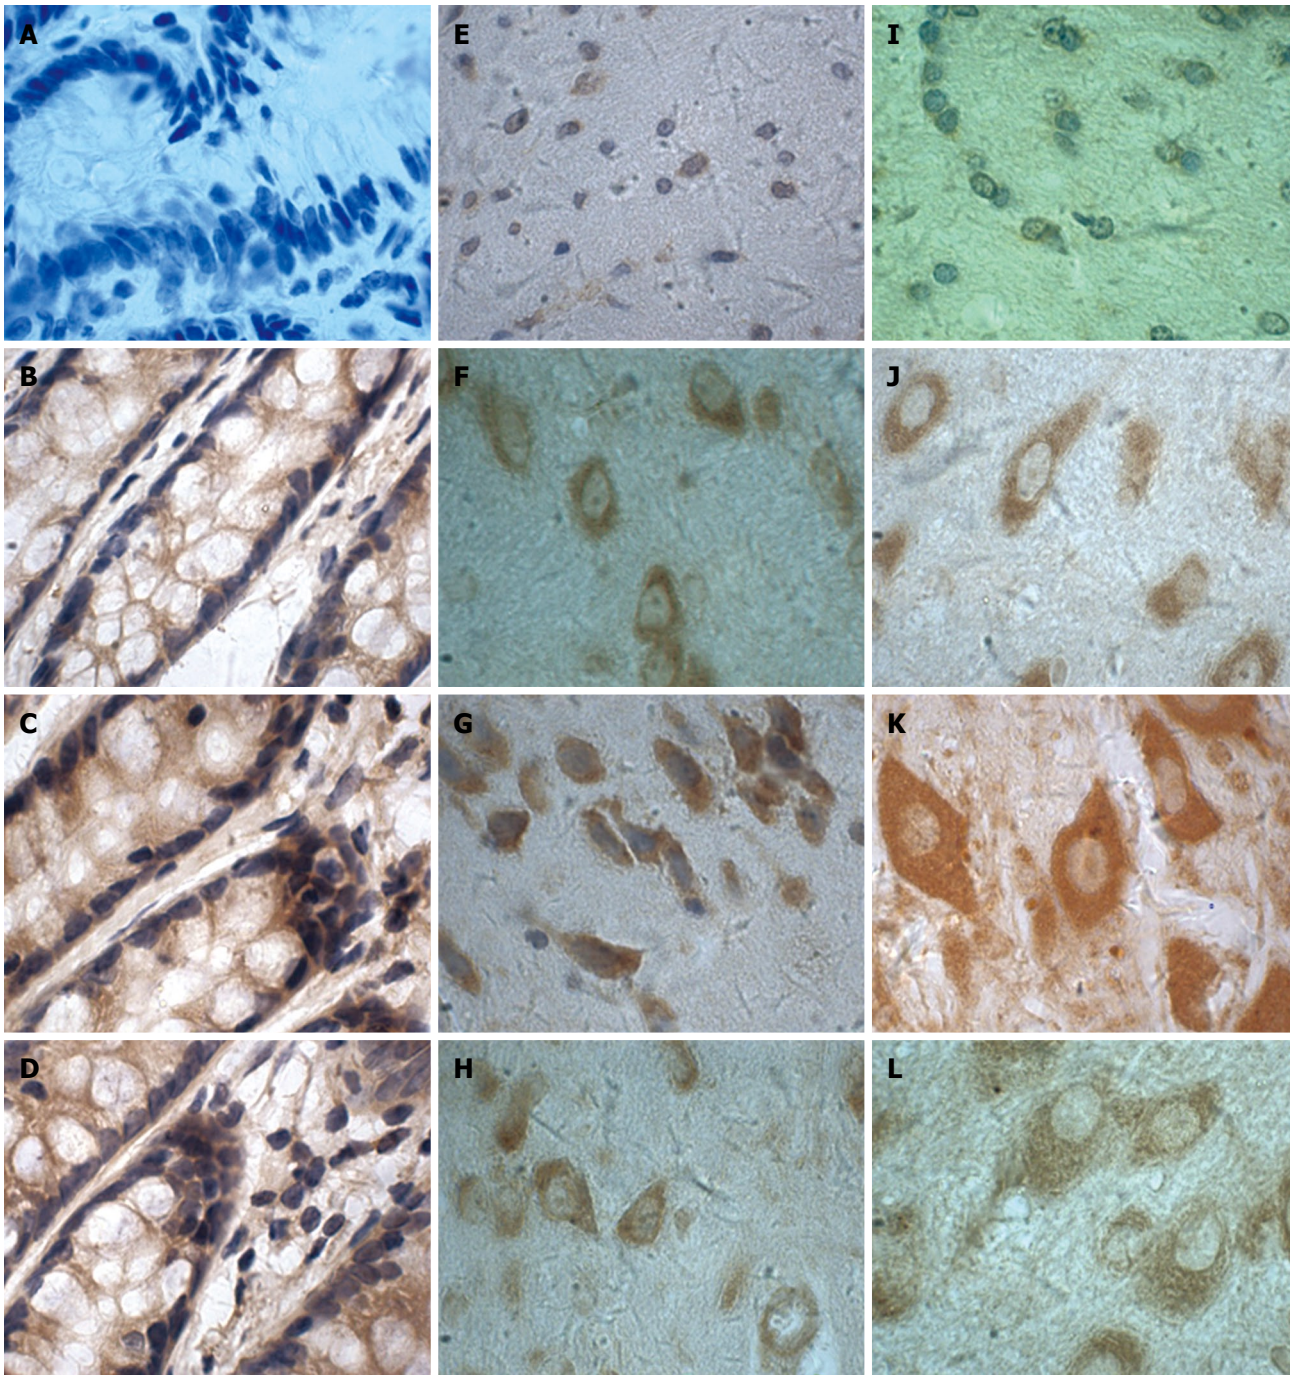

Figure 5 Immunohistochemical localisation of IL-6 proteins in colon (A-D), cerebral cortex (E-H) and hypothalamus (I-L) from TNBS-induced colitis (× 100). plays an important role in the course of colitis[28,29]. IL-6 is one of several inflammatory mediators that induce lesions in the intestinal mucosa; however, if a small amount is generated, the organism's immune function may be enhanced (particularly anti-viral, anti-infectious and anti-tumour activities), while excessive production of IL-6 may induce septic shock and pyosepticaemia. IL-6 expression in CD and UC has been found to be increased[30]. Using RT-PCR, Ishiguro *et al*[31] found enhanced mRNA expression of IL-1β, IL-6, IL-8 and TNF-α in CD and UC, as well as a positive correlation of IL-6 expression levels with severity of inflammation. These results showed that when pathological changes in intestinal canal were increased, IL-6 expression in colonic tissues was gradually enhanced; with the alleviation of pathological changes in the intestinal canal, colonic IL-6 expression gradually declined and tended towards normal. It should be noted that inflammatory cells secreting IL-6 were present in intestinal inflammation sites, and their number was closely related to the severity of inflammation.

There is increased evidence to support the hypothesis of bidirectional circuits between the immune system, CNS and endocrine system[12]. Neuroimmunomodulation is one of the fastest-growing fields of study in current biomedi-

cal science. There is also abundant evidence suggesting that the CNS is not an immune-privileged area and that T lymphocytes are present in the CNS. Microglial cells and astrocytes in the CNS that are equivalent to macrophages in other tissues are the primary cells responsible for an inflammatory reaction. In normal cerebral tissues, these glial cells are quiescent, but they are highly reactive and can secrete cytokines rapidly; this is followed by changes in internal cellular environments and in cell-surface antigens. Cytokines produced by the CNS, including interleukins 1-24, TNF and TGF, can reduce the production of proinflammatory cytokines, lowering the occurrence of some pathological behaviours regulated by the CNS[32,33]. Thus, cytokines may not only play an important role in the immune system, but may also show wide-ranging central regulatory effects. Together with neuromediators and endocrine hormones, cytokines act as the intercellular signalling molecules in organisms and are involved in immune activation and information transmission using neurotransmitters and hormones; thus they are closely related to psychological reactions and mental disorders. In-depth studies on cytokines will contribute to our understanding of IBD pathogenesis and potential therapeutic options. Because neural cells produce IL-6 and have IL-6 receptors, several studies have suggested that IL-6 plays a role in regulating their response to stress. Moreover, IL-6 may be an essential neurotrophic factor in the midbrain after long-term stress[34]. Loss of IL-6 in the CNS does not lead to an improvement in memory function, but instead to memory impairment[35]. Moreover, IL-6 trans-signalling may be of paramount importance in the pathogenesis of several immune-mediated disorders, as well as diseases of the CNS[36,37]. IL-6 is an important CNS-related cytokine and is involved in disease occurrence and course, by direct or indirect regulation of neuronal excitability and neurotransmitter release after receptor binding. IL-6 also plays a significant role in glial cell differentiation and proliferation and reduces antigen presentation by glial cells in the CNS[38]. It is currently recognised that neurons and glial cells can also secrete and express cytokines, and cytokines are active during nerve growth and in the adult nervous system under normal and pathological conditions. This evidence speaks for a potential and crucial role for IL-6 in regulating the interaction of the immune system, CNS and endocrine system. We have confirmed this conclusion through the detection of IL-6 expression in the brains of IBD rats, using IHC and RT-PCR.

Over the course of IBD, we found that expression of IL-6 in cerebral cortex and hypothalamus increased when IBD was exacerbated and gradually declined with disease alleviation. Neither cytokines in cerebral tissues nor those in peripheral blood can cross the blood-brain barrier[39], and there are no reports of an association between cerebral IL-6 expression and colonic cytokines or of what their relationship might be in IBD. The CNS is a central link in the nerve-endocrine-immune regulation network and plays a leading role in the maintenance of the nerve-endocrine-immune network homeostasis. Therefore, by exploring the role of IL-6 in IBD rats from the perspective of the nerve-endocrine-immune network and homeostatic regulation, we have explored the general role of the nerve-endocrine-immune network over the course of IBD. Our results show that pathological changes were most obvious and severe at day 7 after induction of colitis, with necrosis and exfoliation of the intestinal epithelial cells and severe oedema and haemorrhage in the mucosa and muscularis layers, as well as increased expression of IL-6 in the cerebral tissues. Conversely, with the resolution of enteropathy and alleviation of symptoms, IL-6 expression in cerebral tissues began to decline and gradually trended towards levels in normal rats. Therefore, there may be a correlation between IL-6 expression in cerebral and colonic tissues. We propose that cerebral tissues may regulate and control the occurrence and development of IBD *via* IL-6.

This experiment provides new evidence concerning IBD pathogenesis, as well as an experimental model for further enriching and improving the nerve-endocrine-immune network theory. Future studies that explore signal transduction of IL-6, e.g. in IBD rats, may help to further elucidate its role in neuroimmunomodulation.

COMMENTS

Background

Since inflammatory bowel disease (IBD) appeared in Northern Europe and North America, the incidence has been rising in these areas. Currently the incidence of IBD is increasing rapidly in Asian countries especially in the last two decades. Although considerable progress has been made, a major gap in knowledge of the pathogenesis of IBD remains and has precluded the discovery of lasting, effective forms of therapy.

Research frontiers

It has become increasingly evident that interactions between the nervous system and the immune system play an important role in the pathophysiology of IBD. However, how neuroimmunomodulation plays its role in the occurrence and development of IBD is unknown. In this study, the authors demonstrate that interleukin-6 (IL-6) could play a potential role in the course of colitis.

Innovations and breakthroughs

Recent reports have highlighted the importance of cytokines, including pro- and anti-inflammatory cytokines, in the development of IBD. In particular, the imbalance of the cytokines can lead to improper immune responses and initiation of the inflammatory process. So the authors demonstrated similar trends of IL-6 in the brain and in the colon of the experimental IBD model.

Applications

By understanding the role of IL-6 in the development of IBD, this study may open a new strategy for research into the pathogenesis, prevention and treatment of the autoimmune colitis.

Peer review

This is simple and solid work with some new and interesting results.

Abstract

AIM: To compare 2 different types of covered esophageal nitinol stents (Ultraflex and Choostent) in terms of efficacy, complications, and long-term outcome.

METHODS: A retrospective review of a consecutive series of 65 patients who underwent endoscopic placement of an Ultraflex stent (n = 33) or a Choostent (n = 32) from June 2001 to October 2009 was conducted.

RESULTS: Stent placement was successful in all patients without hospital mortality. No significant differences in patient discomfort and complications were observed between the Ultraflex stent and Choostent groups. The median follow-up time was 6 mo (interquartile range 3-16 mo). Endoscopic reintervention was required in 9 patients (14%) because of stent migration or food obstruction. No significant difference in the rate of reintervention between the 2 groups was observed (P = 0.8). The mean dysphagia score 1 mo after stent placement was 1.9 ± 0.3 for the Ultraflex stent and 2.1 ± 0.4 for the Choostent (P = 0.6). At 1-mo follow-up endoscopy, the cover membrane of the stent appeared to be damaged more frequently in the Choostent group (P = 0.34). Removal of the Choostent was possible up to 8 wk without difficulty.

CONCLUSION: Ultraflex and Choostent proved to be equally reliable for palliation of dysphagia and leaks. Removal of the Choostent was easy and safe under mild sedation.

Bona D, Laface L, Bonavina L, Abate E, Schaffer M, Ugenti I, Siboni S, Carrinola R. Covered nitinol stents for the treatment of esophageal strictures and leaks. *World J Gastroenterol* 2010; 16(18): 2260-2264 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i18/2260.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i18.2260

INTRODUCTION

Less than 50% of patients with esophageal carcinoma are suitable for surgery at the time of diagnosis. Most of these patients present with locally advanced or metastatic disease and/or significant comorbidities. In such circumstances, the only therapeutic option is palliative care to treat dysphagia and prevent respiratory complications secondary to aspiration.

Over the past 20 years, the use of covered self-expanding metal stents (SEMS) has proven effective in

patients with unresectable esophageal carcinoma and in those with a tracheo-esophageal fistula[1-3]. In addition, covered SEMS have been successfully used in the management of patients with anastomotic leaks or fistulas[4,5]. Despite the large number of different covered metal stents available on the market, the superiority of one type over another has not yet been proven[6,7]. The aim of this study was to review our experience with 2 types of covered nitinol stents in the management of patients with esophageal strictures and anastomotic complications.

MATERIALS AND METHODS

From July 2001 to October 2009, 422 patients with esophageal stricture due to cancer were seen at our institution. A total of 263 (62.3%) patients had surgical resection with or without neoadjuvant chemotherapy or chemoradiotherapy. We retrospectively reviewed the charts of 65 consecutive patients who underwent endoscopic placement of a covered nitinol stent. Two types of stents were used: Ultraflex (Boston Scientific, MA, USA), and, more recently, Choostent (M.I. Tech, Seoul, Korea). Ultraflex stents had a diameter of 18 or 23 mm and a length of 10 or 12 cm; Choostent stents had a diameter of 18 mm and lengths of 8, 11, 12 or 14 cm.

The indications for placement of the stent are shown in Table 1. The grade of dysphagia at presentation was defined using a 0 to 4 grading system as shown in Table 2. Demographic and clinical data are presented in Table 3.

Assessment of the extent of disease included a videoesophagram, upper endoscopy with biopsy, chest and abdominal computed tomography scan. In a subset of patients, total body positron emission tomography was performed to rule out the presence of distant metastases. If the tumor was in close proximity with the carina, a fiber-optic bronchoscopy was performed to evaluate the presence of infiltration and/or compression that could affect ventilation after placement of the stent. In some patients, Savary esophageal dilators were used to simulate the presence of the stent during the bronchoscopic examination. Written consent for the treatment was obtained from all patients.

Prior to the procedure, an antibiotic (ceftazidime 1 g iv) was administered to the patient. Endoscopic stent placement was performed with fluoroscopic guidance in the operating room, with the patient in left lateral decubitus. In 95% of the cases, conscious sedation with midazolam was used; in 3 patients propofol was required to achieve an adequate level of sedation. If the diameter of the lumen was too small to allow placement of the stent, dilatation up to 9 mm in diameter was performed with Savary bougies.

In patients with tumors of the thoracic esophagus, the proximal and distal margins of the lesion were marked with water-soluble ink injected into the submucosa. In patients with tumors located at the gastroesophageal junction, only the proximal margin was marked. In a few cases the proximal and distal limits of the tumor were marked using metallic endoclips[8]. Complete opening of the stent was expected within 48-72 h after implantation. In most patients, no attempt was made to pass the stent with the endoscope after its deployment in order to prevent migration.

Table 1 Indication for use of the stent in 65 patients

Table 2 Classification of dysphagia

Grade	Definition
0	Normal swallowing
1	Able to swallow some solid food
2	Able to swallow semi-liquid food
3	Able to swallow liquids only
4	Absolute dysphagia

After the procedure, a non-steroidal antiinflammatory (ketorolac) and proton pump inhibitors (e.g. pantoprazole) were administered intravenously. Chest X-ray and a gastrografin swallow study were performed the day after stent placement. Patients were then allowed to eat a semi-liquid diet until discharge.

RESULTS

Stent placement was technically successful in all patients. Nine patients (13.8%) presenting with severe stricture required preliminary dilation before deployment of the Ultraflex (n = 5) or the Choostent (n = 4). The procedure took a mean of 16 min (range, 12-35 min) with the Ultraflex, and 17 min (range, 13-27 min) with the Choostent (P = 0.8). There were no deaths related to the procedure. Periprocedural complications occurred in 4 patients (6.1%): 2 had fever probably related to aspiration pneumonia, 1 had an episode of atrial fibrillation managed with amiodarone iv, and 1 had acute urinary retention requiring catheterization. The 2 types of stent showed equal palliative efficacy against dysphagia. Most patients were discharged within 48 h. The results of the treatment are summarized in Table 4.

Early and late post-procedural complications are shown in Table 5. Severe chest pain immediately after stent insertion was present in 3 patients who had an Ultraflex implanted. The pain disappeared within 36 h of iv infusion of morphine. Overall, 9 patients (14%) needed a second endoscopic intervention. In 1 patient of the

Choostent group, the radiographic control showed malpositioning of the stent (too distal release) thus requiring the insertion of a second device overlapping the first one. No stent migration was observed within 72 h after starting oral intake. Interestingly, symptomatic gastroesophageal reflux occurred in 14 (43.7%) of the 32 patients with a stent placed in the lower esophagus.

Upper gastrointestinal endoscopy was performed 1 mo after the procedure in 21 patients with the Ultraflex and in 19 patients with the Choostent. None of these individuals were complaining of dysphagia. The cover membrane of the Choostent appeared to be damaged more frequently compared to the Ultraflex (26% *vs* 14%, $P = 0.34$).

Satisfactory palliation of dysphagia was achieved also in patients with stricture of the esophagogastric anastomosis, and post-radiotherapy stricture. In the majority of these individuals the Choostent was easily removed 3 to 4 wk after the insertion under mild intravenous sedation. One of the 2 patients with an Ultraflex stent required general anesthesia for removal because of a marked tissue reaction and embedding of the proximal edge of the stent.

The worst clinical outcome was recorded in patients suffering from extrinsic malignant compression. One of these patients with dysphagia caused by a bronchial carcinoma died because of massive bleeding 21 d after stent placement. The other 3 patients did not achieve complete palliation of dysphagia and died within 2 mo because of progression of the underlying disease.

The stenting procedure was effective in 2 of the 3 patients with fistula of the esophagogastric anastomosis. The stent was successfully removed in all patients after a mean of 4 wk. Radiological evaluation showed persistent leakage in 1 patient who required insertion of another stent.

Twenty-six of the 65 patients (40%) received chemotherapy or chemoradiotherapy after stent implantation. In 7 patients, a Choostent was uneventfully removed under mild sedation within 8 wk from the beginning of chemotherapy and oral intake was well tolerated. Three of these patients showed significant down-staging of the disease that eventually allowed esophagectomy to be performed without complications.

The incidence of mechanical complications requiring further endoscopic intervention after stent implantation was similar in patients treated or not with chemotherapy or chemoradiotherapy. In treated patients (n = 26) there was an 11.5% incidence of stent dislocation, whereas in

patients who did not receive additive treatment (n = 31) there was a 12.9% incidence of food obstruction.

DISCUSSION

Self-expanding metal stents came onto the market at the beginning of the 1990s and gradually replaced the old Celestin tube. The endoscopic placement of SEMS has proven to be technically easier, requiring minimal dilatation, and resulting in less morbidity and better palliation of dysphagia. In addition, SEMS provide a better quality of life[9], particularly for patients with a Karnofsky index greater then 50[10]. The efficacy of these stents, the ease of insertion, and the large spectrum of diameters and lengths available has resulted in their widespread use also in patients with anastomotic leaks[11].

The standardization of the endoscopic technique and the precise placement mechanism have reduced, but not eliminated, the rate of intraoperative complications. Late complications range from 26% to 52%, especially in patients with adenocarcinoma, and complications requiring additional intervention are frequent[12]. The choice of the correct stent diameter in each patient may represent an important factor for the success of the procedure. The use of an Ultraflex stent with a large diameter significantly reduced the chances of recurrent dysphagia, formation of granulation tissue, and the risk of food obstruction compared to other SEMS[13]. Despite the reported high incidence of covered stent migration at the gastroesophageal junction[14], we believe this is still the best available palliative option in these patients. However, the overall incidence of symptomatic gastroesophageal reflux was 22% in our series, and was almost double (43.7%) among the 32 patients with a stent placed in the lower esophagus. Theoretically, the use of stents provided with an antireflux valve can prevent gastroesophageal reflux, thereby avoiding the risk of aspiration pneumonia[15].

To date, no significant differences in outcomes or complication rates have been reported with the available covered SEMS. The present study shows that there are no statistically significant differences between the Ultraflex and the Choostent, although insertion of the Choostent in the oro-pharynx was less traumatic and post-procedural pain was reduced in the Choostent group. In general, we found it more convenient to use the Ultraflex in patients with strictures of the proximal esophagus because of the ease of stent application under visual control (proximal release). In contrast, the distal release mechanism of the Choostent still allows the operator to modify the site of delivery before the stent has reached 50% of the maximum diameter. Interestingly, a greater frequency of degeneration of the covering film was observed at the 1-mo follow-up endoscopy in the Choostent group compared to the Ultraflex group.

Another finding of this study is that temporary stent placement has indeed a role in patients undergoing neo-adjuvant therapy and in those with anastomotic complications or post-radiotherapy strictures. In such circumstances, the complete cover membrane of the Choostent may cause less granulation tissue and allows easier removability a few weeks later. The benefit of temporary stent insertion has been suggested as a "bridge" to surgery in patients undergoing neo-adjuvant therapy[16]. This minimally invasive and reversible treatment can represent an alternative to trans-nasal feeding tube placement, endoscopic percutaneous gastrostomy, or jejunostomy. Stent placement is usually better accepted by patients, but no conclusive scientific evidence exists on this issue[16,17]. In our series, the use of a Choostent device allowed optimal nutrition and tolerance of neo-adjuvant therapy until tumor downstaging was documented. The stent was easily removed under mild sedation within 2 mo in 7 patients, 3 of whom underwent surgical resection without complications.

In conclusion, covered nitinol stents are safe and effective devices for palliation of dysphagia in patients with esophageal strictures. The Ultraflex and the Choostent proved to be equally reliable in the achievement of this goal. Close patient monitoring is required to avoid late complications. When temporary stent insertion is required, as in patients undergoing neo-adjuvant therapy and in those with anastomotic complications or post-radiotherapy strictures, the Choostent is preferable because of its easy and safe removal.

COMMENTS

Background

Less than 50% of patients with esophageal carcinoma are suitable for surgery at the time of diagnosis. In such circumstances, the self-expanding metal stents (SEMS) represent an excellent palliative option. Covered SEMS have also been used in the management of patients with anastomotic complications, malignant extrinsic compression of the esophagus, and post-radiotherapy stricture.

Research frontiers

Despite the large number of covered metal stents available on the market, the superiority of one type over another has not been proven yet in the management of esophageal strictures and leaks.

Innovations and breakthroughs

This study compared two different types of nitinol stents that were proven to be equally reliable for palliation of dysphagia and leaks. Both stents also proved to be easily removable up to 2 mo after insertion.

Applications

Temporary stent placement has a role in patients undergoing neo-adjuvant therapy and in those with anastomotic complications or post-radiotherapy strictures. This minimally invasive and reversible treatment can represent an alternative to trans-nasal feeding tube placement, endoscopic percutaneous gastrostomy, or jejunostomy in selected patients.

Peer review

This is an interesting and worthwhile report on the use of expandable covered metal stents for the treatment of esophageal problems.

Abstract

AIM: To elucidate the role of insulin resistance (IR) and serum adiponectin level in hepatocellular carcinoma (HCC) associated with chronic hepatitis C.

METHODS: Clinical and biochemical characteristics were collected from 165 consecutive patients with newly diagnosed HCC. Homeostasis model assessment of IR (HOMA-IR) and serum adiponectin level were investigated in 188 patients with different stages of hepatitis C virus (HCV) infection.

RESULTS: Among HCC patients, type 2 diabetics (DM) was more prevalent in HCV subjects (35.6%, n = 59) compared to hepatitis B virus (HBV; 12.7%, n = 63) or non-HBV, non-HCV cases (7.1%, n = 28). In patients with chronic hepatitis C, HCC subjects had higher blood sugar (P < 0.001), insulin level (P = 0.003) and HOMA-IR (P = 0.018) than those with chronic hepatitis and advanced fibrosis. Age, male sex and body mass index were significantly associated with serum adiponectin level, whereas HOMA-IR was not. Based on stepwise logistic regression analysis, age (OR: 1.124, P < 0.001), serum insulin level (OR: 1.585, P < 0.001), HOMA-IR (OR: 0.495, P = 0.001), DM (OR: 11.601, P = 0.002) and male sex (OR: 3.877, P = 0.016) were independently associated with HCC. This result was similar even if the diabetic subjects were excluded for analysis.

CONCLUSION: Insulin resistance measured by HOMA-IR, regardless of the presence of diabetes, is significantly associated with HCC development in patients with chronic HCV infection.

INTRODUCTION

Hepatitis C virus (HCV) infects hundreds of millions of

people persistently, and induces a spectrum of chronic liver disease worldwide[1]. Chronic HCV infection causes progressive hepatic fibrosis and cirrhosis in up to 20% of patients, and approximately 10%-20% of cirrhotic patients may develop hepatocellular carcinoma (HCC) within 5 years[2-4]. Recent cohort studies have indicated that HCC is the most frequent cause of death in patients infected with HCV, and epidemiological trends suggest that the mortality rate is rising[5]. Thus, understanding the risk factors for HCC development in patients infected with HCV is of great importance.

HCV may contribute to carcinogenesis by causing advanced fibrosis or cirrhosis, which represents a precancerous state accompanied by increased DNA synthesis[6,7]. Nevertheless, several factors associated with HCC development in chronic hepatitis C have been reported, such as male sex, older age at infection, excessive alcohol consumption, coinfection with hepatitis B virus (HBV) and some viral variability in HCV itself[8-11]. Recently, epidemiological studies have demonstrated that diabetes mellitus (DM) is associated with a 2-4-fold increase in the risk of HCC, regardless of the presence of other major HCC risk factors (HBV, HCV, and alcoholic liver disease)[12-15]. In particular, two large cohort studies have shown that DM is associated with a higher risk of HCC development in patients with chronic hepatitis C compared to HBV-infected subjects or those without HBV and HCV infections[12,13].

The mechanisms that may link DM with carcinogenesis in chronic HCV infection remain unclear. Insulin resistance (IR), which correlates inversely with circulating adiponectin concentration, is a consistent finding in patients with type 2 DM[16,17]. Previous studies have shown that patients infected with HCV have significantly higher IR than healthy controls matched for age, sex and body mass index (BMI)[18,19]. Recent studies have suggested that IR plays a crucial role in fibrosis progression, and has been demonstrated to have a negative impact on treatment responses to antiviral therapy in patients with chronic hepatitis C[18,20,21]. IR has emerged as a risk factor for a wide variety of cancers, including endometrial and breast (especially after menopause), colon and rectal, esophageal, kidney, pancreatic, biliary, ovarian and cervical cancer[22-24]. To the best of our knowledge, the role of IR and serum adiponectin level in the development of HCC associated with chronic HCV infection has not been established. In this present study, we prospectively investigated the IR assessed by the homeostasis model (HOMA-IR) and serum adiponectin level in patents with HCC and those with other clinical stages of chronic HCV infection.

MATERIALS AND METHODS

Patients

From January 2007 to August 2008, a total of 165 newly diagnosed patients with HCC (122 men and 43 women; median age: 60.1 ± 12.4 years) who fulfilled all criteria outlined below were consecutively collected in a single center. The diagnosis of HCC was based on either the histopathological findings in tumor tissue, one typical HCC feature on a dynamic image or alpha-fetoprotein (AFP) > 200 ng/mL if the nodule was > 2 cm in cirrhotic liver, or two typical HCC features of dynamic images if the nodule was between 1 and 2 cm in a cirrhotic liver[25]. Patients with concurrent human immunodeficiency virus infection, significant change of body weight (≥ 3 kg within 3 mo), previous history of interferon-based antiviral therapy, and current treatment with any dosage of insulin therapy were excluded.

Of these patients, 63 were positive for hepatitis B surface antigen (HBsAg) (Abbott Laboratories, North Chicago, IL, USA), 59 were positive for anti-HCV antibody (third-generation ELISA; AxSYM HCV 3.0; Abbott Laboratories), 15 were positive for both HBsAg and anti-HCV, and 28 were negative for HBsAg and anti-HCV, in whom alcoholic liver disease (n = 11, 39%) was the major cause of HCC.

During the same period, 129 consecutive patients (61 men and 68 women, 23-77 years old; median age: 53.0 ± 11.5 years) with chronic HCV infection who consulted our clinics were studied, including 86 with chronic hepatitis (F0-2) and 43 with advanced fibrosis (F3-4). All patients had positive anti-HCV antibody and detectable HCV RNA (Amplicor™; Roche Diagnostics, Branchburg, NJ, USA). Pathological diagnosis of chronic hepatitis or advanced fibrosis was made by percutaneous liver biopsies according to the modified Knodell histological activity index[26], which were analyzed by pathologists who were blind to the patients' characteristics. The Human Research and Ethics Committee (Institutional Review Board) approved the study, and informed consent was obtained from each patient involved in the study.

Clinical and laboratory assessments

Patients with a BMI of 18.5-24.9 kg/m^2 were classified as normal, 25-29.9 as overweight, and ≥ 30 as obese. The diagnosis of type 2 DM was based on the American Diabetes Association revised criteria, using a value of fasting blood glucose of ≥ 126 mg/dL on at least two occasions[27], or ongoing treatment with hypoglycemic agents.

Blood glucose, serum insulin level and stored serum samples for adiponectin were collected after 12 h of overnight fasting from each individual. For HCC patients, serum samples were collected before any treatment for tumor. Serum insulin was measured by radioimmunoassay (Coat-A-Count insulin kit; Diagnostic Products Corp., Los Angeles, CA, USA). IR was calculated by the HOMA-IR using the following formula: HOMA-IR = fasting insulin (μU/mL) × plasma glucose (mmol/L)/22.5. Circulating level of adiponectin was measured in duplicate by sandwich ELISA using commercial kits according to the manufacturer's instructions (Quantikine ELISA kits; R&D Systems, Inc., Minneapolis, MN, USA). The differences between duplicate wells were consistently less than 10% of the mean values. The mean values of duplicate measurements were used in the analyses.

Table 1 Comparison of baseline features among HBV, HCV, dual HBV and HCV, and non-HBV, non-HCV related hepatocellular carcinoma patients

	HBV *n* = 63	HCV *n* = 59	HBV + HCV *n* = 15	Non-HBV, non-HCV *n* = 28	*P* value

Statistical analysis

Continuous data are expressed as the median (interquartile range), and the categorical data are expressed as a number (percentage). Comparisons of differences in the categorical date between groups were performed using the χ^2 test. Distributions of continuous variables were analyzed by the Mann-Whitney *U* test or one-way ANOVA test with least significant difference (LSD) post-hoc correction between groups where appropriate. Spearman's correlation coefficient analysis was used to evaluate the factors associated with HOMA-IR and adiponectin level. Multiple linear regression analysis with stepwise variable selection was performed to assess the independent factors. Stepwise logistic regression analysis was performed to assess the influence of each factor on the risk of developing HCC. All analyses were carried out using SPSS software version 15.0 (SPSS Inc., Chicago, IL, USA). All tests were two-tailed, and $P < 0.05$ was considered statistically significant.

RESULTS

Comparison of baseline features among HBV, HCV, dual HBV/HCV, and non-HBV, non-HCV-related HCC

Table 1 shows the comparison of baseline features among the 165 patients with HCC related to different etiology. The median age of HCV-related HCC patients (66 years) was significantly higher than that in HCC patients infected with HBV (55 years) or dual HBV/HCV (60 years) ($P < 0.001$). There was a male predominance among all four groups. The prevalence of DM was higher (35.6%) in patients with HCV-related HCC compared to those infected with HBV (12.7%) ($P < 0.005$) or non-HBV, non-HCV subjects (7.1%) ($P < 0.005$). HOMA-IR was higher in HCC patients with HCV (median 4.4) than in those with HBV (median 3.5) ($P < 0.05$). However, there was no significant difference in BMI and prevalence of overweight and obesity among the four groups. Patients with HCV-related HCC had significantly higher aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels and lower platelet counts than those infected with HBV or non-HBV, non-HCV subjects. In addition, patients with HCV-related HCC had smaller tumors and earlier Barcelona clinic liver cancer stage (BCLC) than HBV or non-HBV, non-HCV subjects.

Comparison of baseline features, serum insulin, HOMA-IR and adiponectin level among chronic hepatitis, advanced fibrosis and HCC patients

The comparison of baseline features, serum insulin, HOMA-IR and adiponectin level in different clinical stages of chronic HCV infection is shown in Table 2. The median age for HCC patients (66 years) was significantly higher than those with advanced fibrosis (56 years) and chronic hepatitis (53 years) ($P < 0.001$). Patients with HCC had a higher male-to-female ratio and higher prevalence of DM than those with advanced fibrosis or chronic hepatitis. There was no significant difference in BMI among these three groups. The HCC subjects had lower AST and ALT levels compared to those with advanced fibrosis; however, the platelet count was comparable between these two groups. Patients with HCC had higher blood sugar ($P < 0.001$), insulin level ($P = 0.003$) and HOMA-IR ($P = 0.018$) than those with chronic hepatitis and advanced fibrosis. As shown in Figure 1, patients with HCC had a higher ratio of HOMA-IR > 4 (61.8%, 95% CI: 48.6%-75.1%) than those with chronic hepatitis (39.5%, 95% CI: 29.0%-50.1%) and advanced fibrosis (48.8%, 95% CI: 33.3%-64.4%) ($P = 0.036$). There was no significant difference in serum adiponectin among the three groups.

Table 2 Comparison of baseline features, HOMA-IR and adiponectin level among chronic hepatitis, advanced fibrosis and HCC patients with chronic HCV infection

	Chronic hepatitis (F0-2) *n* = 86	Advanced fibrosis (F3-4) *n* = 43	Hepatocellular carcinoma *n* = 59	*P* value[2]
Age (yr)[1]	53 (45-58)[a,b]	56 (49-63)[a,c]	66 (57-75)[b,c]	< 0.001
Male sex (%)	44 (51)[b]	17 (40)[c]	41 (69)[b,c]	0.008
DM (%)	13 (15)[b]	12 (28)	21 (36)[b]	0.016
BMI (kg/m^2)[1]	24.3 (21.8-26.3)	25.0 (22.0-29.4)	23.8 (21.8-26.6)	0.227
AST (U/L)[1]	90 (64-122)	114 (87-178)[c]	72 (39-123)[c]	0.085

HOMA-IR[1]	3.5 (2.6-4.7)[b]	4.1 (2.6-5.9)[c]	4.4 (2.9-6.6)[b,c]	0.018
Adiponectin (μg/mL)[1]	5.0 (3.4-8.4)	5.8 (4.1-9.7)	7.9 (5.2-11.0)	0.222

[1]Median (interquartile range); [2]*P* value by one-way ANOVA test or χ^2 test; [a]*P* < 0.05 between chronic hepatitis and advanced fibrosis; [b]*P* < 0.05 between chronic hepatitis and hepatocellular carcinoma; [c]*P* < 0.05 between advanced fibrosis and hepatocellular carcinoma with LSD post-hoc correction.

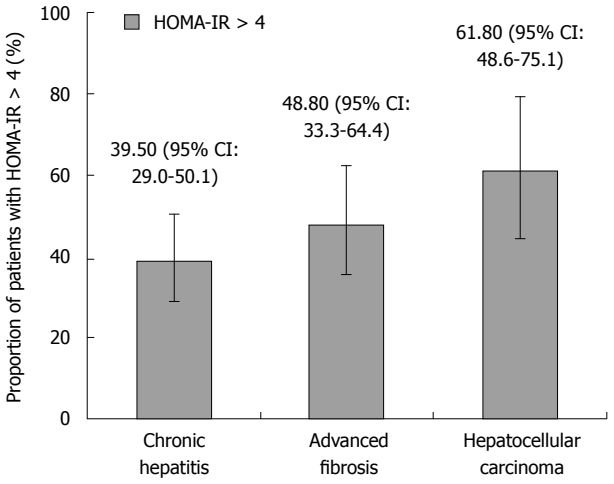

Figure 1 Comparison of high homeostasis model assessment of insulin resistance (HOMA-IR) (> 4) among different stages of chronic hepatitis C virus (HCV) infection (*P* = 0.036).

Factors associated with serum adiponectin level in patients with chronic hepatitis C

Table 3 shows the factors associated with serum adiponectin level in 188 patients with chronic HCV infection. By univariate analysis, age (r = 0.388, P < 0.001), male sex (P < 0.001), BMI (r = -0.281, P < 0.001), AST level (r = 0.159, P = 0.030), platelet count (r = -0.198, P = 0.009), insulin level (r = -0.179, P = 0.014) and HOMA-IR (r = -0.290, P < 0.001) were significant factors associated with serum adiponectin level. Multiple linear regression analysis showed that age (regression coefficient = 0.140, P < 0.001), male sex (regression coefficient = -2.925, P < 0.001) and BMI (regression coefficient = -0.495, P < 0.001) were independent variables.

Stepwise logistic regression analysis for factors associated with development of HCC

Based on stepwise logistic regression analysis, significant factors associated with development of HCC in patients with chronic HCV infection were age (OR: 1.124, 95% CI: 1.067-1.183, P < 0.001), serum insulin level (OR: 1.585, 95% CI: 1.269-1.980, P < 0.001), HOMA-IR (OR: 0.495, 95% CI: 0.330-0.743, P = 0.001), DM (OR: 11.601, 95% CI: 2.50-53.8, P = 0.002) and male sex (OR: 3.877, 95% CI: 1.282-11.729, P = 0.016) (Table 4).

When excluding DM cases, factors independently associated with HCC development in 142 non-DM patients were age (OR: 1.170, 95% CI: 1.075-1.272, P < 0.001), serum insulin level (OR: 2.434, 95% CI: 1.555-3.811, P < 0.001), HOMA-IR (OR: 0.158, 95% CI: 0.055-0.452, P = 0.001) and male sex (OR: 6.111, 95% CI: 1.310-28.49, P = 0.021).

Table 3 Univariate and multivariate analysis of factors associated serum adiponectin level in 188 patients with chronic HCV infection

	Univariate		Multivariate		
	Coefficient	*P* value[1]	Regression coefficient	SE	*P* value[3]

DISCUSSION

There is increasing evidence linking chronic HCV infection and type 2 DM. Large community-based studies have shown that the prevalence of DM in HCV-infected patients is much higher than that observed in the general population, and in patients with other chronic liver diseases such as HBV and alcoholic liver disease[28,29].

Table 4 Stepwise logistic regression analysis of factors associated with HCC

	Comparison	OR	95% CI	*P* value
All patients				
Age	Per 1 year increase	1.124	1.067-1.183	< 0.001
Insulin	Per 1 μU/mL increase	1.585	1.269-1.980	< 0.001
HOMA-IR	Per 1 increase	0.495	0.330-0.743	0.001
DM	Yes *vs* no	11.601	2.500-53.800	0.002
Sex	Male *vs* female	3.877	1.282-11.729	0.016
Non-DM patients				
Age	Per 1 year increase	1.170	1.075-1.272	< 0.001
Insulin	Per 1 μU/mL increase	2.434	1.555-3.811	< 0.001
HOMA-IR	Per 1 increase	0.158	0.055-0.452	0.001
Sex	Male *vs* female	6.111	1.310-28.499	0.021

In this study, we found that among HCC patients, type 2 DM was more prevalent in those infected with HCV compared to those with HBV or non-HBV, non-HCV infection. This observation in accordance with previous studies suggests a strong synergistic effect of metabolic factors and viral hepatitis in HCC development among HCV-infected patients[12,13]. Although there was no significant difference in BMI among HCC patients with different etiology, this could be explained by the low prevalence of obesity in our study population.

Chronic HCV infection is associated with the development of hepatic steatosis and unique, virus-specific alterations in host metabolism leading to the development of IR[19,30,31]. In this present study, we provide the first evidence that IR could potentially increase the risk of developing HCC in patients with chronic HCV infection. In a cross-sectional, hospital-based setting, we prospectively assessed the HOMA-IR value in different clinical stages of chronic HCV infection. Our data showed that patients with HCC had a higher ratio of HOMA-IR > 4 than those with chronic hepatitis and advanced fibrosis. Furthermore, after adjusting for age and sex, HOMA-IR was an independent factor associated with the development of HCC. A novel finding of our work, not specifically evaluated in other studies, was the association of IR, regardless of diabetes, with the development of HCC. An alternative explanation for the observed association between HOMA-IR and HCC is that advanced hepatic fibrosis and disease severity results in IR and impairs insulin clearance. This possibility could be excluded by the similar prevalence of DM and platelet count that has been considered as a fibrosis marker in chronic HCV infection between patients with HCC and those with advanced fibrosis. Also, HOMA-IR did not correlate with Child-Pugh classification, which suggests that disease severity was not associated with IR in patients with HCC or advanced fibrosis.

Although our work was not designed to clarify the pathogenic interaction between IR and the development of HCC, a few hypotheses can be put forward. IR is defined as an increased requirement for insulin to maintain normal metabolic function, which results in the compensatory development of hyperinsulinemia[32]. Recent evidence has suggested that hyperinsulinemia can promote the synthesis and biological activity of insulin-like growth factor 1 (IGF-1), which is a peptide hormone that regulates energy-dependent growth processes[33]. IGF-I stimulates cell proliferation and inhibits apoptosis and has been shown to have strong mitogenic effects on a wide variety of cancer cell lines. Changes in the expression pattern of IGF-system components have been observed in patients with HCC, in human HCC cell lines and in their conditioned culture medium, as well as in rodent models of hepatocarcinogenesis[34].

To study the role of adiponectin in HCC may be more complex because of its underlying chronic hepatitis infection[19,35,36]. Previous studies have demonstrated that circulating adiponectin levels are inversely associated with the risk of malignancies associated with IR, including endometrial, breast, colon and gastric cancer[37-40]. Moreover, serum adiponectin level has been reported to be significantly elevated in chronic liver disease, and correlated with stage of liver cirrhosis, liver cell injury, e.g. aminotransferase activity, and inflammatory markers[35,36]. Thus, serum adiponectin level is modified according to the two opposing factors, IR and underlying liver condition. In this study, we found no difference in serum adiponectin level among different clinical stages of chronic HCV infection. Although HOMA-IR score was inversely associated with serum adiponectin level by univariate analysis, multiple linear regression analysis did not support this correlation.

There are some limitations to our study. First, the analysis was carried out in a cross-sectional setting with a relatively small number of HCC patients, and it would be interesting to determine whether this association holds true in longitudinal follow-up studies of larger groups of patients. Second, the cohort of patients, at low prevalence of obesity, was enrolled in a tertiary referral center for liver disease, which limits the broader application of the results. A further methodological issue resides in the inability to dissect the temporal relation between IR and HCC. Another limitation lies in the fact that there is some concern on the use of HOMA-IR in the presence of long-standing DM. However, a diagnosis of DM is *per se* expression of IR, and HOMA-IR is a less invasive, inexpensive, and less labor-intensive method to measure IR as compared with the glucose clamp test.

In conclusion, we demonstrated the independent association between IR and HCC development in chronic HCV infection. These findings may have important prognostic and therapeutic implications in the management of chronic HCV-infected patients. Since IR is a potentially modifiable factor, therapeutic intervention aimed at decreasing IR may be warranted in these patients.

COMMENTS

Background

Recent studies have demonstrated that diabetes mellitus (DM) is associated with high risk of hepatocellular carcinoma (HCC) in patients with chronic hepatitis C. Insulin resistance (IR), which correlates inversely with circulating adiponectin concentration, is a consistent finding in patients with type 2 DM. Chronic hepatitis C virus (HCV) infection has been reported to be associated with increased IR. Recent studies have suggested that IR plays a crucial role in

fibrosis progression, and has been demonstrated to have a negative impact on treatment responses to antiviral therapy in patients with chronic hepatitis C.

Research frontiers

IR has emerged as a risk factor for a wide variety of cancers. In a cross-sectional, hospital-based setting, the authors assessed the role of IR assessed by the homeostasis model (HOMA-IR) and serum adiponectin level in the development of HCC associated with chronic HCV infection.

Innovations and breakthroughs

The authors have provided the first evidence that IR can potentially increase the risk of developing HCC in patients with chronic HCV infection. A novel finding, not specifically evaluated in other studies, is the association of IR, regardless of diabetes, with the development of HCC.

Applications

These findings may have important prognostic and therapeutic implications in the management of chronic HCV-infected patients. Since IR is a potentially modifiable factor, therapeutic intervention aimed at decreasing IR may be warranted in these patients.

Peer review

The authors present a clinical investigation of the correlation between IR and HCC. The title accurately reflects the major contents of the article, and the abstract delineates briefly and concisely the research background, objectives, materials and methods, results and conclusions.

BRIEF ARTICLE

Distribution of *gyrA* mutations in fluoroquinolone-resistant *Helicobacter pylori* strains

Abstract

AIM: To investigate the resistance of *Helicobacter pylori* (*H. pylori*) to ciprofloxacin (CIP), levofloxacin (LVX) and moxifloxacin (MOX) in the Beijing area and to elucidate the resistance mechanisms.

METHODS: Seventy-nine *H. pylori* clinical strains, isolated from patients who had undergone upper gastrointestinal endoscopy in Peking University First Hospital from 2007 to 2009, were tested for their susceptibility to CIP, LVX and MOX using the *E*-test method. *H. pylori* strain 26695 was included in the susceptibility testing as a control strain. According to the minimal inhibitory concentration (MIC) values, a strain was classified as resistant to CIP, LVX or MOX when the MIC was > 1 μg/mL. We amplified by polymerase chain reaction (PCR) and sequenced the quinolone resistance-determining regions of the *gyrA* and *gyrB* genes from 29 quinolone-resistant and 16 quinolone-susceptible *H. pylori* strains selected at random.

RESULTS: In this study, the resistance rates of *H. pylori* to CIP, LVX or MOX were 55.7% (44/79), and the primary resistance rates were 26.6% (21/79). Patients with secondary resistance had received LVX in previous eradication treatments, but not MOX or CIP. Forty-five strains, including 29 CIP, LVX or MOX-resistant strains (MIC: 1.5-32 μg/mL) and 16 susceptible strains, were selected randomly from the 79 strains and used in PCR analysis. Among these 45 strains, 27 resistant strains had mutations in the *gyrA* gene, including 11 strains with mutations corresponding to Asp-91 (MIC: 2-32 μg/mL), one of which also had a mutation corresponding to Val-150, and 16 strains had mutations at Asn-87 (MIC: 4-32 μg/mL), three of which also had mutations corresponding to Arg-140 or Val-150. In addition, Arg-140, Val-150 or Ala-97 mutations were separately detected in three susceptible strains. Analysis of the *gyrB* gene showed that one strain of low resistance had a mutation corresponding to Ser-457 that coexisted with an Asp-91 mutation. There was a significant difference in the occurrence of mutations in the *gyrA* gene between CIP, LVX and MOX-resistant and -susceptible strains ($P < 0.05$), but 2 resistant strains were found to possess no quinolone resistance-determining region mutations.

CONCLUSION: Resistance is primarily mediated through point mutations in gyrA. Whether other mechanisms are responsible for resistance in strains without mutations in the QRDR should be detected.

INTRODUCTION

Helicobacter pylori (*H. pylori*) infection, which affects half of the world's population, is responsible for gastritis[1], peptic ulcers[2,3] and gastric mucosa-associated lymphoid tissue lymphoma[4], and is a major risk factor for the development of gastric adenocarcinoma[5]. Eradication therapy plays an important role in the treatment of *H. pylori* infection. According to the Maastricht Ⅲ and Chinese Consensus Report, triple therapy using a proton-pump inhibitor (PPI) combined with clarithromycin and amoxicillin or metronidazole, is recommended as the first choice treatment[6,7]. With the increasing frequency of clarithromycin-resistance among *H. pylori* strains, there is rising concern about the potential decline in the eradication rate of this infection[8,9]. There is therefore an urgent need to introduce other treatment options. Fluoroquinolones, such as levofloxacin (LVX) and moxifloxacin (MOX), have been evaluated as an alternative to standard antibiotics against *H. pylori*[6,7].

Some studies have shown good results when using fluoroquinolone-based triple therapies for *H. pylori* eradication. In a German study, a 7-d course including LVX in patients with persistent *H. pylori* infection, resulted in eradication rates of greater than 85%[10]. In an Italian study, *H. pylori* eradication was achieved in 90% of patients treated with MOX, clarithromycin and lansoprazole[11]. However, the widespread use of fluoroquinolones for the treatment of *H. pylori* infection has led to an increase in its resistance rate in some areas, leading to unacceptably low eradication rates[12]. Several studies have shown that LVX-based therapies are not superior to traditional quadruple therapy or Maastricht triple therapy in the treatment of *H. pylori* infection, especially in the case of resistant *H. pylori* strains[13,14]. A Turkish study speculated that the low eradication rate with MOX-containing treatment regimens may be due to the development of resistance to this quinolone[15]. The findings from all of these studies indicate that a regimen that is effective in one area may not be effective in another area, as antibiotic-resistant rates for *H. pylori* may be different in different areas.

The fluoroquinolone resistance rates of *H. pylori* have been reported for several regions, including China (Mainland), Hong Kong, Taiwan, France, Japan and Korea[12,16-20], and range from 3% to about 20%. It was reported that LVX resistance was associated with prior fluoroquinolone use over the previous 10 years, and with the total number of fluoroquinolone courses prescribed[21]. A study from Korea speculated that resistance to MOX might be acquired through prior use of fluoroquinolones due to the development of cross-resistance to other fluoroquinolones like ciprofloxacin (CIP) and LVX[12]. Bogaerts *et al*[22] reported that mutations in the *gyrA* gene elevated the minimal inhibitory concentrations (MICs) to LVX, CIP and MOX.

The mechanism of action of fluoroquinolones is *via* inhibition of DNA gyrase and topoisomerase, which control and modify the topological state of DNA in cells. Fluoroquinolone then interferes with bacterial DNA replication. Both DNA gyrase and topoisomerase are composed of two A and two B subunits, encoded by the *gyrA* and *gyrB* genes for DNA gyrase and the *parC* and *parE* genes for topoisomerase Ⅳ. The mechanism of fluoroquinolone resistance in *H. pylori* has been found to be linked to mutations in the quinolone resistance-determining regions (QRDRs) of the *gyrA* gene. Mutations in the *gyrB* gene have also been reported in LVX-resistant strains isolated in Japan, but these often occurred along with *gyrA* mutations[19]. The resistance of *H. pylori* strains to fluoroquinolones in the Beijing area has not yet been reported. The aim of this study was to assess the prevalence of fluoroquinolone resistance against CIP, LVX and MOX in *H. pylori* strains isolated from patients over the past 3 years in Beijing and to compare the susceptibility of these strains with CIP and two newer fluoroquinolones *in vitro*. Mutations in the QRDRs of the *gyrA* and *gyrB* genes were also evaluated in these strains.

MATERIALS AND METHODS

Patients and bacterial strains

Seventy-nine clinical *H. pylori* strains were collected from adult patients, who were randomly selected and had undergone a gastroduodenoscopy at Peking University First Hospital between January 2007 and July 2009. Some patients had received *H. pylori* eradication therapy before, but none of the patients had received MOX or CIP-based therapy. The biopsy specimens were cultured on Colombia blood agar (BBL Microbiology Systems, Cockeysville, MD, USA), supplemented with 8% defibrinated sheep blood, and incubated for 5-7 d under microaerobic conditions (5% O_2, 10% CO_2, 85% N_2). Clinical isolates were identified as *H. pylori* based on positive tests for urease, oxidase and catalase. All cultures were stored at -80℃ in brain-heart infusion broth (BHI, Difco Laboratory, Detroit, MI, USA) supplemented with 30% glycerol.

MIC determination

The MICs of LVX, CIP and MOX were determined by *E*-test strips (AB Biodisk, Solna, Sweden) according to the recommendations of the Clinical and Laboratory Standards Institute (Pennsylvania, USA) and the manufacturer's instructions. *H. pylori* 26695 was used as the quality control strain. The resistance breakpoints of fluoroquinolones were defined as > 1 μg/mL, as previously suggested[19,20].

Polymerase chain reaction amplification and nucleotide sequence analysis

H. pylori genomic DNA was extracted by the High Pure

polymerase chain reaction (PCR) Template Preparation kit (Tiangen, Beijing China). Oligonucleotide primers gyr APF (5'-AGCTTATTCCATGAGCGTGA-3') and gyr APR (5'-TCAGGCCCTTTGACAAATTC-3'), gyrBPF (5'-CCCTAACGAAGCCAAAATCA-3') and gyr BPR (5'-GGGCGCAAATAACGATAGAA-3') were designed to amplify a 582-bp and 465-bp region of the *H. pylori gyrA* and *gyrB* genes respectively. Primers were synthesized by Shenggong (Shanghai, China). PCR was performed in a 25 μL reaction volume containing 2 pmol of the oligonucleotide primer, 200 μmol/L (each) of dATP, dCTP, dGTP and dTTP (GE Healthcare, Little Chalfont, UK), 1.5 mmol/L of reaction buffer (GE Healthcare), 1 μL of template DNA, and 2.5 U of *Taq* polymerase (GE Healthcare). Thermocycling conditions were 94℃ for 5 min, followed by 35 cycles of 94℃ for 30 s, 53℃ for 30 s and 72℃ for 30 s, with a final extension step of 72℃ for 10 min. The reaction products were visualized by running 5 μL of the reaction mixture on 1.5% agarose gels. Sequencing of the amplified DNA was performed on an ABI 3730xl sequencer (Applied Biosystems, Foster City, CA, USA). The sequences were then compared with the published sequence of the *H. pylori gyrA* and *gyrB* gene (GenBank accession number NC_000915.1).

Statistical analysis

The association between MIC levels and the occurrence of *gyrA/B* mutations relating to quinolone susceptibility was determined using Fisher's exact probability test, a P-value < 0.05 was considered significant.

RESULTS

Antimicrobial susceptibility

The MICs of CIP, LVX and MOX were determined for the 79 *H. pylori* strains isolated between 2007 and 2009 from gastric biopsies. The resistance rate to either CIP, LVX or MOX was 55.7% (44/79). Primary CIP, LVX and MOX resistance was detected in 21 (26.6%) isolates. Based on the breakpoints, we found that the strains susceptible to CIP (MIC ⩽ 1.0 μg/mL) were also susceptible to LVX and MOX, whereas the isolates resistant to CIP (MIC > 1.0 μg/mL) were also resistant to LVX and MOX (Tables 1 and 2).

Mutation analyses of the gyrA and gyrB genes and the association with LVX, MOX and CIP resistance

Of the 45 strains selected randomly, 29 were resistant and 16 were susceptible to LVX, MOX and CIP. Various substitutions in the QRDR of the *gyrA* and *gyrB* genes were observed in 31 of the strains. Mutations in the *gyrA* gene were identified in 27 resistant strains, 11 of which had mutations corresponding to Asp-91 and 16 of which had mutations corresponding to Asn-87. As for the *gyrB* gene, one low-level resistant strain had a mutation corresponding to Ser-457 which coexisted with the Asp-91 mutation. One susceptible strain exhibited a mutation corresponding to Val-451 of the GyrB protein. Amino acid substitutions in the GyrA protein associated with quinolone resistance fell into the following categories: (1) substitution of the amino acid at position 91 in 10 of the 27 isolates; (2) substitution of the amino acid at position 87 in 13 isolates; and (3) two mutations leading to substitution of amino acids in four isolates (Table 1). We also found 2 resistant strains with no QRDR mutations; in these strains the MICs to fluoroquinolones were > 12 μg/mL (Table 2).

Table 1 MICs and amino acid changes in quinolone-resistant and susceptible strains of *H. pylori*

[1]Primary resistance. QRDR: Quinolone resistance-determining region.

DISCUSSION

In this study, we investigated the resistance of *H. pylori* strains isolated from patients at Peking University First Hospital during 2007-2009 to three quinolone antibiotics. Of the 79 *H. pylori* strains isolated, 44 (55.7%) strains

were found to be resistant to quinolones and 21 (26.6%) showed primary resistance to quinolones. This is the first report of primary *H. pylori* resistance to quinolones in the Beijing area. In a previous study carried out in Hong Kong, the prevalence of LVX resistance in *H. pylori* was reported to be 11.5%[16]. An increase in fluoroquinolone resistance has also been reported in other areas, for example, the resistance rate to either CIP or LVX increased from 2.8% (1998-2003) to 11.8% (2004-2007) in southern Taiwan[17]. In other parts of the world, geographical differences and differences in treatment regimens result in a range of resistance rates, for example, rates of more than 20% in Korea[12], 15% in Japan[19] and 14% in Italy[23] have been reported.

According to research from Japan[19], caution is needed when interpreting these results because no criteria have been published for establishing the breakpoint of fluoroquinolones against *H. pylori*. According to the Maastricht Ⅲ Consensus Report[6], the threshold of clarithromycin resistance at which the empirical use of this antibiotic should be abandoned, or pretreatment clarithromycin susceptibility testing performed, is 15%-20%. Although some studies have reported good eradication rates using fluoroquinolones in some areas of China[24,25], quinolone treatment regimens in Beijing should be based on the findings of local antimicrobial susceptibility tests as the resistance rate is higher than 20% in this area.

In China, quinolone antibiotics have been widely used in hospitals to treat various infections and in the poultry industry as a supplement in feed. This has resulted in drug resistance becoming a serious problem[26-28]. In our study and a previous study from Korea[12], cross-resistance of the *H. pylori* strains to MOX, CIP and LVX was observed in patients who had not received MOX before the other eradication regimens.

Fluoroquinolone resistance is attributed to specific mutations in the genes encoding DNA gyrase and/or topoisomerase Ⅳ. In *Neisseria gonorrhoeae*[29], for example, mutations in the QRDRs of the *gyrA* and *parC* genes may be responsible for fluoroquinolone resistance. In *H. pylori*, only mutations in the DNA gyrase gene have been considered responsible for fluoroquinolone resistance because neither *parC* nor *parE* have been detected in the genome sequence and the drug efflux system is not considered important in this organism[30,31]. Consequently, DNA gyrase is the unique target for quinolones in *H. pylori*. Fluoroquinolone resistance of *H. pylori* is considered to depend on point mutations in the QRDR of the *gyrA/B* gene. GyrA mutations at Asn-87 and Asp-91 have been reported previously[19,22]. In our study, 11 resistant strains (37.93%) possessed mutations at Asp-91, 16 resistant strains (55.17%) possessed mutations at Asn-87, but mutations at both Asp-91 and Asn-87 were not found to coexist in any strain. Mutations at position Asn-87 were more frequent than at Asp-91 in LVX-resistant strains in Japan, according to a previous report [19]. We also identified more mutations at Asn-87 than at Asp-91 in this study. In *Escherichia coli*, Nakamura *et al*[32] found that mutations in the *gyrB* gene also lead to low-level quinolone resistance. Yoshida *et al*[33] identified two possible mutations in the GyrB protein of *Escherichia coli*: Asp426→Asn and Lys447→Glu. We also identified mutations in the *gyrB* gene in this study, but there was no statistically significant difference between the genotype of this gene and quinolone resistance. The role of GyrB in fluoroquinolone resistance therefore remains to be determined. In *H. pylori*, one mutation within the QRDR of the *gyrA* gene was associated with low level fluoroquinolone resistance, and two or more mutations may relate to high level of fluoroquinolone resistance[19]. One previous study reported that in *Campylobacter spp.*[34], a single mutation in the *gyrA* gene can lead to a high level of resistance not only to nalidixic acid but also to CIP, but it requires a second mutation to become MOX-resistant. In our study, two strains with two mutations in the QRDR of the *gyrA* gene had different levels of resistance to quinolones. Consistent with the findings of the Japanese study, we were also unable to identify any significant association between *gyrA* mutation patterns and the MICs of three fluoroquinolones[19]. In our study, we found that two resistant strains had no mutations in the QRDR of the *gyrA* and *gyrB* gene, and in these strains the MICs of three fluoroquinolone antibiotics reached 32 μg/mL. We also found that the same mutation can exist in resistant and susceptible strains. We therefore speculate that low-level resistance is most likely mediated through a point mutation in the *gyrA* gene. There may be other mutations in non-QRDRs of the *gyrA* and *gyrB* genes or other mechanisms, such as efflux systems, that lead to high level resistance.

A previous Japanese study reported that differences in amino acid substitutions associated with fluoroquinolone resistance correlate with geographical differences[19], with the occurrence of the Asn-87 GyrA mutation being more frequent than the Asp-91 GyrA mutation in LVX-resistant strains. Different from the findings of our study, it has previously been reported that in Hong Kong the most frequent mutation site in the GyrA protein was position 91[16].

In conclusion, the prevalence of resistance of *H. pylori* to fluoroquinolones is of concern in the Beijing area. Our results suggest that the susceptibility of *H. pylori* to fluoroquinolones should be tested before administration of a therapy, especially in the Beijing area. Resistance is most likely mediated through point mutations in the *gyrA* gene. Future studies should investigate whether other mechanisms are responsible for resistance in strains in which no mutations in the QRDR were detected.

COMMENTS

Background

Resistance to antibiotics is one of the most important reasons behind *Helicobacter pylori* (*H. pylori*) eradication failure. *H. pylori* resistance to metronidazole and clarithromycin is becoming an increasingly serious problem and as a result first-line treatment programs based on these drugs are declining. As an alternative to these standard regimens, quinolones can be recommended for the first-line treatment of *H. pylori* infection.

Research frontiers

Fluoroquinolone-based regimens for *H. pylori* eradication are widely employed

in some areas of China, but studies investigating fluoroquinolone resistance are limited.

Innovations and breakthroughs

Traditional *E*-tests and modern genetic mutation analysis of 45 *H. pylori* isolates showed a high rate of resistance to fluoroquinolones in Beijing. Resistance was found to be most likely mediated through point mutations in the *gyrA* gene, but two resistant strains were found with no quinolone resistance-determining region mutations. The possibility that other mechanisms are responsible for fluoroquinolone resistance in these strains remains to be determined.

Applications

The results of this study show a high prevalence of *H. pylori* resistance to fluoroquinolones in Beijing. The authors recommend that the susceptibility of *H. pylori* to fluoroquinolones is tested before the administration of a therapy.

Terminology

gyrA: The gene encoding DNA gyrase (type Ⅱ topoisomerase), subunit A; *gyrB*: The gene encoding DNA gyrase (type Ⅱ topoisomerase), subunit B.

Peer review

The manuscript investigates the prevalence and mechanisms of resistance of *H. pylori* to fluoroquinolones in Beijing. The methodology of resistance determination consists of a traditional *E*-test and modern genetic testing of *gyrA* mutation. The results show a primary resistance of 26% and secondary resistance of 55%, which is higher than in European countries. The article is good, using a sound methodology and correct conclusions.

Abstract

AIM: To establish the real time fluorescence polymerase chain reaction (RT-PCR) with dual labeled probes for fast detection of *SLC25A13* gene mutation 851del4.

METHODS: Four hundred infants (< 1 year of age) with unexplained intrahepatic cholestasis from 18 provinces or municipalities in China were enrolled in this study for detecting their *SLC25A13* gene mutation 851del4. Suitable primers and fluorescence-labeled probes for detecting *SLC25A13* gene mutation 841del4 were designed. Normal and mutant sequences were detected by PCR with two fluorescence-labeled probes. After a single RT-PCR, results were obtained by analyzing the take-off curves. Twenty-four positive and 14 negative samples were retested by direct sequencing.

RESULTS: Eight homozygous and 30 heterozygous mutations were detected in 46 mutant alleles with a 851del4 mutation rate of 5.8% (46/800). Twenty-six and 20 mutant alleles were observed respectively, in 474 and 242 alleles from the intermediate and southern areas of China. No mutant allele was detected in 84 alleles from northern China. Twenty-four positive samples including 4 homozygous and 20 heterozygous mutations, and 14 negative samples were retested by direct sequencing, which confirmed that the accuracy of RT-PCR was 100%.

CONCLUSION: RT-PCR can detect the mutation 851del4 in infants with intrahepatic cholestasis with an accuracy of 100%.

INTRODUCTION

The *SLC25A13* gene, localized in chromosome 7q21.3, encodes a 3.4kb transcript that is expressed most abundantly in liver[1,2]. *SLC25A13* gene mutations can lead to citrin deficiency, which causes not only onset of type II citrullinemia (CTLN2) in adults[2], but also neonatal intrahepatic cholestasis (NICCD)[3,4]. Clinical manifestations of NICCD

include intrahepatic cholestasis, fatty liver, failure to thrive, hyperaminoacidemia, liver dysfunction, hypoglycaemia, hypoproteinemia, and coagulation disorders. Symptoms of most NICCD patients disappear by 12 mo of age. Specific treatment, except for nutritional program including supplementation of fat soluble vitamins and formulas containing medium-chain triglycerides[3,5-7], is usually not required. However, NICCD is not always benign and a few NICCD patients may have a less favorable clinical course with relatively early liver dysfunction that necessitates management with liver transplantation under the age of 1 year[8]. Some infants with homozygous mutations may suffer from CTLN2 one or more decades later[9,10].

Since the full genomic sequence of the *SLC25A13* gene was published in 1999, over 50 mutations have been identified[11]. It has been reported that more than 100 000 East Asians have two homozygous mutated *SLC25A13* alleles, and the carrier rate in Chinese population is 1/63[11,12]. Mutation 851del4, is a 4-bp (GTAT) deletion from nt 851-854 in exon 9, leading to premature truncation of a protein. Population analysis has shown that mutation 851del4 accounts for 70% of all detected *SLC25A13* gene mutations in general Chinese population[13]. However, its prevalence in infants with intrahepatic cholestasis is unclear.

Traditionally, mutation 851del4 is tested by direct agarose gel electrophoresis or GeneScan[2,12-14]. Since the differences in length between the mutant fragment and wild sequence are quiet small, direct agarose gel electrophoresis depends greatly on experience of the investigator, while GeneScan requiring expensive equipments is time consuming. In this study, real-time fluorescence polymerase chain reaction (RT-PCR) with dual labeled probes was used to detect the most common *SLC25A13* gene mutation 851del4 in 400 Chinese infants with intrahepatic cholestasis.

MATERIALS AND METHODS

Study design

A gene test for mutation 851del4 in 14 infants with intrahepatic cholestasis was carried out by direct sequencing. Four cases were detected to be with mutant alleles, including one homozygote and three heterozygotes. These patients were used as samples to develop the method of RT-PCR. The other ten cases with wild sequence served as the control.

Then, RT-PCR was performed to detect the prevalence of 851del4 mutation in 386 infants with unexplained intrahepatic cholestasis. If a heterozygous mutation 851del4 was found in an infant, the second mutation was identified in all the 18 exons and their flanking sequences by direct sequencing.

The accuracy of RT-PCR was retested by direct sequencing in 24 infants with mutant sequences and 14 infants with normal sequence.

Subjects

From June 2003 to May 2009, 400 infants with idiopathic intrahepatic cholestasis were enrolled in this study for testing their genes. The inclusion criteria were conjugated hyperbilirubinaemia with its serum total bilirubin (TBil) exceeding 5 mg/dL and conjugated bilirubin level > 20% of TBil or > 1 mg/dL if the total serum bilirubin < 5 mg/dL, and development of conjugated hyperbilirubinaemia under the age of 1 year. Those were excluded from the study if they had diseases affecting their extrahepatic biliary system (such as biliary atresia, choledochal cyst or tumor, inspissated bile, or haemangioma), low γ-glutamyl transpeptidase (GGT) level (no more than 50 U/L) that may indicate progressive familial intrahepatic cholestasis[15], and obvious extrahepatic abnormalities or positive serology other than cytomegalovirus (CMV) that may also indicate infection. CMV infection occurs frequently in infants with neonatal hepatitis in Mainland China[16,17], and the outcome is similar in those infected with or without CMV[18,19].

The infants included in this study came from 18 provinces or municipalities in China. Because the most likely boundary between northern and southern China was drawn at an altitude of 30°N, the Yangtze River was considered a historically significant border between northern and southern China as previously described[13,20]. According to such criteria, 237 infants came from a border area (Shanghai City, and Jiangsu, Anhui, Hubei, Sichuan Provinces), 121 from the southern area (Hunan, Jiangxi, Zhejiang, Fujian and Guangdong Provinces), and 42 from the northern area (Jilin, Liaoning, Hebei, Shandong, Ningxia and Henan Provinces) in our study (Figure 1).

RT-PCR assay for mutation 851del4

This study was approved by the Ethics Committee on Human Research of the Children's Hospital of Fudan University. Informed consent was obtained from the parents or the guardians of each participant.

The sequence of upstream primer and downstream primer is 5'-TTGGTATATTTGTTGCTTGTGTTT-3' and 5'-AGAGGGAACTCTGCCCTTTAA-3', respectively. Their normal and mutated sequences were detected with the probe FAM-CCTACAGACGTATGACCTTAGCA-TAMRA and the probe HEX-CCTACAGACGACCTTAGCAGA-TAMRA, respectively. Twenty-five microlitre reaction mixture used in this study contained 2 μL of genomic DNA, 10 μL of 2.5* real Master Mix [Tiangen Biotech (Beijing) Co. Ltd.], 1.25 μL of 20*probe enhancer, 0.25 μL of each FAM- and HEX-labeled probe, 0.5 μL of each upstream primer and downstream primer (diluted to 10 μmol/L), and 10.25 μL of ddH_2O. After overlaying 25 μL liquid, RT-PCR was performed under the following conditions: denaturation at 95℃ for 2 min, followed by 40 thermal cycles, each at 95℃ for 15 s, at 56℃ for 30 s, and at 68℃ for 40 s. The results were obtained by analyzing the curves.

Conventional PCR assay for mutation 851del4

To ensure the specificity and sensitivity of amplification, nested PCR was performed to amplify exons 8 and 9. Thirty cycles of PCR were performed in 30 μL reaction mixture at

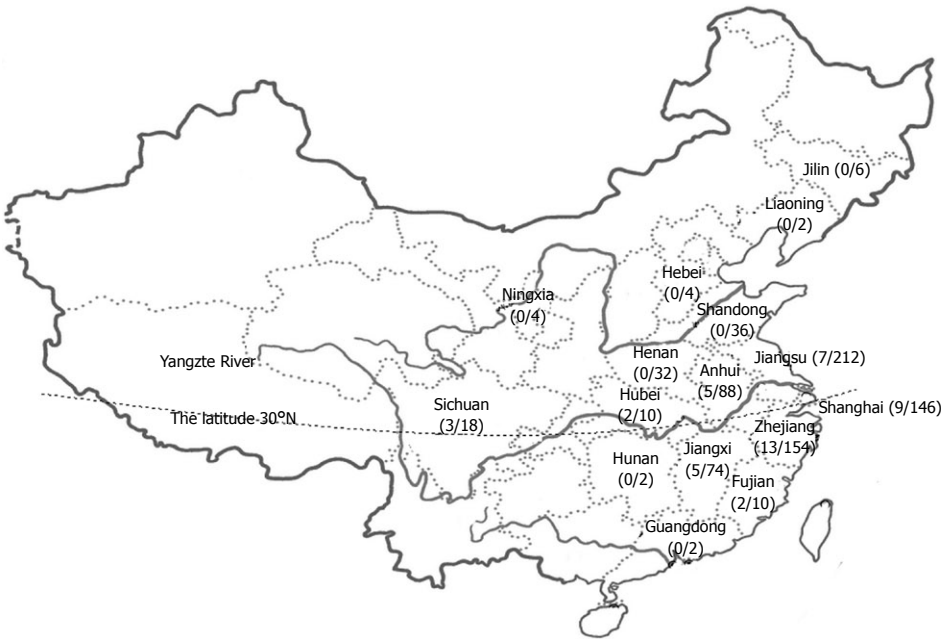

Figure 1 Distribution of idiopathic intrahepatic cholestasis infants enrolled in our study. As shown in the map, the provinces were separated into three parts by the Yangtze River and the northern latitude circle of 30°. The numbers in parentheses are the number of alleles of 851del4 mutation over the tested alleles.

94℃ for 3 min followed by 25 cycles, each at 94℃ for 30 s, at 50℃ for 30 s, at 72℃ for 1 min, and a final extension at 72℃ for 4 min, using primers Ex8/9F(5'-GCCTG-TAATCCCAGCACTT-3') and Ex8/9R(5'-GTTGAGA-GATGTAGCGAAAGAA-3'). The outer PCR reaction mixture consisted of 2*Taq- plus 15 μL PCR Master MIX, 1 μL in each primer (10 μmol/L), 2 μL DNA template, and 11 μL ddH_2O. After the initial outer PCR, inner PCR was conducted at 94℃ for 3 min followed by 30 cycles, each 94℃ for 30 s, at 50℃ for 30 s, at 72℃ for 1 min, and a final extension at 72℃ for 4 min using 1 μL of primers IVS7F (5'-TCACTCATTCCAGTGCCTTG-3') and IVS9B (5'-GCAGTTGCCTTTGCGGCATTG-3') as previously described[2], 2 μL outer PCR product as template, 2*Taq-plus 15 μL PCR Master MIX, and 11 μL ddH_2O.

The PCR products were analyzed by direct sequencing, in which IVS7B and IVS9B were taken as sequence primers for forward and backward sequencing identification. Mutation 851del4 was identified using software (Bioedit, North Carolina State University, NC, USA) and checked by two of the investigators.

RESULTS

Accuracy of RT-PCR

The curves were analyzed in accordance with the direct sequencing in 14 infants with known sequences. In infants with homozygous 851del4 mutation, positive fluorescence was observed only on the HEX-530 curve but not on FAM-490 curve. In those with heterozygous 851del4 mutation, positive fluorescence was found on both FAM-490 and HEX-530 curves, which was very close to each other, with the difference in *Ct* value always less than 2 (Figure 2). In those with the wild sequence, positive fluorescence was detected only on the FAM-490 curve. For any given sample, the experiment was considered a failure if negative fluorescence appeared on both HEX-530 and FAM-490 curves.

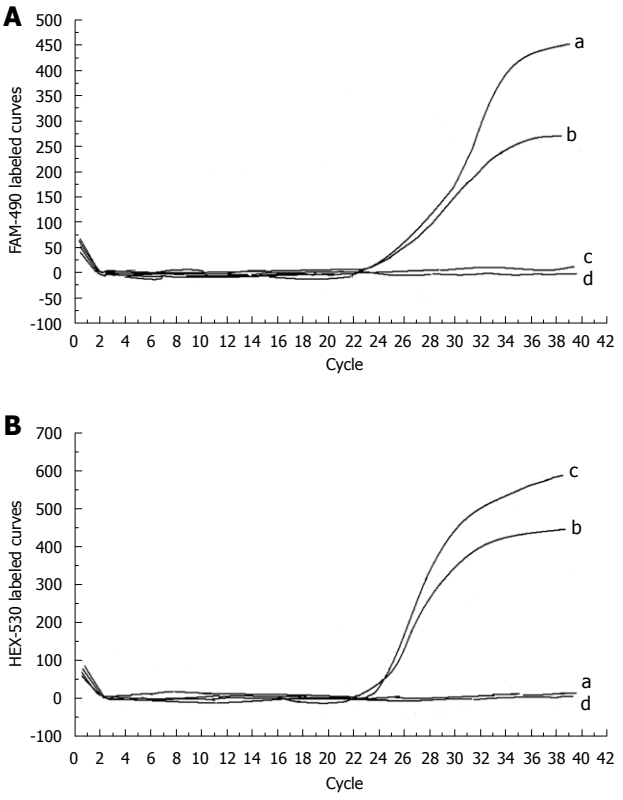

Figure 2 Positive fluorescences on FAM-labeled (A) and HEX-labeled (B) curves for different samples. As shown in the figure, positive fluorescence was observed on both FAM-labeled and HEX-labeled curves in sample b, indicating that b is a heterozygote. In sample c, positive fluorescence was only observed on the HEX-labeled curve, indicating that c is a homozygote. Positive fluorescence was observed on the FAM-labeled curve, otherwise HEX-labeled curve is a horizontal line in sample a, indicating that sample a has a wild sequence. d is a blank control with negative fluorescence on both FAM-labeled curve and HEX-labeled curve.

Positive mutation 851del4 was detected in 24 samples including 4 homozygous and 20 heterozygous mutations, and negative mutation 851del4 was retested in 14 infants

by nested PCR and direct sequencing, which was consistent with that detected by RT-PCR.

Prevalence of mutation 851del4

Eight homozygous and 30 heterozygous mutations were detected in the 400 infants with intrahepatic cholestasis, with a 851del4 mutation rate of 5.8% (46 mutant alleles with 851del4 were detected in 800 tested alleles). Subsequent testing of 18 exons and their flanking sequences in 30 heterozygous mutations showed another 9 mutant alleles including 1638ins23 in 5, R184X in 1 and novel mutations (data will be reported separately, manuscript in preparation) in 3, respectively.

Geographical variation of mutation 851del4 in China

Twenty-six and 20 mutant alleles were detected, respectively in 474 and 242 alleles of the intermediate and southern areas,with a 851del4 mutation rate of 5.5% and 8.3%, respectively. No mutant allele was detected in alleles of northern China (Figure 1).

DISCUSSION

To our knowledge, this is the first study to detect the most common mutation 851del4 of the *SLC25A13* gene in Chinese infants with intrahepatic cholestasis in a relatively large sample size. In this study, we developed a simple, fast, and accurate RT-PCR for detecting the mutation 851del4, the most common mutation of the *SLC25A13* gene, and detected 46 mutant alleles from 800 alleles with it. The prevalence of mutation 851del4 in Chinese infants with intrahepatic cholestasis was 1/17, which is much higher than that in general Chinese population (1/93)[13].

Compared with conventional nested PCR and agarose gel electrophoresis or GeneScan, RT-PCR could detect the mutation alleles and identify patients with homozygous or heterozygous 851del4 mutation, indicating that it can be used in diagnosis of intrahepatic cholestasis in infants.

In the present study, the mutation rate of 851del4 was about 5.8%, which was significantly higher than that in the general population, indicating that the *SLC25A13* gene mutation plays an important role in the pathogenesis of intrahepatic cholestasis of Chinese infants and should be detected in such infants, especially in those with symptoms of NICCD.

Screening of mutation 851del4 by RT-PCR may contribute to the diagnosis of intrahepatic cholestasis in patients with homozygous mutation because testing 18 exons of the *SLC25A13* gene can be omitted and diagnosis of citrin deficiency can be made. Early diagnosis and intervention of NICCD are extremely important[20] for the prevention of its serious consequences.

In this study, 30 heterozygous mutations of 851del4 were detected in 400 intrahepatic cholestasis infants with 9 compound heterozygous mutations detected by examining 18 exons of the *SLC25A13* gene. It is noteworthy that if suspicious patients were found to be heterozygous or when no mutation was found, all the 18 exons and their flanking sequence of the *SLC25A13* gene should be examined.

The *SLC25A13* gene mutation 851del4 has geographical variations in China and can be frequently found in southern China (1/70) but rarely in northern China (1/940)[13]. In this study, mutant alleles were detected in most infants from the intermediate and southern areas but not in those from northern China, showing that the distribution of the *SLC25A13* gene mutation 851del4 is different in south and north areas of China. Our finding is consistent with the reported data[13]. Thus, different methods should be used in dignosis of intrahepatic cholestasis in infants according to their geographical origin.

RT-PCR was established and the *SLC25A13* gene mutation 851del4 was detected in 400 infants using it in this study. However, it was used in detecting only one specific *SLC25A13* gene mutation, its prevalence might be underestimated. Further study is needed to highlight the importance of the *SLC25A13* gene mutations in infants with intrahepatic cholestasis and the application of RT-PCR in clinical practice.

In conclusion, RT-PCR can detect the most common *SLC25A13* gene mutation 851del4 in patients with intrahepatic cholestasis, thus providing a useful and effective tool for the diagnosis of NICCD.

COMMENTS

Background

SLC25A13 gene mutations lead to citrin deficiency, which causes onset of type Ⅱ citrullinemia (CTLN2) in adults and neonatal intrahepatic cholestasis (NICCD). Up to date, over 50 mutations of *SLC25A13* have been identified, in which 851del4 is the most common mutation type. Traditionally, mutation 851del4 is screened by direct agarose gel electrophoresis or GeneScan. Since these methods are highly dependent on personal experience or need special equipments, a simple and accurate method for screening the mutation 851del4 is needed.

Research frontiers

Population analysis has shown that mutation 851del4 accounts for 70% of all mutations of the *SLC25A13* gene in general Chinese population. Mutation 851del4 is a 4-bp (GTAT) deletion from nt 851-854 in exon 9, leading to premature truncation of a protein. Early diagnosis of citrin deficiency is extremely important.

Innovations and breakthroughs

Real-time fluorescent polymerase chain reaction (RT-PCR) with dual-labeled probes was established, which could detect the mutation 851del4. The homozygosity, heterozygosity and wild sequence can be differentiated clearly. Compared with conventional nested PCR and agarose gel electrophoresis or GeneScan, RT-PCR does not require expertise in experimental operation.

Applications

The prevalence of mutation 851del4 in Chinese infants with intrahepatic cholestasis is 1/17, which is much higher than that in general Chinese population (1/93). RT-PCR may be used in diagnosis of intrahepatic cholestasis in infants.

Peer review

The authors obtained infants with intrahepatic cholestasis from various parts of China. Using RT-PCR with dual-labeled probes, they identified patients with homozygous or heterozygous 851del4 mutations and found that the mutation is more prevalent in southern than in northern part of China, indicating that RT-PCR can also be used in diagnosis of other genetic disorders in pediatric patients.

Abstract

AIM: To elucidate the adherence and immunomodulatory properties of a probiotic strain *Bifidobacterium lactis* (*B. lactis*) HN019.

METHODS: Adhesion assays of *B. lactis* HN019 and *Salmonella typhimurium* (*S. typhimurium*) ATCC 14028 to INT-407 cells were carried out by detecting copies of species-specific genes with real-time polymerase chain reaction. Morphological study was further conducted by transmission electron microscopy. *Interleukin-1β* (*IL-1β*), *interleukin-8*, and *tumor necrosis factor-α* (*TNF-α*) gene expression were assessed while enzyme linked immunosorbent assay was used to detect IL-8 protein secretion.

RESULTS: The attachment of *S. typhimurium* ATCC 14028 to INT407 intestinal epithelial cells was inhibited significantly by *B. lactis* HN019. *B. lactis* HN019 could be internalized into the INT-407 cells and attenuated IL-8 mRNA level at both baseline and *S. typhimurium*-induced pro-inflammatory responses. IL-8 secretion was reduced while IL-1β and TNF-α mRNA expression level remained unchanged at baseline after treated with *B. lactis* HN019.

CONCLUSION: *B. lactis* HN019 does not up-regulate the intestinal epithelium expressed pro-inflammatory cytokine, it showed the potential to protect enterocytes from an acute inflammatory response induced by enteropathogen.

INTRODUCTION

The intestinal tract acts as a reservoir for the intestinal microbiota that exert both harmful and beneficial effects on human health; intestinal microbiota contains an extraordinarily complex variety of metabolically active bacteria and fungi which interact with the host's epithelial cells and provide constant antigenic stimulation to the mucosal immune system[1]. The intestinal epithelium presents the

first line of defense against invading or attaching bacteria. In addition to serving as a physical barrier to microbial penetration, the intestinal mucosa is the main interface between the immune system and the luminal environment[2]. Intestinal epithelial cells (IECs) appear as an essential link in communicating with the immune cells in the underlying mucosa and the microflora in the lumen *via* the expression of many mediators. These mediators included antibacterial peptides such as defensins[3], mucins (MUC3), and chemokines and cytokines such as interleukin (IL)-8.

Under certain pathological circumstances, such as enteropathogens infection, the intestinal epithelium releases the chemokine IL-8 and other pro-inflammatory molecules that provoke an acute inflammatory response[4]. Therefore, a prolonged infection can result in a high level and protracted IL-8 release by IECs. The final outcome is a considerable infiltration of neutrophils that may perpetuate inflammation and eventually lead to cell damage, epithelial barrier dysfunction and pathophysiologic change of diarrhea[5].

For the protection against enteropathogen infections, the possibility of using food supplements containing probiotic bacteria has been recently considered. Probiotics are a group of live micro-organisms administered in adequate amounts which confer a beneficial effect on the health of the host[6]. Most probiotics found are resident members of the intestinal flora and are of major economic importance to the food industry. Several health-related effects associated with the intake of probiotics have been reported in different animal models as well as in human studies[7]. This bacterial community plays a pivotal role in human nutrition and health by promoting the supply of nutrients, preventing pathogen colonization and shaping and maintaining normal mucosal immunity[8]. While the precise mechanistic basis of the beneficial effects of probiotics is still obscure and will most likely vary depending on the strain and species used, a number of mechanisms have been suggested[9]. Protecting the host from enteropathogen colonization (barrier effects) and immunomodulatory effects toward host immune response have been demonstrated in humans and laboratory animals[10,11].

The interaction between probiotic strains and the intestinal epithelium is a key determinant for cytokine production by enterocytes, and probably the initiating event in probiotic immunomodulatory activity, as it occurs prior to the encounter with the immune system cells. It has been reported that several strains of probiotics belonging to *Bifidobacterium* and *Lactobacillus* are highly relevant to the prevention of the invasion of tissues by enteropathogens[12]. Moreover, by inhibiting the production of IL-8 in enterocytes, these strains are also found to be effective in modulating the pro-inflammatory response in IECs challenged by enteropathogens such as *Salmonella typhimurium* (*S. typhimurium*); such induction is species and strain specific[13,14].

Since the immunomodulatory properties are strain-specific[15-17], for each probiotic strain, profiles of the cytokines secreted by lymphocytes, enterocytes and/or DCs that come into contact with the strain should be established. Strains belonging to the *Bifidobacterium* are the most widely used probiotic bacteria, and are included in many functional foods and dietary supplements.

We focused our study mainly on how IEC respond to widely used probiotic bacteria. The aim of this work was to study the cytokine pattern induced by the interaction of probiotics with intestinal epithelium cells. Furthermore, whether probiotic bacteria still function after inactivation was evaluated. This study may contribute to verify the pro- and anti-inflammatory properties of the strain in question and define specific clinical applications.

MATERIALS AND METHODS

Bacterial strains and related preparations

A globally consumed commercial probiotic strain *Bifidobacterium lactis* (*B. lactis*) HN019 was studied in the experiment. The *B. lactis* HN019 powder was a gift from Danisco. Live strain was inoculated in De Man, ROGOSA and SHARPE (MRS) broth (Difco) supplemented with 0.05% (w/v) cysteine hydrochloride at 37℃ under anaerobic conditions for 24 h. The stationary-phase bacteria were harvested and Gram-stained to confirm purity. Heat-killed *B. lactis* HN019 were prepared by heating the bacteria at 80℃ for 20 min. Effectiveness of the heat-killing method was confirmed by plating the treated bacteria on MRS agar at 37℃ for 48 h. *S. typhimurium* ATCC 14028 was used as an enteropathogenic reference strain. *S. typhimurium* was cultured in Tryptone Soy broth (TSB) at 37℃ with shaking overnight.

Bacteria number was estimated by measuring the absorbance at 600 nm, and correlating the absorbance value to a standard curve of colony-forming units (CFU) on MRS agar (Merck) estimated in preliminary experiments.

For storage, liquid cultures of *B. lactis* HN019 grown for 24 h were frozen in 30% glycerol at -80℃; vacuum freeze-drying method was also applied.

Cell lines and media

INT-407 cells which derived from human intestinal epithelium, were purchased from American Type Culture Collection (ATCC strain CCL-6). Cells were grown in a humidified incubator at 37℃ under 5% CO_2. INT-407 cells were cultured in Dulbcco's Modifed Eagle Medium (DMEM) (GIBCO) containing 10% (v/v) heat-inactivated fetal bovine serum (Invitrogen), 50 U/mL penicillin, and 50 μg/mL streptomycin. The cells were routinely propagated in 25 cm^2 tissue culture flasks until they approached 80%-90% confluences. Subsequently, the cells were subcultured and the medium was replaced every two to three days in the culturing process.

Adhesion assays

Each adhesion assay was conducted in triplicate over three to five successive passages of INT-407 cells. Briefly, INT-407 cells were seeded on sterile six-well plates and grown to 80% confluence. The monolayers of INT-407 cells were rinsed three times with modified Hank's Balanced Salt Solution (mHBSS) without calcium and magnesium. Late exponential cultures of *B. lactis* HN019 or/

and *S. typhimurium* ATCC 14028 were adjusted at an optical density at 600 nm corresponding to 1×10^8 cells/mL. After rinsing, the bacterial cells were resuspended in DMEM and used for the adhesion assay. After incubation for 2 h and 6 h at 37℃ in the atmosphere of 5% CO_2 and 95% air, unattached bacteria were removed by washing the monolayers four times with sterile PBS. After detachment of the INT-407 cells from the plastic surface by incubation with 200 μL trypsin/EDTA per well (10 min, 37℃), the INT-407 cells and the adhesive bacteria were transferred into a 1.5 mL reaction tube. The wells were rinsed with 200 μL sterile PBS which was also transferred into the 1.5 mL-reaction tube.

Bacterial adhesion to INT-407 cells was evaluated by quantification of INT-407-bound bacteria with genus-specific primers *via* real-time polymerase chain reaction (PCR) as reported by Candela *et al*[18]. To quantify the bacterial cells by real-time PCR, the cell suspensions obtained from the adhesion assays were thawed at room temperature and, after mixing, an aliquot of 20 μL was transferred into a 0.2 mL-reaction tube and incubated for 10 min at room temperature with 3.8 μL of Trypsin inhibitor solution. Then the bacterial cells (Bifidobacterium and Salmonella) were specifically quantified by real-time PCR performed with the genus-specific primers listed in Table 1. pMD19 T-vector which carried genus-specific genes was constructed as internal standards.

Real-time PCR was performed in ABI 7500 instrument and SYBR Green I fluorophore was used to correlate the amount of PCR product with the fluorescent signal. Amplification was carried out in a 20 μL final volume containing 2 μL of cell suspension, 10 μL SYBR Premix Ex Taq (TAKARA), 0.2 μmol/L of each primer and 0.4 μL ROX Reference Dye Ⅱ. The experimental protocol consisted of the following programs: starting preincubation at 95℃ for 10s; amplification including 40 cycles of 95℃ for 5 s, and 60℃ for 34 s. Since the copy numbers of standard plasmids could be quantified, we amplified serial dilutions of the plasmids that represent bacteria number ranging from 1×10^7 to 1×10^3 CFU/μL.

The data reported represent mean values obtained in 3-5 independent experiments. Each experiment was performed in duplicate.

Preparation of samples for electron microscopy

INT-407 cells treated with *B. lactis* HN019 for 2 h and 6 h as previously described were washed three times with PBS buffer solution. Formaldehyde (40%) and glutaraldehyde (10%) were added for fixation. Ultrastructure of the cells was examined under transmission electron microscopy. The micrographs were produced at 5800 × and 13500 × magnification. Cells from the control group which had not been treated with bacteria were processed in the same way. Two samples from each group were analyzed.

INT-407 cells treatment

Monolayer of INT-407 cells were washed in PBS and supplemented with DMEM plus 2% FBS without antibiotics overnight before infection. *B. lactis* HN019 and *S. typhimurium* ATCC 14028 was harvested in stationary-phase, centrifuged and resuspended in fresh DMEM medium. After heat-killing treatment, viable *B. lactis* HN019, *S. typhimurium* ATCC 14028 and inactivated *B. lactis* HN019 were added into six-well plates for co-culture with INT-407 cells at a bacterial to epithelial cell ratio of 10:1. Untreated cells with normal medium were used as negative control. The plates were kept in humidified atmosphere containing 5% CO_2 for 2 h.

Table 1 Primer sequences of genus-specific genes used in adhesion assays

Primer name	Primer sequences (5′-3′)	Specificity	Ref.
BIF 164	GGGTGGTAATGCCGGATG	*Bifidobacterium*	[37]
BIF 662	CCACCGTTACACCGGGAA		
MINf	ACGGTAACAGGAAGCAG	*Salmonella*	[38]
MINr	TATTAACCACAACACCT		

Bacterial interference assays

The ability of *B. lactis* to inhibit binding of *S. typhimurium* to INT-407 cells was also assessed. INT-407 cells (1×10^6) seeded in six-well plates in antibiotic-free medium were incubated for 24 h. After replenishing the medium, the following assays were performed. (1) Coincubation of *B. lactis* HN019 and *S. typhimurium* ATCC 14028 with INT-407 cells for 2 h; (2) INT-407 cells were pretreated with 10:1 *B. lactis* HN019 for 2 h prior to infection with 10:1 *S. typhimurium* ATCC 14028 for further 2 h; (3) INT-407 cells were pre-stimulated with 10:1 *S. typhimurium* ATCC 14028 for 2 h prior to retreatment with 10:1 *B. lactis* HN019 for further 2 h; and (4) Untreated INT-407 cells were used as baseline control.

RNA extraction

Following bacterial treatment, cell culture supernatants were removed and washed three times with sterile D-Hank's. INT-407 cells collected for RNA preparation were immediately lysed in TRIZOL Reagent (Invitrogen). Total RNA was isolated from the lysed cells according to the manufacturer's instructions. Purification of RNA was performed by RNase-free DNase and standard phenol chloroform extraction method. The quantity of RNA was evaluated by spectrophotometric analysis and the quality of RNA samples was determined based on the A260:A280 ratio. All RNA samples were further analyzed by agarose gel electrophoresis to check for the integrity of 5S, 18S and 28S rRNA.

Real-time RT-PCR analysis

Total RNA (2 μg) was reverse-transcribed to yield cDNA using SuperScript Ⅲ First-Strand Synthesis System (Invitrogen) as the manufacture's protocol for the following experiments. Primers targeting four genes of interest were designed for detecting mRNA expression. Real-time RT-PCR was performed in an ABI 7500 system (Applied Biosystems) using SYBR Premix Ex Taq as mentioned

Table 2 Primer sequences used for quantitative real-time PCR analysis

Gene	Primer sequences (5′-3′)	Product size (bp)
IL-1β	ACTCACTTAAAGCCCGCCTG TCAGAATGTGGGAGCGAATG	80
IL-8	CAAGAGCCAGGAAGAAACCAC TGCAGAAATCAGGAAGGCTG	101
TNF-α	TCTTCTCGAACCCCGAGTGA CCTCTGATGGCACCACCAG	150
β-actin	TGTTACAGGAAGTCCCTTGCC AATGCTATCACCTCCCCTGTG	101

PCR: Polymerase chain reaction; IL: Interleukin; TNF: Tumor necrosis factor.

above. Calculations were performed using β-actin as an internal standard. Primer sequences are shown in Table 2. All reactions were performed in triplicate. Relative gene expression data was determined by the $2^{-\Delta\Delta CT}$ method as previously described[19]. Fold changes > 2 or < -0.5 was defined as significantly changed between treated and untreated cells.

IL-8 ELISA

Subconfluent or confluent INT-407 cells were incubated with varying groups of bacteria: (1) Cells were incubated with *B. lactis* HN019 or heat-killed *S. typhimurium* ATCC 14028 at a bacterial to epithelial cell ratio of 10:1 for 12 h; (2) Confluent monolayers of INT-407 cells were stimulated with 10 ng/mL LPS (derived from *S. typhimurium,* Sigma) for 12 h; (3) INT-407 cells were co-incubated with *B. lactis* HN019 (multiplicity of infection = 10) and LPS (10 ng/mL) simultaneously for 12 h; (4) Pretreated with 10:1 *B. lactis* HN019 for 2 h prior to stimulation with 10 ng/mL LPS for further 12 h; (5) Pre-stimulated with 10 ng/mL LPS for 2 h, and then treated with 10:1 *B. lactis* HN019 for further 12 h; and (6) Untreated cells were used as negative control.

Cells from all treatments were washed three times with PBS. Immunoreactive IL-8 protein levels in cell-culture supernatants were quantified using an ELISA Duo-Set kit (R & D Systems) according to the manufacturer's protocol.

Statistical analysis

Values were given as mean ± SD of triplicate measurements. Statistical analyses were performed using unpaired two-tailed Student's *t* test. *P* value < 0.05 was considered to be statistically significant.

RESULTS

Inhibitory effects of B. lactis HN019 on S. typhimurium ATCC 14028 attachment

The *B. lactis* HN019 strains in this study were evaluated with regard to their ability to inhibit the attachment of pathogenic *S. typhimurium* ATCC 14028 to INT-407 cells. Adherence activity of *B. lactis* HN019 and/or *S. typhimurium* ATCC 14028 was evaluated by a real-time PCR as shown in Figure 1.

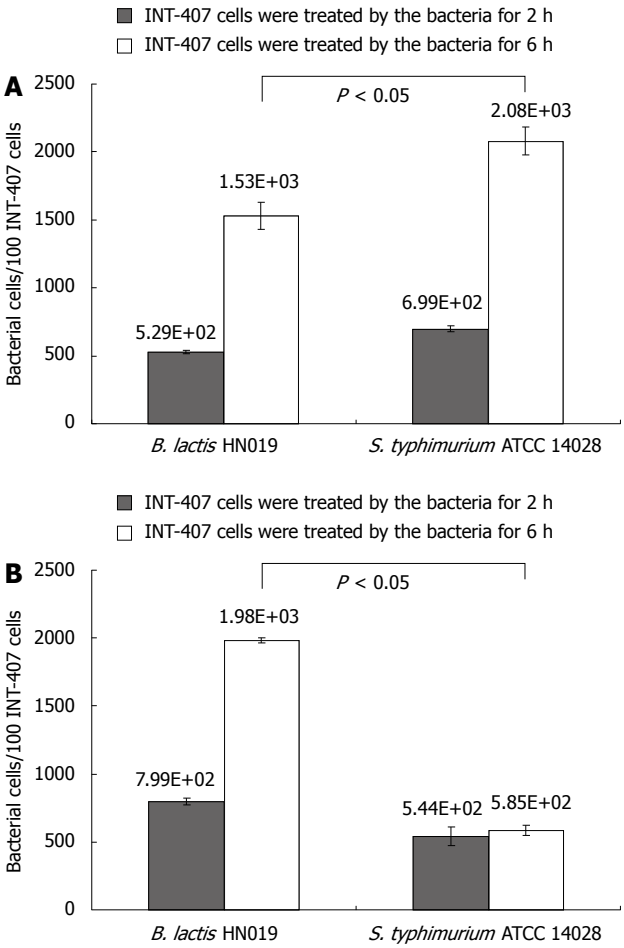

Figure 1 Adherence of *Bifidobacterium lactis* (*B. lactis*) HN019 and *Samonella typhimurium* (*S. typhimurium*) ATCC 14028 to INT-407 cells. A: Number of bacteria bound to 100 INT-407 cells obtained in assays contain each single strain; B: Number of bacteria bound to 100 INT-407 cells obtained in assays contain *S. typhimurium* ATCC 14028 plus *B. lactis* HN019. The error bars represent ± SD of the mean values.

Candela *et al*[18] defined bacterial strains as non-adhesive with less than 5 bacterial cells adhered to one cell. Following this adhesion score, both *B. lactis* HN019 and *S. typhimurium* ATCC 14028 could effectively adhere to INT-407 cells. Moreover, the adhesive capacity of *B. lactis* HN019 was not higher than *S. typhimurium* ATCC 14028 when treated with either strain alone, showing the adhesion values of 5.29×10^2 and 6.99×10^2 bacterial cells/100 INT-407 cells after 2 h while 1.53×10^3 and 2.08×10^3 bacterial cells/100 INT-407 cells after 6 h.

Nevertheless, the adhesion values obtained in co-treated assays showed that the *B. lactis* HN019 could significantly decrease the attached number of *S. typhimurium* ATCC 14028 from 2.08×10^3 to 5.85×10^2 bacterial cells/100 INT-407 cells after 6 h treatment, and the number of attached *B. lactis* HN019 was not affected by the existence of *S. typhimurium* ATCC 14028.

Transmission electron microscopy studies

In these studies we observed that *B. lactis* HN019 was able to interact with the epithelial cells of small intestine (Figure 2), and it was interesting that the *B. lactis* HN019

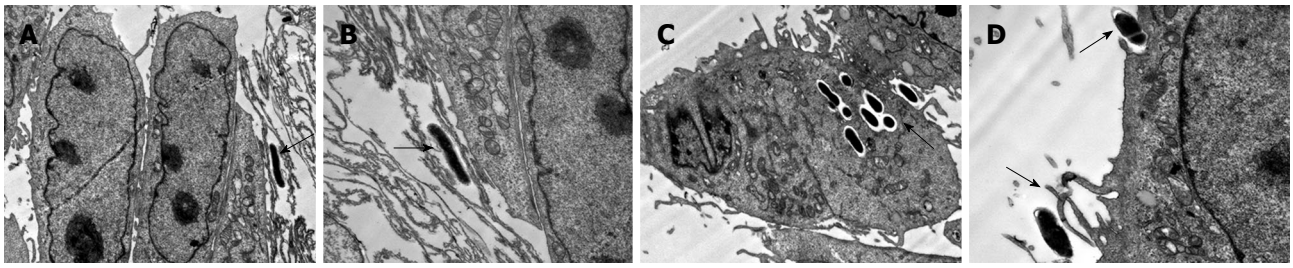

Figure 2 Transmission electron micrograph of INT-407 cells after stimulation with *B. lactis* HN019 (arrows). A: Stimulation for 2 h (× 5800); B: Stimulation for 2 h (× 13500); C: Stimulation for 6 h (× 5800); D: Stimulation for 6 h (× 13500).

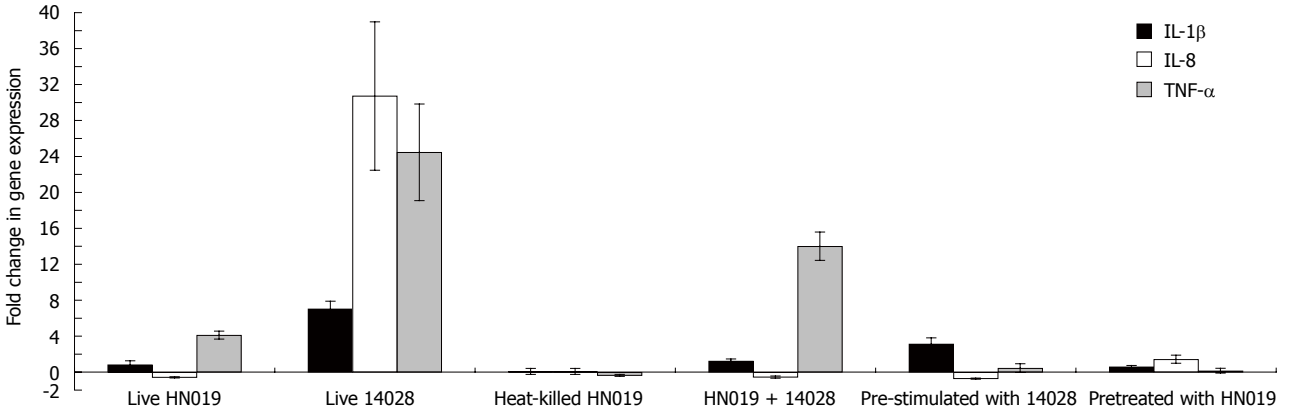

Figure 3 Effects of different bacterial treatment on expression of three genes assessed by real-time polymerase chain reaction. IL: Interleukin; TNF: Tumor necrosis factor.

could be internalized into the INT-407 cells after 6 h treatment.

Inflammatory gene expression following bacteria incubation

Inflammatory gene expression in bacteria-treated INT-407 cells was analyzed with real-time PCR. The results showed that live *B. lactis* HN019 had no effect on gene expression of IL-1β, but could up-regulate TNF-α expression and down-regulate IL-8 expression. Heat-killed *B. lactis* HN019 had no effect on gene expression of IL-1β, IL-8 and TNF-α. Pathogenic *S. typhimurium* ATCC 14028 could significantly up-regulate the mRNA level of pro-inflammatory cytokines. Although co-incubation with *B. lactis* HN019 and *S. typhimurium* ATCC 14028 could induce the gene expression of TNF-α and IL-1β, the extent is significantly lower than in those stimulated with *S. typhimurium* ATCC 14028 alone (Figure 3).

In bacterial interference assays, IL-1β, IL-8 and TNF-α mRNA expression was not changed at baseline after pre-treated with *B. lactis* HN019, and addition with *S. typhimurium* ATCC 14028 also did not activate these pro-inflammatory cytokines expression. For groups pre-stimulated with *S. typhimurium* ATCC 14028, *B. lactis* HN019 lowered the *S. typhimurium* ATCC 14028 induced IL-1β, IL-8 and TNF-α levels from 8.73, 47.97 and 9.3 folds to 2.6, 0.89 and 0.37 folds as compared with the untreated group. The results are summarized in Figure 3.

Through either incubating the INT-407 cells with *B. lactis* HN019 and *S. typhimurium* ATCC 14028 simultaneously or pre-treating with each strain respectively, the pro-inflammatory cytokines induced by *S. typhimurium* ATCC 14028 could be suppressed by *B. lactis* HN019. We therefore compared the inhibitory effects of these three groups and found that for IL-1β, the inhibition rate of *B. lactis* HN019 pretreated group was much lower than the other two groups. For IL-8, there was no significant difference among the three groups. For TNF-α, the inhibition rate of co-treated group was much lower than the other two groups (Figure 4).

IL-8 secretion by INT-407 cells following bacteria incubation

To assess the effects of probiotic strain on IL-8 secretion, INT-407 cells were incubated with live or heat-killed *B. lactis* and *S. typhimurium* and/or lipopolysaccharide. The experiments were performed 2-5 times in replicate; the results are demonstrated in Figure 5.

Firstly, we tested the effects of live *B. lactis* HN019, heat-killed *B. lactis* HN019 and *S. typhimurium* ATCC 14028, LPS derived from *S. typhimurium* on IL-8 secretion. The results showed that both live and dead *B. lactis* HN019 decreased IL-8 levels (844 ± 64 pg/mL and 897 ± 80 pg/mL) compared with the untreated group (1963 ± 77 pg/mL). Co-culturing with heat-killed *S. typhimurium* ATCC 14028 induced no change in IL-8 concentration. However, stimulation of INT-407 cells with LPS resulted in a significant increase of IL-8 production (3104 ± 80 pg/mL).

Secondly, in order to assess the anti-inflammatory

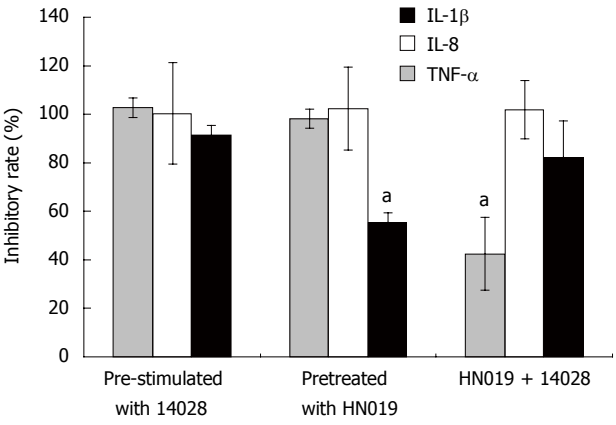

Figure 4 Inhibitory effects of *B. lactis* HN019 on gene expression of pro-inflammatory cytokines. $^{a}P < 0.05$ *vs* other treatment methods.

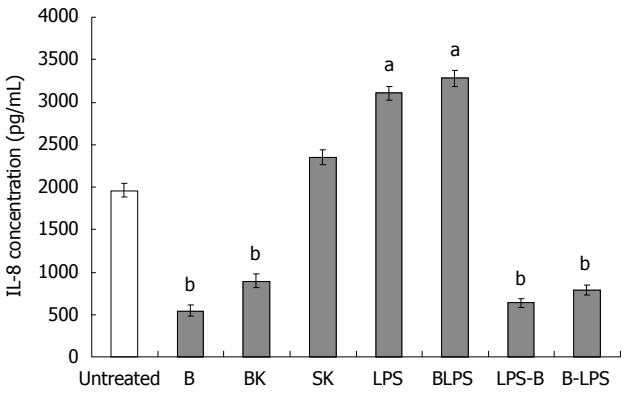

Figure 5 Bacteria modulate IL-8 secretion at baseline. B: *Bifidobacterium lactis* HN019; BK: Heat-killed *B. lactis* HN019; SK: Heat-killed *Salmonella typhimurium* ATCC 14028; LPS: Lipopolysaccharide (10 ng/mL); BLPS: Co-incubation with *B. lactis* HN019 and LPS; LPS-B: Treated with *B. lactis* HN019 after pretreatment with LPS for 2 h; B-LPS: Treated with LPS after pretreatment with *B. lactis* HN019 for 2 h. The data are expressed as pg/mL and represent the mean ± SE. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* untreated monolayers.

properties of the probiotic strain, the IL-8 production was evaluated by incubating INT-407 cell monolayers with *B. lactis* HN019 in the presence of LPS. As presented in Figure 5, IL-8 protein level secreted by the cells noticeably increased after co-incubated with LPS and probiotic strain compared with untreated group. However, the probiotic strain could decrease the LPS-induced IL-8 expression, and the cells pretreated with probiotic strain could also remain at a low level IL-8 secretion even after re-stimulated with LPS as compared with untreated group. This suggests that this probiotic strain *B. lactis* HN019 exerted anti-inflammatory effects on the epithelium by down-regulating the secretion of IL-8.

DISCUSSION

The role of probiotic bacteria derived from normal intestinal microbiota in the physiology of the gastrointestinal tract is not completely understood. In particular, the mechanisms underlying the benefits from biotherapy with probiotics have not been sufficiently elucidated. *B. lactis* HN019 is a world-wide consumed probiotic strain which is associated with several health-related immunomodulatory effects: such as reducing the severity of pathogen infection and enhancing immunity in the elderly[20-22]. Nevertheless, the mechanism is yet to be known. This is the first study on the differential pro-inflammatory cytokine responses of intestinal epithelium under conditions employing live and heat-killed *B. lactis* HN019. Furthermore, the enteropathogen exclusion effect of *B. lactis* HN019 was not evaluated.

In the present study, we used a rapid, accurate and sensitive method for studying bacteria adhesion. Provided specific primers for bifidobacteria are known, our method allows the quantification of this organism's cell number adhering to INT-407 cells which is used as a model in our investigation. A further important advantage of the real-time PCR based method is its efficacy in detecting and quantifying different bacterial genera and species simultaneously adhering to an epithelial cell monolayer. This method can be useful for probiotic strain selection. By this method, we found that *B. lactis* HN019 exerted a strong adhesive activity to human intestinal epithelial cells INT-407. The ability to adhere to the intestinal epithelium represents a significant prerequisite for the transient intestinal colonization of probiotic bacteria[23]. Bifidobacteria are normal gastrointestinal flora of many animals and have been shown to be adherent to a variety of epithelial cells *in vitro*[18,24,25]. However, adherence to INT-407 cells is seldom reported. This adherence to INT-407 cells may be mediated *via* fibronectin binding[26]. It is known that probiotic strains have the ability to counteract the pathogenic bacteria invasion[27,28]. In particular, the bifidobacteria strain tested is effective in inhibiting the adhesion of pathogenic *S. typhimurium* ATCC 14028 to INT-407 cells. This behavior is a fundamental prerequisite for probiotic bacteria to exert antagonistic activities against enteropathogens[29]. Such inhibitory effects of bifidobacteria can be explained by the mechanisms of competition for common adhesive sites or producing antibacterial lipophilic factor(s)[30]. In addition, it is reported that *bifidobacteria* could produce a proteinaceous factor that inhibits *in vitro* adherence of an enterotoxigenic *E. coli* strain to gangliotetraosylceramide molecules, which are physiological constituents of the mammalian intestinal epithelial surface[31].

Interactions of *B. lactis* HN019 and INT-407 cells observed under transmission electron microscope (TEM) indicated that the bacteria are able to contact with the epithelial cells of the small intestine. Moreover, the *B. lactis* HN019 could be internalized into INT-407 cells. It has been described that pathogens (bacteria, virus and parasites) can cross the mucosal barrier through different routes: transcellular route, paracellular route across cells for the tight junctions and *via* M cells[32]. The *B. lactis* used in this study was originally isolated from a human host. Therefore, it may be that this strain can internalize into epithelial cells because of its host specificity. We considered that such internalization may be of potential risks if the safety status of the internalized bacteria were not carefully assessed, especially the translocation capacity which correlate with its ability to induce infections[33].

The colonization of the intestinal tract by enteropathogenic bacteria induces the activation of the inflammatory cascade, resulting in the epithelial cell secretion of IL-8 and other pro-inflammatory molecules and in the consequent recruitment of neutrophils and other inflammatory cells. IL-8 amplifies an ongoing acute immune response and provides a set of signals for the activation of mucosal inflammatory responses in the earliest phases of microbial invasion. In some cases, a massive and prolonged infiltration of neutrophils may perpetuate inflammation and ultimately lead to cell damage, epithelial barrier dysfunction and pathophysiologic change of diarrhea. In the present study, INT-407 cells behaved like human enterocytes and could secrete IL-8 either constitutively or after stimulation with physiological agonists. Probiotic strains presented differences in their capacity to augment IL-8 expression, however, some strains seemed to rather decrease epithelial-cell production of IL-8[15-17,34-36]. Our results showed a robust IL-8 expression of INT-407 cells induced when exposed to *S. typhimurium*. However, live and heat-killed *B. lactis* HN019 not only functionally modulate the epithelium by inhibiting the constitutive mRNA level of IL-8 and attenuating *S. typhimurium*-induced *IL-8* gene expression, but also protect the INT-407 cells from IL-8 protein production activated by LPS. The same results were discovered on *TNF-α* and *IL-1β* gene expression except for up-regulation of TNF-α expression by live *B. lactis* HN019, but the *S. typhimurium* could induce much higher TNF-α expression than live *B. lactis* HN019. High concentrations of IL-1β and TNF-α cause cachexia, tissue injury, disseminated intravascular coagulation and shock. Therefore, the control of secretion of these pro-inflammatory cytokines *in vivo* is very important. *B. lactis* HN019 has a beneficial effect in converting the infection-induced excessive cytokine expression and helping maintain an immunological balance. These data indicated that INT-407 displayed immunological quiescence when exposed to both live and dead *B. lactis* HN019. *B. lactis* HN019 can modulate epithelial responses to limit inflammatory signals and markedly inhibit the inflammatory response induced by pathogen.

We used three approaches to detect the influence of probiotic strain on the pathogenic strain, and found that although the *B. lactis* HN019 could reduce the expression of pro-inflammatory cytokines, the inhibitory effect was different depending on the treatment methods. Pre-stimulated INT-407 cells with *S. typhimurium* ATCC 14028 could strongly induce a high-level of pro-inflammatory cytokine expression and such up-regulation could be reversed to a normal level after re-treatment with probiotic *B. lactis* HN019. This treatment achieved the maximum inhibitory rate. These results indicated that *B. lactis* HN019 may be more effective as adjunctive therapeutic agent than as preventive agent in inflammatory diseases.

In conclusion, our studies revealed that as a probiotic strain, *B. lactis* HN019 could modulate immune system towards anti-inflammatory action and exclude enteropathogenic adhesion, thus contributing to the homeostasis of the intestinal epithelium. This finding will offer, in the near future, new therapeutic means to counteract the inflammatory disorders observed in human inflammatory bowel disease.

COMMENTS

Background

Bifidobacterium lactis (*B. lactis*) HN019 is a world-wide consumed probiotic strain and several health-related effects of the strain have been reported, especially the immunomodulatory effect. The immunomodulatory properties are strain-specific, and the interaction between probiotics and the intestinal epithelium is the initiating event in immunomodulatary activity. The authors focused their studies on how intestinal epithelial cells (IEC) respond to widely used probiotic bacteria to explore the mechanism of the immunomodulatory effects of *B. lactis* HN019.

Research frontiers

Studies in probiotics are one of the hottest research fields at present. The interactions between bacteria and the host may reveal the mechanisms of bacteria on the host. This study may contribute to better applications of probiotic bacteria.

Innovations and breakthroughs

This is the first study on different pro-inflammatory cytokine responses of intestinal epithelium under conditions employing *B. lactis* HN019. The authors used a rapid, accurate and sensitive method for studying bacteria adhesion and found that *B. lactis* HN019 exerted a strong adhesive activity to human intestinal epithelium cells and the bifidobacteria strain tested was effective in inhibiting the adhesion of pathogen. The authors also indicated that *B. lactis* HN019 could modulate epithelial responses to limit inflammatory signals and markedly inhibit the inflammatory response induced by pathogen.

Applications

The study revealed that as a world-wide consumed probiotic strain, *B. lactis* HN019 could modulate immune system towards anti-inflammatory action and exclude enteropathogenic adhesion. These findings may help with better applications of the *B. lactis* HN019 and will contribute to offering new therapeutic means to counteract the inflammatory disorders observed in human inflammatory disease.

Peer review

The manuscript by Liu *et al* describes the adherence and immuno-modulatory properties of *B. lactis* HN019 against INT-407 intestinal epithelial cells, and additionally reports the anti-*S. typhimurium* properties of this probiotic strain. This is an interesting manuscript which has been well executed.

Abstract

AIM: To establish a multidrug-resistant hepatoma cell line (SK-Hep-1), and to investigate its biological characteristics.

METHODS: A highly invasive SK-Hep-1 cell line of human hepatocellular carcinoma, also known as malignant hepatoma was incubated with a high concentration of cisplatin (CDDP) to establish a CDDP-resistant cell subline (SK-Hep-1/CDDP). The 50% inhibitory dose (IC_{50}) values and the resistance indexes [(IC_{50} SK-Hep-1/CDDP)/(IC_{50} SK-Hep-1)] for other chemotherapeutic agents and the growth curve of cells were all evaluated using cell counting kit-8 assays. The distribution of the cell cycles were detected by flow cytometry. Expression of acquired multidrug resistance P-glycoprotein (MDR1, ABCB1) and multidrug resistance-associated protein 1 (MRP1, ABCC1) was compared with that in parent cells by Western blotting and immunofluorescence combined with laser scanning confocal microscopy.

RESULTS: The SK-Hep-1/CDDP cells (IC_{50} = 70.61 ± 1.06 μg/mL) was 13.76 times more resistant to CDDP than the SK-Hep-1 cells (IC_{50} = 5.13 ± 0.09 μg/mL), and CDDP-resistant cells also demonstrated cross-resistance to many anti-tumor agents such as doxorubicin, 5-fluorouracil and vincristine. Similar morphologies were determined in both SK-Hep-1 and SK-Hep-1/CDDP groups. The cell cycle distribution of the SK-Hep-1/CDDP cell line exhibited a significantly increased percentage of cells in S (42.2% ± 2.65% *vs* 27.91% ± 2.16%, $P < 0.01$) and G2/M (20.67% ± 5.69% *vs* 12.14% ± 3.36%, $P < 0.01$) phases in comparison with SK-Hep-1 cells, while the percentage of cells in the G0/G1 phase decreased (37.5% ± 5.05% *vs* 59.83% ± 3.28%, $P < 0.01$). The levels of MDR1 and MRP1 were overexpressed in the SK-Hep-1/CDDP cells exhibiting the MDR phenotype.

CONCLUSION: Multiple drug resistance of multiple drugs in the human hepatoma cell line SK-Hep-1/CDDP was closely related to the overexpression of MDR1 and MRP1.

INTRODUCTION

Multidrug resistance (MDR)[1] is a major obstacle in the chemotherapy of cancer patients and is also one of the reasons for tumor relapse and metastasis. Hepatocellular

carcinoma (HCC) is one of the most common gastrointestinal tumors worldwide, accounting for 70%-90% of primary liver cancers[2], with a high degree of malignancy and poor prognosis. A majority of patients are surgically unresectable at the time of diagnosis, and even for those where surgery is possible, the risk of recurrence is extremely high. Consequently, chemotherapy is an important treatment for most HCC patients. However, HCC responds poorly to chemotherapy owing to acquired MDR[3,4]. The ability to overcome this MDR is a major concern in clinical oncology in successfully treating HCC[5].

Cisplatin (CDDP) is a key drug that is widely used for cancer chemotherapy, but the effectiveness of CDDP for HCC is unsatisfactory because of MDR. To elucidate the CDDP-resistant mechanism in HCC *in vitro*, we established a CDDP-resistant SK-Hep-1 cell line and analyzed its biological behavior.

MATERIALS AND METHODS

Drugs and chemicals

CDDP, doxorubicin (DOX), penicillin, streptomycin, propidium iodide (PI) and RNase A were obtained from the Sigma-Aldrich Chemical Co (St.Louis, MO, USA). Vincristine (VCR) was obtained from Shenzhen Main Luck Pharmaceuticals Inc. (Shenzhen, China). 5-fluorouracil (5-FU) was obtained from Shanghai Xudong Haipu Pharmaceutical Co. Ltd (Shanghai, China). Dulbecco's modified Eagle's medium/high glucose (DMEM/H), fetal bovine serum (FBS) and Trypsin were purchased from Invitrogen (Carlsbad, CA, USA). The phospho-glycoprotein (P-gp, MDR1) mouse monoclonal antibody, multidrug resistance-associated protein 1 (MRP1)-specific mouse anti-human antibody and FITC-conjugated goat anti-mouse IgG were obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA). MitoTracker Red CMXRos dye purchased from Invitrogen (Molecular Probes, Invitrogen Corp.). Cell Counting Kit-8 (CCK-8) was obtained from Dojindo Molecular Technologies (Dojindo, Japan). The cell culture supplies were purchased from Corning Life Sciences (Lowell, MA, USA). Anti-tumor agents were prepared extemporaneously in complete culture medium immediately prior to use *in vitro*.

Cells and cell culture

The human hepatoma cell line, SK-Hep-1, was obtained from the Cell Culture Center, Institute of Basic Medical Sciences within the Chinese Academy of Medical Sciences. SK-Hep-1 cells were cultured in DMEM/H containing 10% (v/v) FBS, penicillin (200 U/mL), streptomycin (100 μg/mL), and were incubated at 37℃ in a humidified incubator with an atmosphere of 50 mL/L CO_2.

Establishment of a CDDP-resistant SK-Hep-1 subline *in vitro*

SK-Hep-1/CDDP was produced by exposing SK-Hep-1 cells to CDDP repeatedly at a single high concentration over a period of 24 h. Briefly, SK-Hep-1/CDDP was selected by a procedure consisting of 6 pulse drug treatments with 5 μg/mL CDDP, with SK-Hep-1 cells (1×10^6) plated onto a 25 cm^2 culture flask in each pulse treatment. When cells were growing exponentially, they were exposed to CDDP for 24 h. The majority of the cells were dead following 24 h exposure to CDDP. The treated cells were then washed with 0.01 mol/L phosphate-buffered saline (PBS) and cultured in CDDP-free growth medium. After 1-2 d, the dead cells were washed out with PBS and fresh medium again added. The resistant subclones were isolated by limiting dilution. After 4 weeks' incubation at 37℃ in a humidified incubator containing 50 mL/L CO_2, the cells recovered at an exponential rate and were then subcultured at a density of 1×10^6 cells/25 cm^2 flasks. Once cells reached 60%-70% confluence, the cells were preserved for further study as described above. The CDDP-resistant subclone was established 6 mo after the treatment was initiated, then the resistant phenotype developed. For maintenance of CDDP-resistant cells, the SK-Hep-1/CDDP cells were grown in the presence of 0.01 μg/mL CDDP. Before experimentation, SK-Hep-1/CDDP cells were maintained in a CDDP-free culture medium and subcultured at least 3 times. The MDR characteristics of these SK-Hep-1/CDDP cells were tested using various concentrations of anticancer drugs including CDDP, DOX, VCR and 5-FU.

CCK-8 cell proliferation and cytotoxicity assay

Cell proliferation assays were performed with CCK-8 according to the manufacturer's instructions. Cells (2×10^3) were seeded into each well of a 96-well plate and cultured in 100 μL of DMEM/H supplemented with 10% FBS. At the indicated time points, medium was exchanged for 110 μL of DMEM/H with CCK-8 reagent (10 μL CCK-8 and 100 μL DMEM/H), and the cells were incubated for 2 h. Absorbance was measured for each well at a wavelength of 450 nm, with the reference wavelength set at 600 nm. An increase or decrease in absorbance values at 450 nm in the experimental wells relative to the initial value indicated cell growth or death, respectively. Cell growth was monitored every 24 h over 5 d, and was repeated in 6 wells. All assays were carried out independently in triplicate.

The effects of chemotherapeutic agents on the growth of SK-Hep-1 and SK-Hep-1/CDDP cells were also evaluated with CCK-8. Cells (2×10^3/well) were seeded into 96-well plates in 100 μL of DMEM/H with 10% FBS incubated at 37℃ in a humidified atmosphere containing 50 mL/L CO_2. After 24 h the medium was aspirated, and exchanged with media containing a test chemotherapeutic agent at various concentrations. After incubation for 24 h at 37℃, the drug-containing growth medium was replaced with 110 μL medium containing CCK-8 reagent. After 2 h, the absorbance was read at 450 nm with a reference wavelength at 600 nm. Six wells were used for each drug concentration and the experiment was replicated 3 times. The IC_{50} was calculated by SPSS13.0 (SPSS Inc., Chicago, IL, USA). The lower the IC_{50} value, the higher the potency against cell proliferation.

Cell cycle analysis

Control and CDDP-resistant cells were harvested, washed twice with ice-cold PBS (pH 7.2) and fixed in ethanol: PBS (9:1) at -20℃ for at least 30 min. The fixed cells were then washed twice with ice-cold PBS and stained with 50 mg/mL PI in the presence of 25 mg/mL RNase A. Cell cycle phase distribution was analyzed in 3 different experiments using a COULTER® EPICS™ XL™ flow cytometer (Beckman Coulter Inc., Brea, CA, USA). Data from 50 000 events/sample were collected and analyzed using CellQuest software (BD Biosciences, San Jose, CA, USA).

Immunolabeling and quantification

For immunofluorescence, cells were grown on glass slides in 6-well culture plates. Two days later, MitoTracker Red in DMEM/H (200 nmol/L) was added to live cells for 30 min at 37℃, and washed twice with ice-cold PBS (0.01 mol/L, pH 7.2). The cells were fixed for 30 min in 4% ice-cold paraformaldehyde followed by permeabilization with 0.3 mg/mL Triton X-100 for 30 min at room temperature. Fixed, permeabilized cells were washed twice with 0.01 mol/L PBS and incubated with blocking buffer containing goat serum for 30 min at room temperature. Cells were washed twice with 0.01 mol/L PBS again and the expression of MDR1 was determined using the mouse monoclonal anti-P-gp antibody (1:100), Expression of MRP1 was determined using the mouse monoclonal anti-MRP1 antibody (1:100). Negative controls for immunofluorescence involved replacing the primary antibodies with an IgG isotype control. The primary antibody incubations were carried out in blocking buffer overnight at 4℃. After incubation with primary antibodies, cells were washed 3 times with 0.01 mol/L PBS, and incubated with secondary FITC-conjugated goat anti-mouse antibody (1:50) in the dark for 1.5 h at 37℃. Cell nuclei were counterstained with DAPI (4,6-diamidino-2-phenylindole; Sigma-Aldrich, St. Louis, MO, USA) solution (1 μg/mL in PBS) for 5 min at room temperature. After washing with 0.01 mol/L PBS, cells were mounted on glass slides using Antifade Mounting Medium (Beyotime Institute of Biotechnology, Jiangsu, China). Confocal laser scanning microscopic analysis of immunolabeling was performed on a Leica TCS SP2 confocal laser imaging system (Leica Microsystems, Wetzlar, Germany). To ascertain localization of the mitochondria, cells were stained with MitoTracker Red CMXRos dye. A merged double image of green MDR1 or MRP1 and MitoTracker Red was obtained. To allow quantitative comparisons of the relative fluorescence intensity of cells between groups, cells were chosen on a random basis and scanned at more than 3 points for analysis. Software Image-Pro Plus Version 6.0 (MediaCybernetics, Bethesda, MD, USA) was used to count the mean value of the fluorescence intensity. Average green fluorescence intensity per cell was determined as the quantity of P-gp or MRP1 protein expression.

Detection of P-gp and MRP1 protein by Western blotting

Total protein was collected from cultured SK-Hep-1 and SK-Hep-1/CDDP cells and the concentration was measured using a BCA Protein Assay Kit (Beyotime Institute of Biotechnology, Jiangsu, China). The protein was denatured in lithium dodecyl sulfate (LDS) sample buffer (106 mmol/L Tris-HCl, 141 mmol/L Tris base pH 8.5, 0.51 mmol/L EDTA, 10% glycerol, 2% LDS, 0.22 mmol/L SERVA blue G250, 0.175 mmol/L phenol red, 0.1 mmol/L 2-mercaptoethanol) for 5 min at 95℃, electrophoresed on a 7.5% SDS-PAGE and blotted onto 0.2 μm PVDF membranes (Roche, Indianapolis, IN, USA). Membranes were blocked with 5% (w/v) dry milk in TBS-T (Tris-buffered saline containing 0.05% Tween 20) for 1 h at room temperature and incubated overnight at 4℃ with antibodies against P-gp (1:500) or MRP1 (1:100). After incubation with the respective primary antibodies, the membranes were washed 3 times for 5 min in TBS containing 0.05% Tween-20, and then the membranes were exposed to species-specific horseradish peroxidase-labeled secondary antibodies (ZhongShan Goldenbridge Biotechnology, Beijing, China) at 37℃ for 1 h, and developed using the ECL plus Western blotting reagent with visualization on X-ray films. The expression of β-actin was detected as an internal control. The band intensity on X-ray films was quantified using Gel-Pro Analyzer software. The ratio of the band intensity for P-gp/β-actin and MRP1/β-actin was used as the relative expression level for P-gp and MRP1 protein, respectively.

Statistical analysis

All experiments were run in triplicate, and the results are given as mean ± SD. Statistical analyses were performed using either an analysis of variance (ANOVA) or Student *t* test. The difference was considered statistically significant when the *P* value was less than 0.05. All statistical analyses were carried out with SPSS 13.0 software.

RESULTS

Establishment of a cisplatin-resistant SK-Hep-1/CDDP cell line

We established CDDP-resistant SK-Hep-1 (SK-Hep-1/CDDP) cells by pulse exposure of SK-Hep-1 cells to high concentrations of CDDP for short periods over 24 h. This caused a marked change in cellular morphology with many elongated cell dendrites and deposits of intracytoplasmic vacuoles observed, and cells membrane became less clear, or cells died. These effects were clearly observed after 24 h treatment with CDDP at 5 μg/mL. The surviving cells recovered exponentially and then were further selected by a procedure consisting of 6 pulse drug treatments with 5 μg/mL CDDP. The SK-Hep-1-resistant subclone was established 6 mo after the treatment was initiated. Microscopic observation revealed that the SK-Hep-1/CDDP cells (Figure 1B) adopted a spindle shape, similar to that of the parent cells (Figure 1A). The sensitivity of SK-Hep-1 and SK-Hep-1/CDDP cells to various concentrations of CDDP was determined by CCK-8 assay. As shown in Table 1, IC_{50} values for CDDP on SK-Hep-1 and SK-Hep-1/CDDP cells were 5.13 ±

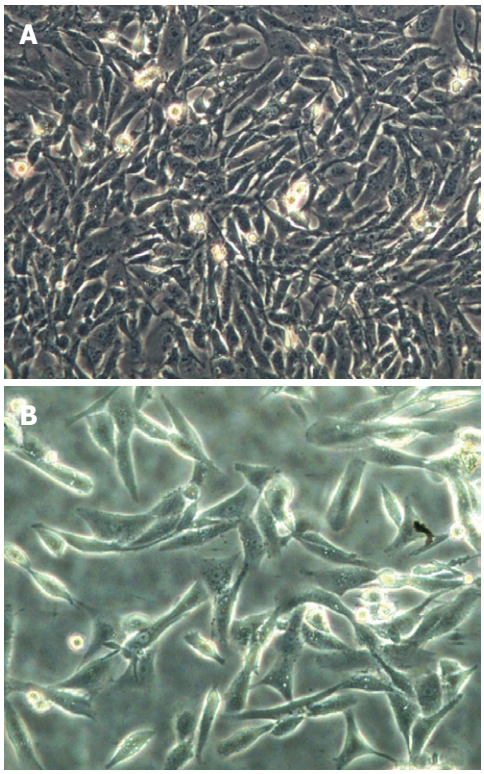

Figure 1 The cell shape of SK-Hep-1 (A) cell line and SK-Hep-1/CDDP (B) cell line (× 100). SK-Hep-1: A highly invasive human hepatoma cell line with a epithelial-like morphology; SK-Hep-1/CDDP: A cisplatin-resistant cell line from the parental cell line.

Table 1 IC_{50} and RI values of SK-Hep-1 and SK-Hep-1/CDDP cells

Drug (μg/mL)	IC_{50} (mean ± SD)		RI
	SK-Hep-1	SK-Hep-1/CDDP	
CDDP	5.13 ± 0.09	70.61 ± 1.06[b]	13.76
DOX	0.74 ± 0.04	4.13 ± 0.23[b]	5.58
VCR	0.76 ± 0.02	2.28 ± 1.06[b]	3.12
5-FU	12.49 ± 0.27	52.79 ± 3.85[b]	4.23

[b]Significant difference in comparison with the parental cells ($P < 0.01$). SK-Hep-1 and SK-Hep-1/CDDP cells were exposed to indicated concentrations of CDDP, DOX, VCR and 5-FU for 24 h and determined using the CCK-8 assay. The IC_{50} values were calculated. Values of 3 independent experiments are represented as mean ± SD. Resistance index (RI) = (IC_{50} SK-Hep-1/CDDP cells)/(IC_{50} SK-Hep-1 cells). CDDP: Cisplatin; IC_{50}: 50% inhibitory dose; DOX: Doxorubicin; VCR: Vincristine; 5-FU: 5-fluorouracil.

0.09 μg/mL and 70.61 ± 1.06 μg/mL, respectively. SK-Hep-1/CDDP cells were 13.76-fold more resistant to CDDP than the parent cells. We also compared the cross-resistance to other anticancer drugs (DOX, VCR, 5-FU) between the parent and CDDP-resistant cells, with our results indicating that the SK-Hep-1/CDDP cells also had cross-resistance to DOX, VCR and 5-FU.

Cell growth and cell cycle

The growth curves for SK-Hep-1 cells and the CDDP-resistant SK-Hep-1 subline are shown in Figure 2A, and the cell cycle distribution of each cell line is shown in Figure 2B and C, and Table 2. The resistant cells grew

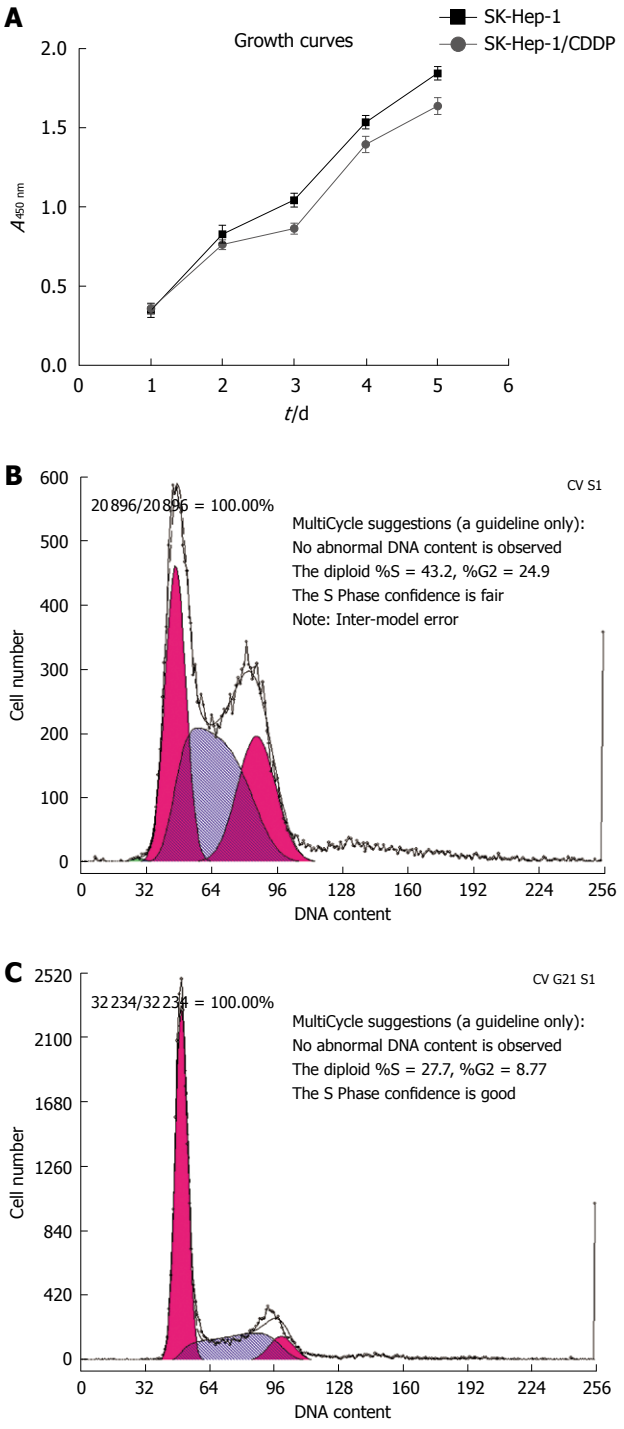

Figure 2 Growth curves of 2 cell lines, SK-Hep-1 and SK-Hep-1/CDDP (A), flow cytometric analysis of cell cycle distribution of SK-Hep-1/CDDP (B) and SK-Hep-1 (C).

more slowly than the the parent cells ($P < 0.05$). Cell cycle analysis revealed that the number of SK-Hep-1/CDDP cells in the G0/G1 phase decreased, accompanied by an increased proportion of cells in the S phase and G2/M phases ($P < 0.05$, Table 2).

Evaluation of MDR1 and MRP1 by laser scanning confocal microscope

We examined the expression of the ATP-binding cassette (ABC) transporters[6], MDR1 and MRP1, by immunofluo-

SK-Hep-1/CDDP (A) and SK-Hep-1 (E) cells were simultaneously stained for the anti-P-gp antibody-FITC (green), (B) and (F) were stained with mitochondria (red), (C) and (G) immunofluorescence images for the nuclei (blue), (D) and (H) the expression of the merged image. MDR1: Multidrug resistant protein 1; P-gp: Phospho-glycoprotein.

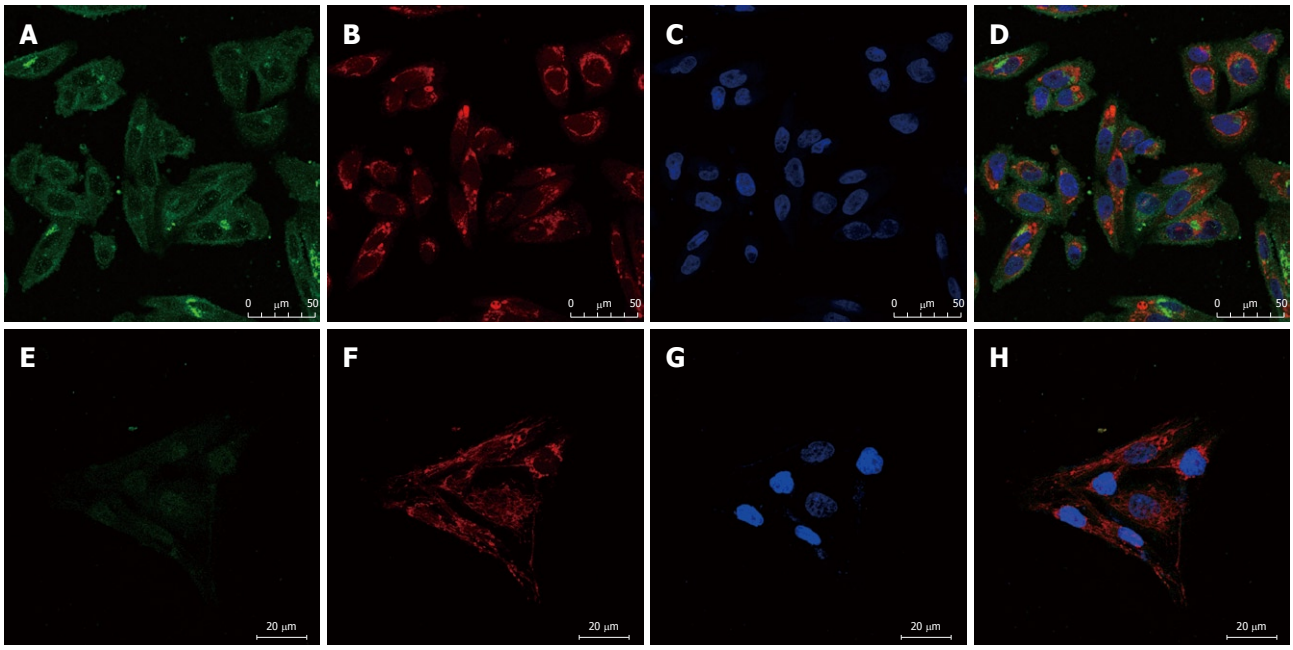

Figure 4 Overexpression of MRP1 in resistant SK-Hep-1/CDDP (A-D) and SK-Hep-1 (E-H) cell lines. Immunofluorescence images for MRP1 (A and E, green), mitochondria (B and F, red), and nuclei (C and G) on the same section were merged to illustrate areas of overlap (D and H). MRP1: Multidrug resistance-associated protein 1.

rescence. Confocal microscopic analysis confirmed that expression of both MDR1 and MRP1 was elevated in SK-Hep-1/CDDP and SK-Hep-1 cells (Figures 3 and 4), MDR1 or MRP1 appeared to localize around the nuclear membranes. To further assess the localization of MDR1 and MRP1, we performed a double stain with MitoTracker Red and DAPI. The green fluorescein fluorescence image was ubiquitous (MDR1 or MRP1). Figure 3 shows the relative level of MDR1/P-gp (green fluorescence) in SK-Hep-1/CDDP (Figure 3A-D) and parent SK-Hep-1 cell (Figure 3E-H) as viewed by confocal microscopy. Figure 4 shows the relative level of MRP1 (green fluorescence) in SK-Hep-1/CDDP (Figure 4A-D) and parent SK-Hep-1 cell (Figure 4E-H).

The results of the quantitative assessment are shown in Table 3. CDDP-resistant cells demonstrate pronounced high levels of green fluorescence and high mean gray density when compared with SK-Hep-1 cells ($P < 0.05$).

Table 2 Cell cycle distribution of SK-Hep-1 and SK-Hep-1/CDDP cells (%)

Cell	G0/G1	S	G2/M
SK-Hep-1	59.83 ± 3.28	27.91 ± 2.16	12.14 ± 3.36
SK-Hep-1/CDDP	37.50 ± 5.05[a]	42.20 ± 2.65[a]	20.67 ± 5.69[a]

[a]$P < 0.05$, resistant cells *vs* SK-Hep-1. SK-Hep-1/CDDP in G0/G1 phase decreased accompanied by an increased proportion of cells in the S phase and G2/M phase.

Table 3 Semi-quantification of P-gp and MRP1 immunofluorescence (mean ± SD)

Cell	P-gp (n = 3)	MRP1 (n = 3)
SK-Hep-1	20.57 ± 6.59	3.75 ± 0.02
SK-Hep-1/CDDP	64.79 ± 12.4[a]	35.78 ± 6.17[a]

[a]$P < 0.05$, resistant cells *vs* SK-Hep-1.

P-gp and MRP1 expression in cells by Western blotting

The expression of P-gp/MDR1 and MRP1 in SK-Hep-1/CDDP cells was evaluated by Western blotting analyses. These proteins were detected in the parental SK-Hep-1 and SK-Hep-1/CDDP cells. The levels of P-gp and, MRP1 were significantly higher in the SK-Hep-1/CDDP resistant cells than in the SK-Hep-1 cells ($P < 0.01$, Figure 5). We considered it important to confirm the maintenance of MDR1 and MRP1 expression and its functionality for our culture conditions. The gray intensity of P-gp/β-actin was 0.58 ± 0.02 for SK-Hep-1 and 1.32 ± 0.04 for SK-Hep-1/CDDP ($P < 0.01$, $n = 3$). The gray intensities of MRP1/β-actin were 0.24 ± 0.01 and 0.59 ± 0.03 for SK-Hep-1 and SK-Hep-1/CDDP cells, respectively ($P < 0.01$, $n = 3$).

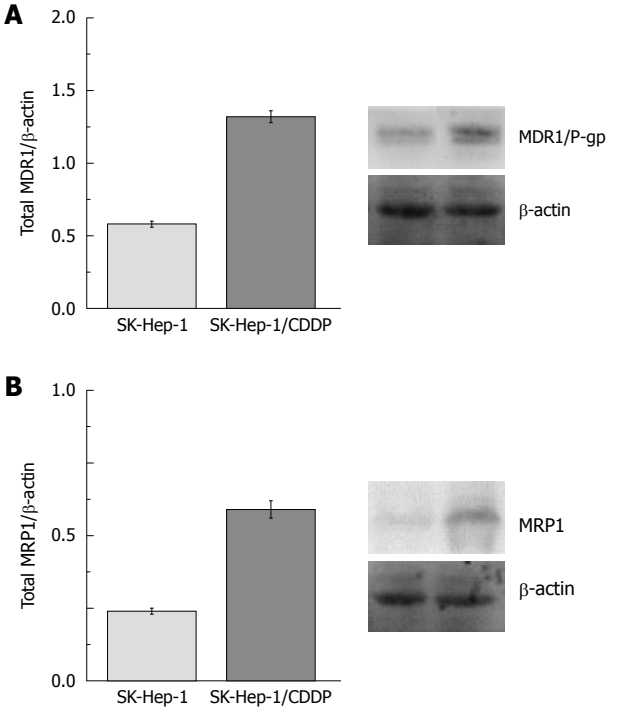

Figure 5 Representative Western blotting of total protein extracts from SK-Hep-1 and SK-Hep-1/CDDP cells. A: Left: The relative level of MDR1/β-actin in each cell line in the bar graph ($P < 0.05$, $n = 3$). Right: Western blotting analysis of MDR1/P-gp; B: Left: The relative level of MRP1/β-actin in each cell line in the bar graph ($P < 0.05$, $n = 3$). Right: Expression level of total MRP1 protein in SK-Hep-1 and SK-Hep-1/CDDP cells. The data are representative of those obtained in 3 other experiments.

DISCUSSION

Intrinsic and acquired resistance to multiple chemotherapeutic drugs is a major obstacle in the clinical treatment of cancer, and the mechanisms responsible for MDR remain unclear. Tumor-derived cell lines in which MDR is induced by the intermittent exposure to drugs[7,8] are frequently used models to study these mechanisms. In order to elucidate the molecular mechanisms of multiple chemotherapeutic drugs resistance in HCC, we established a CDDP-resistant hepatoma cell line as model for investigating chemotherapy resistance.

In this study, the CDDP-resistant subline SK-Hep-1/CDDP was induced by high-concentration, short-duration drug treatment[9]. SK-Hep-1/CDDP cells exhibited strong resistance to CDDP, 13.76 times greater than in SK-Hep-1 cells. The SK-Hep-1/CDDP cells showed significant changes in cell growth compared with SK-Hep-1, growing at a slower rate and exhibiting changes in the cell cycle following the development of drug resistance. The proportion of SK-Hep-1/CDDP cells in the G2/M and S phases increased significantly. Meanwhile SK-Hep-1/CDDP cells also demonstrated cross-resistance to multiple, structurally diverse chemotherapeutic agents, such as DOX, VCR and 5-FU. These resistant phenotypes were stable and the IC_{50} values and resistance index demonstrated no significant change over a 3-mo period in drug-free medium.

HCC resistance to chemotherapeutic treatment is possibly related to the overexpression of MDR proteins belonging to the ABC family. Recent studies showed that HCC expressed *MRP1*, *MDR1*, *MRP3* and breast cancer resistance protein (BCRP/ABCG2), and these might confer tumor cells with a MDR phenotype[10,11]. Some reports stated that MRPs were more likely to be candidates to mediate chemo-resistance in HCC than MDR1[12,13]. *MDR1*, *MRP1* and *MRP2* genes are well known as ABC transporters associated with CDDP-resistance, as these proteins cause the efflux of many anticancer agents that have different mechanisms. Our study revealed that both a CDDP-resistant subline and its parental cells expressed MDR1, but the subline cells overexpressed MDR1 and MRP1.

In summary, although chemotherapy-resistant tumor cell lines have some disadvantages, they do provide model systems where all biological parameters can be controlled and assessed. We established a CDDP-resistant human hepatoma cell line, which provided the basis for further study of resistant mechanisms and reversal of clinical HCC drug resistance.

COMMENTS

Background

Drug resistance, in particular multidrug-resistance (MDR), is still the major cause of anticancer chemotherapy failure. The most important factor of medicating a MDR phenotype is the increased activity of the membrane-embedded drug extrusion pump, MDR1/P-glycoprotein (MDR1/P-gp or ABCB1). The mechanism of the reverse MDR phenotype is thought to involve direct binding to P-gp and displacement of the anticancer drugs, which enhances intracellular toxic efficacy of these agents. Analysis of novel chemotherapy-resistant cell lines may duplicate as far as possible the treatment conditions used *in vivo*.

Research frontiers

Hepatocellular carcinoma (HCC) responds poorly to chemotherapy owing to MDR. Recent studies have shown the tumors derived from the colon, kidney, or adrenal cortex, and HCC exhibited overexpression of MDR1/P-gp. This overexpression results in a primary MDR phenotype of these cancers. Tumor-derived cell lines are one of the most important tools for investigation of the biological mechanisms directly leading to drug resistance in patients. Today, the experimental search for drug resistant mechanisms that are clinically relevant targets whose circumvention can improve cancer therapy is still ongoing.

Innovations and breakthroughs

The model SK-Hep-1/CDDP cell line can be used as an *in vivo* model to investigate the molecular mechanisms involved in MDR-related genes of hepatocarcinoma and to explore the targeted approaches for overcoming MDR in tumor cells.

Applications

The SK-Hep-1/CDDP cells can be employed as a model system as its biological parameters can be controlled and assessed, and novel biomarkers of chemotherapy resistance can be identified. The methods described in this study and the results presented might provide the basis for advanced studies in this field.

Peer review

The manuscript is interesting and could be useful. The establishment of a human hepatoma multidrug-resistance cell line *in vitro* presents interesting results. The data show that a cisplatin-resistant hepatoma cell line increased MDR1 comparing with control cells, and expressed MRP1. They concluded that this fact conferred cross-resistance to the cell line.

Abstract

Aneurysms and pseudoaneurysms of the superior mesenteric artery are potentially lethal and should be treated as urgently as possible. In a 52-year-old man with occasional epigastric pain, we accidentally discovered a superior mesenteric artery aneurysm that was ruptured with spontaneous tamponade in the uncinate process and in the head of the pancreas. The ruptured aneurysm had a heterogeneous appearance due to its thrombotic and hemorrhagic content, and it simulated a voluminous mass in the head and uncinate process of the pancreas, associated with mild dilatation of the main pancreatic duct. Recent advances in multidetector computed tomography and magnetic resonance imaging have enabled radiologists to develop a correct diagnosis of mesenteric aneurysms and pseudoaneurysms of the visceral branches of the abdominal aorta, and to differentiate this diagnosis from that of pancreatic or peripancreatic masses; angiography is currently used to confirm a diagnosis and to develop therapeutic treatments.

INTRODUCTION

Aneurysms of the visceral branches of the abdominal aorta are rare and potentially life-threatening, with a documented prevalence of 0.1%-2%[1]. The superior mesenteric artery is the third most common site of splanchnic aneurysm[2]. Recent advances in computed tomography (CT) vascular imaging and magnetic resonance angiography have provided a highly accurate representation of abdominal splanchnic vessels[3]. Multi-detector computed tomography (MDCT) with 3D post-processing allows for an accurate representation of vascular course and caliber. Thanks to its high-contrast resolution, magnetic resonance imaging (MRI) is used to determine the composition of aneurysmatic masses.

The aim of this case report is to describe the imaging features of a ruptured superior mesenteric artery aneurysm, which created a giant hematoma and mimicked a pancreatic mass, with mild dilatation of main pancreatic duct.

CASE REPORT

A 52-year-old man with intermittent epigastric pain was admitted to our hospital. He had undergone cholecystectomy and left colonic resection for cancer of the large intestine 4 and 2 years earlier, respectively. Preoperative liver ultrasonography and chest X-rays performed during previous hospitalization were normal.

During his last hospital admission, the patient underwent laboratory tests that revealed a mild increase in serum pancreatic amylase and lipase activity (129 and 116 UI/L, respectively). Coagulation tests were normal, and clinical examination did not reveal significant results. The patient was scheduled for abdominal CT. MDCT showed an 8.2 cm × 6.6 cm mass in the area of the uncinate process of the pancreas (Figure 1A). A post-contrast infusion MDCT scan showed enlargement of the proximal portion of the superior mesenteric artery, which had a transverse diameter of 2.2 cm. Multiplanar reconstructions of MDCT images indicated communication of the mass with the enlarged superior mesenteric artery (Figure 1B). The artery was englobed into the mass, which resulted in its complete obstruction. Liver, spleen and kidneys were normal, as was the small bowel, as shown by CT. CT did not show any relapse or residual sign in the area where surgical anastomosis of the colon had been performed.

Enhanced and unenhanced MRI was performed to investigate the mass composition. T1-weighted MR images showed heterogeneous high signal content (Figure 1C); a low peripheral "rim sign" on T1 and T2 images was revealed. Post-gadolinium images confirmed the enlarged superior mesenteric artery and its communication with the mass; there was no significant contrast enhancement in the mass itself. The initial diagnostic hypothesis was of a giant mass of the pancreas, which involved the superior mesenteric artery. The radiologist who performed the examinations described "an expansive lesion in the pancreatic area involving the proximal tract of the superior mesenteric artery", whereas the mass was caused by development and fissuration of the aneurysm into the uncinate process of the pancreas.

Angiography confirmed dilatation of the superior mesenteric artery, without any sign of bleeding. The patient underwent surgical intervention with resection of the thrombotic clot-filled aneurysm (Figure 2), which ruptured with spontaneous tamponade in the pancreatic region and formed a giant hematoma; bowel vitality was good during the provocative occlusive test, and subsequent ligation of the superior mesenteric artery was performed. Distal pancreatectomy was also required for the retropancreatic extension of the hematoma. MDCT performed 6 mo later did not show any complications.

DISCUSSION

Early diagnosis and treatment of aneurysms and pseudoaneurysms of the superior mesenteric artery are essential to prevent them from rupturing and threatening patients' lives[4]. Etiology includes arteriosclerosis, fibromuscular dysplasia, connective tissue disease, infection, and arterial dissection[1,5]. Mycotic aneurysms affect the superior mesenteric artery in 33%-66% of cases[6]. Superior mesenteric artery pseudoaneurysms are often associated with chronic pancreatitis, or they can be a consequence of external or iatrogenic trauma[5,7].

We describe a case of superior mesenteric artery aneurysm which ruptured with spontaneous tamponade in the uncinate process and head of the pancreas, which mimicked a pancreatic mass on MDCT and MRI. The etiology of the superior mesenteric aneurysm in our patient has still not been established; a previous history of pancreatitis, vascular hypertension, connective disease or traumatic abdominal injury was not revealed.

It is known that, on unenhanced MDCT, a superior mesenteric aneurysm can simulate a pancreatic mass[8]; thrombotic or hemorrhagic material in the aneurysm sac provides heterogeneous signal intensity. In our case, the sac filled with blood clots showed a heterogeneous elevated signal on T1 images, which suggested the possibility of a mass with hemorrhagic content or a hematoma.

Without contrast enhancement during the arterial phase, it is very difficult to establish the vascular nature of aneurysms, which is why the radiologist made an incorrect diagnosis[9]. The radiologist who first described MDCT and MRI signs did not explore the vascular structures with multiplanar reconstructions and hypothesized aneurysm not as a primary diagnosis, but as a consequence of a giant mass in the pancreatic tissue. Initially, he did not consider the possibility of a fissurated aneurysm. Pre-angiographic evaluation of multiplanar reconstruction, performed with other colleagues, finally oriented him towards diagnosing a giant aneurysm ruptured into the uncinate process. Axial images and CT reconstructions showed the continuity of the mass and the superior mesenteric artery, and enabled radiologists to diagnose a vascular aneurysm.

There is a large group of peripancreatic structures that can simulate pancreatic cystic lesions, such as aneurysms of the superior mesenteric artery, superior mesenteric vein, hepatic artery and portal vein[10]. Large aneurysms compress the duodenum and biliary duct, thus causing obstructive jaundice[7]. In our case, magnetic resonance cholangiopancreatography (MRCP) showed the dislocation of the pancreatic tract of the main biliary duct, which was caused by the large ruptured aneurysmatic sac (Figure 1D). The choledochus had a caliber of approximately 1 cm, but this was not considered a significant feature since the patient had been cholecystectomized; a diameter of up to 1 cm is frequent in such patients. Dilatation of the main pancreatic duct has not been reported very frequently in the literature. MRCP showed moderate dilatation of the main pancreatic duct and mild ectasia of the side branches

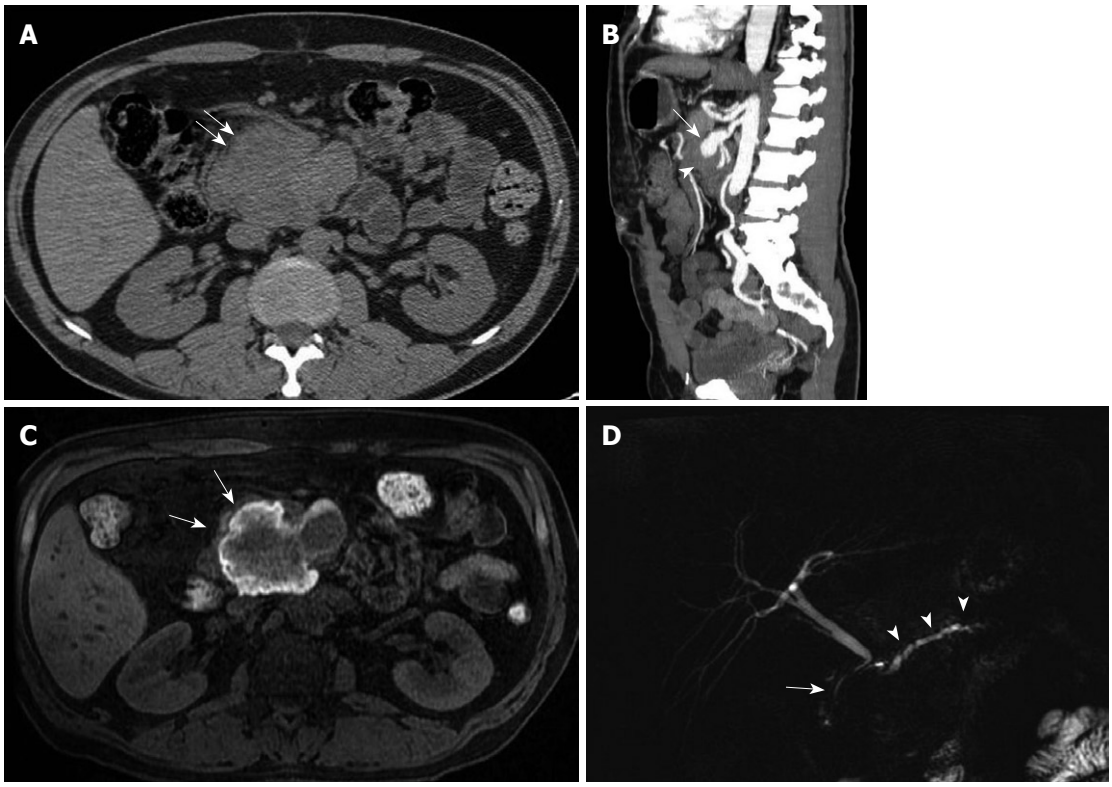

Figure 1 Images of the patient. A: Axial unenhanced multi-detector computed tomography (MDCT) shows a soft-tissue mass (arrows) in the area of the uncinate process of the pancreas. There is no sign of calcification or fluid level; B: Sagittal multiplanar reconstruction clearly shows the superior mesenteric artery (arrow) involved in a giant soft-tissue attenuated mass - the hematoma (arrowhead) - at the pancreatic level. After contrast administration, there was no significant enhancement in the hematoma, due to its thrombotic content; C: Magnetic resonance, axial unenhanced gradient echo T1-weighted imaging with fat suppression. The T1 hyperintense perilesional signal (arrows) was caused by the blood content; D: Magnetic resonance cholangiopancreatography (MRCP) shows dilatation of the main pancreatic duct (arrowheads); the choledochus (arrow) was compressed and dislocated, with mild narrowing of the lumen in the distal tract.

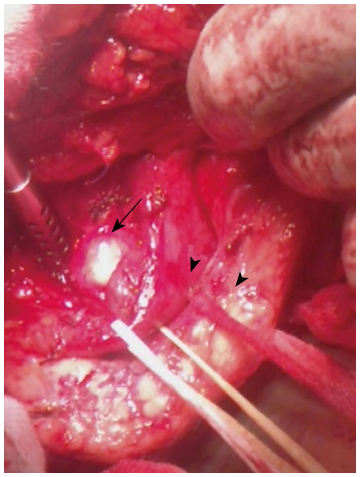

Figure 2 Surgical intervention. Intervention confirmed an aneurysm of the superior mesenteric artery, which ruptured with hematoma in the head of the pancreas. The figure shows the aneurysm (arrow) and superior mesenteric artery and vein (arrowheads).

of the main pancreatic duct (Figure 1D). The dilatation of the pancreatic duct was caused by the hemorrhagic sac, with evident dislocation of pancreatic parenchyma. Mild compression of the main pancreatic duct by the aneurysm sac can also explain minimally increased values of amylase and lipase activity discovered through laboratory tests, which initially physicians interpreted as symptoms of pancreatic disease.

Contrast administration is necessary to demonstrate a patent lumen, and suggests the correct diagnosis. Recent advances in CT technology have allowed for a more accurate multiplanar and 3D reconstruction, which shows the communication between the aneurysm sac and the blood vessels. High table-speed and rapid image acquisition during contrast injection clearly show the arterial anatomy. On CT, large aneurysms and pseudoaneurysms can simulate pancreatic pseudocysts with fluid content[11]. Blood clots and thrombotic deposits in aneurysms and pseudoaneurysms have a density similar to that of soft tissues or of high-density fluid collections. In some cases, pseudocysts have a hemorrhagic content, and on unenhanced CT scans, their density is the same as that of aneurysms.

MRI is very useful in terms of diagnosis because it provides radiologists with accurate information on mass composition: on T1-weighted images the presence of thrombotic and hemorrhagic material is easily demonstrated by the high-signal content of the mass. However, these features are not specific. Since hemorrhagic content on unenhanced T1 images can also be found in mucinous cystic neoplasms, a differential diagnosis is called for. Mucinous cystic lesions have variable signal intensity and sometimes proteinaceous material provides hyperintensity on T1-weighted images. Post-gadolinium images did not reveal internal septa and were very helpful in differentiating the diagnosis from that of cystic mucinous lesions.

In conclusion, aneurysms and pseudoaneurysms of the superior mesenteric artery at the pancreas level can be very insidious for radiologists because they can mim-

ick pancreatic masses. Significant advancements in 3D and multiplanar imaging software have made it possible to obtain high-resolution images of the abdominal aorta and its branches: radiologists need to keep in mind the diagnostic value of multiplanar reconstructions.

Abstract

Celiac disease (CD) is manifested by a variety of clinical signs and symptoms that may begin either in childhood or adult life. Neurological symptoms without signs of malabsorption have been observed for a long time in CD. In this report, an 8-year-old girl with CD presented with rarely seen dilated cardiomyopathy and stroke. The girl was admitted with left side weakness. Her medical history indicated abdominal distention, chronic diarrhea, failure to thrive, and geophagia. On physical examination, short stature, pale skin and a grade 2 of 6 systolic murmur were detected. Muscle strength was 0/5 on the left side, and 5/5 on the right side. Coagulation examinations were normal. Tests for collagen tissue diseases were negative. Factor V Leiden and prothrombin GA20210 mutations were negative. Tandem mass spectrophotometry and blood carnitine profiles were normal. Brain magnetic resonance imaging and cerebral angiography showed an infarction area at the basal ganglia level. Examinations of serologic markers and intestinal biopsy revealed CD. We emphasize that in differential diagnosis of ischemic stroke, CD should be kept in mind.

INTRODUCTION

Celiac disease (CD) is a disease of the small intestine caused by an immune response to ingested gluten. This response results in characteristic damage to the villi, leading to malabsorption[1]. CD is manifested by a variety of clinical signs and symptoms that may begin in either childhood or adult life. Neurological symptoms without malabsorption signs have been observed for a long time in CD. Epilepsy, bilateral occipital calcification, cerebellar ataxia, degenerative central nervous system disease, peripheric neuropathy, myopathy and, rarely, stroke were defined as neurologic manifestations[2]. Tissue transglu-

taminase enzyme is an auto-antigen, which is related to gluten-associated immune events[3]. In this case report, an 8-year-old girl with CD presented with rarely seen stroke.

CASE REPORT

An 8-year-old girl was admitted to our emergency department with weakness of the left lower and upper extremities. It was learnt that the patient had geophagia, abdominal distention and chronic diarrhea for 2 years. On physical examination, her body weight and height were 16 kg (-2 SD) and 110 cm (-2.6 SD), respectively. Blood pressure was 110/70 mmHg. She had pale skin and mucosa, and a grade 2 of 6 systolic murmur at the inferior left side of the sternum. Muscle strength was determined as 0/5 on the left upper and lower extremities and 5/5 on the right side. The laboratory analysis, hemogram, serum electrolytes, glucose, cholesterol, triglyceride levels, liver and renal function tests were within normal limits. Thyroid hormone values were also found to be within the normal range [free T_4: 1.4 ng/dL (normal range: 0.8-2.2 ng/dL), total T_4: 7.4 mg/mL (normal range: 5.5-12.8 mg/L), thyroid stimulating hormone: 1.2 mU/mL (normal range: 0.6-5.5 mU/mL), total T_3: 170 ng/dL (normal range: 119-218 ng/dL), free T_3: 3.2 pg/mL (normal range: 2.0-4.0 pg/mL)]. C-reactive protein was negative and erythrocyte sedimentation rate was 19 mm/h. Vitamin B12 and folate levels were normal. Prothrombin time and activated partial thromboplastin time were 13.6 s (normal range: 11-14 s) and 29 s (normal range: 31-40 s), respectively. Fibrinogen, protein C, protein S, factors V, Ⅶ, Ⅷ, Ⅺ, Ⅻ and antithrombin Ⅲ levels were within normal limits. Serologic tests for human immunodeficiency virus, lupus anticoagulants, antinuclear antibody, anti-double-stranded DNA, anticardiolipin antibody immunoglobulin (Ig) G and M serologies were negative. Factor V Leiden and prothrombin GA20210 mutations were not detected. The tandem mass metabolic disease screening panel and detailed blood carnitine profile were normal.

On brain magnetic resonance imaging, an infarction measuring 31 mm × 14 mm at the right basal ganglia level was seen (Figure 1). On cerebral angiography examination, a 1 cm segment occlusion was detected at the M2 branch of the right middle cerebral artery (Figure 2). Although dilated cardiomyopathy was identified on transesophagial and transthoracic echocardiographic examination, thrombus or vegetation was not seen. Serologic markers of CD were examined because of chronic diarrhea, abdominal distention, short stature, cerebral infarction and dilated cardiomyopathy, and anti-tissue transglutaminase IgA and IgG, and anti-endomysium IgA were found at a highly positive rate. Additionally, the examination of intestinal biopsy revealed CD. Duodenal biopsy showed villous atrophy with hyperplasia of the crypts and an increased intraepithelial lymphocyte count (above 40%).

A gluten-free diet and nadroparin calcium treatment were initiated and physiotherapy was performed. At the 18th day of hospitalization, the patient, whose symptoms had regressed, was discharged with a gluten-free diet, nadroparin calcium, co-enzyme Q and salicylate treatment. Symptoms resolved by the following 7th wk. Muscle strength at the left upper and lower extremities was 5/5, and other neurologic examinations were normal.

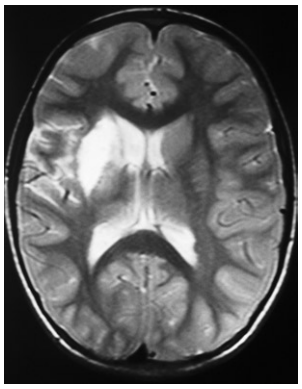

Figure 1 Brain magnetic resonance imaging shows an infarction area measuring 31 mm × 14 mm at the right basal ganglia level.

Figure 2 Cerebral angiography examination shows a 1 cm segment occlusion at the M2 branch of the right middle cerebral artery.

DISCUSSION

Classical findings of CD usually begin at 1-3 years of life. Toddlers and young children classically present with chronic diarrhea, vomiting, poor appetite, abdominal distension, abdominal pain, irritability, and failure to thrive some time after the introduction of gluten in the diet[1]. In adults, a variety of neuropsychiatric conditions, such as depression and anxiety, have been reported in individuals with CD[1]. In our case, abdominal distention, chronic diarrhea, geophagia, and short stature were observed. In addition, infarction and dilated cardiomyopathy were present.

The diagnosis of CD is established by positive results of serological testing and evidence of characteristic histopathology on intestinal biopsy[4]. If results of serologic testing are negative but clinical suspicion is high, intestinal biopsy should be performed. Characteristic histologic features of CD include varying degrees of villous atrophy, with hyperplasia of the crypts and an increased intraepithelial lymphocyte count[5]. Consistent with the literature, our case was positive for anti-tissue transglutaminase IgA and IgG, and anti-endomysium IgA, and duodenal biopsy examination showed villous atrophy

with hyperplasia of the crypts and increased intraepithelial lymphocyte count (above 40%).

Development of autoimmune diseases is one of the complications of the CD. Tissue transglutaminase enzyme is an auto-antigen that is related to gluten-associated immune events. Evidence of a central nervous system vasculitis was reported by Ozge *et al*[6] in a patient with recurrent stroke and CD. Pratesi *et al*[7] found that sera from patients with active CD contain IgA antibodies that reacted with human brain vessel structures, giving intense fluorescence. These antibodies were not present in sera from celiac patients on a gluten-free diet or non-celiac controls. They emphasized that this finding might be involved in the abnormal nervous system manifestations frequently described in association with CD. Tissue transglutaminase is the major auto-antigen in CD and is thought to maintain vascular endothelial integrity. Anti-endomysial IgA antibodies, demonstrated to be the same autoantibody as anti-transglutaminase, react with the cerebral vasculature, suggesting an autoimmune mechanism for CD-associated vasculopathy. Because CD is a potentially treatable cause of cerebral vasculopathy, serology (specifically for anti-tissue transglutaminase antibodies) should be included in the evaluation of cryptogenic stroke in childhood, even in the absence of typical gut symptoms.

Dilated cardiomyopathy is the most commonly seen type of cardiomyopathy. Regarding its etiology, genetic causes, endocrine disorders, collagen vascular diseases, drugs, congenital metabolism diseases, muscular dystrophies, structural heart diseases, acute and chronic myocarditis and toxins can be present. However, 50% of cases remain idiopathic. An increased incidence of CD in patients with idiopathic dilated cardiomyopathy as well as in patients with secondary cardiomyopathy has been reported recently[8]. In our case, dilated cardiomyopathy was diagnosed with echocardiography. However, dilated cardiomyopathy was not thought to be the primary factor causing the stroke, because there was no thrombus or vegetation at echocardiography, and regression of symptoms occurred with a gluten-free diet. In addition, in patients with a cryptogenic stroke, the presence of a patent foramen ovale should be evaluated. Transthoracic 2-dimensional echocardiography can generally show the atrial septum and the flap of the foramen ovale in infants and small children. Color Doppler flow across the atrial septum proves the presence of the foramen ovale. In older children and adults, transthoracic echocardiography does not visualize the atrial septum as well. Transesophageal echocardiography is preferred in patients where the atrial septum is inadequately visualized by transthoracic echocardiography. Older children and adults fall into this category. In addition to a patent foramen ovale, redundancy of the septum primum can also be seen. When the redundancy of the septum moves more than 1 cm, it is called an atrial septal aneurysm. In the presence of a patent foramen ovale in patients who have had a prior stroke, an atrial septal aneurysm confers an increased risk for a subsequent neurologic event[9,10]. In our patient, a patent foremen ovale was not found in both transthoracic and transesophageal echocardiographic examination. Therefore, a patent foremen ovale was not thought to be a cause of the stroke in our patient.

In conclusion, the cause of ischemic stroke in our case is thought to be multifactorial. We suggest that CD was a primary factor in its etiology, secondary to a contribution from dilated cardiomyopathy. In conclusion, we emphasize that in the differential diagnosis of ischemic stroke, CD should be kept in mind.

Abstract

Duodenal perforation during endoscopic retrograde cholangiopancreatography (ERCP) is a rare complication, but it has a relatively high mortality risk. Early diagnosis and prompt management are key factors for the successful treatment of ERCP-related perforation. The management of perforation can initially be conservative in cases resulting from sphincterotomy or guide wire trauma. However, the current standard treatment for duodenal free wall perforation is surgical repair. Recently, several case reports of endoscopic closure techniques using endoclips, endoloops, or fully covered metal stents have been described. We describe four cases of iatrogenic duodenal bulb or lateral wall perforation caused by the scope tip that occurred during ERCP in tertiary referral centers. All the cases were simply managed by endoclips under transparent cap-assisted endoscopy. Based on the available evidence and our experience, endoscopic closure was a safe and feasible method even for duodenoscope-induced perforations. Our results suggest that endoscopists may be more willing to use this treatment.

Primary endoscopic approximation suture under cap-assisted endoscopy of an ERCP-induced duodenal perforation. *World J Gastroenterol* 2010; 16(18): 2305-2310 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i18/2305.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i18.2305

INTRODUCTION

Although MR cholangiopancreatography has almost completely replaced endoscopic retrograde cholangiopancreatography (ERCP) in the diagnosis of pancreato-biliary diseases, the risk of ERCP complications has increased as therapeutic endoscopists have taken on increasingly more complex cases, particularly at tertiary referral centers[1]. The frequency of duodenal perforation is 0.5%-2% of patients[2]. However, because of a relatively high mortality rate of 16%-18%, all duodenal perforations should be treated immediately after diagnosis[2-5].

Traditionally, the standard treatment for traumatic or iatrogenic duodenal perforation is surgical closure. Recently, endoscopic trials of perforation management have increased and successful primary repair of duodenal perforation using the endoscope itself has been reported. However, there is no clear consensus for primary repair due to the limited number of cases seen[6-8].

We report four cases in which ERCP done at tertiary referral centers induced a large duodenal perforation, which was then successfully managed with endoscopic approximation suture using multiple endoclips under transparent cap-assisted endoscopy.

CASE REPORT

Case 1

An 80-year-old woman with Klatskin tumor underwent ERCP. Three days later after endoscopic biliary drainage and biopsy, ERCP was attempted for the placement of the metallic stent. During the procedure, the duodenoscope slipped into the duodenum and caused an approximately 13 mm-sized perforation in the duodenal bulb. After early recognition of perforation, an immediate attempt to seal the perforation with 8 endoclips (Endoclip HX-600-090L; Olympus Optical Co., Ltd., Tokyo, Japan) was made successfully under transparent cap-assisted endoscopy (Figure 1A and E). Following the endotherapy, placement of percutaneous transhepatic biliary drainage (PTBD), peripheral parenteral nutrition, intravenous high-dose proton pump inhibitor (PPI), and broad-spectrum antibiotics (3rd generation cephalosporin + metronidazole) was initiated. A nasoduodenal tube was not placed. An abdominal X-ray showed a pneumoperitoneum in the subphrenic area (Figure 2A). However, she remained symptom-free without additional complications. Six days later, a contrast passage *via* endoscope showed no evidence of leakiness and the pneumoperitoneum was completely resolved (Figure 2B). She resumed a scheduled diet 6 d after the clipping and was discharged on day 12 (Tables 1 and 2).

Case 2

A 72-year-old woman with a history of left hepatic lobectomy and cholecystectomy 11 years prior to the procedure underwent ERCP for the segmental stricture of right intrahepatic duct and stones after PTBD. During the insertion of the duodenoscope into the stomach, severe rigidity was felt and the duodenoscope suddenly slipped into the duodenum. This caused an approximately 13 mm-sized perforation in the lateral wall of the second portion of the duodenum. Subsequently, an attempt to seal the perforation was successfully made with 5 endoclips under transparent cap-assisted endoscopy (Figure 1B and F). Peripheral parenteral nutrition, intravenous high-dose PPI, and broad-spectrum antibiotics were initiated. An abdominal computed tomography (CT) showed a pneumoretroperitoneum (Figure 3A). She remained symptom-free 2 d later, and did not develop any complications. A repeat abdominal CT performed 6 d later showed markedly decreased pneumoretroperitoneum and fluid collection, and there was no contrast leak on upper gastrointestinal investigations (UGIs) (Figure 3B). She resumed a normal scheduled diet 7 d after clipping and was discharged on day 10.

Case 3

A 69-year-old woman was referred due to pancreatic cancer. An abdominal CT scan revealed about a 5 cm-sized pancreatic head cancer with multiple hepatic metastases. ERCP was considered for jaundice and evaluation of the biliary system. At first, a trainee who had less than 6 mo experience inserted the duodenoscope. He tried to shorten the scope loop in the duodenum several times, but failed to shorten the scope loop due to duodenal rigidity resulting from the duodenal invasion of pancreatic cancer. The trainee then notified his supervisor, who was observing the procedure. He found about a 10 mm-sized duodenal perforation, which might have been caused by excessive shortening of the scope in the restricted lumen. Successful closure was immediately performed using 4 endoclips under transparent cap-assisted endoscopy (Figure 1C and G). The next day, the patient complained of abdominal pain, but there was no interval change except mild leukocytosis. Fasting and hydration were ordered and abdominal CT scans were taken twice, 24 h apart, but the pneumoperitoneum was not found to be progressive (Figure 4A). On the 8th day after duodenal perforation, UGIs showed no contrast leakage (Figure 4B), and she was put on a diet. After discharge from the hospital 10 d later, the patient received gemcitabine chemotherapy.

Case 4

A 63-year-old man with a history of cholecystectomy 10 years before the procedure underwent ERCP for choledocholithiasis. During insertion of the duodenoscope, an approximately 12 mm-sized perforation occurred in second portion of the duodenum secondary to trauma from difficult passage of the duodenoscope due to bulb deformity caused by recurrent duodenal ulcers. A successful attempt to seal the perforation with 5 endoclips was made under long transparent cap-assisted endoscopy (Figure 1D and H), followed by PTBD. Conservative managements were initiated as mentioned above. Simple X-ray and abdominal CT showed a pneumomediastinum, pneumoperitoneum, and subcutaneous emphysema. The patient remained symptom-free 3 d later and did not develop any complications. An abdominal CT repeated 4 d later showed markedly decreased pneumoretroperitoneum (Figure 5) and a scheduled diet was started. The remaining CBD stones were removed by ERCP 25 d later.

DISCUSSION

Duodenal perforation is an infrequent complication of ERCP. It extends beyond the intramural portion of the bile duct and is usually associated with sphincterotomy in about 1% of patients[9]. Retroperitoneal duodenal perforations represent the majority of cases and usually are

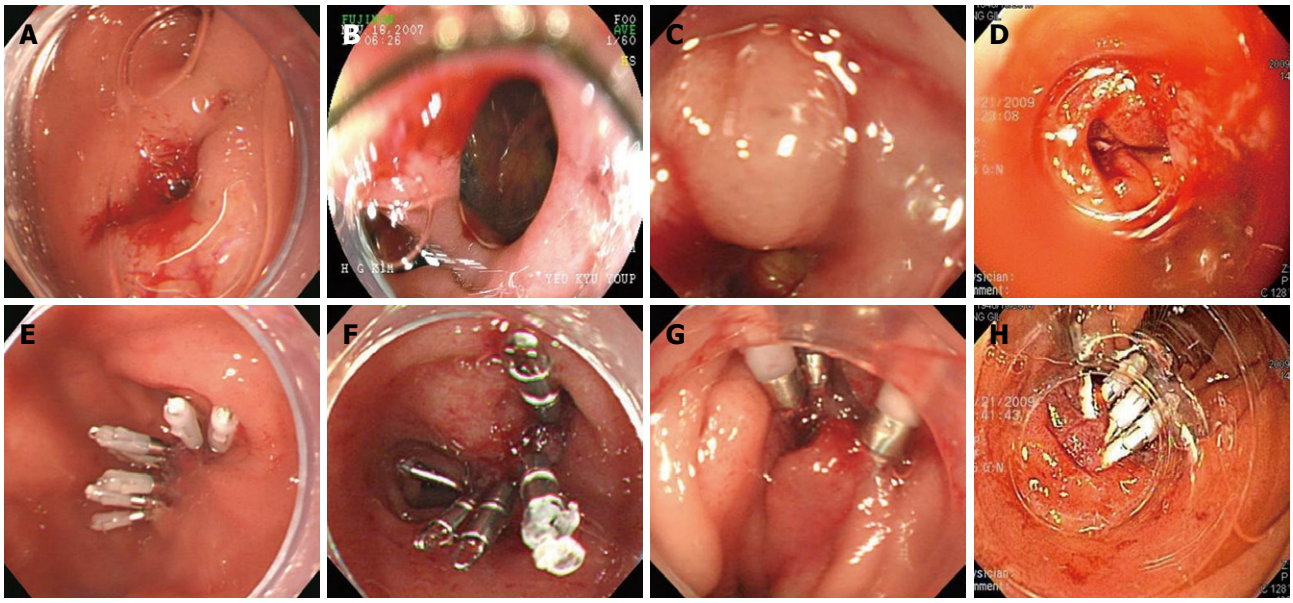

Figure 1 Endoscopic images of four cases demonstrating a large perforation on bulb and lateral wall of the second portion of duodenum, and successful primary endoscopic closure using multiple endoclips.

Table 1 Patient characteristics

Case No.	Age (yr)/sex	ERCP indication	Perforation site	Perforation size (mm)	Diagnosis	Experience of ERCPs (yr)
Case 1	80/F	Klatskin tumor	Bulb	> 10	During ERCP	< 2
Case 2	72/F	IHD stricture	2nd portion, lateral wall	> 10	During ERCP	< 2

PPI: Proton pump inhibitor; PTBD: Percutaneous transhepatic biliary drainage; PTCS: Percutaneous transhepatic cholangioscopy.

due to papillotomy, whereas intraperitoneal perforations are much less common and caused by the endoscope itself[10]. Direct duodenoscope-induced perforation is much less common, accounting for 0.1% of patients who undergo ERCP, but tends to be large and further away from the ampulla[4,5,11,12]. Known risk factors of an ERCP-related perforation might include old age, suspected sphincter of Oddi dysfunction, dilated bile duct, papillary stenosis, Billroth-Ⅱ reconstruction, pre-cut sphincterotomy, and long procedure duration[5,13-15].

Immediate surgery after diagnosis is the current standard treatment for duodenal perforations caused by an endoscope. Stapfer *et al*[4] and Howard *et al*[3] have proposed a classification scheme for duodenal injury by dividing it into four and three types, respectively, according to anatomical location, mechanism of injury, and severity. Type I (lateral or medial wall duodenal perforation; Stapfer *et al*) or Group Ⅲ (duodenal perforation remote from the papilla; Howard *et al*) injuries are usually large and require immediate surgery for repair. In a study by Stapfer *et al*, surgery was recommended for patients with the following criteria: large contrast extravasation on ERCP/UGIs, contrast-enhanced CT scans showing intra- or retroperitoneal fluid collection, massive subcutaneous emphysema or suspected perforation in association with retained material (i.e. stones, ERCP wire/basket)[4]. In cases of perivaterian injuries, they suggested conservative management with serial radiographic examination. Howard *et al*[3] also suggested the use of endoscopic drainage to divert the bile, pancreatic, and/or duodenal

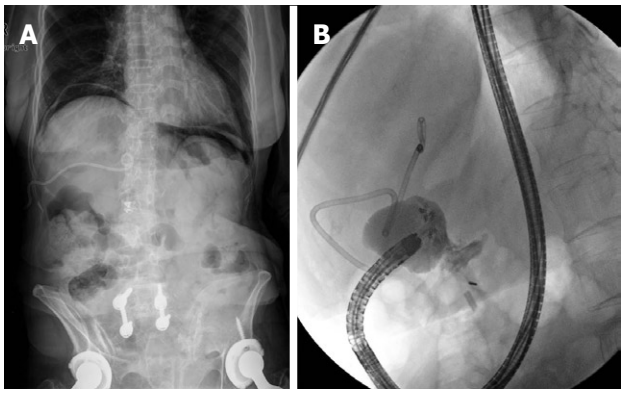

Figure 2 A simple abdomen X-ray shows both subphrenic pneumoperitoneum (A) and 6 d later, the follow-up upper gastrointestinal investigation (UGI) reveals no contrast leaks (B).

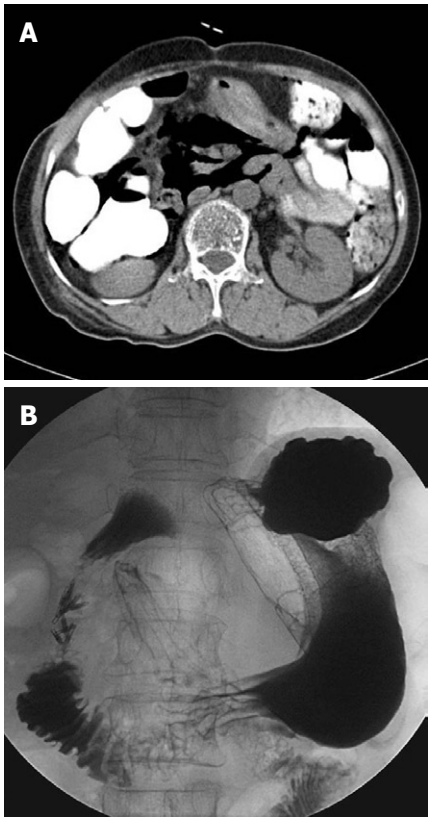

Figure 3 An abdominal computed tomography (CT) shows a severe pneumoretroperitoneum (A), and follow-up UGIs done 6 d later reveal no contrast leaks (B).

fluids away from the perforation, and showed that the endoscopic approach reduced the rates of surgery, mortality, and length of hospital stay.

However, unlike more common spontaneous perforation resulting from peptic ulcer disease, endoscopic therapy-related iatrogenic perforations have a relatively lower chance of bacterial contamination in a fasting state, and there is therefore sometimes an opportunity to manage these patients using nonsurgical means. A small amount of bacterial contamination may be controlled by the administration of antibiotics[16]. Recently, trials of endoscopic

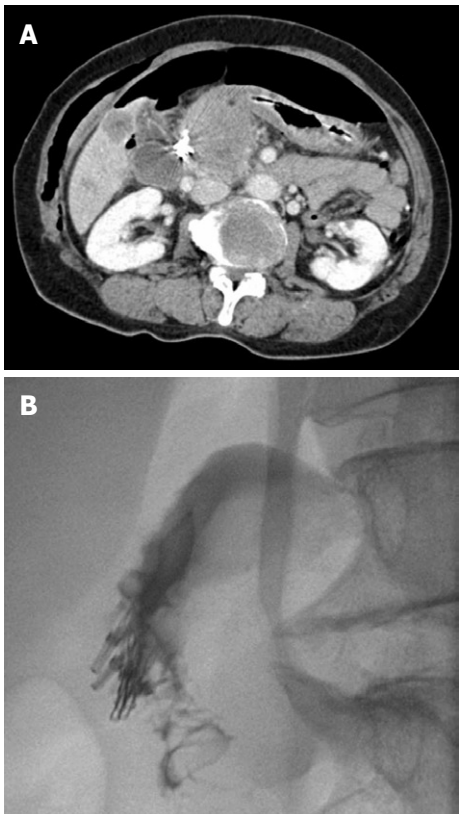

Figure 4 Initial abdominal CT following perforation shows pneumoperitoneum and subcutaneous emphysema (A), and follow up UGIs performed 8 d later reveal no contrast leaks (B).

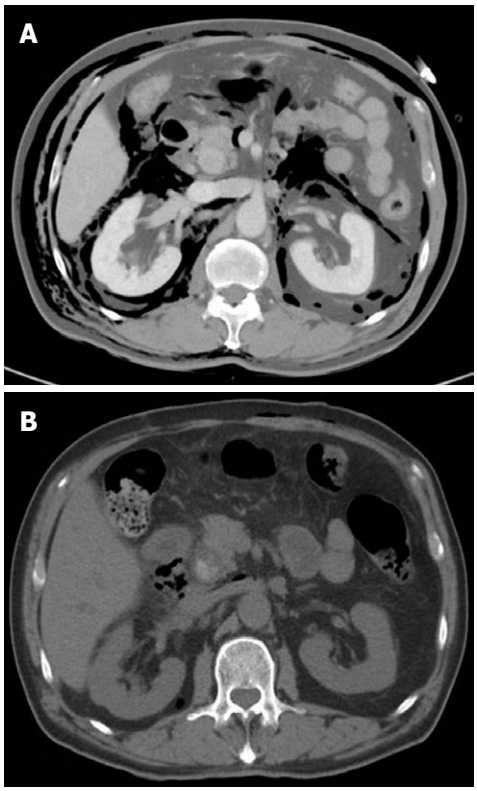

Figure 5 Abdominal CT images showing a pneumoretroperitoneum, and subcutaneous emphysema following perforation (A) and a marked improvement 4 d after conservative management (B).

management have been performed. There have been sporadic reports about the use of an endoscopic clipping device for the closure of iatrogenic perforations during endoscopic mucosal resection (EMR) or sphincterotomy in the esophagus, stomach, and duodenum[17-19]. Though surgery remains the standard treatment for duodenal perforations caused by the endoscope itself, the outcomes from case reports support the beneficial role of endoclips in the closure of these defects[6-8,20]. In particular, some reports described that nonsurgical treatment is possible for the perforation of the upper gastrointestinal tract when peritonitis remains localized. The clinician's familiarity with endoclips and their immediate availability and proper use may avoid surgery for a selected group of patients with a high surgical risk.

Kaneko *et al*[16] suggested some conditions for endoscopic repair using a clipping device in EMR-related perforation. Their suggestions included prior preparation of the patients, quick recognition of perforation, the diameter of perforation being less than the width of the clip's nail, the shape of the opening must be smooth and suitable for drawing the edges together, and an excellent visual field. In endoscopic management, quick recognition and rapid endoscopic closure were the keys to success in limiting the degree of peritoneal contamination and pneumoperitoneum, as delayed diagnosis and surgery are associated with a high mortality rate[4,21]. However, nonsurgical suturing therapy using endoclips is not yet widely accepted as the primary management of ERCP-related duodenal perforation.

In the four cases presented here, the experience of endoscopist and patient old age may be risk factors. All the perforations were done by inexperienced endoscopists who only had one or two years of therapeutic ERCP experiences. However, routine surgery was not required in all patients. The endoscopists could detect the injury early, the visual field was relatively clear, and the endoscopic manipulation was performed in minimal time in all cases. These were the reasons why the primary closure was successful despite a large perforation of more than 10 mm. The perforation was detected very early during ERCP because it occurred in the course of duodenoscope insertion. Cap-assisted endoscopy method under direct vision through a transparent hood was also helpful in reducing the manipulation time of the procedure by allowing a good visual field and ensuring the safety margin during clipping. The cap can facilitate the displacement of any mucosal folds that obscure the lumen and is very useful for overcoming the sharp angulations[22].

Conservative treatment includes giving the patients nothing by mouth, broad-spectrum antibiotics, PPI, and diversion of the bile and pancreatic secretion, or nasogastric or nasoduodenal decompression. However, there were differences in the follow-up method and interval, duration of conservative management methods (fasting, PPI, and antibiotics), and the time when a normal diet was started. Following immediate closure, the use and duration of broad-spectrum antibiotics or PPI was not clear. In our cases, routine nasogastric or duodenal drainage was not used because of early successful closure and biliary diversion by PTBD. Therefore, we think that these procedures are not always required in such cases. Normal diet should be resumed after confirming the complete closure of the wound by UGIs. If patients don't have any clinical symptoms and contrast leakage, earlier resumption of normal diet may be possible.

In summary, primary approximation closure using endoclips under cap-assisted endoscopy of iatrogenic duodenal perforation during ERCP was a safe and feasible technique for even a large free wall perforation. Although the surgical operation remains the standard treatment for duodenal perforation, these cases support the use of endoscopic closure of the perforation with conservative treatments for selected cases of the injury caused by the endoscope itself.

Abstract

This recipient with situs inversus totalis (SIT) was a 60-year-old female who had hepatitis B-related end-stage liver disease. Preoperative donor evaluation showed that the right posterior section satisfied graft volume and was space-fitting in the recipient hepatic fossa when it was rotated 180 degrees. The operation and postoperative course progressed satisfactorily. Three weeks after living donor liver transplantation (LDLT), the graft function was disturbed by compression of bottom-placed right hepatic vein. This was treated with a vascular stent and subsequently the graft function was normalized. The present case shows that LDLT for patients with SIT using a right posterior section graft is feasible.

INTRODUCTION

Situs inversus totalis (SIT) is a rare congenital anomaly with complete reversal of all visceral organs. It occurs once in about 15 000 to 20 000 births and has unknown cause. Sometimes SIT is associated with other anomalies such as biliary atresia, visceral vascular anomaly, and polysplenia. In general, most people with SIT have no complications and perform normal physical activities. However, this condition could be a serious problem when he/she needs liver transplantation because the liver has asymmetrical anatomy that causes technical difficulties in graft positioning and vascular anastomoses in the SIT recipient. For this reason, it has been regarded as a contraindication to liver transplantation.

There are some technical reports of whole graft liver transplantation for adult SIT recipients[1-3]. Also, cases of living donor liver transplantation (LDLT) for the adult patient with SIT have been reported using the left or right lobe with midline positioning of the graft[4,5]. However, midline positioning in the SIT recipient may present two major concerns. Firstly, graft displacement due to redundant space of recipient's hepatic fossa could result in vascular torsion and kinking; and secondly, the recipient's inferior vena cava could be compressed by the graft. To overcome these problems, we performed reversed orthotopic implantation using right posterior section, Couinaud segment VI + VII, grafted into the recipient's hepatic fossa[6].

CASE REPORT

Our recipient was a 60-year-old female with advanced liver cirrhosis caused by hepatitis B virus. Her body weight was 60 kg and the Model for End-stage Liver Disease (MELD) score was 19. The donor was her nephew, a 45-year-old male with a suitable volume of right posterior sector on preoperative computed tomography (CT) scan. Preoperative CT scan showed hilar trifurcation of portal vein and measurement of total liver volume (TLV) was 1100 mL. The right liver volume of the donor was 780 mL (71% of TLV), the left lobe volume was 320 mL, and the right posterior section volume was 510 mL (46.4% of TLV). A right posterior section graft was the only suitable type of donor hepatectomy to ensure donor safety and appropriate volume of graft to the recipient. Preoperative measurement of the right posterior section graft to recipient weight ratio (GRWR) was 0.85%. Preoperative simulation showed that the donor's right posterior section fit well into the recipient's left subphrenic space with 180-degree flip-over (facing backward) implantation method.

The donor operation was performed uneventfully according to the usual procedure of right posterior sectionectomy including right hepatic vein (RHV). There was no significant inferior right hepatic vein in the graft. The actual graft weight was 470 g. On the back table, protruded liver tissue behind the right posterior portal vein and RHV was cut out with an ultrasonic dissector to expose the portal and hepatic veins in reversed graft position. Under laparotomy of the recipient with inverted T-incision, complete rotation of all internal organs along the midline was observed without any vascular anomaly. Recipient hepatectomy was not complicated. The anhepatic time was 45 min. The reversed right posterior section graft was located in the recipient's left subphrenic space. To gain sufficient graft outflow, a piece of cryopreserved vein patch was applied on the ventral portion of the graft's RHV and a modified piggyback anastomosis was done. Vascular anastomoses of the portal vein and hepatic artery were performed as usual. The cold ischemic time was 2 h and the warm ischemic time was 45 min. In the reversed position of the right posterior section graft, the bile duct was located behind the portal vein. Thus, temporary downward traction of the portal vein was necessary for biliary anastomosis (Figure 1). Biliary anastomosis between the recipient's common hepatic duct and the graft's duct was performed successfully with 7-0 prolene continuous suture. Splenectomy was performed according to our indication of thrombocytopenia and splenomegaly. Total operation time was 11 h and 35 min.

The patient's postoperative course was excellent for 3 wk after transplantation, but the serum levels of liver enzymes subsequently started to elevate. However, there was no evidence of acute rejection on needle biopsy. Abdominal CT scan and hepatic Doppler ultrasound showed disturbance of blood flow in segment 6 RHV (V6 RHV) due to compression by the graft itself. A long endovascular stent was inserted into V6 RHV and the liver recovered quickly (Figure 2). Consequently, the patient was discharged at postoperative day 45 with good liver function. She has maintained good general condition and liver function for 8 mo postoperatively, up to the present time.

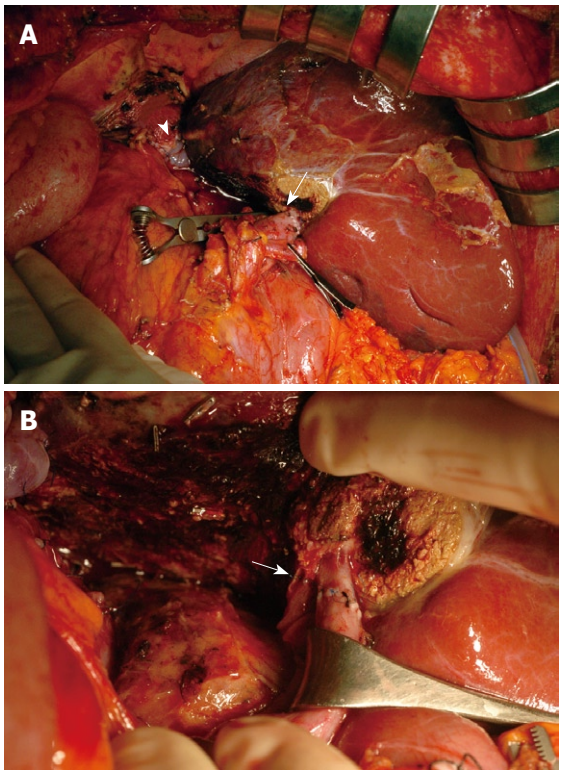

Figure 1 Reversed implantation of the right posterior section graft. A: Modified piggyback anastomosis of right hepatic vein (arrow head) and portal vein anastomosis (arrow); B: Duct opening of the graft (arrow).

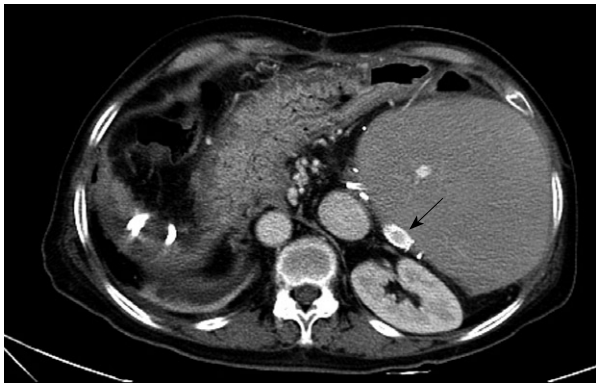

Figure 2 Postoperative 6 mo computed tomography scan showing good graft positioning and patent endovascular stent in the right hepatic vein (arrow).

DISCUSSION

The major technical problem of liver transplantation for adult SIT is the spatial mismatch between the graft's and recipient's left upper quadrant space. Liver transplantation for the SIT patient has been performed at several centers, mainly using techniques of midline positioning or left shifting with/without clockwise rotation of the graft.

However, these techniques have possible complications, such as graft displacement due to unfavorable position and vena cava compression by large right lobe of the graft.

Recently, Rayhill *et al*[7] reported a novel technique of 180-degree flip-over (facing backward) implantation of the whole liver graft into the recipient's left subphrenic space. They reported excellent outcome without complication. Their technique provided not only orthotopic implantation of the whole graft but also good arrangement of portal vein, hepatic artery, and bile duct. We agree that orthotopic reversed graft implantation could overcome the possible complications of midline graft positioning for the SIT recipient.

Regarding LDLT, Chun *et al*[8] reported orthotopic implantation of a right lobe graft with 180-degree flip-over method from a living SIT donor to a recipient with normal anatomy. This technique is similar to ours in reversing the graft, but when using a reversed right lobe graft, the hilar plate is located more ventrally due to voluminous anterior sector behind the hilum. This could result in shortage of portal vein and bile duct, which leads to unavoidable tension in the anastomoses, and consequent vascular stretching or kinking. To avoid such complications, Chun *et al* used a special technique to achieve sufficient length of recipient's portal vein and bile duct.

In our case, the location of the hilar plate of the right posterior sector was almost at the same level within the SIT recipient's hepatic fossa in the reversed position. This allowed us to perform easy vascular and duct-to-duct biliary anastomoses without any of the complications mentioned above. To our knowledge, this is the first report of liver transplantation using a right posterior section graft for the adult patient with SIT. According to our experience, the only disadvantage of this technique using right posterior section graft is the possible compression of the V6 RHV, located at the bottom, by the graft itself during rapid liver regeneration after LDLT. The compression of the bottom-located RHV in reverse positioning of the right posterior section graft would be a common phenomenon, because there is little space to expand behind the RHV during rapid liver regeneration. Thus, we suggest that the surgeon should be alert to detect compression of the RHV during the early postoperative period. However, this complication could easily treated by inserting an endovascular stent.

In conclusion, reversed implantation of the right posterior section graft is one good option for liver transplantation in the adult recipient with SIT. This procedure provides not only orthotopic transplantation to the SIT recipient but also convenient vascular and duct-to-duct biliary anastomoses. In using this technique, however, we have to be alert during the postoperative course because the bottom-located RHV could be compressed by the graft.

Abstract

Duodenocaval fistula (DCF) is an uncommon but lethal clinical entity. The high mortality has been attributed to the difficulty of diagnosis before attempts at definitive therapy. In this case report, we describe a patient with a series of computed tomography (CT) examinations over a 2-mo period in hospital. A low-density air bubble appeared in the inferior vena cava (IVC) on the second day in hospital and became clear on day 19, and gradually enlarged. Magnetic resonance imaging (MRI) also clearly demonstrated a high-signal enteric contrast medium or thrombus and signal-void air bubbles in the IVC. However, cavography did not show the filling defect. We suggest that noninvasive CT and MRI should be chosen as a first-line investigation, and IVC, including the surrounding structures, should be carefully reviewed on images if DCF is clinically considered.

INTRODUCTION

Duodenocaval fistula (DCF) is an uncommon but lethal clinical entity that has previously been reported in only 39 patients in the English-language literature[1-9]. The high mortality of 41% (16/39) has been attributed to the difficulty of diagnosis before attempts at definitive therapy. We present a case of DCF that underwent a series of endoscopy, computed tomography (CT), magnetic resonance imaging (MRI), and cavography examinations, and a review of the literature with respect to radiological manifestation of DCF.

CASE REPORT

A 78-year-old man was hospitalized because of right-sided abdominal pain for 1 mo, associated with fever, rigors, and chills for 1 d. His medical history was significant for right nephrectomy 5 years ago because of renal cell carcinoma. A mass was found in the right adrenal gland and gamma knife radiotherapy was performed 10 mo ago. On physical examination, his initial vital signs were temperature 39.5℃, heart rate 120 beats/min, blood pressure 110/70 mmHg, respiration 25 breaths/min, and SaO_2 97%. Initial laboratory studies showed a leukocyte count of 22 × 10^9/L, hemoglobin 80 g/L, platelet count 33 × 10^9/L, and normal blood chemistry, clotting parameters, and liver function tests. Blood cultures revealed *Enterococcus faecium* and *Enterobacter cloacae* bacteremia and *Candidia albicans* fungemia. Treatment with intravenous broad-spectrum antibiotics and antifungal

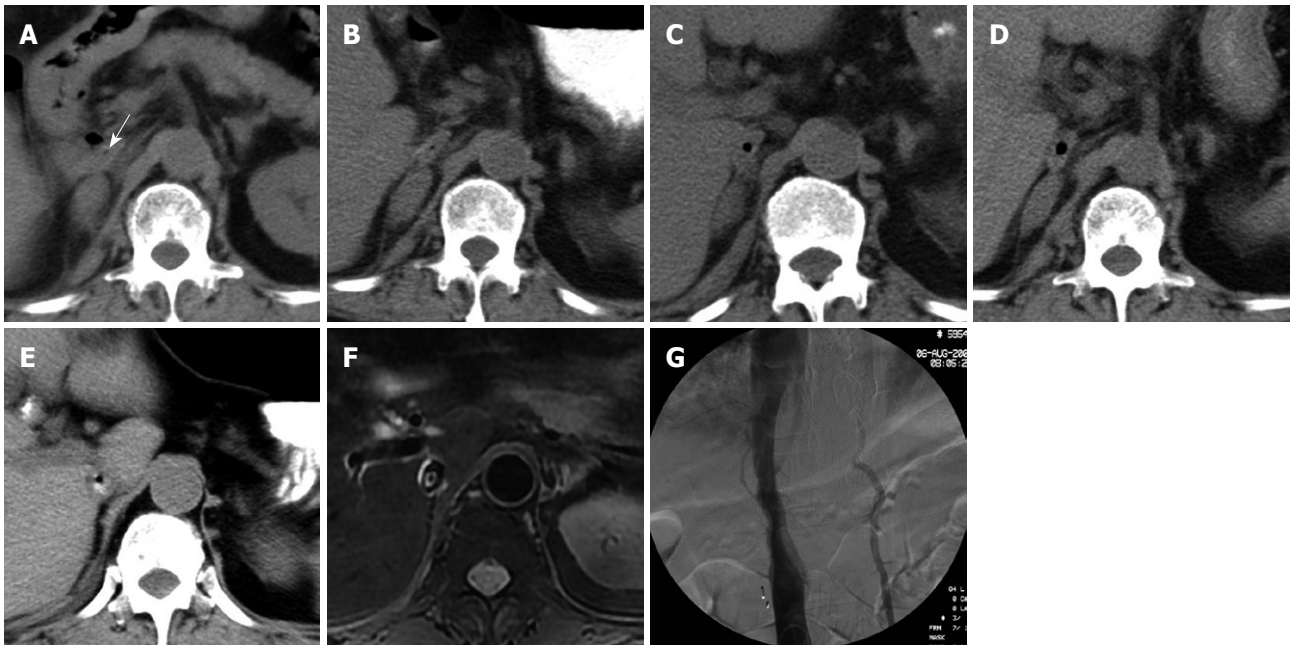

Figure 1 During the 2-mo hospital stay, a small, low-density air bubble appeared in the inferior vena cava (IVC) and gradually enlarged on follow-up computed tomography (CT) scans. Enteric contrast medium leaked into the IVC. Magnetic resonance imaging (MRI) clearly demonstrated the high-signal enteric contrast medium or thrombus and signal-void air bubbles. Cavography did not reveal the thrombus in the IVC. A: CT scan on the second hospital day. A low-density dot loomed up in the IVC (arrow). A mass in the right side adrenal gland was also seen; B: CT scan on the 19th hospital day. The low-density dot became more evident; C, D: CT scan on the 59th and 67th hospital day. The low-density dot (air bubble) was gradually enlarged; E: CT scan on the 73rd hospital day with water-soluble enteric contrast demonstrated air bubble surrounded by contrast medium in the IVC; F: MRI T2WI on the 74th hospital day demonstrated the high signal enteric contrast medium or thrombus and signal void air bubble in the IVC; G: Inferior vena cavogram on the 75th hospital day showed no evident thrombus in the IVC.

therapy (meropenem and caspofungin) resulted in some improvement. However, during the 76 d in hospital, the patient developed intermittent fever, high leukocyte count, sepsis and fungemia. About 1 mo after admission, the patient had watery stools, which were positive for occult blood. A series of upper gastrointestinal (GI) endoscopy examinations, abdominal ultrasound, CT, MRI and inferior vena cavography were performed during the hospital stay. Upper GI endoscopy (on day 3 in hospital) revealed a giant ulcer in the second portion of the duodenum, but no active bleeding. Abdominal ultrasound found nothing except a mass in the right adrenal gland. A series of abdominal CT scans were performed on days 2, 19, 59, 67 and 73 in hospital (Figure 1). Low-density air bubbles were incidentally found in the inferior vena cava (IVC) (at the level of the first lumbar vertebra, adjacent to the duodenum) by CT on day 67. A review of the previous CT scans showed a low-density dot in the IVC on the second day in hospital, which became clear on day 19, and gradually enlarged. A repeat abdominal CT scan (day 73) with water-soluble enteric contrast demonstrated low-density air bubbles surrounded by high-density contrast medium or thrombus in the IVC, which suggested DCF. T2-weighted MRI (day 74th day of hospitalization, Figure 1) revealed high-signal enteric contrast medium or thrombus and signal-void air bubbles in the IVC. However, inferior vena cavography (day 75 of hospitalization) showed no evidence of IVC thrombus (Figure 1). Surgical consultation was scheduled but before it could be performed, the patient had an episode of hematemesis. Massive hemorrhage ensued and the patient died despite aggressive resuscitation efforts. Postmortem examination revealed a fistula between the second portion of the duodenum and the IVC.

DISCUSSION

DCF is a rare occurrence that typically arises as a complication from migrating IVC filters, peptic ulcer disease related to retroperitoneal tumor resection in association with radiation therapy, or transmural migration of ingested foreign bodies. Diagnosis of this entity is challenging because of the nonspecific nature of the symptoms and is rarely made before laparotomy or autopsy. The most common presentations of DCF are sepsis and GI hemorrhage. Sepsis is generally polymicrobial in origin, and caused by Gram-positive and Gram-negative enteric bacteria in the systemic circulation. Fungemia may also occur, as in the present case[1-9]. Endoscopy typically discloses a duodenal ulcer that may show visible bleeding, but the extent of penetration of the ulcer is often underappreciated[1]. CT provides noninvasive evaluation of the IVC and the adjacent structures. It is capable of detecting thrombus and air bubbles in the IVC, infectious fluid collection or abscess around the IVC and duodenum, incarcerated foreign bodies, and migrated caval filters[1-4]. CT correctly can identify DCF in approximately 50% of patients[2]. In this case, a low-density dot appeared in the IVC on the second day in hospital, became clear on day 19, and gradually enlarged over the 2-mo hospital stay. Air bubbles in the IVC may have been produced by bacteria or pushed in by gut peristalsis. Repeated CT

examinations are necessary when air bubbles are too small to make a diagnosis. For detecting thrombus in the IVC, enhanced CT is essential. MRI was not used for the diagnosis of DCF in previous studies. With conventional or flow-sensitive sequences, MRI can clearly delineate thrombus in the IVC, even without intravenous contrast medium[10,11]. Thrombus, intestinal contents and enteric contrast show abnormal signals against signal-void blood flow in the IVC. In the present case, MRI clearly demonstrated high-signal enteric contrast medium or thrombus and signal-void air bubbles in the IVC. Cavography has revealed thrombus or filling defects in the IVC, but was diagnostic of DCF in only two out of six cases[1,4,12]. In the present case, cavography did not show enteric contrast medium or thrombus in the IVC. The most likely reason was that the thrombus was flushed out by the high-pressure injection of intravenous contrast medium. Fatal pulmonary embolization composed of intestinal contents through a DCF has been reported[13]. Our patient died of hematemesis 24 h after cavography. Therefore, care should be taken to perform invasive cavography to detect unstable thrombus of DCF in the IVC.

In summary, we report this case to remind clinicians that noninvasive CT and MRI should be chosen as a first-line investigation for diagnosis of DCF. If DCF is clinically considered, IVC and the surrounding structures should be carefully reviewed by imaging.

Abstract

AIM: To analyze the contribution of *Orvosi Hetilap* (Hungarian Medical Journal) to the field of gastroenterology.

METHODS: All issues of the journal between 1857 and 2008 and identified original articles and reviews dealing with gastroenterology were reviewed. The rate of publications, the thematic distribution and foreign sources of knowledge were assessed. The dates that major achievements in gastroenterology were introduced in Hungary were compared to those dates in Western medicine.

RESULTS: A total of 4799 original/research articles on gastroenterology were published, which represents 11.1% of the total publications. Thematic rankings showed that liver and biliary diseases represented 20.36% of the total, followed by gastric diseases (9.35%) and surgery (8.77%). A total of 268 foreign journals were reviewed: 50.9% were German, 30.4% English, 12.1% French and only 6.6% were in other languages. The major achievements of gastroenterology were introduced with varying delays compared to Western countries.

CONCLUSION: *Orvosi Hetilap* has made a large contribution to the development of Hungarian gastroenterology. The high proportion of gastroenterology studies underlines the importance of digestive diseases in public health.

INTRODUCTION

Nineteenth century Europe witnessed the publication of national medical journals. In Hungary, *Orvosi Hetilap* (*OH*; Hungarian Medical Journal) was first published in 1857, thus making it one of the first medical journals worldwide (Table 1). The importance of the journal in the development of Hungarian medical science and medical language is unrivalled, a fact that has been recognized many times. Much less is known, however, about the role of *OH* in the development of special fields, such as Hungarian gastroenterology. Medical historians divide the past 150 years into six periods according to the editors-in-chief of *OH* (Table 2)[1]. Most of the editors were eminent figures in Hungarian medicine, and were quoted in foreign textbooks of medical history. To the best of my knowledge, this is the first complete content analysis of a medical journal in the field of gastroenterology.

The aim of the study was to track the timeline and make a thematic analysis of the papers dealing with diseases of the gastrointestinal tract, as published in *OH* between 1857 and 2008.

Table 1 Publishing timeline of the national medical journals

1798: *Journal de Medécine*	Paris
1809: *Journal of the Royal Society of Medicine*	London
1812: *New England Journal of Medicine*	Boston
1823: *The Lancet*	London
1840: *British Medical Journal*	London
1850: *Wiener Medizinische Wochenschrift*	Vienna
1854: *Nederlander Tijdschrift der Geeneskunde*	Amsterdam-Utrecht
1857: *Orvosi Hetilap*	Budapest
1875: *Deutsche Medizinische Wochenschrift*	Stuttgart
1883: *Journal of American Medical Association*	Chicago
1893: *La Presse Médicale*	Paris

Total No.	43446	4799 (11.1)	71803	7423 (10.3)

MATERIALS AND METHODS

I manually reviewed the journal volumes between 1857 and 2008. The full papers (both original research and reviews) as well as foreign journal article reviews were identified and classified according to their subjects and origin. All gastrointestinal, liver, biliary tract and pancreatic diseases were included. Articles on epidemics (cholera and typhus) that involved the digestive tract were excluded, being more the subject of epidemiology and microbiology, as considered by medical historians[2]. The thematic analysis of the articles and journal reviews was performed using specific key words that occurred in the titles. The data were entered into an Excel database. The differences between the editorial periods were assessed using analysis of variance and the Kruskal-Wallis test, with a significance level of $P = 0.05$. The statistical work was performed using Statsoft Inc. version 9.0 software (Tulsa, OK, USA). The dates when some major achievements in gastroenterology were introduced in Hungary were compared to those for Western medicine.

Table 4 Thematic breakdown of full papers published in *OH* between 1857 and 2008[1] *n* (%)

Subject	Articles
Anatomy	18 (0.30)
Pathology	121 (2.02)
Physiology	132 (2.20)
Esophagus	194 (3.24)
Stomach	559 (9.65)
Small bowel	298 (4.98)
Appendix	93 (1.55)
Large bowel	268 (4.63)
Liver	871 (14.57)
Biliary tract	346 (5.79)
Pancreas	354 (5.92)
Peritoneum	102 (1.70)
Tumors	195 (3.26)

General topics	252 (4.28)
Total	5974 (100)

[1]Some articles are included more than once, based on keywords in the title.

RESULTS

General data

The volume of *OH* gradually increased from about 400 pages a year at the outset to 800 pages at the turn of the century, before increasing further. During World Wars I and II, both the extent and the number of publications decreased. Between 1944 and 1948, the publication of *OH* was interrupted because of the post-war economic depression (mainly due to lack of paper and printing facilities). After 1948, the volume averaged out at 2469 pages/year, which reflected the increasing number of original articles, journals and book reviews.

Full papers (original research and reviews)

A total of 43446 papers were published during the period studied (Table 3). While the editorial periods were unequal, the number of papers/year was calculated and it increased from 36 (1857-1904) to 64 (1905-1922) ($P = 0.0002$), before changing to 60 (1923-1944) ($P = 0.46$), 89 (1948-1989) ($P = 0.0001$) and 53 (1989-2008) ($P = 0.48$). For the whole period, gastroenterology articles represented 11.1% (6.8-13.9) of the total number of papers published in *OH*. The thematic breakdown of full papers on gastroenterology is shown in Table 4.

Table 5 Introduction of some major gastroenterology achievements in Western countries and Hungary[2-6]

Achievement	International application (year, author, location)	Hungarian application (year, author, location)
Rigid gastroscopy	1868 (A. Kussmaul, Freiburg)	1902 (J. Zimmermann, Budapest)
Gastric resection	1880 (L. Rydiger, Vienna)	1900 (M. Herczel, Budapest)
Radiography	1895 (K. Roentgen, Würzburg)	1896 (J. Klupathy, Budapest)
Cholecystectomy	1881 (C. Langenbuch, Berlin)	1889 (D. Velits, Budapest)
Liver biopsy	1938 (I. Silverman, New York)	1948 (L. Friedrich, Budapest)
Vagotomy	1943 (L. Dragstedt, Chicago)	1948 (E. Hedri, Budapest)
B-mode abdominal ultrasound	1957 (I. McDonald, London)	1973 (Á. Szebeni, Budapest)
Fiberoptic gastroscopy	1958 (B. Hirschowitz, Birmingham, USA)	1965 (T. Jávor, Debrecen)
Fiberoptic colonoscopy	1970 (F. Matsunaga, Tokyo)	1972 (L. Simon, Jászberény)
Endoscopic retrograde cholangio-pancreatography	1970 (I. Oi, Tokyo)	1971 (L. Sáfrány, Budapest)
Endoscopic sphincterotomy	1973 (M. Classen, Munich)	1976 (J. Papp, Budapest)
Liver transplantation	1967 (T. Starzl, Denver)	1995 F. Perner, Budapest)
Laparoscopic cholecystectomy	1985 (T. Mühe, Bobelein)	1990 (I. Kiss, Pécs)
Capsule endoscopy	2000 (P. Swain, London)	2002 (I. Rácz, Győr)

Table 6 Profile of foreign journal reviews in *OH* between 1857 and 2008

Editorial period	No. of articles reviewed	No. of journals	English (%)	German (%)	French (%)	Other Languages (%)
1857-1888	211	86	17.9	52.5	15.9	13.2
1888-1904	381	113	12.6	64.5	17.7	5.2
1905-1922	658	112	15.6	62.2	14.6	7.6
1922-1944	936	121	19.6	57.1	16.9	6.4
1948-1989	3965	178	52.4	38.4	2.9	6.3
1989-2008	1698	113	64.4	31.0	2.9	0.9
Total	7849	268	30.4	50.9	12.1	6.6

Table 7 Ranking of core journals reviewed in *OH* between 1857 and 2008 *n* (%)

Journal	Articles reviewed
Deutsche Medizinische Wochenschrift	1147 (31.2)
Lancet	584 (15.9)
British Medical Journal	410 (11.2)
New England Journal of Medicine	313 (8.5)
American Journal of Roentgenology	263 (7.1)
Zentralblatt für Chirurgie	227 (6.1)
Radiology	204 (5.5)
Schweizerische Medizinische Wochenschrift	194 (5.2)
Journal of American Medical Association	167 (4.5)
Münchener Medizinische Wochenschrift	157 (4.2)
Total	3666 (100)

The dates when some major achievements in gastroenterology were first introduced in Hungary were compared with their first application in Western countries (Table 5)[2-7].

Journal article reviews

Foreign medical journal reviews appeared in the pages of *OH* from the very beginning. Two hundred and sixty-eight different journals were reviewed. Between 1948 and 1959, however, their publication was interrupted for political reasons. The number and language breakdown of the journals in the editorial periods are given in Table 6.

The 10 most reviewed core journals are listed in Table 7. Overall, 3666 articles were reviewed in these journals, which represented 9.7% of the total reviews. The six English journals (60%) had 1941 articles reviewed (52.5%), while the four German journals had 1725 articles reviewed (47.5%).

DISCUSSION

During the 150 years of its publication, *OH* has covered all aspects of developing gastroenterology, from basic sciences (anatomy, physiology and pathology) to the latest achievements (abdominal imaging, laparoscopic surgery, transplantation and genetics) (Table 5). Published every week, it became the main source of professional knowledge for Hungarian physicians. The 11.7% ratio of papers dealing with diseases of the gastrointestinal tract underlines their importance in public health. Diseases of the liver and biliary tract (20.36%) and the stomach (9.35%) (especially peptic ulcers, 3.16%) were studied in most detail, although there were considerable fluctuations in the publication rates. Content analysis revealed that milestone developments of gastroenterology, as quoted, mentioned or even canonized by leading historians[3-8], were introduced in Hungary with varying degrees of delay.

A large variety of foreign journals were reviewed. An analysis of journal reviews reveals that until the 1960s, German literature was the main source of information. The reasons for this are rooted in history, given that the country was part of the Austro-Hungarian monarchy. From the 1960s onwards, British and American journals gradually became the dominant source of information until the dawn of the internet. Even so, the German weekly *Deutsche Medizinische Wochenschrift* was and remains the most frequently reviewed journal. For a closer look at the foreign sources, it would have been better to conduct a citation analysis of the full articles. However, accurate reference lists only appeared after the 1920s. Until then, references were mentioned only as footnotes, indi-

cating the name of the authors; therefore, the impact of major advances and seminal articles on the Hungarian literature cannot be calculated.

In spite of its longevity and indexing in Medline/PubMed, Index Medicus, Embase, Index Copernicus and Google Scholar, *OH* has not been assigned an impact factor. To overcome this, the current Editor-in-Chief, J. Fehér, introduced a 2-monthly English version of *OH* called the *Hungarian Medical Journal*, which has published selected articles of the parent journal since 2007. Another alternative would be the bilingual (Hungarian-English) publication of the high-quality articles. *OH* has been accessible on the internet (http://www.akademiaikiado.hu) since 2008.

The complete archive of *OH* is available in just a few university and hospital libraries. These collections have not benefited from the passing of time. In the future, the digitalization of the journal is vital to save its valuable scientific content for future generations.

ACKNOWLEDGMENTS

This work would not have been possible without the help of Mrs. Anna Kelemen Balázs and Mr. László Bujdosó (librarians at the Unified Saint Stephen and Saint László Hospital, Budapest). The statistical and editorial help of Mrs. Jolán Józan (Semmelweis University, Institute of Physiology) is gratefully acknowledged. The author is indebted to Mr. Douglas Arnott (EDMF Language Services, Etyek, Hungary) for correcting the English manuscript.

COMMENTS

Background

The development of a medical specialty can be followed by the analysis of articles, journals and book reviews published over time in a given field.

Innovations and breakthroughs

The paper is believed to be the first content analysis of the complete edition of a time-honored medical journal, *Orvosi Hetilap* (Hungarian Medical Journal; 1857-2008).

Applications

The author overviews the development of gastroenterology in Hungary over 150 years by analyzing and classifying the original articles, journal and book reviews in the field of gastroenterology, covering both basic (anatomy, pathology and physiology) and applied sciences (esophageal, gastric, intestinal, liver and biliary diseases, and diagnostic procedures), with an emphasis on the main achievements as they have occurred in the literature.

Peer review

This is an interesting historical review of 150 years of gastroenterology articles published in a weekly Hungarian medical journal.

Abstract

We read with great interest the article by Tang *et al* published in issue 4 of *World Journal of Gastroenterology* 2010. The results of their study indicate that percutaneous catheter drainage in combination with choledochoscope-guided debridement is a simple, safe and reliable treatment procedure for peripancreatic infections secondary to severe acute pancreatitis. However, there are some points that need to be addressed, including data about the patients in the study and their clinical characteristics, data about infection and superinfection during the treatment and type of treatment of patients with acute necrotizing pancreatitis.

Zerem E, Imamović G. Comments on the article about the treatment of peripancreatic infection. *World J Gastroenterol* 2010; 16(18): 2321-2322 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i18/2321.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i18.2321

TO THE EDITOR

We read with great interest the article by Tang *et al*[1] published in issue 4 of *World Journal of Gastroenterology* 2010. The article provides important data because it evaluated the new method used in treatment of pancreatic and peripancreatic infections secondary to severe acute pancreatitis (SAP). The results of their study indicate that percutaneous catheter drainage in combination with choledochoscope-guided debridement is a simple, safe and reliable treatment for peripancreatic infections secondary to SAP. The authors suggested that the procedure performed in their study could be used as an alternative to the conventional open-abdominal surgical or laparoscopic debridement in treatment of peripancreatic infection of early SAP patients.

However, there are some points that need to be addressed. In the section of RESULTS, the authors specified "the time from the onset of pancreatitis to drainage was 4-11 d (mean 5.3 d). Before the sinus tract was expanded, the external drainage was maintained for 3-5 d (mean 3.6 d)". Hence, practically all interventions were performed during the first two weeks from the onset of pancreatitis. However, it is known that SAP runs a biphasic course[2]. During the first 1-2 wk, there is a pro-inflammatory response, resulting in a systemic inflammatory response syndrome. It is a sterile response in which sepsis or infection hardly ever occurs. However, after the first 1-2 wk, there is a transition from a pro-inflammatory to an anti-inflammatory response. It is during this anti-inflammatory response that the patient is at risk for the translocation of intestinal flora and the development of infection of necrotic tissue and fluid collections. It is quite uncommon that all patients in the study had pancreatic infection in the first two weeks of the disease. In the article, there are no data confirming that peripancreatic necroses and collections were infected. Also, it is well known that continuous percutaneous drainage often leads to colonization of the cavity with microorganisms and results in frequent superinfection[3,4]. However the authors did not report any data about it.

The authors had impressive results comparing to other similar studies[3-5], but it is disputable if comparable patients were treated in this study since the authors did not present data about the clinical scoring and multiple organ failure of the included patients.

Finally, on the basis of our long-term experience, we believe that the disease catheter drainage of infected necrotic tissue is very poor in the beginning, irrespective of the catheter size we used. However, during the course of SAP, a transition from solid necrotic tissue to more liquid contents leads to a higher success rate of the evacuation of necrotic tissue from the cavities, regardless of the catheter size. Therefore, we consider that only conservative treatment with proper intravenous hydration and administration of proper antibiotics should be performed in beginning of the disease. Percutaneous drainage with vigorous irrigation should be considered when truly conservative treatment fails to resolve infected pancreatic necrosis. We consider that necrosectomy, including choledochoscope-guided debridement, may represent an overtreatment in beginning of the disease in these patients with usually poor general condition. However, it is difficult to discriminate between necrotic tissue and normal tissue, and a very high risk of bleeding from vessels may occur in necrotized tissue during or immediately after the intervention.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in tahe field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Patent (list all authors)

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

World Journal of Gastroenterology

Contents

Weekly Volume 16 Number 19 May 21, 2010

EDITORIAL

2323 Safety of the long-term use of proton pump inhibitors
Thomson ABR, Sauve MD, Kassam N, Kamitakahara H

2331 Double balloon enteroscopy and acute pancreatitis
Kopacova M, Tacheci I, Rejchrt S, Bartova J, Bures J

REVIEW

2341 Progress in laparoscopic anatomy research: A review of the Chinese literature
Li LJ, Zheng XM, Jiang DZ, Zhang W, Shen HL, Shan CX, Liu S, Qiu M

2348 Circulating microRNAs: Novel biomarkers for esophageal cancer
Zhou SL, Wang LD

ORIGINAL ARTICLE

2355 Butyrate stimulates IL-32α expression in human intestinal epithelial cell lines
Kobori A, Bamba S, Imaeda H, Ban H, Tsujikawa T, Saito Y, Fujiyama Y, Andoh A

2362 Dicoumarol enhances gemcitabine-induced cytotoxicity in high NQO1-expressing cholangiocarcinoma cells
Buranrat B, Prawan A, Kukongviriyapan U, Kongpetch S, Kukongviriyapan V

2371 Effect of 5-Aza-2'-deoxycytidine on immune-associated proteins in exosomes from hepatoma
Xiao WH, Sanren GW, Zhu JH, Li QW, Kang HR, Wang RL, Song LP, Ye M

2378 Chronic niacin overload may be involved in the increased prevalence of obesity in US children
Li D, Sun WP, Zhou YM, Liu QG, Zhou SS, Luo N, Bian FN, Zhao ZG, Guo M

BRIEF ARTICLE

2388 Quality of life after curative liver resection: A single center analysis
Bruns H, Krätschmer K, Hinz U, Brechtel A, Keller M, Büchler MW, Schemmer P

2396 Narrow-band imaging endoscopy to assess mucosal angiogenesis in inflammatory bowel disease: A pilot study
Danese S, Fiorino G, Angelucci E, Vetrano S, Pagano N, Rando G, Spinelli A, Malesci A, Repici A

2401 Disagreement between symptom-reflux association analysis parameters in pediatric gastroesophageal reflux disease investigation
Lüthold SC, Rochat MK, Bähler P

2407 Alkaline phosphatase predicts relapse in chronic hepatitis C patients with end-of-treatment response
Bodlaj G, Hubmann R, Saleh K, Stojakovic T, Biesenbach G, Berg J

2411 Increased levels of homocysteine in patients with ulcerative colitis
Akbulut S, Altiparmak E, Topal F, Ozaslan E, Kucukazman M, Yonem O

2417 eGFR is a reliable preoperative renal function parameter in patients with gastric cancer
Kosuge T, Sawada T, Iwasaki Y, Kita J, Shimoda M, Tagaya N, Kubota K

2421 EZH2 and STAT6 expression profiles are correlated with colorectal cancer stage and prognosis
Wang CG, Ye YJ, Yuan J, Liu FF, Zhang H, Wang S

2428 Expression of calreticulin is associated with infiltration of T-cells in stage ⅢB colon cancer
Peng RQ, Chen YB, Ding Y, Zhang R, Zhang X, Yu XJ, Zhou ZW, Zeng YX, Zhang XS

Abstract

The proton pump inhibitors (PPIs) as a class are remarkably safe and effective for persons with peptic ulcer disorders. Serious adverse events are extremely rare for PPIs, with case reports of interstitial nephritis with omeprazole, hepatitis with omeprazole and lansoprazole, and disputed visual disturbances with pantoprazole and omeprazole. PPI use is associated with the development of fundic gland polyps (FGP); stopping PPIs is associated with regression of FGP. In the absence of *Helicobacter pylori* infection, the long-term use of PPIs has not been convincingly proven to cause or be associated with the progression of pre-existing chronic gastritis or gastric atrophy or intestinal metaplasia. Mild/modest hypergastrinemia is a physiological response to the reduction in gastric acid secretion due to any cause. The long-term use of PPIs has not been convincingly proven to cause enterochromaffin-like cell hyperplasia or carcinoid tumors. PPIs increase the risk of community acquired pneumonia, but not of hospital acquired (nosocomial) pneumonia. There is no data to support particular care in prescribing PPI therapy due to concerns about risk of hip fracture with the long-term use of PPIs. Long-term use of PPIs does not lead to vitamin B12 deficiencies, except possibly in the elderly, or in persons with Zollinger-Ellison Syndrome who are on high doses of PPI for prolonged periods of time. There is no convincingly proven data that PPIs increase the risk of *Clostridium difficile*-associated diarrhea in persons in the community. The discontinuation of PPIs may result in rebound symptoms requiring further and even continuous PPI use for suppression of symptoms. As with all medications, the key is to use PPIs only when clearly indicated, and to reassess continued use so that long-term therapy is used judiciously. Thus, in summary, the PPIs are a safe class of medications to use long-term in persons in whom there is a clear need for the maintenance of extensive acid inhibition.

Thomson ABR, Sauve MD, Kassam N, Kamitakahara H. Safety of the long-term use of proton pump inhibitors. *World J Gastroenterol* 2010; 16(19): 2323-2330 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i19/2323.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i19.2323

INTRODUCTION

The risk of minor adverse effects from proton pump inhibitors (PPIs) is low, approximately 1%-3%, with rates of withdrawal from clinical research studies being 1%-2%, with no significant differences noted between the PPIs[1-6]. The risk of symptomatic adverse effects with the PPIs is low as well. In pooled data from published trials involving 2812 patients, omeprazole was

reported as causing headache (2.4%), diarrhea (1.9%), nausea (0.9%), and rash (1.1%), a profile similar to that of cimetidine and ranitidine[7]. In a prospective follow-up study of 5669 patients on lansoprazole, the most common reported adverse effects were diarrhea (4.1%), headache (2.9%), and nausea (2.6%). A similar profile has been reported for pantoprazole: diarrhea, 1.5%; headache, 1.3%; dizziness, 0.7%; pruritus, 0.5%[8]; rash, 0.4%[9]; and nausea, 0.015%. Compiled data from 3556 patients taking rabeprazole for up to one year demonstrated that the most common adverse effect was headache with an incidence (2.4%) similar to placebo (3.1%).

Serious adverse events are rare, with case reports of interstitial nephritis with omeprazole, hepatitis with omeprazole and lansoprazole[10-12], and disputed visual disturbances with pantoprazole and omeprazole[13,14]. An anticipated physiological effect of acid suppression with PPIs is an elevated serum gastrin concentration, which occurs with all PPIs. Gastrin elevation may be higher with omeprazole than with pantoprazole, and higher with lansoprazole than with omeprazole[15-17], and higher with rabeprazole than with omeprazole[18]. This variation in PPI-associated elevation of gastrin concentration is not clinically relevant.

Some persons with dyspeptic conditions such as gastroesophageal reflux disease (GERD) may need to be maintained long-term on PPIs. For this reason, we have reviewed the literature on possible long-term adverse effects of PPIs. Narrative or qualitative reviews, when compared to their systematic review cousins, trade off depth in favor of breadth. After all, reviews can be comprehensive and primary, or narrow in scope and heavily guarded against various biases. Narrative reviews remain, despite a heavy battering by hordes of high quality randomized controlled trials and mathematically endowed structured reviews, on their pedestal as a premier venue for medical educators and historians. This review fits in that important tradition, and purports to fill a need for a comprehensive review on the safety of long-term use PPIs. Mulrow published criteria for minimizing bias in narrative reviews[19]. Deeks summed up these as being rigorous, informative, comprehensive, and explicit[20]. Collins and Fauser, in their editorial, enforced the view of the importance of "balancing the strengths of systemic and narrative reviews"[21]. To achieve this balance and complement a primarily journalistic approach, a search of PubMed, Google Scholar and UpToDate for articles published since 1999 on the topic of "PPI" and "safety" (and related MESH terms) was conducted to identify English language meta-analysis, publications in one of the top biomedical journals in this field (NEJM, Annals, Lancet, JAMA, American Journal of Gastroenterology, Gastroenterology, American Journal of Gastroenterology, Alimentary Pharmacology and therapeutics, Drugs, BMJ) as well as major North American and European guidelines. Checklists have been proposed for systematic and qualitative research[22,23], aiding in the review. We present this information on the long-term safety of PPIs with a series of questions, a summary of the literature, and our proposed answer.

THE USE OF PPIS IS NOT ASSOCIATED WITH AN ALTERATION OF GASTRIC HISTOLOGY

In *Helicobacter pylori* (*H. pylori*) negative persons PPIs do not worsen pre-existing gastritis[24,25], and may even improve pre-existing gastritis[26]. PPIs do not cause atrophic gastritis[27,28].

In contrast, in *H. pylori* positive persons, *H. pylori* is associated with antral or body acute or chronic gastritis, atrophy and metaplasia[29]. *H. pylori*-associated chronic gastritis may progress to gastric atrophy, intestinal metaplasia, and gastric cancer[25,27,30,31], or may not[32]. *H. pylori* and PPIs may cause progression or acceleration from gastric antrum-predominant chronic gastritis to body-predominant chronic gastritis, and it is controversial whether gastric body-predominant atrophic gastritis (gastric atrophy) is a risk factor for gastric cancer[33]. *H. pylori* eradication may cause regression of gastric atrophy or intestinal metaplasia[26,27,29,34-37] or may not[33,38-44].

Thus, the long-term use of PPIs has not been convincingly proven to cause or accelerate the progression of pre-existing chronic gastritis, corpus gastric atrophy or intestinal metaplasia.

PHYSIOLOGICAL HYPERGASTRINEMIA DOES NOT CAUSE GASTRIC CARCINOIDS OR CANCER

H. pylori infection (without use of PPIs) itself increases serum gastrin concentration[29,45].

PPIs modestly increase serum gastrin concentration in persons who are *H. pylori*-negative or positive[46,47]. While PPI's may increase apoptosis[48], PPIs do not increase risk of gastric or esophageal cancer[49-51].

It is controversial whether the hypergastrinemia associated with the use of PPIs increase enterochromaffin-like (ECL) cell numbers, as well as linear or micronodular hyperplasia - Yes[52-54] in *H. pylori* positive persons[55], and No[43,56,57]. Hypergastrinemia associated with Zollinger-Ellison Syndrome (ZES), rarely is associated with an increase in ECL cell growth or ECL carcinoid[58]. Furthermore, there is only one published report in world literature of a ZES patient treated with PPIs for associated gastric hypersecretion, who developed gastric cancer[59]. This is probably a chance association.

Thus, mild/modest hypergastrinemia is a physiological response to a reduction in acid secretion due to any cause. The long-term use of PPIs has not been convincingly proven to cause ECL cell hyperplasia or carcinoid tumors. Even when hypergastrinemia is marked and prolonged (such as with ZES or MEN-1), gastric carcinoids are rare.

THE USE OF PPIS IS ASSOCIATED WITH THE DEVELOPMENT OF FUNDIC GLAND POLYPS

PPI use is associated with parietal cell hyperplasia, and an

up to fourfold increased incidence of fundic gland polyps (FGP)[60-62]. FGP also occur in the presence of *H. pylori* infection, likely incidentally[63,64]. Eradication of *H. pylori* or stopping long-term use of PPIs is associated with regression of FGP[62,65,66]. FGP in sporadic cases is rarely associated with dysplasia, but never gastric adenocarcinoma[67]. Dysplasia may occur in 25%-44% of gastric polyps in persons with familial adenomatous polyposis[63,68].

In summary, PPI use is associated with the development of FGP. FGP occur in the presence or absence of *H. pylori* infection. The eradication of *H. pylori* or stopping PPI is associated with regression of FGP. FGP may rarely become dysplastic, but almost exclusively this rare event is seen in persons with familial adenomatous polyposis.

PPIs may mask the symptoms of gastric cancer (GC), heal malignant gastric ulcers, or shorten survival in the patient with GC.

PPIs may mask the symptoms or heal early GC, but there is no data on the effect of PPIs on rates of survival[69]. H2RA's may[70] or may not[71] actually produce longer survival in patients with GC.

BIOAVAILABILITY OR METABOLISM OF A FEW OTHER DRUGS

PPIs reduce gastric acid, and thereby reduce the bioavailability of drugs requiring intragastric acidity to maximize their absorption and bioavailability[51]. Examples of such drugs would include ketoconazole, itraconazole and indinipur[72], and may reduce the effects of locally acting drugs such as sucralfate.

PPIs may alter the intestinal first pass metabolism or the hepatic clearance of some drugs, and thereby modify their pharmacodynamics[72]. They have no effect on n-acetyltransfer or xanthine oxidase activities[73], and may show a rare class action effect on vitamin K antagonists[74]. PPIs have a low drug interaction through phase I / II effects[5,75], and may differ in their possibility of causing drug interactions. Omeprazole and lansoprazole have a high affinity for CYP2C19 and CYP3A4 but these cytochromes contribute little to rabeprazole metabolism. Pantoprazole is completely metabolized by these cytochrome enzymes, but it uniquely has no drug interactions with a wide range of drugs[72,76-78].

PPIs, with the exception of pantoprazole, have been associated with reduced effectiveness of clopidogrel and a resulting 40% increased risk of coronary stent occlusions[79]. There is no consensus yet on how to manage this[80].

Thus, PPIs have an effect in common with all acid lowering therapy to reduce the absorption of acid-dependent medications. The metabolism of PPIs by hepatic cytochrome enzymes varies significantly between drugs.

THE USE OF PPIS AND DEFICIENCIES IN IRON AND VITAMIN B12

Iron

PPIs reduce gastric acidity, and in patients treated long-term with high dose PPIs duodenal absorption of organic and non-organic iron may be reduced[81]. This effect however is small, and PPIs are not associated with an increased risk of latent iron deficiency or iron deficiency[82].

Vitamin B12

PPIs reduce gastric acidity, which is necessary to activate pepsinogen to pepsin to release vitamin B12 from B12-containing foods. PPIs used short-term may minimally reduce the absorption of protein-bound B12 in food[83-85]. In elderly patients who may already have gastric atrophy (possibly from *H. pylori* infection), PPIs used long-term may reduce serum vitamin B12 concentrations[85-87]. Five out of six studies have shown that PPIs used long-term in non-elderly patients do not reduce serum vitamin B12 concentrations, and therefore body B12 stores[81,88-93].

In ZES patients treated long-term with high dose PPIs, the serum concentration of vitamin B12 may be reduced[94]. And yet, in cystic fibrosis (CF) children with reduced secretion of pancreatic bicarbonate and increased duodenal acidity, there is no reduction in the intestinal absorption of B12[76].

Thus, long-term use of PPIs does not lead to vitamin B12 deficiencies, except possibly in the elderly or in persons with ZES who are on high doses of PPI for prolonged periods of time[95,96].

RISK OF OSTOPENIA, OSTEOPOROSIS AND WITH BONE METABOLISM

PPIs alter osteoclastic vacuolar mechanisms which may reduce bone absorption[97], and thereby actually reduce the risk of OP. PPIs have no known adverse effect on vitamin D absorption or metabolism.

What is the link between PPI use and metabolic bone disease? There is a highly variable effect of acid suppression on calcium absorption[98,99]. In persons with achlorhydria due to pernicious anemia, Ca^{2+} absorption is normal or reduced[100,101].

The real question is whether PPI use is associated with an increased risk of osteoporosis/osteopenia, and more importantly with bone fractures. In case controlled studies, PPI use long-term is associated with an increased risk of bone fractures, and this increased risk depends on the duration and dose of chronic use of the PPI[102] (e.g. Manitoba Population Health Research Data Repository[103]). Use of PPI $\geqslant$ 5 years can increase the risk of osteoporotic fractures by 1.62-fold (95% CI: 1.02-2.58). Other studies confirm that use of PPI $\geqslant$ 7 years increases the risk of osteoporotic hip fractures by 4.55-fold (95% CI: 1.68-12.29) and PPI use for 6-12 mo has been reported to be associated with an increased risk of osteoporotic hip and spine fractures[103-105]. Osteoporotic fractures of the hip and spine may be associated with many factors, which must be carefully taken into account in any case-controlled study which suggests a new association, such as the use of PPIs. However, case control studies on the risk of OP may be criticized on a methodological basis, such as the lack of appropriate stratification of the risk of other

factors known to be associated with an increased risk of OP[106]. The Canadian Association of Gastroenterology (CAG) position paper suggests that "current data would not support particular care in prescribing PPI therapy due to concern about risk of hip fracture"[107].

COMMUNITY ACQUIRED NOSOCOMIAL PNEUMONIA

What is the physiological background to speculating that PPIs might result in pulmonary complications? PPI use is associated with increased intragastric aerobic bacteria, and with the production of acetaldehyde from alcohol[108]. The increased bacterial colonization of the stomach observed with PPI users may be associated with pulmonary micro-aspiration and lung colonization[109,110]. In addition, it is postulated that secretions from the oropharynx may pass by micro-aspiration into the lower lung airways[111]. Furthermore, lung colonization may occur as a result of mechanisms other than micro-aspiration of gastric contents, because different organisms may grow from cultures of gastric juice and from bronchoalveolar lavage[112].

From the clinical perspective, the risk of community acquired pneumonia (CAP) is 0.6 per 100 person years. In persons on PPIs, the odds ratio (OR) is 1.89 (95% CI: 1.36-2.62) for current PPI use and 1.5 (95% CI: 1.3-1.7) for past PPI use (95% CI: 0.9-1.6, and 0.8-1.3, respectively)[113].

In the short-term, PPI use increases the risk of CAP: use of PPI for 2 d, OR = 6.53 (95% CI: 3.95-10.80); for 7 d, OR = 3.79 (95% CI: 2.65-5.42); for 14 d, OR = 3.21 (95% CI: 2.46-4.18); but long-term use of PPIs does not increase the risk of CAP[114], and furthermore meta-analyses have shown that there is no significant association between PPIs and CAP[115].

In contrast, PPIs do not increase the risk of hospital acquired (nosocomial) pneumonia (NP). In fact, there is a reduced risk of NP in patients with nasogastric tubes on a PPI[116]. For ventilated pediatric patients in ICU, there is no increased risk of NP[117-119].

Thus, short-term PPI use increases the risk of CAP, but PPI use does not increase the risk of hospital acquired pneumonia.

CLOSTRIDIUM DIFFICILE-ASSOCIATED PNEUMONIA

There are numerous risk factors for CDAD (use of antibiotics, age, contact with an infected patient or healthcare worker, crowding, lack of cleanliness, post-pyloric tube feeding, patient immunosuppression)[120]. These factors must be taken into account for the attribution of risk, e.g. before assigning a possible role to a new factor, such as PPIs. Some observational studies show an association between PPI use and risk of CDAD[121-132]. For example, for PPI use and CDAD in chronic renal failure patients, the AOR is 5.7 (95% CI: 1.3-39.1) (P = 0.02)[133]. In meta-analyses of studies of CDAD and PPIs, the AOR is 1.96 (95% CI: 1.28-3.00). Some of these reports involve a hypervirulent strain of *C. difficile*, and after correcting for other factors such as antibiotic use, there is no association with PPIs[134]. The bottom line is that there is no convincingly proven data that PPIs increase the risk of CDAD[134,135].

SMALL BOWEL CONTAMINATION SYNDROME AND ENTERIC INFECTIONS

It is thought that PPIs have a minor effect on altering the intestinal bacterial microbiota[136]. Observational studies have suggested that PPIs may[137] or may not[138] increase risk of enteric infections.

Thus, PPIs do not have a convincingly proven adverse effect on the enteric microbiota, and if such an effect does exist, there is no proven clinically important adverse effect[139,140].

The use and subsequent withdrawal of PPIs may be associated with an exaggeration of, or new onset of, acid-related symptoms. PPIs are a medication that is generously prescribed for a variety of symptoms that are thought, and not necessarily confirmed, to be acid-induced. One reason for this is the relatively low number of adverse effects that have been shown in the short- or long-term. One study suggests that symptoms that commence following the discontinuation of PPIs due to rebound acid hypersecretion may be as troublesome as the symptoms that the PPIs were being used to treat in the first place[141]. Because of these rebound symptoms, there may be a need for further and continuous PPI use. As with all medications, the key is to use PPIs only when clearly indicated, and to reassess continued use so that long-term therapy is used judiciously.

The risk of false-negative urea breath tests (UBT) for the diagnosis of an *H. pylori* infection is lower for pantoprazole[142,143]. While it is recommended that acid suppression therapy should be discontinued prior to a UBT, the false-negative effect is lower for pantoprazole.

The biological plausibility is poor for the possibility that PPI use is associated with an increased risk of colorectal cancer or adenomatous polyps, and there is no clinical data to suggest this possibility.

Abstract

Double balloon enteroscopy (DBE) is a new technique, first published and introduced into clinical practice in 2001 by Yamamoto, the inventor of this outstanding method. DBE allows complete visualization, biopsy and treatment of the small bowel. Nowadays, we have some experience of this method for evaluation of the complication rate. Severe complications are described in 1%-1.7% of patients. Acute pancreatitis is a rare complication of the investigation. The incidence of acute pancreatitis after diagnostic DBE is 0.3% in most studies. More than 50 cases of acute pancreatitis have been described in the literature so far. On the contrary, hyperamylasemia after DBE seems to be a rather common condition. Association with acute pancreatitis is supposed to be possible, but not obligatory. The causal mechanism of post-DBE acute pancreatitis is uncertain, and there are several theories in the literature. The most probable cause seems to be a mechanical straining of the endoscope with over-tube on the pancreas or in the papillary area.

INTRODUCTION

Double balloon endoscopy (DBE) is a method of enteroscopy that was introduced 8 years ago. Despite 8 years of experience, the complication rate is still under evaluation. Acute pancreatitis is the most feared complication in oral DBE. The cause of acute pancreatitis is uncertain. The aim of this paper is to provide an in-depth overview of possible risk factors for acute pancreatitis in DBE.

HISTORY

The small intestine was inaccessible to endoscopic methods for a long time. Too far from the mouth and the anus, it seemed to be unreachable for the endoscopist. The history of endoscopy investigation of the small bowel is quite short but accompanied by long-lasting skepticism.

In 1999, Mosse and Swain still stated in their work: "Enteroscopy remains the procedure in the gastrointestinal tract that is most inaccessible to endoscopy, and technical limitations severely impair the ability to advance and examine the small bowel reliably or completely"[1].

In 2000, Oates and Morris[2] published in their article: "It is now more than 25 years since small bowel enteroscopy was first described. For several reasons, this technique developed more slowly than other more usual forms of endoscopy. The small bowel disease is relatively rare in comparison with other gastrointestinal diseases. Also, there

was lack of initial design agreement in different types of enteroscopes. Finally, commercial interests of the manufacturers of endoscopes were mainly focused on the more conventional, large volume markets. Problem areas remain, but with advancing technology and more professional interest in this area, these will be addressed during the next few years"[2].

Attempts to observe the entire gastrointestinal tract began even with early fibroscopes, but only two applicable methods were developed in addition to intra-operative enteroscopy: the ropeway method described by Deyhl *et al*[3] and Classen *et al*[4] in 1972 and the sonde endoscope described by Tada *et al*[5] in 1977. The first successful total enteroscopy was performed in March 1971 by Hiratsuka, using the ropeway method[6]. Both methods were soon abandoned due to the complexity of the technique, patient discomfort, and the long time needed to complete the procedure (and the high rate of complications of ropeway enteroscopy).

Push enteroscopy using a long endoscope was regarded as the gold standard then, but most of the small intestine remained beyond its reach. The first procedure was performed by Parker using a colonoscope in 1983[7]. Push enteroscopy can definitely not evaluate the non-resected small bowel in its entire length. Nowadays, push enteroscopy is reserved exclusively for investigation of the duodenum and oral end of the jejunum[8].

Recent innovations and introduction of two new methods (wireless capsule endoscopy and DBE) have made observation of the entire small intestine possible[6]. Both of these techniques are now available in clinical practice and are complementary: capsule endoscopy for screening and DBE for further diagnostics and/or therapy.

Capsule enteroscopy was invented by Swain and initial experiences in 4000 patients were published by Fritscher-Ravens and Swain in 2002[9]. The introduction of DBE for investigation of the small bowel in 2001 was a milestone in gastrointestinal endoscopy because it allows us to carry out therapeutic interventions as well as diagnostic procedures in the small bowel[10,11].

Double balloon (push-and-pull) enteroscopy (Fujinon, Inc., Saitama, Japan) represents an endoscopic method that enables us to investigate a substantial part or even the entire small bowel. The device was developed by Yamamoto and colleagues, introduced by him into clinical practice, and their first experiences were published in 2001[12]. Several subsequent studies[13-18] have suggested that this method is feasible for diagnostic and therapeutic purposes. Nevertheless, DBE is still under evaluation and its yield and safety aspects must be further determined[19-22].

Single balloon enteroscopy (SBE) is a modification of DBE, and is another system for small bowel enteroscopy (Olympus, Tokyo, Japan). The endoscope (XSIF-Q160Y) consists of a high-resolution enteroscope with a working length of 200 cm. The device is equipped with a transparent silicone overtube with a silicone balloon attached to its distal part. In contrast to the DBE device, there is no balloon attached to the enteroscope, and therefore stable position of the device must be maintained by hooking the distal tip of the enteroscope on the small-bowel wall[23].

Balloon-guided enteroscopy (BGE) is another modification of the DBE method. The advantage of this novel push-pull technique is that it is cheaper than other balloon-assisted methods (DBE and SBE). The device can be used with standard endoscopic equipment. The BGE device comprises a double balloon added onto a disposable element and an air supply unit (NavAid ASU; Smart Medical Systems, Ra'anana, Israel) to control the inflation and deflation of the balloons. The disposable BGE element is slipped over the tip of a standard endoscope and then fixed to the endoscope. At the tip of the endoscope is an inflatable stabilizing balloon. During diagnostic or therapeutic interventions through the endoscope's instrument channel, the advancing catheter with its front balloon deflated can be pulled back and "parked" in its dedicated channel in the BGE device[24].

Spiral enteroscopy is a new technique for deep small-bowel intubation that uses a special overtube (Endo-Ease Discovery SB; Spirus Medical, Stoughton, MA, USA) to pleat the small bowel. Any type of enteroscope can be passed through the overtube, which has helical spirals at its distal end and rotates independently from the endoscope. The enteroscope can be locked in the overtube, which allows the option of spiral enteroscopy, or unlocked and advanced through the overtube[25,26]. Now, it is necessary to gain more data on its usefulness and safety and to compare this method with balloon-assisted enteroscopy[27].

Intra-operative enteroscopy is still a useful method for a specific group of patients (in case of failure of DBE, adhesions, multiple small transmural lesions unresolvable by endoscopic methods, such as carcinoids, and blue rubber bleb nevus syndrome), and therefore, it is necessary to be able to use this method in carefully considered cases[28-31].

PARTICULARITY OF DBE

As DBE is a lengthy procedure, a large volume of air is usually insufflated, which leads to significant distension of the small bowel (with the formation of distended bowel loops and acute angulations with increasing amounts of gases intraluminally). CO_2, unlike air, is rapidly absorbed from the bowel. Preliminary data indicate that bowel insufflation with CO_2, instead of air, enhances patient comfort and decreases the need for sedation[23,31]. We have used CO_2 insufflation in DBE procedures regularly from 2007. We had no complications with hyperinflation, and the comfort of the patient rapidly increased. This type of insufflation is helpful for easier and deeper insertion of the endoscope, because the absorption of CO_2 is 150 times faster than absorption of air in the bowel. Indeed, a recent randomized double-blind trial showed that insufflation with CO_2 is safe, reduces patient discomfort, and significantly improves intubation depth[32].

Combination of water with simethicone is used rou-

tinely to do away with bubbles in the intestine. During withdrawal of the endoscope and during therapeutic interventions, spasmolytics might improve visualization of the small-bowel mucosa by reducing motility of the small bowel[23]. We administer intravenous crystalloids, mostly saline solution, to all patients during DBE lasting over 30 min. Conscious sedation is thought to be sufficient for DBE[23]. It seems to be much better in DBE in comparison with general anesthesia, according to our experience. Abdominal pain is an important warning signal, and it is necessary to terminate the procedure immediately in such cases. Intense pain may be a sign of inadequate pressure on the pancreas and poses a high risk of post-DBE pancreatitis[21,22]. We use small intravenous repetitive doses of midazolam and pentazocine for conscious sedation (batchwise). The duration of the procedure and discomfort for the patient caused by oral passage of the overtube requires deep analgosedation. The procedure requires an experienced endoscopist and the possibility of fluoroscopy if needed, especially during the learning period[33].

COMPLICATIONS

DBE has been reported as a safe endoscopic technique. In initial series on DBE, no complications during or after the procedure were reported[34-37]. Recently, the overall complication rate is stated as being about 1.7%[38,39].

A complication of endoscopy is defined as any event that negatively changes the health status of the patient, and that occurs during the 30-d period after the investigation. Complications are usually categorized as minor when requiring up to 3 d of hospitalization, moderate when requiring 3-10 d and major or severe when requiring > 10 d, and/or an endoscopic, radiological or surgical intervention, and/or contribute to the death of the patient[38,40]. Procedure-related mortality is defined as mortality within 30 d of DBE[38]. Complications are divided into two main categories, those directly attributed to the procedure and those secondary to anesthesia or conscious sedation[23]. The most common complications secondary to anesthesia or conscious sedation are respiratory depression, aspiration, and pneumonia, with a frequency of < 1%[23].

Until now, no standards or definitions for complications during or after DBE have been established. Potential complications during or after DBE might be: perforation, bleeding, balloon dislocation, sedation-related, segmental enteritis after argon plasma coagulation[41], intestinal necrosis after epinephrine injection[42], paralytic intestinal ileus[43], and acute parotitis[44].

Recently, post-DBE pancreatitis has been recognized as a complication[39,45]. In diagnostic procedures *via* the anterograde approach, pancreatitis is the most common and most severe complication[23]. The very first post-DBE acute pancreatitis was reported by Honda *et al*[46] in 2006.

An international symposium held in Atlanta, GA, USA in 1992 has established a clinically based classification system for acute pancreatitis[47,48]. The goal was to establish international standards for definition of acute pancreatitis and its complications, to facilitate valid comparisons of severity of illness and results of therapy, and also to establish criteria for patient selection in randomized prospective trials. According to the Atlanta symposium, acute pancreatitis is defined as an acute inflammatory process of the pancreas that may also involve peripancreatic tissues and/or remote organ systems. Mild acute pancreatitis is defined as pancreatitis associated with minimal organ dysfunction and uneventful recovery. Severe pancreatitis is defined as pancreatitis associated with organ failure and/or local complications (necrosis, abscess, or pseudocyst). Criteria for severity included organ failure (particularly shock, pulmonary insufficiency, and renal failure) and/or local complications (especially pancreatic necrosis but also including abscess and pseudocyst). Early predictors of severity within 48 h of initial hospitalization included Ranson signs and APACHE Ⅱ (Acute Physiology and Chronic Health Evaluation Ⅱ) points[47-49].

In the Atlanta symposium, a uniform threshold was not established for serum amylase and/or lipase for the diagnosis of acute pancreatitis. In recently published articles, the threshold varies from ⩾ 2 to ⩾ 4 times the upper limit of normal. Criteria for severe pancreatitis include organ failure and/or local complications. This broad definition describes a heterogeneous group of patients with varying levels of severity. For example, the prognosis of pancreatic necrosis is more serious than a pseudocyst or pancreatic abscess. Also, almost all patients with necrotizing pancreatitis without organ failure survive, whereas those with multisystem organ failure do not[49].

Bollen *et al*[50] have revised the Atlanta symposium in their review. The authors propose the following recommendations for revision of the classification of acute pancreatitis. (1) The diagnosis should incorporate two of the following three items: upper abdominal pain, amylase and/or lipase levels ⩾ 3 times the upper limit of normal (as this cut-off is used most frequently in the literature), and computed tomography (CT) or magnetic resonance imaging findings compatible with acute pancreatitis; (2) Persistent organ failure (for at least 48 h) should have an important role in defining the severity of acute pancreatitis; and (3) Decisions should be made as to which predictive scoring system, including cut-off value, should be used to define predicted severe acute pancreatitis, based on a systematic review of the available data.

Progress in the field of acute pancreatitis is hampered greatly when various author groups use their own idiosyncratic definitions[50].

According to the literature on post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis [American Society for Gastrointestinal Endoscopy (ASGE) guidelines], post-DBE pancreatitis is defined as newly developed or worsened abdominal pain after the procedure, with a serum amylase ⩾ 3 times the upper limit of normal as the upper limit 24 h after the procedure and requiring at least 2 d of unplanned hospitalization after the procedure[51]. According to these guidelines, the severity of the disease has been classified as follows: mild, requiring 2-3 d

hospitalization; moderate, 4-10 d hospitalization; and severe, > 10 d hospitalization, and/or the occurrence of pseudocyst and/or the need for surgery[52]. The duration of pain after the procedure is crucial for defining post-endoscopy pancreatitis[53].

We found the definition from UpToDate 2009 to be fundamental. Acute pancreatitis is an acute inflammatory process of the pancreas. It is usually associated with severe acute upper abdominal pain and elevated blood levels of pancreatic enzymes. Acute pancreatitis can be suspected clinically, but requires biochemical, radiologic, and sometimes histological evidence to confirm the diagnosis. Clinical, biochemical, and radiologic features need to be considered together since none of them alone is diagnostic of acute pancreatitis. Acute pancreatitis is an important cause of acute upper abdominal pain. Because its clinical features are similar to a number of other acute illnesses, it is difficult to base a diagnosis only on symptoms and signs. The disease varies in severity and the diagnosis is often missed at the extreme ends of the spectrum[54].

It is not usually difficult to recognize severe pancreatitis. The mild form may pose a problem. Abdominal pain and hyperamylasemia after DBE need not mean pancreatitis. On the other hand, a lot of mild pancreatitis could be missed in patients with DBE performed on an outpatient basis.

The complication rate of diagnostic procedures is low (0.4%-0.8%) according to the literature[10,11,38,45]. The overall complication rate of therapeutic DBE is 3%-4%. However, difficult therapeutic endoscopic procedures (e.g. resection of large polyps) may increase the risk to 10%[10,11,23,38]. The perforation rate is significantly elevated in patients with postsurgical anatomical changes undergoing diagnostic retrograde DBE examinations[55].

The overall complication rate was reported to be about 1.7% in a recent international multicenter survey of 2362 DBE procedures. The complications were rated minor in 0.9%, moderate in 0.3% and severe in 0.6% of procedures. The complication rate is significantly higher in therapeutic procedures in comparison with diagnostic ones (4.3% *vs* 0.8%). An exception to the rule is acute pancreatitis, the most common complication in diagnostic DBE procedures. Acute pancreatitis was reported in 0.3% of DBEs[38,39].

A recent report from the National German DBE Register showed an overall complication rate of 1.2% in a large series of 3894 DBE procedures. The incidence of acute pancreatitis was also 0.3% in that study[11].

A study by May *et al*[41] evaluated the acute complication rate of DBE in 353 patients. Only therapeutic procedures were evaluated, with a complication rate of 3.4%. No acute pancreatitis was reported[41].

In general, DBE is associated with a higher complication rate compared with standard endoscopic procedures.

OUR OWN EXPERIENCE

We began with DBE in our department in March 2006. All of our investigations were performed using EN-450T5 and EN-450P5 endoscopes (Fujinon, Inc., Saitama, Japan). Being aware of the possibility of acute pancreatitis as a complication of DBE, we started with our prospective study on hyperamylasemia after DBE right from the start of DBE in 2006. This prospective study is still continuing. All patients were admitted to our department and followed prospectively for at least 2 d after oral DBE.

Urine and serum amylase, serum pancreatic lipase and C-reactive protein (CRP) were investigated before and 4 h and 24 h after DBE. Abdominal pain was evaluated using a three-step scale. Hyperamylasemia (exceeding the upper normal limit) and marked hyperamylasemia (reaching ⩾ 3 times the upper limit of normal) were distinguished.

Normal ranges of the following values in our laboratory were: serum amylase 0.44-1.67 μkat/L (i.e. 28-100 U/L); urine amylase 0-7.67 μkat/L (i.e. 0-460 U/L); serum lipase 0.22-1 μkat/L (i.e. 13-60 U/L); and serum CRP 0-5 mg/L.

Acute pancreatitis was diagnosed in accordance with clinical signs (abdominal pain, fluid sequestration and lack of peristalsis), CRP level and CT scan in addition to the above.

Risk factors for acute pancreatitis and the importance of hyperamylasemia associated with DBE have not been satisfactorily resolved yet. The aim of our prospective study was to clarify the relationship between oral DBE and amylasemia and lipasemia, and to address the possible role of the learning curve for DBE for risk of acute pancreatitis.

A total of 138 DBEs were carried out from March 2006 to November 2009 in 60 men and 56 women under deep conscious sedation (midazolam and pentazocine). The mean time of DBE was 110 min (range 12-270 min), and the mean number of push-and-pull cycles was 15 (range 1-47).

Amylase was set after 128 DBEs; elevation was found in 61 (48%), and marked hyperamylasemia in 27/128 (21%). Abdominal pain was recorded in 19/96 (20%). Elevated lipase levels were found in 55/94 (59%); including 38/94 (40%) with ⩾ 3 times the upper limit of normal. We observed elevation of CRP after DBE in only 18/100 (18%). Peak values of serum amylase and lipase levels were found 4 h after DBE, and peak values of CRP at 24 h after the procedure.

Total panenteroscopy (i.e. investigation of the entire small intestine by one oral approach in one session) was accomplished in 12 DBEs (9%). In this subgroup, we found only four patients with hyperamylasemia and two with marked hyperamylasemia. We had no complications in this subgroup. Compared to the total number of patients, in this subgroup, there was a younger mean age and longer duration of DBE (mean 148 min *vs* 106 min; $P = 0.010$), but there was no acute pancreatitis and no significant difference in amylase and lipase and/or abdominal pain.

In all DBEs, we did not identify any risk factor for abdominal pain and/or elevated pancreatic amylases (sex, age, previous abdominal surgery, panenteroscopy, indica-

tion or endoscopic finding, type of endoscope, number of push-and-pull procedures, diagnostic or therapeutic procedure).

Three patients (2.1%) developed acute pancreatitis after DBE, one necrotizing and two edematous. Two had inflammatory affection of the pancreatic tail, the third of the head region. All of them had abdominal tenderness during the procedure.

Subsequently, we divided our patients into two groups (the first 69 and second 69 procedures) to assess possible influence of the learning curve. Diagnostic and therapeutic DBEs (using Fujinon EN 450P5 or 450T5) were proportionally included in both groups. Neither group differed in age, sex, diagnoses or previous surgery. Differences in amylase and lipase (4 or 24 h after minus basal values before DBE) were used as a major indicator.

The difference in abdominal pain, DBE duration, amylase or lipase was not significant in either of the two groups. Marked hyperamylasemia (≥ 3 times above the upper limit; in 21% after DBE) was not associated with marked pain. There was a weak but significant correlation between amylase difference and abdominal pain (P = 0.003), the number of push-and-pull cycles (P = 0.018), and negative correlation with age (P = 0.029). Lipase difference 4 h after DBE weakly correlated with abdominal pain (P = 0.034). Our three cases of acute pancreatitis were numbers 24, 50 and 57 of 138 DBE procedures, without any evidence of further consequences. DBE lasted 12-270 min (mean: 110 min). Shorter (≤ 120 min, 64%) and longer (> 120 min; 50/138, 36%) DBEs did not differ in terms of post-DBE abdominal pain (P = 0.784). There was a borderline significant difference between longer and shorter DBEs for amylase (P = 0.047) but not lipase (P = 0.225) differences 4 h after DBE.

Elevation of amylase and lipase is often associated with DBE, but acute pancreatitis is however a rare complication. Duration of DBE is not a risk factor for post-DBE acute pancreatitis. Abdominal pain during DBE should be considered as a possible risk factor for acute pancreatitis. That is why we prefer conscious sedation to general anesthesia in oral DBE. The initial learning curve for DBE is not associated with higher amylase or lipase in our setting, and it does not signify a risk factor for post-DBE acute pancreatitis[21,22,56]. The most important point of our study was that it was prospective, solely on an inpatient basis, and all consecutive patients who underwent oral DBE were included.

CLINICAL OUTCOMES

Our center has long-term experience (since 1994) with push-enteroscopy[57] and intraoperative enteroscopy[28-31]. We have never registered acute pancreatitis as a complication of either push-enteroscopy or intraoperative enteroscopy in our setting. However, acute pancreatitis as a complication of push-enteroscopy, caused by an overtube, has been described previously by other authors[58]. Acute pancreatitis has even been described after uneventful upper and lower gastrointestinal endoscopy[59-61]. Blackwood *et al*[62] have detected asymptomatic hyperamylasuria in 6.6% of patients undergoing gastrointestinal endoscopy[62].

Pelletier *et al*[63] have studied the prevalence of hyperamylasemia 2 and 24 h after upper gastrointestinal endoscopy in 50 consecutive patients. In the 2-h sample, hyperamylasemia was observed in nine patients (18%), and in the 24-h sample, in five patients. Pelletier *et al*[63] have concluded that the cause of hyperamylasemia may be due to hypersalivation during the procedure. In our opinion, hypersalivation cannot affect the serum amylase level in such a way (most of the saliva runs out of the mouth during endoscopy and is not swallowed). Furthermore, it cannot affect abdominal pain or pancreatic lipase elevation[21,22,56].

DBE was initially described as a safe procedure[6], with the rate of severe complications ranging from 0 to 1.4%[14,18,64]. However, abdominal pain lasting 1-2 d occurred in 9% of patients in one study[13], or even in 20% according to another[14]. Abdominal discomfort reducing within 72 h was reported in three out of six patients after a DBE procedure[65].

There have been 51 published cases of post-DBE acute pancreatitis on PubMed to date.

Eisen and Schreiner[45] have presented a study of 275 consecutive patients who underwent DBE at two tertiary referral hospitals. The most common complication of DBE was abdominal pain which was seen in 20% of cases. This was typically self-limiting, yet a systematic analysis was not performed. Three cases of pancreatitis occurred (1%), two of which were mild and one of which was of intermediate severity[45]. It is hard to say how many patients with self-limited abdominal post-DBE pain had mild acute pancreatitis, because of inadequate follow-up.

Honda *et al*[46,66] described one and Groenen *et al*[67] two (one necrotizing) cases of acute pancreatitis after DBE. Heine *et al*[14] and Jarbandhan *et al*[52] from the same Dutch group have studied 603 DBE procedures (441 oral DBEs) on an outpatient basis, with six cases of post-DBE acute pancreatitis (1% of all DBEs, i.e. 1.4% of oral DBEs); all cases of pancreatitis were diagnosed after oral procedures. None of the cases of pancreatitis were in the head of the pancreas[52]. In a retrospective analysis of 378 DBEs by Zhong *et al*[68], two patients (0.7%) suffered from abdominal pain with an unspecified elevation of serum amylase. Unfortunately, it was not stated if they required hospitalization[68]. Möschler *et al*[10,11], in a German multicenter retrospective study, have reported 3894 DBEs with an overall complication rate of 1.2%. They quoted nine cases of acute pancreatitis with one lethal disease course after oral DBE, with a complication rate of 0.34%[10,11]. A retrospective study by Gerson *et al*[55] in nine United States centers collected data from 2478 DBEs, with a total of 0.9% major complications (22 DBEs), among which there were six cases of acute pancreatitis (0.2%). Surprisingly, one case of acute pancreatitis was reported after an anal DBE procedure[55]. Another multicenter study by Mensink *et al*[38] investigated 2362 DBEs. The majority of these (87%) were performed on an inpatient basis. The overall complication rate was 1.7%;

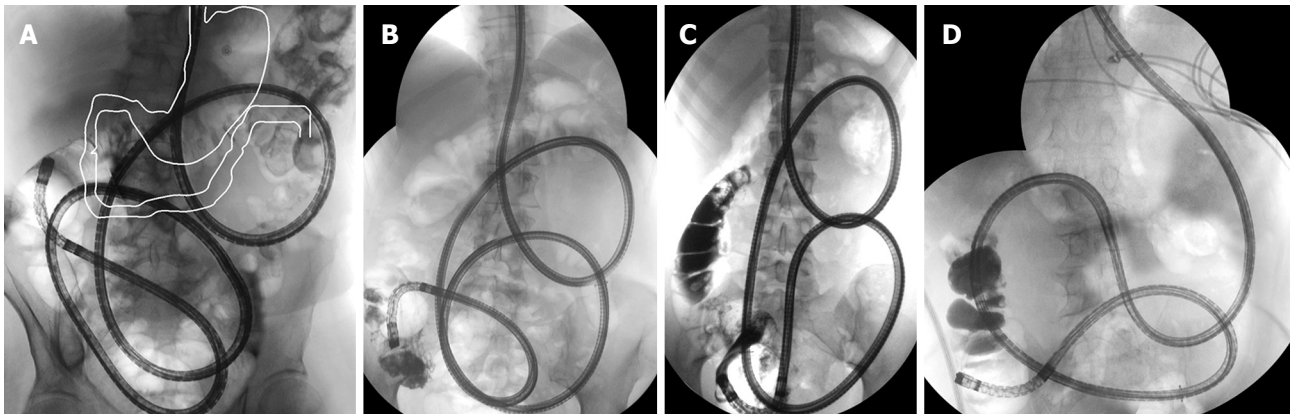

Figure 1 DBE, panenteroscopy *via* oral approach (plain radiograph) in supine position. In comparison with the normal situation (A, white outline), the duodenum is shifted markedly to the left, straightened and shortened. A-C: Normal anatomy; D: After B Ⅱ resection.

six patients suffered from acute pancreatitis (0.3%). The location of the pancreatitis was the body and/or the tail of the pancreas in four patients, the entire pancreas in two, and the head of the pancreas in one[38]. One case of post-DBE acute pancreatitis that affected the pancreatic tail has been reported at the Mayo Clinic (Rochester, MN, USA)[69], along with another case from Osaka, Japan[70], and Rotterdam (one case of pancreatitis of unknown location from 135 patients, 0.7%)[71]. In a recent study by Sunada and Yamamoto, four cases of acute pancreatitis in 1092 DBEs (0.37%) were diagnosed, although the severity and location were not mentioned[72].

In agreement with the Dutch study, we believe that post-DBE pancreatitis is underestimated in retrospective studies on an outpatient basis. In particular, retrospective questionnaire-based surveys might be at risk from an inaccurate report or inclusion bias[52]. As the distinction between clinically mild pancreatitis and hyperamylasemia with transient abdominal discomfort is somewhat arbitrary, it seems likely that an under-diagnosis of post-DBE pancreatitis might have occurred, especially in outpatients.

There was no association with sex, duration of the procedure, or type of endoscope in most of the studies mentioned above.

Surprising results have been reported by Pata *et al*[73] in their study of 48 oral DBE procedures. Pancreatitis was observed in six patients (12.5%). Acute pancreatitis was diagnosed when amylase and/or lipase reached ⩾ 3 the upper limit of normal in the presence of pancreatic-type abdominal pain[73]. The question is whether the diagnostic criteria of acute pancreatitis are sufficient in the case of post-DBE pancreatitis. Asymptomatic hyperamylasemia may occur in nearly half of DBE procedures[21,22,27,56,66,74]. Honda *et al*[66] have investigated 13 patients who underwent DBE. Hyperamylasemia occurred in six of them after the procedure, and one of these developed acute pancreatitis. In agreement with our results, this study demonstrates that latent hyperamylasemia without the development of pancreatitis occurs after peroral DBE more frequently than was previously thought[66]. It may be that some other criteria for the diagnosis of post-DBE acute pancreatitis should be added: ultrasound and/or CT scanning, peristalsis weakening, or compartment sequestration syndrome. Time will tell if the significance of post-DBE and post-ERCP enzyme elevation is absolutely comparable. Pata *et al*[73] have verified only two reported cases of pancreatitis using CT.

The causal mechanism of post-DBE acute pancreatitis is uncertain, and there are several hypotheses. Nevins assumes local trauma to the pancreas during the procedure or release of as-yet-undefined inflammatory mediators[59]. May *et al*[75] assume that the length of the examination time is an important factor, because they did not observe pancreatitis in more than 500 DBEs and had a strict maximum examination time limit of 2 h[75]. However, data from other authors (including our own data) do not support this assumption. In our study, in agreement with other studies[66,70], we found hyperamylasemia and pancreatitis in patients with shorter procedures, and we had fewer patients with hyperamylasemia and no case of pancreatitis in the subgroup of 12 patients with panenteroscopy *via* an oral approach (mean time: 148 min)[21,22,56]. We therefore believe, like Honda *et al*[76], that it is the technique of DBE itself, with the shortening of the small bowel, that may be a factor in pancreatitis after peroral DBE, rather than the length of the examination time (Figure 1)[21,22,56].

Honda *et al*[66] think that, in peroral DBE, the duodenum and proximal jejunum are markedly shortened, and the duodenum is sometimes found to be nearly straight from the pyloric ring to the ligament of Treitz on fluoroscopy. In these conditions, the pancreas body and/or tail may be subject to severe strain, with traumatic injury and/or ischemia. Intraluminal pressure in the duodenum may increase in such a way as to disturb the secretion of pancreatic juice. This mechanism might be associated with the occurrence of hyperamylasemia and pancreatitis after peroral DBE[66]. This hypothesis is supported by the finding that, in most cases in which early CT was performed, pancreatitis was located in the tail or body-tail region of the pancreas[52].

Heine *et al*[14] state that pancreatitis probably results from prolonged mechanical stress on the organ due to re-

peated stretching by the endoscope[14]. Sunada and Yamamoto suggest that the possible mechanism is mechanical torsion of the pancreatic body during insertion of the endoscope. Therefore, for oral insertion, extreme shortening should not be performed, and counter-clockwise rotation is preferred[72].

Another possibility is ischemia of the pancreas, which could induce acute pancreatitis. This has been confirmed in an animal model[77].

Groenen *et al*[67] hypothesize that acute pancreatitis is caused by an increase in intraluminal duodenal pressure during the endoscopic procedure caused by inflation of the two balloons, which leads to reflux of duodenal fluids into the pancreatic duct[67]. A closed duodenal loop has indeed become an established animal model for acute pancreatitis[78,79]. However, the question is whether the duodenal intraluminal pressure during DBE really can reach such a high level. On the other hand, the pancreatitis caused by reflux should affect the whole pancreas, with diffuse swelling, not only in the body or pancreatic tail.

Some endoscopists prefer to inflate the balloons after passing the ligament of Treitz[52,71], or after two insertions (being at least 50 cm distal from the papilla of Vater)[39]. Unfortunately, precise description of this technique and its control (by fluoroscopy?) was not incorporated in their work. Frankly, it is difficult to believe that by pushing the endoscope with the overtube, without pulling back and straightening out the looping, they were able to pass the ligament with a 129-cm long device (the balloon on the tip is 7 cm long and the rest of working part of the overtube is 129 cm). On the other hand, the papilla is about 80-90 cm from the incisors when inserting the endoscope, therefore, both balloons are probably beyond the papilla of Vater. However, even with this safe technique of endoscope insertion, the Dutch group had a post-DBE acute pancreatitis rate of 1.4%, using the oral approach[52].

Other possible causes are direct trauma to the ampullary area or a direct obstruction of the pancreatic duct by the insufflated balloon[67]. In our opinion, this hypothesis seems also to be unlikely.

Another consideration is the question of whether the elevation of amylase is always a result of pancreatitis or whether it could be of intestinal origin and related to manipulation of the gut[80,81]. However, this mechanism could hardly explain the elevation of pancreatic lipase.

The method of insertion and withdrawal of the endoscope might be a factor in the origin of post-DBE pancreatitis. However, in accordance with the literature[52], we did not find any differences in technique between our center and others that are performing DBE in Europe, and we did not see any differences even observing the masterful work of Professor Yamamoto during his live workshops at our endoscopy unit.

Differences in definitions of post-procedural complications offer a likely explanation for the difference in reported post-DBE pancreatitis[52].

In our opinion, mechanical stress on the pancreas seems possible, and the increased level of pancreatic lipase could be a correlate of this. We considered a possible influence of our learning curve on the incidence of hyperamylasemia in our patients, but we did not confirm this by subsequent analysis. The second point of our reflection was the type of endoscope. We used the thicker and stiffer EN-450T5 endoscope, so we were afraid of more forceful pressing of this device onto the pancreas. However, three cases of acute pancreatitis after peroral DBE using the EN-450P5 have been reported in the Netherlands[14] and one after DBE using the EN-450T5[66], and there were no differences in the type of endoscope in large studies[38].

Another question is prevention of post-DBE pancreatitis. We use parenteral hydration during after the oral procedure. The usual dose is 1 L of saline solution during a 2-h procedure. We believe that hydration could improve blood supply to the splanchnic region, pancreatic microcirculation, and post-procedure recovery. The use of proteinase inhibitors such as gabexate mesylate for the prevention of post-endoscopic pancreatitis has been disappointing[53,82]. There have been some studies of intravenous nitroglycerin[83], ulinastatin[84], somatostatin[53,82,85,86], rectal diclofenac[84], and other drugs for the prevention of post-procedure pancreatitis, but the results have not been significant.

CONCLUSION

Acute pancreatitis is a feared complication of oral DBE (51 cases of acute pancreatitis have been described in the literature to date, one of them fatal). Acute pancreatitis is the most common complication seen after diagnostic oral DBE (complications of therapy itself prevail in therapeutic procedures). Hyperamylasemia and elevation of pancreatic lipase after DBE seems to be a common occurrence. Association with acute pancreatitis is possible, but not obligatory. The diagnosis of acute pancreatitis is complex. It can be suspected clinically, but requires biochemical, radiological, and sometimes histological evidence to confirm the diagnosis. The complication rate of acute pancreatitis is reported at about 0.3% of DBEs according to large studies, almost solely after oral DBE. Drawbacks and possible bias of those studies are that they were mostly retrospective, a substantial number of DBEs were performed on an outpatient basis, and the follow-up was inadequate. Nowadays, it is clear that the oral DBE procedure is of higher risk in comparison with the anal one. It would be more precise to count the pancreatitis risk from oral procedures separately. By including anal procedures in determination of post-DBE pancreatitis rate, we obtain much lower and biased numbers. The presumable number of cases of acute pancreatitis after oral DBE is 1.5%-2%. In all patients with abdominal pain during the procedure and/or after oral DBE, diagnosis of acute pancreatitis should be considered and treatment should be provided in good time, the same as in post-ERCP pancreatitis. From the results of our study, we established the following rules in our clinical practice. Conscious sedation seems to be more favorable than general anesthesia due to monitor-

ing of the patient's pain during the procedure. Intense pain during the procedure may be a sign of inadequate pressure on the pancreas and pose a high risk of post-DBE pancreatitis. CO_2 insufflation during DBE is highly recommended as it prevents over-inflation of the small bowel, however, a possible preventive relationship to post-DBE pancreatitis has not been determined yet.

Abstract

The development of laparoscopic surgery has generated the new field of study, laparoscopic anatomy. This article reviews the reported literature on laparoscopic anatomy and explores how it has evolved along with advances in abdominal surgery. In addition, the principal concerns in current laparoscopic anatomy research are discussed, including: (1) types of special adjacent anatomical structures; and (2) special surgical planes and anatomical landmarks. Understanding of systematic laparoscopic anatomy can provide the junior surgeons a clear procedural approach, and would benefit laparoscopic surgeons in training.

INTRODUCTION

The current surgery relies heavily on the use of laparoscopy due to its minimally invasive nature. In the field of abdominal surgery, the traditional approach of open surgery and related surgical anatomy are well established, while laparoscopic surgery and correlative laparoscopic anatomy are still under study.

Since laparoscopic surgery produces less trauma, and yields rapid recovery and superior cosmetic effects, it has become increasingly popular among both patients and physicians. However, laparoscopic surgery is not yet advanced enough to overcome its disadvantage of the lack of tactile sense. This impedes the sensitivity of applied laparoscopy to define the important anatomic features, structure locations, and boundary and texture of excision target tissues. Hand-assisted laparoscopy was developed to give surgeons more control and sensitivity while using laparoscopic instrumentation and digital visualization tools, which has been applied widely in abdominal surgery. Unfortunately, the lap-disc sealing and access device is costly and not extensively used in operations.

A second compelling disadvantage in the laparoscopic procedure is the loss of hand flexibility of the surgeon due to limited availability of space in the patient's body, thus increasing the technical difficulty of the procedure.

However, a systematical knowledge of laparoscopic anatomy can help surgeons to address this challenge. Clarified anatomical structures in the high-resolution and high-magnified view are of great significance in miniscule anatomical procedures, with little bleeding in the laparoscopic field of sight in the correct surgical plane while dissection was performed. Thus, gaining a thorough understanding of the laparoscopic anatomy is crucial to a successful laparoscopic surgery.

In order to provide guidance for laparoscopic surgeons in anatomy and technique, we have reviewed and summarized the current laparoscopic anatomical studies on abdominal surgery published in the literature. Although there are variations in anatomy among individual patients and in procedures used among surgeons, many commonalities exist and can be generalized to aid in the application of laparoscopy.

Systematic literature search was performed on PubMed, Medline, ScienceDirect, SpringerLink, CMCI, VIP, and CNKL to find relevant articles using the terms "laparoscopy", "anatomy", and "minimally invasive". Papers both in English and Chinese concerning anatomical characteristics in laparoscopic procedures in the fields of abdominal surgery were identified. The search results were classified as: (1) anatomical descriptions; (2) anatomical variations; (3) surgical planes and landmarks; and (4) measurements of certain structures. Papers dealing with different types of laparoscopic procedures were summarized according to the above classifications to identify the key points of each procedure.

LAPAROSCOPIC CHOLECYSTECTOMY

Studies on laparoscopic anatomy of laparoscopic cholecystectomy (LC) mainly focused on Calot's triangle, including the cystic artery and cystic duct[1,2]. The cystic artery normally has 1-3 branches into the gallbladder, originates from the proper hepatic artery, and is located within Calot's triangle. The variation of the common structure included origination from the right hepatic artery (Figure 1A), or from gallbladder bed of an aberrant type. The cystic duct is normally connected directly to the right wall of the hepatic duct; variations included connection to the left wall of the hepatic duct through an anterior or posterior approach (Figure 1B). Other structural differences reported in the literature were as follows: cystic duct location in parallel with the common hepatic duct (Figure 1C), presentation as an aberrant bile duct, adhesion and atresia, and an even connection to the right hepatic duct (Figure 1D).

Anatomical landmarks in the LC were mainly reported as Rouviere's sulcus, cystic lymph nodes and arteries[3]. The Rouviere's sulcus is a useful demarcation for the division between the S5 and S6 of the liver. When the gallbladder ampulla is stretched to the head side, the Rouviere's sulcus can be exposed. The Rouviere's sulcus was reported as an accurate landmark for the common hepatic duct plane, as they are on the same transversal level, above which the dissection of Calot's triangle is safe. When the fascial strip in Calot's triangle was flattened, the cystic artery could be identified by its visible pulsation and the presence of an adjacent, cystic lymph node. The cystic artery has been reported to run through the level of the gallbladder neck; exposure of the cystic artery may help surgeons locate the gallbladder neck at the same level. In addition, identification of the cystic lymph node may help define the cystic duct and the cystic artery structures (Figure 1E).

The key concerns in LC anatomy research are how to protect the common bile duct and right hepatic duct, which are injury-prone during the laparoscopic procedure. It is necessary to clarify the anatomy of Calot's triangle and ensure that the superior Rouviere's sulcus is on a safe surgical plane.

LAPAROSCOPIC INGUINAL HERNIORRHAPHY

Studies on the laparoscopic anatomy of herniorrhaphy focused primarily on inguinal hernias. Currently, there are two main approaches for laparoscopic inguinal herniorrhaphy (LIH), i.e. the transabdominal pre-peritoneal and the totally extra-peritoneal. Using laparoscopy, the presence of a direct hernia, indirect hernia or femorocele is readily found according to the position of the hernial ring, as shown in Figure 2A. There are marked differences in anatomical structure between oblique hernia and direct hernia. Thus, the size of mesh used in the operation should be decided according to each individual patient's anatomic data[4].

In the reported LIH procedures, meshes were always secured by either staples or sutures. Three potentially hazardous regions (Figure 2B) were identified and were seriously considered. (1) The so-called triangle of doom, wherein the medial margin is the deferent duct and the lateral margin contains the funicular vessels, should not be subject to staples or sutures because the iliac artery resides in this region; (2) An unexpected source of hemorrhage is identified as the corona mortis (translated as the crown of death), wherein lies the aberrant obturator artery and vein. Branches and distribution of the vascular connection between the obturator system and the external iliac or inferior epigastric systems, are located over the superior pubic ramus[5]; and (3) The triangle of pain, wherein the superior margin is the iliopubic tract (inguinal ligament), and the medial margin is the funicular vessel, is the region where the femoral branch of the genitofemoral nerve and the lateral femoral cutaneous nerve reside. The occurrence of post-operative pain was reported to have originated from staples or sutures placed in this region. It is reported that 15% of the lateral femoral cutaneous nerve was within 0.5 cm of the iliopubic tract or in the vertical plane of the anterior superior iliac spine[6]. To avoid post-operative pain, some surgeons opted against all use of the stapler.

Methods for distinguishing these important structures

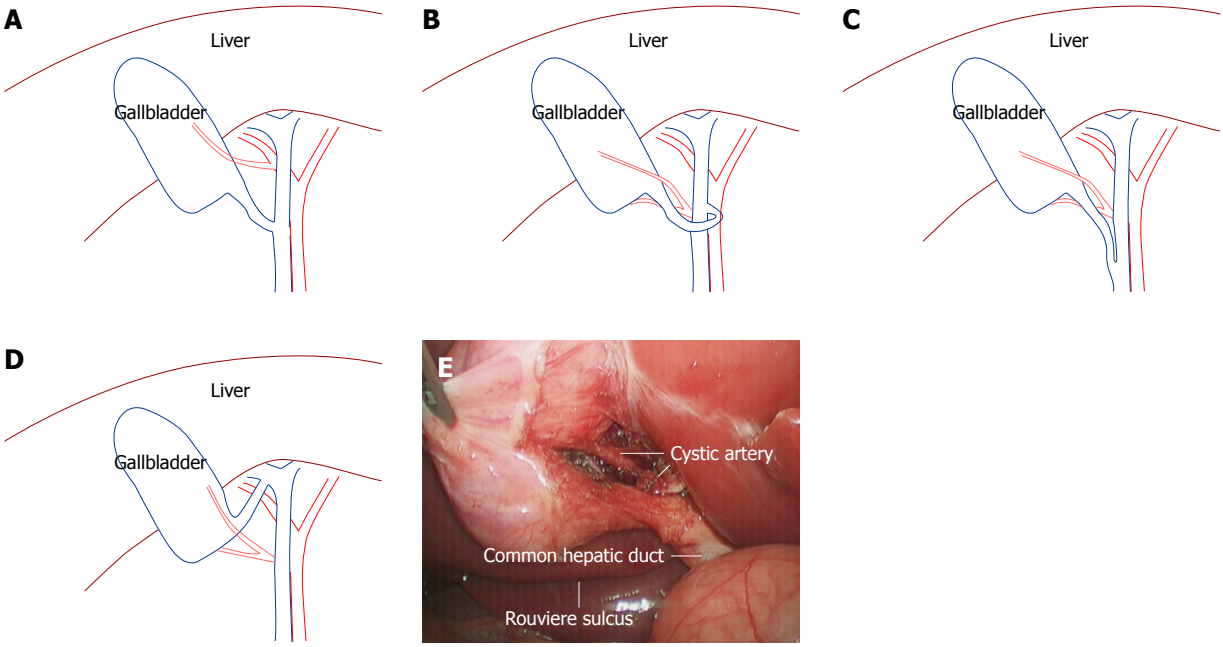

Figure 1 Anatomy of laparoscopic cholecystectomy (LC) (blue curves stand for bile duct and gallbladder and red curves for arteries). A: Illustration of a variant cystic artery originating from the right hepatic artery; B: Cystic duct connected to the left wall of hepatic duct *via* an anterior approach; C: Cystic duct parallel with common hepatic duct; D: Cystic duct connected to the right hepatic duct; E: Calot's triangle and Rouviere sulcus in LC.

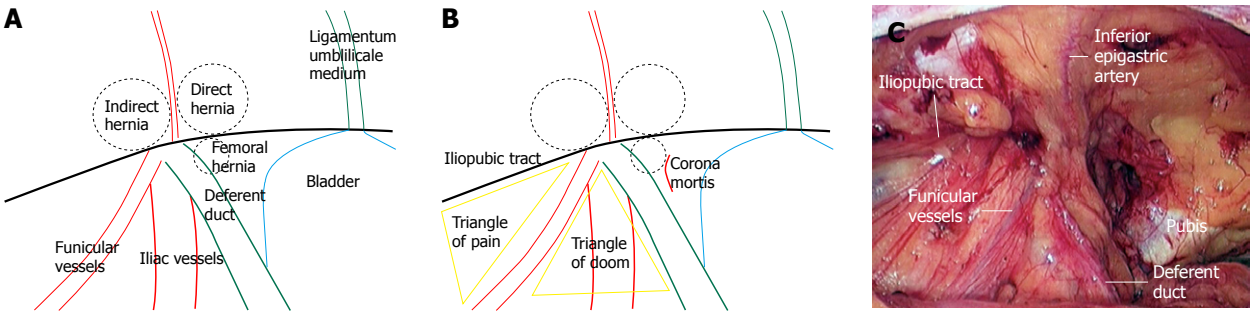

Figure 2 Illustration of inguinal hernia structures. A: Direct hernia was located medially to the inferior epigastric artery, an indirect hernia was located laterally to the inferior epigastric artery, and a femoral hernia was located at the inferior iliopubic tract; B: The three regions, where staples or sutures should not be placed: the triangle of doom, triangle of pain, and corona mortis; C: Live procedure after the peritoneum was absolutely dissected and removed from the abdominal wall.

are a main focus throughout the laparoscopic anatomy literature[7-9]. In live procedures, the structures could be totally exposed after the peritoneum was completely removed from the abdominal wall, as shown in Figure 2C.

The obvious hazards in LIH are the potential for injury of the deferent duct and unexpected hemorrhea. The major technique to protect the deferent duct in this procedure is skeletonization of the spermatic cord. In a nutshell, surgeons should take heed of one "cord", one "crown" and two "triangles".

LAPAROSCOPIC COLORECTAL RESECTION

Studies on the laparoscopic anatomy of colonic resection have focused on the left colon and rectum. Locating the root of the inferior mesenteric artery (IMA) and protecting the autonomic nerve and ureter are of importance in total mesorectal excision. The reports identified a particular landmark and a surgical plane.

IMA is located between the horizontal portion of the duodenum and the bifurcation of the abdominal aorta; the pulsation of the aorta made the identification easy. The landmark used to find the root of IMA was the convex stalk on the surface of the abdominal aorta. The superior sigmoid colon mesentery was lifted to the left side, straightening out the IMA to form an included angle, and the margins were defined as the abdominal aorta and the root of IMA[10] (Figure 3).

The important surgical plane that is yet to be defined is known as Toldt's space. During embryonic development, the mid-gut mesentery after succeeding in the volvulus combined with the peritoneal wall layer to form Toldt's fascia. Toldt's space appeared and remained consistently between the lateral left mesocolon and pre-renal fascia, as well as between the medial left mesocolon and

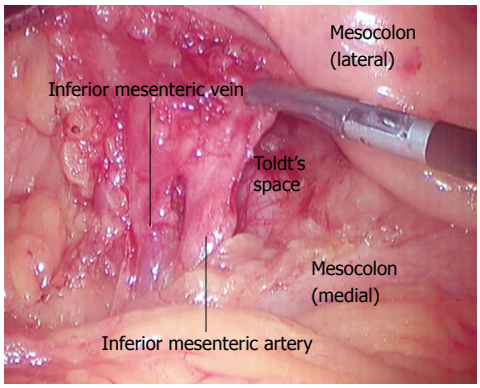

Figure 3 The root of inferior mesenteric artery. The inferior mesenteric artery and vein were identified when the superior sigmoid colon mesentery was lifted to the left side. Toldt's space was found in the included angle of the inferior mesenteric artery and abdominal aorta.

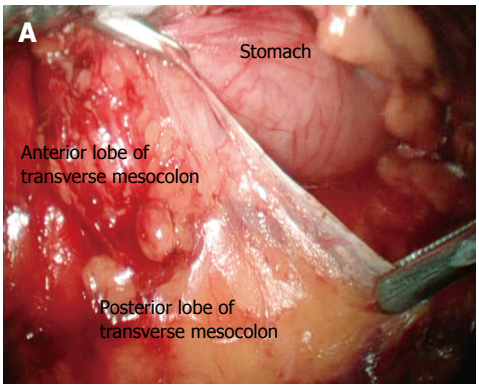
pre-aortic fascia. The space also appeared between the mesorectum and parietal layer of the pelvic fascia.

On the medial side, Toldt's space in the angle of the abdominal aorta and IMA was a vessel free area (Figure 3). IMA ran along the surface of the cephalic abdominal aorta, down to the pelvic cavity and pre-sacral space[11,12]. On the lateral side, an obvious yellow-white borderline was visible. The yellow portion is a part of the sigmoid mesocolon, and the white is a lateral abdominal wall. Dissecting from the medial and lateral space frees the colorectal mesentery completely. The surgical planes are between the colorectal mesenteries and the continuous pre-renal fascia.



Dissecting in the Toldt's space might protect autonomic nerves and the ureter because they are all located beneath the pre-renal fascia. The superior hypogastric plexus closely associates with the back of the IMA. No obvious branches of autonomic nerves were found in the loose space between the visceral layer fascia (mesorectum) and the wall layer fascia (parietal pelvic fascia) at the back of the rectum[13].

In summary, the root of IMA and Toldt's space, which guided most total dissections of lymph nodes and protected the autonomic nerve, appear to be the most important anatomic structures in laparoscopic colorectal resection.

LAPAROSCOPIC GASTRECTOMY

Laparoscopy was often used to treat benign gastric diseases during the early stages. Recently, laparoscopic surgery has been increasingly used in radical gastrectomy, and more researches in laparoscopic anatomy have appeared[14,15], focusing on identifying crucial surgical planes and anatomical landmarks.

In LRG, there appeared to be two surgical planes that were important to define. The first was found between the posterior layer of the dorsal mesogastrium and the pancreas. The derivation of the posterior layer of the dorsal mesogastrium formed the gastrosplenic ligament, pancreatic fascia, pancreaticoduodenal fascia and the anterior lobe of the transverse mesocolon, which was continuous with each other as integrity. The surgical plane could be fixed in the space between the anterior and posterior lobe of the transverse mesocolon (Figure 4A). The plane could be reached more easily for dissection from the shortest distance of connecting fascia from the transverse colon to the descending part of the duodenum. The second surgical plane was identified in the space between the retropancreatic and pre-renal fascia, a safe plane for retropancreatic lymph node dissection. The pre-renal fascia was the post-boundary for ensuring a safe operational plane.

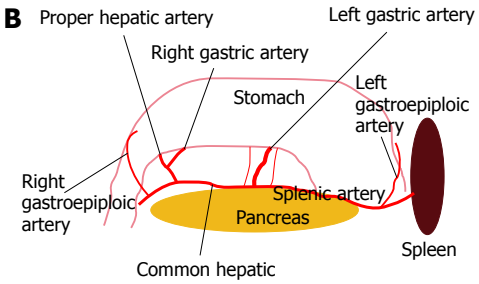


Figure 4 Anatomy of LRG. A: Dissection in the first surgical plane, i.e. the space between anterior and posterior lobes of the transverse mesocolon; B: The main vessels in the space of the posterior layer of dorsal mesogastrium and pancreas when the paries posterior gastricus was turned over to the head side.

Because of restricted laparoscopic sight and instrument manipulability, the procedure was performed from the caudal end to head. Therefore, the main vessels were identified in the space of the first surgical plane mentioned above. The paries posterior gastricus was gradually turned over to the head side following the opening of the first surgical plane, where each important vessel could be identified with the guidance of the following landmarks (Figure 4B). The pancreas was the largest central landmark. When dissecting in the gastropancreatic ligament near the pancreas head, the gastroduodenal artery and right gastroepiploic artery could be identified. Likewise, when dissecting in the splenocolic ligament near the pancreas tail, the left gastroepiploic vessels could be exposed. After the pre-pancreas fascia was absolutely dissociated, two folds were formed by the pre-pancreas fascia and its related vessels. The hepatopancreatic fold was the landmark used to find the common hepatic artery and proper hepatic artery at the inferior

margin of the pancreatic neck. The gastropancreatic fold was used to locate the left gastric artery.

In LRG, lymph nodes dissection was complicated, which could be achieved by recognizing and skeletonizing the related vessels. In summary, one center (pancreas), two ligaments (gastropancreatic and plenocolic ligaments), and two folds (hepatopancreatic and gastropancreatic folds) are the key landmarks identified in the literature used to find each vessel. These landmarks could be readily defined if the surgical plane (space between posterior layer of dorsal mesogastrium and pancreas) was appropriately identified.

OTHER LAPAROSCOPIC PROCEDURES

Anatomic studies of laparoscopic liver resection were mainly carried out by autopsy. The research priorities were placed on the first and the secundum porta hepatis[16,17]. Laparoscopic procedures were mostly performed as hepatic left lateral lobectomies. Therefore, the important structure of the left triangle ligament was defined as the peritoneal reflection of the diaphragm and the left lateral lobe. Superior hepatic arteries, branches originating from the left gastric artery and inferior phrenic artery, could be found after the left triangle ligament was opened (taking up 80%). The trunk of the superior hepatic arteries crossing the left hepatic veins of the superior posterior margin was an important landmark for locating the hepatic vein, as well as the secundum porta hepatis[18]. The falciform ligament was found as the anterior pathway to reach the secundum porta hepatis by laparoscopy. The left, inferior phrenic artery and middle segment artery of the liver formed a vessel that arched and gave off 6-12 branches to the falciform ligament, finally draining into the left inferior phrenic vein. The falciform ligament provides significant collateral circulation to the liver and is an important landmark for laparoscopic liver surgery[19].

Laparoscopic pancreaticoduodenectomy (LPD) is recognized as an extremely difficult laparoscopic operation due to the emergency status of the laparoscopic surgery. Chinese surgeons[20] developed a method of retroperitoneal laparoscopic dissection to expose the pancreatic body and tail. The retro-pancreatic space was reached using testis (ovarian) vessels as anatomical landmarks. The peritoneum was a landmark for the belly side of the para-renal space, and the splenic artery was a landmark of the upper pancreatic edge. The left renal vein was a landmark of the lower pancreatic edge, the left diaphragm colon ligament (or splenic lower pole) was a landmark for the pancreatic tail, and the intersection point between the right edge of the inferior mesenteric vein and the inferior margin of the pancreas were landmarks for the transition part of the pancreatic neck and body. Lu *et al*[21] developed the duodenal wall approach, in which the lateral wall of the duodenum was dissected and the root of the mesenteric vessel could be seen at the horizontal level of the duodenum; and the posterior pancreatic segment of the visible portal vein could be located by searching along the superior mesenteric vein.

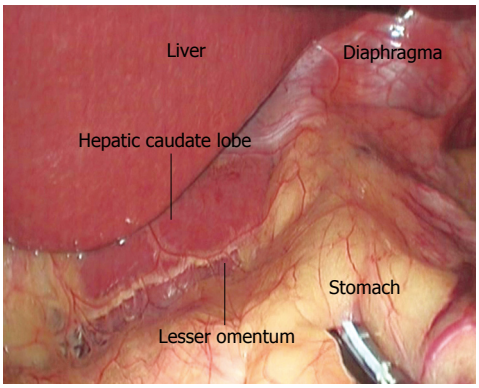

Figure 5 The lesser omentum above the hepatic caudate lobe.

Laparoscopic fundoplication, routinely used in laparoscopic anti-reflux surgery (LS), is a classical approach for the treatment of gastroesophageal reflux disease. Its related laparoscopic anatomy emphasized the anatomic landmark and surgical plane. The procedure is initiated by opening the lesser omentum above the hepatic caudate lobe, the landmark for finding the right crura of diaphragma. The space between the right crura of diaphragma and the esophagus is the surgical plane for dissociating the esophagus[22] (Figure 5). Special anatomical variations, such as an aberrant left hepatic artery, can complicate the procedure[23].

Anatomic studies on laparoscopic splenectomy focused on the splenic vessels. In most cases, splenic arteries and veins run together along the superior edge of the pancreatic body and tail; the arteries are located above the veins. In some reported cases, the splenic arteries ran along the superior edge of the pancreatic body tail, and the splenic arteries and veins were either found at the back of the pancreas, or the arteries were absolutely absent around the pancreatic body and tail. It was required that two (in most cases), three, and four splenic, lobar branches should be clamped[24,25].

CONCLUSION

What can we learn from the entire body of literature on laparoscopic anatomy?

Researches on laparoscopic anatomy have not been extensively carried out or reported throughout the world. Perusal and a summary of all of the relevant studies indicated that China-based scholars did most of the research work on laparoscopic anatomy. Some works were initially carried out by autopsy, and the results were provided to surgeons for guidance in live procedures. Procedures that were already extraordinarily familiar by surgeons, such as LC and LIH, were initiated in live surgeries.

Studies on the laparoscopic anatomy of abdominal surgery mainly focused on the following aspects: (1)

Simulating laparoscopic surgery on cadavers, or relevantly studying endoscopic anatomy through clinical laparoscopic surgery; (2) Obtaining relevant data by measuring the length, distance, and diameter of the tissue under the study; (3) Calculating the case percentage of special adjacent anatomical structures; and (4) Finding relevant anatomical planes, landmarks and providing relevant intraoperative pictures.

Due to the various surgical approaches, the portion of our study that focused on certain laparoscopic anatomy also varied. During laparoscopic procedure, the size and boundary of target tissues and the distance between two structures in laparoscopy sight were estimated by surgeons based on their experience. These data could not be obtained accurately by the naked eye using the existing laparoscopic technology. Therefore, some data in the autopsy studies could only be used as a reference during live laparoscopic procedures. The key point for laparoscopic surgeons was to understand the special, adjacent anatomical structure and the location of the correct anatomical plane and anatomical landmark. Gaining a definite understanding will guide future prospective studies of laparoscopic anatomy.

Surgical planes and anatomic landmarks

Why could there be less bleeding in the laparoscopic sight if manipulation occurs in certain surgical planes? Each surgical plane and natural space in the human body, are formed by stratum membranosum, like the membranous layer of the superficial fascia present in many regions of the body[26]. The basic research on surgical planes in laparoscopic anatomy should focus on vessel-less stratum membranosum.

Anatomical landmarks are descriptions of neighboring structures crucial to identifying the proper target tissue for resection. Although individual patients vary in their anatomical structure, certain commonalities exist. These commonalities become obvious through the numerous cases and procedures reported. Laparoscopic surgeons must rely on landmarks in each procedure; it is crucial in laparoscopy that detours must be minimized, otherwise an unexpected injury is likely to occur.

Sometimes, the surgical planes and anatomical landmarks can assist each other. In an appropriate plane, it would be easy to identify certain landmarks. Take LRG for example; if the space between the posterior layer of dorsal mesogastrium and pancreas could be found correctly, the landmarks of one center, two ligaments and two folds would be immediately obvious. Likewise, a landmark can help find readily a surgical plane. In LAS, the hepatic caudate lobe was the landmark for finding the right crura of diaphragma, the surgical plane for dissociating the esophagus.

Significance and prospective

Currently, laparoscopy is usually performed using the approach of natural orifice transluminal endoscopic surgery and a single entry port. These techniques require advanced skills of surgeons and a detailed knowledge of laparoscopic anatomy.

In the field of abdominal surgery, laparoscopic surgery has become increasingly popular. Systematic laparoscopic anatomy can provide laparoscopic surgeons with a clear idea to design their operation, and is particularly important for practicing novices. Laparoscopic anatomy is a basic curriculum for laparoscopic surgeons, and will certainly become an important new subject as the use of laparoscopic procedures increases.

Abstract

Esophageal carcinogenesis is a multi-stage process, involving a variety of changes in gene expression and physiological structure change. MicroRNAs (miRNAs) are a class of small non-coding endogenous RNA molecules. Recent innovation in miRNAs profiling technology have shed new light on the pathology of esophageal carcinoma (EC), and also heralded great potential for exploring novel biomarkers for both EC diagnosis and treatment. Frequent dysregulation of miRNA in malignancy highlights the study of molecular factors upstream of gene expression following the extensive investigation on elucidating the important role of miRNA in carcinogenesis. We herein present a thorough review of the role of miRNAs in EC, addressing miRNA functions, their putative role as oncogenes or tumor suppressors and their potential target genes. The recent progresses in discovering the quantifiable circulating cancer-associated miRNAs indicate the potential clinical use of miRNAs as novel minimally invasive biomarkers for EC and other cancers. We also discuss the potential role of miRNAs in detection, screening and surveillance of EC as miRNAs can be a potential target in personalized treatment of EC.

INTRODUCTION

Esophageal cancer (EC) is the eighth most common cancer and the sixth most common cause of cancer death worldwide, affecting more male than female[1]. The dramatic geographic difference in incidence is the striking characteristic for EC. The EC incidence in the high-risk northern Chinese exceeds 100/100000, while that in the low-risk western Africa can be 20-fold lower[2]. EC remains the leading cause of cancer-related death in the high-risk areas, especially in Henan Province, northern China[3]. Esophageal squamous cell carcinoma (ESCC) and adenocarcinoma (EAC) are the two main forms of EC; each of them has different etiologic and pathologic characteristics. ESCC remains the predominant subtype of EC, especially in China; in contrast, EAC is the most common type in Western countries.

The survival and prognosis of EC patients depend on the stage of the tumor at the time of detection. Despite significant investment and advances in the treatment of cancer, the overall survival for advanced and metastatic cancer is still dismal, with a 5-year survival rate of less than 15% for advanced tumors[1,4,5]. The concept of early detection of esophageal cancer has been established

among clinicians and scientists for years. The 5-year survival rate was more than 90% for early EC[1,4,5], about 50% of cancers extend beyond the primary local region at the time of diagnosis and almost 75% of surgically treated patients have proximal lymph node metastasis[6]. At present, gastrointestinal endoscopy remains the primary screening tool, by which the suspected lesions can be biopsied for histopathological analysis. This invasive test, even though it is proved to increase the detection of early tumor and therefore can prolong the survival of the patient, is generally considered to be inconvenient and painful. Because of its limitation, there is an urgent request for discovery of novel predictive markers for EC.

Micro ribonucleic acids (miRNAs) are a class of single-stranded, evolutionarily conserved non-coding RNAs, only 17-25 ribonucleotides long[7]. The first known microRNA (miRNA), the lin-4, was discovered in 1993 through the study of heterochronic gene lin-14 in worms[8]. Since then, miRNA has shown the great potential regulating roles in many aspects of biological and pathological processes. The miRBase, which is the international registries for miRNAs, clearly described their nomenclature, targets and functions and implications in different diseases[9]. The biogenesis of miRNAs is a multi-step process involving a complex protein system, which includes members of the Argonaute family, Pol Ⅱ-dependent transcription and the RNase Ⅲs Drosha and Dicer[10]. MiRNAs are involved in crucial biological processes, including development, differentiation, apoptosis and proliferation[11,12]. The mechanism is still under debate, but probably related to inhibition of translation and messenger RNA degradation[13]. These small RNAs regulate gene expression at the level of translation through imperfect pairing with target messenger RNAs (mRNAs) of protein-coding genes[10]. The specific region in miRNA, which is important for messenger RNA target recognition, is referred to as the "seed sequence", and located at the 5- end of the mature miRNA sequence, from bases 2 to 8[11]. With the seed sequence, we can search for the complementary sequences in the 3'-untranslated regions (3'-UTRs) of known genes that exhibit conservation across species[11]. In animals, most miRNAs are thought to form imperfect base pairs with their target mRNA(s) and these interaction sites are enriched in 3'-UTRs[11]. To date, in the human genome, over 700 mature miRNAs have been identified, and the number is still increasing with the future studies. Up to 1000 miRNAs have been predicated by the bioinformatics studies of the human genome[14].

EXPERIMENTAL TECHNIQUES FOR MIRNA ANALYSIS

It is necessary to explore effective tools for detection, quantification, and functional analysis of miRNAs. Oligonucleotide miRNA microarray analysis has been extensively used as high-throughput technique for the assessment of cancer-specific expression levels in a large number of samples[10,13,15]. Another method to gauge miRNA expression level includes utilizing a bead-based flow-cytometric technique by which hybridization occurs in solution and provides a high specificity for closely related miRNAs[16]. The miRNA microarray platform with locked nucleic acid-modified capture probes can improve probe thermostability and increase specificity, so that it can discriminate miRNAs with even single nucleotide differences[17]. Quantitative real-time polymerase chain reaction (PCR) have also been widely applied to miRNA research because of its cost-effectiveness, high throughput and superior detection of low-abundance species[18]. All of these technologies facilitating miRNAs expression profiling are essential for validation of microarray data.

It is also necessary to develop methods of manipulating miRNA expression for elucidating biological significance and manipulating miRNA expression. MiRNA inhibitors such as 2-O-Methyl antisense single-strand oligonucleotides and locked nucleic acid modified oligonucleotides, made the suppression of endogenous miRNA activity and its downstream effect on messenger RNA expression possible[19]. The latest improvement of miRNA inhibition could control miRNA expression *in vivo* by expressing decoy miRNA targets *via* lentiviral vectors[20], with it we can inhibit specific miRNA by expressing various miRNA inhibitors. MiRNA mimicry could be used to identify the cellular processes and phenotypic changes through transfecting specific miRNAs into cell lines[21]. Although these techniques are of different strength and weakness, the large size studies have shown common characteristics of miRNA deregulation in human cancers[13] and shed light on the application of miRNAs as novel biomarkers finally.

MIRNA AND EC

Early studies demonstrated the aberrant expression of miRNA in cancers and the fact that approximately half of miRNA genes are localized in cancer-associated genomic regions or in fragile sites[22] indicates the potential role of miRNAs as a promising class of oncogenes or tumor suppressor gene in human carcinogenesis. MiRNAs still largely intact in conventionally collected, formalin-fixed and paraffin-embedded tissues and even a modest number of miRNAs are adequate to discriminate human tumors according to the developmental lineage and differentiation state of the tumors[16]. Furthermore, compared with messenger RNA (mRNA) profiles, it is easier to use these miRNA expression profiles to classify poorly differentiated tumors[23]. Here, we will focus on the miRNA expression profiles of EC, especially ESCC, to reveal the oncogenic mechanism by miRNA mediated post-transcriptional pathway. We will first discuss the identification of EC specific miRNA signatures for a new class of screening, diagnostic and prognostic biomarkers through miRNA expression profiling of EC; then we will concentrate on how to clarify the functional roles of miRNA in EC and the potential clinical valuation of the circulating miRNAs in EC. We believe that the study of miRNA's role in EC will provide new sight into this disease.

Role of miRNAs in carcinogenesis, progression, invasion and metastasis of EC

MiRNA acts as oncomiRNA or tumor suppressors to affect the tumorigenesis if their target mRNAs were encoded by tumor suppressor genes or ontogenesis[24]. Aberrant miRNA expression has been identified and confirmed in EC (Table 1). Comparing the miRNAs expression in ESCC with EAC, we can find that only a few miRNAs expressions were the same in these two diseases, each of which has the different miRNAs expression profiling, indicating that both of ESCC and EAC have distinct etiologic and pathologic characteristics. The miRNAs which are highly expressed in tumor can act as tumor promoter by targeting and inhibiting different tumor suppressor genes such as B-cell CLL/lymphoma 2 (BCL2)[31], *tension homologue* gene (PTEN)[32], large tumor suppressor homolog 2 (LAST2)[25], annexin A1 (ANXA1)[33]. Those genes were all studied in EC tissues and it was suggested that all of them were involved in carcinogenesis of esophagus. Those mature miRNAs with relatively lower expression in cancer may act as tumor suppressor miRNAs. The loss of such miRNAs may enhance the activity of oncogenes.

Apart from identifying different cancer-related miRNAs, efforts have been made to identify their target genes, messenger RNAs and receptors, which will lead to further studies about their contribution in cancer treatment. For example, the putatively identified targets[31,32,34] of miR-21 are BCL2, PTEN, tumor suppressor gene tropomyosin 1 (TPM1), programmed cell death 4 (PDCD4) and maspin. Zhu *et al*[34] found that the biological function of miR-21 is probably due to the simultaneous repression of multiple tumor suppressor genes, including PTEN, TPM1, PDCD4, and maspin. PTEN is capable of restricting growth and survival signals by limiting the activity of the phosphoinositide 3-kinase (PI3K)/AKT pathway[35]. A decrease in functional PTEN causes constitutive activation of downstream components of the PI3K/AKT pathway, leading to tumor progression and metastasis[35]. Thus, down-regulation of PTEN by miR-21 may contribute to transformation and increased tumor cell survival[35]. TPM1 is an actin-binding protein which is capable of stabilizing microfilaments, regulating both microfilament organization and anchorage-independent growth, so its importance in cell transformation has been highlighted[36]. Another important mechanism of cancer development is epigenetic silencing of tumor suppressor genes. DNA hypomethylation, CpG island hypermethylation and histone-modification losses represent epigenetic markers of malignant transformation[37]. Calin *et al*[22] showed that some miRNA (e.g. miR-127) are located in a CpG island, a region that is involved in several types of translocations identified in hematological cancers and deleted by loss of heterozygosity in solid tumors. This phenomenon gives us a clue that the expression of tumor suppressor can be altered in epigenetic silencing mechanism through expression of miRNA.

Dysplasia and Barrett's esophagus are precursors of EC and the progression of these lesions to cancer is a multistep process that involves different sequential DNA aberrations and changes in gene expression. MiRNA expression profiles in tissues of Barrett's esophagus with high-grade dysplasia were significantly different from

their corresponding normal tissues/EAC tissues, but, no significant difference was found between low-grade dysplasia and paired normal tissues[28]. These observations were consistent with the finding of Feber *et al*[25], which suggests that low-grade dysplasia was with a lower malignant transformation rate compared with high-grade dysplasia. Yang *et al*[28] found that seven miRNAs (hsa-let-7b, hsa-let-7a, hsalet-7c, hsa-let-7f, hsa-miR-345, hsa-miR-494, and hsa-miR-193a) were potentially important in the progression from high-grade dysplasia to EAC. Hsa-let-7b, hsa-let-7a, hsalet-7c and hsa-let-7f belong to the let-7 miRNA family, most of their members function as tumor suppressors through negative regulation of the *RAS* gene[38]. Accordingly, RAS mutations and amplifications have been frequently identified in precancerous tissues and EC tissues[39,40]. Oncogene RAS may play a role in cell growth and differentiation[41].

Diagnostic and prognostic value of miRNA for EC

To date, the available data of miRNA expression profile in cancer suggest that miRNA may have diagnostic and prognostic potential. It is crucial to correlate miRNA expression with tumor subtypes or clinical parameters.

Lu *et al*[16] were the first to systematically demonstrate that the specific miRNA expression can be applied not only for diagnosis but also for classification of different tumors, and the accuracy is 70%. Guo *et al*[6] were the first to investigate the expression of miRNA in EC tissues using miRNA microarray techniques. They found that five miRNAs (miR-335, miR-181d, miR-25, miR-7 and hsa-miR-495) correlate with gross pathologic classification (fungating *vs* medullary) and two miRNAs (miR-25 and miR-130b) correlate with differentiation classification (high *vs* middle *vs* low)[6]. The miRNA expression profiling of ESCC is distinct from EAC[25]. Compared with its expression in normal epithelium (NSE), miR-194, miR-192 and miR200c are significantly up-regulated in EAC but not in ESCC[27]. Oppositely, miR-342 is aberrantly expressed in ESCC but not in EAC[25]. Furthermore, the miRNA expression profiling of NSE and SCC samples are more similar to each other than to the EAC samples[26]. The Barrett's esophagus (BE) samples sit between the EAC and NSE and one high-grade dysplasia specimen has a miRNA expression profile similar to the EAC[24]. This makes good biological sense that miRNA expression profiles can distinguish esophageal tumorigenesis and may be proven useful for identifying BE patients who are at high risk for progression to EAC.

As we mentioned before, the survival and prognosis of EC is dismal. Therefore, the discovery of new prognostic markers could be a prodigious advantage for identification of patients that would benefit from more aggressive therapy. The high expression of both miR-103 and miR-107 has been shown to correlate with poor survival in 53 Chinese patients with ESCC either by univariate analysis or by multivariate analyses[6]. In an independent study of 30 Japanese patients with ESCC, overexpression of miR-129 was found to significantly correlate with a shorter survival and miR-129 was identified as a significant and independent prognostic factor in surgically treated ESCC patients[27]. The largest study so far, found that low expression of miR-375 in EAC patients was strongly associated with worse prognosis, whereas ESCC patients with high expression of miR-21 had poor prognosis[29]. An earlier study conducted by Sugito *et al*[42], measured the expression levels of DICER1, DGCR8, and RNASEN messenger RNA in 73 surgically treated ESCC patients by real-time reverse-transcription PCR, and clarified that high RNASEN expression correlate with poor prognosis in ESCC, indicating that RNASEN may be a good candidate for molecular prognostic marker. Altered expression of these miRNAs is tissue specific, which may provide clues as to the different molecular progression undertaken by these cancers, and opens a potential avenue for targeted therapy to improve prognosis[29].

Circulating microRNAs: Novel minimally invasive biomarkers for EC

Scientists studying on EC are continually dedicated to search for sensitive, and minimally invasive markers which can detect early neoplastic changes, thus identifying EC at an early stage, as well as monitoring the progress of patients with EC and their response to treatment. Existing methods for identification of EC have many inherent deficiencies. Endoscopic biopsy and histopathological examinations are currently the golden standard diagnostic methods for EC. However, it has limitations, including the use of invasive tool and limited number of experienced physicians. Besides, it is difficult to be applied in large-scale studies because of its tedious approaches. To date, there are still no other effective biomarkers established in the routine assessment of EC.

The much desirable biomarker should be sensitive enough and easily accessible to detect the cancer patients at early stage. Recent studies have shown that tumor-derived miRNAs are resistant to endogenous ribonuclease activity so it can be present in human serum in remarkably stable form[43]. Furthermore, the expression level of serum miRNAs is reproducible and consistent among individuals[43,44]. These tumor-derived miRNAs are present in the circulating blood at levels sufficient to be measurable as biomarkers for the detection of tumors and more than 100 circulating miRNAs can be detected in the blood of healthy individuals[43]. Either plasma or serum can be used for identification of these blood-based biomarkers because the miRNAs levels in plasma and serum are strongly correlated[43,45]. Chen *et al*[44] demonstrated that the colorectal cancer patients shared a large number of serum miRNAs with lung cancer patients. Moreover, they identified a unique expression profile of serum miRNAs for colorectal cancers that were not present in lung cancer. Though miRNA research is only emerging recently, it has aroused great interest in clinical and scientific communities. Since the presence of miRNA in serum was first described in patients with diffusive large B-cell lymphoma[46],

a number of studies on other solid cancers (ovarian cancer[47,48], lung cancer[49,50], breast cancer[51], colorectal cancer[52,53]) have been reported about the presence of miRNA in circulation and their potential for use as novel biomarkers. Taylor *et al*[48] demonstrated that the expression of 8 miRNAs in the serum of patients with ovarian cancer were significantly distinct from their expression observed in benign diseases, yet could not be detected in the serum of healthy controls. Another study indicated that miRNA levels were significantly different between lung cancer patients and controls[49]. Both of these studies suggested that there was no significant difference in the miRNA expression between peripheral circulation and tumors tissues[48,49], indicating that circulating miRNA could act as surrogate of tissue miRNA for early diagnosis. And this will initiate a new application that will be widespread in clinical treatment and disease prevention.

Blood-based miRNAs provide a novel class of minimal invasive biomarkers for high-risk subject screening and early diagnosis for cancers. At the time of writing, there was no article about circulating miRNAs profile of EC. We focus on the circulating miRNA expression profiles of ESCC which is the main type of EC, especially in Asia. Checking circulating miRNA expression profiles of ESCC can help identify EC specific circulating miRNAs signatures for a new brand of screening, diagnostic and prognostic biomarkers. Studies can also be performed to clarify the functional role(s) of miRNAs in EC.

Potential in screening, surveillance and treatment of EC

So far, endoscopic biopsy and histopathological examinations are the golden standard for high-risk subject screening and early detection for EC worldwide. We can only identify 1%-2% early carcinomas and 15%-20% precancerous lesions in asymptomatic population aged higher than 35 years in high-incidence areas of EC through endoscopic biopsy and histopathological examinations[3]. Yet nearly 80% asymptomatic populations were in the normal range. In other words, there exists over endoscopic application. Besides, as there are no sufficient experienced physicians in the countryside, the misdiagnosis and missed diagnosis would be inevitable. In addition, standard sterilizing procedure also restricts the wide application of endoscopy in asymptomatic population. Furthermore, the projected cost of mass screening in China for detection of cancers is increasing annually. An urgent and important problem to be solved is to diminish blindness in the screening, minify the range of endoscopy and elevate the detection sensitivity of early carcinoma in high risk subjects. Easily accessible and minimal invasive biomarkers for EC and for other diseases are much desirable. The PCR technique for detection and quantification of miRNA[18] in the blood would be one of the promising methods of screening individuals for EC and other cancers because of its universal application, convenient management, low cost and high sensitivity. Rouet *et al*[54] set up a model of qRT-PCR for serum RNA analysis, suggesting that its cost was only less than £1 for each clinical specimen when used in a group of 84 patients. Once the accuracy of detection is established, MiRNAs test should be introduced into the national EC and other disease screening programs. The best option might be that annual miRNA blood test in asymptomatic populations in high risk areas of EC, and then the patients with positive test result can choose endoscopic biopsy and histopathological examinations for final diagnosis.

Given the emerging evidence of miRNAs acting as oncogenic or tumor suppressor activities, it is important to seek approaches to interfere with the miRNA[55], and eventually, develop these as novel biomarkers into EC therapies. Scientists are making efforts to explore miRNA and utilize that in cancer. Meng *et al*[32] showed that miRNA expression profiles changed during treatment with gemcitabine, and the sensitivity of cholangiocarcinoma tumor cells to this chemotherapy *in vitro* are increasing with the modulation of some miRNAs. On the contrary, it could be feasible to introduce tumor suppressor miRNA which are tissue-specific to the target gene, and then it may help prevent further progression, or even shrink EC. Yet, recently identified genomic and proteomic biomarkers, tumor cell mutations and microsatellite instability cannot be recommended for clinical use because of insufficient available data[56]. Though recent studies on miRNA in EC are limited, the potential value of miRNAs as prognostic and predictive biomarkers in EC is elegantly highlighted and will be elucidated eventually. However, experimental miRNA therapy need to be validated comprehensively through studies involving different cohorts of patients before introduced into clinical practice.

CONCLUSION

Although much of the work on miRNA is still in its infancy, the previous studies have demonstrated the significant role(s) of miRNA in the initiation and progression of cancer and other diseases. Further exploration is required for better understanding their role in carcinogenesis of EC and for better application in the future. Notwithstanding there are still many questions to be answered about circulating miRNA, there is no doubt that further studies will lead to great progress in the future therapy of EC. The exploration of miRNA will improve our knowledge of the roles of these novel biomarkers, and further demonstrate their true potential in therapeutic methods.

Abstract

AIM: To investigate the effects of butyrate on interleukin (IL)-32α expression in epithelial cell lines.

METHODS: The human intestinal epithelial cell lines HT-29, SW480, and T84 were used. Intracellular IL-32α was determined by Western blotting analyses. IL-32α mRNA expression was analyzed by real-time polymerase chain reaction.

RESULTS: Acetate and propionate had no effects on IL-32α mRNA expression. Butyrate significantly enhanced IL-32α expression in all cell lines. Butyrate also up-regulated IL-1β-induced IL-32α mRNA expression. Butyrate did not modulate the activation of phosphatidylinositol 3-kinase (PI3K), a mediator of IL-32α expression. Like butyrate, trichostatin A, a histone deacetylase inhibitor, also enhanced IL-1β-induced IL-32α mRNA expression.

CONCLUSION: Butyrate stimulated IL-32α expression in epithelial cell lines. An epigenetic mechanism, such as histone hyperacetylation, might be involved in the action of butyrate on IL-32α expression.

INTRODUCTION

Interleukin (IL)-32 was originally reported as natural killer (NK) transcript 4, and has been described as a cytokine produced mainly by T-lymphocytes, NK cells, epithelial cells, and blood monocytes[1-3]. The gene encoding IL-32 is located on human chromosome 16p13.3 and is organized into eight exons[4]. There are four splice variants, and IL-32α is reported as the most abundant transcript[5,6]. Recently, IL-32 was defined as a proinflammatory cytokine characterized by the stimulation of secretion of IL-1β, tumor necrosis factor (TNF)-α, IL-6,

and IL-8 *via* the activation of p38 mitogen-activated protein kinases (MAPKs), nuclear factor (NF)-κB and activating protein (AP)-1 signal transduction pathways[3,7]. Recently, we reported the overexpression of IL-32α in the inflamed mucosa of inflammatory bowel disease (IBD)[8]. *In vitro* experiments on human intestinal epithelial cell lines showed that IL-32α expression was induced by IL-1β, IFN-γ and TNF-α through the activation of Akt-phosphatidylinositol 3-kinase (PI3K)[8].

Dietary fiber (nonstarch polysaccharides) and resistant starch escape digestion in the upper gastrointestinal tract, and undergo anaerobic bacterial fermentation in the colon. This process produces short-chain fatty acids (SCFAs), predominantly acetate, propionate, and butyrate, as the major by-products[9,10]. The typical concentration of each SCFA has been reported as approximately 10-20 mmol/L[11]. SCFAs have been shown to have significant effects on the colonic epithelium both *in vivo* and *in vitro*. Butyrate serves as the primary energy source for the normal colonic epithelium[12], and stimulates the growth of the colonic mucosa[13]. However, in tumor cell lines, it induces apoptosis and inhibits cell growth[14]. Butyrate has also been reported to modulate gene transcription through the induction of histone hyperacetylation. Since butyrate inhibits histone deacetylation and induces histone hyperacetylation, it is categorized as a histone deacetylase (HDAC) inhibitor[15].

In the present study, we investigated the *in vitro* effects of the SCFAs on IL-32α expression in human intestinal epithelial cell lines.

MATERIALS AND METHODS

Reagents

Recombinant human IL-1β and TNF-α were purchased from R&D Systems (Minneapolis, MN, USA), and human IFN-γ was obtained from Pepro Tech (Rocky Hill, NJ, USA). SCFAs (sodium acetate, sodium propionate and sodium butyrate) were purchased from Sigma Chemical Co. (Dorset, UK). Biotinylated anti-human IL-32α antibodies were purchased from R&D Systems, and horseradish peroxidase (HRP)-conjugated streptavidin was purchased from Dako Japan (Kyoto, Japan). Antibodies against phosphorylated and total Akt were obtained from Cell Signaling Technology (Beverly, MA, USA). Trichostatin-A was purchased from Tocris Cookson (St. Louis, MO, USA).

Cells

The human intestinal epithelial cell lines HT-29[16], SW480[17], and T84[18] were obtained from the American Type Culture Collection (Manassas, VA, USA). The cells were cultured as described previously[16-18].

Real-time polymerase chain reaction

Total RNA was isolated by the acid guanidinium thiocyanate-phenol-chloroform method, and was then reverse-transcribed into cDNA using a PrimeScript RT reagent kit (TAKARA-BIO, Shiga, Japan). The expression of human IL-32α mRNA was assessed by real-time polymerase chain reaction (PCR) analyses. Real-time PCR was performed using a LightCycler 2.0 system (Roche Applied Science, Tokyo, Japan). The oligonucleotide primers used in this study were specific for human IL-32α as follows: 5'-AGCTGGAGGACGACTTCAAA [nucleotides 192-211, GenBank accession no. BC018782[19,20]] and 3'-AGGTGGTGTCAGTATCTTCA (nucleotides 642-623)]. The PCR was conducted using a SYBR Green PCR Master Mix (Applied Biosystems, Foster City, CA, USA). β-actin was used as an endogenous control to normalize for differences in the amount of total RNA in each sample.

Western blotting analysis

The intracellular expression of IL-32α protein was determined by Western blotting. Briefly, the cells were washed and lysed in sodium dodecyl sulphate (SDS) sample buffer containing 100 μmol/L orthovanadate. The lysates were homogenized, and the protein concentration was measured by the Bradford method. For Western blotting, 10 μg of protein from each sample was subjected to SDS-PAGE on a 4%-20% gradient gel under reducing conditions. The proteins were then electrophoretically transferred onto a nitrocellulose membrane, and the membrane was blocked with 5% skimmed milk. After washing with PBS containing 0.1% Tween-20 (PBST), the membrane was incubated with a biotinylated anti-human IL-32α antibody at 4℃ overnight. Next, the membrane was reacted with HRP-conjugated streptavidin at room temperature for 1 h. The detection was performed using enhanced chemiluminescence (ECL) Western blotting systems (Amersham Biosciences).

Detection of global histone H3 acetylation

Histone extraction and the detection of global histone H3 acetylation were performed using the Epiquik global histone H3 acetylation assay kit (Epigentek; Brooklyn, NY, USA). The histone protein content was detected by the Bradford method.

Statistical analysis

Statistical significance of the differences was determined using unpaired *t* test (Statview version 4.5). Differences resulting in *P* values less than 0.05 were considered to be statistically significant.

RESULTS

Effects of SCFAs on IL-32α mRNA expression

To evaluate the effects of SCFAs on IL-32α mRNA expression, intestinal epithelial cells (HT-29, Caco-2, T84 cells) were stimulated with 10 mmol/L of each SCFA (acetate, propionate, and butyrate) for 12 h, and then the expression of IL-32α mRNA was determined by real-time PCR. Acetate had no effect, but butyrate significantly increased IL-32α mRNA expression in all cell lines. Propionate increased the expression of IL-32α

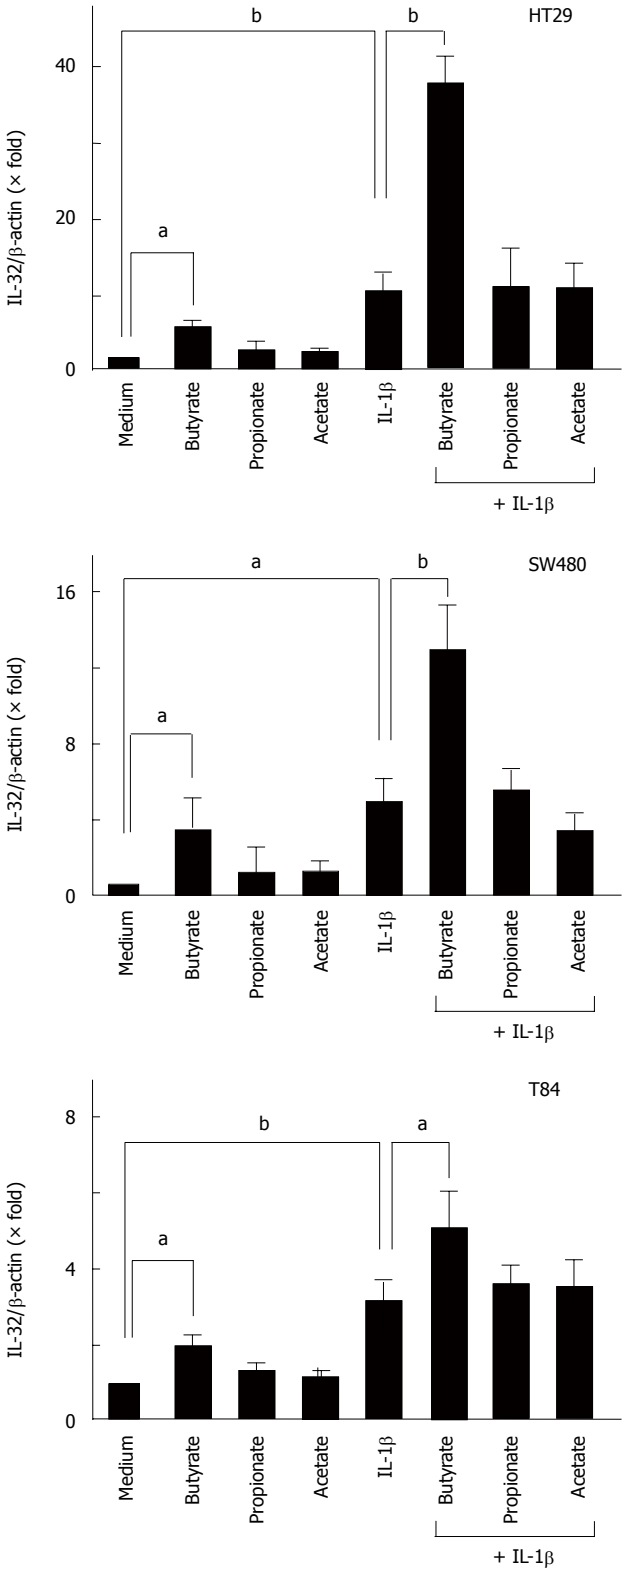

Figure 1 Effects of short-chain fatty acids (SCFAs) on IL-32α mRNA expression in colon cancer cell lines. The cell lines (HT-29, SW480, T84) were incubated for 12 h with each SCFA (10 mmol/L). In another experiment, the cells were stimulated with IL-1β (50 ng/mL) in the presence or absence of each SCFA (10 mmol/L). The IL-32α mRNA expression was determined by real-time PCR. The data are expressed as mean ± SD (n = 4). $^{a}P < 0.05$, $^{b}P < 0.01$.

mRNA only in T84 cells, but in the other cell lines it had no effect (Figure 1).

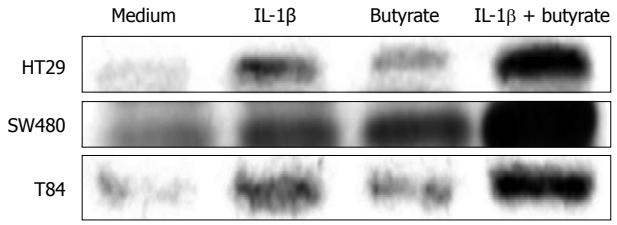

Figure 2 Effects of SCFAs on IL-32α protein secretion in colon cancer cell lines. The cell lines (HT-29, SW480, T84) were stimulated for 48 h with IL-1β (50 ng/mL) in the presence or absence of butyrate (10 mmol/L), and the intracellular IL-32α protein levels were detected by Western blotting.

Effects of SCFAs on cytokine-induced IL-32α mRNA expression

Next, we investigated the effects of SCFAs on cytokine-induced IL-32α mRNA expression. We recently reported that IL-1β, IFN-γ and TNF-α stimulate IL-32α mRNA expression in intestinal epithelial cells[8], and the cells were stimulated with cytokines in the presence or absence of each SCFA (10 mmol/L). In all cell lines, butyrate by itself stimulated IL-32α mRNA expression, and enhanced the IL-1β-induced IL-32α mRNA expression. SCFAs did not modulate IFN-γ- and TNF-α-induced IL-32α mRNA expression in any of the cell lines (data not shown).

Effects of SCFAs on intracellular IL-32α protein accumulation

To confirm the effects of SCFAs on IL-32α protein expression, the cells were stimulated for 48 h with IL-1β and/or SCFAs. Intracellular IL-32α was detected as a 25 kDa protein[8,21]. The effects of the SCFAs were similar to those observed at the mRNA level. The combination of IL-1β and butyrate enhanced IL-32α protein expression additively (Figure 2).

Dose responses

To examine the effects of butyrate on IL-1β-induced IL-32α expression more precisely, HT-29 cells were incubated for 12 h with IL-1β (50 ng/mL) plus increasing concentrations of butyrate. The effects of butyrate on IL-1β-induced IL-32α secretion appeared at the concentration of 5.0 mmol/L, and the most significant difference was observed at 10 mmol/L (Figure 3).

Effects of butyrate on the phosphorylation of Akt

We tested the effects of butyrate on the IL-1β-induced phosphorylation of Akt, which plays a major role in IL-32α induction[8,19]. As shown in Figure 4, there were no effects of butyrate on IL-1β-induced Akt phosphorylation. These observations suggest that the modulation of Akt activity is not involved in the actions of butyrate on IL-1β-induced IL-32α expression.

Effects of trichostatin-A on cytokine-induced IL-32α mRNA expression

Previous studies have demonstrated that butyrate exerts its biological effects through the induction of histone

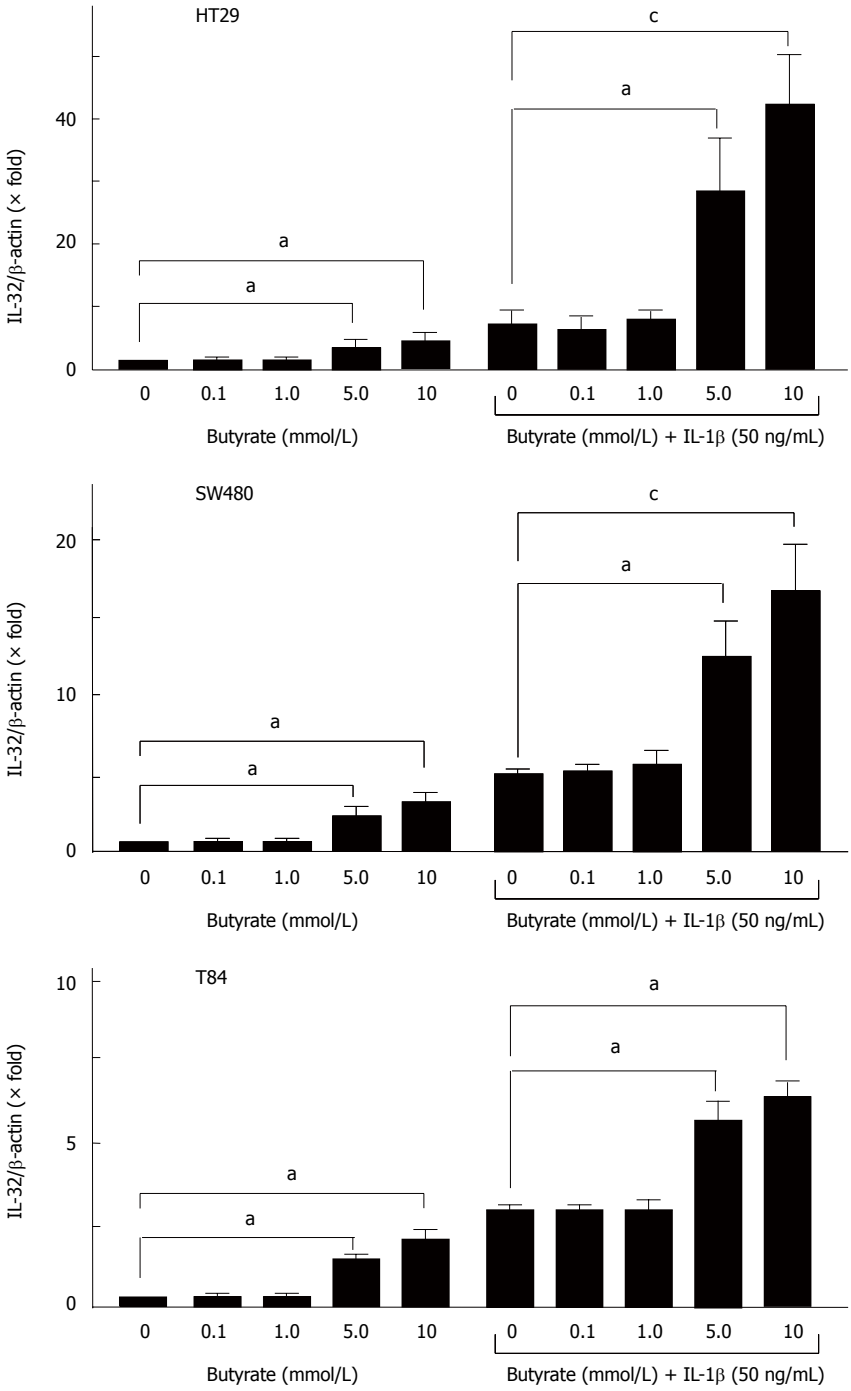

Figure 3 Dose-dependent effects of butyrate on IL-1β-induced IL-32α mRNA expression in colon cancer cell lines. The cell lines (HT-29, SW480, T84) were stimulated for 12 h with increasing concentrations (0-10 mmol/L) of butyrate in the presence or absence of IL-1β (50 ng/mL). IL-32α mRNA expression was then analyzed by real-time PCR. The data are expressed as mean ± SD (n = 4). [a]$P < 0.05$, [c]$P < 0.005$.

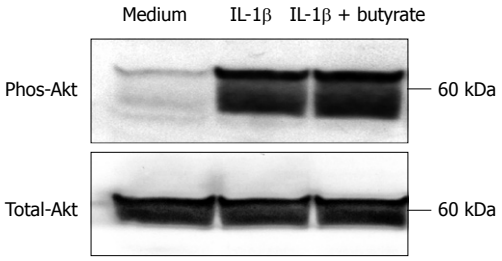

Figure 4 Effects of butyrate on Akt phosphorylation. The cells were stimulated in the presence of butyrate (5 mmol/L) and/or IL-1β (50 ng/mL) for 15 min, and then Akt phosphorylation was determined by Western blotting.

hyperacetylation[15]. To examine the relationship between histone acetylation and the effects of butyrate on IL-32α mRNA expression, we tested the effects of trichostatin-A (TSA), a potent histone deacetylase inhibitor[22-24].

The cells were stimulated with cytokines in the presence or absence of TSA (5 μmol/L), and the expression of IL-32α mRNA was then analyzed by real-time PCR. As shown in Figure 5, TSA enhanced the IL-1β-induced IL-32α mRNA expression in all cell lines.

Effects on histone H3 acetylation

We tested the effects of butyrate and IL-1β on histone H3 hyperacetylation in HT-29 cells. As shown in Figure 6, butyrate induced histone H3 hyperacetylation in HT-29 cells (Figure 6).

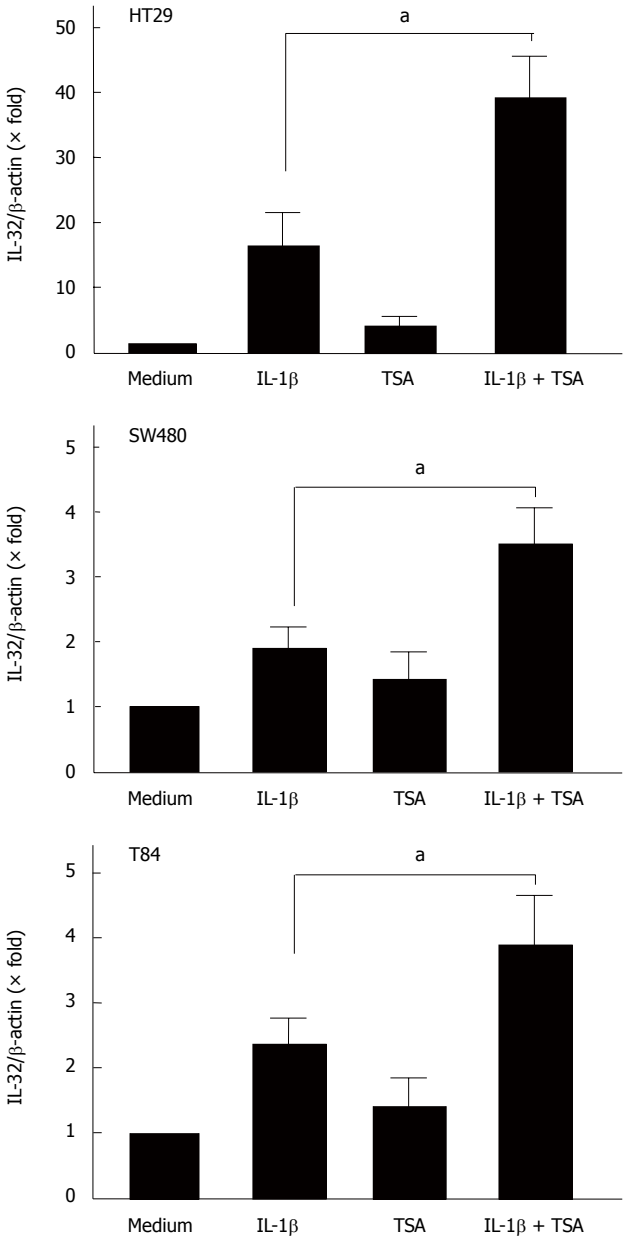

Figure 5 Effects of trichostatin-A (TSA) on IL-32α mRNA expression. The cells (HT-29, SW480, T84) were incubated for 12 h with IL-1β (50 ng/mL) in the presence or absence of TSA (5 μmol/L), and then the IL-32α mRNA expression was determined by real-time PCR. The data are expressed as mean ± SD (n = 4). $^{a}P < 0.05$.

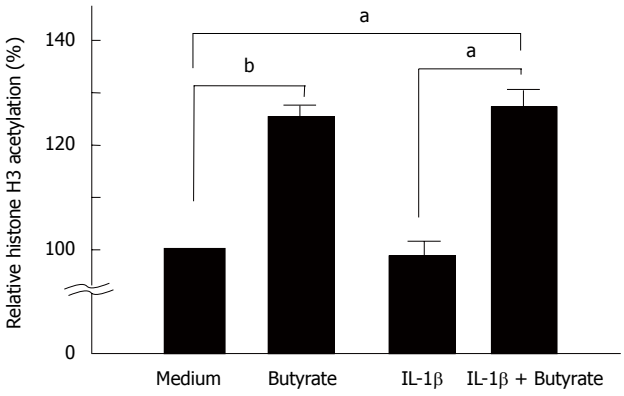

Figure 6 Effects of butyrate on histone H3 acetylation. HT-29 cells were stimulated for 12 h with IL-1β (50 ng/mL) in the presence or absence of butyrate (10 mmol/L). Histone H3 acetylation was then detected by histone H3 acetylation assay kits (Epigentek; Brooklyn, NY, USA). Histone H3 acetylation was expressed as a value relative to medium alone. The data are expressed as mean ± SD (n = 4). $^{a}P < 0.05$, $^{b}P < 0.01$.

DISCUSSION

Among SCFAs, the biological actions of butyrate have been well investigated. Butyrate is easily absorbed in the large intestine, and plays a role as the energy source for intestinal epithelial cells[13]. On the other hand, previous studies have demonstrated that butyrate blocks NF-κB activation in intestinal epithelial cells, and is thought to have an anti-inflammatory effect[25,26]. Based on this hypothesis, some clinical trials have been performed to test the therapeutic effects of butyrate enemas on ulcerative colitis lesions[27-29].

In this study, we examined the effects of SCFAs on IL-32α expression in intestinal epithelial cells. Initially, we hypothesized that SCFAs, in particular butyrate, might suppress IL-32α expression in these cells, since IL-32α expression has been reported to depend on NF-κB activation, and butyrate has been reported to suppress NF-κB activation. However, contrary to our initial expectation, butyrate stimulated IL-32α expression in these cells. This was characterized by two actions: butyrate by itself could stimulate IL-32α expression, and the synergistic effects of butyrate on cytokine-induced IL-32α expression was observed specifically in combination with IL-1β.

Recently, we reported that IL-32 expression mainly depends on the Akt-PI3K signaling pathway and NF-κB activation. As shown in Figure 6, butyrate did not affect Akt phosphorylation, indicating that the Akt-PI3K pathway was not involved in butyrate-mediated IL-32 expression. Furthermore, we have previously shown that butyrate inhibits IL-1β-induced NF-κB activation in HT-29 cells[26,30,31]. This suggests that the modulation of NF-κB activation is not involved in the effects of butyrate on IL-1β-induced IL-32 expression. This concept is supported by the finding that butyrate did not affect IL-32 expression by TNF-α, which is a potent stimulator of NF-κB activation[32,33]. Thus, the mode of action of butyrate on IL-32 expression in intestinal epithelial cells is mediated by different mechanisms from those reported previously.

It is generally accepted that butyrate leads to the development of reversible histone hyperacetylation *via* the inhibition of histone deacetylase activity[14,15]. Reversible histone hyperacetylation is now believed to play an important role in the regulation of chromatin structure[34,35]. Histone hyperacetylation leads to a more relaxed chromatin structure, and thus facilitates transcription factor access to the promoter regions of certain genes without directly initiating gene transcription[23,24]. Based on this knowledge, the mechanisms by which butyrate selectively induces the increase in IL-1β-induced IL-32 gene expression might be explained by an enhancement of transcription by histone hyperacetylation. This was supported by the effects of trichostatin A, a potent histone deacetylase

inhibitor, on IL-32 expression in these cells. On the other hand, although the precise molecular mechanisms remain to be investigated, increased transcriptional activity by histone hyperacetylation might not account for the effects of TNF-α- and IFN-γ-on IL-32 expression. In order to clarify the precise mechanisms by which butyrate specifically stimulates IL-1β-stimulated IL-32 expression, further studies such as the effects of butyrate on signaling pathways to induce IL-32 expression are needed.

Clinical application of this study is limited because the role of IL-32α in inflammatory bowel disease (IBD) is still obscure. Netea *et al*[2] demonstrated recently that IL-32 augments the production of IL-1α, TNF-α, IL-6 and IL-8 by means of the nucleotide-binding oligomerization domain proteins (NOD1 and NOD2) through a caspase-1-dependent mechanism. NODs are a family of intracytoplasmic bacterial peptidoglycans which subsequently induce NF-κB activation. Mutations in *NOD2* have been implicated in the pathogenesis of Crohn's disease (CD). Recently, it has been shown that the *NOD2* mutation in CD patients potentiates NF-κB activity and IL-1α processing. Thus, these findings suggest a pivotal role of IL-32 in the pathophysiology of IBD, and CD in particular. Our study also augments the proinflammatory aspect of butyrate.

In conclusion, we observed that butyrate stimulates IL-32α expression in intestinal epithelial cells. Since IL-32α is considered to be a proinflammatory cytokine, our finding might be a part of the proinflammatory picture of butyrate in mucosal inflammatory responses in the intestine. As the next step, the *in vivo* effects of butyrate on mucosal IL-32 expression should be investigated in the future.

COMMENTS

Background

Recently, interleukin (IL)-32 was defined as a proinflammatory cytokine characterized by the stimulation of secretion of IL-1β, tumor necrosis factor (TNF)-α, IL-6, and IL-8. Dietary fiber (nonstarch polysaccharides) and resistant starch escape digestion in the upper gastrointestinal tract, and undergo anaerobic bacterial fermentation in the colon. This process produces short-chain fatty acids (SCFAs), predominantly acetate, propionate, and butyrate, as the major by-products.

Research frontiers

The authors have previously reported that IL-32α is overexpressed in inflammatory bowel disease (IBD). IL-32α was overexpressed in the inflamed mucosa of IBD patients and was strongly induced by IL-1β, IFN-γ and TNF-α. However, the role of IL-32α is yet to be elucidated. In this study, they investigated the *in vitro* effects of butyrate on IL-32α expression in human intestinal epithelial cell lines.

Innovations and breakthroughs

The authors observed that butyrate stimulates IL-32α expression in intestinal epithelial cells. Since IL-32α is considered to be a proinflammatory cytokine, their finding might be a part of the proinflammatory picture of butyrate in mucosal inflammatory responses in the intestine.

Applications

Clinical application of this study is limited because the role of IL-32α in IBD is still obscure. A recent report demonstrated that IL-32 augments the production of IL-1α, TNF-α, IL-6 and IL-8 by means of the nucleotide-binding oligomerization domain proteins (NOD1 and NOD2) through a caspase-1-dependent mechanism. NODs are a family of intracytoplasmic bacterial peptidoglycans which subsequently induce NF-κB activation. Mutations in *NOD2* have been implicated in the pathogenesis of Crohn's disease (CD). Recently, it has been shown that the *NOD2* mutation in CD patients potentiates NF-κB activity and IL-1α processing. Thus, these findings suggest a pivotal role of IL-32 in the pathophysiology of IBD, and CD in particular. This study also augments the proinflammatory aspect of butyrate.

Terminology

IL-32 was originally reported as natural killer (NK) transcript 4, and has been described as a cytokine produced mainly by T-lymphocytes, NK cells, epithelial cells, and blood monocytes. The gene encoding IL-32 is located on human chromosome 16p13.3 and is organized into eight exons. There are four splice variants, and IL-32α is reported as the most abundant transcript. Recently, IL-32 was defined as a proinflammatory cytokine characterized by the stimulation of secretion of IL-1β, TNF-α, IL-6, and IL-8 *via* the activation of p38 mitogen-activated protein kinases, nuclear factor (NF)-κB and activating protein-1 signal transduction pathways. Recently, the authors reported the overexpression of IL-32α in the inflamed mucosa of IBD. *In vitro* experiments on human intestinal epithelial cell lines showed that IL-32α expression was induced by IL-1β, IFN-γ and TNF-α through the activation of Akt-phosphatidylinositol 3-kinase.

Peer review

Kobori *et al* present an interesting study of a novel pro-inflammatory cytokine IL-32. They investigated the effects of butyrate on IL-32α expression in epithelial cell lines.

Abstract

AIM: To investigate whether dicoumarol, a potent inhibitor of NAD(P)H quinone oxidoreductase-1 (NQO1), potentiates gemcitabine to induce cytotoxicity in cholangiocarcinoma cells (CCA) and the role of reactive oxygen generation in sensitizing the cells.

METHODS: Four human cell lines with different NQO1 activity were used; the human CCA cell lines, KKU-100, KKU-OCA17, KKU-M214, and Chang liver cells. NQO1 activity and mRNA expression were determined. The cells were pretreated with dicoumarol at relevant concentrations before treatment with gemcitabine. Cytotoxicity was determined by staining with fluorescent dyes. Oxidant formation was examined by assay of cellular glutathione levels and reactive oxygen species production by using dihydrofluorescein diacetate. Measurement of mitochondrial transmembrane potential was performed by using JC-1 fluorescent probe. Western blotting analysis was performed to determine levels of survival related proteins.

RESULTS: Dicoumarol markedly enhanced the cytotoxicity of gemcitabine in KKU-100 and KKU-OCA17, the high NQO1 activity and mRNA expressing cells, but not in the other cells with low NQO1 activity. Dicoumarol induced a marked decrease in cellular redox of glutathione in KKU-100 cells, in contrast to KKU-M214 cells. Dicoumarol at concentrations that inhibited NQO1 activity did not alter mitochondrial transmembrane potential and production of reactive oxygen species. Gemcitabine alone induced activation of NF-κB and Bcl-$_{xL}$ protein expression. However, gemcitabine and dicoumarol combination induced increased p53 and decreased Bcl-$_{xL}$ levels in KKU-100, but not in KKU-M214 cells.

CONCLUSION: NQO1 may be important in sensitizing cells to anticancer drugs and inhibition of NQO1 may be a strategy for the treatment of CCA.

INTRODUCTION

NAD(P)H quinone oxidoreductase-1 (NQO1 or DT-diaphorase) is a ubiquitous flavoprotein localized widely in body tissues. It is an obligated two-electron reductase that reduces quinones to hydroquinones, thus bypassing the toxic semiquinone intermediates, and these resultant hydroquinones are thus ready for further conjugation and excretion[1]. Several functions of NQO1 have been proposed including xenobiotic detoxification, superoxide scavenging, maintenance of endogenous antioxidant, modulation of p53 and proteasomal degradation[2-4]. It is conceivable that NQO1 functions primarily to protect normal cells from oxidant stress and electrophilic attack. A number of experimental models and epidemiological studies support the concept that intake of dietary phytochemicals confers a cancer chemoprevention effect and these chemicals have been shown to induce increased expression of phase Ⅱ drug detoxifying enzymes including NQO1[5,6]. The cytoprotective role of NQO1 is supported by reports that disruption of the *NQO1* gene or genetic polymorphism increase the risk of chemical-induced toxicity and carcinogenesis[7,8]. The expressions of *NQO1* and antioxidant enzymes are recognized as an adaptive response to chemical stress[6,9]. On the other hand, analysis of several solid tumors found an over-expression of the *NQO1* gene in cancers of the liver, thyroid, breast, colon, lung, and pancreas[10,11]. Under these circumstances, NQO1 probably functions to protect cancer cells by eliminating oxidant species and making cells resistant to anticancer drugs that induce oxidative injury[12].

Inhibition of NQO1 activity by dicoumarol has been shown to suppress urogenital and pancreatic cancer cell growth and potentiate cytotoxicity of cisplatin and doxorubicin[13,14]. The inhibition of NQO1 with dicoumarol was suggested to stimulate formation of superoxide, oxidative stress and subsequent suppression of pancreatic cancer cell growth and induction of apoptosis[15,16]. However, dicoumarol has been shown to induce formation of reactive oxygen species (ROS) independently from NQO1 activity by inhibition of the mitochondrial electron transport chain[17]. Therefore, the question as to whether inhibition of NQO1 renders cancer cells more sensitive to chemotherapeutic agents is still not clear. More study is necessary to define the role of NQO1 in cancer cells. Sensitizing cancer cells to be more susceptible to radiotherapy or chemotherapy may be an important strategy to overcome resistance in cancer chemotherapy.

Cholangiocarcinomas (CCA) are rare types of liver cancers arising from the biliary duct system. Surgical resection with a histologically free margin is the only chance for cure[18]. Unfortunately, only few patients are eligible for surgery. Furthermore, current chemotherapy and radiotherapy regimens do not substantially improve survival in CCA patients[18,19]. Gemcitabine has been the most important nucleoside analog which has wide spectrum activity against various solid and hematological tumors[20]. It shows some efficacy and is well tolerated in CCA patients[21]. It is essential to gain insight into molecular mechanisms by which cancer cells operate to survive and evade the attack by chemotherapeutic agents.

Because NQO1 appears to be a potential target for exploitation in cancer chemotherapy, we investigated whether dicoumarol, a potent inhibitor of NQO1, sensitized CCA cells to respond to the cytotoxicity of gemcitabine. Furthermore, we examined whether dicoumarol- and gemcitabine-induced cell killing was associated with ROS generation, mitochondrial dysfunction and apoptotic protein expression.

MATERIALS AND METHODS

Human cell line cultures

Three human CCA cell lines established in our institute, KKU-100, KKU-OCA17 and KKU-M214, were derived from human intrahepatic CCA tissues with the histological types of poorly differentiated, well differentiated and moderately differentiated adenocarcinoma, respectively[22,23]. Chang liver cells were also used in the study. CCA cells and Chang liver cells were routinely cultured as previously described[24] in Ham's F12 media, supplemented with 4 mmol/L L-glutamine, 12.5 mmol/L N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid (HEPES), at pH 7.3, 100 U/mL penicillin 100 μg/mL streptomycin sulfate and 10% fetal calf serum. The media was renewed every 3 d, trypsinized with 0.25% trypsin-EDTA and subcultured in the same media.

NQO1 activity assay

NQO1 assay was performed essentially according to a previously published method[25]. Cells were seeded onto 96-well cultured plates overnight. Cells were then lysed with 50 μL of 0.8% digitonin in 2 mmol/L EDTA at room temperature for 10 min. The assay was performed using menadione and MTT [3-(4,5-dmethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide, a tetrazole] in the substrate coupling reaction and measured as rate-kinetics in a micro-plate reader at a wavelength of 620 nm. The initial velocity of reaction was calculated as NQO1 activity using the extinction coefficient of formazan of MTT of 11 300 L/mol per cm and correction factor for the light path. In the determination of the enzymatic property of NQO1 in each cell line, cells were incubated with varying concentrations of dicoumarol for 10 min before carrying out assays as above.

Cytotoxicity assay

CCA cells (KKU-100, KKU-OCA17, and KKU-M214) and Chang liver cells were seeded onto 96-well cultured plates at a density of 5×10^3 cells/well (KKU-M214 and Chang cells) or 7.5×10^3 cells/well (KKU-100 and KKU-OCA17) for an overnight, then media was renewed with fresh media containing test compound and further incubated for the indicated times. The cytotoxicity was determined by fluorescence microscopy[26]. In brief, cells were washed once with phosphate-buffered saline (PBS) and the following added: 4 μL mixture of acridine orange, ethidium bromide (each 1 μg/mL) and trace amount of he-

moglobin. The cells were examined using a Nikon Eclipse TS100 inverted microscope with excitation and emission filters of 480 and 535 nm, respectively. The microphotographs were taken at predetermined three areas per well in triplicate wells per concentration with a Nikon Coolpix digital camera. The numbers of viable and non-viable cells were counted. The viable cells were colored green with intact nuclei. The non-viable cells included necrotic and apoptotic cells which showed bright orange staining and green fluorescence, with appearance of cell shrinkage and condensation and fragmentation of the nuclei, respectively. The antiproliferation value was calculated as = (number of viable cells in control wells - viable cells in treatment wells)/(number of viable cells in control wells) × 100.

Determinations of glutathione and glutathione disulfide

Total glutathione assay was performed essentially according to Tietze methods[27]. Glutathione disulfide (GSSG) was assayed by the previously described method[28] using 1-methyl-2-vinylpyridinium triflate (M2VP) as a glutathione scavenger. Cell cultures were trypsinized and washed three times with cold PBS buffer and centrifuged at 1500 *g*, 4℃ for 10 min and resuspended in PBS buffer. Cell suspension of 100 μL was reacted with M2VP (33 mmol/L in DI) or without M2VP. The solution was mixed gently and stored frozen at -20℃ until analysis. An aliquot of cell suspension was saved for protein determination by Bradford's dye binding assay.

Measurement of mitochondrial transmembrane potential

To measure the change in mitochondrial transmembrane potential ($\Delta\Psi_m$), the lipophilic cation fluorescent dye JC-1 (5,5',6,6'-tetrachloro-1,1',3,3'-tetraethyl-benzimidazolylcarbocyanine iodide) was used. After treatment with dicoumarol, gemcitabine or the combination at defined period of times, cultured cells were loaded with JC-1 mitochondrial membrane potential assay kit (Clayman Chemical, Ann Arbor, Michigan) by incubation for 30 min at 37℃. After that, cultured cells were rinsed, incubated in JC-1 assay buffer and mitochondrial transmembrane potential was analyzed by a fluorescent plate reader. In healthy mitochondria, JC-1 forms J-aggregates which display strong fluorescent intensity with excitation and emission wavelength at 560 and 595 nm, respectively. In depolarized mitochondria, JC-1 exists as J monomers which show strong fluorescence with excitation and emission wavelength at 485 and 535 nm, respectively. The shift down in ratio of fluorescent intensity of JC-1 aggregates to fluorescent intensity of monomers is used as an indicator of depolarization of $\Delta\Psi_m$.

Determination of formation of reactive oxygen species

Reactive oxygen species (ROS) levels generated from cultured cells were determined by incubating the cells in Hank's buffer supplemented with 15 mmol/L HEPES containing 1.2 μg/mL dihydrofluorescein diacetate (H_2-DHFDA) (Sigma-Aldrich, St. Louis, MO) for 30 min at 37℃. H_2-DHFDA was taken up into the cells, hydrolyzed and oxidized to the fluorescent product DHF by ROS. The fluorescent signal was determined by a fluorescent plate reader with a setting of the excitation and emission wavelengths at 485 and 520 nm, respectively.

RNA isolation and reverse transcription-polymerase chain reaction

Total RNA was extracted from liver tissues and the four cell lines using Trizol®LS reagent following the manufacturer's instructions. Total RNA (3 μg) was reverse-transcribed in 20 μL containing 0.5 μg of oligo(dT)$_{15}$ primer, 20 U of RNasin® ribonuclease inhibitor and 200 U of ImProm-Ⅱ™ reverse transcriptase in 10 × PCR buffer, 3 mmol/L $MgCl_2$, and 1 mmol/L dNTPs. The first-strand cDNA was synthesized at conditions of 42℃ for 60 min. The reverse transcription products served as a template for real-time PCR. PCR amplification was performed using specific primers for the NQO1 and the internal control using FDFT1. The PCR primer sequences were as follows: NQO1; forward primers: 5'GGCAGAAGAGCACTGATCGTA3', NQO1; reverse primers: 5'TGATGGGATTGAAGTTCATGGC3', GenBank accession number BC007659.2, FDFT1; forward primers: 5'TTTAACTTCTGTGCTATTCCAC3', FDFT1; reverse primers: 5'TCTCCAGTCTGAACATAGTC3', GenBank accession number NM_004462.3. The real-time fluorescence PCR, based on SYBR Green, was carried out in a final volume of 20 μL containing 1 × SYBR Green PCR Master Mix (DyNAmo™ Flash SYBR® Green qPCR Kit), 0.5 μmol/L of each NQO1 or FDFT1 primer. Thermal cycling was performed for each gene in duplicate on cDNA samples in 96-well reaction plates using the ABI 7500 Sequence Detection system (Applied Biosystems). A negative control was included in the experimental runs. The negative control was set up by substituting the template with deionized H_2O and this routinely had a high Ct value which represented the lower detection limit. Real-time PCR was conducted with the following cycling conditions: 95℃ for 10 min, followed by 40 cycles of 95℃ for 15 s, 55℃ for 30 s and 72℃ for 45 s. To verify the purity of the products, a melting curve analysis was produced after each run. Upon completion of 40 PCR amplification cycles, there was a dissociation step of ramping temperature from 60℃ to 95℃ steadily for 20 min, while the fluorescence signal was continually monitored, for melting curve analysis. The relative expression ratio (R) of target genes is calculated based on efficiency (E) and Ct deviation and expressed in comparison to a reference gene. The corresponding real time PCR efficiencies were calculated according to the equation $E = 10^{[-1/slope]}$. All data were analyzed using Sequence Detector Software Version 1.4 (Applied Biosystems).

Western blotting analysis of whole cell and nuclear protein extracts

The whole cell lysates and nuclear protein were prepared according to a previous report[29]. Treated KKU-100 and KKU-M214 cells were washed with PBS, collected and lysed at 4℃ with cell lysis buffer [20 mmol/L Tris-HCl (pH 7.5), 150 mmol/L NaCl, 1 mmol/L Na_2EDTA, 1 mmol/L EGTA, 1% Triton, 2.5 mmol/L sodium py-

rophosphate, 1 mmol/L β-glycerophosphate, 1 mmol/L Na_3VO_4, 1 μg/mL leupeptin, 1 mmol/L dithiothreitol, 0.1 mmol/L phenylmethylsulfonyl fluoride (PMSF)] with vigorous shaking. Following centrifugation at 10000 *g* for 15 min, supernatant was collected and stored at -80℃ until use. Nuclear protein was prepared by lysis of cultured cells with hypotonic buffer A [10 mmol/L HEPES-KOH pH 7.9, 1.5 mmol/L $MgCl_2$, 10 mmol/L KCl, 0.5 mmol/L DTT, 0.2 mmol/L PMSF, 0.1 mmol/L EGTA], incubated in an ice bath for 15 min and then 1% NP-40 was added, cells were centrifuged at 12000 *g*, 4℃ for 15 min, the nuclear pellet was resuspended in ice-cold buffer B (20 mmol/L HEPES-KOH pH 7.9, 25% glycerol, 1.5 mmol/L $MgCl_2$, 420 mmol/L NaCl, 0.2 mmol/L EDTA, 0.5 mmol/L DTT, 0.2 mmol/L PMSF, and 1 mmol/L EGTA), followed by incubation at 0℃ for 45 min. After vortex mixing, the suspension was centrifuged at 12000 *g*, 4℃ for 30 min. The supernatant containing nuclear proteins was stored at -80℃ for the NF-κB Western immunoblot analysis.

The protein samples were mixed with 5 × loading dye buffer, heated at 95℃ for 5 min and proteins were separated by electrophoresis in 10% SDS-polyacrylamide gel. Proteins were transferred to polyvinylidene difluoride (PVDF) membranes at 50 V for 2 h. The PVDF membranes were blocked for 1 h at room temperature with 5% (w/v) skimmed milk powder in Tris buffer saline (TBS) with 0.1% Tween-20. PVDF membrane was incubated overnight at 4℃ with primary antibodies of rabbit polyclonal IgG NF-κB p65 subunits (dilution 1:500) (sc-109: Santa Cruz Biotechnology), mouse monoclonal IgG Bcl-xL (1:1000) (sc-8392), rabbit polyclonal IgG Bax (1:2000) (sc-493), rabbit polyclonal IgG cyclin D1 (1:1500) (sc-718), and mouse monoclonal IgG1 β-actin (1:2500) (sc-8432) diluted with TBS. The primary antibody was then removed and the blots were extensively washed with TBS/Tween-20. Blots were then incubated for 2 h at room temperature with the secondary antibody horseradish peroxidase goat anti-mouse IgG (sc-2005) and goat anti-rabbit IgG (sc-2004) at 1:5000 dilutions in TBS buffer. After removal of the secondary antibody and washes in TBS buffer, the blots were incubated in the ECL substrate solution (Supersignal® West Pico Chemiluminescent Substrate). Densities of the specific bands of NF-κB, Bcl-xL, Bax, cyclin D1, and β-actin were visualized and captured by Imagequant 350 (GE Healthcare).

Statistical analysis

Data are expressed as mean ± SE of duplicate assays from three independent experiments. An analysis of variance with repeated measurement was used to determine significant differences between each experimental group. The level of significance was set at $P < 0.05$.

RESULTS

Activity and expression of NQO1 in CCA cells

Three CCA cell lines with different histological backgrounds were employed in this study for assessing the status of NQO1. The CCA cells illustrated varying degrees of NQO1 activity and mRNA expression. KKU-100 and KKU-OCA17 cells had high NQO1 activity, whereas KKU-M214 showed low NQO1 activity. Moreover, Chang liver cells, which were derived from normal liver tissue, showed relatively low NQO1 activity and were comparable to KKU-M214 cells (Figure 1A). Consistently, NQO1 mRNA expression in KKU-100 cells showed higher levels than in the other cell lines (Figure 1B).

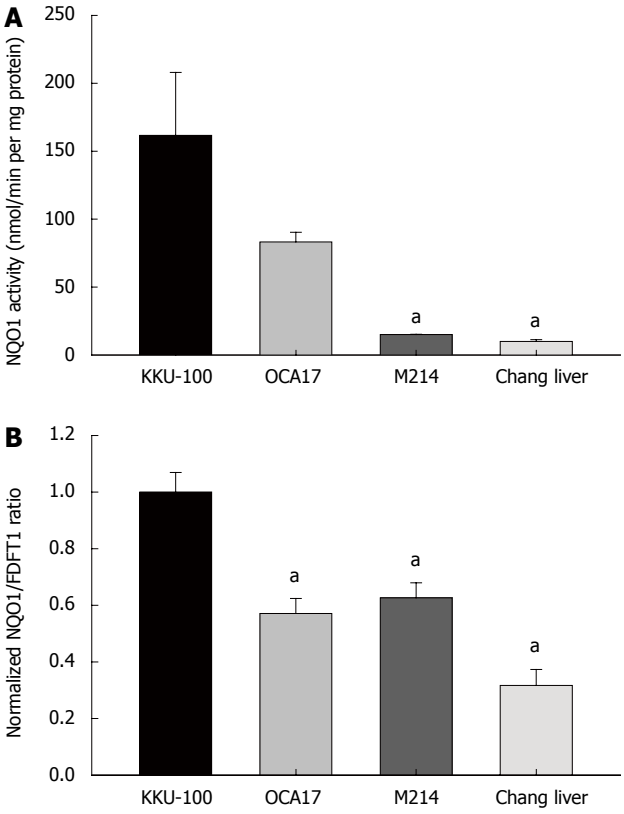

Figure 1 NQO1 activity and mRNA expression of cultured cells. A: NQO1 activity: Cholangiocarcinoma cells, KKU-100, KKU-OCA17, KKU-M214, and Chang liver cells were cultured in 96-well plates for assay of NQO1 activity by enzymatic methods; B: Expression of NQO1 mRNA: The cells were cultured in 6-well plates. Total RNA was extracted by Trizol reagent, converted to cDNA and analyzed by real-time PCR using FDFT1 as internal control. Bars represent mean ± SE, each from 3 experiments. $^aP < 0.05$ *vs* control group.

Sensitivity of NQO1 to dicoumarol

Dicoumarol is a very potent inhibitor of NQO1 activity. All four cell lines were tested against dicoumarol. NQO1 in CCA and Chang cell lysates were assayed for kinetics of inhibition by dicoumarol. The inhibition of NQO1 activity was rapid, within 10 min, and was apparent with a comparable potency among the 4 cell lines (Figure 2) with IC50 of 0.15 ± 0.07, 0.15 ± 0.07, 0.24 ± 0.14 and 0.10 ± 0.22 μmol/L for KKU-100, KKU-OCA17, KKU-M214 and Chang cells, respectively. Since the enzyme activity in all cell lines was almost completely abolished at a dicoumarol concentration of 10 μmol/L, in subsequent experiments dicoumarol was used at the concentration of 10 μmol/L.

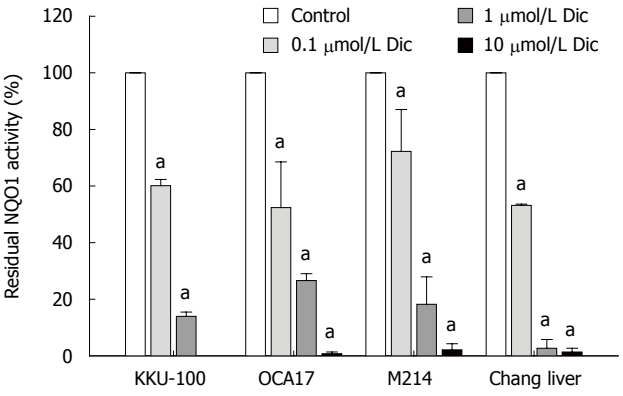

Figure 2 Concentration response of NQO1 inhibition by dicoumarol. KKU-100, KKU-OCA17, KKU-M214, and Chang liver cells were cultured in 96-well plates overnight. The NQO1 activity was assayed in the presence of the inhibitor dicoumarol at concentrations from 0.1-10 μmol/L. Bars represent mean ± SE, each from 3 experiments. $^aP < 0.05$ *vs* control group.

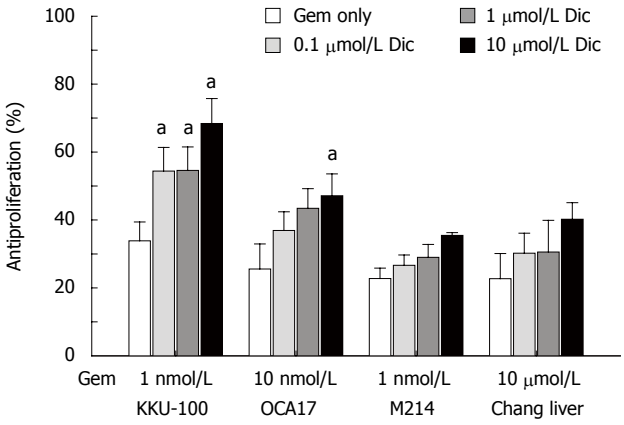

Figure 3 Potentiation of cytotoxicity of gemcitabine by dicoumarol. KKU-100, KKU-OCA17, KKU-M214, and Chang liver cells were cultured in 96-well plates overnight. Cultured cells were pretreated with dicoumarol (0.1-10 μmol/L) for 4 h before treatment with gemcitabine at 1 nmol/L, 10 nmol/L, 1 nmol/L and 10 μmol/L, for KKU-100, KKU-OCA17, KKU-M214, and Chang liver cells, respectively. Antiproliferation was analyzed by staining the cells with fluorescent dyes before examination under fluorescent microscope. Bars represent mean ± SE, each from 3 experiments. $^aP < 0.05$ *vs* control group.

Enhancement of cytotoxicity of gemcitabine by dicoumarol

To investigate whether inhibition of cellular NQO1 activity was associated with increased anticancer drug sensitivity, CCA cells were preincubated with dicoumarol at varied concentrations for 4 h followed by an addition of gemcitabine at predetermined concentrations. The concentrations of gemcitabine that caused cytotoxicity of about 20%-30% were used in the experiments. Those for KKU-100, KKU-OCA17, KKU-M214 and Chang cells were 1, 10, 1 nmol/L and 10 μmol/L, respectively. Treatment with dicoumarol alone at concentrations of 0.1-10 μmol/L caused modest cytotoxicity after incubation for 24 h. Dicoumarol at a concentration of 10 μmol/L induced ⩽ 10% cytotoxicity in all cell types.

Combination of gemcitabine and dicoumarol produced a markedly enhanced cytotoxic effect, particularly in KKU-100 and KKU-OCA17 cells. The enhanced cytotoxic effect in both cell lines was conceivably more than a simple additive effect of the drug and dicoumarol (Figure 3). The cytotoxicity of gemcitabine in KKU-100 cells was enhanced from 34% to 68% and in KKU-OCA17 cells from 25% to 47% in the presence of dicoumarol. On the other hand, the drug combination produced only an additive cytotoxicity in KKU-M214 and Chang cells, i.e. increased from 23% to 36% and 23% to 40%, respectively. It is noted that KUU-100 and KKU-OCA17 cells are high NQO1 activity cells when compared with KKU-M214 and Chang cells.

Dicoumarol-induced oxidative stress in CCA cells

The interactive effect of dicoumarol with gemcitabine in enhancing cytotoxicity was explored with regard to whether dicoumarol induced cellular stress, rendering the cells more susceptible to gemcitabine. In this study, KKU-100 and KKU-M214 cells were employed as representatives of high and low NQO1 activity cells, respectively. The basal total GSH levels in KKU-M214 were higher than that in KKU-100 cells and significantly increased by the treatment with dicoumarol (10 μmol/L) (Figure 4A). On the other hand, glutathione disulfide (GSSG) levels in KKU-100 were dramatically increased with the treatment of dicoumarol, whereas the levels in KKU-M214 were decreased (Figure 4B). This indicates that the two cell types have different oxidative responses after the treatment with dicoumarol.

Determination of the mitochondrial transmembrane potential and formation of reactive oxygen species

Disruption of $\Delta\Psi_m$ is recognized as one of the critical steps leading to apoptotic cell death. The integrity of the inner mitochondrial membrane can be assessed by monitoring of the potential gradient across the membrane using the fluorescent dye JC-1. There was no change in $\Delta\Psi_m$ in cells after treatment with dicoumarol, gemcitabine or the drug combination in both cell types, at an early time (6 h) as well as at 24 h (Figure 5A and B). In contrast, dicoumarol at excessive concentrations (50 and 150 μmol/L) showed a rapidly depolarized $\Delta\Psi_m$, as shown by decrease in the ratio of fluorescent intensity of JC-1 aggregates/JC-1 monomers after 3 h incubation (Figure 5C). The formation of ROS by cultured cells was monitored by a fluorescent dye, DHFDA. It was apparent that there was no increase in ROS formation in cells treated with dicoumarol, gemcitabine or the combination in both cell lines (data not shown), even at a concentration and time where cell apoptosis was evident. High concentrations of dicoumarol also did not induce ROS production, even at those concentrations which caused cell death.

Alteration of survival response proteins induced by gemcitabine and dicoumarol

In order to understand how the combination of gemcitabine and dicoumarol enhanced cytotoxicity in high NQO1 activity cells, proteins related to cell survival were analyzed by Western immunoblotting. Protein p53 is a tumor suppressor protein that responds to various noxious stimuli.

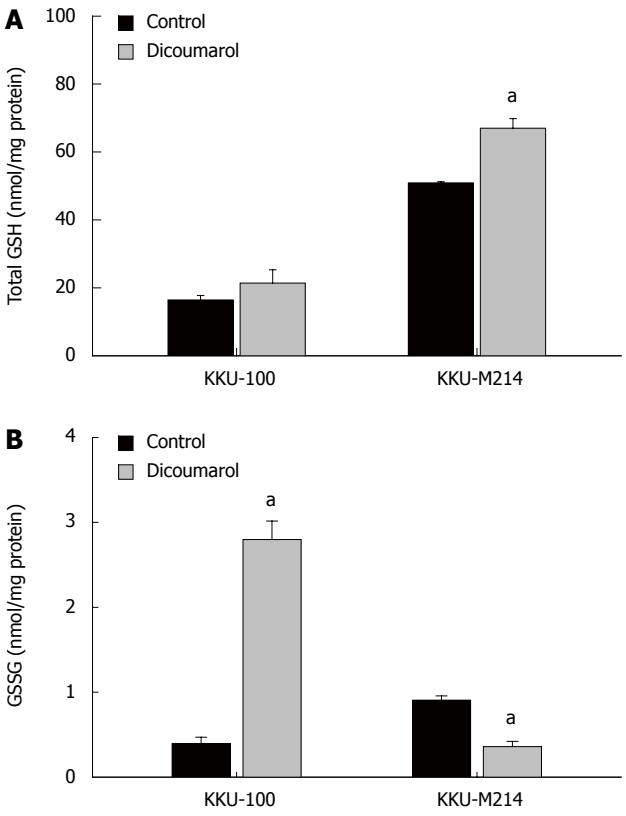

Figure 4 Glutathione redox status in cells treated with dicoumarol. KKU-100 and KKU-M214 cells were cultured and treated with dicoumarol (10 μmol/L) for 4 h, and cells were scraped for assays of (A) total glutathione and (B) glutathione disulfide. Bars represent mean ± SE, each from 3 experiments. $^{a}P < 0.05$ *vs* control group.

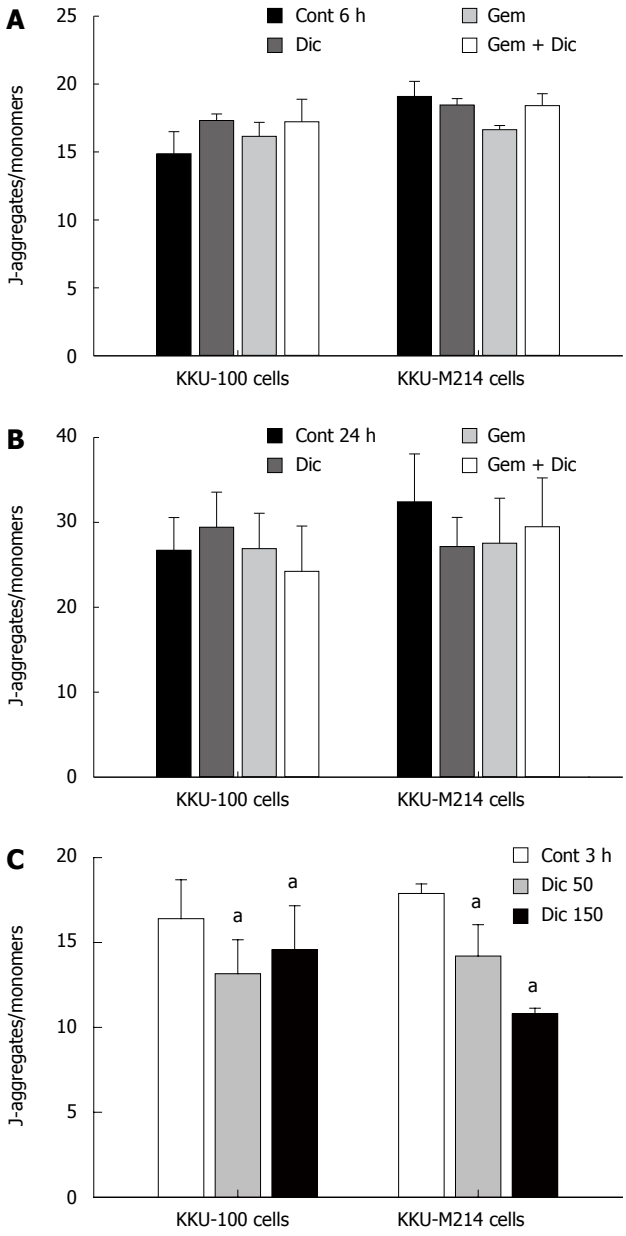

Figure 5 Assay of mitochondrial transmembrane potential and reactive oxygen in CCA cells. The mitochondrial transmembrane potential was analyzed by using JC-1 fluorescent probe. Fluorescent readings of the J-aggregates and J monomers were used as measurement of mitochondrial transmembrane potential. KKU-100 and KKU-M214 cells were cultured in 96-well black plates. The cultured cells were pretreated with dicoumarol at 10 μmol/L for 4 h, then gemcitabine at 1 nmol/L was added and incubated at various times. A: Incubation for 6 h; B: Incubation for 24 h; C: Other cultured cells were treated with dicoumarol at 50 and 150 μmol/L for 3 h. Bars represent mean ± SE, each from triplicate assay. $^{a}P < 0.05$ *vs* control group.

Dicoumarol or gemcitabine treatment induced increased p53 levels in KKU-100 cells and the level was further increased during the treatment with the drug combination. On the other hand, dicoumarol or gemcitabine or the combination did not alter p53 levels in KKU-M214 cells. Bcl-2 proteins consist of proapoptotic (Bax) and antiapoptotic proteins (Bcl-xL) where they regulate mitochondria outer membrane permeabilization. Bcl-xL levels were induced by gemcitabine in both cell types, however, the combination of gemcitabine with dicoumarol suppressed elevated Bcl-xL levels in KKU-100 cells but not in KKU-M214 cells. On the other hand, the changes in Bax levels were found with a similar pattern in both cell types, i.e. Bax levels were induced with gemcitabine, while drug combination induced no changes when compared with controls. Cyclin D1 levels were decreased upon the treatment with dicoumarol in both cell types, but not by gemcitabine. However, the drug combination apparently suppressed cyclin D1 levels when compared with gemcitabine alone.

The expression of the nuclear p65 subunit of NF-κB was slightly increased after the treatment with gemcitabine and showed little change induced by the co-treatment with dicoumarol in both cell lines. Figure 6 shown the Western analysis of proteins related to survival.

DISCUSSION

NQO1 is one of the attractive targets in development of chemotherapy, since NQO1 may function to protect normal cells, as well as tumor cells, particularly when it is highly expressed[12,30]. Suppression of NQO1 induced by proinflammatory cytokines or genetic defects may render normal cells susceptible to oxidant-mediated cell toxicity and carcinogenesis[7,8,22]. Inhibition of NQO1 activity with dicoumarol at relevant concentrations which produced modest cytotoxicity when administered alone potentiated gemcitabine-induced cytotoxicity in cells with high NQO1 activity. The combination of dicoumarol with gemcitabine

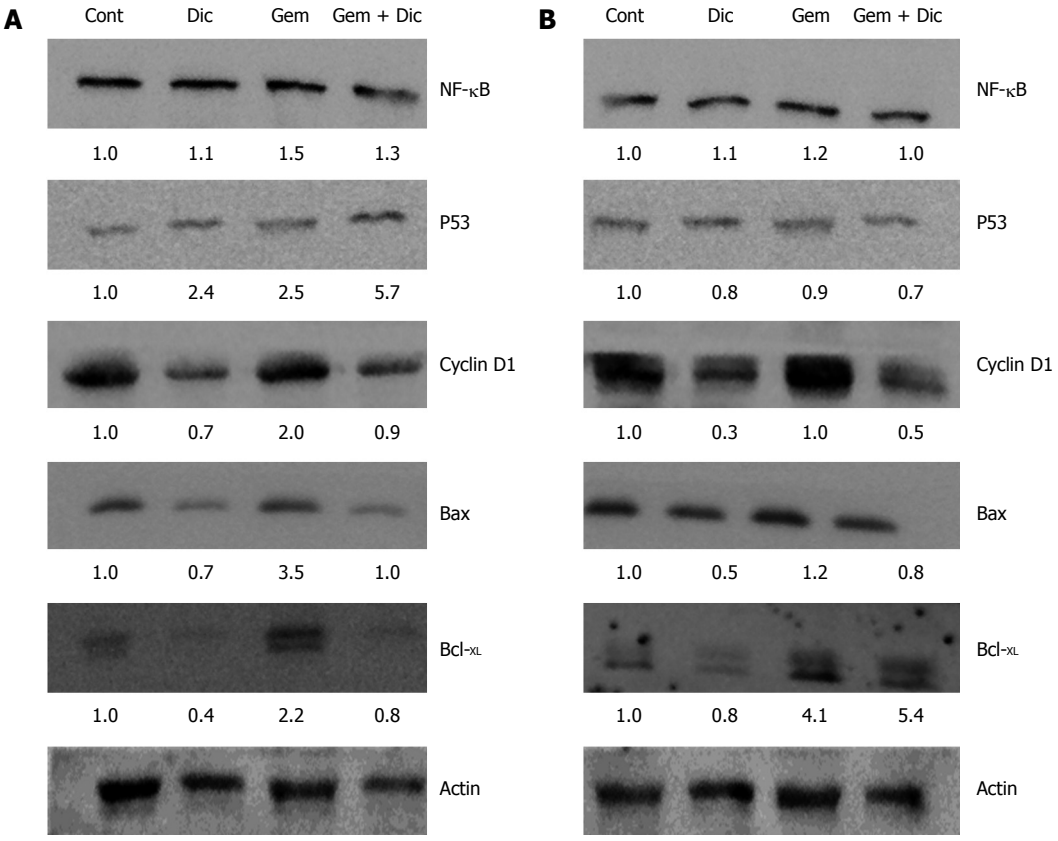

Figure 6 Western blotting analysis of proteins related to survival. KKU-100 and KKU-M214 cells were cultured overnight, pretreated with 10 μmol/L dicoumarol for 4 h before being treated with 1 nmol/L gemcitabine for 24 h. Cultured cells were collected for Western blotting analysis using β-actin as an internal control for equal protein loading. A: KKU-100 cells; B: KKU-M214 cells. Cont: Controls; Dic: Dicoumarol alone; Gem: Gemcitabine alone; Gem + Dic: Combination of gemcitabine and dicoumarol. Values were an average from two experiments of the target protein normalized with the internal control.

enhanced p53 and decreased Bcl-xL expression, and this may be related to the mechanism of cell sensitization and killing.

NQO1 is well known to function as a drug metabolizing and antioxidant enzyme, protecting the cell from oxidative injury[3]. Previous studies suggested that NQO1 modulates p53 expression by interference with 20S proteasome-mediated degradation of p53[3,31]. *P53* is a tumor suppressor gene that upon stimulation by DNA damage or oxidative stress, induces either growth arrest or apoptosis[32]. Our study showed that dicoumarol increased levels of p53 in KKU-100 cells, but these levels were unchanged in KKU-M214 cells. The increased p53 expression, together with decreased Bcl-xL protein expression, was associated with enhanced cytotoxicity of gemcitabine. However, dicoumarol has been previously reported to decrease p53 protein levels and this was associated with either inhibition or induction of apoptosis in myeloid leukemic cells or urogenital cancer cells, respectively[14,31]. The discrepancy in p53 levels induced by the treatment with dicoumarol is not readily comprehensible, although our study used much lower concentrations of dicoumarol. Moreover, treatment of gemcitabine apparently induced the activation of NF-κB and expression of Bcl-xL. This increase of antiapoptotic proteins may be a survival signal engaged in response to gemcitabine[33]. Interestingly, the combination with dicoumarol diminished the expression of Bcl-xL in KKU-100 cells concurrent with potentiation of the cytotoxicity of gemcitabine, while this did not happen in KKU-M214 cells.

Protein p53 and the Bcl-2 protein family regulate mitochondrial outer membrane permeabilization[34]. Induction of apoptotic cell death is often associated with disruption of the mitochondrial inner membrane which is reflected as dissipation of $\Delta\Psi_m$ and formation of mitochondrial permeability transition pore (MPTP) with subsequent cell death[35]. In the treatment with low concentrations of dicoumarol with or without gemcitabine, $\Delta\Psi_m$ appeared to be well maintained according to the assay of JC-1, despite the drug combination inducing marked CCA cell killing. This suggests no disruption of the mitochondrial inner membrane at the concentrations that potentiate gemcitabine cytotoxicity. Likewise, it was shown that prostaglandin A2 induced human promyelocytic leukemia cell death associated with cytochrome c release, with no change in $\Delta\Psi_m$[36]. However, dicoumarol at the high concentrations caused disruption of $\Delta\Psi_m$ and rapid cell killing which is consistent with many previous reports[14,17].

Dicoumarol has been suggested to trigger cell killing *via* increased formation of ROS[15-17]. We did not observe an increased ROS formation when cells were treated with dicoumarol or dicoumarol with gemcitabine combination. Dicoumarol, even at high concentrations

(150 μmol/L) that rapidly killed both types of CCA cells within 3 h of incubation (data not shown), had no significant effect on ROS formation. This suggests that superoxide formation may not be an important mediator of cell killing by dicoumarol[17]; it is probable that dicoumarol exerts its cell killing mechanism on CCA cells differently from other epithelial cells.

GSH, a tripeptide found abundantly in cells, functions as antioxidant and regulates activities of various redox-sensitive proteins[37]. Although dicoumarol did not increase formation of ROS, it induced oxidant stress in KKU-100 cells, but not in KKU-M214 cells, evidently by increasing and decreasing GSSG levels, respectively. The increased cellular oxidant may be implicated in several signal transduction pathways which eventually lead to enhanced susceptibility of KKU-100 cells. Nonetheless, dicoumarol has been reported to show several different pharmacological activities[15,17,38] and apoptotic cell killing may be dissociated with NQO1 inhibition[39], as some synthetic mechanism-based NQO1 inhibitors have shown lack of association between enzyme inhibition and cytotoxic effect. The discrepancy of the reports may be explicable partly on the grounds that the sensitizing effect of dicoumarol may be dependent on inherent activity of NQO1 in these cell types.

In conclusion, NQO1 may play roles in the sensitivity of CCA cells to gemcitabine. When using dicoumarol at relevant concentrations to inhibit NQO1 activity, dicoumarol enhances gemcitabine cytotoxicity in high NQO1 activity CCA cells. Furthermore, the mechanism of dicoumarol-induced cell killing may not be mediated *via* disruption of mitochondrial function and formation of ROS, but may be related to suppression of the pro-survival response to the chemotherapy. NQO1 is a potential target in the development of chemotherapy for tumors with high enzyme expression.

COMMENTS

Background

NAD(P)H quinone oxidoreductase-1 (NQO1) is a drug metabolizing and antioxidant enzyme which plays important roles in protection of cells against electrophiles and oxidants. Some cancers exhibit high activity of NQO1 which suggests a cytoprotective role in the cancer.

Research frontiers

Inhibition of NQO1 activity may abate the adaptive survival response of cancer cells induced by gemcitabine therapy and render cancer cells more susceptible to the drug.

Innovations and breakthroughs

This report shows that dicoumarol, a potent inhibitor of NQO1 at low concentrations, potentiates cytotoxicity of gemcitabine in cholangiocarcinoma cells which inherently have high NQO1 activity. Disruption of cellular glutathione redox may be associated with modulation of redox-sensitive signaling proteins such as p53 and render enhanced cells susceptible to gemcitabine.

Applications

Inhibition of NQO1 is suggested to be a potential strategy for development in cancer chemotherapy, particularly for cholangiocarcinoma which was used in this study.

Peer review

The methodology and the results are appropriate and support the findings in the literature.

Abstract

AIM: To study the effect of 5-Aza-2′-deoxycytidine (5-Aza-CdR) on heat shock protein 70 (HSP70), human leucocyte antigen-Ⅰ (HLA-Ⅰ) and NY-ESO-1 proteins in exosomes produced by hepatoma cells, HepG2 and Hep3B.

METHODS: Exosomes derived from HepG2 and Hep3B cells treated with or without 5-aza-CdR were isolated and purified by ultrafiltration centrifugation and sucrose gradient ultracentrifugation. The number of exosomes was counted under electron microscope. Concentration of proteins in exosomes was measured by bicinchoninic acid protein assay. Expression of HSP70, HLA-Ⅰ and NY-ESO-1 proteins in exosomes was detected by Western blotting and immunoelectron microscopy. mRNA expression of *p53* gene was detected by reverse transcription polymerase chain reaction.

RESULTS: The mRNA expression of *p53* gene was increased in both hepatoma cell lines after treatment with 5-Aza-CdR. The number of exosomes and the concentration of total proteins in exosomes were increased significantly after treatment with 5-aza-CdR ($P < 0.05$). After treatment with 5-Aza-CdR, immunoelectron microscopy and Western blotting showed that the HSP70, HLA-Ⅰ and NY-ESO-1 proteins were increased in exosomes produced by both hepatoma cell lines.

CONCLUSION: 5-aza-CdR, an inhibitor of DNA methyltransferase, can increase exosomes produced by hepatoma cells and immune-associated protein component of exosomes, which may be mediated by *p53* gene up-regulation and 5-Aza-CdR demethylation.

Effect of 5-Aza-2′-deoxycytidine on immune-associated proteins of exosomes from hepatoma. *World J Gastroenterol* 2010; 16(19): 2371-2377 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i19/2371.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i19.2371

INTRODUCTION

Human hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide, with an annual incidence of over half a million. Despite the improvements in surveillance, imaging technology, surgical techniques, and perioperative care, its mortality rate still increases, ac-

counting for 53% of all liver cancer deaths worldwide in China[1]. The most effective treatment modalities available for HCC to date are surgical resection, liver transplantation, and ablative therapy[2,3]. However, they are not indicated for patients who have relapse or are at advanced stage of the disease[4]. Moreover, the most commonly used treatment methods for various cancers, such as radiotherapy and chemotherapy, are often excluded in treatment of HCC due to their intolerable toxicity and insensitivity[5]. It is therefore necessary to develop a novel strategy against the progression and recurrence of HCC.

Exosomes secreted by tumor cells have become a recent hot spot in research of tumor immunology, raising intriguing attention to their immune-stimulating function *in vitro* and tumor model experiments[6,7]. However, acquiring a sufficient number of exosomes with a high quality for more powerful immune-stimulating effects has remained a great challenge for tumor immunotherapy[8-10]. Apart from the p53-dependent pathway, the mechanisms by which tumors secrete exosomes have not been well understood[11].

5-Aza-2'-deoxycytidine (5-Aza-CdR), a DNA methyltransferase inhibitor and a demethylation promoter in CpG regions of many genes, including the *p53* gene, can significantly restore or increase their expression[12,13], including the expression of *p53* by damaging DNA[14]. It has been shown that 5-Aza-CdR can significantly increase the expression of immune molecules necessary for antitumor cellular immunity by demethylating DNA, such as human leucocyte antigen (HLA)-Ⅰ, and HLA-Ⅱ, and significantly enhance the therapeutic effect of anti-tumor immunity *in vitro* and in animal experiments[15-17]. However, few reports are available on the effects of 5-Aza-CdR on the secretion of exosomes and the protein level in exosomes. This study was to explore the effect of 5-Aza-CdR on the secretion of exosomes, tumor-associated antigens and immune molecules in exosomes, and its mechanisms by which hepatocellular carcinoma cell lines secrete exosomes, in an attempt to provide preliminary experimental evidence for 5-Aza-CdR-modified exosomes-based anti-hepatoma immunotherapy.

MATERIALS AND METHODS

Materials

HepG2 cell line was generously provided by Professor You-Yong Lu, Beijing Cancer Institute. Hep3B cell line was purchased from Shanghai Institute of Cell Biology, Chinese Academy of Sciences (CAS).

Drugs and reagents

5-Aza-CdR, heavy water, cane sugar (analytically pure) and protein A colloidal gold (SPA) were purchased from Sigma Company (Santa Clara, CA, USA). FBS and DMEM culture media were purchased from GIBCo Company (Carlsbad, CA, USA). Western blotting reagents used in this study included rabbit anti-human heat shock protein 70 (HSP70) polyclonal antibody from Abcam (Cambridge, UK), mouse anti-human HLA-Ⅰ monoclonal antibody from Chemicon (Los Angeles, CA, USA), mouse anti-human NY-ESO-1 monoclonal antibody from ZyMed (San Diego Diego, South CA, USA). Western blotting kit was obtained from Pierce (Rockford, IL, USA), and BCA protein assay kit was from Puli Lai Gene Technology Co., Ltd (Beijing, China).

Instruments

Instruments used in this study included a Himac-CP70G low-temperature ultra-high speed centrifuge and a Hitachi TEM H-7500 transmission electron microscope (Hitachi Corporation, Tokyo, Japan). Electrophoresis devices used in this study included an electrophoresis tank and a transmembrane tank (Beijing 61 Instrument Factory, China), a GelDoc2000 gel imager (Bio-Rad Corporation, Chicago, IL, USA), a 100 ku MWCO Centriplus centrifugal ultrafiltration tube and a 100 ku MWCO Millipore Amicon high recovery-high-flow tangential flow ultrafiltration centrifuge tube (Millipore Corporation, Bedford, MA, USA).

Cell culture

Human hepatoma cell lines, HepG2 and Hep3B, were maintained at 37℃ in 10% DMEM containing 10% FCS (Gibco Corporation, Carlsbad, CA, USA), 100 U/mL penicillin, and 100 μg/mL streptomycin (Sigma Corporation, Santa Clara, CA, USA). HepG2 and Hep3B cells were divided into 3 control groups and 3 experimental groups, respectively, for regular culture. Cell viability was 95% as determined by trypan blue exclusion. Twenty-four hours after inoculation, cells in experimental groups were treated with 5-aza-CdR at a concentration of 1×10^{-6} mol/L and 150 mL of culture supernatant was collected 72 h later from each group, while cells in control groups were cultured without any drug and 150 mL of culture supernatant was collected from each group as controls.

Isolation and purification of exosomes

Exosomes were isolated as previously described[18]. In brief, 150 mL of a medium from confluent cultures (5-7 d) was harvested and centrifuged twice (2000 *g* and 10000 *g*) to remove cells and debris. Clarified supernatant was then ultrafiltrated using 100 ku MWCO Centriplus centrifugal ultrafiltration tubes to remove big-molecule compounds and reduce the volume of samples before ultracentrifugation on a 30% sucrose/D_2O cushion, which was collected and diluted in PBS. Ultrafiltration was then performed using a 100 ku MWCO Millipore Amicon high recovery-high-flow tangential flow ultrafiltration centrifuge tube. Finally, 5 mL of exosomes was obtained and stored at 4℃ for no more than 48 h before use.

Reverse transcription polymerase chain reaction

Total RNA was extracted from HepG2 and Hep3B cells using a Promega's total RNA extraction kit 72 h before and after 5-Aza-Cdr treatment. The sequences of p53 upstream and downstream primers used in this study are 5'-ACCCAGGTCCAGATGAAG-3' and 5'-CACTCGGATAAGATGCTGA-3', respectively. The length of amplified fragments was 422 bp. The sequences of β-actin upstream and downstream primers used in this

study are 5'-CGGGAAATCGTGCGTGACATT-3' and 5'-GGAGTTGAAGGTAGTTTCGTGG-3', respectively. The length of amplified fragments was 150 bp. RT reaction system contained 2 μg total RNA, 150.5 μg oligo (dT), 5 × PCR buffer, 1 mmol/L dNTP, 20U RNasin, 200 U M-MLV reverse transcriptase. PCR system contained 2 μL reverse transcriptase reaction products, 500 pmol/L of each upstream and downstream primer, 200 μmol/L of each dNTP, 1 U Taq DNA synthesis enzyme, and 10 × PCR buffer. The total reaction volume was 20 μL. Thirty cycles of PCR amplification were performed under the following conditions: predenaturation at 94℃ for 5 min, denaturation at 94℃ for 30 s, annealing at 55℃ for 30 s, extension at 72℃ for 30 s, and a final extension at 72℃ for 5 min. Finally, 6 uL of PCR products was electrophoresed on 1.5% agarose gel. The results were recorded using a gel imaging system for semi-quantitative analysis by grey ratio of target gene to β-actin. Reverse transcription polymerase chain reaction (RT-PCR) reagents were purchased from Promega Company (San Luis Obispo, CA, USA) and primers were synthesized in Beijing Bioko Biotech Co., Ltd (Beijing, China).

Marking and counting exosomes under colloidal gold immunoelectron microscope

An antigen-antibody complex was prepared. In brief, 10 μL of exosomes was obtained and mixed with an equal volume of rabbit anti-human HSP70 monoclonal antibody (1:50 dilution), mouse anti-human HLA- I monoclonal antibody (1:100 dilution) or mouse anti-human NY-ESO-1 monoclonal antibody (1:50 dilution), respectively. These samples were dropped onto a copper mesh surface and incubated for 1 h at room temperature. Twenty μL of SPA diluted at 1:15 was dropped onto the hydrophobic membrane to form liquid beads. The copper mesh was floated in SPA droplets with its membrane surface faced down at room temperature for 30 min. Then, 15 μL of uranyl acetate drops was put onto the copper mesh surface and stained at room temperature for 30 s. A SPA-coated copper mesh was taken as a control. Exosomes with black colloidal gold particles on the capsular membrane and cavity were marked as positive under transmission electron microscope.

Quantification of exosome immune molecules under electron microscope

Exosomes and their labeled colloidal gold particles were counted under each camera view of exosome samples. Each protein was represented by the number of colloidal gold particles in 100 exosomes. The data were expressed as mean ± SD for further statistical analysis.

Exosome counting under electron microscope

The area under each photographic view was 1000 nm × 700 nm. The number of exosomes under each field of vision was counted. The average number of exosomes under each camera view was calculated in 10 randomly selected horizons. The number of exosomes in each mL supernatant of the cells was figured out by copper mesh diameter (2.5 mm) and area (1.25 mm × 1.25 mm × 3.14). The cells in each of experimental and control groups were counted three times and averaged for statistical analysis.

Western blotting

Forty microgramme of exosomes was taken and 10% SDS-PAGE electrophoresis was performed at a constant electric power. After electrophoresis, the gels were transferred to NC membrane, incubated with HSP70, HLA- I and NY-ESO-1 antibodies diluted at 1:500 overnight at 4℃. Then, horseradish peroxidase-tagged antibody was added and incubated at room temperature for 2 h. Photography was performed with a Kodak X-OMAT film (Eastman Kodak, Rochester, NY). The light absorption value *A* of target bands and β-actin was determined using the imaging analysis system. The results were indicated by the absorption ratio of target bands and β-actin, and averaged from three independent experiments.

Determination of protein concentration in exosomes

Exosomes in two cell lines of experimental and control groups were taken to determine the protein concentration with a bicinchoninic acid (BCA) protein assay kit following its manufacturer's instructions.

Statistical analysis

The data were expressed as mean ± SD. Statistical analysis was performed using the SPSS13.0 statistical software. $P < 0.05$ was considered statistically significant.

RESULTS

Exosomes and their related immune molecules identified by immunoelectron microscopy

Immunoelectron microscopy showed that exosomes, secreted from HepG2 and Hep3B cells, had the membranous structure of microcapsules, 30-80 nm in diameter. They were round or oval and their cavities were full of components with a low electron density. After colloidal gold immunoelectron marking, dotted, granular colloidal gold markers could be observed in the capsular membranes and cavities. Each kind of immune molecules had no more than two gold-labeled particles in the control groups. However, after treatment with 5-Aza-CdR, 5, 4, and 3 gold-labeled HSP70, HLA- I and NY-ESO-1 molecules were observed in exosomes, respectively. The number of gold-labeled particles in each immune molecule was significantly greater in experiment groups than in control groups ($P < 0.05$, Figure 1, Table 1).

Tumor antigen and immune molecules in exosomes detected by Western blotting

In the supernatant of exosomes from two cell lines, a clear specific protein band could be detected by Western blotting at the molecular weights of 73, 40 and 18 kDa. After treatment with 5-Aza-CdR, the HLA- I and NY-ESO-1

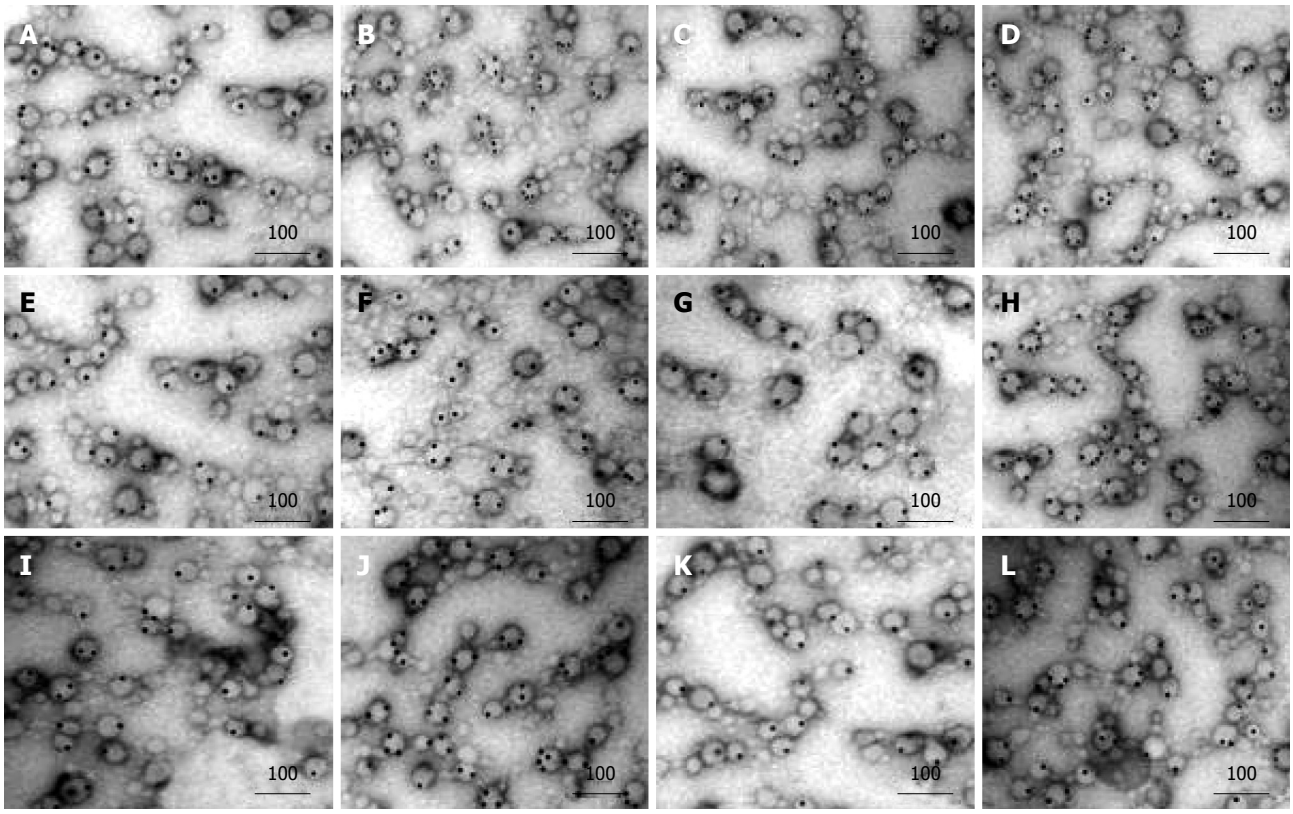

Figure 1 Immunoelectron microscopy showing colloidal gold HSP70 labeled HepG2 exosomes in control group (A) and in experiment group (B), colloidal gold HLA-Ⅰ labeled HepG2 exosomes in control group (C) and experiment group (D), colloidal gold NY-ESO-1 labeled HepG2 exosomes in control group (E) and experiment group (F), colloidal gold HSP70 labeled Hep3B exosomes in control group (G) and experiment group (H), colloidal gold HLA-Ⅰ labeled Hep3B exosomes in control group (I) and experiment group (J), colloidal gold NY-ESO-1 labeled Hep3B exosomes in control group (K) and experiment group (L) (× 140 000).

Table 1 Immune-related molecules of exosomes in control and experimental groups (mean ± SD)

	n	HepG2		*P*	Hep3B		*P*
		Control group	Experiment group		Control group	Experiment group	
HSP70	3	74.2 ± 3.1	99.8 ± 5.2	< 0.01	70.2 ± 5.1	99.9 ± 3.8	< 0.01
HLA-Ⅰ	3	53.3 ± 2.5	79.6 ± 6.1	< 0.01	40.6 ± 2.7	86.7 ± 3.6	< 0.01
NY-ESO-1	3	38.2 ± 4.2	58.2 ± 4.3	< 0.01	32.1 ± 4.6	70.3 ± 2.9	< 0.01

expression level was significantly higher in experimental groups than in control groups ($P < 0.05$), while the HSP70 expression did not increase significantly (Figure 2).

Exosomes and protein in exosomes under electron microscope

The number of exosomes secreted from both cell lines and the total protein in exosomes were significantly higher after treatment with 5-Aza-CdR than before treatment with 5-Aza-CdR ($P < 0.05$, Table 2).

Change of wild-type P53 gene expression in HepG2 and Hep3B cells after 5-Aza-CdR treatment

The *p53* gene was moderately expressed in HepG2 cells but not in Hep3B cells before 5-Aza-CdR treatment. However, the *p53* gene mRNA was significantly expressed in two cell lines after 5-Aza-CdR treatment (Figure 3).

DISCUSSION

5-Aza-CdR can recover some genes with CpG islands in their promoter regions, or significantly increase the expression of these genes by directly inhibiting the DNA methyltransferase activity[19]. It has been shown that DNA methylation can regulate cancer/testis antigen (CTA), MHC Ⅰ, MHC Ⅱ, and a variety of immune adhesion molecules[20,21]. 5-Aza-CdR can significantly increase their expression in tumor cells and improve anti-tumor immune response capacity[17].

Exosomes, originating as vesicles in some late endosomes, would release when these mature endosomes or multivesicular bodies (MVBs) are fused with cell membranes. Exosomes carry a variety of specific proteins, such as antigen-presenting-associated protein, T cell activation-associated protein, and some tumor antigens and antigen

chaperones[7]. Exosomes themselves offer an antigen delivery system and can transfer tumor antigens to antigen-presenting cells, causing anti-tumor responses[22].

For these reasons, use of exosomes in immunotherapy and research requires high-quality exosomes. However, the mechanism underlying exosome secretion has not been well elucidated. Yu *et al*[11] found that activation of wild-type p53 increases exosome production by upregulating a transmembrane protein, TSAP6, which selectively transports proteins to exosomes and adjusts exosome formation. 5-Aza-CdR can increase *p53* gene expression by damaging or methylating DNA[12,14]. In addition, it has been reported that 5-Aza-CdR increases the expression of CTA, HLA- I , and HLA- Ⅱ through demethylation, thus improving anti-tumor specific immune response and decreasing the size of transplanted tumors in mice[15,16]. Therefore, this study investigated whether 5-Aza-CdR can increase the number of exosomes and the immune molecule level in exosomes secreted by hepatoma cells through *p53* gene activation and DNA demethylation pathways.

Immunoelectron microscopy and Western blotting in this study showed that exosomes derived from HepG2 and Hep3B cells were rich in HSP70 protein both before and after 5-Aza-CdR treatment. However, after 5-Aza-CdR treatment, electron microscopy showed that the tagged HSP70 proteins in exosomes were increased, while Western blotting showed that they did not, possibly due to the fact that *HSP70* gene expression is not regulated by DNA methylation. Moreover, HLA- I and NY-ESO-1 molecules were clearly regulated by DNA methylation, the expression of these molecules especially that of HLA- I in Hep3B cells, was relatively low in control groups. After 5-Aza-CdR treatment, these molecules were significantly increased in both cell lines. The number of exosomes secreted by treated and untreated hepatoma cells was calculated and changes of protein in exosome stock solutions treated and untreated with BCA were observed under electron microscope, showing that after 5-Aza-CdR treatment, the number of exosomes secreted by hepatoma cells and the protein in exosomes are significantly increased ($P < 0.05$). Furthermore, immune electron microscopy and Western blotting revealed that the number of exosomes was increased by almost an order of magnitude. Although there was a difference in *p53* mRNA expression between the two hepatoma cell lines before treatment with 5-Aza-CdR, the *p53* expression was significantly increased in both cell lines, especially in Hep3B cell line after 5-Aza-CdR treatment,. The number of exosomes and the expression of HSP70 protein were slightly higher in Hep3B cells than in HepG2 cells. However, the expression of HLA- I and NY-ESO-1 molecules was significantly higher in Hep3B cells than in HepG2 cells, indicating that exosomes secreted by hepatoma cells are regulated by the *p53* gene, while

HLA-Ⅰ and NY-ESO-1 proteins in exosomes are mainly regulated by DNA methylation. As a "molecular chaperone", HSP70 can actively deliver antigens through receptors on antigen-presenting cell membranes, thus increasing the efficiency of antigen presentation by 104-folds of pure pinocytosis or phagocytosis. Tumor-specific antigens are released from HSP within cells and presented to cytotoxic T cells, which are activated to execute immune responses to different tumors[23]. NY-ESO-1, belonging to the CTA family, is expressed in a variety of tumor tissues. Anti-NY-ESO-1 specific antibodies and sensitized lymphocytes can be found in serum of hepatoma patients[24,25]. Thus, NY-ESO-1 is currently thought to be a tumor-specific antigen with the strongest antigen immunogenicity[26]. However, NY-ESO-1 re-expression in tumor cells is not homogeneous and its low expression level is insufficient to stimulate cell-mediated immunity. To enhance tumor-specific immunity, sufficient tumor-specific antigens or immune-associated molecules are needed.

In conclusion, hepatoma cells secrete more exosomes after 5-Aza-CdR treatment. Moreover, the expression of tumor-specific antigen, NY-ESO-1, and tumor-specific immune stimulating molecule, HLA-Ⅰ, increase significantly. While 5-Aza-CdR up-regulates *p53* gene expression, it may play a more important role in DNA demethylation. Exosomes secreted from hepatoma cells after 5-Aza-CdR treatment are more able to stimulate anti-tumor-specific immune response, which may be useful for the preparation of a new cancer therapeutic vaccine for hepatoma.

COMMENTS

Background

Human hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide. However, no effective curative therapy for it is currently available. It is therefore necessary to develop a novel strategy against HCC. Tumor-derived exosomes, containing tumor-associated antigens and chaperones, are membrane nanoparticles, which make them stable, easy to maintain and susceptible to uptake by immune cells. However, cancer/testis antigens (CTAs) with a strong immunity and immune-associated molecules with adjuvant anti-cancer effects are heterogeneous and insufficient in cancer cells to emit specific immune reactions. Therefore, getting enough quantity and quality of exosomes for a sufficient immune effect remains a great challenge for tumor immunotherapy. 5-Aza-CdR, an inhibitor of DNA methyltransferase, can restore or increase CTAs and HLA-Ⅰ/Ⅱ expression in cancer cells by demethylation and induce *p53* gene expression by damaging DNA, while p53 can increase exosome production. The authors hope to get more exosomes with a large number of CTAs and immune-associated molecules by modifying hepatoma cells with 5-Aza-CdR.

Research frontiers

Exosomes secreted by tumor or dendritic cells are a recent hot spot in tumor immunology research. However, insufficient tumor-associated antigens and tumor-derived immune stimulated molecules are still a problem in such a research. Various methods, such as *IL-2* gene transfection and curcumin-modified exosomes, have been used to improve exosome immune stimulation. In this study, hepatoma was treated with 5-Aza-CdR, and more powerful exosomes were produced.

Innovations and breakthroughs

5-Aza-CdR, a DNA methyltransferase inhibitor and a demethylation promoter of CpG in many genes including the *p53* gene, can significantly restore or increase their expression. It has been shown that 5-Aza-CdR can significantly increase the expression of molecules necessary for anti-tumor cellular immunity such as HLA-Ⅰ and HLA-Ⅱ, and the therapeutic effect of anti-tumor immunity *in vitro* and in animal experiments. However, no report is available on the effect of 5-Aza-CdR on the number of exosomes in cancer cells. This study showed that 5-Aza-CdR could increase exosomes in hepatoma cells and immune-related molecules of exosomes. Although its mechanism remains unclear, it may be related to demethylation and the p53-induction effect of 5-Aza-CdR. These findings suggest that 5-Aza-CdR can modify exosomes, thus offering an interesting possibility for developing a cancer vaccine.

Applications

This study has confirmed that 5-Aza-CdR-modified exosomes from hepatoma cells contain more CTAs, chaperones and immune-stimulating molecules, which may be used in preparation of a new cancer therapeutic vaccine *in vitro* for hepatoma.

Terminology

Exosomes, secreted by many kinds of cells including blood and tumor cells, have a membrane structure, 30-100 nm in size, consisting of proteins and RNA, and function as a vehicle for messages from cell to cell.

Peer review

The authors studied the effect of 5-Aza-CdR on the number of exosomes and immune-associated proteins in them produced by hepatoma cell lines, HepG2 and Hep3B, showing that exosomes function as a vehicle for messages from cell to cell, which may be used in preparation of a new cancer therapeutic vaccine for hepatoma.

Abstract

AIM: To investigate nicotinamide's action on glucose metabolism, and the association between niacin consumption and obesity prevalence.

METHODS: Dynamic nicotinamide's effect on plasma hydrogen peroxide and glucose metabolism was investigated using oral glucose tolerance tests with or without nicotinamide in the same five healthy subjects. Lag-regression analysis was used to examine the association between the niacin consumption and the obesity prevalence among US children using the data from the Economic Research Service of the US Department of Agriculture and from US Centers for Disease Control and Prevention, respectively.

RESULTS: Compared with the control oral glucose tolerance test, the 1-h plasma hydrogen peroxide (1.4 ± 0.1 μmol/L *vs* 1.6 ± 0.1 μmol/L, $P = 0.016$) and insulin levels (247.1 ± 129.0 pmol/L *vs* 452.6 ± 181.8 pmol/L, $P = 0.028$) were significantly higher, and the 3-h blood glucose was significantly lower (5.8 ± 1.2 mmol/L *vs* 4.5 ± 1.1 mmol/L, $P = 0.002$) after co-administration of glucose and 300 mg nicotinamide. The obesity prevalence among American children increased with the increasing per capita niacin consumption, the increasing grain contribution to niacin due to niacin-fortification, and the increasing niacin-fortified ready-to-eat cereal consumption, with a 10-year lag. The regression analyses showed that the obesity prevalence in the US children of all age groups was determined by niacin consumption ($R^2 = 0.814$, 0.961 and 0.94 for 2-5 years, 6-11 years and 12-19 years age groups, respectively).

CONCLUSION: The appetite-stimulating effect of nicotinamide appears to involve oxidative stress. Excess niacin consumption may be a major factor in the increased obesity prevalence in US children.

INTRODUCTION

The high prevalence of obesity, a major risk factor for type 2 diabetes, has been recognized as a serious global health problem[1]. It is likely that both dietary factors and physical inactivity may contribute to the development of obesity[2,3]. However, the reason why the prevalence of obesity suddenly increased dramatically starting around 1980 in the US is not well understood[4]. It is argued that eating and dietary quality factors may act as a primary driver for the obesity epidemic[2,4]. Therefore, exploring dietary risk factors should be of importance for the prevention and treatment of obesity and type 2 diabetes.

During the past few decades, one of the significant, but relatively overlooked worldwide changes in dietary composition has been the marked increase in the content of niacin (nicotinamide and nicotinic acid). For example, as shown in Figure 1A, the daily US per capita niacin consumption has maintained an increasing trend since the early 1940s, and has reached 33 mg in the early 2000s[5], which is more than two times the recommended dietary allowance (RDA) by the US Food and Nutrition Board (RDA: 14 and 16 mg/d for adult women and men, respectively)[6]. Animal flesh (meat, poultry and fish) and grains are the largest contributors of dietary niacin. Most of the increased niacin consumption comes from grain products due to the implementation of mandatory niacin-fortification (i.e. the addition of niacin to food) started from the early 1940s[7]. Most significantly, a sharp increase in the grain contribution in 1974 due to an update of niacin-fortification standards has made grains the largest contributor (Figure 1B)[8,9]. However, the effect of long-term exposure to excess niacin on human health is poorly understood.

Niacin-fortification has been practiced first in many developed countries to prevent pellagra, a disease due to niacin deficiency[10], and then introduced to developing countries[11]. Soon after the introduction of niacin-fortification, the prevalence of obesity and diabetes has begun to increase rapidly first in developed countries and then in developing countries[12,13], basically in a similar way as the niacin-fortification spread. Thus, there is the possibility that niacin-fortification-induced increase in dietary niacin may be involved in the increased global prevalence of obesity and diabetes. However, there are very limited data regarding the possible adverse long-term consequences of niacin-fortification.

Grains (flour and cereals), the main source of carbohydrate, are the most widely used vehicles for niacin-fortification[11]. As a result, the niacin content in the fortified grain products has been significantly increased. Traditionally, low-fat, high-carbohydrate diets were used to treat type 2 diabetes[14,15]. However, since the implementation of niacin-fortification in the US from the early 1940s and the significant increase in carbohydrate consumption during the past three decades, more and more studies from the US have found that high-carbohydrate diets increase, instead of decrease, the risk for obesity and type 2 diabetes[12,16,17]. Then, low-carbohydrate diets have been used to treat obesity and diabetes since the late 1990s[18-20]. Whether such a profound change in the effect of carbohydrate diets is related to niacin fortification of grains is not known.

Obesity is characterized by increased appetite and insulin resistance[21,22], whereas niacin is a potent stimulator of appetite and niacin deficiency may lead to appetite loss[10]. Moreover, large doses of niacin have long been known to impair glucose tolerance[23,24], induce insulin resistance and enhance insulin release[25,26]. Evidence suggests that niacin-induced increase in insulin release may be a compensation of pancreatic islet β cells in response to the insulin resistance[25,26]. However, whether excess niacin intake is involved in the increased appetite and the insulin resistance of obesity is unclear. Our recent study found that oxidative stress may mediate excess nicotinamide-induced insulin resistance, and that type 2 diabetic subjects have a slow detoxification of nicotinamide. These observations suggested that type 2 diabetes may be the outcome of the association of high niacin intake and the relative low detoxification of niacin of the body[27]. Based on these lines of evidence, we postulated that excess niacin intake may also play a role in obesity. To address this issue, this study explored the mechanism underlying niacin's action on glucose metabolism, and the association between the US per capita niacin consumption and the obesity prevalence in the US.

MATERIALS AND METHODS

Nicotinamide load test

The present study was approved by the relevant ethics committee, and all the participants gave informed consent. Five healthy young male volunteers aged 20-24 years participated in the two oral glucose tolerance tests (glucose dose 75 g) with (NM-OGTT) or without (C-OGTT) oral co-administration of 300 mg nicotinamide (Lisheng Pharma, Tianjin, China), respectively, with an interval of 4 d. Each test was conducted after an overnight fast, venous blood (1.8 mL) was collected into sodium citrate tubes before, and 1, 2, 3, and 4 h after the administration. The blood samples were separated by centrifugation (1500 × *g*, 10 min). Aliquots of each plasma sample were placed directly in liquid nitrogen and then transferred to -80℃ for later analysis.

Assays of blood glucose, plasma insulin and hydrogen peroxide

Blood glucose was measured using a glucometer (One-Touch Ultra, LifeScan Inc.). Plasma insulin was measured by radioimmunoassay using commercial kits (Beijing North Institute of Biological Technology, China). Plasma hydrogen peroxide (H_2O_2) concentration was measured using an H_2O_2 Assay Kit (Beyotime Biotechnology, Jiangsu, China).

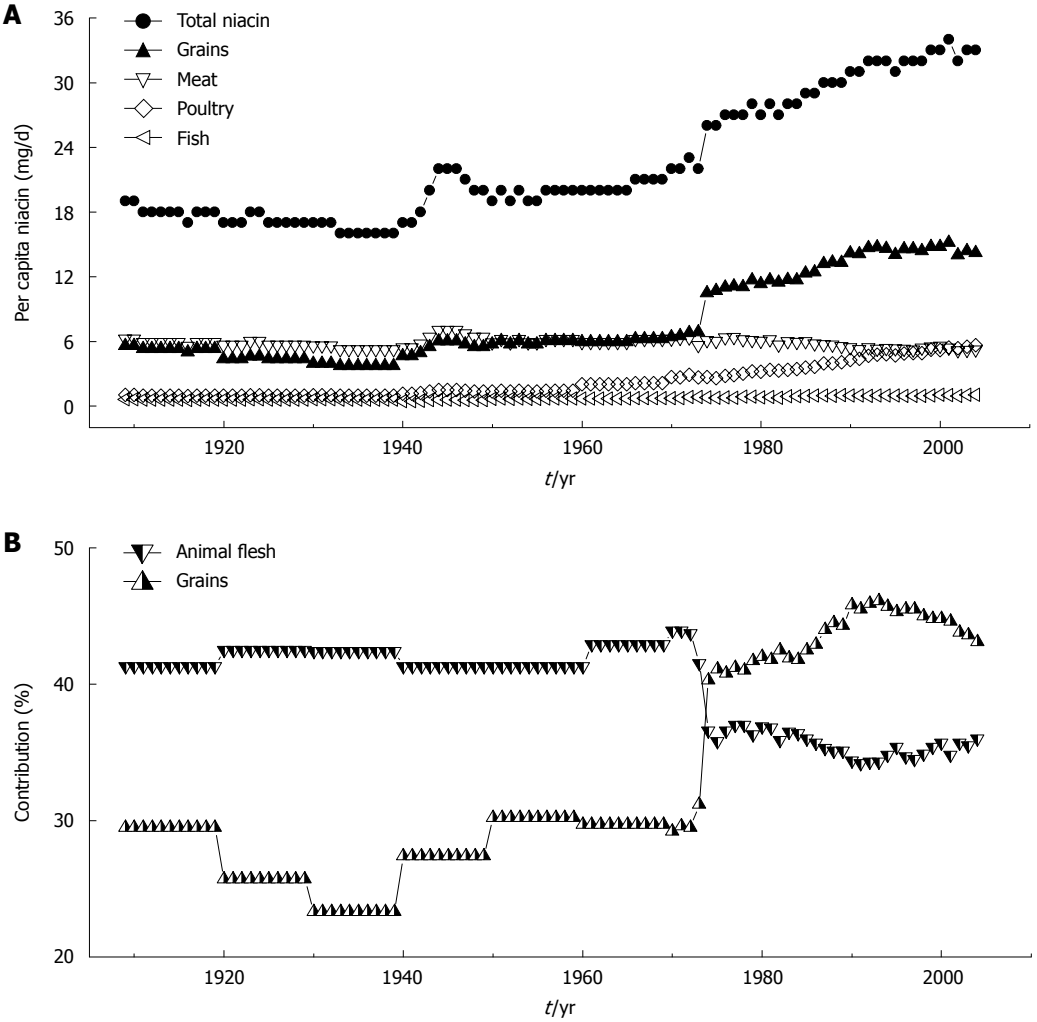

Figure 1 Trends in per capita niacin consumption and contributions of grains and animal flesh to niacin in the US. A: The trends in total niacin consumed per capita per day in 1909-2004 and in the amounts from grains and animal flesh (meat, poultry and fish); B: Changes in the percentage of grain and animal flesh contribution to dietary niacin. The data on niacin consumption are derived from Ref. 5. The data on the grain and animal flesh contribution to niacin are derived from Ref. 8 (1909-2000) and Ref. 9 (2001-2004). The per capita niacin consumption (A) and the grain contribution to niacin (B) have been suddenly increased since 1974 due to an update in niacin-fortification standards.

Determination of nicotinamide and N^1-methylnicotinamide

Nicotinamide and N^1-methylnicotinamide were analyzed, as previously described[27], using a high-performance liquid chromatography (HPLC) system that consisted of an LC-9A pump (Shimadzu, Kyoto, Japan), a Rheodyne 7725i sample injector with a 20-μL sample loop (Rheodyne LLC, Rohnert Park, CA, USA), a Hypersil ODS C18 column (Thermo, Bellefonte, PA, USA) and a Waters 470 fluorescence detector (Milford, MA, USA).

Data sources

The data used for assessing the relationship between niacin consumption and obesity prevalence were derived from the databases of the US Centers for Disease Control and Prevention (CDC) and of the Economic Research Service of the US Department of Agriculture. The data on the prevalence of obesity (body mass index ≥ 95th percentile for age and sex) in US children and adolescents were from National Health Examination Survey (NHES) 2 (1963-1965, only available for the age group of 6-11 years), NHES 3 (1966-1970, only available for the age group of 12-19 years), the National Health and Nutrition Examination Surveys (NHANES) I (1971-1974), Ⅱ (1976-1980), Ⅲ (1988-1994), and the continuous NHANES data collection (1999-2000, 2001-2002, 2003-2004)[28-30]. NHES and NHANES are conducted by the CDC, and include a series of cross-sectional nationally representative health examination surveys. Each cross-sectional survey provides a national estimate for the US population at the time of the survey. Detailed descriptions of the survey methods are available elsewhere[29,30], and on-line (http://www.cdc.gov/nchs/nhanes.htm). The nutrient data on the US per capita niacin consumption in 1909-2004[5], grain consumption in 1909-2007[31], grain contribution to niacin in 1909-2000[8] and in 2001-2004[9] and ready-to-eat cereal (RTE) consumption[32] were derived from the databases of the Economic Research Service (ERS) of the US Department of Agriculture. ERS annually calculates the amounts of several hundred foods

available for human consumption in the US and provides estimates of per capita availability. The estimates of nutrients in the food supply reflect Federal enrichment and fortification standards and technological advances in the food industry[8].

Statistical analysis

The data are presented as mean ± SD. Statistical differences in the data were evaluated by paired Student's *t* test. Lag-regression analysis was used to test the relationships between the consumption of niacin or grain and the obesity prevalence in the US children and adolescents using SPSS software (SPSS Inc., Chicago, USA). Statistical significance was set at $P < 0.05$.

RESULTS

Dynamic effect of nicotinamide on blood glucose metabolism

The methylation of nicotinamide to N^1-methylnicotinamide is a major mechanism to eliminate excess nicotinamide[27]. As shown in Figure 2, in C-OGTT, the plasma concentrations of nicotinamide and N^1-methylnicotinamide were fairly constant (Figure 2A and B), and the 2-h plasma level of H_2O_2, a major reactive oxygen species (ROS), was slightly increased, but without statistical significance compared with the value before C-OGTT (Figure 2C). In contrast, NM-OGTT led to a significant increase in plasma nicotinamide and N^1-methylnicotinamide levels, with a peak at approximate 2 h (Figure 2A and B). In parallel with the rising phase of plasma nicotinamide and N^1-methylnicotinamide, there was a significant increase in 1-h and 2-h plasma H_2O_2 levels in NM-OGTT (Figure 2C). Importantly, although the 1-h and 2-h blood glucose values were similar in the two tests (Figure 2E), however, the 1-h plasma insulin level was much higher in NM-OGTT than in C-OGTT (Figure 2D). As the plasma H_2O_2 returned to the basal level at 3 h in NM-OGTT (Figure 2C), there was a sharp decrease in the blood glucose concentration (Figure 2E). Two of the five subjects in NM-OGTT had reactive hypoglycemia symptoms (i.e. sweating, dizziness, faintness, palpitation and intense hunger) with the blood glucose levels below 3.6 mmol/L. In contrast, no subjects had reactive hypoglycemic symptoms during C-OGTT. These results indicated that nicotinamide overload might induce a biphasic effect, i.e. insulin resistance followed by hypoglycemia.

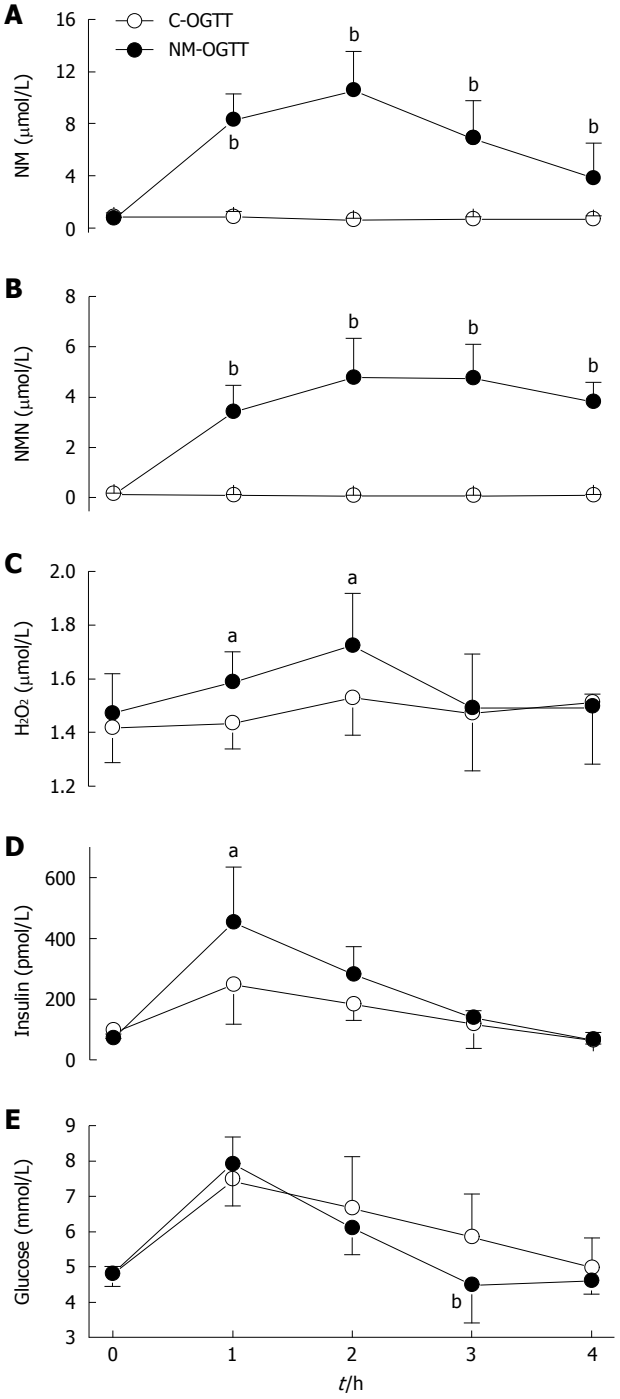

Figure 2 Dynamic effect of nicotinamide on plasma H_2O_2 level and glucose metabolism. A-E: Dynamic changes in the concentrations of plasma nicotinamide (NM), N^1-methylnicotinamide (NMN), H_2O_2, insulin and blood glucose in C-OGTT and NM-OGTT (co-administration of 300 mg nicotinamide and 75 g glucose). For each point, $n = 5$. Values represent mean ± SD, $^aP < 0.05$, $^bP < 0.01$ *vs* C-OGTT.

Association between niacin consumption and obesity prevalence in US children

We next investigated the relationship between the daily per capita niacin consumption and the obesity prevalence in US children and adolescents. There were two historical events in niacin-fortification in the US. The first is the initial introduction of niacin-fortification in the early 1940s and the second is the update of fortification standards in 1974. These two events resulted in significant increases in the per capita niacin consumption respectively in the 1940s and in the mid-1970s. Evidently, the prevalence of obesity in US children of all age groups increased in parallel with the increase in the per capita niacin consumption with a 10-year lag (Figure 3A, C and E). Lag-regression analysis revealed that the obesity prevalence in the children of all age groups was determined by niacin consumption (Figure 3B, D and F). This relationship was observed in both sexes (Figure 3G and H) (R^2 = 0.958 and 0.96 for boys and girls aged 6-11 years, P = 2.6e-17 and 1.6e-17,

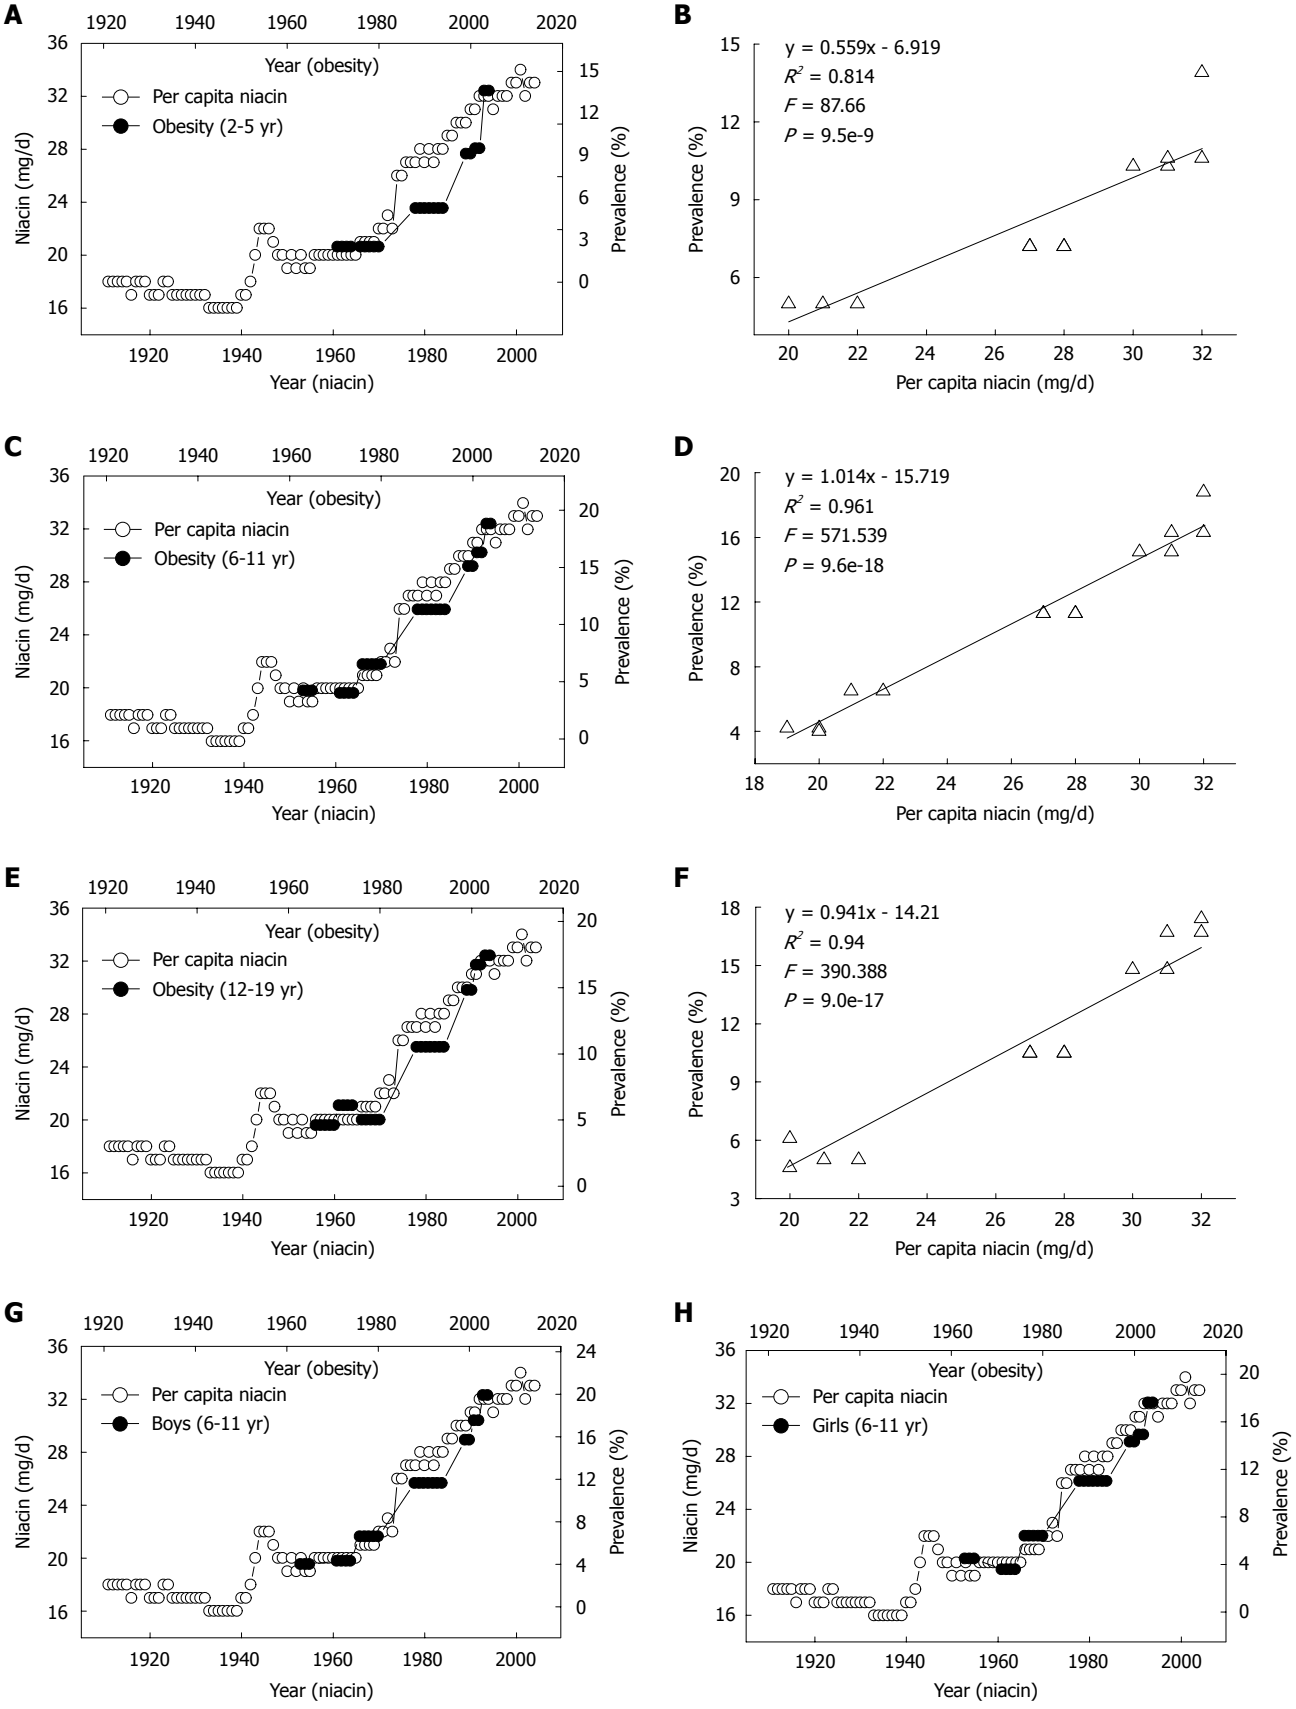

Figure 3 Correlations between US per capita niacin consumption and obesity prevalence in US children. A, C and E: The trends in the daily per capita niacin consumption in 1909-2004 (Ref. 5) and in the obesity prevalence in the children aged 2-5, 6-11 and 12-19 years (Ref. 28); B, D and F: The 10-year lag-regression plots of the obesity prevalence in different age groups against daily per capita niacin consumption using the data in A, C, and E; G and H: The obesity prevalence in the age group of 6-11 years of either sex in 1963-2004 (Ref. 29 and 30) increased in parallel with the per capita niacin consumption in 1953-1994.

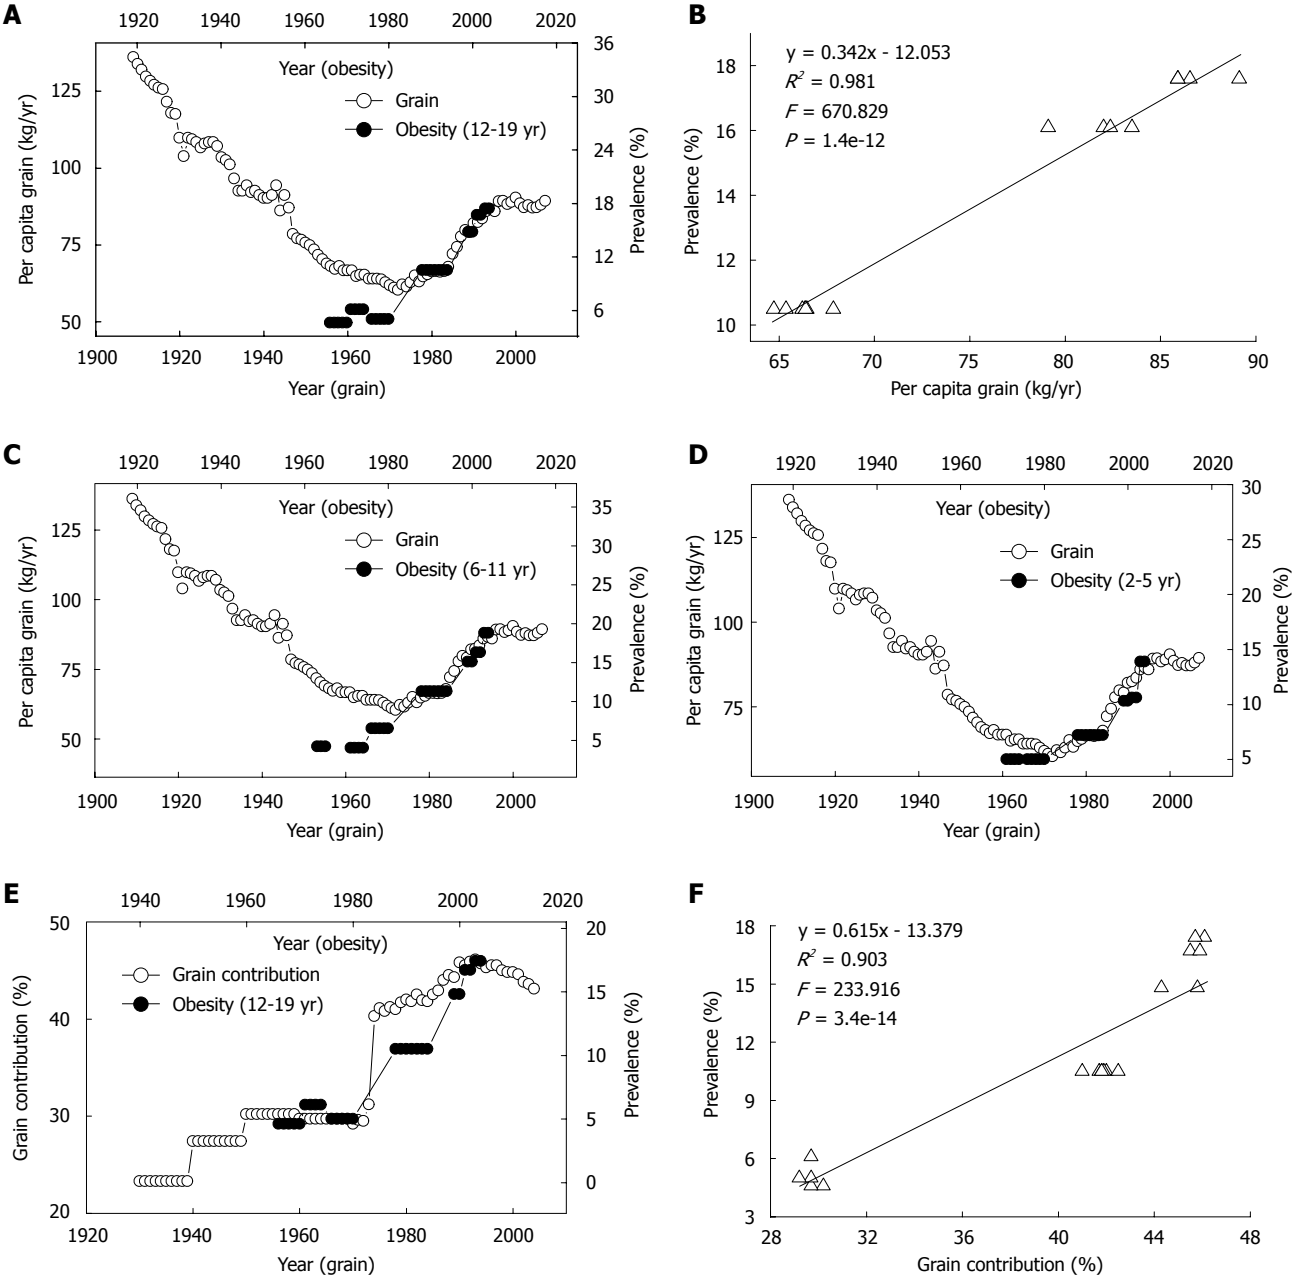

Figure 4 Correlations between consumption and contribution of grain and prevalence of obesity in US children. A: Trends in US per capita grain consumption in 1909-2007 (Ref. 31) and in the obesity prevalence in the children aged 12-19 years in 1966-2004 (Ref. 28); B: The linear regression plot of the obesity prevalence in 1988-2004 against grain consumption in 1978-1994 using the data in A; C and D: Relationships between the grain consumption (Ref. 31) and the prevalence of obesity in the children aged 6-11 and 2-5 years (Ref. 28). R^2 = 0.902 (P = 7.1e-7) and 0.955 (P = 9.7e-9), for 2-5 years age group and 6-11 years age group; E: Trends in the grain contribution to niacin (Ref. 8 and Ref. 9) and in the obesity prevalence in the children aged 12-19 years (Ref. 28); F: The linear regression plot of the prevalence of obesity in 1966-2004 against grain contribution in 1956-1994 using the data in E.

respectively; R^2 = 0.949 and 0.92 for boys and girls aged 12-19 years, P = 1.2e-17 and 3.4e-15, respectively).

Association between grain consumption and obesity prevalence in US children

Grains have been used as a major vehicle for niacin-fortification. The increase in the daily per capita niacin consumption from grains reflects the fortification level and the trend toward the consumption of fortified grain products. Although the US per capita grain consumption steadily decreased from the late 1930s through the early 1970s (Figure 4A), the grain contribution to niacin actually significantly increased due to niacin-fortification (Figure 4E). In the early 20th century, high per capita consumption of non-fortified grains was associated with a low prevalence of obesity in US children and adolescents. However, the re-increase in the consumption of the grain products fortified with more niacin since 1974 was followed by a steep increase in the obesity prevalence in the US children of all age groups in the 1980s and 1990s. The lag was ten years (Figure 4A, C and D). Moreover, the obesity prevalence in US children also increased in parallel with the increase in grain contribution to niacin with a 10-year lag (Figure 4E). The regression analyses showed

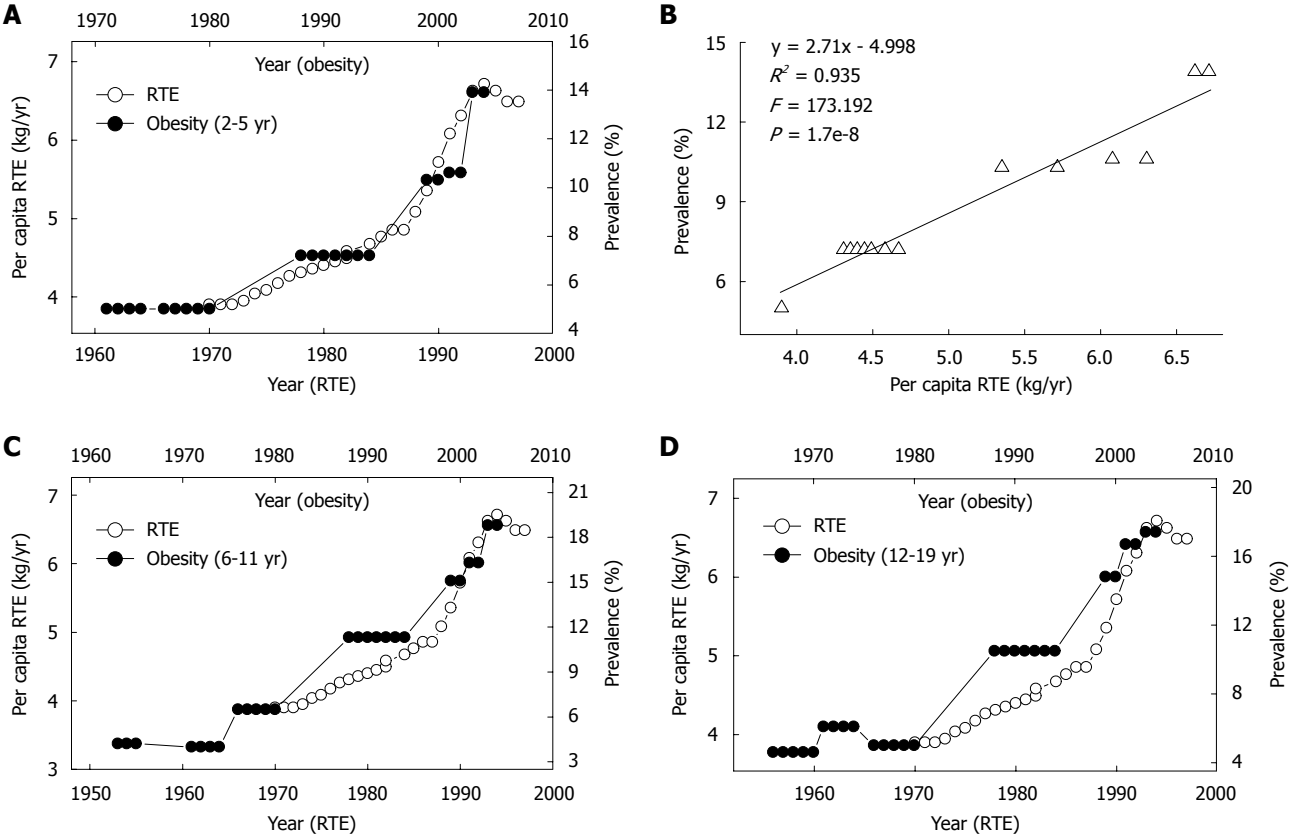

Figure 5 Relationship between per capita ready-to-eat cereal (RTE) consumption and prevalence of obesity in US children. A: Trends in US per capita RTE consumption in 1970-1997 (Ref. 32) and in the prevalence of obesity in the 2-5 years age group; B: The linear regression plot of the obesity prevalence in 1980-2004 against RET consumption in 1970-1994 using the data in A; C and D: A similar relationship between the RTE consumption and the obesity prevalence in the 6-11 years and 12-19 years age groups.

significant lag-correlations between the grain contribution to niacin and the obesity prevalence of US children aged 2-5 years (R^2 = 0.726, P = 4.8e-7), 6-11 years (R^2 = 0.898, P = 6.8e-13) and 12-19 years (Figure 4F).

Association between RTE consumption and the obesity prevalence in US children

ERT, a popular food item for many Americans, especially children, is the most common vehicle for niacin-fortification in the US. The continued upward trend of niacin since the mid-1970s has been primarily due to the increase in the fortification standards of RTE in 1974 and the greater use of enriched grain products[8]. As shown in Figure 5, the yearly per capita consumption of RTE has rapidly increased since 1970, and the obesity prevalence in the US children of all age groups increased in parallel with the increase in the RTE consumption with a 10-year lag. There were significant correlations between the RTE consumption in 1970-1994 and the obesity prevalence in US children aged 2-5 years (Figure 5B), 6-11 years (R^2 = 0.933, P = 2.1e-8) and 12-19 years (R^2 = 0.913, P = 1.0e-7) in 1980-2004.

DISCUSSION

The major findings of this study are: (1) nicotinamide overload may induce a biphasic effect on glucose metabolism, characterized by insulin resistance followed by hypoglycemia; and (2) there is a significant association between the US per capita niacin consumption and the obesity prevalence in US children and adolescents. These findings may help explain both the development of obesity and the increased prevalence of obesity.

Insulin resistance is a key feature of obesity[22]. Increasing evidence has indicated that systemic oxidative stress, characterized by elevation of plasma ROS, is an important trigger of insulin resistance[33]. In agreement with this suggestion, this study found that the plasma insulin level increased in parallel with the rise of plasma H_2O_2, the major mediator of oxidative stress, while decline in the H_2O_2 level led to hypoglycemia, which suggested that the insulin sensitivity increased. It seems that the oxidative stress plays a critical role in nicotinamide-induced insulin resistance. The present findings are in agreement with the hypothesis that niacin-induced increase in β-cell secretory capacity is the result of pancreatic islet adaptation to niacin-induced insulin resistance[25,26].

It is generally accepted that obesity results from excess energy intake and physical inactivity. A recent hypothesis suggests that factors favoring a trend toward hypoglycemia might induce excess energy intake and overweight[34]. Interestingly, the present study demonstrated that nicotinamide overload induced a biphasic response: insulin resistance in the early phase characterized by more insulin

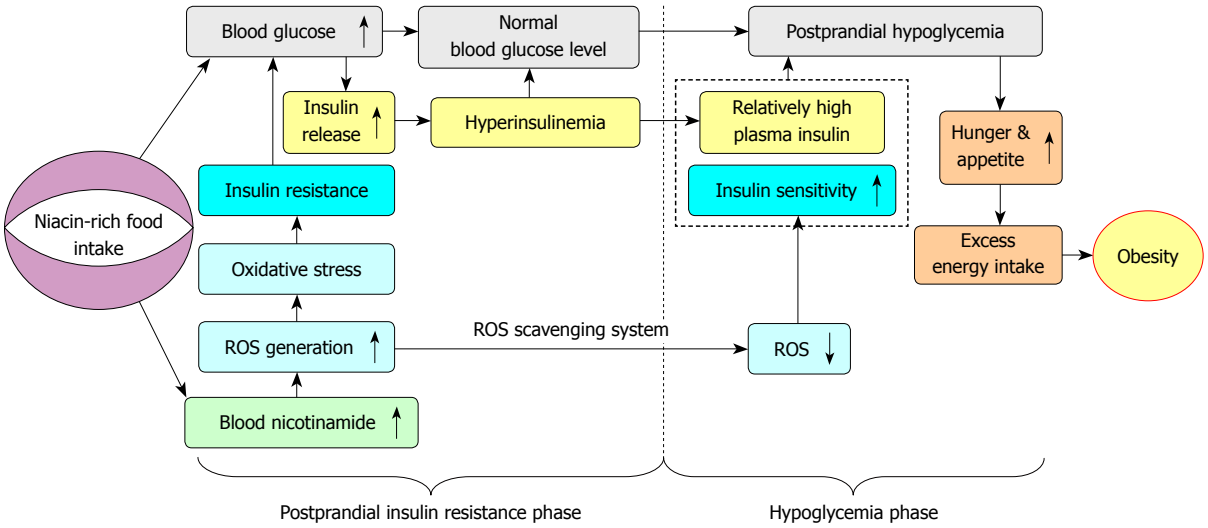

Figure 6 Proposed model of the role of niacin overload in obesity development. Excess nicotinamide metabolism may induce a biphasic effect: postprandial hyperinsulinemia followed by postprandial hypoglycemia, in which reactive oxygen species (ROS) generation and scavenging may play a central role.

release due to the enhanced ROS production, and hypoglycemia in the late phase due to the different clearance rates of plasma ROS and insulin. The biphasic response may underlie the increased appetite in obesity: high nicotinamide diet may produce more ROS and decrease insulin sensitivity, which leads to more insulin release. Then, with the relative rapid fall of plasma ROS and the re-increase in insulin sensitivity, the relative high insulin level may lead to hypoglycemia, which may induce hunger, eating behavior change, and subsequent excess energy intake (Figure 6). As such, it is not difficult to imagine that long-term nicotinamide overload-induced insulin resistance may eventually lead to β-cell failure. From this point of view, it seems that long-term excess nicotinamide intake may be a primary cause of obesity and type 2 diabetes. Moreover, our previous study demonstrated that sweat is an effective way to eliminate excess nicotinamide from the body[27]. Thus, physical activity not only increases energy expenditure but also decreases insulin resistance by facilitating the elimination of excess nicotinamide through sweating, which may help explain why sweat-inducing activities are effective in preventing obesity and type 2 diabetes. It should be pointed that excess niacin-induced oxidative stress and abnormal glucose metabolism is expected to involve other blood glucose-controlling hormones, such as glucagon and glucagon-like peptides. Further studies are warranted to examine the effect of excess niacin intake on these hormones.

Since niacin overload may be involved in the development of obesity, determining whether there is niacin overload in the modern diet may be helpful for understanding the global prevalence of obesity. Generally, dietary niacin comes mainly from the following two main sources: niacin-rich foods and niacin fortified foods. In term of the development of obesity and diabetes, the known high-risk foods are those rich in niacin, such as meat[35,36]. Most importantly, niacin fortified-grain products have been the most significant source of niacin. As shown in Figure 1, the daily US per capita niacin consumption has been kept a rising trend since the implementation of mandatory niacin-fortification, and has been two times higher than the RDA in the early 2000s. The amount of the daily per capita niacin consumption from grains and animal flesh was 3.7 and 6.8 mg, respectively, before the introduction of mandatory niacin-fortification in the 1930s, and has increased to 14.8 and 11.8 mg, respectively, in 2000. The percentage of grain contribution to dietary niacin has been increased four times since the implementation of niacin fortification. It is obvious that niacin-fortification may be mainly responsible for niacin overload, and may play a role in the increased prevalence of obesity in the US. To test this hypothesis, we examined the relationship between US per capita niacin consumption and the prevalence of obesity in US children and adolescents. Indeed, the present results showed that the obesity prevalence in the US children of all age groups increased in parallel with the increase in the per capita niacin consumption and the increase in the grain contribution to niacin, with a 10-year lag. RTE is a popular food item for many Americans, especially children. The update of fortification standards in the US in 1974 has led to a significant increase in niacin content in RTE[8]. The present study also revealed that there was a significant lag-correlation between the obesity prevalence in US children and the RTE consumption. Since the late 1990s, the US per capita niacin consumption has remained relatively stable (around 32-33 mg/d per capita)[9]. According to the regression equations shown in Figure 3, the obesity prevalence in the US children of all age groups should have been near its peak now. Indeed, the most recent NHANES data showed that there was no significant change in obesity prevalence between 2003-2004 and 2005-2006 in US children[37].

Dietary factors play a key role in the development and prevalence of obesity and diabetes[12,16,35,36]. The increasing global prevalence of obesity and diabetes implies that there may be a common change in diet composition worldwide. It should be pointed out that one of the common and major global changes in diet composition in the

last few decades is the significant increase in the content of dietary vitamins due to the spread of food fortification worldwide. The global prevalence of obesity and diabetes has spread in much the similar way as that of niacin-fortification, in contrast, those countries that had not introduced niacin-fortification or that prohibited niacin fortification before the early 1990s, such as Norway[38,39], have a low prevalence of obesity and diabetes in the 1990s, compared with the niacin-fortified countries such as the US and Canada. Thus, the possibility cannot be ruled out that the rapid global increase in the prevalence of obesity in the past three decades may be, at least in part, a man-made event due to niacin fortification.

Obesity is strongly associated with non-alcoholic fatty liver disease (NAFLD), a common disease characterized by an increase in intrahepatic triglyceride content with or without steatohepatitis[40]. As early as in 1964, Rikans *et al*[41] found that excess niacin in high fat diets can induce fatty liver in rats. Moreover, numerous case reports have shown that excess niacin can induce liver injury[6]. Thus, there is the possibility that excess niacin intake may play a role in the development of NAFLD. Investigating excess niacin metabolism and its toxic effects may be of help in gaining insight into the development of not only obesity but also NAFLD.

In summary, the present study demonstrates for the first time that nicotinamide overload-induced biphasic response in glucose metabolism may play a role in the development of obesity, and suggests that the high prevalence of obesity in US children and adolescents may involve a long-term niacin overload largely due to the grain fortification with niacin. It seems that the long-term safety of niacin fortification needs to be carefully evaluated.

COMMENTS

Background

Niacin, a potent stimulator of appetite, may induce insulin resistance at high doses. Global prevalence of obesity which is characterized by increased appetite and insulin resistance has occurred following the spread of grain fortification with niacin worldwide. However, how niacin stimulates appetite and whether excess dietary niacin plays a role in the obesity epidemic are not known.

Research frontiers

Obesity is directly related to diet and physical activity. Therefore, exploring the dietary risk factors for obesity and understanding the underlying mechanism of increased appetite and insulin resistance in obesity are important issues in the prevention and treatment of overweight and obesity.

Innovations and breakthroughs

The present study demonstrated for the first time that excess nicotinamide, when co-administered with glucose, induces biphasic response: insulin resistance in the early phase characterized by more insulin release due to the enhanced reactive oxygen species (ROS) production, and hypoglycemia in the late phase due to the different clearance rates of plasma ROS and insulin. The excess niacin-induced biphasic response may play a role in the development of obesity. This study also revealed for the first time that the obesity prevalence among US children and adolescents increased in parallel with the increase of the per capita niacin consumption with a 10-year lag, in which niacin fortification-induced sharp increase in niacin contents in grain products may play a major role. The present findings may help explain why there has been a sudden sharp increase in the obesity prevalence among US children and adolescents starting around the early 1980s, i.e. about 10 years after updating the niacin fortification standards in 1974.

Applications

Reducing niacin intake and facilitating niacin elimination through sweat-inducing physical activity may be a key factor in the prevention and treatment of obesity.

Peer review

Li *et al* studied in a small (pilot) study the effects of niacin overload on glucose metabolism in relation with a study performed in a large cohort, and this paper would be of interest.

Abstract

AIM: To evaluate quality of life (QoL) after curative liver resection and identify variables associated with decreased QoL.

METHODS: From October 2001 to July 2004, 323 patients underwent liver resection. At 3-36 mo after discharge, 188 patients were disease free. QoL was assessed using the Short Form (SF)-12 Health Survey with mental and physical component scales (SF-12 MCS and PCS), supplemented with generic questions concerning pain and liver-specific items.

RESULTS: Sixty-eight percent (128/188) returned the questionnaire, which was completed in 75% (96/128) of cases. Median SF-12 PCS and MCS were 46.7 (interquartile range: 34.2-53.9) and 54.1 (42.8-58.2). Fifty percent were pain free with a median symptom score of 1.75 (1.38-2.13). PCS was higher after major hepatectomy [57% (55/96)] compared to minor resection (P = 0.0049), which represented an improved QoL. QoL was not affected by sex but by age compared to the general German population. MCS was higher after liver surgery for metastatic disease [55.9 (47.5-58.8)] compared to primary carcinoma [49.6 (36.5-55.1)] and benign disease [49.2 (37.7-56.3)] (P = 0.0317). There was no correlation between length of postoperative period and QoL. Pain, deficiencies in everyday life and a high symptom score significantly decreased MCS and PCS.

CONCLUSION: Most patients were only marginally affected even after major liver resection; however, minor complications were associated with decreased SF-12 MCS and PCS and need careful attention.

INTRODUCTION

Over the past few decades, the multimodal concept of

quality of life (QoL) has been appreciated in many areas of medical practice[1]. Social, physical and mental factors contribute to QoL[2,3]. QoL assessment has proven to be a valuable parameter for patients and surgeons and may be helpful in determining the optimal treatment. As an outcome parameter, QoL is considered as important as disease-free and overall survival[4]. For many different procedures in surgery, the effect on QoL has been assessed, including liver resection for primary and secondary cancer, organ transplantation and gastrectomy[5-13].

In various benign and malignant liver diseases, resection is a common procedure with curative intention. While major and minor hepatectomy are both safe procedures, little is known about postoperative QoL in these patients[14-16]. Erim *et al*[17,18] have investigated QoL of live donors who have undergone liver resection for living related liver transplantation. Anxiety and depression increased in live donors, and improved 3 mo after surgery. Furthermore, Kaneko *et al*[19] have published a study on laparoscopic *vs* open liver resection in patients with hepatocellular carcinoma. QoL improved earlier after laparoscopic surgery. Their finding is similar to other studies that have compared various laparoscopic with open surgical procedures[19,20]. Recently, it has been published that QoL returns to baseline after liver resection for malignancies in most cases[21,22]. Martin *et al*[21] have shown in a prospective study of 36 patients that QoL returns to baseline at about 3 mo after liver resection for cancer.

Thus, the present study was designed to assess postoperative QoL of patients who underwent curative liver resection. Curative resection was defined as the absence of recurrent disease at the time of assessment. QoL was compared with that of the general German population, with a special focus on demographics (e.g. age and sex) and medical history (e.g. indication, type of resection, complications and impairment).

Although several studies on QoL after liver resection have been performed, to the best of our knowledge, this is the largest study on QoL of patients who have undergone curative liver resection[19,21,23,24]. In our opinion, this study's value is the exclusion of any bias caused by the palliative situation of the study population. It seems plausible that patients in a palliative situation might be impaired in their physical and especially mental QoL scores. Therefore, we decided to exclude any patients with signs of recurrence or active disease.

MATERIALS AND METHODS

Study population

Patients who underwent curative partial hepatectomy from October 2001 to July 2004 were recruited for this single-center, observational study on QoL after liver resection. While all patients underwent liver resection with curative intention, curative treatment in the context of this study was defined as the absence of recurrent disease at the time of assessment. The study protocol was approved by the ethical committee and all patients provided informed consent.

A total of 323 patients underwent partial hepatectomy in our hospital from October 2001 to July 2004. One hundred and eighty-eight patients were disease-free at the time of assessment and were eligible to participate in the study, and questionnaires were mailed to these patients. A return rate of 68% (128 patients) for the questionnaires, of which in 75% were filled out completely, further decreased the final study population to 96 patients. Thus, the final population consisted of almost 50% of the eligible study population.

Measures

QoL was assessed by the Short-Form (SF)-12 Health Survey, which is the abbreviated version of the widely used generic profile SF-36[25,26]. Both questionnaires have been validated for numerous populations and quantify the overall physical and mental aspects of QoL[27-34]. The SF-12 provides a subset of 12 items from which two summary measures of physical and mental health status (SF-12 PCS and SF-12 MCS) can be derived from subscales for physical function, physical role, pain, general health, vitality, social function, emotional role, and mental health with high validity, reliability and sensitivity[35].

The demographic and postoperative data, and results of the SF-12 Health Survey, a well-established QoL questionnaire, were analyzed, together with a pain assessment on a 0-10 scale and relevant liver-specific items.

Additional illness-specific items were used to assess liver-specific issues, for example, fever, dyspepsia, heartburn, lack of appetite, nausea, vomiting, night sweat and exhaustion. Patients indicated on a scale of 1-5 (1, never; 2, rarely; 3, sometimes; 4, often; 5, very often) the frequency of the individual symptom postoperatively. The calculated mean was used as a symptom score that ranged from 1 to 5. Impairment in everyday activities was measured on a scale of 1-5 (1, none; 2, light; 3, moderate; 4, heavy; and 5, strongest) and patient autonomy was measured as a variable indicating "independent" and "help needed". Pain was assessed using a 0-10 scale.

Surgery

As described by Belghiti *et al*[36], major hepatectomy was defined as resection of three or more segments and minor hepatic resection as resection of two or fewer segments. Thus, our patients were divided into a major and minor hepatectomy group.

Complications

Postoperative complications were stratified into surgical (e.g. bile leak or biloma, pneumothorax, wound infection, liver abscess, bleeding, and surgical dehiscence) and medical (e.g. pleural effusion, renal failure, hepatic failure, pneumonia, cardiac insufficiency, and cholangitis), and were assessed from patient records. Complications were defined as described elsewhere[16].

Study procedures

QoL was assessed at least 3 mo after discharge from hospital (range: 3-36 mo). Medical data were collected from

follow-up examinations as proof of patient eligibility (e.g. no signs of recurrence). In patients with malignant diseases, staging was performed according to the guidelines of the Association of the Scientific Medical Societies in Germany. Only patients without signs of recurrence were eligible for the study. Subsequently, questionnaires were sent to the patients by mail. Furthermore, patients were contacted by telephone to increase the return rate of questionnaires. Clinical data such as indication for liver resection, type of liver resection, medical and surgical postoperative complications were collected and documented in a database in a prospective manner.

Statistical analysis

SAS software (version 9.1; SAS Institute, Cary, NC, USA) was used for statistical analysis. The quantitative parameters SF-12 PCS, SF-12 MCS, pain, symptom score, and age are presented as median with interquartile range. Mann-Whitney *U* test and Kruskal-Wallis one-way analysis of variance were chosen to compare the quantitative parameters between subgroups of patients. Patients were stratified for age, sex, type of resection and indication for surgery. The relationships between the quantitative parameters were analysed using Spearman's rank correlation coefficient *r* and its corresponding *P* value. Two-sided *P* values were always calculated; $P < 0.05$ was considered statistically significant, and $P < 0.001$ was considered highly significant.

RESULTS

Study population

One hundred and eighty-eight patients underwent partial hepatectomy for benign and malignant hepatic lesions and were recurrence-free at the time of assessment. While 128 patients (68%) returned their questionnaire, it was fully completed in only 96 cases (52% of recurrence-free patients), of which 50% were male. Thus the final study population comprised 96 patients (Table 1). No significant difference could be found in demographics, indications and type of resection between patients with fully and partial filled questionnaires.

Indication for liver resection

The diagnoses are listed in Table 1; almost 21% of patients resected had benign lesions and > 79% had malignant liver tumors. Of the latter, > 72% were metastatic. More than 69% of metastases had spread from a colorectal tumor.

Surgical procedures

The procedures performed are listed in Table 1. There were 55 (57%) major and 41 minor hepatic resections. Patients underwent hemi-hepatectomy or extended hemi-hepatectomy in 45% and > 6% of the cases, respectively. Furthermore, six patients (6%) underwent resection of ⩾ 3 segments other than (extended) hemi-hepatectomy. Minor resection was performed in 43% of patients. These patients underwent resection of one segment (24%), or segmental resection that consisted of *en bloc* resection of two segments or resection of two discontinuous segments (20%).

Table 1 Demographics, indications and type of resection

	n = 96	100%
Median age (yr)	63.4	IQR: 54.5-70.5
Male/female	48/48	50/50
Primary malignant	21	21.9
Hepatocellular carcinoma	12	12.5
Cholangiocellular carcinoma	8	8.3
Gallbladder carcinoma	1	1.0
Metastatic	55	57.3
Colorectal	38	39.6
Other	17	17.7
Benign	20	20.8
Adenoma	4	4.2
Focal nodular hyperplasia	6	6.3
Cysts	1	1.0
Echinococcus	3	3.1
Haemangioma	2	2.1
Other	4	4.2
Major hepatectomy	55	57.3
Right hemi-hepatectomy	35	36.5
Extended right hemi-hepatectomy	3	3.1
Left hemi-hepatectomy	8	8.3
Extended left hemi-hepatectomy	3	3.1
Segmentectomy ($n > 2$)	6	6.3
Minor hepatectomy	41	42.7
Segmentectomy ($n = 1$)	23	24.0
Segmentectomy ($n = 2$)	18	18.8
Concomitant extrahepatic resection	10	10.4

Patients were stratified for demographic data, indications and type of resection. Patients suffering from benign, primary malignant and metastatic liver diseases were included. IQR: Interquartile range.

Morbidity

At least one of both medical and surgical postoperative complications occurred in about 30 (31%) patients (Table 2). Pleural effusion was the most frequent medical complication and occurred in about 9% of all cases. The most frequent surgical complication was bile leakage or biloma, which occurred in 6% of all cases (Table 2). Type of surgery (i.e. major or minor hepatectomy) was not significantly associated with frequency of surgical and medical complications.

QoL and symptom scores

Table 3 shows the SF-12 PCS and SF-12 MCS median scores stratified for demographic items, type of resection, indication and overall morbidity.

The age-dependent distribution of physical and mental SF-12 scores is shown in Figure 1 for patients *vs* the population norm. Patients younger than 40-51 years who underwent liver resection showed significantly lower SF-12 PCS (Figure 1A) and SF-12 MCS (Figure 1B) scores compared to their age-matched normal group ($P < 0.05$).

The mental QoL score was significantly higher ($P < 0.05$) in patients who underwent liver resection for

Table 2 Morbidity and postoperative complications

Complication	Total		Major hepatectomy		Minor hepatectomy	
	n = 96	100%	*n* = 55	100%	*n* = 41	100%
Total morbidity	30	31.2	20	36.4	10	24.4
Surgical complications	19	19.8	14	25.5	5	12.2

Revision laparotomy	3	3.1	2	3.6	1	2.4

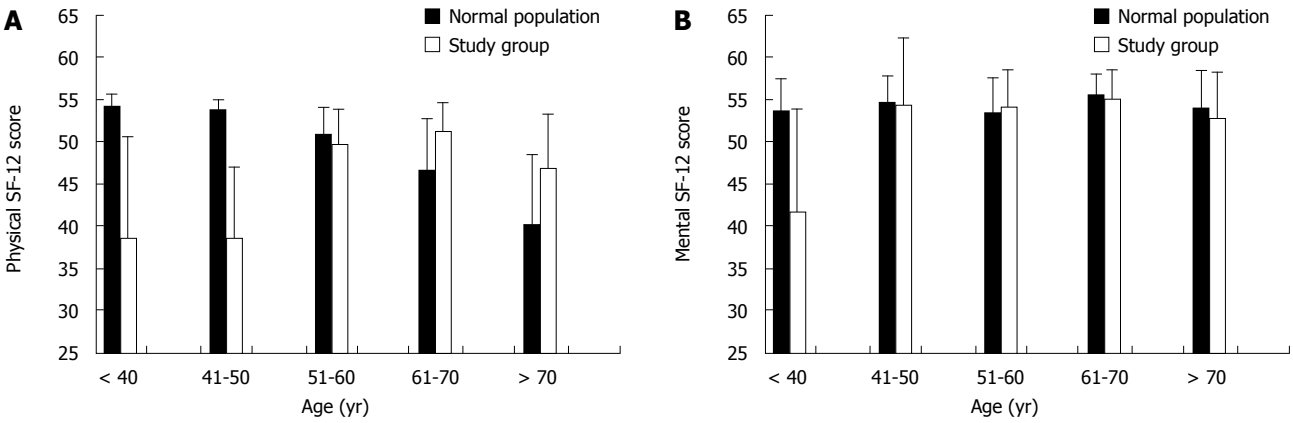

Figure 1 SF-12 scores *vs* general population. A: Physical SF-12 score. Although younger patients experienced lower physical scores than did the general population, the difference between the groups decreased; B: Mental SF-12 score. Older patients experienced the same levels of mental QoL as younger patients. The younger the patients were, the more significant was the impact of surgery on their scores.

metastases, with almost 56 (48-59) compared to patients with primary liver malignancies or benign liver disease with scores of about 49 (38-56) and 50 (37-55), respectively. Physical QoL varied according to the type of liver resection. While patients who underwent major resection reached a physical score of 52 (39-54), values after minor resection were about 41 (32-51) ($P < 0.005$). Sex, age and postoperative morbidity did not have a significant impact on mental or physical QoL.

Postoperative symptoms rarely occurred (Figure 2). The median value of symptom scores was 1.75 (1.38-2.13).

Subjective impairment after surgery correlated with lower summary score ($P < 0.001$) (Table 4). Patients who were not able to manage their living alone without the help of others had lower scores for both SF-12 PCS ($P < 0.05$) and SF-12 MCS ($P < 0.001$) (Table 4). The occurrence of medical problems considered to be minor was associated with decreased QoL scores (Table 4). Patients with postoperative wound infections showed significantly lower values for both SF-12 PCS ($P < 0.05$) and SF-12 MCS ($P < 0.05$) compared to patients without this complication and population norm.

High symptoms scores, pain and deficiencies had significant negative correlations to physical and mental SF-12 scores. Furthermore, high symptom scores correlated with high levels of pain and deficiencies in day-to-day life experienced by patients. Pain and scores of SF-12 PCS had a significant negative correlation ($r = -0.65$, $P < 0.0001$), while high degrees of deficiencies in the patients' daily routine correlated with low QoL values ($r = -0.59$ and -0.51 for PCS and MCS, respectively, $P < 0.0001$). Furthermore, high symptom scores were associated with pain and the feeling of being handicapped in life.

DISCUSSION

In mail surveys, non-responder bias has to be kept in mind. Our study provided valid data for 68% of our

Table 3 Median SF-12 scores

	n	Physical score		Mental score	
		Median	IQR	Median	IQR

No	66	50.2	37.4-54.1	54.1	42.4-58.8

Mental and physical SF-12 scores were stratified for sex, age, indication, type of resection and morbidity. Higher SF-12 scores represent better QOL. *P* values physical/mental scores: [a]$P = 0.2966/0.0317$ (metastatic *vs* primary malignant); [b]$P = 0.0049/0.4176$ (major *vs* minor resection).

Table 4 Impaired autonomy and wound healing after resection, and median physical and mental scores

	n = 96	Physical score	Mental score
Impairment			
None	35	53.8	57.9
Slight	30	43.3	54.4
Moderate	20	43.3	45.4
Heavy	9	33.7	36.9
Strongest	2	21.8	41.6

Help needed[a]	6	28.3	41.6
Wound healing deficiency			
Yes	10	33.0	43.0
No	85	46.9	54.8
Not stated[b]	1	25.8	55.1

Questions on impairments in everyday activities, autonomy and wound healing were included in the survey. [a]$P < 0.0008$ for physical SF-12 scores, $P < 0.0354$ for mental SF-12 scores; [b]$P = 0.0474$ for physical SF-12 scores, $P = 0.0062$ for mental SF-12 scores.

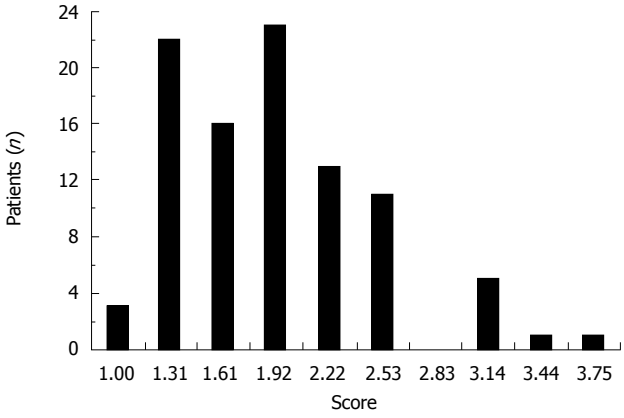

Figure 2 Distribution of liver-specific symptom score. Patients were asked about fever, dyspepsia, heartburn, lack of appetite, nausea, vomiting, night sweat and exhaustion. Patients were stratified for mean levels of symptom scores ranging from 1 to 5. The mean value of 1.82 ± 0.51 indicated that postoperative symptoms rarely occurred.

patients, and data for the missing 32% could only be generated by extrapolation. Different approaches exist for the extrapolation of data from mail surveys, which have been discussed previously[37-39]. Due to the relatively high response rate - compared to a mean response rate to mail surveys published in medical journals of 30%-60% - and since there was no systematic difference as far as demographic and medical characteristics were concerned, we assumed that our data were valid in the context in which they were investigated[38].

Postoperative QoL has been assessed for many medical and surgical treatments[40-43]. Most of these studies aimed not only at providing descriptive data, but also to help physicians and surgeons to choose optimal treatment[44]. Our results describe QoL after liver resection for patients who received curative treatment. In contrast to Martin *et al*[21], we included patients with all common types of indication for liver resection. Furthermore, we ensured that only patients who were disease free at least 3 mo after liver resection were included.

The present study found that patients younger than 50 years of age had lower QoL compared to their age-matched normal population group and to older patients. The impact of surgery on younger patients' QoL might

be stronger for several reasons. Besides medical reasons (i.e. comorbidity and different indications), it has to be taken into account that, in general populations, QoL (especially physical) is usually found to decline with age, and patients might have different expectations in different age groups. Patients older than 70 years of age reported a higher physical QoL than their age-matched controls.

Patients with liver metastases reported a higher physical as well as mental QoL than those who underwent resection for primary malignant or benign liver lesions (Table 3). We assumed that most patients who underwent surgery for metastatic disease already knew from the primary surgical intervention that physical wellbeing would return some time after surgery. Furthermore, we assumed that the fulfilled hope to be cured from the metastases of an already resected primary tumor might have a great impact on QoL[45].

Surprisingly, patients who underwent major liver resection reported a higher physical QoL compared to those who underwent minor resection (Table 3). Patients might compare their QoL to their recovery period, which may be prolonged and more complicated after extensive surgery, thus leading to a subjectively improved QoL.

Neither surgical nor medical complications were more frequent after major compared to minor hepatectomy (Table 2). Furthermore, postoperative complications that are considered to be minor medical problems, such as impaired wound healing, were found to interfere with QoL (Table 4). In all patients, the symptom score, pain and deficiencies in daily routine correlated significantly with QoL.

Data presented here show that 3-36 mo after discharge from hospital, mental and physical scores tended to be close to those of the general population, as long as QoL-decreasing factors (e.g. pain, or impaired wound healing) were absent. Furthermore, we were also able to identify important determinants of QoL.

QoL is always subject to individual judgement and compared by the patients to their own experience. Thus, elderly patients, who generally experience decreased physical QoL in comparison to younger patients, might find the effect of surgery less invasive. While this is clearly speculative, this might be an explanation for the higher physical QoL scores after surgery in elderly patients.

Moreover, individual judgement of QoL offers an explanation for the counter-intuitive finding of higher QoL scores after major hepatectomy in comparison to minor resection. Patients undergoing major resection most likely experience a higher impact of the more invasive surgery. Thus, after recovery, they might experience a higher change in their physical scores.

In contemporary surgery, QoL is considered as important as disease-free survival and morbidity. Thus, we investigated important factors that potentially determine QoL in patients undergoing curative hepatic resection. This study clearly demonstrates that even after a short time following liver resection, the vast majority of patients score equal or even higher in SF-12 compared to that of the population norm.

However, there is a small number of patients whose QoL might be affected by pain, impaired wound healing and subjectively perceived deficiencies in their daily routine following liver resection. This implies that appropriate pain and wound management is needed and coping with deficiencies in daily routine needs to be addressed postoperatively.

Furthermore, clinicians should be aware that QoL might be appraised differently depending upon age and underlying disease, in order to discuss the expectations of the surgical procedure.

COMMENTS

Background

Quality of life (QoL) has been appreciated in many areas of medical practice and has proven to be helpful in determining the optimal treatment. As an outcome parameter, QoL is considered as important as disease-free and overall survival. Although major and minor hepatectomy are both safe procedures, little is known about their postoperative QoL. Thus, this study was designed to assess the postoperative QoL of patients who underwent curative liver resection and to compare their QoL to that of the general German population, with a special focus on demographics and medical history.

Research frontiers

Although several studies on QoL after liver resection have been performed, to the best knowledge of the authors of this article, this is the largest study on QoL of patients who underwent curative liver resection. In the authors' opinion, this study's value is the exclusion of any bias caused by the palliative situation of the study population. It seems plausible that patients in a palliative situation might be impaired in their physical and especially mental QoL scores. Therefore, the authors decided to exclude any patients with signs of recurrence or active disease.

Innovations and breakthroughs

In contrast to other studies, the authors eliminated the palliative bias and thus were able to evaluate the effect of surgery itself on QoL. While interpretation of our findings needs to be done with due care and, as in other studies on this subject, is speculative, they were able to identify contributors to QoL, and more importantly, did not identify a negative effect of curative hepatectomy on QoL.

Applications

The authors think that their findings are helpful in defining the optimal treatment for patients who require liver resection. Thus, their data justify the indication for surgery and can help surgeons to recommend major and minor hepatectomy to patients who need this type of surgery.

Terminology

QoL is a multimodal concept and can be measured with standardized questionnaires such as the Short-Form Health Survey (SF). Both versions (SF-12 and SF-36) have been validated and provide information on both physical and mental QoL.

Peer review

This is a large study of QoL in 323 patients undergoing liver resection for various indications. QoL was assessed using standard verification protocols.

Abstract

AIM: To investigate whether narrow band imaging (NBI) is a useful tool for the *in vivo* detection of angiogenesis in inflammatory bowel disease (IBD) patients.

METHODS: Conventional and NBI colonoscopy was performed in 14 patients with colonic inflammation (8 ulcerative colitis and 6 Crohn's disease). Biopsy samples were taken and CD31 expression was assayed immunohistochemically; microvascular density was assessed by vessel count.

RESULTS: In areas that were endoscopically normal but positive on NBI, there was a significant ($P < 0.05$) increase in angiogenesis (12 ± 1 vessels/field *vs* 18 ± 2 vessels/field) compared with areas negative on NBI. In addition, in areas that were inflamed on white light endoscopy and positive on NBI, there was a significant ($P < 0.01$) increase in vessel density (24 ± 7 vessels/field) compared with NBI-negative areas.

CONCLUSION: NBI may allow *in vivo* imaging of intestinal angiogenesis in IBD patients.

INTRODUCTION

Angiogenesis plays a crucial role in neoplastic and non-neoplastic chronic inflammatory disorders[1-4], including the inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC)[4,5]. Potent angiogenic activity has been demonstrated in histological specimens from the mucosa of both UC and CD patients, as assessed by CD31 staining[6]. Several reports have shown that blockade of angiogenesis in preclinical models of IBD is a promising new therapeutic approach[7,8]. Narrow band imaging (NBI) is a new endoscopic technology that highlights mucosal surface structures and microcapillaries. Optical filters achieve sequential green and blue illumination, narrowing the bandwidth of spectral transmittance, and thus obtaining tissue illumination at selected narrow

wavelength bands[9,10] to achieve the greatest contrast between vascular structures and the surrounding mucosa.

The diagnostic accuracy of NBI in detecting colorectal neoplasia in patients with or without concomitant UC is superior to conventional colonoscopy and equivalent to that of chromoendoscopy[11,12]. A recent meta-analysis concluded that NBI is accurate, with high diagnostic precision for *in vivo* diagnosis of neoplasia across a range of organs (colon, esophagus, duodenal ampulla and lung)[13].

Very recently, NBI has been proposed as a tool to assess the grade of inflammation in patients with inactive or mildly active UC[14]. In the preliminary study described herein, we investigated whether NBI colonoscopy could be a useful tool to detect *in vivo* angiogenesis in IBD patients with colonic inflammation.

MATERIALS AND METHODS

This was an open study involving patients with a diagnosis of IBD referred to our Gastrointestinal Endoscopy Unit for follow-up colonoscopy. A total of 14 patients were included (8 UC and 6 colonic CD). The extent of the disease was determined by previous colonoscopy. At the time of enrollment in the study, 3 (3/8) UC patients presented with inactive disease (Mayo score = 0) while 5 (5/8) had active disease (2 patients Mayo score = 1, 2 patients Mayo score = 2 and 1 patient Mayo score = 1); 3 (3/6) patients with CD presented with inactive disease and 3 (3/6) had active disease. For CD patients endoscopic activity was assessed by Crohn's Disease Endoscopic Index of Severity (CDEIS). After obtaining informed consent from all patients, white light colonoscopy and NBI (Olympus Medical System, Tokyo, Japan) examinations were performed.

For the white light colonoscopy, the vascular pattern was defined as normal if it did not show any irregularities, or as distorted if the pattern was tortuous. When the vascular pattern intensity was visualized with NBI, we were able to distinguish 2 different mucosal patterns: a stronger (blacker) capillary vascular pattern (NBI+), and a milder or regular capillary vascular pattern (NBI-). For this reason, in our study the vascular pattern could be classified into 4 categories: normal (with white light colonoscopy) and NBI-; distorted (with white light colonoscopy) and NBI-; normal (with white light colonoscopy) and NBI+; distorted (with white light colonoscopy) and NBI+.

For each patient, after determining the vascular pattern by NBI, biopsy specimens were obtained from 5 areas that were normal with conventional endoscopy and NBI-, 5 areas that were normal with conventional endoscopy but NBI+, and 5 areas that were endoscopically inflamed and NBI+. CD31 staining was performed by immunohistochemistry, and microvascular density was assessed by vessel count in colonic biopsies. The pathologist was blinded to the subjects.

Statistical analysis

The parametric data are expressed as the mean ± SD and non parametric data as percent. Fischer's exact probability test and the χ^2 test were used to evaluate statistical differences. A *P*-value less than 0.05 was considered statistically significant.

RESULTS

For each of the 14 patients enrolled in the study, the mucosal vascular pattern was assessed by both conventional and NBI colonoscopy.

Mucosal areas normal with white light colonoscopy and NBI-

In the uninflamed mucosa of patients with IBD, classified as normal with white light colonoscopy and NBI-, the NBI pattern was similar to that in the mucosa from healthy control individuals. At the same time, the vascularization pattern and the microvessel density, as revealed by CD31 staining, were similar in the specimens from the uninflamed, NBI- mucosa from patients with IBD and from healthy controls. No differences were found between UC and CD patients.

Comparison of NBI+ and NBI- areas that were normal with white light colonoscopy

Compared to areas that were endoscopically normal under white light colonoscopy and NBI-, endoscopically normal but NBI+ areas displayed a significant ($P < 0.05$) increase in angiogenesis (12 ± 1 vessels/field *vs* 18 ± 2 vessels/field) (Figure 1A and B). The importance of our findings lies in the evidence that in patients with normal white light colonoscopy, areas positive on NBI showed an increased leukocyte infiltrate and a significantly increased microvessel density ($P < 0.05$) as assessed by histological analysis (Figure 1A-C). As revealed by staining for CD31, the mean microvessel diameter in IBD was 0.1 mm, a size histologically compatible with the diameter of a dot observed on the NBI image. No differences were found between UC and CD patients (not shown).

Areas inflamed on white light colonoscopy and NBI+

Lastly, in areas from IBD patients that were inflamed under white light endoscopy and were NBI+, a significant ($P < 0.01$) increase in vessel density (24 ± 7 vessels/field) was found compared with endoscopically normal, NBI- areas (Figure 2A and B), a finding compatible with a high degree of microscopical inflammation and immune-driven angiogenesis. No differences were found according to Mayo score in vessel density (not shown). No differences were found between UC and CD patients (not shown).

DISCUSSION

Angiogenesis is an integral component of non-neoplastic chronic inflammatory disorders, such as IBD[15,16]. Microscopic imaging is the approach that has thus far proven most valid for quantification of vasculature in normal and pathological tissue[17-19]. NBI has been successfully used to visualize angiogenesis and thereby to detect cancerous areas in the colon. Because of the improved mucosal contrast provided, NBI may improve the detection of colon polyps compared with standard

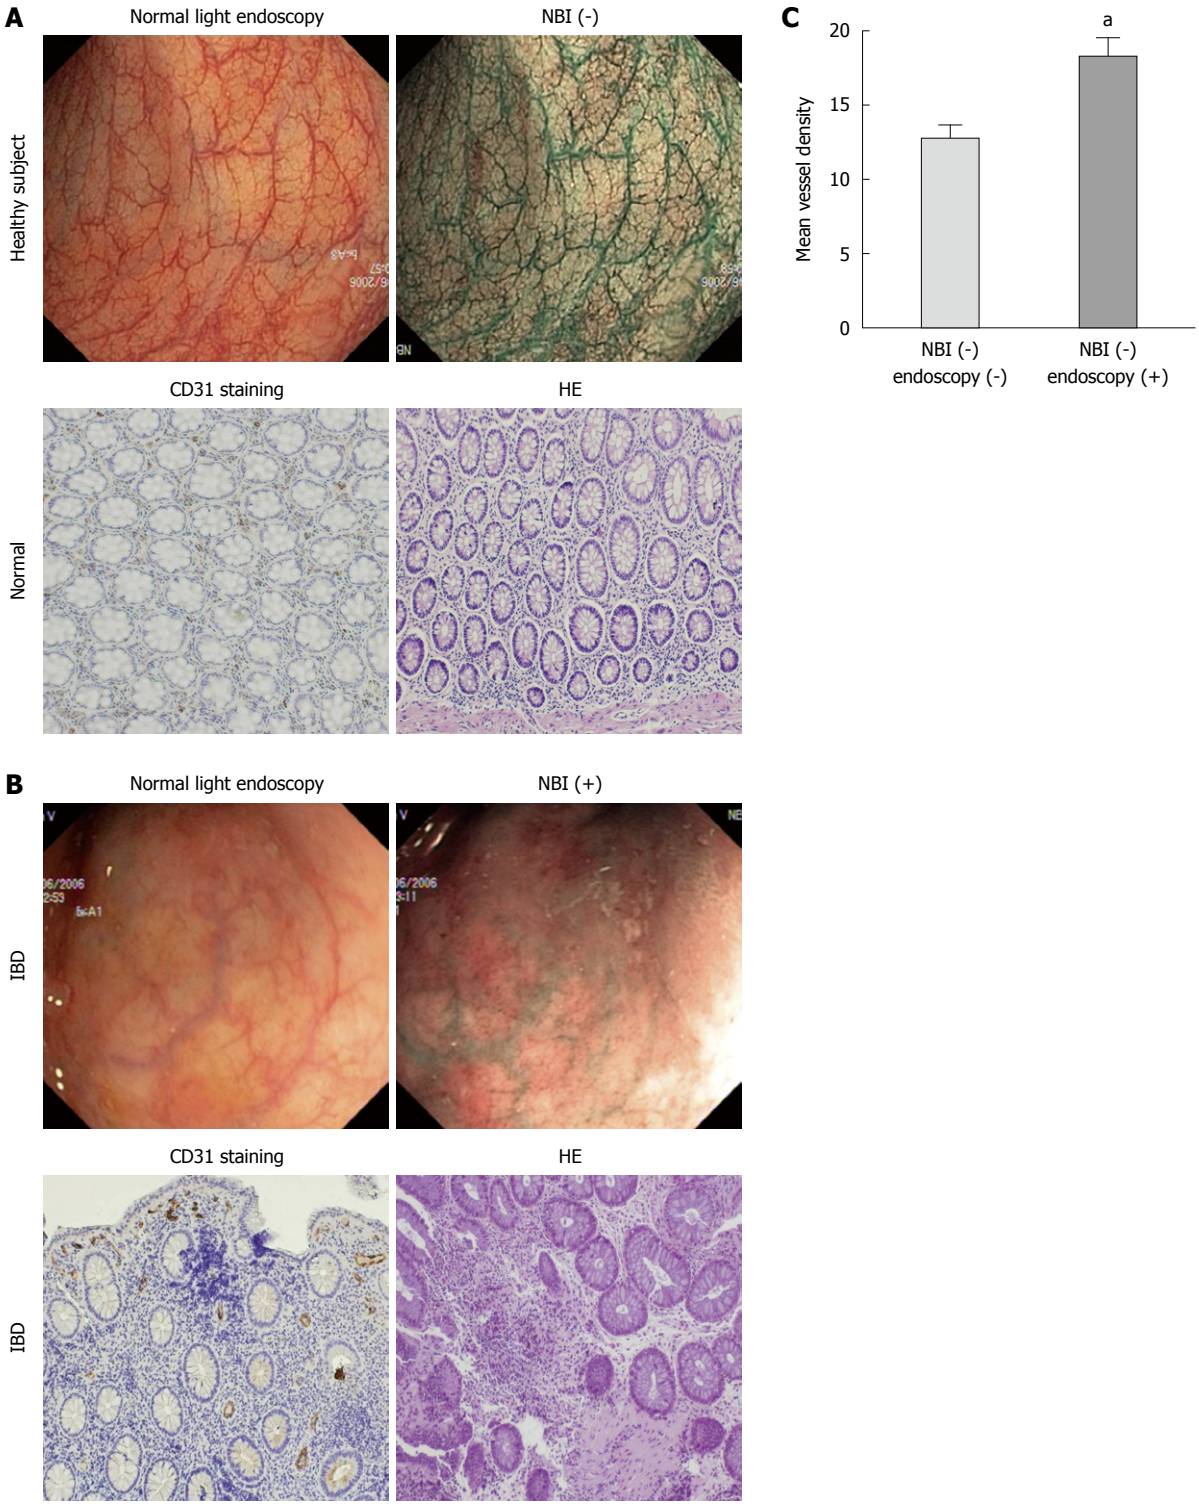

Figure 1 Colonic mucosa of healthy individuals and uninflamed but narrow-band imaging (NBI)+ regions from patients with inflammatory bowel disease (IBD), visualized using white light colonoscopy and NBI endoscopy. The microvasculature of histologically normal control and IBD uninflamed colonic mucosa was immunohistochemically stained for CD31 and von Willebrand/factor Ⅷ. There was increased vascularization in uninflamed IBD mucosa that presented an aberrant NBI+ pattern, in the NBI+ areas compared with controls. A: Healthy subjects. The vascular pattern was normal on both conventional colonoscopy and NBI, which was confirmed by immunohistochemical staining; B: Areas of the IBD mucosa that were not inflamed on conventional colonoscopy and showed an aberrant NBI+ pattern. Immunohistochemical staining confirmed an increased vascularization in these areas compared with NBI- areas; C: Computerized morphometric analysis of the microvasculature in control and IBD uninflamed mucosa that was NBI+. After immunohistochemical staining, sections were analyzed for the total number of vessels/field (microvascular density). [a]A statistically significant difference was found between sections from areas of uninflamed IBD colonic mucosa that were NBI+ and from controls.

white light colonoscopy. NBI has also been widely used to detect dysplasia in patients with long-standing UC, achieving good results in terms of diagnostic accuracy and detection of polyps, although if did not show any statistically significant differences compared with standard white light colonoscopy[19,20].

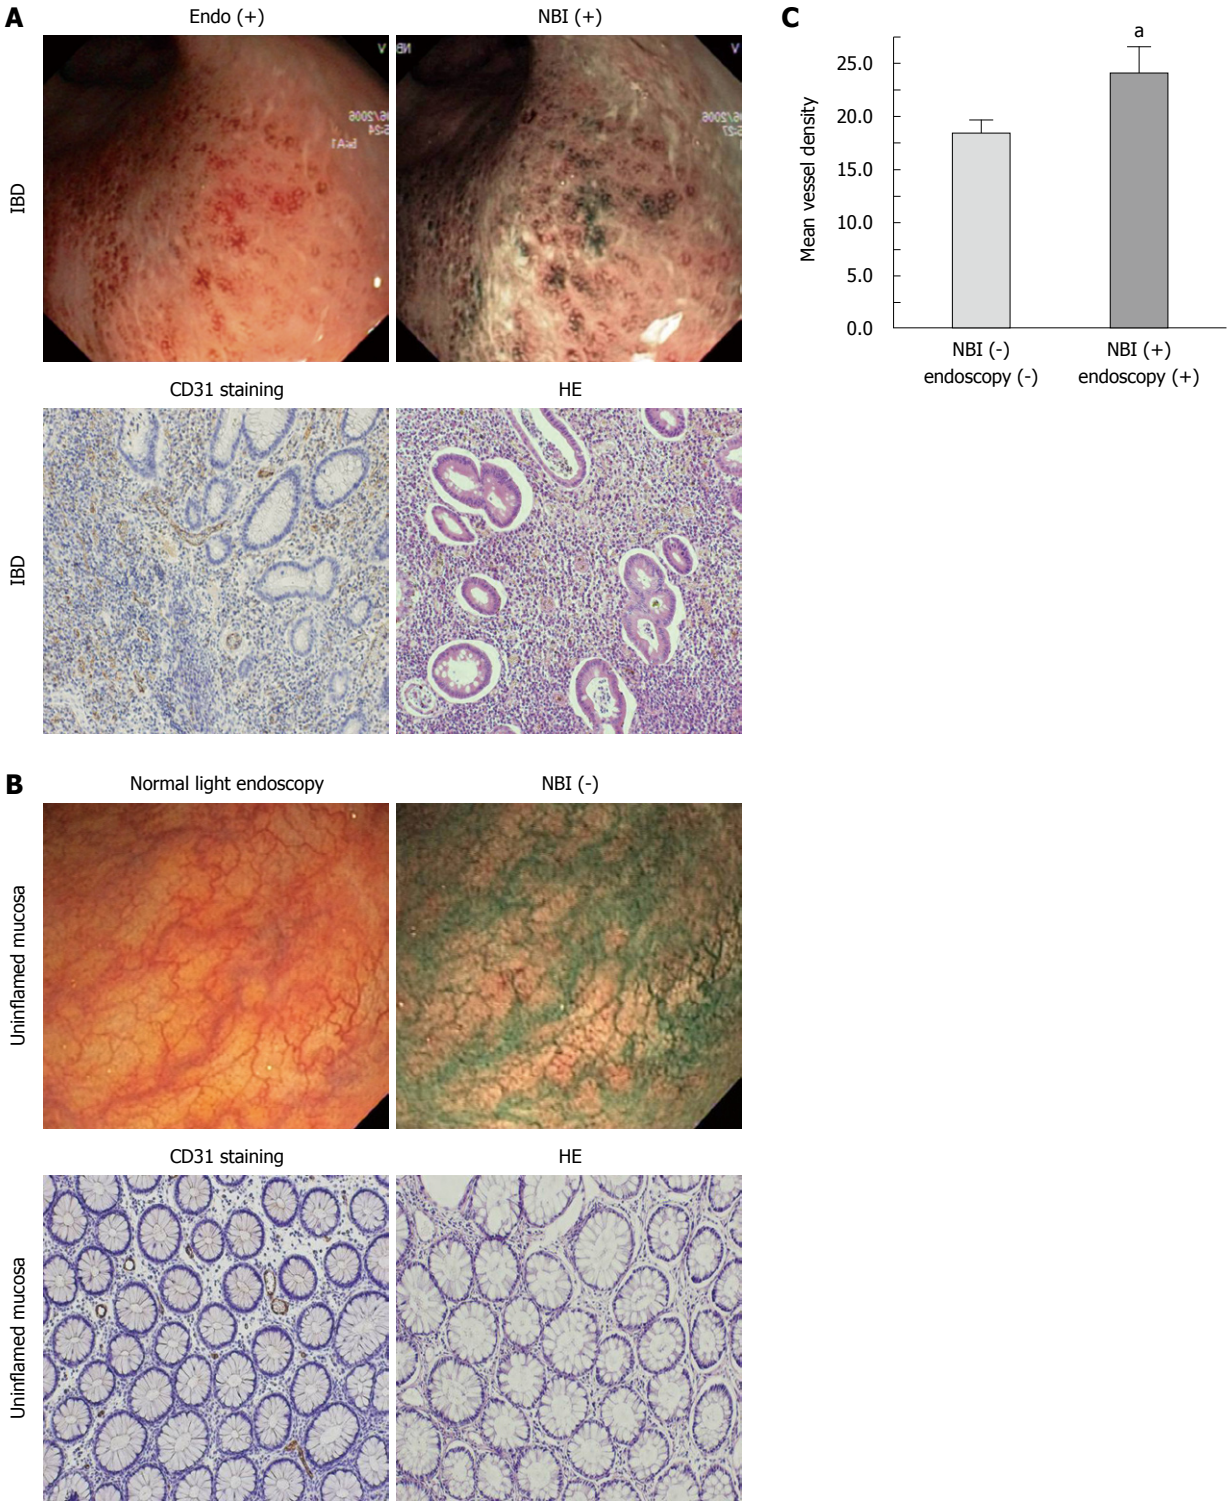

Figure 2 Inflamed colonic mucosa of IBD patients visualized using white light colonoscopy and NBI. The microvasculature of IBD inflamed colonic mucosa was immunohistochemically stained for CD31 and von Willebrand/factor Ⅷ. A: Areas of the IBD mucosa that were inflamed on white light colonoscopy showing an aberrant NBI+ pattern. There was increased vascularization in the inflamed IBD mucosa in areas where there was an aberrant NBI+ pattern, which was confirmed by immunohistochemical staining; B: Areas of the IBD mucosa that were not inflamed on conventional colonoscopy and showed an aberrant NBI+ pattern. Immunohistochemical staining confirmed an increased vascularization in these areas compared with NBI- areas; C: Computerized morphometric analysis of the microvasculature in the IBD inflamed mucosa. After immunohistochemical staining, sections were analyzed for the total number of vessels/field (microvascular density). [a]A statistically significant difference was found between sections from areas of inflamed IBD colonic mucosa that were NBI+ and areas of uninflamed IBD mucosa that were normal under white light colonoscopy but were NBI+ .

In a recently published study, NBI was proposed as a tool to assess the grade of inflammation in patients with inactive or mildly active UC[12]. In our study, we found that NBI could also be used to visualize areas of abnormal microvascular changes, not observed at white light colonoscopy. A statistically significant correlation exists between NBI pattern positivity (both in inflamed and normal areas at conventional endoscopic examination) and microves-

sel density, as confirmed by CD31 staining in histological specimens from the same areas. In patients who were normal under standard colonoscopy, there was increased leukocyte infiltration and microvessel density in NBI+ areas, as assessed by histological analysis.

Blockade of angiogenesis could be beneficial in patients with chronic inflammation and some drugs that have demonstrated efficacy for the treatment of IBD, such as tumor necrosis factor-α inhibitors, have potent antiangiogenic activity. Our preliminary findings suggest that NBI could be a novel tool for the *in vivo* assessment of mucosal angiogenesis. However since our study is still a preliminary study because of the limited number of patients, a larger study should be performed to define the exact role of NBI in IBD patients, and the correlation of mucosal angiogenesis with endoscopic activity.

Endoscopic imaging and monitoring of angiogenesis has the potential to be a valuable biomarker in monitoring the grade of intestinal inflammation *in vivo*, monitoring response to and optimization of available treatments, and finally in evaluating the response to new agents for the treatment of IBD in randomized clinical trials.

COMMENTS

Background

Angiogenesis plays a crucial role in neoplastic and non-neoplastic chronic inflammatory disorders, including inflammatory bowel diseases (IBD).

Research frontiers

Narrow-band imaging (NBI) is a new endoscopic technology that highlights mucosal surface structures and microcapillaries. A recent meta-analysis concluded that NBI is accurate, with high diagnostic precision for *in vivo* diagnosis of neoplasia across a range of organs (colon, esophagus, duodenal ampulla and lung).

Innovations and breakthroughs

Very recently, NBI has been proposed as a tool to assess the grade of inflammation in patients with inactive or mildly active ulcerative colitis. In this preliminary study, the authors investigated whether NBI colonoscopy could be a useful tool to detect *in vivo* angiogenesis in IBD patients with colonic inflammation.

Applications

Several reports have shown that blockade of angiogenesis in preclinical models of IBD is a promising new therapeutic approach. Visualize angiogenesis *in vivo* may represent the first step for such a therapeutic approach.

Terminology

Angiogenesis: the process of new capillary formation from pre-existing vasculature in adult tissues; Narrow-band imaging: a new endoscopic technology that highlights mucosal surface structures and microcapillaries.

Peer review

The authors report that NBI may be a novel modality for imaging of intestinal angiogenesis in IBD. The results provide sufficient evidence to draw scientific conclusions. The statistical data reflect the results and are adequate for a clinical study. The discussion is well organized, and valuable conclusions are provided.

Abstract

AIM: To assess the agreement within 3 commonly used symptom-reflux association analysis (SAA) parameters investigating gastroesophageal reflux disease (GERD) in infants.

METHODS: Twenty three infants with suspected GERD were included in this study. Symptom index (SI), Symptom sensitivity index (SSI) and symptom association probability (SAP) related to cough and irritability were calculated after 24 h combined pH/multiple intraluminal impedance (MII) monitoring. Through defined cut-off values, SI, SSI and SAP values are differentiated in normal and abnormal, whereas abnormal values point towards gastroesophageal reflux (GER) as the origin of symptoms. We analyzed the correlation and the concordance of the diagnostic classification of these 3 SAA parameters.

RESULTS: Evaluating the GER-irritability association, SI, SSI and SAP showed non-identical classification of normal and abnormal cases in 39.2% of the infants. When irritability was taken as a symptom, there was only a poor inter-parameter association between SI and SSI, and between SI and SAP (Kendall's tau b = 0.37, $P < 0.05$; Kendall's tau b = 0.36, $P < 0.05$, respectively). Evaluating the GER-cough association, SI, SSI and SAP showed non-identical classification of normal and abnormal cases in 52.2% of the patients. When cough was taken as a symptom, only SI and SSI showed a poor inter-parameter association (Kendall's tau b = 0.33, $P < 0.05$).

CONCLUSION: In infants investigated for suspected GERD with pH/MII-monitoring, SI, SSI and SAP showed a poor inter-parameter association and important disagreements in diagnostic classification. These limitations must be taken into consideration when interpreting the results of SAA in infants.

INTRODUCTION

Gastroesophageal reflux disease (GERD) remains one of the most common diagnoses made by pediatric gastroenterologists. By definition, gastroesophageal reflux (GER) is the involuntary passage of gastric contents into the esophagus or oropharynx, which is a physiological process that appears in every individual particularly after meals[1]. When GER causes troublesome symptoms and/or complications, it is referred to as GERD[2]. Clinical manifestations in infants include among others regurgitation, vomiting, irritability and cough[1]. A main problem in the diagnosis of GERD is the association of symptoms with GER, especially the non-specific ones. While endoscopy can detect GER complications such as mucosal inflammation, symptom-reflux association analysis (SAA) is the only available method that can adequately identify GER as the cause of short lived symptoms[3].

SAA aims to show and quantify a temporal relation between symptoms and GER. With qualification, a significant temporal relation between symptoms and GER, thus an abnormal result of the SAA parameter, may suggest GERD. Three parameters are often used to address this temporal relationship: Symptom index (SI), symptom sensitivity index (SSI) and symptom association probability (SAP)[3-6]. A pre-condition required for SAA is a technical measure that identifies GER episodes in the individual esophagus. Two methods can be used: pH-monitoring and a combined pH/multiple intraluminal impedance (MII) monitoring.

In infants, GERD occurs frequently during the first months of life. During this period GER is often non-acid, because the frequent milk intake acts as a potent buffer of gastric acidity. pH-monitoring alone has the disadvantage of only detecting acid GER. The newer MII technique to measure GER allows the additional detection of non-acid GER and thus more GER events. This is the main difference from pH-measurement alone. It is likely that a combined pH/MII measurement will replace single pH-measurement in the future[4,7,8].

Defined cut-off values of the SAA parameters help to decide whether symptom episodes which occurred during GER monitoring are related to GER or not. Despite routine clinical use in pediatrics[6], SAA parameters have never been validated in children or in infants. The problem is the lack of an objective and reliable gold standard to which these parameters can be compared, as well as the ethical difficulty posed by obtaining data from healthy children. The correlation of these 3 parameters as well as the concordance of abnormal results within these parameters in infants is unknown. Therefore, a comparison between studies using different SAA parameters is not possible. Additional questions arise as to whether only one SAA parameter could be a substitute for the others or how to interpret different results of the various SAA parameters measured in one individual.

Condino *et al*[5] reported that in infants hospitalized for evaluation of GER, fussiness/pain and cough were the most frequent symptoms and were found to be the most frequent symptoms related to GER detected by combined pH/MII monitoring. We assessed SI, SSI and SAP for irritability and cough in a group of infants who underwent combined pH/MII monitoring for suspected GERD. In order to evaluate the agreement between these 3 parameters we analyzed the correlation and the concordance between them in normal and abnormal classification.

MATERIALS AND METHODS

In this retrospective study, combined pH/MII tracings of consecutively investigated infants performed between October 2006 and January 2009 were reviewed. All infants included had irritability and cough among other GER-like symptoms and underwent 24 h combined pH/MII monitoring for suspicion of GERD. Patients were clinically evaluated prior to combined pH/MII analysis. Various investigations such as barium swallow, esophagogastroduodenoscopy and laboratory analysis were performed based on history and clinical signs. A barium swallow was performed in infants with suspected anatomic upper gastrointestinal anomalies. Esophagogastroduodenoscopy was performed in the case of GERD resistant to therapy and to detect eosinophilic esophagitis. Diagnosis of esophagitis was based on histology of esophageal biopsies[9]. Therapy was prescribed by the referring physicians or by one of the authors (P.B.). Therapy was not discontinued during the entire observation period.

Twenty four h combined pH/MII measurement was performed using hardware and software by Sandhill Technologies (Sandhill Scientific Inc., Highlands Ranch, CO, USA). A single-use catheter (ConforTEC® pH-MII probe ZIN-BS 45) with a diameter of 2.13 mm was placed transnasally. This probe consisted of six 1.5 cm impedance recording segments and one pH-electrode, located within the distal impedance segment. The middle of each impedance segment was located at 0, 1.5, 3, 4.5, 6 and 7.5 cm above the pH-electrode. The initial positioning of the catheter was estimated using the following formula: (0.156 × height in cm) + 6.88 cm = length of pH-electrode from nose to distal esophagus[10]. Proper positioning of each catheter was confirmed by X-ray. The pH-electrode was placed 2 vertebral bodies above the diaphragm with a tolerance margin of 5 mm. The probe was connected to the portable recording device. An external reference electrode was attached posteriorly to the patient's chest.

The studies were performed on an inpatient basis. The caregivers (nurse and parents) were properly instructed by the attending physician on how to register the irritability and cough events on the portable recording device. We defined the term "irritability" as crying or whining. A child was irritable either if it cried or if it showed behavior of being unwell, expressed as making a grimace on the verge of crying. The latter was the perception of the parents. The pH/MII tracings were evaluated using the BioVIEW analysis software (Sandhill Scientific, Inc.) and each study was manually reviewed by a pediatric gastroenterologist. Patients with less than 20 h of recording were excluded from the study. A (liquid) GER episode detected by im-

pedance was defined as a retrograde drop in impedance by more than 50% of baseline in the distal 2 channels[11]. Gas only episodes were not included in the analysis. A symptom was considered related to a GER event if it occurred within a 5 min window from the GER event[12,13].

The SI was defined as the number of GER-related symptoms divided by the total number of symptoms, reflecting the percentage of symptoms related to GER episodes[12]. The SSI was defined as the number of GER-related symptoms divided by the total number of GER episodes, reflecting the percentage of GER associated with symptoms[14]. SAP was defined as the likelihood that the patients' symptoms were related to GER based on a statistical analysis (cross tabulation) of a contingency table consisting of 4 possible combinations of GER and symptoms. The SAP was calculated as $(1\text{-}P) \times 100\%$, with the *P*-value calculated using Fisher's exact test[15]. The SAP calculation was provided in the software package of the pH/MII monitoring device. Based on the literature, SI values of $\geqslant 50\%$, SSI values of $\geqslant 10\%$ and SAP values of $\geqslant 95\%$ were considered abnormal[3,5,6].

Statistical analysis

Statistical analysis was performed with SAS 9.2 (The SAS Institute, Cary, NC, USA). Continuous variables are presented as median and interquartile range (IQR) or, if an approximately normal distribution was assumed, as mean ± SD. *P*-values < 0.05 were considered significant. Concordance between the different SAA methods was assessed by Kendall's tau-b. Kendall's tau-b calculates a measure of concordance based on the number of concordant and discordant pairs and uses a correction for tied pairs. It ranges between -1 and +1, where +1 is perfect concordance and -1 perfect discordance. A value of zero indicates the absence of any concordance. In the case of continuous variables, rankings were compared[16].

The study was approved by the local ethics committee of the University of Fribourg, Switzerland.

RESULTS

Patient characteristics

Twenty-three infants aged 2 wk to 11 mo (median 3 mo, IQR 2.8 mo) were included in this study. 19 patients were male. One patient was under ranitidine treatment, 4 patients were under sucralfate treatment, 3 patients were under omeprazole treatment and 7 patients had thickened feeding. Mean duration of the procedure was 22 h and 44 min ± 1 h 11 min. A previous barium meal was performed in 11 patients and showed a hiatus hernia in 1 case. Two patients had undergone esophagogastroduodenoscsopy and biopsies after combined pH/MII monitoring, which showed esophagitis in both.

A total of 1692 GER episodes were detected, 395 were acid (23%) and 1297 non-acid (77%). 421 irritability episodes were reported, 165 (39%) were related to GER. There were 155 cough episodes, 73 (47%) related to GER. Table 1 summarizes the characteristics of the registered GER and symptom episodes.

Table 1 Characteristics of the registered reflux and symptom episodes

	GER episodes	Irritability episodes	Cough episodes
Min	22	2	1
Max	141	82	19
Median	67	11	5
IQR	48	18	10
Sum	1692	421	155

GER: Gastroesophageal reflux; Min: Minimal number for a single patient; Max: Maximal number for a single patient; Median: Median value for all patients; IQR: Interquartile range.

Symptom-reflux association analysis

We investigated the GER-irritability association and found the following overall values: SI 25%, IQR 37.5%; SSI 4.5%, IQR 8.1%; and SAP 54%, IQR 78%. Additionally, we investigated the GER-cough association and found the following overall values: SI 50%, IQR 75%; SSI 3.6%, IQR 4.3%; and SAP 38.4% ± 43.3%. Abnormal results for the GER-irritability association were found for 8 patients in SI (34.8%), for 5 patients in SSI (21.7%), and 3 patients in SAP (13.0%). We found abnormal results for the GER-cough association in 13 patients for SI (56.5%), 2 patients for SSI (8.7%), and in 1 patient for SAP (4.3%). Evaluation of the diagnostic classification in normal and abnormal cases for the GER-irritability association showed 60.8% of the patients with identical classification, and 39.2% with non-identical classification. Evaluation of the diagnostic classification in normal and abnormal cases for the GER-cough association showed 47.8% of the patients with identical classification, and 52.2% with non-identical classification. Table 2 summarize the data obtained.

All SAA parameters for the GER-irritability association were positive in one infant. This infant showed a notable GER on barium swallow without an anatomic anomaly. One infant had 3 positive SAA parameters for the GER-cough association. This infant had chronic esophagitis on esophagogastroduodenoscopy.

Evaluation of the diagnostic classification between the GER-irritability SAA parameters showed the following values: SI and SSI Kendall's tau b = 0.2791, $P = 0.2153$; SI and SAP Kendall's tau b = 0.2593, $P = 0.2748$; SSI and SAP Kendall's tau b = 0.4219, $P = 0.1618$. Evaluation of the diagnostic classification between the GER-cough SAA parameters showed the following values: SI and SSI Kendall's tau b = 0.2707, $P = 0.1255$; SI and SAP Kendall's tau b = 0.1870, $P = 0.2987$; SSI and SAP Kendall's tau b = 0.6908, $P = 0.2847$.

We found a poor correlation between the parameters SI and SSI in both symptom categories, irritability and cough. We also found a poor correlation between SI and SAP for the irritability symptom category (Table 3).

DISCUSSION

We investigated the agreement of different SAA parameters in infants who underwent combined pH/MII moni-

Table 2 Categorization of SI, SSI and SAP

SI	SSI	SAP	Number of infants	Percent	Cumulative frequency	Cumulative percent
Irritability/reflux association						
Abnormal	Abnormal	Abnormal	1	4.35	1	4.35
Abnormal	Abnormal	Normal	2	8.70	3	13.04
Abnormal	Normal	Abnormal	1	4.35	4	17.39
Abnormal	Normal	Normal	4	17.39	8	34.78
Normal	Abnormal	Abnormal	1	4.35	9	39.13

toring for suspected GERD using unspecific symptoms such as irritability and cough. To the best of our knowledge this is the first study in children to compare the correlation and concordance of the diagnostic classification between SAA parameters. Taken together SI, SSI and SAP show important disagreements in the diagnostic classification of normal and abnormal symptom-GER association. Within the different SAA parameters a week correlation could be seen at most. This renders the interpretation of the SAA results and the diagnosis of GERD based on SAA parameters difficult as the detection of a pathologic symptom association depends on the SAA parameter chosen. Additionally, the comparison between different studies should be based on the same SAA parameters because our study shows that SI, SSI and SAP are not interchangeable.

Our study showed a higher frequency of non-acid GER (77%) compared to acid GER. This is comparable to the incidence of non-acid GER in infants found in the literature[17]. The high proportion of non-acid GER in our study could also be explained by the fact that some of our patients were examined under treatment. To leave the patients under treatment while presenting GER-like symptoms reflects a clinical situation common in pediatric gastroenterology, as pediatric gastroenterologists are currently increasingly asked to evaluate a patient on proton pump inhibitor treatment after an unsuccessful medical trial. Condino *et al*[5] found no relation between category of GER (acid or non-acid) and the association between GER and the symptoms irritability and cough. In that study, 49.8% of fussiness and pain episodes (comparable to irritability) were related to GER, whereas in our study only 39% of the irritability symptoms were related to GER. In addition, it was reported that 33.5% of cough episodes were related to GER, whereas our study shows that 47% of cough episodes were related to GER.

While our findings are interesting, obviously the limitations of our study must be pointed out. As with many other studies investigating the role of MII in children, the sample size is rather small[18]. Evaluation of the diagnostic classification did not show significant concordance. This is probably due to true discordance, but could also be due to a too weak study power. Furthermore, it must be noted that this study predominantly consists of male infants which reduces the possibility of generalizing the findings to female infants.

The question arises as to which of the three SAA parameters is the best for the diagnosis of GERD. To date the only study to evaluate the diagnostic accuracy of SI, SSI and SAP is a work by Taghavi *et al*[19] on an adult study group. That study validated the SAA parameters obtained on 24 h pH-monitoring against a PPI treatment-trial dividing the study group into responders and non-responders. Patients were given a high dose of omeprazole treatment and asked to complete a symptom score before and after the treatment. Those who showed an effect were considered to have GERD. SSI, with an adapted cut-off value of 1.3%, showed the highest positive and negative predictive values, followed by SAP. SI had the poorest performance

with absence of a meaningful cut-off value making it almost useless. Despite the routine clinical use of SAA parameters in pediatrics there is currently no validation study for combined pH/MII monitoring. The problem is the lack of an objective gold-standard test for the detection of GERD, independent from combined pH/MII monitoring. In an analogy to the work of Taghavi *et al*[19], we would need to perform a reference test in infants, with symptom scoring before and after treatment (e.g. proton pump inhibitors, prokinetics, surface agent, *etc*.) including combined pH/MII monitoring. This is ethically and methodologically challenging in infants.

In general use of SAA is hampered by numerous question marks concerning its accuracy. Firstly, it depends on a technique that correctly detects the GER events. It is likely that the introduction of combined pH/MII-monitoring adding the detection of non-acid GER events, compared to single pH-monitoring, makes SAA more accurate. A study of Rosen *et al*[6] showed that significantly more children had a positive SI using combined pH/MII-monitoring, than using pH-monitoring alone. A possible shortcoming of the 24 h-monitoring technique is the fact that the number of acid and non-acid GER events in MII varied significantly on 2 consecutive days in an adult study[20]. Additionally, investigating 48 h ambulatory pH-monitoring doubled the SI and SAP in adults with atypical GER symptoms compared to 24 h monitoring[21]. Furthermore, automatic MII analysis considers only a drop of impedance of 50% or more as a GER event; however, it is very likely that a drop of 49% could also be attributed to a GER event[4]. To date there are very few studies which evaluate the efficacy of automated analysis. A study by Roman *et al*[22] in adults however showed good agreement between visual analysis and the automated analysis used in our study.

Secondly, results of SAA may have some methodological weaknesses. It depends on the active participation of the observers, in our case nurse and parents[4], thus being impacted by the compliance and the variable work intensity on the ward. It has been shown that adults record only 39% of the cough episodes detected by simultaneous manometry[23]. The arbitrary choice of the time window influences the symptom association parameters. The 5 min time window used within this automatic analysis tool and in other studies may not be optimal for the evaluation of symptoms such as irritability and cough. In this context one has to keep in mind, that SAA detects timely association, which does not necessarily mean causal relation. Unspecific symptoms in infants such as irritability and cough can be evoked by a large number of factors. The temporal association of GER and an unspecific symptom can therefore be a coincidence. SI and SSI have cut-off values that were arbitrarily chosen. In addition, they do not take into account the total number of GER episodes and total number of symptoms, respectively. Therefore, the SI can be positive simply because of a high number of GER episodes, whereas the SSI can be falsely positive because of a high number of symptoms[18].

By showing poor inter-parameter association and important disagreements in diagnostic classification with the 3 established SAA parameters SI, SSI and SAP using combined pH/MII monitoring technique, we showed a common problem encountered with SAA, which is the difficulty of choosing the appropriate parameter to use. Our study cannot give an answer to this problem. Because of unanswered technological, methodological and validation questions and the limited concordance between the SAA parameters, we believe that at the moment, SAA based on combined pH/MII monitoring is a poorly reliable tool for the diagnosis of GERD. Diagnosis of GERD in infants with GERD-like symptoms therefore remains based on several elements such as the absence of more probable reasons for GERD-like symptoms, the positive response to treatment or the detection of GERD complications. However, combined pH/MII-monitoring can argue against GER as the origin of GERD-like symptoms, when showing absent or very low frequencies of GER episodes. Studies in infants are needed in order to obtain reference values and to adjust SI, SSI and SAP cut-off values for GERD, validated for the infant population.

COMMENTS

Background

Gastroesophageal reflux (GER), defined as passage of gastric contents into the esophagus is a normal process that occurs in healthy infants, children and adults. When GER causes troublesome symptoms and/or complications it is referred to as gastroesophageal reflux disease (GERD). During infancy GER is common and can manifest with specific symptoms as vomiting and non-specific symptoms as irritability and cough. Association of non-specific symptoms with GER is a main problem in the diagnosis of GERD.

Research frontiers

Combined pH/multiple intraluminal impedance (MII) detects GER episodes in the individual esophagus. The better the timely association of GER episodes and symptom episodes the more probable it is that GER is the origin of symptoms. Timely association of GER episodes and symptom episodes are expressed by symptom-reflux association analysis (SAA) parameters. Abnormal results of SAA parameters point towards GERD. Three SAA parameters are commonly used, symptom index (SI), symptom sensitivity index (SSI) and symptom association probability (SAP) but they were never validated for the diagnosis of GERD in the infant population. In this study the authors analyzed the agreement between SI, SSI and SAP.

Innovations and breakthroughs

This is the first study in infants to show an important disagreement between the 3 commonly used SAA parameters SI, SSI and SAP, which puts the accuracy of SAA into question. The study shows that the results of SI, SSI and SAP for the diagnosis of GERD often differ. In consequence, the diagnosis of GERD in infants cannot be based on a single SAA parameter as it remains unknown which SAA parameter is the most accurate for the diagnosis of GERD.

Applications

The limited agreement of these parameters must be taken into consideration when interpreting the results of SAA. The diagnosis of GERD should be based on a combination of pH/MII-monitoring, SAA results as well as on other factors such as clinical judgment, gastroscopy and follow-up under medical therapy. Validation studies to enhance the accuracy of SAA parameters and to answer the question which SAA parameter is the most accurate are needed.

Terminology

MII in combination with pH-measurement, a technique based on the fact that the passage of gastric content into the esophagus changes the impedance (electrical resistance) between esophageal segments, is more and more replacing the classic single pH-measurement as a diagnostic tool for GERD. A catheter with multiple impedance recording segments and one distal pH-electrode

connected to an exteriorly portable recording device is placed transnasally into the patient's esophagus in order to detect acid and nonacid GER events.

Peer review

This is an important topic and it has been little addressed in children.

Abstract

AIM: To investigate relapse predictors in chronic hepatitis C (CHC) patients with end-of-treatment response (ETR), after pegylated interferon-α (PegIFN-α) and ribavirin treatment.

METHODS: In a retrospective study we evaluated a spectrum of predictors of relapse after PegIFN-α and ribavirin treatment in 86 CHC patients with ETR. Viral loads were determined with real-time reverse transcription polymerase chain reaction. Hepatitis C virus genotyping was performed by sequencing analysis. Patients with genotype 1 were treated for 48 wk with 180 μg PegIFN-α2a or 1.5 μg/kg PegIFN-α2b once weekly plus ribavirin at a dosage of 1000 mg/d for those under 75 kg or 1200 mg/d for those over 75 kg. Patients with genotypes 2 and 3 were treated for 24 wk with 180 μg PegIFN-α2a or 1.5 μg/kg PegIFN-α2b once weekly plus ribavirin at a dosage of 800 mg/d.

RESULTS: In all ETR patients, binary logistic regression analysis identified absence of complete early virological response (cEVR) (OR 27.07, 95% CI: 3.09-237.26, $P < 0.005$), serum alkaline phosphatase (ALP) levels prior to therapy < 75 U/L (OR: 6.16, 95% CI: 2.1-18.03, $P < 0.001$) and body mass index > 26 kg/m^2 (OR: 8.27, 95% CI: 2.22-30.84, $P < 0.005$) as independent predictors of relapse. When cEVR patients were analyzed exclusively, ALP prior to therapy < 75 U/L remained the only predictor of relapse.

CONCLUSION: Lower levels of ALP prior to, during and after therapy seem to be associated with a higher risk of relapse in CHC patients with ETR.

INTRODUCTION

Chronic hepatitis C (CHC) is a major public health problem due to late complications, such as liver failure and hepatocellular carcinoma[1]. The prevalence of CHC has been estimated to be 3% worldwide[2]. Pegylated interferon-α (PegIFN-α) with ribavirin is currently the

treatment of choice for CHC[3]. Treatment response depends on patient and viral factors, the viral genotype being the most important[4]. Several studies have defined further predictive factors for response, such as hepatitis C virus (HCV)-RNA serum level, stage of liver disease, body weight, age, sex and race[5-10]. After completion of treatment, HCV may become detectable again considerably reducing sustained virological response (SVR) rates even after achievement of end-of-treatment response (ETR). The relapse rate of genotype 1 seems to be higher than in other genotypes, being as high as 30%-40%[11]. The risk of relapse was also shown to relate to treatment duration, and several efforts have been undertaken to identify those patients who would benefit from extended treatment duration[12].

In this retrospective study we investigate in a cohort of ETR patients whether further predictors of relapse may exist after treatment with PegIFN-α and ribavirin.

MATERIALS AND METHODS

Patient population

We reviewed the records of all CHC patients with an ETR who started PegIFN-α and ribavirin treatment between April 2005 and August 2007 at our clinic. Exclusion criteria were age < 18 years; any bone or bowel diseases, chronic renal failure, use of medication that could cause an elevation of liver enzymes; biliary obstruction confirmed sonographically; hepatitis B virus or human immunodeficiency virus co-infection; daily ethanol ingestion greater than 20 g for women and 40 g for men; drug abuse; history of previous antiviral treatment. Finally, 86 patients (62 men and 24 women, mean age 42.5 ± 11.3 years, range 18-67 years) were included. Genotypes 1, 2 and 3 were present in 52 (60.5%), 9 (10.5%) and 25 (29%) patients, respectively. Patients with genotype 1 were treated for 48 wk with 180 μg PegIFN-α2a or 1.5 μg/kg PegIFN-α2b once weekly plus ribavirin at a dosage of 1000 mg/d for those under 75 kg or 1200 mg/d for those over 75 kg. Patients with genotypes 2 and 3 were treated for 24 wk with 180 μg PegIFN-α2a or 1.5 μg/kg PegIFN-α2b once weekly plus ribavirin at a dosage of 800 mg/d. Patients with extended treatment duration were not included in this study. A complete early virological response (cEVR) was considered present, when HCV-RNA by polymerase chain reaction (PCR) was negative 12 wk after initiation of therapy. Patients, who did not achieve a cEVR showed at least a partial early virological response (pEVR), defined as a 2-log-decline of HCV-RNA at 12 wk after the initiation of therapy compared to baseline viral load. ETR was defined as negative HCV-RNA at the end of treatment, and SVR was defined as persistent absence of HCV-RNA by PCR at 6 mo, thereafter.

Laboratory analysis

Alkaline phosphatase (ALP), alanine aminotransferase, aspartate aminotransferase and γ-glutamyl transferase were assessed by routine colorimetric assays on the Modular Clinical Analyzer (Roche, Vienna, Austria). Diagnostic ranges were 1-1200 U/L, 4-600 U/L, 4-800 U/L and 3-1200 U/L, respectively. Normal ranges of ALP were 40-129 U/L for males and 35-104 U/L for females. The precision of the ALP assay was > 99.3%.

Viral loads were determined with the Cobas TaqMan HCV assay (Quantification range 10 to 6.9×10^7 IU/mL; Roche). HCV genotyping was performed by sequencing with the TruGene™ HCV 5'NC Genotyping Kit (Siemens Medical Solutions Diagnostics, Bad Nauheim, Germany).

Liver biopsy was available in 33 patients. Stages of liver fibrosis and inflammatory activity were classified according to the Metavir score[7].

Statistical analysis

Statistical analysis was performed using the Statistical Package for Social Sciences (version 10, SPSS Inc., Chicago, Illinois, USA). Values are expressed as mean ± SD or as median (range). Differences between groups were compared by Student's *t*-test or Mann-Whitney *U* test where appropriate. Fisher's exact test was used to assess possible differences in categorical variables between patients with SVR and relapse. Possible correlations between variables were analyzed using the Spearman rank test. Binary logistic regression analysis was performed to identify independent predictors of relapse. Significance tests were 2-sided, and *P*-values < 0.05 were considered significant.

RESULTS

The clinical characteristics of the ETR patients are summarized in Table 1. Relapse occurred in 26 patients (30.2%), 17 patients (65.4%) with genotype 1, three patients (11.5%) with genotype 2 and 6 patients (23.1%) with genotype 3. The frequency of patients with genotype 1 was not significantly different between the relapse and the SVR group (Table 1). Median ALP prior to therapy was significantly higher, whereas mean body mass index (BMI), stage of liver fibrosis and viral load prior to therapy were significantly lower in patients with SVR compared to those with relapse. The frequency of cEVR was significantly higher in the SVR group compared to the relapse group (Table 1).

In all ETR patients, binary logistic regression identified absence of cEVR (OR 27.07, 95% CI: 3.09-237.26, $P < 0.005$), ALP prior to therapy < 75 U/L (OR: 6.16, 95% CI: 2.1-18.03, $P < 0.001$) and BMI > 26 kg/m^2 (OR: 8.27, 95% CI: 2.22-30.84, $P < 0.005$) as independent predictors of relapse. When only cEVR patients were analyzed, ALP prior to therapy < 75 U/L (OR: 7.79, 95% CI: 1.96-30.98, $P < 0.005$) remained the only predictor of relapse.

Prior to therapy, all ALP levels in patients with relapse were within the normal range.

During PegIFN-α and ribavirin treatment, ALP levels showed variations: in patients with SVR there was a significant decline, whereas in patients with relapse there was a slight non-significant variation (Figure 1A). Similar results were obtained when patients with genotype 1 were analyzed, only (Figure 1B).

Table 1 Clinical and biochemical characteristics of the patients prior to therapy

	SVR (n = 60)	Relapse (n = 26)	P-value
Age (yr)	41.3 ± 11.3	45.4 ± 10.9	NS
Male/female	43/17	19/7	NS
Body mass index (kg/m^2)	24.9 ± 4.0	28.7 ± 5.5	< 0.010
Systolic blood pressure (mmHg)	119 ± 14	119 ± 12	NS
Diastolic blood pressure (mmHg)	73 ± 10	75 ± 10	NS
Genotype 1, n (%)	35 (58.3)	17 (65.4)	NS
HCV-RNA prior to therapy (IU/mL)	480 500 (2430-23 000 000)	806 000 (107 000-8 400 000)	< 0.050
PegIFN α2a/PegIFN α2b	32/28	14/12	NS
cEVR, n (%)	58 (96.7)	17 (65.4)	< 0.001
Histological fibrosis stage	1 (0-4)	3 (1-4)	< 0.050
Histological activity	1 (1-3)	2 (1-3)	NS
Aspartate aminotransferase (U/L)	40 (15-416)	47.5 (24-156)	NS
Alanine aminotransferase (U/L)	72.5 (17-560)	70 (32-214)	NS
γ-glutamyl transferase (U/L)	39 (3-693)	48 (11-183)	NS
Alkaline phosphatase (U/L)	84 (40-232)	67 (48-129)	< 0.005
Cholinesterase (kU/L)	7.22 ± 2.18	7.50 ± 2.37	NS

SVR: Sustained virological response; HCV: Hepatitis C virus; PegIFN: Pegylated interferon; cEVR: Complete early virological response; NS: Not significant.

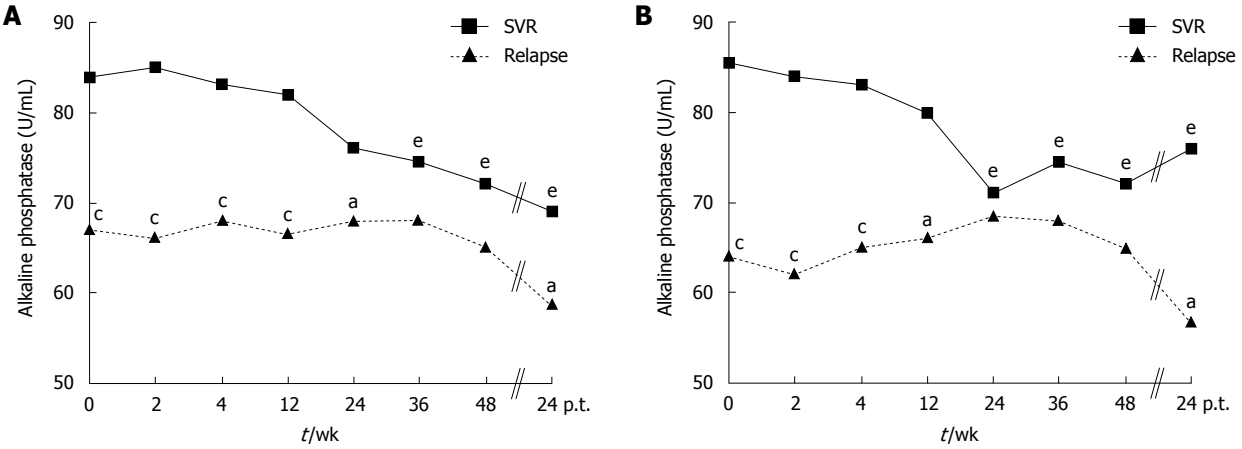

Figure 1 Time course of median serum levels of alkaline phosphatase (ALP) in patients with sustained virological response (SVR) and patients with relapse. A: All patients with genotypes 1-3 from week 0 to week 24. The 36 and 48 wk values exclusively represent genotype 1 patients (n = 52), as patients with genotypes 2 and 3 were only treated for 24 wk; B: Genotype 1 patients, only. $^aP < 0.05$ *vs* SVR; $^cP < 0.005$ *vs* SVR; $^eP < 0.05$ *vs* baseline. p.t.: Post treatment.

DISCUSSION

The results of our study indicate that serum levels of ALP are related to the risk of relapse in CHC patients with ETR after treatment with PegIFN-α and ribavirin.

Elevated levels of ALP are found in bone, bowel and bile duct diseases. As our study did not include patients with bone or bowel diseases, the observed significant difference in pre-treatment ALP between patients with relapse and those with SVR might be caused mainly by differing amounts of ALP from the liver or the bile ducts as the primary source of disease. Bile duct inflammation has been reported in up to 95% of HCV patients and was shown to correlate with serum ALP[13]. Since immune response and inflammation play key-roles in the elimination of HCV, the higher pre-treatment ALP levels in patients with SVR may possibly reflect a higher degree of inflammation with a more sustained response to therapy. However, the histological activity score in our patients failed to show this, as there was no significant difference between patients with SVR and relapse, which could be due to our limited sample size. The observed decline in ALP during PegIFN-α and ribavirin treatment may possibly be due to a decrease of intrahepatic inflammation, which initially could have been higher in those patients with SVR. PegIFN-α and ribavirin may also influence bone metabolism and levels of bone-derived ALP, however, other studies were unable to confirm these findings[14-16]. Any pathophysiological reasoning for the association of ALP levels and risk of relapse of CHC is speculative at present.

Our study is the first to focus on ETR-patients treated with PegIFN-α and ribavirin. Most patients in our study exhibited ALP levels within the normal range with

only 5% of patients with SVR exceeding the upper limit of the normal range. The limits of normal ranges are different in males and females, but gender distribution was almost equal in both patient groups.

In previous studies, genotype 1 was associated with increased relapse rates compared to the other genotypes[11]. In our study, the relapse rate in genotype 1 patients was not significantly higher probably due to the limited number of patients studied.

The strongest predictor of relapse in our study was absence of cEVR. Nearly all patients with SVR and almost two thirds of patients with relapse exhibited a cEVR. When cEVR is achieved, treatment duration is usually not extended. As prolongation of treatment has been shown to reduce relapse rates, ALP may possibly help to identify those patients, who would benefit from extended treatment duration[12].

Limitations of our study comprise its retrospective nature, limited sample size and lack of histological examinations in all patients. As ALP is elevated in a variety of diseases, we cannot exclude that some subclinical diseases with minor ALP elevations confounded our data. Despite those limitations, median ALP was higher in our SVR patients compared to those with relapse at all time points.

In conclusion, lower levels of ALP prior to, during and after therapy with PegIFN-α and ribavirin seem to be associated with a higher risk of relapse in patients with ETR. Further studies are required to clarify whether our observation could help to identify those patients who would benefit from extended therapy despite the presence of cEVR.

COMMENTS

Background

Chronic hepatitis C (CHC) is a major public health problem due to late complications, such as liver failure and hepatocellular carcinoma. Pegylated interferon-α (PegIFN-α) together with ribavirin is currently the treatment of choice for CHC. After achievement of end-of-treatment response (ETR) in CHC patients, the occurrence of relapse reduces sustained virological response (SVR) rates.

Research frontiers

Treatment response in CHC patients depends on patient and viral factors, the viral genotype being the most important. Several studies have defined further predictive factors for response, such as hepatitis C virus (HCV)-RNA serum level, stage of liver disease, body weight, age, sex and race. In this study the authors investigated in a cohort of ETR patients, whether further predictors of relapse may exist after treatment with PegIFN-α and ribavirin.

Innovations and breakthroughs

Previous studies investigated predictors of relapse in HCV infected individuals after PegIFN-α and ribavirin therapy. Those studies examined responding as well as non-responding patients, and predictive factors for response, such as HCV-RNA serum level, stage of liver disease, body weight, age, sex and race were identified. After completion of treatment, recurrence of the virus is still a major issue and a quest has been initiated to determine whether there may be predictors of relapse, in order to identify those patients who might benefit from extended treatment duration up front. The result of this study would suggest that alkaline phosphatase (ALP) might be such a predictor in ETR patients. This study is the first to focus on ETR patients, exclusively.

Applications

The authors suggest that apart from monitoring the already known predictors of relapse, ALP monitoring should be included in the work-up of HCV infected patients in preparation for anti-HCV treatment. Furthermore, ALP as an inexpensive clinical parameter should be monitored through-out the treatment period. Their results warrant larger studies to be conducted in a prospective fashion, in order to elucidate the clinical value of ALP monitoring in HCV patients undergoing treatment.

Peer review

It's a very interesting paper and I propose it to be published. Sure AP is not the only important tool to guarantee a SVR but can be useful to speak with patient's about this possibility.

Abstract

AIM: To investigate serum levels of homocysteine (Hcys) and the risk that altered levels carry for thrombosis development in ulcerative colitis (UC) patients.

METHODS: 55 UC patients and 45 healthy adults were included. Hcys, vitamin B12 and folic acid levels were measured in both groups. Clinical history and thromboembolic events were investigated.

RESULTS: The average Hcys level in the UC patients was 13.3 ± 1.93 μmmol/L (range 4.60-87) and was higher than the average Hcys level of the control group which was 11.2 ± 3.58 μmmol/L (range 4.00-20.8) ($P < 0.001$). Vitamin B12 and folic acid average values were also lower in the UC group ($P < 0.001$). When multivariate regression analysis was performed, it was seen that folic acid deficiency was the only risk factor for hyperhomocysteinemia. Frequencies of thromboembolic complications were not statistically significantly different in UC and control groups. When those with and without a thrombosis history in the UC group were compared according to Hcys levels, it was seen that there were no statistically significant differences. A negative linear relationship was found between folic acid levels and Hcys.

CONCLUSION: We could not find any correlations between Hcys levels and history of prior thromboembolic events.

INTRODUCTION

Inflammatory bowel diseases (IBD) are chronic disorders of unknown etiology characterized by destructive inflammation of the gastrointestinal tract, acute exacerbations and remission periods. IBD is exemplified by two major groups of diseases. These include ulcerative colitis (UC) and Crohn's disease (CD). These two diseases are indistinguishable in 10%-15% of IBD patients. This is termed

Indeterminate Colitis (IC)[1]. Patients with IBD are at increased risk of experiencing thromboembolic complications. The incidence of arterial and venous thromboembolic diseases has been reported to be 1%-8% in UC and CD, however some autopsy studies have reported this incidence to be as high as 39%[2,3]. In the study of Bernestein *et al*[4], the risks of deep vein thrombosis and pulmonary emboli were found to be 3 times higher than that of the general population. In addition, venous thrombosis occurs earlier in IBD patients compared to the general population[5]. Thromboembolism is a multifactorial condition. Studies have indicated a state of hypercoagulability involving all the components of the coagulation system in patients with UC[6-8]. The exact etiology and pathogenesis of hypercoagulability have not been explained, however it is widely accepted that this condition is associated with acquired or genetic defects of the coagulation system and the procoagulant effect of proinflammatory cytokines[9-14]. This hypercoagulability increases the risk of thromboembolic events and has a role in the pathogenesis of UC *via* formation of microthrombi in the intestinal microcirculation[15,16].

Homocysteine (Hcys), which was first defined in 1932 by Butz and Vigneaud, is a sulphur-containing amino acid synthesized during transformation of methionine to cysteine in methionine metabolism[17]. Mild hyperhomocysteinemia occurs in about 5%-7% of the general population[18-24]. Increased Hcys levels are due to enzyme abnormalities in metabolic pathways or to nutritional deficits, including folate and vitamin B2, B6 and B12 deficiencies[25,26]. The exact relationship between hyperhomocysteinemia and induction of thrombosis is unknown, however, a state of hypercoagulability resulting from endothelial dysfunction has been blamed[26,27].

Vitamin B12 and folic acid deficiencies due to malnutrition, malabsorption and antifolate medications including methotrexate and sulphasalazine are quite common in IBD. The deficiency of these key nutrients leads to increased Hcys levels in IBD. Several recent studies have reported increased Hcys levels in IBD[28-33]. The objective of this study was to determine levels of homocysteine, folic acid and vitamin B12 in patients with UC; to compare these data with those of a healthy control group; and to investigate the relationship between homocysteine levels and disease activation, thromboembolic complications, localization of disease, and levels of folic acid and vitamin B12.

MATERIALS AND METHODS

Subjects

A total of 55 UC patients [38 males, 17 females; mean age (± SD) 47.4 ± 13.80, age range 20-78 years] were recruited in the study. The patient group consisted of patients followed up and treated for IBD at the outpatient clinic between the dates March 2006 and January 2007. Diagnosis of UC was established using clinical, endoscopic and histological criteria. All patients underwent appropriate endoscopy (colonoscopy or rectosigmoidoscopy) to determine endoscopic activity indices and localization of disease. Biopsy samples were obtained for histopathologic examination when necessary. Rachmilewitz Endoscopic Activity Index was used to determine the degree of endoscopic activity[34]. Clinical activity index was determined according to Truelove and Witts criteria[35].

Current complaints, duration of disease, extraintestinal symptoms, smoking status, history of thromboembolic events (deep vein thrombosis, pulmonary emboli, myocardial infarction, stroke and peripheral arterial obstruction) and medications were recorded. Patients with any other systemic disorders including diabetes mellitus, hyperthyroidism, chronic liver and renal disease, and history of cancer, as well as patients on vitamin B12, folic acid and oral multivitamin supplements, were excluded from the study.

A detailed clinical history was obtained from all patients regarding any previous events of arterial or venous thrombosis. A total of 3 subjects (5.5%) had history of arterial and venous thromboembolic events. Two of these (3.63%) were peripheral deep vein thrombosis, and 1 (1.81%) was myocardial infarction (deep vein thrombosis was diagnosed using Doppler USG, and myocardial infarction using ECG and cardiac enzymes).

A healthy control group was composed of patients with similar age and sex distribution, and without any metabolic, neoplastic or inflammatory diseases or any history of thromboembolic diseases. The healthy control group consisted of a total of 45 healthy individuals [31 males, 14 females; mean age (± SD) 46.4 ± 13.89, age range 20-77 years].

Blood samples

Blood samples were obtained from all patients following 12-h fasting and these samples were used for complete blood count, sedimentation rate, C reactive protein (CRP), routine biochemical analysis (including total cholesterol, triglycerides, LDL cholesterol, VLDL cholesterol), thyroid function tests, folic acid, vitamin B12, homocysteine level examinations. Biochemical parameters were measured using standard methods. Serum levels of folic acid and vitamin B12 were measured using chemiluminescent microparticle immunoassay (CMIA) (Abbott System). Serum homocysteine levels were measured with high pressure liquid chromatography (HPLC) (Betamed, Agilent 1100 series, Chromosystems Reagent Kit).

Statistical analysis

Data were analyzed using SPSS 11.5 package software. Definitive statistics were indicated as mean ± SD or median (minimum-maximum) in continuous variables, whereas categorical data were expressed as number of observations (%). Presence of any significant differences between case and control groups in terms of measurements was evaluated using Mann Whitney *U* test. In contrast, Kruskal Wallis was used to determine any significant differences between treatment types, clinical activity index and localization groups in terms of Hcys levels. Spearman correlation test was used to determine the asso-

Table 1 Demographic features of UC and control groups

	Patients with UC (n = 55)	Healthy controls (n = 45)	P
Mean age (yr ± SD)	47.4 ± 13.80	46.4 ± 13.89	0.484
Gender (male/female)	38/17	31/14	0.983
Smoking status (%)	17 (30.9)	15 (33.3)	0.796

ciation of Hcys levels and duration of disease, clinical activity index, vitamin B12, folic acid and CRP. χ^2 or Fisher's exact test was used for categorical comparisons. A P level of < 0.05 was accepted for statistical significance.

RESULTS

Fifty-five patients with UC were recruited into the study. Patients consisted of 38 (69.1%) males, 17 (30.9%) females and mean age was 47.4 ± 13.80 years with a range between 20-78 years. Forty-five healthy individuals were recruited in the control group, consisting of 31 (68.9%) males, 14 (31.1%) females, with a mean age of 46.4 ± 13.89 years, range between 20-77 years. Groups did not differ statistically significantly in terms of age, sex and smoking status (P = 0.484, P = 0.983, P = 0.796, respectively).

Analysis of distribution of disease localizations in the UC group indicated that 34 (61.8%) patients had distal involvement, 12 (21.8%) patients had left colitis and 9 (16.4%) had pancolitis. Clinical activity indices of patients in the UC group showed that mild, moderate and severe cases were 28 (50.9%), 21 (38.2%) and 6 (10.9%) in number. Analysis of current treatment indicated that 41 patients (74.5%) received 5-ASA, 11 (20%) received azothioprine and 3 (5.5%) received corticosteroid treatment (Table 1).

Mean homocysteine level was 13.3 ± 1.93 μmol/L (range 4.60-87) in the UC group and 11.2 ± 3.58 μmol/L (range 4.00-20.8) in the control group ($P < 0.001$). Mean serum folic acid level was 5.1 ± 2.19 ng/mL (range 1.90-10.90) in the UC group and 6.3 ± 0.87 ng/mL (range 5-10) in the control group ($P < 0.001$). Mean level of vitamin B12 was 250.4 ± 82.49 pg/mL (range 96-505) in the UC group and 327.4 ± 73.90 pg/mL (range 200-482) in the control group ($P < 0.001$).

Thromboembolic events had similar prevalence in UC and control groups and did not differ statistically significantly in this respect (P = 0.250) (Table 2). It was determined that a total of 3 (5.5%) subjects had a history of arterial and venous thromboembolic events. Two

Table 2 Hcys, folic acid and vitamin B12 levels in UC and control groups (95% CI)

	Patients (n = 55)	Controls (n = 45)	P
Hcy (μmol/L)	13.3 ± 1.93	11.3 ± 3.58	< 0.001
Folic acid (ng/mL)	5.1 ± 2.19	6.3 ± 0.87	< 0.001
Vitamin B12 (pg/mL)	250.4 ± 82.49	327.4 ± 73.90	< 0.001
Thromboemboli	3 (5.5%)	0 (0%)	0.250

Table 3 Correlation between Hcys and other variables among patients with UC

	Relationship coefficient	P
Disease duration	0.105	0.447
Folic acid	-0.311	0.021
Vitamin B12	-0.146	0.288
CRP	0.244	0.073
Clinical activity index	0.115	0.403

of these (3.63%) were peripheral deep vein thrombosis and 1 (1.81%) was myocardial infarction (diagnoses were established using Doppler USG for deep vein thrombosis and ECG plus cardiac enzymes for myocardial infarction). The UC group did not differ from control to a statistically significant degree (P = 0.250). These three patients had normal Hcys levels.

No directly proportional relationship was determined in the UC group between homocysteine levels and disease duration, vitamin B12, CRP and clinical activity index; however, there was a negatively proportional relationship found between folic acid and homocysteine levels (r = -0.311 and P = 0.021) (Table 3).

There were no statistically significant differences within the disease localization groups of UC in terms of homocysteine levels (P = 0.096). Additionally, there were no statistically significant differences within the clinical activity index groups of UC in terms of homocysteine levels (P = 0.698). Similarly, there were no statistically significant differences within the treatment groups of UC in terms of homocysteine levels (P = 0.695).

DISCUSSION

Studies have shown that the risks of deep vein thrombosis and pulmonary emboli are three times higher in patients with IBD compared to the general population[4]. The exact pathogenesis of thromboembolism is not known and considered to be multifactorial[36-38]. Moderate hyperhomocysteinemia (hHcy) has been shown to be one of the independent risk factors associated with development of arterial and venous thrombosis[24,39-44].

Elevated Hcys might be due to genetic factors (MTHFR mutation), nutritional factors (deficiencies of folic acid, vitamin B6, vitamin B12) or medications (salazopyrin, methotrexate, corticosteroids)[28,45]. The most common cause of hHcy has been found to be folic acid deficiency in patients with UC[31,46,47].

Several previous studies also reported higher Hcys levels in patients with UC[28-33,45,48,49]. In our study, serum Hcys levels were higher in patients with UC than in healthy controls. Increased Hcys levels were negatively correlated with lower vitamin B12 and folic acid levels. However, multivariate regression analysis demonstrated that decreased folic acid levels were the most significant parameter in determining increased Hcys levels. In a similar study by Mahmut *et al*[28], increased Hcys levels were found to be associated particularly with folic acid deficiency. Hcys levels were observed to decrease following folate replacement and the authors recommended that folic acid levels should be determined and prophylactic folate treatment should be initiated in all patients with IBD. Zezoz *et al*[50] performed a similar study and found that the prevalence of increased Hcys was higher in the UC group compared to the control group (prevalence of Hcys was 30% in UC patients and 10% in control group). Statistical analysis showed that male sex, decreased folic acid and vitamin B12 levels were indicators of hHcy in patients with UC and that decreased folic acid levels were the most important factor. In our study also, decreased folic acid level was found to be the most important indicator of hHcy.

Folic acid deficiency might be associated with several factors in patients with IBD. These include inadequate intake, increased consumption or folate malabsorption in patients using medications, including particularly sulphasalazine (SASP)[30]. In the study of Zezos *et al*[50], one patient who was receiving SASP was found to have increased Hcys levels. An antifolate effect of SASP has also been demonstrated in other studies[28,29]. Only one patient was receiving SASP in our study and this patient had low folic acid and high Hcys levels.

Vitamin B12 levels were found to be decreased in our UC group compared to our control group; however this finding did not attain statistical significance. Studies have shown normal vitamin B12 levels among patients with increased Hcys levels[32,47]. The study of Romagnuolo *et al*[32] performed with regard to this issue has indicated that the prevalence of hHcy was 15.4% in IBD patients and that 80% of these patients had normal vitamin B12 levels. These authors suggested that there could be significant deficiency of vitamin depots or subclinical vitamin B12 deficiency in IBD patients with increased homocysteine and normal serum vitamin levels. In the study by Lambert *et al*[47], vitamin B12, B6 and folate deficiencies were determined as the most sensitive indicators of hHcy. These authors also suggested that subclinical vitamin deficiencies or intracellular vitamin deficiencies heralded vitamin deficiencies in circulation and that multivitamin (including folate) supplements were effective in decreasing Hcys levels. Similar to several previous studies, we found that hHcy did not correlate with disease activation, localization and medications[28,29,31,33]. However, some studies have shown a statistically significant relationship between disease activation and hHcys and reported that Hcys levels were markedly higher in patients with active disease compared to those with inactive disease[49,51].

Two recent studies have investigated Hcys levels in colon mucosa and aimed to discover the role of Hcys in the pathogenesis of UC[52,53]. Morgenstern *et al*[52] obtained biopsy samples from transverse colon and sigmoid or descending colon mucosa of 11 UC and 5 CD patients and examined these samples using high performance liquid chromatography (HPLC). Concentrations of Hcys were found to be higher in the UC and CD patients compared to healthy individuals. This study is the first to demonstrate elevated Hcys levels in human colon mucosa. No statistically significant differences were determined between Hcys levels, and disease activation or current treatment (particularly those receiving and not receiving sulphasalazine) in IBD patients. Interestingly, patients with other chronic inflammatory bowel diseases had normal Hcys levels; and patients with history of colorectal cancer had higher Hcys levels in colon mucosa compared to the normal[52]. The incidence of colon cancer among patients with UC is about 8 times higher than sporadic colon cancer. Hcys has mitogenic and proliferative features[54]. Elevated Hcys levels have been reported to be a risk factor for carcinogenesis[52].

In their study, Danese *et al*[53] measured both plasma and colon mucosal Hcys levels concomitantly in patients with IBD. They reported that Hcys levels were increased in both plasma and colonic mucosa of patients with UC and CD and suggested that Hcys could have a proinflammatory role in IBD. Similar to our study, this investigation did not determine any correlation between Hcys levels and disease activation or medications. A negative correlation was determined between circulatory and mucosal Hcys levels and folic acid levels, emphasizing the necessity of folic acid supplementation in patients with IBD[53].

Large retrospective studies have shown the rate of thromboembolic complications in patients with IBD to be between 1.3%-6.4%[55,56]. Oldenburg *et al*[29] reported that the rate of complications in a total of 231 patients with IBD was 5.7% in those with CD, and 9.0% in those with UC. Comparison of patients with and without venous thrombosis did not yield any statistically significant difference with regard to Hcys concentration. They suggested that hHcy did not influence the prevalence of thrombosis in patients with IBD; but that thrombosis developed secondary to multifactorial phenomena. These authors also suggested that hHcy could contribute to the pathogenesis of thromboembolic events in some of these patients[29].

Papa *et al*[33] reported the rate of thromboembolic complications to be 9.4% (6 patients) in 39 UC and 25 CD patients. There was hHcy in 2 of these patients. There was no statistically significant difference compared to the control group. Additionally, no statistically significant differences were found in Hcys levels in the within group comparison of IBD patients with regard to history of previous thromboembolic events[33]. In our study there were 3 patients with history of thromboembolic events and no statistically significant differences were present compared to the control group. We concluded that hHcy is not the major factor contributing to the development of thromboembolic complications; and that multifactorial etiology was more relevant.

In conclusion, hyperhomocysteinemia is a common

phenomenon in patients with IBD. Vitamin deficiencies should be determined in all patients with IBD and folate and vitamin B complex supplementations should be included in their treatment. In our study, we could not find any correlation between Hcys levels and history of arterial and venous thrombosis. Further studies should be performed to investigate the multifactorial etiology in the development of thromboembolic events in patients with IBD.

COMMENTS

Background

Patients with inflammatory bowel diseases (IBD) are at increased risk of experiencing thromboembolic complications. Studies have indicated a state of hypercoagulability involving all the components of the coagulation system in patients with ulcerative colitis (UC). The exact etiology and pathogenesis of hypercoagulability have not been explained, however, it is widely accepted that this condition is associated with acquired or genetic defects of the coagulation system and with the procoagulant effect of proinflammatory cytokines.

Research frontiers

In their study, Danese *et al* measured both plasma and colon mucosal homocysteine (Hcys) levels concomitantly in patients with IBD. They reported that Hcys levels were increased in both plasma and colonic mucosa of patients with UC and Crohn's disease (CD) and suggested that Hcys could have a proinflammatory role in IBD.

Innovations and breakthroughs

The results of studies investigating the influence of hyperhomocysteinemia on thrombosis in patients with IBD are controversial. Some studies suggest that it could contribute to the pathogenesis of thrombosis whereas other authors suggest that thrombosis develops in IBD patients secondary to multifactorial phenomena.

Applications

In this study, the authors found that the average Hcys level in UC patients was significantly higher than the average Hcys level of the control group. They could not find any correlation between Hcys levels and history of arterial and venous thrombosis. No directly proportional relationship was determined in the UC group between homocysteine levels and disease duration, vitamin B12, CRP level and clinical activity index; however there was a negatively proportional relationship found between folic acid and homocysteine levels. Vitamin B12 and folic acid average values were also lower in the UC group ($P < 0.001$). When multivariate regression analysis was performed, it was seen that folic acid deficiency was the only risk factor for hyperhomocysteinemia. For this reason the authors think that vitamin deficiencies should be determined in all patients with IBD and folate and vitamin B complex supplementation should be included in their treatment.

Terminology

Homocysteinemia is defined as elevation of homocysteine (a sulphur-containing amino acid) level in blood. It is an established risk factor for cardiovascular diseases and premature atherosclerosis.

Peer review

The study demonstrates increased levels of Hcys related to a decrease of folic acid and B12 in patients affected by UC. These data are not associated with an increase of thromboembolic events. The manuscript is well structured.

Abstract

AIM: To evaluate the validity of the estimated glomerular filtration rate (eGFR) as a preoperative renal function parameter in patients with gastric cancer.

METHODS: A retrospective study was conducted in 147 patients with gastric cancer. Preoperative creatinine clearance (Ccr), eGFR, and pre- and postoperative serum creatinine (sCr) data were examined. Preoperative Ccr and eGFR were then compared for their reliability in predicting postoperative renal dysfunction.

RESULTS: Among 110 patients with normal preoperative Ccr values, 7 (6.3%) had abnormal postoperative sCr values, and among 112 patients with normal preoperative eGFR values, postoperative sCr was abnormal in 5 (4.5%) (P = 0.53). Among 37 patients with abnormal preoperative Ccr values, 30 (81.1%) had normal postoperative sCr values, and of 35 patients with abnormal preoperative eGFR values, postoperative sCr was normal in 25 (71.4%) (P = 0.34). Preoperative Ccr was significantly correlated with eGFR (r = 0.514), and postoperative sCr was significantly correlated with preoperative Ccr (r = -0.334) and eGFR (r = -0.02).

CONCLUSION: Preoperative eGFR is as effective as Ccr for predicting postoperative renal dysfunction. eGFR should therefore be used as an indicator of preoperative renal function in place of Ccr since it is a cheaper and easier to perform test.

INTRODUCTION

The creatinine clearance (Ccr) test has been used as a gold standard for evaluation of preoperative renal function in patients with gastric cancer[1,2]. However, it is known that Ccr is not strictly equivalent to glomerular filtration rate (GFR) because of the intrinsic secretion of creatinine into urine from tubuli[3]. Furthermore, in order to measure Ccr, it is necessary to collect 2-h or

24-h urine samples, which is inconvenient in older patients and relatively expensive to implement.

Chronic kidney disease (CKD) is defined as a person having GFR less than 60 mL/min, and the frequency of CKD in the Japanese population is around 10%[4]. Therefore, in patients with gastric cancer, the detection of CKD before operation is a crucial matter to prevent postoperative renal complications. If there are other tests which reflect GFR more accurately and that can be performed easily and cheaply, this would be valuable in a clinical setting[5,6].

Although inulin clearance can be used for measuring GFR, it is not a standard preoperative renal function test because of its cumbersome methodology, and alternatively, the Ccr test has been used. In 1999, Levey *et al*[7] reported an equation for the estimation of GFR. The Modification of Diet in Renal Disease (MDRD) equation includes age, sex, race, serum creatinine (sCr) value, serum blood urea nitrogen value, and serum albumin value. It was suggested that the MDRD equation precisely reflects the GFR in Caucasians but not in Asians, and therefore an equation for estimating the GFR for Japanese individuals (eGFR) was postulated[8,9]. eGFR is calculated using three parameters: sex, age, and sCr. If eGFR is at least as precise as Ccr for estimation of postoperative renal dysfunction, it would be valuable as a preoperative renal function parameter for patients with gastric cancer, as eGFR is easier and cheaper to measure. To clarify this issue, therefore, we analyzed Ccr and eGFR retrospectively in a series of gastric cancer patients.

MATERIALS AND METHODS

One hundred and forty-seven patients diagnosed histologically as having gastric cancer who underwent surgery between January 2003 and December 2005, and for whom preoperative Ccr data were available, were enrolled in the present study. The patients' backgrounds are summarized in Table 1. Gastrectomy was performed based on the guidelines of the Japan Gastric Cancer Study Group[10]. Basically, patients took meals until lunch on the day before operation, and no hyperalimentation was performed. As antibiotics, 2 g/d of cephalosporin was administered from the day of the operation for 3 d.

Measurement of sCr was performed by standard enzymatic method. Ccr was measured by 24-h urine collection, and a value of less than 50 mL/min was regarded as abnormal. eGFR was calculated using the following equation[9]: eGFR (mL/min per 1.73 m^2) = $194Cr^{-1.094} \times Age^{-0.287}$ (× 0.739; for female patients). eGFR of less than 60 mL/min was regarded as abnormal. The upper normal limits of sCr for male and female patients were 1.1 mg/dL and 0.8 mg/dL, respectively.

The reliability of preoperative Ccr and eGFR for detecting postoperative renal dysfunction was analyzed.

Statistical analysis

Data were expressed as actual number of patients or mean ± SD. χ^2 test was used for two-group comparisons.

Table 1 Patients' backgrounds

Age (yr)	68.3 ± 9.8
Sex (M/F)	107/40
Pre-sCr (mg/dL)	0.74 ± 0.20
Pre-Ccr (mL/min)	71.5 ± 24.5
Pre-eGFR (mL/min)	71.1 ± 20.5
Post-max-sCr (mg/dL)	0.82 ± 0.30
Method of operation	
Distal gastrectomy	79
Total gastrectomy	59
Others	9

Pre-sCr: Preoperative serum creatinine; Pre-Ccr: Preoperative creatinine clearance; Pre-eGFR: Preoperative estimated glomerular filtration rate; Post-max-sCr: Maximum value of postoperative sCr.

Table 2 Preoperative Ccr and eGFR

	Normal	Abnormal	*P*-value
Pre-Ccr	37	110	0.89
Pre-eGFR	35	112	

There were no differences between Ccr and eGFR, with regard to abnormalities in preoperative tests.

Table 3 Distribution of postoperative sCr in patients with preoperative Ccr and eGFR abnormality

	Abnormal pre-Ccr	Abnormal pre-eGFR	*P*-value
Post-sCr			
Normal	8	5	0.29
Abnormal	9	12	

Postoperatively, 17 patients had abnormal sCr values. Of these 17 patients, 9 (52.9%) had abnormal preoperative Ccr values and 12 (70.6%) had abnormal preoperative eGFR values.

Statistical analyses were performed by using Graphpad software version 4.0. Significance of correlations was calculated by the Spearman correlation coefficient test. Differences at $P < 0.05$ were considered significant.

RESULTS

Preoperative Ccr was abnormal in 37 patients (25.2%) and preoperative eGFR was abnormal in 35 patients (23.8%) (Table 2, $P = 0.79$). Postoperatively, 17 patients had abnormal sCr values. Of these 17 patients, 9 (52.9%) had abnormal preoperative Ccr values and 12 (70.6%) had abnormal preoperative eGFR values (Table 3, $P = 0.29$).

Among the 110 patients who had normal preoperative Ccr values, 7 (6.3%) had postoperative sCr abnormality, and among the 112 patients who had normal preoperative eGFR values, 5 (4.5%) had postoperative sCr abnormality (Table 4, $P = 0.53$).

Among the 37 patients who had abnormal preoperative Ccr values, 30 (81.1%) had normal postoperative sCr values, and among the 35 patients who had abnormal preoperative eGFR values, 25 (71.4%) had normal postoperative sCr values (Table 5, $P = 0.34$).

Table 4 Distribution of postoperative sCr in patients with preoperative Ccr and eGFR normality

	Post-sCr		*P*-value
	Normal	Abnormal	
Normal pre-Ccr	103	7	0.53
Normal pre-eGFR	107	5	

Among the 110 patients who had normal preoperative Ccr values, 7 (6.3%) had postoperative sCr abnormality, and among the 112 patients who had normal preoperative eGFR values, 5 (4.5%) had postoperative sCr abnormality.

Table 5 Distribution of postoperative sCr in patients with preoperative Ccr and eGFR abnormality

	Post-sCr		*P*-value
	Abnormal	Normal	
Abnormal pre-Ccr	7	30	0.34
Abnormal pre-eGFR	10	25	

Among the 37 patients who had abnormal preoperative Ccr values, 30 (81.1%) had normal postoperative sCr values, and among the 35 patients who had abnormal preoperative eGFR values, 25 (71.4%) had normal postoperative sCr values.

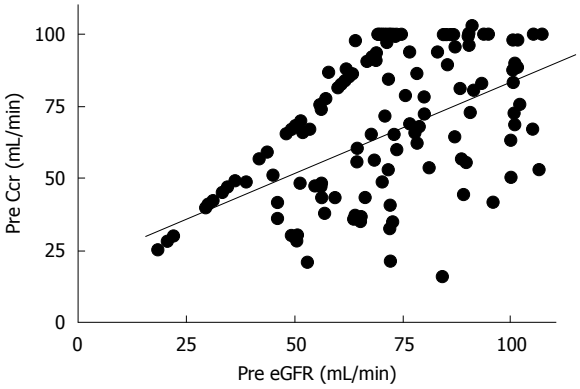

Figure 1 Correlation between preoperative creatinine clearance (Ccr) and estimated glomerular filtration rate (eGFR). Preoperative Ccr and eGFR were significantly correlated ($r = 0.514$, $P < 0.01$).

Next, we evaluated the correlation between preoperative Ccr, eGFR, and the maximum postoperative sCr value. Preoperative Ccr and eGFR showed a significant correlation ($r = 0.514$, $P < 0.01$, Figure 1). Preoperative Ccr was correlated with the maximum postoperative sCr value ($r = -0.334$, $P < 0.01$, Figure 2A). Also, preoperative eGFR was correlated with the maximum postoperative sCr value ($r = -0.188$, $P = 0.02$, Figure 2B).

There were no severe postoperative complications, such as anastomotic leakage, bleeding, or infection in the patients who had abnormal preoperative Ccr or eGFR values. None of the patients required postoperative hemodialysis.

DISCUSSION

The present study showed that eGFR was as equally reliable as Ccr for assessment of preoperative renal function in patients with gastric cancer.

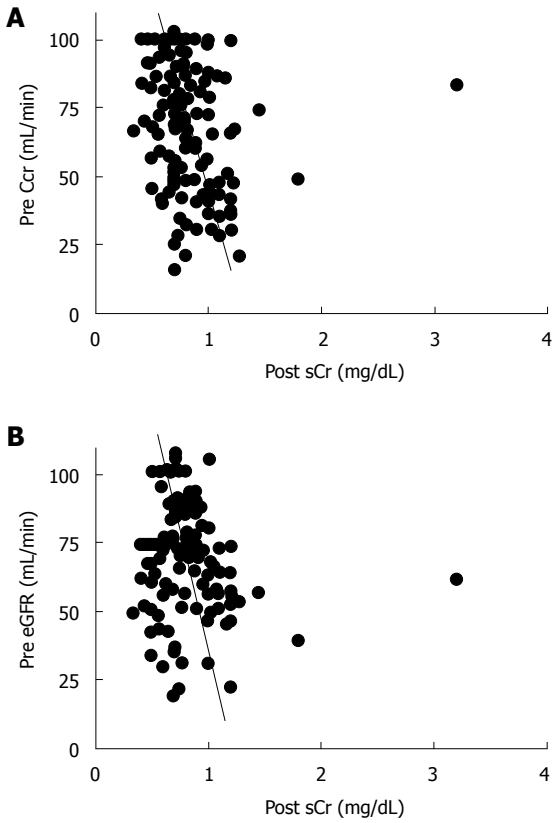

Figure 2 Correlation between preoperative Ccr and eGFR, and maximum postoperative serum creatinine (sCr). The maximum value of sCr was correlated with preoperative Ccr ($r = -0.334$, $P < 0.01$) (A) and eGFR ($r = -0.188$, $P = 0.02$) (B).

To date, Ccr has been used as a preoperative renal function parameter in patients with gastric cancer. Ccr is measured by 24-h or 2-h urine collection, and it has been suggested that either method can sometimes be inappropriate because of the difficulty involved in implementation, especially in older patients. Furthermore, there is a dissociation between Ccr and GFR in individuals with a low GFR[1]. Although sCr is a simply determined parameter for estimating renal function, it is not a reliable indicator of preoperative renal function because it is easily influenced by sex, muscle volume, and exercise. Also, sCr usually remains normal until GFR decreases to 50 mL/min[11].

GFR has not been used as a gold standard of preoperative renal function because measurement of inulin clearance is more labor-intensive than measurement of Ccr. However, the establishment of the MDRD equation by Levey *et al*[7] in 1999, and its modification postulated by the Japan Kidney Association, has made it possible to estimate GFR[8,9]. Therefore it is expected that eGFR will replace Ccr in various clinical settings.

In this study, we set the cut-off values of Ccr and eGFR at 50 mL/min and 60 mL/min, respectively. The validity of these cut-off values was endorsed by our finding that there was no significant difference in the number of patients who had abnormal postoperative sCr values between patients having preoperative Ccr ab-

normality and preoperative eGFR abnormality (Table 3).

There was no difference in the number of patients who had abnormal sCr values between patients who had normal preoperative Ccr values and normal preoperative eGFR values (Table 4), and also no difference in the number of patients who had normal sCr values between patients with preoperative Ccr abnormality and preoperative eGFR abnormality (Table 5). These results indicate that there is no significant difference in reliability between preoperative Ccr and eGFR for detecting postoperative renal dysfunction.

Preoperative Ccr and eGFR values showed a significant correlation (Figure 1), and Ccr and eGFR were correlated with the maximum postoperative sCr value (Figure 2). Thus, either Ccr or eGFR can be used to predict the maximum postoperative sCr value.

Cystatin C is a cysteine protease and a member of the cystatin super family. Cystatin C is excreted from the glomerulus and reabsorbed by the proximal tubuli, and has been used as a marker for GFR[12,13]. sCr is influenced by prerenal factors, such as muscle volume; on the other hand, cystatin C is not influenced by sex, age, and other prerenal factors. In this retrospective study, cystatin C was not included as a parameter; it would be valuable to evaluate the relationship between eGFR and cystatin C as a preoperative renal function test of gastric cancer.

We conclude that eGFR is as equally valuable as Ccr as an indicator of preoperative renal function in patients with gastric cancer, and that eGFR may now be used in place of Ccr in view of the former's clear medical and socioeconomic advantages.

COMMENTS

Background

Creatinine clearance (Ccr) is not strictly equal to glomerular filtration rate (GFR). It has been accepted that estimated GFR (eGFR) is equal to measured GFR in chronic kidney disease. However, there have been no previous studies regarding the reliability of eGFR as a preoperative renal function test in gastric cancer patients.

Research frontiers

If eGFR is as good as Ccr as a preoperative renal function test, eGFR may replace Ccr because of its simplicity of measurement.

Innovations and breakthroughs

eGFR is useful as a preoperative renal function parameter in patients undergoing gastrectomy. Ccr is no longer recommended as a first-choice preoperative renal function test.

Applications

eGFR should replace Ccr as a routine preoperative renal function test in various surgical fields.

Terminology

eGFR is estimated GFR which is calculated from age, sex, serum creatinine value (eGFR3), or by adding serum albumin concentration and blood urea nitrogen value (eGFR5).

Peer review

I think the conslusion should state "may be as good" not be as categorical as eGFR should be used instead of Ccr. This study based on a 147 patient is a good proof of principle but certainly does not have the power to change the standard of care.

Abstract

AIM: To investigate the role of enhancer of zeste homologue 2 (EZH2) and STAT6 immunohistochemistry in the evaluation of clinical stages and prognosis of colorectal cancer (CRC).

METHODS: The expression patterns were examined by immunohistochemistry in both tumor and adjacent non-neoplastic tissues of 119 CRC patients who underwent operation during the time period from 2002 to 2004.

RESULTS: The positive rates of EZH2 and STAT6 in CRC cases were 69.7% (83 of 119) and 60.5% (72 of 119), respectively, and there was significant difference when compared with tumor adjacent non-neoplastic tissues ($P < 0.05$). In all CRC cases, patients with EZH2-positive, or STAT6-positive expression had lower survival rates than those with EZH2-negative or STAT6-negative expression ($P = 0.002$ and $P = 0.005$, respectively). Co-expression of EZH2 and STAT6 showed significantly higher levels in CRC cases of high clinical TNM stages ($P = 0.001$), and the expression of STAT6 was also correlated with lymph node metastasis and distant metastasis ($P = 0.001$ and $P = 0.016$, respectively). Multivariate analysis revealed that EZH2 expression was an independent prognostic indicator of CRC ($P = 0.039$).

CONCLUSION: EZH2 and STAT6 expressions have significant values in distinguishing clinical stages of CRC and predicting the prognosis of the patients.

INTRODUCTION

Colorectal cancer is the third most common cancer, and the second leading cause of death from cancers in the United States[1]. Many Asian countries, including China, Japan, South Korea, and Singapore, have experienced an increase of 2-4 times in the incidence of CRC during the

past few decades[2]. To reduce the mortality and improve treatment, a number of studies have been performed to search for tumor biomarkers, especially for those highly correlated with both staging and prognosis that can help not only predict patients' survival, but also lead to optimal therapeutic project.

EZH2 is a member of the polycomb group of genes (PcG), which is important for transcriptional regulation through nucleosome modification, chromatin remodeling, and interaction with other transcription factors[3]. EZH2, also called histone lysine methyltransferase (HKMT), has the function of methylating lysine 9 and 27 of histone H3, which consequently leads to the repression of target gene expression. Furthermore, dysregulation of this gene silencing mechanism may lead to cancer[4,5]. Recently, EZH2 has been investigated as a potential molecular biomarker for the diagnosis and prognosis of prostate cancer by Varambally *et al*[6], using cDNA microarray analysis. Overexpression of EZH2 has been observed in the most aggressive forms of prostate cancer, exhibiting a correlation with poor clinical outcome, thus acting as a novel marker of aggressiveness and unfavorable prognosis in this type of cancer. A causal effect between EZH2 up-regulation and poor prognosis was also observed in human gastric cancers[7]. However, there have been few reports of EZH2 expression in CRC, and its relationship with clinicopathological characteristics or prognostic value is yet unclear.

Like other members of the signal STAT (transcriptional activation by signal transducer and activator of transcription) family of proteins, STAT6 has a dual role as a signaling molecule and transcription factor. STAT6 is activated in response to interleukin (IL)-4 and IL-13 stimulation, and plays a key role in Th2 polarization of the immune system[8]. Recently, the STAT6 signaling pathway was found to be highly activated in some tumors, such as prostate cancer, mammary carcinoma and lymphoma[9-11]. In addition, a close correlation between IL-4/STAT6 activities and apoptosis and metastasis of colon cancer was reported by Li *et al*[12] in a study using STAT6-high and STAT 6-null colon cancer cell lines to analyze anti-apoptotic and pro-metastatic genes expression. Nevertheless, there have been no studies investigating the clinicopathological features and prognosis of CRC in relation to STAT6 expression. In this study, we analyzed the expression of EZH2 and STAT6 in biopsied CRC tissues to determine their relationship with clinicopathological features and clinical outcome of CRC patients.

MATERIALS AND METHODS

Patient and follow-up

A group of 119 consecutive patients with CRC were studied. All patients were diagnosed and treated in the Beijing People's Hospital between December 2002 and June 2004. There were 74 men and 45 women with a mean age of 62.2 ± 12.8 years (range 25-89 years). No patient had received preoperative chemotherapy or radiotherapy. All of the patients were followed up by direct evaluation or phone interview until death or December 2008. This study was approved by the Ethics Committee of People's Hospital, Peking University.

Tissue samples and tissue array

Core tissue biopsies (2 mm in diameter) were taken from Formalin fixed paraffin-embedded tumor samples and adjacent non-neoplastic tissues. These blocks were arranged in a new recipient paraffin block (tissue array block) using a commercially available micro-array instrument (Beecher Instruments, Micro-Array Technologies, Silver Spring, MD). Two cores were sampled from each case. From the 119 tumor samples and adjacent non-neoplastic tissues, 11 tissue array blocks were prepared, each containing 10-12 tumor and adjacent non-neoplastic sample cores. To qualify for this study, a case needed to have a tumor occupying more than 10% of the core tissue area. Clinical and pathological information for this group of patients was obtained by review of histopathological reports and medical records.

Immunohistochemistry

Eleven paraffin-embedded blocks of tissue arrays were cut into 4-mm sections. The sections were put in the oven at 59℃ for 1h, deparaffinized in xylene, rehydrated in a graded ethanol series, and treated with 3% hydrogen peroxide solution for 10 min. Antigen retrieval was done by microwaving the tissue in 10 mmol/L citric acid buffer for 10 min, then cooling to room temperature for 1 h. The sections were incubated with an anti-EZH2 monoclonal antibody (1:500, Invitrogen), and an anti-STAT6 monoclonal antibody (1:100, Abcam) overnight at 4℃. Primary antibodies were detected using the Powervision two-step histostaining reagent (Zhongshan, Beijing), with PV-6001 as the secondary antibody and detection was performed by diaminobenzidine (DAB) chromogenic reaction. Tissues were counterstained with hematoxylin, 1% hydrochloric acid of alcohol, dehydrated with graded ethanols, and mounted. Positive and negative immunohistochemical controls were included. Two experienced pathologists independently examined EZH2 and STAT6 staining while blinded to the clinicopathological data and clinical outcomes of the patients. Cases with > 30% positive tumor cells in a section were recorded as having positive expression. As negative controls, samples were stained with only secondary antibody. A total of 119 cases were used for data analysis.

Statistical analysis

All data were analyzed using SPSS 11.0 software. The association of EZH2 and STAT6 expression with various clinicopathological features was analyzed using χ^2 test. Cumulative survival was estimated by the Kaplan-Meier method and differences between survival curves were analyzed by log-rank test. The influence of each variable

on survival was analyzed by multivariate analysis using the Cox proportional hazard model. Differences with $P < 0.05$ were considered statistically significant.

RESULTS

EZH2 and STAT6 expression

Positive and negative staining of EZH2 and STAT6 are illustrated in Table 1. The positive rates of EZH2 and STAT6 were 69.7% (83 of 119) and 60.5% (72 of 119), respectively in CRC cases, and there was an obvious difference when compared with tumor adjacent non-neoplastic tissues ($P < 0.05$). We observed that EZH2 expression was mainly present in the nuclei in most of the cases, and EZH2 immunoreactivity was found not only in the nuclei but also in the cytoplasm in a few CRC samples (8 of 110). STAT6 expression was mostly detected in the cytoplasm, and at cell membranes in some cases (Figure 1).

The expression of EZH2 in CRC samples was significantly correlated with more malignant phenotypes, including TNM classification ($P = 0.049$), and tumor invasion depth ($P = 0.014$). The expression of EZH2 had nothing to do with gender, tumor location, differentiation, lymph node metastasis, or distant metastasis. There was no significant correlation between cytoplasmic EZH2 immunoreactivity and clinicopathological features in the CRC carcinoma tissue samples (data not shown).

We found a positive correlation between STAT6 expression and TNM classification ($P = 0.004$), and expression of STAT6 was significantly associated with lymph node metastasis ($P = 0.001$) and distant metastasis ($P = 0.024$). As shown in Table 1, expression of STAT6 was not correlated with other clinicopathological features.

Prognostic implications of EZH2 and STAT6 expression in CRC

Tissue biopsies with EZH2-positive cells had a significantly lower post-operative survival rate than tissue biopsies with EZH2-negative cells ($P = 0.02$, Figure 2A). The STAT6-positive group also had significantly lower survival rates than the STAT6-negative group ($P = 0.005$, Figure 2B).

On the basis of the expression profiles of EZH2 and STAT6, the 119 patients were categorized into three groups: Group A: EZH2-/STAT6- ($n = 30$); Group B: EZH2+/STAT6- or EZH2-/STAT6+ ($n = 40$); and Group C: EZH2+/STAT6+ ($n = 59$). There were significant differences in survival rates between group A and one of the other groups ($P = 0.006$, Figure 2C). The survival rate of group A was significantly higher than that of group B ($P = 0.008$), the survival rate of group B was not

Table 3 Relationship between EZH2 and STAT6 expressions

EZH2	STAT6		Total
	+	-	
+	59	24	83
-	13	23	36
Total	72	47	119

r_s = 0.329, *P* = 0.00.

significantly higher than that of group C (*P* = 0.333), and the survival rate of group A was significantly higher than that of group C (*P* = 0.001, Figure 2C).

Using Cox regression analysis for the 119 patient samples, positive EZH2 expression (*P* = 0.039), distant metastasis (*P* = 0.000), and lymph node metastasis (*P* = 0.018) seemed to be independent prognostic indicators (Table 2).

Combined analysis of EZH2 and STAT6 expression in distinguishing TNM classification

A significant association was found between EZH2 and STAT6 expression by Spearman's correlation analysis (r_s = 0.329, *P* = 0.00; Table 3), when EZH2 and STAT6 expressions were evaluated. Table 4 shows the relationship between the expression profile of EZH2 and STAT6 and TNM classification assignment for 119 CRC samples. Co-expression of EZH2 and STAT6 was significantly correlated with high clinical TNM classification (*P* = 0.003). Furthermore, the expression levels of co-expression of EZH2 and STAT6 tended to rise as the TMN staging increased (18%, 40%, 59% and 72% in stages I -Ⅳ, respectively).

DISCUSSION

In the present study, we have found that EZH2 and STAT6 are sensitive and potential biomarkers that can be used for the prediction of clinical TNM classification and prognosis of CRC. An association between EZH2 overexpression and the biological malignancy of tumors has been reported in many cancers, including breast cancer, lymphoma, bladder carcinoma and hepatocellular carcinoma. Those studies suggested that EZH2 may play a role in carcinoma progression and indicate

Table 4 Relationship between EZH2 and STAT6 co-expression and TNM classification

P = 0.003.

a worse clinical outcome[13-16]. Fluge *et al*[17] investigated the expression of EZH2 in colorectal cancer by IHC. The authors concluded that a strong EZH2 expression indicated an improved relapse-free survival. Notably, this finding was only seen in colonic cancer, but not in rectal cancer. Interestingly, this result is conflicted with Mimori' study[18], who believes that EZH2 may be an oncogene and a prognostic marker in either colonic or rectal cancer. In our study, no relationship was found between the expression of EZH2 and colorectal tumor location. Furthermore, those CRC cases with higher levels of EZH2 expression were of more malignant phenotypes and have poorer prognosis.

The underlying mechanism is related, most probably, to tumor suppressor gene silencing by EZH2 mediated histone methylation and DNA methylation[19]. We found a positive correlation between EZH2 expression and TNM staging. Multivariate analysis revealed that EZH2 represents an independent prognostic indicator. These findings suggest the potential clinical utility of incorporating EZH2 into clinical consideration to help determine the clinical TNM staging and predict the outcome.

Our data showed that STAT6 expression was positively related to clinical TNM staging, lymph node metastasis and distant metastasis, suggesting that STAT6 may promote the progression of cancer. STAT6 is a member of STAT family of latent transcription factors known to be activated constitutively in cancers[20]. STAT6 is activated in response to interleukin (IL)-4 and IL-13 stimulation, STAT6-/-mice were deficient in responsiveness to IL-4 and IL-13, hence preferentially producing CD4_Th1 cells rather than CD4_Th2[21]. This observation may indicate that STAT6-deficient mice might have heightened immuno-surveillance against primary and metastatic tumors, because the development of Th1 cells optimized CD8-mediated tumor immunity[22]. Our data support these mechanism studies about STAT6, and suggest that STAT6 plays a key role in progression and metastasis of CRC.

In this study, STAT6 expression was also found to be associated with a poorer prognosis and TNM classification, which was consistent with EZH2 expression. Consequently, STAT6 enhanced the predictive efficiency of EZH2 expression, and patients with positive expres-

sion of EZH2 and STAT6 had the worse outcome and higher TNM staging than patients with negative expression of EZH2 or STAT6. These results suggest that combined analysis of EZH2 and STAT6 may be a powerful biological marker to predict clinical TNM staging and prognosis. According to the NCCN guidelines, patients with different clinical stages should receive correspondingly optimal treatment protocols. Therefore, it is critical to find effective biomarkers which can predict clinical staging in order to enable clinicians to make a more precise prejudgment. Our data suggest that combined EZH2 and STAT6 analysis may have a potential ability for this purpose.

In conclusion, the prognosis of CRC patients with EZH2-positive or STAT6-positive expression is significantly worse than those CRC patients with EZH2-negative or STAT6-negtive expressions. In addition, combined analysis of EZH2 and STAT6 expressions could enable clinicians to prejudge a more accurate clinical TNM staging before operation.

COMMENTS

Background

Enhancer of zeste homologue 2 (EZH2) is a member of the polycomb group of genes that is involved in epigenetic silencing and cell cycle regulation. Recently, EZH2, as well as STAT6 signaling pathway, were found to be highly activated in some tumors. However, the clinical significance of these proteins has not yet been determined in colorectal cancer (CRC).

Research frontiers

Recently, EZH2 has been under investigation as a potential molecular biomarker for the diagnosis and prognosis in prostate cancer. Overexpression of EZH2 has been observed in the most aggressive forms of prostate cancer, exhibiting a correlation with poor clinical outcome, thus acting as a novel marker of aggressiveness and unfavorable prognosis in this type of cancer. A causal effect between EZH2 up-regulation and poor prognosis was also observed in human gastric cancer. STAT6 has a dual role as a signaling molecule and transcription factor. STAT6 signaling pathway was found to be highly activated in some tumors, such as prostate cancer, mammary carcinoma and lymphoma. In addition, a close correlation between IL-4/STAT6 activities and apoptosis and metastasis of colon cancer was reported.

Innovations and breakthroughs

The authors found that patients with EZH2-positive expression had lower survival rates than those with EZH2-negative expression in both colonic and rectal cancers. Furthermore, the data suggest that combined analysis of EZH2 and STAT6 expression can be of significant value in distinguishing clinical stages of CRC and predicting prognosis.

Applications

The combined analysis of EZH2 and STAT6 may be a powerful biological marker, which could enable clinicians to prejudge a more accurate clinical TNM staging and prognosis of CRC patients before operation.

Terminology

EZH2 is a member of the polycomb group of genes (PcG), which is important for transcriptional regulation through nucleosome modification, chromatin remodeling, and interaction with other transcription factors. EZH2, also called histone lysine methyltransferase (HKMT), has the function of methylating lysine 9 and 27 of histone H3, which consequently leads to the repression of target gene expression.

Abstract

AIM: To investigate the correlation between expression of calreticulin and infiltration of lymphocytes in stage ⅢB colon cancer.

METHODS: Sixty-eight pathologically-confirmed specimens were obtained from stage ⅢB (T3N1M0) colon cancer patients who underwent radical resection between January 1999 and May 2002 at the Cancer Center of Sun Yat-Sen University, Guangzhou, China. Immunohistochemical analysis was performed to show infiltration of lymphocytes and expression of calreticulin in colon cancer. Association between calreticulin expression, infiltration of lymphocytes, and 5-year survival rate of patients was assessed.

RESULTS: The expression level of calreticulin was lower in cancer nest than in its adjacent normal epithelium since 61.8% (42/68) of the samples were stained with calreticulin in colon cancer. The expression of calreticulin in colon cancer was associated with the infiltration of CD45RO+ cells rather than with that of CD3+ cells. In addition, the stronger expression of calreticulin and the higher infiltration of CD3+ and CD45RO+ cells in colon cancer were associated with the higher 5-year survival rate of patients.

CONCLUSION: Expression of calreticulin is associated with infiltration of T-cells, which implies that a low expression level of molecular marker may represent a new mechanism underlying immune escape in colon cancer.

INTRODUCTION

Mounting evidence indicates that colorectal cancer is immunogenic[1]. For example, when immunologic effector cells, such as CD3+ T-cells, CD45RO+ T-cells and macrophages, infiltrate colorectal cancer tissue, tumor progression is decreased[2-7]. However, colorectal cancer cells have developed multiple immune escape mechanisms, such as reduced expression of HLA-I molecules, expression of immune inhibitors including TGF-β and indoleamine 2,3-dioxygenase (IDO), and induction of Treg cells[8-11]. More importantly, targeting the immune system can stimulate an immune response in colorectal cancer[12-16].

The mechanisms by which colorectal cancer cells induce an immunologic response remain unknown. Recently, evidence indicates that a subset of damage-associated molecular patterns (DAMPs) is involved in the induction of immune response. During the apoptosis of cancer cells, translocation of calreticulin (CRT) from endoplasmic reticulum (ER) to membrane (ecto-CRT exposure), expression of heat-shock proteins, release of HMGB1 from cells, and expression of NKG2D may serve as danger signals, thereby inducing an immune response[17,18]. CRT is a highly conserved 46 kDa Ca^{2+}-binding protein, which is mainly located in the lumen of ER and has various versatile functions, such as chaperone activity, regulation of Ca^{2+} homeostasis, adhesion signaling, involving gastrointestinal mucin synthesis at the stage of folding and oligomerization in ER, inhibiting angiogenesis and tumor growth[19-23]. Within ER, CRT interacts with various molecules like ERp57 and calnexin (CNX) to aid in proper folding of proteins[24]. Furthermore, CRT plays an important role both in the assembly of MHC class I molecule and in the loading of antigen peptides onto the MHC- I molecule within ER[25]. Besides, it has been shown that nuclear CRT can regulate nuclear protein transport and influence signaling *via* nuclear steroid receptors and integrins[26,27]. When cells are treated with anthracyclines, oxaliplatin, radiation and hypoxia, ecto-CRT exposure works as an "eat me" signal for dendritic cells and macrophages, initiating an immune response[28-30].

Altered expression of calreticulin has been detected in melanoma, and in liver, bladder, prostate, lung, pancreatic and breast cancers[31-37]. However, the clinical significance of CRT expression remains poorly understood and controversial. It has been reported that overexpression of CRT is related to the promotion of breast cancer and decreases the progression of prostate cancer[34,36]. Additionally, interaction between calnexin and calreticulin contributes to metastasis of melanoma[31]. Since the clinical evidence supporting the immune regulation of CRT is scant, this study examined the expression of CRT in stage ⅢB colon cancer patients to evaluate whether the expression of CRT is associated with the immunogenicity of colon cancer.

MATERIALS AND METHODS

Materials

Sixty-eight pathologically-confirmed specimens were obtained from patients with stage ⅢB (T3N1M0; AJCC, 2002) colon cancer between January 1999 and May 2002 at the Cancer Center of Sun Yat-Sen University, Guangzhou, China (Table 1). All the patients underwent radical resection and 5-FU-based adjuvant chemotherapy after operation for 6 mo. The patients were evaluated every 3 mo during the first year, every 6 mo in the second year, and once every year thereafter for a total of 5 years. If a recurrence or a metastasis occurred, 5-FU-based chemotherapy was given according to the national comprehensive cancer network (NCCN) guidelines. No patients received preoperative blood transfusion or non-steroidal anti-inflammatory drugs. Overall survival was defined as the time from surgery to death. Data analysis was done on the last known day when the patient was alive.

Immunohistochemical assay and scoring systems

Formalin-fixed, paraffin-embedded tissue was cut into 4-μm thick sections. The size of each tissue section was about 1 cm × 1 cm. Then, the sections were dewaxed, rehydrated, and blocked with hydrogen peroxide. Antigens were retrieved in 10 mmol/L citrate buffer (pH 6.0) for 10 min and cooled to room temperature. After blocked with sheep serum, the sections were incubated overnight at 4℃ with either rabbit polyclonal antibody against human calreticulin at a dilution of 1:2000 (Abcam, Cambridge, MA, USA) or mouse monoclonal antibody against human CD3 and CD45RO (Zymed, San Diego, CA, USA), both of which were diluted to 1:100. Subsequently, biotinylated secondary antibodies and streptavidin-biotinylated horseradish peroxidase complexes were used. The sections were developed with diaminobenzidine tetrahydrochloride (DAB) and counterstained with hematoxylin. Negative controls in which primary antibody was replaced with a phosphate buffered solution (PBS), were employed.

Infiltration of lymphocytes in the tumor was scored with Hussein's method[38] and expression of calreticulin in colon cancer was interpreted *via* immunoreactivity using the 0-4 semi-quantitative system derived from Remmele and Stegner for both the intensity of staining and the percentage of positive cells (labeling frequency percentage)[39]. The cells were counted in at least 10 different fields for each section, and the size of each high-power field (× 400) was about 300 μm × 300 μm. The cells were counted in tumor stroma. The highest infiltration areas of lymphocytes were chosen. Necrotic areas were avoided. Two observers counted the cells at the same time and in the same field under a multiple-lens microscope. The results were expressed as mean ± SE. Cytoplasm staining

Table 1 Parameters of patients (n = 68)

Parameters	n (%)
Age (yr)	
< 60	30 (44.1)
⩾ 60	38 (55.9)

Survival time (mo)	
⩾ 60	52 (76.5)
< 60	16 (23.5)

was divided into no staining/background of negative controls (score = 0), weak staining above background (score = 1), moderate staining (score = 2), and intense staining (score = 3). The labeling frequency was scored as 0 (⩽ 1%), 1 (1%-24%), 2 (25%-49%), 3 (50%-74%), and 4 (⩾ 75%), respectively. The product index was obtained by multiplying the intensity and percentage and scored as (-), (+), (++), and (+++), which indicate the cross-indices of 0-2, 3-5, 6-8, and 9-12, respectively. (-) was defined as no or negative expression, and (+)-(+++) as positive expression. Each section was independently scored by two pathologists. If an inconsistency occurred, a third pathologist was consulted to achieve a consensus.

Statistical analysis

Correlation between calreticulin expression, or infiltration of lymphocytes and parameters of patients was analyzed by χ^2 test or Fisher's exact test. Factors, including gender and age of the patients, pathologic grade, tumor site, infiltration of CD3+ cells and CD45RO+ cells, and calreticulin expression level in colon cancer, were assessed by univariate and multivariate analysis to determine their influence on the overall survival rate of patients. Kaplan-Meier curve and log-rank test were used to estimate the distribution of variables in relation to survival. Cox regression model was used to correlate the assigned variables with the overall survival rate. All statistical analyses were carried out using SPSS 13.0 software (SPSS Inc., Chicago, IL, USA). $P < 0.05$ was considered statistically significant.

RESULTS

Expression of CRT and infiltration of lymphocytes in stage ⅢB colon cancer

CRT was stained in cytoplasm rather than in nuclei of cancer cells and normal epithelium. The expression level of CRT was lower in colon cancer than in its adjacent normal epithelium. Of the stained samples, 61.8% (42/68) were positive for CRT in cancer nest (Figure 1A and B,

⩽ 26	11	6	

Table 2). CD3+ and CD45RO+ cells were observed in all samples from tumor stroma and its adjacent normal mucosa. Positively stained antigens were found on cell membrane (Figure 1C-F).

Relation between expression of CRT and infiltration of CD3+ or CD45RO+ cells

The cut-off value for infiltration of lymphocytes in colon cancer was 75%. Infiltration of 18 CD3+ cells and 26 CD45RO+ cells was observed in per high-power field, and was thus recorded as high and low infiltration. Log-rank test was used to analyze the relation between expression of CRT and infiltration of CD3+ and CD45RO+ cells in colon cancer, showing that positive expression of CRT (+-+++) was associated with high infiltration of CD45RO+ cells (P = 0.010, Table 2). No correlation was observed between expression of CRT and infiltration of CD3+cells or other parameters of the patients, such as age, gender, tumor site.

Univariate and multivariate survival analysis

By the end of a 5-year follow-up period, 52 patients were alive with a 5-year survival rate of 76.5%. Kaplan-Meier survival analysis indicated that positive expression of CRT was associated with a higher 5-year survival rate. The 5-year survival rate of patients with positive and negative expression of CRT was 85.5% (36/42) and 61.5% (16/26), respectively (P = 0.022, Table 3). However, the survival curves for patients with positive and negative expression of CRT were crossed at 18 mo (Figure 2). In addition, high infiltration of CD3+ and CD45RO+ cells in colon cancer was associated with a higher 5-year survival rate (P = 0.000, Figure 3).

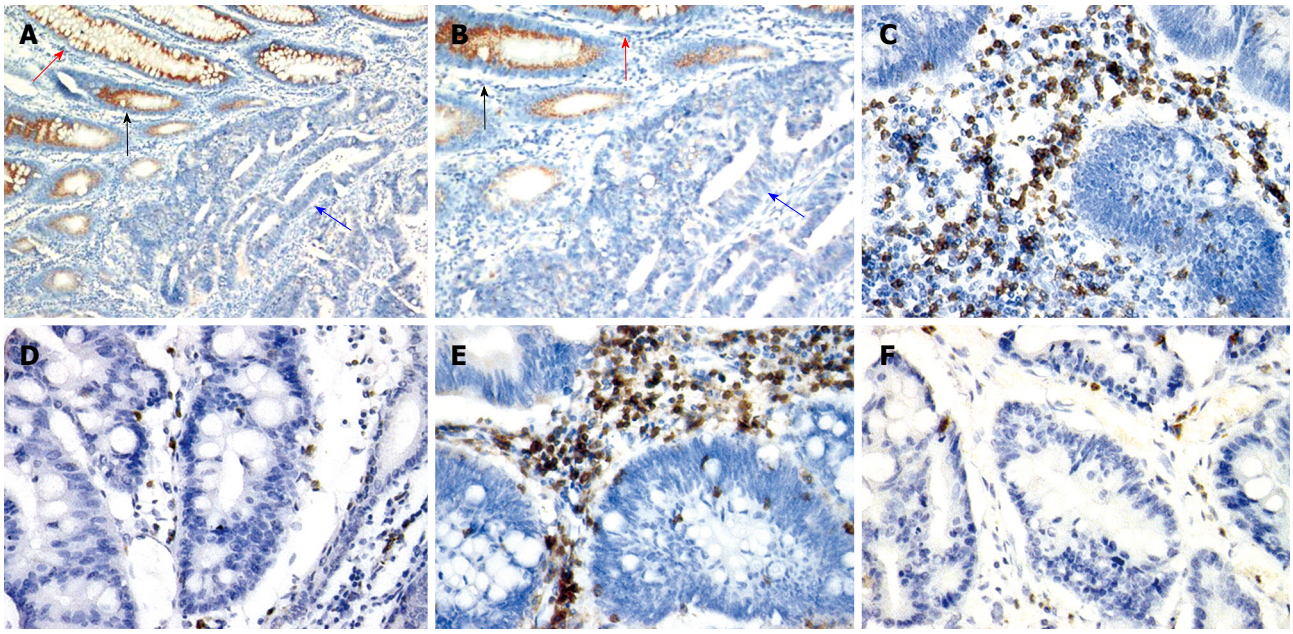

Figure 1 Expression level of CRT in cancer nest (A) and in its adjacent normal epithelium (B) [× 100 in A, × 200 in B, normal epithelium (red arrow), atypical hyperplasia (black arrow) and tumor tissue (blue arrow), respectively], high infiltration of CD3+ cells (C) and CD45RO+ cells (E) in colon cancer stroma (× 400), low infiltration of CD3+ cells (D) and CD45RO+ cells (F) in colon cancer stroma (× 400).

Cox regression model revealed that neither expression of CRT nor infiltration of CD3+ cells or CD45RO+ cells in colon cancer had an independent prognostic value (Table 4).

DISCUSSION

In this study, the expression level of CRT was lower in colon cancer than in its adjacent normal epithelium, indicating that expression of CRT is associated with infiltration of CD45RO+ cells rather than with CD3+ cells and may serve as a mechanism underlying immune escape in colon cancer, although it is not an independent prognostic indicator.

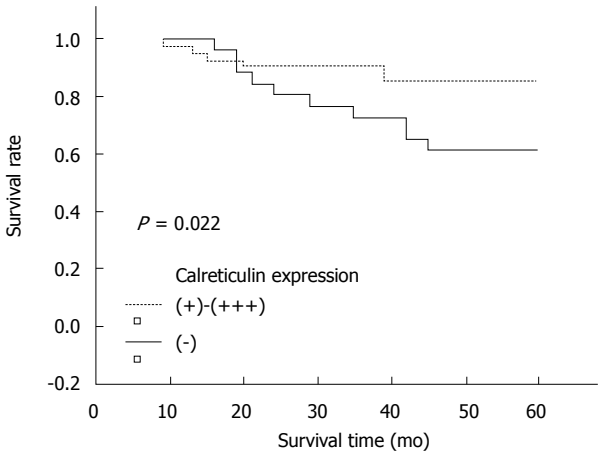

Figure 2 Relation between CRT expression and 5-year survival rate.

A few studies have examined the role of CRT in the progression of colon cancer[40,41]. Toquet *et al*[40] reported that the expression of CRT is decreased in non-mucinous colonic adenocarcinoma while Vougas reported that the expression of CRT is increased in poorly-differentiated colon cancer and advanced tumor[41]. In this study, however, neither the pathological classification nor the differentiation grade was associated with the expression level of CRT.

It is still unknown whether CRT is involved in the mechanism underlying immune escape in colon cancer. Colorectal cancer with microsatellite instability (MSI-H) is immunogenic due to infiltration of a large number of lym-

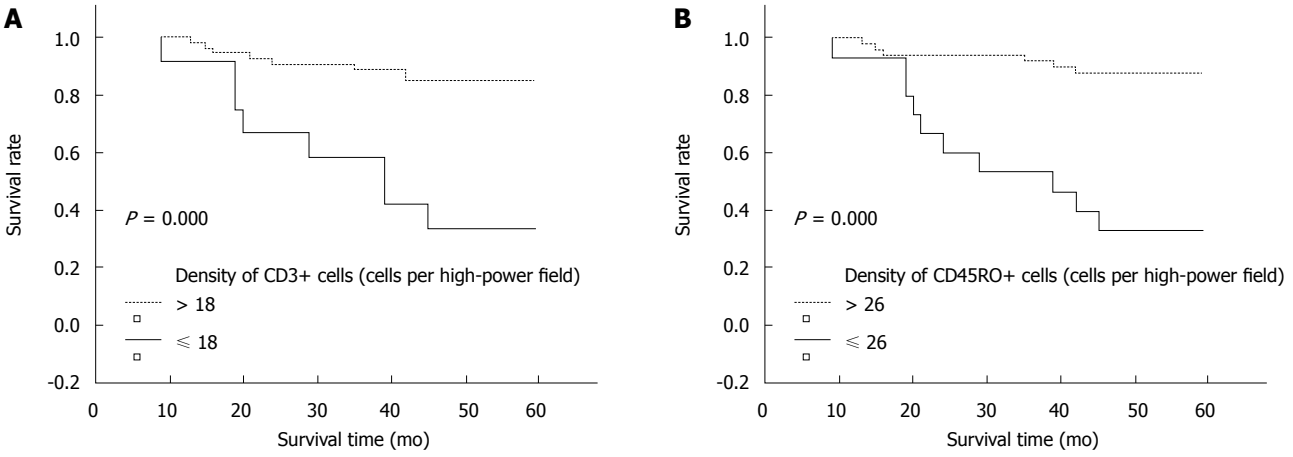

Figure 3 Correlation between high infiltration of CD3+ cells (A) and CD45RO+ cells (B) in colon cancer and 5-year survival rate of patients.

phocytes, resulting in a favorable prognosis[42,43]. Microarray analysis showed that CRT expression was up-regulated in 27 cases of colorectal cancer with MSI-H, while quantitative RT-PCR analysis failed to confirm it in another 26 cases of colorectal cancer with MSI-H[44]. In this study, the relation between expression level of CRT and infiltration of lymphocytes was assessed, which indicates that expression of CRT is related with infiltration of CD45RO+ cells in colon cancer. Since CD45RO+ cells contribute to a favorable prognosis of colon cancer patients, it is reasonable to infer that CRT expression is involved in immune response that occurs in colon cancer. However, this study failed to show that either CRT expression or infiltration of CD45RO+ cells was associated with the 5-year survival rate in a Cox statistical model. Therefore, further study is needed to confirm the role of CRT expression in the progression of colon cancer.

In conclusion, a low expression level of endogenous "danger signals", such as CRT, may represent a new mechanism underlying immune escape in colon cancer.

COMMENTS

Background

There is evidence that colorectal cancer is immunogenic. The mechanisms by which colorectal cancer cells induce an immunologic response remain unknown. A subset of damage-associated molecular patterns (DAMPs) has been recently found to be involved in the induction of immune response. Calreticulin is one of the most important DAMPs. Whether calreticulin is associated with the immunogenicity of colon cancer remains controversial.

Research frontiers

Calreticulin is a multifunctional chaperone protein which mainly locates in the lumen of endoplasmic reticulum (ER). When exposed on the cell surface, calreticulin works as an "eat me" signal for dendritic cells and macrophages, initiating an immune response. Whether the expression of calreticulin in colon cancer is involved in induction of immune response is a hot topic on the role of calreticulin in pathogenesis of colon cancer.

Innovations and breakthroughs

Studies indicate that the expression of calreticulin is decreased in non-mucinous colonic adenocarcinoma while is increased in poorly -differentiated colon cancer and advanced tumor. Other studies have shown that one of the calreticulin fragments inhibits angiogenesis and growth of colon cancer cells. However, the correlation between expression of calreticulin and survival of colon cancer patients remains unknown. In this study, the expression of calreticulin in stage ⅢB colon cancer was associated with the lower infiltration of CD45RO+ lymphocytes which was associated with a shorter 5-year survival time, suggesting that reduced expression of CRT may serve as a mechanism underlying immune escape in colon cancer.

Applications

In this study, reduced expression of endogenous "danger signals", such as calreticulin, was found to be a new mechanism underlying immune escape in colon cancer, which is important for a better understanding of the immunogenicity of colon cancer, thus providing a new immunotherapy for colon cancer.

Terminology

Calreticulin: A highly conserved 46 kDa Ca^{2+}-binding protein, which is mainly located in the lumen of ER and has various versatile functions, like chaperone activity, regulation of Ca^{2+} homeostasis, and adhesion signaling. When cells were treated with anthracyclines, oxaliplatin, radiation and hypoxia, calreticulin exposure works as an "eat me" signal for dendritic cells and macrophages, initiating an immune response.

Peer review

This is a well-conducted study on the correlation between calreticulin expression and infiltration of lymphocytes in colon cancer and their impact on the 5-year survival time of patients with stage ⅢB colonic cancer.
