Abstract

AIM: To investigate the early mortality of placebo-treated alcoholic hepatitis patients.

METHODS: Mortality data about alcoholic hepatitis patients who participated in randomized placebo-controlled trials were searched from PubMed, EMBASE, and Cochrane Library, extracted and analyzed.

RESULTS: A total of 661 placebo-treated patients in 19 trials were included. The overall mortality rate was 34.19% with a median observation time of 160 d (range 21-720 d). Hepatic failure, gastrointestinal bleeding and infection were the three main causes of death, accounting for 55.47%, 21.17% and 7.30% of all deaths, respectively. One-month mortality data about 324 placebo-treated alcoholic hepatitis patients in 10 trials were reported with a pooled mortality rate of 20.37%. The one-month mortality rate of patients with moderate to severe alcoholic hepatitis tended to be higher than that of general patients (22.69% *vs* 10.93%, $P < 0.05$), whereas no significant difference was observed between the patients from North America or Europe (22.43% *vs* 18.45%, $P > 0.05$), neither any difference was found between the studies published before and after 1990 (18.18% *vs* 21.88%, $P > 0.05$).

CONCLUSION: Alcoholic hepatitis is a severe liver disease with a high mortality rate, and hepatic failure, gastrointestinal bleeding and infection are the three main causes of death.

INTRODUCTION

Alcohol abuse causes a variety of liver diseases including alcoholic steatosis, alcoholic hepatitis, liver fibrosis and cirrhosis[1,2]. Generally, alcoholic steatosis is a benign lesion with a favorable prognosis if the patient abstains from alcohol use, whereas alcoholic hepatitis, which is observed in approximately 20% of heavy drinkers, is much more serious and requires treatment[3]. With increasing alcohol consumption worldwide, alcoholic liver disease has become a significant global health concern[4,5].

Alcoholic hepatitis is characterized by the development of hepatocellular necrosis and inflammation in

alcoholic patients[6]. Its pathogenesis is a multifactorial process involving metabolism of alcohol to toxic products, Kupffer cell stimulation by endotoxin and nutritional impairment lead to liver injury and inflammation[7]. The treatment of alcoholic hepatitis is still mostly symptomatic or empirical at best. Abstinence and supportive care are the two critical principles for the treatment of alcoholic hepatitis[7]. Several clinical trials have shown that corticosteroids can improve the short-term survival of patients with severe alcoholic hepatitis[8]. Recent evidence also suggests that inhibiting tumor necrosis factor-alpha release is beneficial for alcoholic hepatitis[9].

Since most studies on alcoholic hepatitis have focused either on its pathogenesis or on its potential therapies[7-9], its natural history has not been clearly defined. One possible explanation for this is that many alcoholic hepatitis patients are treated with available therapies immediately upon its diagnosis. Active therapies may significantly influence its natural progression and it is inappropriate to withdraw the treatment for studying its natural history. An understanding of the progression of alcoholic hepatitis would contribute to its prevention and treatment.

Randomized placebo-controlled clinical trials are considered the gold standard for evaluating the efficacy of medical interventions on the disease[10]. Data from placebo-controlled trials may also provide valuable information about its natural history. Since the use of placebo has very little effect on the progression of alcoholic hepatitis[11], placebo-treated patients may be the most suitable subjects for studying its natural history. Since a number of randomized placebo-controlled clinical trials are available on evaluating the treatment of alcoholic hepatitis worldwide[9], it has become feasible to study its natural history by extracting data from these studies.

In this study, we conducted a pooled analysis of data about alcoholic hepatitis patients who were treated with placebo in the eligible randomized placebo-controlled trials, in an attempt to evaluate the early mortality of such patients.

MATERIALS AND METHODS

Systematic literature search

English literature on alcoholic hepatitis patients in randomized placebo-controlled trials was searched from PubMed (1966 - March 2009), EMbase (1974 - March 2009), and Cochrane Library (2009, Issue 1) by two independent investigators using the search terms "alcoholic hepatitis", "alcoholic steatohepatitis", "alcoholic liver disease", "placebo" and "randomized controlled trial". Editorial or letter or comment or review was excluded. Reference lists of the retrieved relevant articles were also searched for additional trials.

Study selection

Two investigators independently performed the study selection. Search findings were screened for potentially eligible trials and full-text articles were obtained for their detail evaluation. Disagreements between the two investigators regarding studies included were solved by consensus.

Studies fulfilling the following criteria were included: studies of a randomized placebo-controlled clinical trial in alcoholic hepatitis patients, studies with enrollment, treatment and analysis of patients well-defined, and studies with more than 15 patients involved in the placebo arm, since we believed that they would not generate enough meaningful data to allow quality assessment. Trials were excluded if relevant data were not extractable or if the case-mix included unclassified alcoholic liver disease patients. Alcoholic hepatitis patients in the placebo arms that received basic active treatment with drugs such as steroids were also excluded.

Data extraction and quality assessment

Data extracted from the studies included name of the first author, publication year, study design, location(s), sample size, randomized method, and gender, mean age and disease severity of patients, description of active therapy, duration of therapy, duration of follow-up, mortality data and causes of death. Data extraction was performed by two independent reviewers. Sections of METHODS and RESULTS were coded to blind reviewers to the above information. Primary investigators were contacted if data were incomplete. The methodological quality of studies included was assessed using a validated quality checklist[12] with a maximum score of 32. A score of 12 (38%) or greater was considered to have acceptable quality[13].

Statistical analysis

Pooled estimate of each variable of interest was calculated and presented as a mean. The cumulative rate of each outcome of interest was calculated in the placebo arm of eligible studies. χ^2 test was used to compare qualitative variables. $P < 0.05$ (2-tailed test) was considered statistically significant.

RESULTS

Description of trials

We identified 892 potentially relevant articles and excluded 845 articles describing studies that obviously did not fulfill the inclusion criteria in this study by reviewing their titles and abstracts. Of the 47 studies selected for full-text review, 19 were excluded because they were not designed as placebo-controlled trials, 3 were excluded because the patients received other active medications[14-16], 4 were excluded because less than 15 patients received placebo[17-20], 1 was excluded because detailed survival data were not available[21], and 1[22] sharing the same placebo with a previous patient[23] was also excluded. Thus, only 19 studies fulfilled the inclusion criteria in this study (Figure 1).

Of these 19 clinical trials, 9 were single center studies, 10 were multi-center studies. A total of 661 patients with a mean age of 46.4 years served as placebo controls. Detailed information and summarized information about the studies included are shown in Tables 1 and 2, respectively.

Pooled mortality

Of the 661 patients, 226 (34.19%) died during a median

NA: Not available.

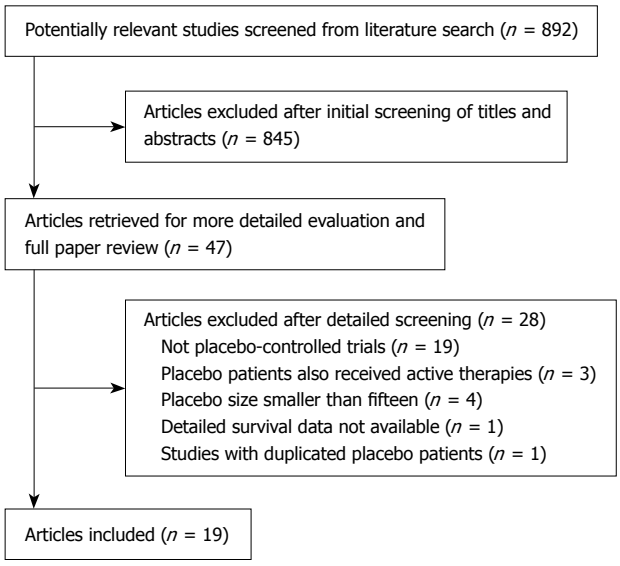

Figure 1 Schema for literature search and study inclusion.

observation time of 160 d (range 21-720 d). Detailed causes of 137 deaths were available from 13 of the studies. Hepatic failure, gastrointestinal bleeding and sepsis were the three main causes of death, accounting for 55.47%, 21.17% and 7.30% of all deaths, respectively. One-month mortality data were available in 10 studies and the pooled mortality rate for these patients was 20.37% (66/324).

Subgroup analysis

Since the observation time was different among the studies included, we did not directly compare the overall mortality rate of alcoholic patients. In subgroup analysis, we compared the one-month mortality rate of alcoholic patients based on the data extracted from 10 studies.

Of the 10 studies selected for comparison, 2 were performed in moderate to severe alcoholic hepatitis patients, 6 in severe alcoholic hepatitis patients, 2 in unclassified alcoholic hepatitis patients. The pooled one-month mortality rate of such patients tended to increase with increasing severity of the disease. The pooled mortality rate of unclassified, moderate to severe and severe alcoholic hepatitis patients was 10.94% (7/64), 20.75% (11/53), and 23.19% (48/207), respectively (Table 2).

Of the 10 studies, 5 were conducted in the United States and 5 in Europe (UK, France, Belgium and Spain) showing a pooled mortality rate of 22.44% (35/156) and 18.45% (31/168), respectively. No significant difference was found in pooled mortality rate between the patients from North America or Europe ($\chi^2 = 0.791$, $P = 0.409$) (Table 2).

Of the 10 studies, 5 were published before December 31, 1990, showing a pooled total mortality rate of 17.86% (30/168), 5 were published after January 1, 1991, showing a pooled mortality rate of 23.08% (36/156). No significant difference was observed in pooled mortality rate between the publication time ($\chi^2 = 1.359$, $P = 0.244$) (Table 2).

DISCUSSION

In this study, we extracted data about alcoholic hepatitis patients in randomized placebo-controlled trials and

Table 2 Comparison of pooled one-month mortality by different variables

	Studies (*n*)	Placebo-treated patients (*n*)	Gender (M/F)	One-month death (*n*)	One-month mortality rate (%)	χ^2	*P* value
Severity of disease							
Unclassified	2	64	33/31	7	10.94	4.375	0.038
Moderate to severe	8	260	171/89	59	22.69		
Geographical area(s)							
US	5	156	119/37	35	22.44	0.791	0.409
Europe	5	168	85/83	31	18.45		
Publication year							
Before 1990	5	168	118/50	30	17.86	1.359	0.271
After 1991	5	156	86/70	36	23.08		

analyzed their mortality, showing that the mortality rate of alcoholic hepatitis patients is positively correlated with the severity of the disease. Our pooled analysis also showed that hepatic failure, gastrointestinal bleeding and infection were the three main causes of early death of alcoholic hepatitis patients, which may be of great importance in clinical practice.

Unlike nonalcoholic hepatitis, a chronic form of liver disease associated with obesity, alcoholic hepatitis is an acute and potentially life-threatening form of liver disease[41]. The cause of its early mortality is not clear since it is difficult to evaluate a sufficient number of such patients without prompt treatment upon diagnosis. In this study, the data about 661 placebo-treated patients extracted from 19 placebo-controlled trials were evaluated, showing that the mortality rate of alcohol hepatitis patients is 34.19% with a pooled one-month mortality rate of 20.37%, which increases with increasing disease severity. These findings suggest that alcoholic hepatitis patients should be treated promptly upon diagnosis.

Recognizing the causes of death in alcoholic hepatitis patients contributes to the treatment of alcoholic hepatitis. Hepatic failure, gastrointestinal bleeding and infection are the three main causes of early death in alcoholic hepatitis patients. Hepatic failure can be prevented by avoiding exposure to certain hepatotoxic drugs, such as acetaminophen, carbon tetrachloride and galactosamine. Corticosteroid therapy is effective against alcoholic hepatitis[8], but it may result in complications such as gastrointestinal bleeding. It is, therefore, necessary to evaluate the risks and benefits of corticosteroid therapy for alcoholic hepatitis before it is used.

Due to the limited available data, there are some limitations in this study. First, we did not analyze the factors predicating the early mortality rate of alcoholic hepatitis patients since necessary data could not be extracted from the studies included. However, our pooled analysis provided the main causes of death, which may be of importance in clinical practice. Second, we did not clarify whether the mortality rate of alcoholic hepatitis patients varies between males and females. Since females are reported to be more sensitive to alcohol abuse[7], it would be of interest to compare mortality rates of both genders. Third, we did not analyze the potential heterogeneity due to the relative small number of placebo patients. We grouped all the patients irrespective of their age, gender, ethnic distinction, or severity of disease. The pooled analysis of all these cases provided a clearer general picture of early mortality rate in a relatively large sample of alcoholic hepatitis patients.

In summary, alcoholic hepatitis is a severe liver disease with a high early mortality, especially among those with moderate to severe alcoholic hepatitis. Hepatic failure, gastrointestinal bleeding and infection are the three main causes of early death in alcoholic hepatitis patients.

COMMENTS

Background

Alcoholic hepatitis is a potentially life-threatening complication of alcohol use, but its natural history has not been clarified so far.

Research frontiers

This study investigated the early mortality of placebo-treated alcoholic hepatitis patients.

Innovations and breakthroughs

This study has confirmed that alcoholic hepatitis is a severe liver disease with a high early mortality, especially among those with moderate to severe disease.

Applications

The results of this study suggest that hepatic failure, gastrointestinal bleeding and infection should be treated in order to prevent early death of alcoholic hepatitis patients.

Terminology

Alcoholic hepatitis is a disease resulting from hepatocellular necrosis and inflammation in alcoholic patients. Its pathogenesis is a multifactorial process involving metabolism of alcohol to toxic products. Kupffer cell stimulation by endotoxin and nutritional impairment lead to liver injury and inflammation, *etc*.

Peer review

This is an interesting review of data concerning the early mortality of alcoholic hepatitis. The authors critically discussed the limitation of their survey.

Abstract

Various extraintestinal manifestations including pulmonary abnormalities have been reported in patients with ulcerative colitis. Acute respiratory distress syndrome (ARDS) is a serious and fatal pulmonary manifestation. We have experienced a 67-year-old male patient with ARDS associated with a severe type of ulcerative colitis (UC). Severe dyspnea symptoms occurred during the treatment of UC in a previous hospital and the patient was transferred to our hospital on June 27, 2007. Both blood and sputa cultures for bacteria and fungi were negative. Cytomegalovirus antigenemia was also not detected. From the clinical and radiological [Chest X-ray, computed tomography (CT)] findings, the patient was diagnosed with ARDS on the basis of the definition of ARDS developed by the European-American Consensus Conference on ARDS. Both colonic inflammations and ARDS symptoms of the patient were resistant to any medical treatment including corticosteroids and antibiotics. However, ARDS symptoms were dramatically improved after surgical colectomy. We believe that severe colonic inflammation from UC was closely associated with the onset of ARDS of the patient. Our case report suggests that a severe type of ulcerative colitis might be taken into consideration as one of the predisposing factors of ARDS.

INTRODUCTION

Ulcerative colitis (UC) is a chronic intractable colitis with unknown etiology. Various extraintestinal manifestations, including hepatobiliary, musculoskeletal, dermatologic, ocular and pulmonary symptoms, have been reported in patients with UC[1-3]. Acute respiratory distress syndrome (ARDS) is a serious and fatal pulmonary manifestation and overall mortality from ARDS has been typically reported to be greater than 50%[4]. Here, we showed an ARDS patient associated with severe UC. ARDS symptoms of the patient were resistant to any medical treatment but dramatically improved after surgical colectomy. Our case suggests that severe colonic inflammation from UC was closely associated with the onset of ARDS.

CASE REPORT

A 67-year-old male patient visited a previous hospital due to bloody diarrhea on March 1, 2007. He was diagnosed as having UC based on clinical, endoscopic and histological criteria. He was admitted to the hospital and underwent treatment with mesalamine, prednisone (40 mg), and azathioprine (50 mg). Leukocytapheresis therapy was also performed. However, his abdominal symptoms and endoscopic findings got worse and an intensive intravenous steroid regimen with 60 mg prednisone was started. During the treatment, he complained of severe dyspnea and a chest-X ray revealed pulmonary edema. Treatment with azathioprine and mesalamine was discontinued after he complained of severe dyspnea. Then, the patient was transferred to Akita University Hospital for intensive treatment on June 27, 2007. On physical examinations, he had tachycardia (134 bpm) and a fever (38.1℃), and coarse crackles were audible in both lung fields. Tenderness was observed in the lower abdomen but no symptoms suggesting peritonitis were found. Blood chemistry values on June 28 were as follows: hemoglobin (Hb) 8.9 g/dL, hematocrit (Ht) 27.9%, white blood cell count (WBC) 3100/L, C-reactive protein (CRP) 2.92 mg/dL, total protein (TP) 4.4 g/dL, albumin 2.4 g/dL, L-aspartate 2-oxoglutarate aminotransferase (AST) 74 U/L, L-alanine 2-oxoglutarate aminotransferase (ALT) 73 U/L, alkaline phosphatase (ALP) 785 U/L, blood urea nitrogen (BUN) 31.9 mg/dL, creatinine (Cr) 0.38 mg/dL. Anemia, inflammatory changes, hypoproteinemia, and liver dysfunction were observed. Chest X-ray showed pulmonary edema without enlargement of the heart (Figure 1A). Arterial blood gas values were PaO_2 39 mmHg; $PaCO_2$ 35.7 mmHg; pH 7.518; and HCO_3 28.4 mEq/L, showing impaired oxygenation. Ultrasound cardiography showed normal heart function, with no enlargement of the right atrium and ventricle. From these clinical and radiological findings, the patient was diagnosed as having ARDS. Chest computed tomography (CT) scan images of the patient were also compatible with ARDS (Figure 2). Both blood and sputum cultures for bacteria and fungi taken in the hospital were negative. Low levels of Candida antigen and a slight increase of β-D glucan were found in the patient's blood. However, serum Candida antigen promptly decreased after treatment with an antifungal drug (fosfluconazole). Cytomegalovirus antigenemia was not detected. Dyspnea of the patient was severe and not improved by nasal oxygen supplementation. Then, the patient was admitted to the intensive care unit (ICU) with intubation and positive pressure ventilation. However, despite intensive medical treatment including prednisone, antibiotics (cefazolin sodium, imipenem/cilastatin sodium), and sivelestat sodium hydrate, pulmonary condition and abdominal symptoms of the patient were not improved. Colonoscopic examination on July 2nd also showed severe colonic inflammation with multiple deep ulcers (Figure 3). However, cytomegalovirus antigenemia was not detected. Both fecal culture and fecal Clostridium difficile toxins were negative. Bronchoscopy on July 6th showed wet bronchial mucosa with a little inflammatory change, and no bacteria and fungi were detected by culturing the sputa collected by bronchoscopy. Colonoscopic findings together with his clinical course strongly suggested that the predisposing factor of ARDS of the patient might be severe inflammation of the colon. Thus, we thought that surgical colectomy was essential to rescue the patient from ARDS, and subtotal colectomy was performed on July 11. Postoperatively, gas exchange was dramatically improved, and he was weaned off the ventilator on July 19. A chest X-ray taken August 11 (Figure 1B) was also significantly improved. After an additional 55 d recovery, he was discharged from the hospital with no respiratory symptoms.

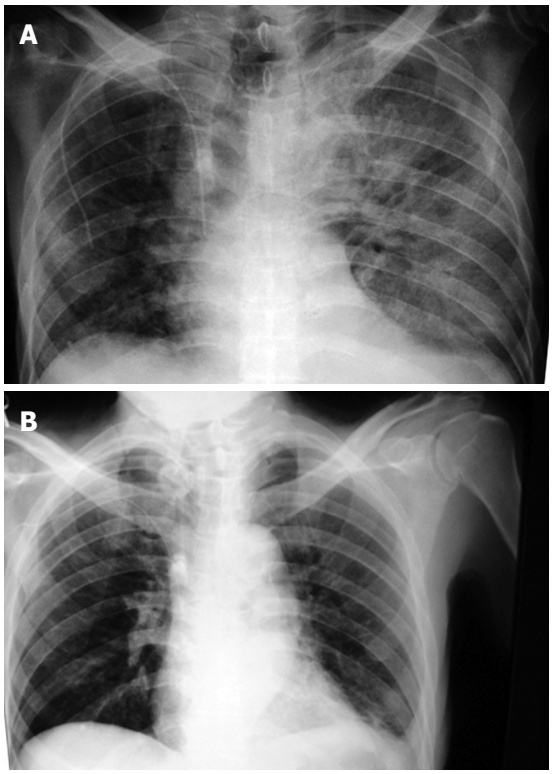

Figure 1 Chest X-ray. A: Chest X-ray taken at time of admission showing Acute respiratory distress syndrome (ARDS); B: Chest X-ray after surgical colectomy showing a significant improvement of ARDS.

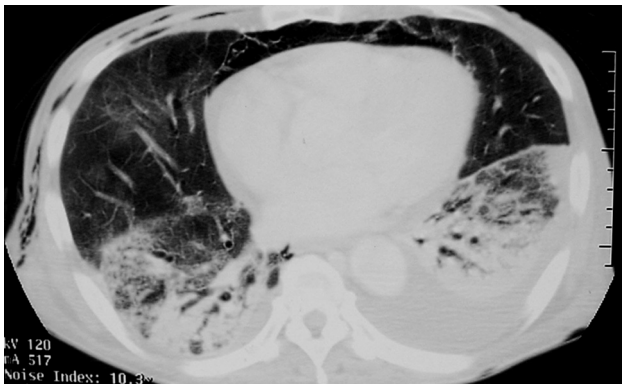

Figure 2 Chest computed tomography (CT) scan image taken before surgical treatment showing compatibility with ARDS.

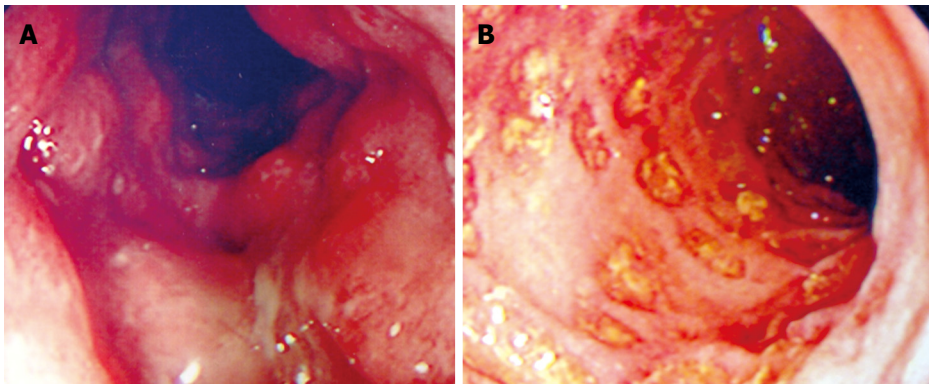

Figure 3 Colonoscopic images showing deep ulcer with severe mucosal edema (A) and multiple discrete ulcers (B).

DISCUSSION

Both UC and Crohn's disease are chronic intractable inflammatory bowel diseases (IBD). It has been shown that 30%-50% of IBD patients have pulmonary abnormalities[1]. In addition, drug-induced lung injuries have also been reported in IBD patients[5,6]. ARDS is a complex response of the lung to direct and indirect insults and numerous predisposing factors causing ARDS, such as toxic inhalation, diffuse infection, sepsis, pancreatitis, *etc*., have been reported[4]. With regard to an association between UC and ARDS, only one ARDS patient accompanied by UC has been reported to date[7]. In this report, we diagnosed the patient as having ARDS based on the definition of ARDS developed by the European-American Consensus Conference on ARDS[4], namely, $PaO_2/FiO_2 < 200$, the detection of bilateral pulmonary infiltrates on frontal chest radiography, and no clinical evidence of elevated left atrial pressure. With regard to the predisposing factors of ARDS, we could not detect particular factor that clearly caused ARDS in our patient. Although very low levels of Candida antigen was detected in the blood, Candida was not detected by sputa cultures and ARDS symptoms of the patient were not improved after the decrease in the Candida antigen. Thus, we did not think that Candida was the predisposing factor of ARDS in our patient. Other fungi as well as Candida were not detected by sputa cultures, which were examined several times. Although severe inflammation with deep ulcers was endoscopically observed in the colonic mucosa, Cytomegalovirus antigenemia was not detected in the patient during the admission.

Nagy *et al*[6] recently reported a case of interstitial pneumonitis, which was suggested to be ARDS, in a patient with UC treated with azathioprine (150 mg/d, 10 years). They demonstrated that the pulmonary condition of this patient was gradually improved by the discontinuation of azathioprine and treatment with corticosteroids. Our patient was also treated with azathioprine. However, the dose of azathioprine of our patient (50 mg/d, 2 mo) was much smaller than that of Nagy *et al*'s case[6]. Although an association between azathioprine and the onset of ARDS of our patient was not completely excluded, we consider that ARDS symptoms of our patient were not due to administration of azathioprine but due to severe inflammation of ulcerative colitis on the basis of the following findings. First, ARDS symptoms were not improved but worsened after the discontinuation of azathioprine. In addition, ARDS symptoms were not improved by the intravenous corticosteroid treatment. Second, ARDS symptoms of the patient appeared to be correlated with the severity of UC and were dramatically improved after surgical colectomy. From these findings, we believe that severe colonic inflammation from UC was closely associated with the onset and the persistence of ARDS of our patient. It is suggested that pathogenic factors that caused ARDS in our patient were probably produced in the inflamed colon. ARDS is a serious and fatal pulmonary manifestation caused by a systemic inflammatory status. Our case report suggests that a severe type of UC might be taken into consideration as one of the predisposing factors of ARDS.

Abstract

Filiform polyposis is a rare condition of uncertain pathogenesis that is usually found in association with Crohn's disease, ulcerative colitis, intestinal tuberculosis or histiocytosis X. We report seven interesting cases of polyposis with various pathologic components, mainly located in the left side of the colon with no associated inflammatory bowel disease, intestinal tuberculosis or histiocytosis X. Multiple finger-like polypoid lesions with the appearance of stalactites were noted on the left side of the colon, especially in the sigmoid area, at the time of colonoscopy. The polyps had a variety of sizes and shapes and were shown to have various histopathologic components among the different patients. Although filiform polyposis localized in the sigmoid colon appears not to have high oncogenic potential, periodic follow-up seems to be needed.

INTRODUCTION

Filiform polyposis is a rare form of pseudopolyposis associated with ulcerative colitis, Crohn's disease, or granulomatous disease, which is formed by non-specific mucosal and submucosal reactions to previous severe inflammation[1-5]. The transverse and descending colon are the most common locations, although the polyps can be seen in any portion of the large bowel[3-6]. However, reports regarding filiform polyposis confined to the sigmoid colon, and the natural history or management of incidentally detected filiform polyposis in patients without the definite history of ulcerative colitis, Crohn's disease, or intestinal tuberculosis are inadequate[7,8].

We report seven interesting cases of filiform polyposis with mixed histologic components, including mainly inflammatory and hyperplastic or adenomatous components, located in the sigmoid area, without a definite history of severe inflammation such as inflammatory bowel disease (IBD) or intestinal tuberculosis.

CASE REPORT

Case 1

A 38-year-old male patient had sudden onset abdominal pain, diarrhea, and hematochezia for 2 d and had been diagnosed as having infectious colitis. He did not have a medical history of tuberculosis, IBD, or infectious colitis. Colonoscopic examination showed multiple, variable-sized polyps that were found in the sigmoid colon (Figure 1A). These polyps were histopathologically proven to be inflam-

matory and hyperplastic. Up to 44 mo later, there was no evidence of malignant change in the polyposis on follow-up colonoscopy examination.

Case 2

A 64-year-old healthy male patient had no medical history of IBD or lower gastrointestinal symptoms. Colonoscopy was performed for screening purposes. On the colonoscopic examination, multiple long worm-like polyps were noted at the sigmoid colon (Figure 1B). These growths were histopathologically proven to be inflammatory polyps. Two large polyps were also found in the ascending colon and snare polypectomy was performed. These polyps were adenomas by pathologic evaluation.

On the follow-up colonoscopic examination 6 mo later, multiple finger-like polypoid lesions with the appearance of stalactites persisted on the left side of the colon, especially in the sigmoid area (Figure 1C). Large polyps with a hyperemic mucosa were removed by snare. These polyps were hyperplastic, tubular adenomas and filiform polyps with lymphoid hyperplasia. Up to 43 mo later, there was no evidence of malignant change in the polyposis on follow-up colonoscopy examination.

Case 3

A 37-year-old male patient had frequent intermittent diarrhea after abdominal pain and was diagnosed as having irritable bowel syndrome. Colonoscopy was performed and multiple polyps were seen, which were densely packed, forming a roof in the sigmoid colon (Figure 1D). A representative polyp was removed by snare and shown to be a filiform or hyperplastic polyp on pathologic assessment. Up to 46 mo later, there was no evidence of malignant change in the polyposis on follow-up colonoscopy examination.

Case 4

A 67-year-old asymptomatic male patient stated that colonofiberscopy had been performed at another hospital 2 years previously and the colonoscopic findings were lesions suspicious for intestinal tuberculosis. Colonofiberscopy was conducted again and multiple polypoid lesions with variable shape and size were found at the sigmoid colon (Figure 1E). To establish the exact pathologic diagnosis, snare polypectomy was performed. The pathologic results revealed that the polyps were mainly filiform and hyperplastic. Up to 46 mo later, there was no evidence of malignant change in the polyposis on follow-up colonoscopy examination.

Case 5

A 77-year-old male patient generally had no lower gastrointestinal symptoms. The colonoscopic findings showed multiple polyps forming a densely packed bridge in the sigmoid colon (Figure 1F). These polyps were pathologically diagnosed as being mainly filiform and hyperplastic. Up to 34 mo later, there was no evidence of malignant change in the polyposis on follow-up colonoscopy examination.

Case 6

An 81-year-old female patient was referred to our hospital for evaluation of sigmoid polyposis. Colonoscopy was performed and worm-like polyps located in the sigmoid colon were shown (Figure 1G). In addition, one polyp was reported as chronic non-specific inflammation with crypt cell hyperplasia and another was a hyperplastic polyp with focal atypical glands, favoring a reactive hyperplasia. Up to 38 mo later, there was no evidence of malignant change in the polyposis on follow-up colonoscopy examination.

Case 7

A 63-year-old female had a history of diarrhea, abdominal pain, and weight loss for several months. The patient was referred to our hospital for further evaluation of multiple colon polyps. On colonoscopy, multiple variable polyps were noted in the cecum, ascending colon, and mainly in the sigmoid colon. Multiple finger- or worm-like polypoid lesions were noted in the sigmoid colon (Figure 1H and I). The polyps were of various size and shape. The tips of the polyps adhered to other parts of the mucosa, forming loops or bridges between opposing walls. Large polyps were removed by snare. All these polyps, except one, were shown to be hyperplastic or filiform (inflammatory) based on pathologic evaluation (Figure 2A and B). Only one polyp was shown to be a villous adenoma (Figure 2C). Up to 36 mo later, there was no evidence of malignant change in the polyposis on follow-up colonoscopy examination. We recommended periodic colonoscopy for cancer surveillance.

DISCUSSION

We report here seven cases of previously undiscovered polyposis in the sigmoid colon without a definite history of severe chronic inflammation including IBD or intestinal tuberculosis. This report is intended to characterize the clinical and pathologic features of filiform polyposis mainly located in the sigmoid colon. The clinicopathologic characteristics of filiform polyposis in the sigmoid colon of all the seven cases are shown in Table 1.

Filiform polyposis is an uncommon entity that is most often encountered in the colon of patients with a history of IBD[2]. Filiform polyposis is characterized by a large number of worm-like polyps lined by histologically normal colonic mucosa[5,8]. Filiform polyps usually have a thin, straight shape resembling the stalks of polyps without the heads[4]. The polyps can range in size from 1.5-3.0 cm in length and up to 0.5 cm in diameter[2,3]. The projections can occur as solitary polyps or as diffuse polyposis distributed over large areas of the colonic mucosa[8]. Long-term inflammation of the colonic mucosa during chronic IBD with alternating periods of ulceration and healing may lead to the formation of finger-like projections, these so-called filiform polyps[2-4]. Only rare cases without a history or evidence of IBD have been reported[3]. Additionally, in rare cases, several

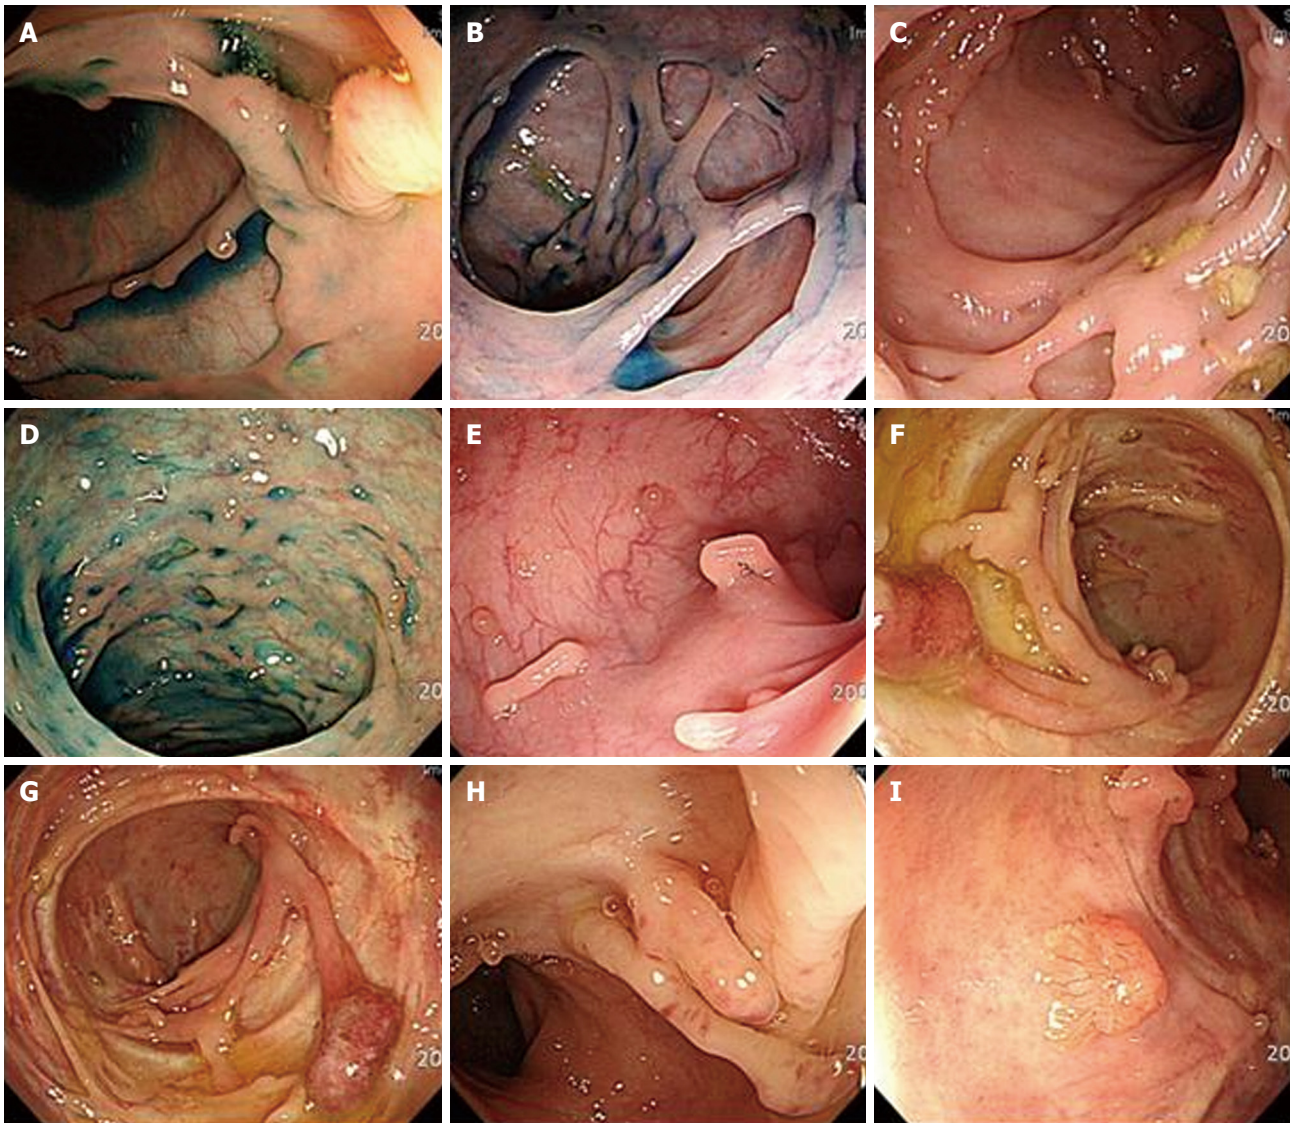

Figure 1 Colonoscopic findings show multiple worm-like or finger-like polypoid lesions, with a stalactite appearance, in the left-sided colon, especially in the sigmoid area (A-I).

IBD: Inflammatory bowel disease.

typic studies regarding filiform polyposis without IBD demonstrate that there is generalized polyposis, generally considered to be an asymptomatic sequela of ulcerative colitis[2]. Generally, there is no definite evidence that filiform polyposis itself represents a pre-cancerous condition[2]. Filiform polyposis may resemble villous adenomas on colonoscopy[4]. Therefore, biopsy should be recommended in all cases of filiform polyposis if it is necessary[3,8,9]. Filiform polyposis alone is not an indication for surgical resection, but complications, such as acute massive hemorrhage or intestinal obstruction, may necessitate surgical intervention[10,11].

In our case series it cannot be completely excluded that filiform polyps may have emerged as asymptomatic sequelae of intestinal tuberculosis, IBD, other infectious colitis, ischemic colitis, or histiocytosis X.

Sporadic hyperplastic polyps are generally thought to be non-malignant and malignant transformation into adenocarcinoma has been rarely reported[12]. However, contrary to single sporadic hyperplastic polyps, hyperplastic polyposis is considered to be a pre-cancerous lesion[12-17]. Our case series is distinct from hyperplastic polyposis syndrome. The diagnostic criteria for hyperplastic polyposis generally include the presence of (1) at least 5 histologically diagnosed hyperplastic polyps proximal to the sigmoid colon, of which two are > 10 mm in diameter, or (2) any number of hyperplastic polyps proximal to the sigmoid colon in an individual who has a first degree relative with hyperplastic polyposis, or (3) > 30 hyperplastic polyps of any size that are distributed throughout the colon[12-15]. Our case series did not satisfy these diagnostic criteria.

Diffuse colonic mucosal ulceration is a possible finding in histiocytosis X[18]. Histiocytosis X may have gastrointestinal symptoms such as diarrhea, malabsorption, or gastrointestinal bleeding[18]. However, these gastrointestinal symptoms are rare[18]. Diagnosis of histiocytosis X is based on mucosal biopsy and immunopathologic findings which demonstrate the presence of a disseminated proliferation of histiocytes[18]. Our case series did not satisfy this pathologic finding.

We report seven patients with filiform polyposis mainly localized in the sigmoid colon. Although none of our cases showed progression into adenocarcinoma, various pathologic findings, including mainly filiform polyps, hyperplastic polyps or adenomas, were found. None of the patients had a definite history of IBD, intestinal tuberculosis, infectious or ischemic colitis, but the filiform polyposis seemed to be a sequela of asymptomatic chronic colonic inflammation. Although definite evidence is insufficient, filiform polyposis localized in the sigmoid colon appears not to have high oncogenic potential. However, periodic follow-up seems to be necessary because large polyps were intermittently proven to be adenoma in our case series.

We have reported seven cases of filiform polyposis involving the sigmoid colon in Koreans who had no definite history of IBD or intestinal tuberculosis. Up to the present, studies regarding filiform polyposis syndrome located in the left side of the colon are insufficient. Continuous close follow-up of these seven patients and collection of large numbers of cases should be performed in order to understand the natural history and observe the possibility of progression into cancer.

Abstract

Many plant-derived natural products have the potential to be hepatoprotective and therefore can be used to treat acute and chronic liver diseases. The challenge is to identify the most promising compounds and evaluate their protective mechanism. In a recently published article, Wang *et al* evaluated extracts of the plant *Gentiana manshurica* Kitagawa (GM) in a model of acetaminophen hepatotoxicity. The authors concluded that GM is hepatoprotective against acetaminophen-induced liver injury due to its antioxidant properties and anti-apoptotic capacity. We would like to discuss the limitations of this experimental approach and question the conclusion based on the data presented in this manuscript and the published literature.

TO THE EDITOR

We read with interest a recent paper published in *World Journal of Gastroenterology* by Wang *et al*[1], who showed that 2 h pretreatment with an extract of the plant *Gentiana manshurica* Kitagawa (GM) could protect mice against acetaminophen (APAP) hepatotoxicity (300 mg/kg). The authors concluded that GM is hepatoprotective against acetaminophen-induced liver injury due to its antioxidant properties and anti-apoptotic capacity. A comparison of GM to the well-established clinically used antidote *N*-acetyl-*L*-cysteine (NAC) resulted in similar beneficial effects. According to the authors, their data suggest that GM is a potent hepatoprotective agent with a comparable mechanism to NAC. However, some of these mechanistic conclusions are clearly not justified by the data and whether or not GM is actually hepatoprotective under clinically relevant conditions has not been established.

The first concern is the authors' conclusion that GM has an anti-apoptotic effect. Apoptotic cell death is characterized by cell shrinkage and nuclear condensation[2,3]. However, none of these morphological features was evident from the liver sections shown by Wang *et al*[1]. In contrast, extensive centrilobular necrosis was shown, which correlates with the extensive release of liver enzymes into the plasma. The cells that are stained positive for DNA strand breaks with the transferase-mediated

dUTP nick end-labeling (TUNEL) assay are not apoptotic. These cells show the characteristic nuclear and cytosolic staining of oncotic cells, which has been extensively described for APAP hepatotoxicity[2-4]. The nuclear fragmentation is caused by the mitochondrial release of endonuclease G and apoptosis-inducing factor[4,5], rather than by caspase-activated DNase, which is responsible for DNA fragmentation during apoptosis[6]. Although the authors claimed that caspase-3 was activated based on the appearance of a 17 kD cleavage product, no other bands (pro-caspase-3) have been shown and no positive controls as reference points were included. Most importantly, a dramatic increase in procaspase-3 cleavage should go along with a dramatic increase in caspase-3 enzyme activity, which has never been shown in APAP-induced liver injury[2,7-9]. Consistent with these observations, caspase inhibitors do not protect against APAP hepatotoxicity arguing against a relevant role of caspase activation in the pathophysiology[8,9]. Furthermore, in both primary cultured mouse[10] and human hepatocytes[11], APAP induces necrotic cell death. Taken together, oncotic necrosis is the predominant mode of cell death (> 95%) during APAP hepatotoxicity in animal models *in vivo* and in humans[2]. The only exception is APAP-induced cell death in metabolically incompetent hepatoma cell lines. However, these mechanisms have no relevance to the *in vivo* hepatotoxicity of this drug[7].

A second major concern is related to the extensive mechanistic conclusion including the hypothesis that GM acts as an antioxidant. There is direct evidence that reactive oxygen species and peroxynitrite are formed in mitochondria during APAP hepatotoxicity and play a critical role in cell death[4,12,13]. However, the fact that at 12 h after APAP administration, there was less lipid peroxidation, together with other evidence for reduced tissue injury, does not prove that GM acts as an antioxidant. The same results would be obtained if GM protected and improved cell viability through other mechanisms with the consequence of less oxidant stress. In fact, one of the most likely mechanisms of protection, i.e. that one or several compounds in this plant extract may have inhibited cytochrome P450 activities or may have competed with APAP for metabolism, was not investigated. Toxicity of APAP is entirely dependent on its metabolic activation[14], which means that any interference with its reactive metabolite formation will substantially reduce or even eliminate toxicity. In the absence of clear evidence that this extract does not affect reactive metabolite formation, any conclusion regarding more distal mechanisms is not justified.

The third concern is the conclusion that GM acts as a hepatoprotectant similar to NAC. However, in clinically relevant situations of drug overdose, the antidote has to be effective when administered after the insult not as a pretreatment. The effectiveness of GM against APAP hepatotoxicity when treated after drug overdose has not been investigated. Furthermore, the comparison to NAC is not justified. NAC given as pretreatment to fasted animals will support glutathione (GSH) synthesis in the liver resulting in much higher GSH levels than the respective controls 2 h later[15]. These elevated GSH levels will more effectively scavenge the reactive metabolite of APAP and therefore prevent initiation of liver injury[16]. This protection mechanism of NAC is independent of the antioxidant effect of GSH mainly because no oxidant stress is generated at this point. However, if NAC is administered several hours after APAP, i.e. at a time when hepatic GSH is depleted and mitochondria have already generated an oxidant stress, GSH synthesized at this time is used to scavenge reactive oxygen species and peroxynitrite[13,17]. In addition, some of the excess NAC will also be used to support the impaired mitochondrial energy metabolism[17]. Both mechanisms contribute to the late protection against APAP hepatotoxicity[13,17]. Thus, NAC can have 3 different mechanisms of action depending on the time of administration relative to APAP. The pretreatment with NAC as used by Wang *et al*[1] will mainly scavenge the reactive metabolite of APAP, an effect that is unlikely to be relevant to GM.

Taken together, the protective effect of GM against APAP hepatotoxicity is an interesting observation. However, GM as a hepatoprotectant against drug toxicity under clinically relevant conditions has not been demonstrated. In addition, the actual protection mechanism of GM remains unclear. More mechanistic studies considering clinically relevant conditions are needed to evaluate the potential of this plant extract as an antidote against drug hepatotoxicity.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in tahe field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

Various types of sedation and analgesia technique have been used during gastrointestinal endoscopy procedures. The best methods for analgesia and sedation during gastrointestinal endoscopy are still debated. Providing an adequate regimen of sedation/analgesia might be considered an art, influencing several aspects of endoscopic procedures: the quality of the examination, the patient's cooperation and the patient's and physician's satisfaction with the sedation. The properties of a model sedative agent for endoscopy would include rapid onset and offset of action, analgesic and anxiolytic effects, ease of titration to desired level of sedation, rapid recovery and an excellent safety profile. Therefore there is an impulse for development of new approaches to endoscopic sedation. This article provides an update on the methods of sedation today available and future directions in endoscopic sedation.

INTRODUCTION

The best methods for analgesia and sedation during gastrointestinal endoscopy are still debated. Providing an adequate regimen of sedation/analgesia might be considered an art, influencing several aspects of endoscopic procedures: the quality of the examination, the patient's cooperation and the patient's and physician's satisfaction with the sedation[1].

Ensuring adequate sedation and analgesia and the patient's clinical stability by appropriate monitoring during endoscopic procedures has become extremely important over the last 10 years or so[2,3]. Open-access endoscopy, where no outpatient evaluation is required before the procedure, is increasingly common. Patients, sometimes with comorbidities, arrive for screening or routine endoscopy without having been assessed for pathologies that might influence procedural sedation. In addition, in situations where the examination is more invasive or time-consuming, the level of sedation must be optimized in order to achieve ideal procedural conditions.

The best sedation strategy should be tailored to the individual patient, based on the clinical risk evaluation and the type of procedure to be done[3-5]. Sedation can be defined as a drug-induced depression in the level of consciousness. Sedation and analgesia comprise a continuum

of states ranging from minimal sedation (anxiolysis) through general anesthesia. The majority of endoscopic procedures are done under a regimen of moderate sedation and the literature suggests that combining a benzodiazepine with an opioid provides an effective level of sedation. Targeting a moderate level of sedation gives a better overall profile than a deeper level and should also give a better safety margin for a non-anesthesiologist[3]. However, Patel *et al*[6], measuring sedation levels during endoscopic procedures performed with a combination of meperidine and midazolam, observed that unintended excursion into a deeper level of sedation did not generally result in adverse outcomes and suggest the safety margin is wide around targeted moderate sedation.

An important general principle about achieving moderate sedation with a combination of drugs is that the combined effect of an opiate and benzodiazepine is much greater than the additive effects of the single drugs so there is a greater risk of complications[7].

The target level of sedation and the agents chosen will depend on the characteristics of the endoscopic procedure (length and painfulness), individual patient's factors (age, comorbidities, anxiety, *etc.*), patient's preferences, and the need for cooperation[8]. A critical point for the non-anesthesiologist is that although a patient's characteristics help establish the target dosage, it is impossible to predict accurately the exact dose needed to complete the procedure. Even when the blood levels of a particular drug are similar, one patient's experience of sedation can be quite different from that of another. Therefore, a successful outcome is dependent on an understanding of incremental dosing, the synergistic effects of drug classes, and the onset of action and peak effects of sedation agents. In addition, clinicians must always be prepared to rescue patients who move to the next deeper level of sedation[7].

Propofol is a short-acting intravenous agent with a rapid onset of action, short recovery profile, anti-emetic proprieties and good amnesic effects. Several studies have suggested that propofol offers significant advantages over benzodiazepines and opioids for sedation during endoscopic procedures and two large prospective studies indicated it was more effective and safer than midazolam and meperidine for reaching and maintaining an adequate level of sedation during endoscopic procedures, resulting in better titration of the level of sedation, and shorter recovery times[9-14].

In 2004 the American College of Gastroenterology, American Gastroenterology Association and the American Society for Gastrointestinal Endoscopy issued a joint statement affirming that large case studies indicate that adequately trained nurses, supervised by a physician, can safely and effectively administer propofol. Worldwide experience with gastroenterologist-directed sedation with propofol combined with improvements in our understanding of its dosing and titration for moderate sedation, as stated by Cohen *et al*[15], have prompted several medical societies to question the real necessity of restricting its use to anesthesiologists. In 2004 the American Society for Gastrointestinal Endoscopy, in its Training Guidelines for Use of Propofol in Gastrointestinal Endoscopy, stated: "While properly trained physicians can administer propofol, regulations governing its administration by non-physician personnel are variable on a state-by-state basis"[4,15]. Nevertheless, in April 2004 the American Society of Anesthesiologists (ASA) recommended that, when propofol is used for moderate sedation and analgesia, it should be administered by someone trained in administering general anesthesia. This is in line with the "black box" warning for propofol, in which the manufacturer makes the same recommendations. Furthermore, in 2005 the ASA stated that: "Propofol is an anesthetic drug and the ASA believes that the involvement of an anesthesiologist in the care of every patient undergoing anesthesia is optimal"[16].

In a recent update article Rex *et al*[17] opined that given the big financial incentives from special interest groups, such as the anesthesiologists' community, it is unlikely that non-anesthesiologist-directed propofol administration will expand dramatically in the near future.

NON-ANESTHESIOLOGIST PROPOFOL SEDATION

Many studies address the safe and effective administration of propofol during gastrointestinal endoscopy, by either physicians or trained nurses. In 2005 the cumulative reported experience with nonanesthesiologists-administered propofol during gastrointestinal endoscopic procedures was more than 80 000 patients[18-26]. In these reports there were no patients requiring endotracheal intubation or resulting in death. In 2005, in a large prospective trial involving three endoscopy units (Indiana, Oregon and Switzerland) and 36 743 cases of nurse-administered propofol sedation, the authors concluded: "Trained nurses and endoscopists can administer propofol safely for endoscopic procedures. Nurse-administered propofol sedation is one potential solution to the high cost associated with anesthesist-delivered sedation for endoscopy" and moreover: "It remains uncertain whether large prospective series of NAPS with safe performance will satisfy the concerns of anesthesia societies regarding the safety of propofol administration for endoscopy by appropriately trained registered nurse/endoscopy teams"[25].

In 2007 Cohen and the AGA Institute, reviewed the standard practice of endoscopic sedation and, regarding the use of gastroenterologist-directed propofol, recommended that: (1) Gastroenterologist-directed propofol sedation is medicolegally reasonable, but requires appropriate endoscopist training, patient selection and adherence to protocols for administration as well as compliance with institutional and local regulation; and (2) The endoscopist should be ACLS certified and provide sedation in keeping with expert practice guidelines and with institutional and state guidelines. Endoscopy Units should conform to practice guidelines regarding procedure-related sedation, including documentation, training of staff, maintenance of rescue equipment, creation of appropriate emergency protocols and quality assurance programme[15].

In 2008 Rex, in an update about gastroenterologist-directed propofol, summarized published literature on the safety of gastroenterologist-directed propofol reporting more than 220 000 cases without a single reported death. In only 1 case endotracheal intubation was required during endoscopic retrograde cholangiopancreatography (ERCP) with full patient's recovery. As stated by Rex, despite evidence that there are large case series supporting the use of propofol sedation by non-anesthesiologists, numerous obstacles have persisted regarding its expansion; most prominent of these is the institutional control that anesthesiologists maintain over sedation policies[17]. The ASA Task Force recommends that patients receiving propofol should receive care consistent with deep sedation and that those personnel should be capable of rescuing the patient from general anesthesia[2]. However, there is abundant evidence that propofol can be administered safely by non-anesthesiologist.

In a recent paper by Rex *et al*[26], a world-wide multicenter safety review of 646 080 (223 656 published and 422 424 unpublished) endoscopist-directed propofol sedation cases was conducted. Endotracheal intubation, permanent neurologic injuries and deaths were 11, 0 and 4, respectively. The 4 deaths occurred in patients with significant comorbid illness. In this series endoscopist-directed administration of propofol appears to have a lower mortality rate than that in published data on traditional sedation with benzodiazepines and opioids and a comparable rate to that on general anesthesia by anesthesiologists.

The Endoscopic Section of the German Society for Digestive and metabolic Diseases have recently published the Guideline for Sedation for Gastrointestinal Endoscopy 2008. This guideline states: "For simple endoscopic examinations and in low-risk patients, sedation (with propofol) should be induced by a properly qualified physician and can then be monitored by an experienced person with appropriate training. The person must not have any other tasks while monitoring the sedation. Propofol may be administered by a properly trained and experienced person who has this as his or her sole task (recommendation grade A, strong consensus)"[28]. Furthermore, the literature findings on the safety of endoscopist-administered show that the use of an anesthesiologist for sedation for endoscopic procedures is costly. The recommendation of the German guideline is still that calling in an anesthesiologist should be considered only for patients with a high risk profile such as high ASA grade (Ⅲ-Ⅳ), or pathological and anatomical features associated with a higher risk of airway obstruction during the intervention.

Recently, the American Association for the Study of Liver Disease, American College of Gastroenterology, American Gastroenterological Association and American Society for Gastrointestinal Endoscopy have released the "Position statement: nonanesthesiologists administration of propofol for GI endoscopy" published in 2009 December, which concludes that the administration by non-anesthesiologists of propofol *vs* standard sedation with benzodiazepines and opioids is comparable with respect to their efficacy and safety profile[29].

Proper training and patient selection are mandatory for the safe practice of nonanesthesiologists-administered propofol sedation.

The Sedation Task Force, which was chaired by Cohen LB and included representatives from each of the four societies, was convened to develop a document designed to provide an evidence-based assessment of propofol-mediated sedation by properly trained nonanesthesiologists. The document was approved by the governing boards of all four societies.

A number of recommendations are made in the statement regarding non anesthesiologist propofol sedation (NAPS): (1) The safety profile of NAPS is equivalent to that of "standard sedation" with respect to the risks of hypoxemia, hypotension and bradycardia for upper and lower endoscopy, ERCP and endoscopic ultrasound (EUS). The worldwide experience with NAPS during EUS and ERCP, however, is insufficient to draw definitive conclusions about its use in these setting; (2) For upper and lower endoscopy, ERCP and EUS, the time for sedation induction and the recovery time using NAPS are shorter in comparison to that with standard sedation; patient satisfaction is equivalent or slightly superior; and (3) For ERCP and EUS, NAPS is more cost-effective than standard sedation. The use of anesthesiologist-administered sedation for healthy, low-risk patients undergoing routine gastrointestinal endoscopy results in higher costs with no proven benefit with respect to patient safety or procedural efficacy.

NAPS requires the acquisition of skills and abilities that are distinct from those necessary for standard sedation. Training programs that are both didactic and practical should be provided by Scientific Societies.

Although current methods of sedation are effective for the majority of patients undergoing endoscopy, techniques that enhance patient satisfaction, safety and recovery are desirable.

Infusion platforms that permit control of drug delivery by the patient are promising alternatives to current methods of sedation.

PROPOFOL INFUSION PLATFORMS

New concepts in endoscopic sedation include enhanced mechanisms for drug delivery such as target-controlled infusion (TCI) and patient-controlled sedation or analgesia (PCS or PCA). The TCI pump, first described in the 1980s, provides infusions based on pharmacokinetic models of the specific drug, using a computer-controlled pump; the target concentration (in μg/mL) is automatically achieved and maintained over time by varying the infusion rate according to a three-compartment pharmacokinetic model, with very good predictive performance. The infusion rate is directly and automatically adapted by the software managing the pump, without the need for any of the complex calculations required for a manual scheme.

The ASA guidelines recommend accurate titration of sedative/analgesic medications to improve patients' comfort and safety and avoid the risk of over-sedation[2]. Among different systems available for administration of

propofol, the TCI pump is undoubtedly one of the most sophisticated and several studies have shown that target-controlled drug infusion ensures excellent and safe sedation during endoscopic procedures[30-32].

For PCS or PCA, the patient self-administers the medication in response to pain; therefore, the patient must be conscious enough to press the hand-held button. A lock-out time is programmed in order to prevent the delivery of additional doses until the previous dose has taken full effect. PCA, which allows the patient to self-administer frequent, small doses of opioids, as needed to manage pain, could be an effective method for pain control during gastrointestinal endoscopy[33-35].

Pambianco *et al*[36] reported on the investigational computer-assisted personalized sedation system with propofol (CAPS), designed to enable physician-nurse teams to keep patients undergoing endoscopic procedures at minimal to moderate sedation levels, preventing them slipping into deep sedation with drops in cardio-respiratory function. The report described two open-label single-center trials of the CAPS device on 48 patients undergoing either colonoscopy or EGD procedures and found that the results were reproducible across two countries and two practice settings. The system continuously monitors six parameters including oxygen saturation, respiratory rate, heart rate, non-invasive blood pressure, end-tidal carbon dioxide and patients' responsiveness to verbal and tactile stimuli. In this trial the moment-to-moment control of propofol infusion led to very rapid post-procedure recovery from sedation (< 30 s), and the system, also known as SEDASYS™, performed as designed, reducing or stopping propofol infusion at the first signs of over-sedation, with a very low incidence of desaturation. Pambianco *et al*[36] said that the CAPS device detected apnea more sensitively than clinical observation. In their trial there was no need for airways management or mechanical ventilation.

The CAPS device facilitates the titration of propofol to the desired clinical effect by automatically calculating and delivering a loading dose. The platform continuously checks for early signs of potential adverse effects and the level of sedation, so the physician/nurse teams can adjust the infusion as required, to the targeted degree of sedation. The system is also designed to respond to early signs of over-sedation, as indicated by apnea or hypoxemia, by stopping or reducing delivery of propofol, increasing oxygen delivery and automatically instructing patients to take a deep breath.

In two feasibility studies of CAPS involving 96 patients undergoing elective upper endoscopy and colonoscopy, patients remained minimally to moderately sedated throughout the procedure. For the majority, recovery time was less than 1 min and there were no serious adverse events.

The nurses assisting in the procedures reported that the system was intuitive and user-friendly, and the built-in dosing limits and automated response algorithms allowed the team to be confident that an appropriate level of sedation was being maintained.

A multi-center prospective, randomized, controlled pivotal trial, presented at Digestive Disease Week in May 2008, compared the safety and effectiveness of propofol plus a single dose of fentanyl administered with the CAPS system, or physician-administered standard sedation regimens involving opioids and benzodiazepines (midazolam with either fentanyl or meperidine) in 1000 patients. Patients who received CAPS sedation had significantly lower measures of cumulative oxygen desaturation than those assigned standard sedation). There were 34 adverse events, no serious adverse events and no rescue interventions among patients sedated with CAPS; there was one rescue intervention in the control group[37]. As stated by Pambianco *et al*[37], the trial investigators, the system made it possible to maintain minimal to moderate sedation with propofol during upper endoscopy and colonoscopy, and helped prevent patients entering deep sedation, which is traditionally associated with propofol.

The system seems to offer a way to personalize the level of sedation appropriate for each patient because it combines propofol delivery with sophisticated monitoring for better control of the sedation regimen, by predicting the patient's level of sedation. Based on the findings of these investigations, the system has been submitted to the US FDA for pre-marketing approval under the brand name SEDASYS™ System.

Most states require the presence of an anesthesiologist during propofol administration, an expensive and unfavorable arrangement for most gastrointestinal endoscopy centers. Current propofol black-box labeling states that only persons trained in general anesthesia should administer the drug. However, pending a favorable FDA review, labeling for the CAPS system will allow physicians and nurses to administer propofol sedation for endoscopic procedures, without the assistance of an anesthesiologist.

In the light of the increasing use of propofol by non-anesthesiologists, some anesthesiologists remain sceptical about CAPS systems, asserting that they cannot substitute for a trained professional, particularly in an emergency. In view of the specific risks of propofol, even if only moderate sedation is intended, patients receiving the drug should receive care consistent with that required for deep sedation, considering the potential for abrupt onset of airway obstruction and apnea and the lack of a specific antidote.

As stated by Iravani[38] in a recent editorial, "the intriguing question is whether the use of CAPS in administering propofol prevents the progression of sedation to unintended depths, deep sedation or general anesthesia. In other words, does this precise moment-to-moment control of the propofol infusion titrated to clinical effect obviate the need for the presence of personnel proficient in airway management and advanced life support?".

Could this technology facilitate access to propofol sedation by gastroenterologists? The Anesthesia and Respiratory Device Review panel met on May 28, 2009 and, by an 8-2 margin, approved the CAPS platform for use by endoscopist/nurse teams in EGDS/colonoscopy in ASA Ⅰ / Ⅱ adults under the age of 70 years, with BMI < 35 kg/m^2.

Major hurdles that still remain for propofol adoption are the diversity of medical society guidelines, the costs of anesthesiologist-attended endoscopic procedures, and the immutable, indelible black-box warning about propofol administration. Furthermore, until there is a training program for the use of propofol by non-anesthesiologists, FDA approval of CAPS will probably not be forthcoming.

DRUGS: WHAT'S NEW?

A number of prodrug formulations of propofol have been developed to overcome the disadvantages of the current lipid-based formulations, including stability, the potential complications of lipid infusion, the risk of contamination and fluctuations in propofol plasma levels due to the bolus injection.

Fospropofol disodium (FD), which now goes by the brand names of Lusedra or Aquavan, is a water-soluble prodrug of propofol with pharmacokinetic and pharmacodynamic properties that differ from propofol emulsion. FD is the first propofol prodrug to be studied for moderate sedation. After IV injection, propofol is released from FD by tissue alkaline phosphatases with a predictable pattern of plasma concentrations, resulting in lower peak concentrations and a more gradual decline in drug concentrations than with a standard propofol injection. Due to the different and complex pharmacokinetics of FD, time to peak sedative effect after a bolus injection is between 3 and 7.5 min, compared with 1 min 36 s for propofol[39].

Although the anesthesiologist community has shown only limited interest, FD has been investigated for sedation by non-anesthesiologists. In 2008 Cohen stated in a review that "FD may be an attractive agent for gastroenterologists interested in realizing the benefits of propofol without the requirement of an anesthesia specialist in the endoscopy suite"[40]. In July 2008 the FDA approved FD with a "MAC label", which means that this drug, like propofol, will be used mostly by anesthesiologists and certified registered anesthetist nurses. The drug manufacturer has been in discussions with FDA regarding additional studies and remains committed to getting the product approved for use by non-anesthesiologists.

The ideal drug for sedation for non-anesthesiologists should have certain properties to ensure safe, effective sedation. These include a predictable pharmacokinetic profile, rapid onset of action, analgesic and anxiolytic effects, short recovery time, minimal associated risks and no requirement for the presence of an anesthesiologist. Ketamine[41,42], nitrous oxide[43,44] and dexmedetomidine[45,46] have all been studied for procedural sedation. While some results have been promising, none fulfil all these criteria or offer any true advance in sedation during gastrointestinal endoscopy.

Remifentanil, an ultra-short-acting μ-opioid receptor agonist, has some advantages over other opioids because of its rapid onset and offset times, making it suitable for controlling pain during endoscopic procedures[35,47,48]. The combination of rapid onset and offset of action translates clinically to easy titrability. However, its respiratory depressant effect has been amply reported[49,50]. On account of this, remifentanil is typically administered in a moderate sedation/analgesia setting, by continuous infusion using a programmable infusion pump. There are many reports of the use of remifentanil in different settings (obstetrics, gastrointestinal endoscopy, pain control after abdominal surgery) using PCA, with or without background infusion, and the quality of analgesia and patient satisfaction seem to be the same as with standard sedation/analgesia[35,52-55].

New sedatives and delivery systems under development have the potential to improve the quality of endoscopic sedation/analgesia. Scientific societies now need to establish training schemes for the use of sedatives and delivery systems. These should include training in advanced cardiac life support, the pharmacokinetics and pharmacodynamics of the drugs to be used, airway assessment, and training in simple measures of ventilatory support in patients with apnea or airway impairment during sedation for gastrointestinal endoscopy[15].

CONCLUSION

Most guidelines all over the world recommend the sedation of patients when undergoing gastrointestinal endoscopy. Benzodiazepines combined with opioids are the most frequently used sedative agents; however there are a number of potential concerns/problems with available sedative agents. In fact, most complications in gastrointestinal endoscopy are not related to the procedure, but to sedation and include cardiopulmonary events such as hypoxemia, hypoventilation, airway obstruction, apnea, arrhythmias, hypotension and vasovagal episodes. Finding an ideal regimen of sedation seems to be similar to "Searching the Holy Grail". Since the introduction of propofol in the 1980s, for the induction and maintenance of anesthesia, its clinical application have expanded to include monitored anesthesia care and procedural sedation. The use of propofol for endoscopic sedation has increased markedly during the past 10 years. Several studies have established that propofol is superior to traditional sedative regimens because of its superior recovery profile and its safety profile.

The worldwide safety experience of endoscopist-administered propofol sedation now exceeds 460 000 patients. We look forward to a time when a sedation team will be qualified to administer propofol during gastrointestinal endoscopy without the presence of the anesthesiologist, following a proper training program. The new emerging technology could facilitate access to propofol sedation.

Abstract

Knowledge of etiology and timely treatment of underlying causes, when possible, play an important role in the successful therapy of patients with pyogenic liver abscess (PLA). Recent publications from Central Europe and Southeast Asia hint at considerable differences in etiology. In this article, we aim to elaborate these differences and their therapeutic implications. Apart from some special types of PLA that are comparable in Southeast Asia and Central Europe (such as posttraumatic or postprocedural PLA), there are clear differences in the microbiological spectrum, which implies different risk factors and disease courses. *Klebsiella pneumoniae* (*K. pneumoniae*) PLA is predominantly seen in Southeast Asia, whereas, in Central Europe, PLA is typically caused by *Escherichia coli*, *Streptococcus* or *Staphylococcus*, and these patients are more likely to be older and to have a biliary abnormality or malignancy. *K. pneumoniae* patients are more likely to have diabetes mellitus. Control of septic spread is crucial in *K. pneumoniae* patients, whereas treatment of the underlying diseases is decisive in many Central European PLA patients.

Key words: Liver abscess; *Klebsiella pneumoniae*; Biliary tract diseases; Drainage; Antibiotics

INTRODUCTION

Pyogenic liver abscess (PLA) is the result of bacterial infection of the liver parenchyma, with subsequent infiltration by inflammatory cells and formation of a collection of pus. It is still a severe disease with considerable mortality (6%-14%)[1,2]. Chen *et al*[3] recently have reported an intensive care unit mortality rate of 28%. Treatment policies have changed in recent decades as a result of developments in interventional radiology that offer imaging-guided percutaneous puncture and drainage as procedures that are less invasive than surgical therapy. However, several studies have shown that underlying diseases and the overall condition of the patients have major prognostic significance[4,5]. Both the APACHE (acute physiology and chronic health evaluation) II and the SAPS (simplified acute physiology score) II scoring methods are appropriate for assessing mortality of PLA patients[6]. Thus, knowledge of etiology and timely treatment of underlying causes, when possible, play an important role in successful treatment. Recent publications from Central Europe and Southeast Asia hint at considerable differences in etiology. This editorial aims to elaborate these differences and their therapeutic implications. Information from recent publications on liver abscesses from PubMed was used. *Klebsiella* PLA is mainly described in series from Southeast Asia, whereas

European and American studies usually comprise a mixture of different etiologies. Special interest was placed on publications devoted to characteristics and specific features of *Klebsiella* abscesses as compared to those of other origin.

GENERAL CONSIDERATIONS ON CLINICAL MANAGEMENT

Antibiotic treatment is the basis of clinical PLA management. Gram stain, abscess culture (with sensitivity testing) and blood culture provide valuable information to guide successful therapy. Chemaly *et al*[7] have found that the sensitivity and specificity of Gram stains of liver abscess material were 90% and 100% for Gram-positive cocci (GPC) and 52% and 94% for Gram-negative bacilli (GNB). The sensitivities of the blood cultures for any GPC and GNB present in the liver abscess were 30% and 39%, respectively. Of the positive blood cultures, 35% contained organisms not recovered from abscess cultures. On the other hand, PLA pathogens are usually underrepresented in blood cultures. In a recent study from Pakistan with a total of 966 patients, 540 responded to medical therapy, whereas adjunctive percutaneous aspiration was performed in 426. Predictive factors for aspiration of liver abscess were: age $\geqslant$ 55 years, size of abscess $\geqslant$ 5 cm, involvement of both lobes of the liver, and duration of symptoms $\geqslant$ 7 d[8]. Microbiology also hints at pathogenesis: local spread typically leads to mixed flora[9], and hematogenous seeding to a single microorganism (typically *Staphylococcus aureus* or *Streptococcus* spp.).

Apart from choosing the right antibiotic, another crucial concern is whether a sufficient concentration of the antibiotic reaches the target site. In this context, Matoba *et al*[10] have published an article on intermittent hepatic artery antibiotic infusion therapy, especially for patients in whom percutaneous drainage could not be performed and intravenous administration of antibiotics was ineffective. The value of this treatment (for a highly selected patient group) still has to be shown with a larger number of patients.

As for abscess drainage, the percutaneous technique has often come to replace surgical procedures. Surgery nonetheless still plays an important role when percutaneous drainage fails[11] or when underlying pathology such as biliary disease and malignancy has to be addressed[12]. In selected cases, drainage may also be done laparoscopically[13] or *via* a trocar in local anesthesia[14]. Hsieh *et al*[15] have found that aggressive hepatic resection for patients with liver abscesses and APACHE Ⅱ scores of $\geqslant$ 15 produce better clinical outcomes than other therapeutic options.

PLA IN CENTRAL EUROPE

Our patients[5] show the etiological spectrum typical for our region, with biliary disorders first, followed by cryptogenic abscess, PLA due to systemic infection, and posttraumatic origin. Some other, rarer causes were also identified (portal route of infection, hydatid origin, postoperative/postprocedural, foreign body). The microorganisms found most frequently were *Staphylococcus*, *Streptococcus* and *Escherichia coli* (*E. coli*). *Klebsiella* spp. were only found in 5% of cases. In about 25% of the patients, the abscesses were sterile and this was at least partly due to antibiotic pretreatment. Anaerobic agents are encountered with increasing frequency but this might be attributable to improved transport and culture techniques. A recent study from Spain[16] has shown similar results, with *Streptococcus* and *E. coli* found most frequently, but a higher number of *Klebsiella* spp. (14%). The most common complication was pleural effusion.

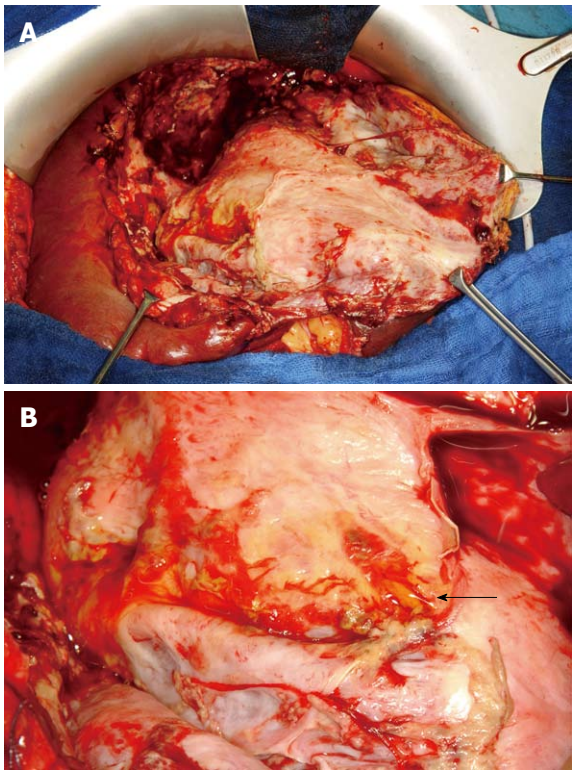

Figure 1 Posttraumatic liver abscess. A: Intraoperative image after evacuation of putrid fluid; B: Detail from the floor of the abscess cavity showing a biliary fistula (arrow).

Prolonged disease course may result from unexpected or particularly aggressive agents, underlying pathology or constant inflammatory stimuli provoked by a foreign body. As a rare cause of pyogenic abscesses, *Salmonella* infection (hematogenous or ascending *via* the biliary tree) has been described[17-23].

Underlying pathology is frequently found in our region and is often the crucial prognostic factor. This includes gallbladder empyema, biliary fistula[24] (Figures 1 and 2), pylephlebitis secondary to acute appendicitis[25,26], and malignancy (e.g. hepatocellular carcinoma, cholangiocarcinoma, liver metastases, gallbladder carcinoma, carcinoma of the papilla, and pancreatic cancer). Operative treatment of the underlying disease is indicated whenever feasible. For the healing of biliary fistula, good bile

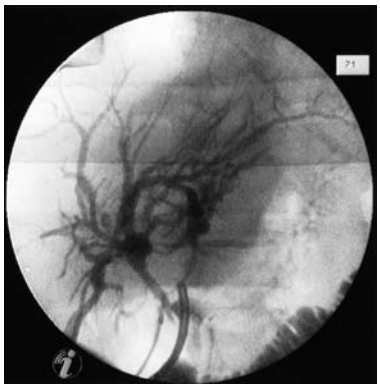

Figure 2 Intraoperative cholangiogram (injection of contrast medium into the fistula ostium).

flow is crucial and may be provided by papillotomy and biliary stenting. In patients with cryptogenic PLA, silent abdominal pathology should always be considered and further studies such as colonoscopy are recommended[27].

In special cases, a foreign body penetrating from the digestive tract may provide a constant stimulus for inflammation. Several kinds of foreign bodies such as toothpick[28,29], pin[30], needle, bone[31,32], pen, dental plate, clothespin, wire crucifix, and rosemary twig[33] have been described[9]. Removal of the foreign body is crucial for successful treatment.

PLA IN SOUTHEAST ASIA

Klebsiella pneumoniae (*K. pneumoniae*) liver abscess[34-42] recently has been reported as the leading cause of PLA in Korea and Taiwan, and is described as a globally emerging infectious disease. *K. pneumoniae* is found as a harmless commensal but is also a frequent nosocomial pathogen (causing urinary, respiratory and blood infections) and the agent of specific human infections including Friedländer's pneumonia, rhinoscleroma and PLA[43].

Literature on this entity predominantly comes from Southeast Asia but it has also been reported as an emerging problem in North America[44]. In a recent report from New York, 60% of the patients with *Klebsiella* PLA were of Asian origin, although many of them had not resided in their country of origin for quite some time[45]. Although *K. pneumoniae* is prevalent in patients with diabetes, it can also attack healthy people or alcoholics[46]. Foo *et al*[47] have found that diabetes mellitus is not a predictor of fatality. The MagA virulence gene has been described in invasive strains. According to Yeh *et al*[48], and in accordance with the bacterial polysaccharide gene nomenclature scheme, MagA should be renamed Wzy (KpK1), the capsular polymerase specific to *K. pneumoniae* serotype K1. Gas formation by mixed acid fermentation of glucose is a typical feature.

K. pneumoniae PLA constitutes a clinical entity distinct from polymicrobial liver abscess, has a high propensity to metastasize, and rarely is associated with intra-abdominal abnormalities. PLA-producing strains are commonly resistant to ampicillin. Complications include metastatic meningitis, endophthalmitis, acute respiratory distress syndrome, septic pulmonary emboli, and necrotizing fasciitis. Braiteh *et al*[49] have described three distinct *K. pneumoniae* liver abscess syndromes: the polymicrobial liver abscess, the monomicrobial cryptogenic noninvasive liver abscess, and the monomicrobial cryptogenic invasive *K. pneumoniae*-associated liver abscess (CIKPLA) syndromes, with distinct clinical, epidemiological and outcome features. CIKPLA syndrome typically affects diabetic patients, mainly in Southeast Asia, and is complicated by septic spread to other organs.

Chen *et al*[50] have found that, in contrast to patients with *K. pneumoniae*, patients with *E. coli* liver abscess were more likely to be older and female, have a biliary abnormality or malignancy, pleural effusion, polymicrobial infection with anaerobic or multi-drug-resistant organisms, a higher APACHE Ⅱ score, and to have been treated initially with ineffective antibiotics. *K. pneumoniae* patients were more likely to have diabetes mellitus and the cause of infection was often cryptogenic. A higher APACHE Ⅱ score at admission and higher frequency of coexisting malignancy may have contributed to the higher mortality in *E. coli* PLA, but the difference was not statistically significant. Tsai *et al*[51] also have reported lower death rates for *Klebsiella* PLA. As for older patients, Chen *et al*[52] have found that they have a fair outcome but require longer hospitalization. After successful treatment, the recurrence rate of *Klebsiella* liver abscesses is reported to be low[53,54]. Kim *et al*[55] have described the differences in CT findings of *Klebsiella* and non-*Klebsiella* liver abscesses. The former has a series of characteristic intra-abscess features: septal breakage, turquoise-like structure, hairball-like content, air-fluid level, and no enhanced rim.

Another entity well known in endemic areas of echinococcosis, but only occasionally found in Central Europe, is liver abscess of hydatid origin[56]. It is usually associated with few symptoms, because the pericystic structure acts as a nonspecific defense mechanism. Anthelminthic drugs are of limited value.

POSTPROCEDURAL AND POSTTRAUMATIC PLA

These special forms of PLA are seen in Central Europe and South East Asia. Postprocedural PLA may occur after hepatic resection; formation of pus in the operation cavity is usually amenable to percutaneous drainage. Post-transplantation liver abscesses, however, pose more complex problems. The most common predisposing factor is hepatic artery thrombosis, which may lead to fulminant hepatic necrosis, delayed bile leakage or relapsing bacteremia. In contrast to the normal liver, the graft lacks natural attachments and collaterals. Mortality of this type of PLA is still high (42%)[57] and mean duration of drainage is long. PLAs may also occur after transarterial chemoembolization[58,59] for malignant hepatic tumors, particularly after biliary reconstructive surgery (aggressive antibiotic prophylaxis is recommended for these patients). They are also seen as rare complications after radiofrequency ablation[60-62] or cryosurgery[63].

About 5% of PLAs are of posttraumatic origin; they occur in 0.7%-1.5% of patients undergoing nonoperative treatment of liver trauma caused by bacterial seeding of hematoma or necrosis[64,65]. Risk factors include enteric injuries, persistent hemorrhage with excessive need of blood transfusions, and extensive parenchymal damage. The necessity for antibiotic prophylaxis in liver trauma patients remains an unresolved question; it might be justified with liver injury of at least grade 3 and is usually given with associated open wounds.

CONCLUSION

Apart from some special types of PLA that are comparable in Southeast Asia and Central Europe (such as posttraumatic or postprocedural PLA), there are clear differences in the microbiological spectrum, which also implies different risk factors and courses. *K. pneumoniae* PLA is predominantly seen in Southeast Asia, whereas, in Central Europe, PLA is typically caused by *E. coli*, *Streptococcus* or *Staphylococcus* and these patients are more likely to be older and to have a biliary abnormality or malignancy, pleural effusions, and a higher APACHE Ⅱ score. *K. pneumoniae* patients are more likely to have diabetes mellitus and the cause of infection is often cryptogenic. The typical complication for *Klebsiella* infection is metastatic spread to various organs. On the other hand, high APACHE Ⅱ scores at admission and a high frequency of coexisting malignancy may often contribute to a critical course in Central European PLA patients. Control of septic spread is crucial in *K. pneumoniae* patients, whereas treatment of the underlying diseases is a decisive issue in many Central European PLA patients.

Abstract

Hepatocellular carcinoma (HCC) is a major cause of cancer death, and chronic hepatitis B is a serious worldwide problem. The epidemiology of HCC is distinctive. Hepatitis B virus (HBV) plays a major role in hepatocarcinogenesis. Prevention of HBV-related HCC is a key issue in current hepatology. This paper describes the prevention and clinical features of HBV-related HCC, along with a short review of the disease.

INTRODUCTION

Persistent infection by hepatitis C virus (HCV) or hepatitis B virus (HBV) is a background factor in almost all cases of hepatocellular carcinoma (HCC) in Japanese patients, as it causes chronic hepatitis and liver cirrhosis, and ultimately HCC. Several studies have indicated that HCC develops mainly in the cirrhotic liver and alongside chronic liver diseases. It is widely accepted that viral cirrhosis caused by HBV or HCV infection is an important risk factor for the development of HCC. However, HCC can develop in non-cirrhotic livers, particularly in countries where HBV is endemic. The present paper discusses the clinical features of HBV-related HCC and the importance of viral status and viral eradication for improving the prognosis of HBV-related HCC.

CARCINOGENIC FACTORS AFFECTING CHRONIC LIVER DISEASE (TYPE B)

It is believed that the incidence of carcinogenesis is low in cases with fibrotic severity index F0 according to the new Inuyama classification of chronic hepatitis related to HBV, whereas it increases with a decrease in cure rate in association with an increase in the fibrotic severity index F. It is thus believed that the incidence of carcinogenesis also increases with increased severity of cirrhosis in patients with chronic hepatitis.

Accordingly, we examined carcinogenesis-modulating factors by long-term observation of patients with HBV-related liver cirrhosis[1].

Several studies have indicated that HCC develops mainly in the cirrhotic liver. It is widely accepted that viral cirrhosis due to infection by HBV or HCV is an important risk factor for the development of HCC. It has also been indicated that various factors and their interactions are involved in the etiology and pathogenesis of HCC. We thus determined the rate of HCC development to assess the risk factors for hepatocellular carcinogenesis in patients with HBV-related compensated viral cirrhosis.

Table 1 Carcinogenic factors involved in hepatocellular carcinoma in patients with type B cirrhosis[1]

Variable	*n*	Univariate analysis			Multivariate analysis		
		P-value[1]	RR[2]	95% CI	*P*-value[3]	RR[2]	95% CI
ALT (IU/L)							
⩾ 100	14	0.0083	2.044	1.098-4.677	0.025	4.525	1.202-17.030
< 100	51		1.000			1.000	
LDH (IU/L)							
⩾ 480	30	0.0138	2.000	0.878-4.558	NS (0.081)	2.880	0.881-9.412
< 480	35		1.000			1.000	
HBV-DNA (LGE/mL)							
⩾ 3.7	46	0.0082	2.836	1.269-6.340	0.014	7.712	1.511-39.365
< 3.7	19		1.000			1.000	

[1]*P*-values were obtained by using the log-rank test; [2]Relative risks were calculated by comparing classes using a Cox regression analysis; [3]*P*-value were obtained by using a Cox regression analysis. HBV: Hepatitis B virus; ALT: Alanine aminotransferase; LDH: Lactate dehydrogenase; NS: Not significant.

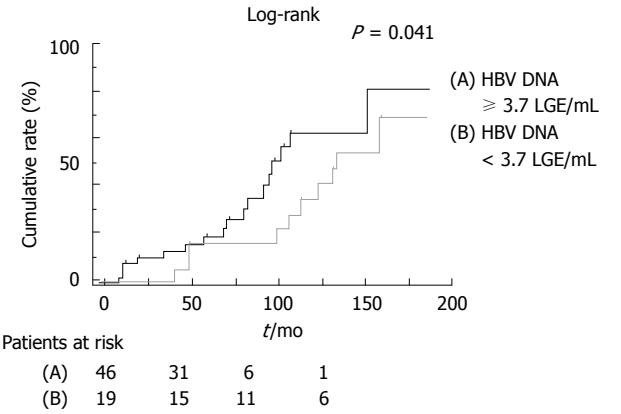

Figure 1 Comparison of the cumulative incidence of hepatocellular carcinoma by viral level in patients with type B cirrhosis[1]. HBV: Hepatitis B virus.

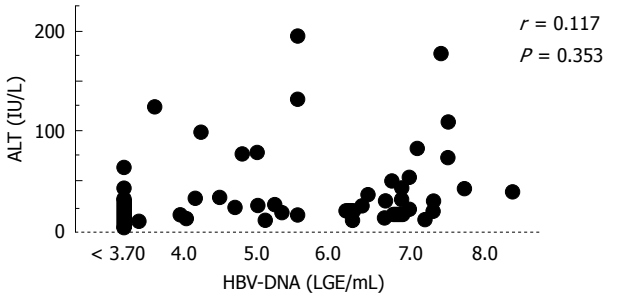

Figure 2 Correlation between HBV-DNA and alanine aminotransferase (ALT) levels in patients with type B cirrhosis[1].

We previously concluded that a high HBV-DNA titer (more than 3.7 LGE/mL) was the most predictive factor of the development of HCC in HBsAg-positive liver cirrhosis. It was found by univariate analysis that the incidence of carcinogenesis was affected by the following three factors with statistical significance: alanine aminotransferase (ALT) ⩾ 100 IU/L ($P = 0.008$), lactate dehydrogenase (LDH) ⩾ 480 IU/L ($P = 0.014$), and HBV-DNA ⩾ 3.7 LGE/mL ($P = 0.008$). Relative risks for HCC were 2.04 (95% CI: 1.10-4.68), 2.00 (95% CI: 1.08-4.56), and 2.84 (95% CI: 1.27-6.34) for these respective factors[1].

It was found by multivariate analysis using these factors that ALT and HBV-DNA levels were independent significant risk factors for HCC. The risk ratio in patients with ALT ⩾ 100 IU/L to that in those with ALT < 100 IU/L was 4.53, while the risk ratio in patients with HBV ⩾ 3.7 LGE/mL to that in those with HBV-DNA < 3.7 LGE/mL was 7.71 (Table 1).

In fact, the interval from suspected diagnosis of cirrhosis to development of HCC in the high-HBV DNA group was shorter than that in the persistently low-HBV DNA group (Figure 1). Moreover, ALT in the high-HBV-DNA titer group was higher than that in the low-HBV-DNA titer group. Despite this finding, serum ALT level was not correlated with HBV-DNA level (Figure 2, $P = 0.353$)[1].

As in our data, Ikeda *et al*[2] reported that the development of HCC in the high-HBV-DNA group was shorter than that in the low-HBV-DNA group. Moreover, they reported that interferon could be effectively administered in a selected group of patients as a strategy for cancer prevention, even in those with cirrhosis. In addition, many reports have revealed that continuous treatment with lamivudine (LAM) delays clinical progression in patients with chronic hepatitis B and advanced fibrosis or cirrhosis, significantly reducing the incidence of hepatic decompensation and the risk of HCC[3,4].

These findings suggest that clinical efforts for viral eradication or reduction of viral load will reduce the risk of HCC in both HBV and HCV-related liver disease. However, in contrast to chronic hepatitis C, the carcinogenesis in chronic hepatitis B in many cases is not correlated with the severity of the fibrotic changes. These epidemiological results suggest that there may be differences in disease activity and mode of disease progression, as well as cancer development, between hepatitis B and hepatitis C viral infections.

HBV-related hepatocarcinogenesis is associated with viral DNA integration into the host genome. Suppression of inflammation and regeneration may reduce the opportunity for DNA integration and, hence, the risk of HCC, although this effect remains to be confirmed in clinical trials[5,6]. Most cases of late-phase recurrence are thought to be due to metachronous multicentric or *de novo* carcinogenesis.

HBV-related hepatocellular carcinogenesis appears to be caused by the hepatitis virus itself rather than the

inflammatory state characteristic of hepatitis. Persistent high HBV-DNA concentration may itself increase the risk of carcinogenesis. Furthermore, clinical and pathological differences exist between HBV genotypes B and C, and genotype C has a higher risk of HCC development than genotype B[7]. Genotype B-related HCC is less associated with liver cirrhosis and has a higher frequency of solitary tumor as well as more satellite nodules than genotype C-related HCC[7].

Sequential analysis of HBV-DNA is the key to assessing the risk of carcinogenesis. HCC develops in younger patients at a higher incidence and more rapidly due to HBV-DNA integration in the early stages of chronic infection.

Previous studies have reported that the incidence of HCC is higher in males than in females, and that the rate of progression of HBV infection is faster in males. As to HBV genotype, on the other hand, no Japanese HCC patients under 35 years in age had the B genotype (genotype Bj), which is different from the B genotype identified in Taiwan (genotype Ba): the genotype Bj is believed to give a relatively good prognosis[8].

Furthermore, HBV-related HCC often occurs in children, and HCC induced by chronic HBV infection also tends to occur much earlier in patients infected in childhood than that in those infected in adulthood.

CLINICAL CHARACTERISTICS OF HBV-RELATED HCC

HBV-related HCC occurs more often in younger patients with mild inflammation and fibrosis than in patients with HCV-related HCC. It has been reported in a domestic multicenter clinical study that liver function is relatively good in patients with HBV-related HCC and they are in disease stage I in many cases, and that the diagnostic age of HBV-related HCC is 52.1 years, while that of HCV-related HCC is 62.9 years, about 10 years later than in HBV-related HCC patients[9].

However, in many cases of HBV-related HCC, the tumor disease stage is advanced (stage Ⅲ/Ⅳ), presenting an undifferentiated cancer type with portal vein infiltration, suggesting that HBV-related HCC has a worse prognosis and a more refractory character than HCV-related HCC. Moreover, HBV-related HCC is infiltrative, showing multinodular growth, unlike HCV-related HCC[10-12].

HBV-related HCC is often accompanied by portal vein tumor thrombus (PVTT). In our study, HBsAg-positive cases were found in 70% of PVTT patients, while anti-HCV serology was positive in 30% of them. Although the prognosis was poor in most patients with HCC accompanied by PVTT, our combination chemotherapy is likely to be effective in achieving long-term survival and appears to exert anti-tumor activities with tolerable adverse effects in patients with advanced HCC accompanied by PVTT[13].

Although recurrence of HBV-related HCC occurs often within 3 years of hepatic resection, the rate of recurrence decreases thereafter. In addition, large tumors are found in many cases of HBV-related HCC, but there are few cases of multicentric recurrence, suggesting that hepatic resection should be the first-choice therapy in such cases[14].

On the other hand, multicentric recurrence occurs at a high incidence after resection in HCV-related HCC patients with impaired liver function, infrequently showing multicentric carcinogenesis at the time of resection in elderly patients, which is a characteristic of HCV-related HCC. Nagasue *et al*[15] reported that the 5-year disease-free survival rate was 58% in patients with HBV infection, whereas it was 6% in those with HCV infection ($P < 0.001$). Thus, major hepatectomy is recommended for treating HBV-related HCC without cirrhosis to prevent early recurrence.

Furthermore, Roayaie *et al*[16] have reported the 5-year disease-free survival rate to be significantly higher in HBV patients treated with resection than in patients with HCV (49% *vs* 7%, $P = 0.0480$). Depending on preoperative liver function and tumor location, a much higher proportion of patients with HBV-related HCC may become candidates for hepatic resection. There are significant differences in preoperative status, tumor characteristics and disease-free survival rate between HCC patients with chronic HBV infection and those with HCV infection whose liver disease has not yet reached the end stage.

In light of these points, curative treatments such as hepatectomy may become the first choice therapy of HBV-related HCC, since many large tumors are found and there are few cases of multicentric carcinogenesis, suggesting that systematic hepatectomy focusing on the morphological type of the portal vein branch may be desirable.

Hepatitis B status, tumor factors, and surgical type affected cancer recurrence after resection in patients with HCC related by concurrent chronic HBV infection, whereas only tumor factors affected recurrence in patients with HCC related by previous chronic HBV infection. Furthermore, Kubo *et al*[14] have reported viral status, defined by a high viral load, the presence of HBeAg, the absence of anti-HBe antibody, and the absence of precore mutant type HBV, as well as low platelet count and positive surgical margin, to be risk factors for recurrence after resection of HCC in HBsAg-positive patients.

In response to these findings, viral elimination has been suggested as a strategy for improving recovery from HBV-related HCC. This prompted Koike *et al*[17] to conduct a univariate analysis, in which they reported that degree of fibrosis, pathological grade of HCC, and serum AFP levels were significantly linked to intrahepatic recurrence. In their multivariate analysis, degree of fibrosis was the strongest factor in the recurrence of HCV-related HCC ($P = 0.004$). In contrast, degree of fibrosis did not influence the recurrence of HBV-related HCC ($P = 0.51$) or NBNC-related ($P = 0.77$) HCC. Risk factors for HCC recurrence varied according to the state of viral infection.

De novo carcinogenesis may be present not only in well-differentiated HCC, but also in less-differentiated HCC, especially in HBV-related HCC; and the carcinogenesis in HBV-related HCC may have different impacts from that in HCV-related HCC. The clinical conditions of hepatitis virus have an impact on the outcomes of resection of HBV-related HCC, making it necessary to position antiviral therapy for prevention of recurrence as one therapeutic option for treating HBV-related HCC.

ANTIVIRAL THERAPY OF HBV-RELATED HCC

Kubo *et al*[18] concluded that the prognosis after resection of HCC was worse in HBeAg-positive patients than in HBeAg-negative patients. Among patients who had undergone transarterial chemolipiodolization, high HBV viral load was the most important risk factor for post-treatment recurrence in cases of complete necrosis, irrespective of the locational pattern of recurrence. The current findings underscore the need for future studies to examine the applicability of antiviral therapy for reducing the risk of HCC recurrence[19].

Recently, LAM, a nucleoside analog that inhibits reverse transcriptase, has been developed. Long-term treatment with LAM has been found to inhibit HBV replication, attenuate hepatitis and improve histological findings of the liver. However, LAM therapy is not free from problems that require resolving, such as relapse of hepatitis as a consequence of the emergence of YMDD viral mutants. The effects of LAM on the therapeutic outcomes of HBV-related HCC patients have not been confirmed in randomized clinical trials (RCTs).

Kubo *et al*[20] have reported that LAM therapy improves the tumor-free survival rate after curative resection in HBV-related HCC patients showing a high serum concentration of HBV DNA, although careful follow-up was necessary for detection of YMDD viral mutants. Kuzuya *et al*[21] reported that there was no significant difference in cumulative recurrence rate of HCC between the LAM group and the control group ($P = 0.622$). However, the median Child-Pugh score at the time of HCC recurrence was significantly different, being 5 (range: 5-6) in the LAM group and 7 (range: 5-12) in the control group ($P = 0.005$).

LAM therapy may be beneficial in patients with HBV-related HCC after initial treatment, since the treatment may contribute to improvement in remnant liver function; therefore, LAM therapy may reduce the risk of liver failure and extend the therapeutic options available for treatment of recurrent HCC.

It is likely that other antiviral therapies such as interferon (IFN) treatment will be effective in HCV-related HCC[22].

Since the HBV-DNA level is a recurrence factor after transcatheter arterial chemoembolization (TACE) in patients with HBV-related HCC, IFN therapy may suppress recurrence and improve convalescence. IFN is believed to suppress tumor recurrence after treatment of HCC in patients with HBV-related cirrhosis, especially in the high-aspartate transaminase (AST) subgroup. In any case, the usability of the prescription of LAM in the following therapy should be reviewed from the viewpoint of versatility. It is expected that the usefulness of LAM will be verified by RCTs, although there is the potential issue of drug tolerance stock.

Therefore, it is likely that LAM will be replaced by entecavir (ETV), the appearance rate of tolerance stock of which is low, as a standard remedy in the future. In this context, it may be necessary to review anew the cancer-suppressive effects as well as the recurrence-suppressive effects of ETV. On the other hand, with respect to HBV-related HCC, IFN was assumed to suppress tumor recurrence after treatment of HCC in patients with HBV-related cirrhosis, especially in the high-AST subgroup[23].

It appears that IFN may suppress recurrence by reducing the viral level or by direct antitumor effects in both HBV-related HCC and HCV-related HCC. Recently, Sun *et al*[24] conducted an RCT, reporting that IFN therapy improved overall survival of patients with HBV-related HCC after curative resection, probably by delay in recurrence.

It will be necessary to review the significance of antiviral therapy in the future, focusing on whether antiviral drugs such as LAM, ETV and IFN can contribute to improved convalescence from HBV-related HCC[25]. Futhermore, LAM will most likely be replaced by tenofovir. Although ETV and pegylated interferon are the other 2 drugs recommended as first-line therapy for HBV, tenofovir remains the first choice. In the future, tenofovir may prove to be effective in preventing recurrence and further investigations involving more cases are needed.

CONCLUSION

Chronic HBV infection is the primary risk factor for the future development of HCC worldwide. Prevention of HBV-related HCC is accomplished by preventing HBV infection *via* HBV vaccination. Broad public health strategies should include routine testing to identify chronic HBV infection, improved health infrastructures including human resources to provide diagnosis and treatment assessment. For persons who are already chronically infected, development of more effective antiviral therapies that can result in sustained suppression of viral replication and hepatic necroinflammation may reduce the incidence of HCC. In the future, it will be necessary to review the significance of antiviral therapy to improve convalescence from HBV-related HCC.

Abstract

Hepatitis B virus (HBV)-related liver disease is the leading indication for liver transplantation (LT) in Asia, especially in China. With the introduction of hepatitis B immunoglobulin (HBIG) and oral antiviral drugs, the recurrent HBV infection rate after LT has been evidently reduced. However, complete eradication of recurrent HBV infection after LT is almost impossible. Recurrent graft infection may lead to rapid disease progression and is a frequent cause of death within the first year after LT. At present, the availability of new oral medications, especially nucleoside or nucleotide analogues such as adefovir dipivoxil, entecavir and tenofovir disoproxil fumarate, further strengthens our ability to treat recurrent HBV infection after LT. Moreover, since combined treatment with HBIG and antiviral agents after liver re-transplantation may play an important role in improving the prognosis of recurrent HBV infection, irreversible graft dysfunction secondary to recurrent HBV infection in spite of oral medications should no longer be considered an absolute contraindication for liver re-transplantation. Published reviews focusing on the therapeutic strategies for recurrent HBV infection after LT are very limited. In this article, the current therapeutic strategies for recurrent HBV infection after LT and evolving new trends are reviewed to guide clinical doctors to choose an optimal treatment plan in different clinical settings.

INTRODUCTION

Hepatitis B virus (HBV)-related liver disease accounts for approximately 5%-10% of all liver diseases after liver transplantations (LT) performed each year in the United States and is the leading indication for LT in Asia[1,2]. It was reported that the recurrent HBV infection rate after LT is as high as 80%-100% without any prophylaxis[3,4]. The recurrent HBV infection rate has been decreased from 90% to approximately 30%-40% since the introduction of hepatitis B immunoglobulin (HBIG)[5,6]. With the advances in oral antiviral drugs, combined treatment with HBIG and lamivudine (LAM), recommended by many centers, has achieved encouraging outcomes, with the recurrent HBV infection rate reduced to less than 10% during a follow-up period of 1-2 years[7-11].

However, combined treatment with HBIG and LAM cannot control recurrent HBV infection. Recurrent graft infection may lead to rapid disease progression and is a frequent cause of death within the first year after LT[12].

Furthermore, the incidence of acquiring *de novo* HBV infection after LT in patients who are negative for hepatitis B surface antigen (HBsAg) is 1.7%-3.5%, and patients with *de novo* HBV infection are also at a risk for severe progressive liver injury[13-15]. The aggressive clinical course is probably due to stimulation of viral replication and direct cytotoxicity of HBV under immunosuppressive therapy. Therefore, suppression of HBV replication is paramount to prevent disease progression in the transplanted liver.

Unfortunately, almost all published reviews focusing on the prophylactic strategies against recurrent HBV infection after LT, have drawn less prominence to the treatment of recurrent HBV infection in recipients after LT. Published reviews, focusing on the therapeutic strategies against recurrent HBV infection after LT, are very limited, and almost all of them are already nearly obsolete. In the following, the current therapeutic strategies for recurrent HBV infection after LT and evolving new trends are reviewed.

INTERFERON

In the pre-LAM era, interferon α is a common therapeutic option for patients with recurrent HBV infection after LT. However, with the advent of LAM, it has not been used as a first-line treatment drug. Patients using interferon α have a lower efficacy and a higher risk of precipitating allograft rejection than those using LAM[16,17]. Furthermore, treatment of recurrent HBV infection after LT with interferon α can lead to side effects such as neutropenia.

LAM

LAM can potentially inhibit HBV replication by competitively suppressing the reverse transcriptase and termination of proviral DNA chain extension, and has been used in treatment of recurrent HBV infection, with an excellent safety profile in both compensated and decompensated cirrhotic patients. The use of LAM in treatment of recurrent HBV infection after LT has shown promising results as is shown in a multicenter North American study on 52 patients with chronic hepatitis B after LT, demonstrating that use of LAM for 52 wk can result in loss of serum HBV DNA in 60%, undetectable hepatitis B e antigen (HBeAg) in 31%, undetectable HBsAg in 6%, normalization of serum alanine transaminase (ALT) levels in 71% of patients, respectively[18]. The results from other studies[19-27] are summarized in Table 1, showing that LAM can suppress HBV DNA to undetectable levels in 32.5%-100%, anti-HBeAg seroconversion in 4.2%-100%, and anti-HBsAg seroconversion in 0%-83.3% of patients, respectively, after 4.6-36 mo of treatment. Notably, use of LAM in treatment of *de novo* HBV infection or acute recurrent HBV infection of the graft after LT tends to effectively suppress HBV DNA, and converse serum anti-HBeAg and anti-HBsAg.

However, the major factor limiting the use of LAM in treatment of graft HBV infection after LT is the development of mutations in thyrosine-methionine-aspartate-aspartate (YMDD) motif of the HBV DNA polymerase gene, which confers resistance to LAM. In non-immunosuppressed patients, the LAM resistance rate is 15%-20%[28]. LAM resistance can be detected in 45% of immunosuppressed patients within the first year of treatment[29,30]. It has been reported that YMDD mutation occurs in 26.9%, 27.3%, 29.4% and 62.5% of patients with recurrent HBV infection[18,20,22,24] after 12, 15, 21 and 36 mo of treatment with LAM, respectively. It has also been reported that YMDD mutation occurs in patients with *de novo* HBV infection after LT, in 0%, 0% and 14.3% of patients with recurrent HBV infection[19,21,27] after 4.6, 11 and 24.5 mo of treatment with LAM, respectively. One possible explanation for it is the short-term use of LAM in patients with *de novo* HBV infection and low HBV-DNA levels at the acute phase of *de novo* HBV reactivation.

Available data from the literature regarding the outcomes secondary to YMDD mutation are controversial. Perrillo *et al*[18] reported that the YMDD mutant virus is not consistently associated with hepatic disease progression, whereas elevated serum ALT can be frequently observed at the time when serum HBV DNA becomes detectable again, and the mean ALT values after breakthrough often remain below the pretreatment values. However, McCaughan *et al*[31] reported that patients infected with procure mutant strains of HBV develop drug resistance or liver failure after 11 mo of rescue therapy with LAM. Mutimer *et al*[32] also demonstrated that LAM-resistant phenotype can cause severe graft damage. Hence, long-term, randomized, blinded, and controlled clinical trials are needed to further observe the clinical outcomes following LAM resistance.

In summary, LAM therapy results in not only a loss of viral replication markers in serum and an improved hepatic biochemical profile, but also improvement or stabilization in liver histology. However, LAM resistance and its possible accompanying clinical deterioration have limited its long-term use in treatment of recurrent HBV infection after LT.

Adefovir dipivoxil

Adefovir dipivoxil (ADV), a nucleotide analog that selectively inhibits viral polymerases and reverse transcriptase, is effective against both negative and positive HBeAg[33-36]. Furthermore, it has been shown that ADV has an excellent activity against wild-type as well as LAM-resistant HBV strains[37-41], suggesting that ADV contributes to the development of LAM-resistant mutants and *de novo* LAM-resistant HBV infection after LT. Schiff *et al*[42] in a landmark multicenter study showed that PCR DNA levels are decreased with a 1-year survival rate of 93%, undetectable serum HBV DNA, normal serum ALT, albumin, bilirubin and prothrombin time in 34%, 49%, 76%, 75% and 20% of patients, respectively, after 24 and 48 wk of treatment with ADV. Four years later, Schiff *et al*[43] further showed that the serum HBV DNA

[1]LAM was changed to ADV in 5 patients and ADV was added to LAM in the other 2 patients. ADV: Adefovir dipivoxil.

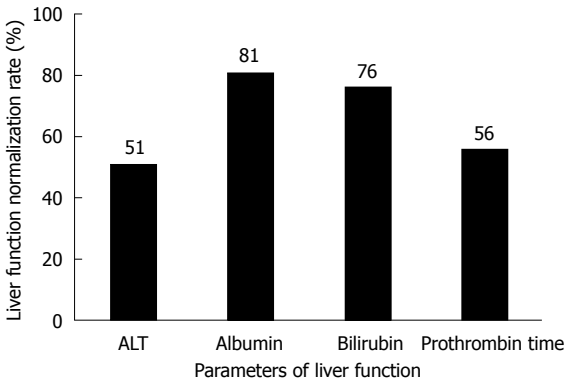

Figure 1 Alanine transaminase (ALT), albumin and bilirubin levels and prothrombin time 48 wk after adefovir dipivoxil treatment[43].

levels are undetectable in 40%, 65% and 78% of patients with recurrent HBV infection and LAM resistance 48, 96 and 114 wk after ADV treatment (10 mg, once a day), respectively, as well as loss or seroconversion of HBeAg in 31% and 11% of patients by week 48, and in 58% and 34% of patients by week 96. Liver function and other parameters after treatment with ADV are shown in Figure 1. Other studies[44-48] are summarized in Table 2. Toniutto *et al*[38] reported that ADV plus LAM can achieve favorable outcomes of HBsAg seroconversion and undetectable HBV DNA in patients with *de novo* graft HBV infection and LAM resistance.

Mildly elevated serum creatinine level may occur after treatment with ADV, especially with calcineurin inhibitors, but only a small number of patients require dose adjustment, and even discontinuance. However, renal function should be regularly monitored, with dose adjustments based on renal function, as necessary.

In short, ADV is a safe and effective treatment option for recurrent HBV infection, especially as a salvage treatment for recurrent HBV infection due to LAM resistance.

Entecavir

Entecavir (ETV), a very potent anti-HBV selective guanosine analogue, approved by the US FDA in 2005, can be used in treatment of chronic HBV infection. Unfortunately, few reports are available on ETV in treatment of recurrent HBV infection. Most data concerning its efficacy and safety are obtained from patients with no LT. It was reported that 0.5 mg of ETV or 100 mg of LAM, once daily for 48 wk, can improve the histology

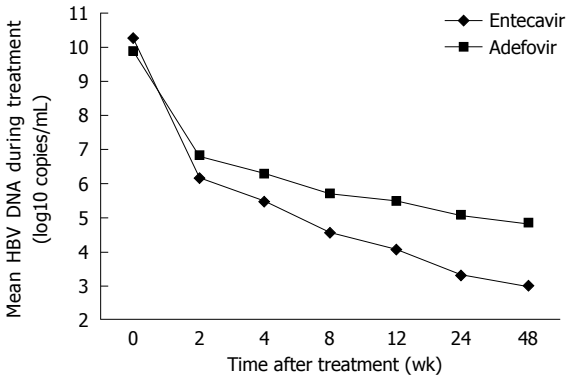

Figure 2 Mean serum hepatitis B virus (HBV) DNA level in patients after entecavir (ETV) and adefovir (ADV) treatment[53].

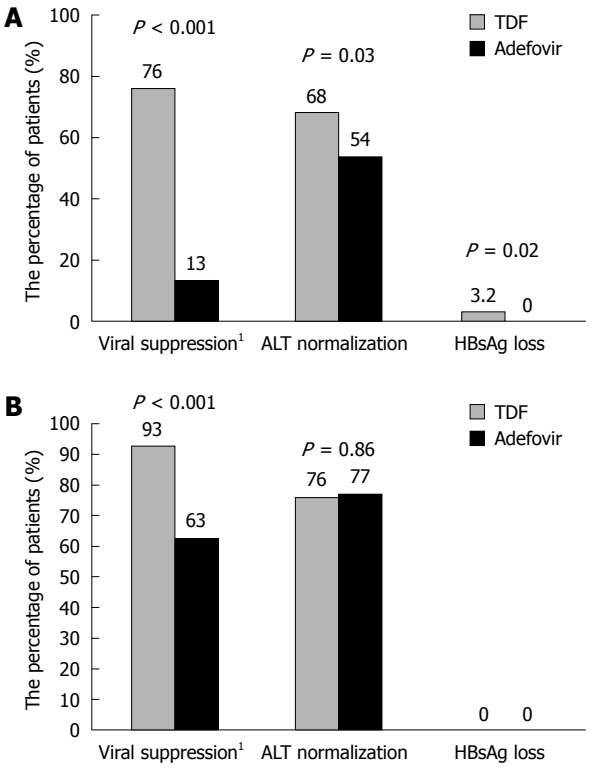

Figure 3 Viral suppression, ALT normalization and hepatitis B surface antigen (HBsAg) loss in hepatitis B e antigen (HBeAg)-positive (A) and HBeAg-negative (B) patients after tenofovir disoproxil fumarate (TDF) and adefovir treatment[61]. [1]HBV DNA level of less than 400 copies/mL.

in 72% and 62% of patients, respectively, with serum HBV DNA undetectable in 67% and 36% of patients, respectively, and normal ALT in 68% and 60% of patients, respectively, and no evidence of viral resistance to ETV[49]. It has been shown that 0.5 mg of ETV or 100 mg of LAM, once daily for 48 wk, can also achieve favorable outcomes in patients with nucleoside-naive HBeAg-negative chronic hepatitis B[50], suggesting that the histologic, virologic and biochemical improvement rates are significantly higher after ETV treatment than after LAM treatment, in patients with nucleoside-naive HBeAg-positive or -negative chronic hepatitis B, with no evidence of viral resistance to ETV, which is consistent with the findings in other studies[51-53]. The mean decrease in serum HBV DNA after 2, 4, 8, 12, 24 and 48 wk of ETV and ADV treatment in patients is shown in Figure 2. A recent study demonstrated that ETV therapy is safe and efficient for recipients with ADV-resistant HBV infection[54].

ETV resistance is associated with the LAM-resistance substitutions M204V/I and L180M in combination with an additional substitution at residues T184, S202 or M250 in the reverse-transcriptase region of HBV polymerase[55]. In other words, ETV is associated with a high genetic barrier to resistance requiring multiple mutations for resistance development. In nucleoside-naïve patients, the probability of developing resistance to ETV remains consistently low (< 1.2%) even after 96 wk of treatment[56]. By contrast, ETV gives rise to ETV-resistant mutants in patients with LAM resistance. The rate of ETV resistance in LAM-resistant patients 4 years after treatment of may reach 35%[57], which is due to a particular selection mode of ETV strains that follows a 2-step process, with the selection of primary resistance mutations at position M204V/I (which are also resistant to LAM) followed by the addition of secondary resistance mutations on the same viral genomes[58]. Once these secondary substitutions occur, high-level resistance to ETV occurs. Therefore, the high probability of resistance to long-term ETV in LAM resistant patients with no LT suggests that ETV is not a good choice for LAM-resistant patients after LT, although ETV has been tried in some LAM resistant patients after LT[54]. However, ETV can be used in non-LAM resistant patients, due to its great potency, high genetic barrier and absence of nephrotoxicity. More data are urgently needed to confirm the safety and efficacy of ETV after LT.

Tenofovir disoproxil fumarate

Tenofovir disoproxil fumarate (TDF), a nucleotide analogue, inhibits viral polymerases by direct binding to DNA or by terminating the DNA chain due to the absence of a requisite 3' hydroxyl on the tenofovir molecule[59]. In 2001, TDF was licensed for HIV therapy as a potent inhibitor of HIV replication. Subsequently, it has been proved to be a potent and selective anti-HBV agent *in vitro*[60]. Several clinical studies have currently confirmed the efficacy of TDF in suppressing HBV replication. Marcellin *et al*[61] showed that the antiviral efficacy of TDF is higher than that of ADV with no resistance mutation in patients with HBeAg-negative or HBeAg-positive chronic HBV infection. Detail data regarding viral suppression, liver function improvement, and serologic response are shown in Figure 3. It has been shown that TDF has an excellent antiviral activity against both wild-type and LAM-resistant HBV both *in vitro* and *in vivo*[62,63]. Furthermore, TDF shows a stronger antiviral effect than ADV on LAM-resistant HBV[64,65]. Hann *et al*[66] reported that the mean level of HBV DNA is 1.5 ± 1.0 log10 copies/mL and 4.3 ± 2.2 log10 copies/mL, respectively, in patients with LAM

resistance after treatment with TDF and ADV. A recent study demonstrated that TDF plus LAM can safely and markedly suppress HBV replication in patients with or without resistance to ADV[67].

The daily TDF dose (300 mg) has been approved as a standard dose for controlling HBV infection. To reduce the cost of therapy, a low TDF dose (75 mg) can be used to control HBV viremia in patients with chronic HBeAg-negative hepatitis B, which can more effectively inhibit HBV replication than ADV at the standard dose[68]. However, further studies are needed to determine its efficacy and safety in a larger number of HBeAg-positive subjects.

Only 2 reports are available on TDF-related mutations conferring resistance to TDF[69,70]. Transfection experiments showed that rtA194T mutation alone can result in a 7.6-fold decrease in susceptibility to TDF, but rtA194T mutation in combination with ADV-resistant mutations can lead to a more than 10-fold decrease in susceptibility to TDF[70]. However, TDF susceptibility to rtA194T mutation is not consistent with its clinical significance. Since 2005, ADV-resistance mutations (rtN236T, rtA194T, rtA181V) have not caused a significant change in TDF susceptibility[71,72]. Only one study is available on the application of TDF in treatment of recurrent HBV infection after LT[73]. Although TDF can significantly decrease LAM-resistant HBV variant replication after LT, further studies are needed to determine its efficacy and safety profile with a long follow-up time and a large cohort of patients.

RETRANSPLANTATION

With the advent of new antiviral drugs such as ADV, ETV and TDF, satisfactory outcomes can be achieved in patients with recurrent HBV infection by suppressing viral replication. However, some patients with irreversible graft dysfunction secondary to recurrent HBV infection still need a second LT to replace the primary graft[74,75]. To date, second LT accounts for 5%-22% of all LTs in adults[76]. Samuel *et al*[77] reported that recurrent graft HBV infection is the direct cause of death in patients with hepatitis B after a second LT. Crippin *et al*[78] showed that the mortality rate of patients with recurrent HBV infection is 95% after a second LT, which is consistent with the findings in other studies[12,79-81].

Ishitani *et al*[82] showed that long-term HBIG therapy can continuously maintain a serum anti-HBs level > 500 IU/L and prevent recurrent HBV infection in 86% of patients after a second LT. Roche *et al*[80] reported that prophylactic intravenous ganciclovir can maintain an anti-HBs titre greater than 500 IU/L, with a satisfactory prognosis of all patients after a second LT. Lo *et al*[83] demonstrated that combined injection of ADV, LAM and HBIG can maintain an anti-HBs titre greater than 100 IU/L in patients with LAM-resistant HBV mutants after a second LT.

In summary, recurrent HBV infection after a primary LT should no longer be considered an absolute contraindication for a second LT. Combined HBIG and antiviral agents may play an important role in improving the prognosis of patients with recurrent HBV infection after a second LT. Further randomized study is needed to definitely confirm it.

Table 3 Summary of recommended therapeutic strategies for recurrent HBV infection after LT

Clinical setting	Recommended first line therapies	Recommended second line therapies
De novo HBV infection, wild-type HBV infection	LAM for short-term therapy; ADV for long-term therapy	ETV, TDF
LAM resistance	ADV, ADV + LAM	TDF
ADV resistance	ETV	TDF + LAM
Irreversible graft dysfunction	SLT	

ETV: Entecavir; TDF: Tenofovir disoproxil fumarate; SLT: Second liver transplantation.

CONCLUSION

The emergence of new oral medications, especially nucleoside or nucleotide analogues such as ADV, ETV and TDF, further increases our ability to treat recurrent HBV infection after LT. By recognizing the efficacies and features of such drugs, various therapeutic strategies, according to different clinical settings, have been recommended to control the recurrent graft infection after LT (Table 3). For the *de novo* or wild-type HBV infection after LT, long-term use of LAM is limited by the high risk of developing mutations in YMDD motif. Hence, ADV is the first choice in this setting, if needing long-term administration. For the LAM-resistant HBV infection after LT, ADV, administered in combination with LAM or as a monotherapy, appears to be safe and effective in this setting. Theoretically, "add therapy" may minimize the risk of resistance, but needs long-term, randomized, blinded, controlled clinical trials to further confirm it. In addition, ETV is not a good choice for LAM-resistant patients after LT because of its high probability of resistance in patients with LAM resistance without LT. ETV therapy for ADV-resistant HBV infection after LT is safe and efficient in this setting. Additionally, combined TDF and LAM therapy may be an alternative approach based on its favorable therapeutic effects in patients without LT. However, no or few data are available on the efficacy of ETV and TDF in patients after LT. Further clinical trials are needed to evaluate their efficacy and safety in this special setting. Second LT is the only rescue procedure for patients with irreversible graft dysfunction secondary to recurrent HBV infection. Since combined HBIG and antiviral agents may play an important role in improving the prognosis of patients with recurrent HBV infection after LT, recurrent HBV infection after a primary LT should no longer be considered an absolute contraindication for a second LT.

Abstract

AIM: To analyze α-methylacyl CoA racemase (AMACR) expression in relation to various dysplasia phenotypes and clinicopathological parameters of sporadic colorectal adenomas.

METHODS: Fifty-five cases of sporadic colorectal adenomas were categorized according to the Vienna classification for Gastrointestinal Neoplasia. These corresponded to a total of 98 different intra-lesion microscopic fields that were further independently assigned a histological grade based on the old nomenclature (mild, moderate, severe dyplasia and carcinoma *in situ*). AMACR expression was evaluated by immunohistochemistry and statistical analysis was performed to investigate possible associations with various clinicopathologic parameters of adenomas i.e. gender, age, localization, grade of dysplasia, size and configuration.

RESULTS: Patient age ranged from 41 to 84 years (mean 65 ± 13.2 years); 37 patients were males and 18 were females. Adenomas ranged in size between 0.5 and 30 cm (mean 2 ± 1.3 cm), including 18 tubular, 16 villous, 20 mixed or tubulovillous, and 1 giant sessile villous adenoma. AMACR expression was observed in 3 out of 16 (18.8%) of low-grade *vs* 23 out of 35 (62.8%) of high-grade lesions (P = 0.002). Most adenomas exhibiting high grade dysplasia with *in situ* carcinoma-like areas stained positive for AMACR (15/17 or 88.2%) as compared to adenomas with high grade dysplasia which contained severe dysplasia-like foci (6/15 or 40%), (P = 0.005). In AMACR positive adenomas featuring severe dysplasia-like or *in situ* carcinoma-like areas, AMACR staining was not necessarily observed in the *in situ* component. Positivity in intra-lesion of mild, moderate or severe dysplasia-like foci was more often encountered in adenomas harboring *in situ*, intramucosal or infiltrative carcinoma [21/33 (63.6%) *vs* 9/40 (22.5%), P < 0.001]. Strong AMACR expression was found in 11 out of 17 villous adenomas, but in only 1 out of 18 tubular lesions (P = 0.005). Larger lesions, i.e. > 1 cm stained more frequently for AMACR than smaller ones [27/45 (60%) *vs* 2/10 (20%), P = 0.02]. Overall, AMACR expression was associated with the grade of dysplasia, as well as with the size and configuration of adenomas, i.e. the consensus risk factors applied to colorectal adenoma patient surveillance.

CONCLUSION: It may be worthy to further evaluate the possible use of AMACR as an additional risk factor for the assessment of colorectal adenoma patients.

INTRODUCTION

α-methylacyl CoA racemase (AMACR) is a mitochondrial and peroxisomal enzyme implicated in the degradation of branched chained fatty acids and fatty acid derivatives. Conversion of several (2R)-methyl-branched-chain fatty acyl-coenzyme-A esters to their (S)-stereoisomeres, which is catalyzed by AMACR, is necessary for the completion of the β-oxidation pathway[1-3]. AMACR is expressed in a variety of tumors and precancerous conditions[4-6], with prostate cancer being the one most extensively investigated[7,8]. Various studies have analyzed AMACR expression in adenocarcinoma of the colon, where it is thought to be associated with tumor differentiation and localization[9-14]. Recently, much attention has been given to the expression of this biomarker in preneoplastic conditions arising in the gastrointestinal tract. It has been suggested that AMACR could be used as an adjunct in the characterization of dysplasia in Crohn's disease, ulcerative colitis and Barrett's esophagous[15-17]. In spite of all this promising data, there is still limited information regarding AMACR expression in relation to clinicopathologic parameters as well as to various dysplasia phenotypes in sporadic colorectal adenomas[5,6,10,11,17]. In the paper by Went *et al*[5], no significant differences were found between mild, moderate and severe dysplasia. On the contrary, Strater *et al*[17] found moderate to strong AMACR expression in 73% of high-grade cases but only in 37% of low-grade lesions. However, the results of these studies appear contradictory; in addition, given the degree of interobserver variability in regard to dysplasia classification, interpretation of these findings is hindered by the absence of criteria upon which dysplasia of adenomas was categorized[5,17]. Current guidelines on the classification of dysplasia in sporadic adenomas of the colorectum, namely those published by the American College of Gastroenterology and included in the Vienna classification of Gastrointestinal Neoplasia, strongly discourage the use of terms such as carcinoma *in situ*/intramucosal carcinoma due to, among other reasons, concerns for misinterpretation of their clinical significance that might lead to overtreatment[18-23]. Nonetheless, albeit prone to interobserver variability, specific cytoarchitectural features, including mild, moderate, severe and carcinoma *in situ* changes, do correspond to the biologic progression of dysplasia[20,23]. The goal of our study was to analyze the immunohistochemical expression of AMACR in various histologic patterns of dysplasia in sporadic colorectal adenomas in the frame of clinically oriented current classification schemes.

MATERIALS AND METHODS

Case selection

Fifty-five cases of colorectal adenomas including 4 adenomatous polyps having undergone malignant transformation with submucosal invasion were retrieved from the surgical pathology archives at "Georgios Gennimatas" General Community Hospital from 2005 to 2009. All 55 cases came from individual patients. Out of these, 51 were endoscopically or surgically removed adenomatous polyps and 4 were incidental findings in patients who had undergone colectomy for adenocarcinoma of the colorectum. Clinical data were reviewed to ensure that all cases were indeed sporadic adenomas. Hyperplastic polyps and serrated adenomas were not included in this study based on evidence of their distinguishing biology[24-26]. Hematoxylin-eosin (HE) stained slides were reviewed by two different pathologists in a blinded manner. For diagnostic purposes, each case was characterized by the highest grade of dysplasia present, according to the modified Vienna classification of Gastrointestinal Neoplasia using both the main categories (classical Western classification) as well as the subdivisions of group 4 (high-grade dysplasia)[19,21]. In addition, when more than one dysplastic pattern was histologically recognized on the same slide, these were given a separate grade of dysplasia corresponding to the presumably different biologic potentials and based upon previously reported pathologic criteria[20,27]. In this context terminology was based on the old nomenclature (mild, moderate, severe dysplasia, carcinoma *in situ* and intramucosal carcinoma). Interobserver disagreement on the interpretation of histology was present in 5 cases and a consensus diagnosis was reached at a multi-headed microscope. Size, architectural configuration and localization of lesions were also recorded. Normal appearing non-neoplastic intestinal mucosa was present in 29 cases.

Immunohistochemistry

One 4 micron formalin-fixed, paraffin-embedded tissue section including the highest grade of dysplasia was selected for each case. Prostate cancer sections were used as a positive control. Immunohistochemistry was carried out on a Bond Automated Immunostainer using the Bond Polymer Define Detection Kit (Cat. No. DS9713). Briefly, sections were deparaffinized, rehydrated and treated with 3% H_2O_2 to block endogenous peroxidase activity. Antigen retrieval was performed at 100℃/pH 6 for 30 min. After incubation with the primary polyclonal antibody to AMACR (P504S) (Biocare Medical, Concord, USA) at 1:30 dilution for 30 min, sections were further incubated with a secondary Polymer Poly-HRP anti-mouse/rabbit IgG. 3,3'-diaminobenzidine was used

Table 1 Incidence of various dysplasia histological phenotypes *n* (%)

Clinically oriented	Biologic potential	Total cases	Subgroups
Low grade dysplasia	Mild	16 (29.1)	6 (10.9)
	Moderate		10 (18.2)
High grade dysplasia	Severe	35 (63.6)	15 (27.3)
	In situ carcinoma		17 (30.9)
	Intramucosal carcinoma		3 (5.5)
Infiltrative carcinoma	Submucosal carcinoma	4 (7.3)	

as a substrate for visualization. Finally, slides were counterstained with hematoxylin.

Interpretation

A lesion was considered negative when less than 5% of cells showed immunoreactivity. Positivity was divided into weak (mild, cytoplasmic granular staining) and strong (diffuse, intense cytoplasmic staining). Intra-lesion areas with different grades of dysplasia were evaluated separately, but case-specific intensity was based on the interpretation of immunostaining in the most intense focus, independently of the corresponding dysplastic grade. For example, adenomas containing strongly positive severe dysplasia and negative carcinoma *in situ* foci were considered positive (case 52 in Figure 1A).

Statistical analysis

Statistical analysis was performed using the SPSS software v.17. A P value of < 0.05 was considered statistically significant as determined by the Mann-Whitney test for two independent samples.

RESULTS

Clinicopathological features of colorectal adenomas

Patient age ranged from 41 to 84 years (mean 65 ± 13.2 years); 37 patients were males and 18 were females. Adenomas ranged in size between 0.5 and 30 cm (mean 2 ± 1.3 cm, whereby the largest lesion corresponded to a giant sessile, villous adenoma), including 18 tubular, 17 villous (containing a villous component > 75%), 20 mixed or tubulovillous (containing a villous component > 25%, but < 75%). The majority were retrieved from the left colon with only 7 cases being located in the proximal 2/3 of the transverse colon. The incidence of dysplastic lesions based on the Vienna classification is summarized in Table 1. The well established interrelations between size, histological configuration of colorectal adenomas and grade of dysplasia[28] were reproduced by our data. High grade dysplasia was assigned to 33 out of 41 adenomas greater than 1 cm and 30 out of 34 containing a villous component. In contrast the majority of smaller (7/10) or tubular lesions (12/17) were low grade adenomas. ($P = 0.004$ and $P < 0.001$, respectively). Similarly, lesions ⩾ 1 cm were more likely to contain villous features [31/41 (75.6%) *vs* 3/10 (30%), $P = 0.007$]. Not surprisingly the 3 out of 4 high grade polyps showing evidence of submucosal invasion were villous adenomas and all 4 measured more than 1 cm.

Table 2 AMACR expression in sporadic colorectal adenomas *n* (%)

Vienna classification of GI neoplasia	Biologic potential	Staining				
		Negative	Weak	Strong	Subtotal positive	Total
Low grade ($n = 16$)	Mild moderate	13 (81.3)	3 (18.8)	0 (0)	3 (18.8)	16
High grade ($n = 35$)	Severe	9 (60)	6 (40)	0 (0)	6 (40)	15
	In situ carcinoma	2 (11.8)	3 (17.6)	12 (70.6)[1]	15 (88.2)	17
	Intramucosal carcinoma	1	0	2	2	3
Infiltrative carcinoma ($n = 4$)	Submucosal carcinoma	1	1	2	3	4
		26 (47.3)	13 (23.7)	16 (29)	29 (52.7)	55

[1]In 3 cases (#48, 49, 52 in Figure 1A) higher grade focus and focus of most intense staining did not match, as described in Materials and Methods, Interpretation. AMACR: α-methylacyl CoA racemase; GI: Gastrointestinal.

Immunohistochemical findings

The results of immunohistochemistry are summarized in Table 2 and Figure 1A. AMACR was positive in 29 adenomas (52.7%), and in all 4 adenocarcinomas, but was consistently negative in nonneoplastic intestinal mucosa in all 29 cases where normal appearing colonic epithelium was included in the section. Immunopositivity was strongly related to the grade of dysplasia independent of staining intensity (Figure 1A-C). Twenty-three out of 35 high grade but only 3/16 low grade lesions showed immunopositivity for AMACR ($P = 0.002$). Moreover, when staining was compared among adenomas containing only severe dysplasia-like areas and those with carcinoma *in situ*-like morphology, the latter group was more often positive [6/15 (40%) *vs* 15/17 (88.2%), $P = 0.005$] (Figure 1B and C).

As shown in Figure 1A, with the exception of 3 cases (#48, 49, 52), the most intense AMACR staining was observed in areas with the highest degree of dysplasia. On the contrary, no significant difference in staining intensity was observed between adenomas with mild to moderate dysplasia *vs* adenomas with severe dysplasia (3/16 *vs* 6/15, $P = 0.2$). AMACR immunostaining was also found to be associated with size and configuration of adenomas. Adenomas with a villous component (villous or tubulovillous) were more often positive for AMACR [22/37 (59.5%) *vs* 7/18 (37.5%), $P = 0.03$] and the same applied to lesions measuring ⩾ 1 cm in greatest diameter [27/45 (60%) *vs* 2/10 (20%), $P = 0.02$]. Moreover, as shown in Table 3, strong expression was found in more than half of villous adenomas (11/17), but in only 1 tubular lesion ($P = 0.005$).

When areas with different degrees of dysplasia (and, hence, putative different biologic potential) within the same lesion were separately evaluated for AMACR expression ($n = 98$), positive staining in intra-lesion mild,

Table 3 AMACR expression in relation to pathological features of adenomas *n* (%)

	n	Staining			
		Negative	Weak	Strong	Total positivity
Configuration	55				
Tubular	18	11 (61)	6 (33)	1 (6)	7 (39)
Villous	17	5 (29.4)	1 (5.9)	11 (64.7)	12 (76.5)
Tubulovillous	20	10 (50)	6 (30)	4 (20)	10 (50)
Size	55				
< 1 cm	10	8 (80)	1 (10)	1 (10)	2 (20)
⩾ 1 cm	45	18 (40)	12 (26.7)	15 (33.3)	27 (60)

Table 4 AMACR staining in areas with mild/moderate or severe dysplasia *n* (%)

Higher grade component	Staining			
	Negative	Weak	Strong	Total positivity
Present (*n* = 33)	12 (36.4)	11 (33.3)	10 (30.3)	21 (63.6)
Absent (*n* = 40)	31 (77.5)	9 (22.5)	0 (0)	9 (22.5)

moderate or severe dysplasia-like foci was more frequently encountered in adenomas also harboring a higher grade focus, i.e. *in situ*, intramucosal or infiltrative carcinoma, [21/33 (63.6%) *vs* 9/40 (22.5%), $P < 0.001$], (Table 4 and Figure 1A). Interestingly strong AMACR expression in 9 foci with severe dysplasia and in 1 focus with mild/moderate dysplasia was restricted in adenomas exhibiting intra-lesion cytological and architectural features of a higher grade component in another field (Figure 1A, cases # 43, 47-53, 55). This intra-lesion heterogeneity of AMACR expression is exemplified in Figure 2.

However, when considering severe dysplasia-like and *in situ* carcinoma-like foci as individual cases (that is, not taking into account their occurrence within the same or in different lesions), we did not observe significant differences in AMACR expression ($P = 0.06$). Similarly, no association was found between AMACR expression and either age, gender or localization of adenomas (data not shown).

DISCUSSION

Colonic adenomas are considered adenocarcinoma precursors[29]. Even though this might not be entirely endorsed[30], the predictive value of high grade dysplasia for the subsequent development of advanced adenomas and cancer is well documented and indisputable[31-34]. In this setting, it is widely accepted that severe dysplasia and carcinoma *in situ* bear a similar clinical significance and are therefore merged into a single category in most classification/reporting protocols. Molecular studies have shown an increased frequency of genetic alterations and DNA aneuploidy with increasing grade of dysplasia as assigned by the Vienna classification[35]. Following a detailed evaluation of the examined dysplastic lesions and taking into account intra-lesion heterogeneity, our study is the first one to report a positive association between AMACR and increasing grade of dysplasia in sporadic colorectal adenomas at the immunohistochemical level.

The observed overall prevalence of AMACR expression in colorectal adenomas in our study (52.7%) appears to be somewhat lower than in previous publications (64%-91%)[5,6,10,11,17]. It was difficult to compare our findings with the ones presented in these studies, in which the applied criteria for the classification of dysplasia were not provided. In the two studies that, to our knowledge, evaluated AMACR expression in relation to dysplasia, results did not significantly differ between low and high grade adenomas[17] or among adenomas with mild, moderate or severe dysplasia[5]. The above discrepancies can be attributed to the different antibodies used in each case and also to the different evaluation criteria set for immunopositivity, such as lower thresholds. These differences are further reflected in the reported positivity of normal colonic epithelia[5,11,14,17], which was not observed in our series.

It was previously suggested that AMACR expression might be closely related to the early stages of neoplastic progression in the colon[10]. The estimated prevalence of AMACR in adenomas bearing *in situ* carcinoma cytoarchitectural features in our study (88.2%) is similar to that reported for colorectal carcinoma in the majority of publications (62%-83%)[5,9-12]. In comparison, we observed AMACR positivity in only 40% of severely dysplastic and 18.8% of low grade lesions. These findings might suggest a more advanced state towards malignancy of *in situ* carcinoma as compared to severe dysplasia, although both lesions are currently incorporated into the high grade category for management reasons.

The differences observed between lesions exhibiting morphological changes corresponding to the previously used terms of severe dysplasia and *in situ* carcinoma at the molecular level prompt for morphologically identifying these lesions at least for research purposes[20,21]. Of note, however, co-existing severely dysplastic and *in situ* carcinoma areas in the same lesion did not significantly differ in terms of AMACR expression. AMACR expression seemed to be related to the co-existence of *in situ* carcinoma rather than to *in situ* carcinoma itself, since it was present in severely dysplastic areas in the vicinity of negative *in situ* carcinomas. Severe dysplasia-like morphology does not differ in the simultaneous presence or absence of adjacent *in situ* carcinoma. However, the same morphologic features might bear significant differences at the molecular level that seem to be more prominent in later stages of the dysplasia-carcinoma sequence.

Another implication of the above described intra-lesion AMACR heterogeneity is that, when examining the expression of AMACR and possibly other markers in adenomas on tissue microarrays, multiple areas should be sampled for adequate evaluation of the lesion.

Taken together, our data indicate that AMACR may

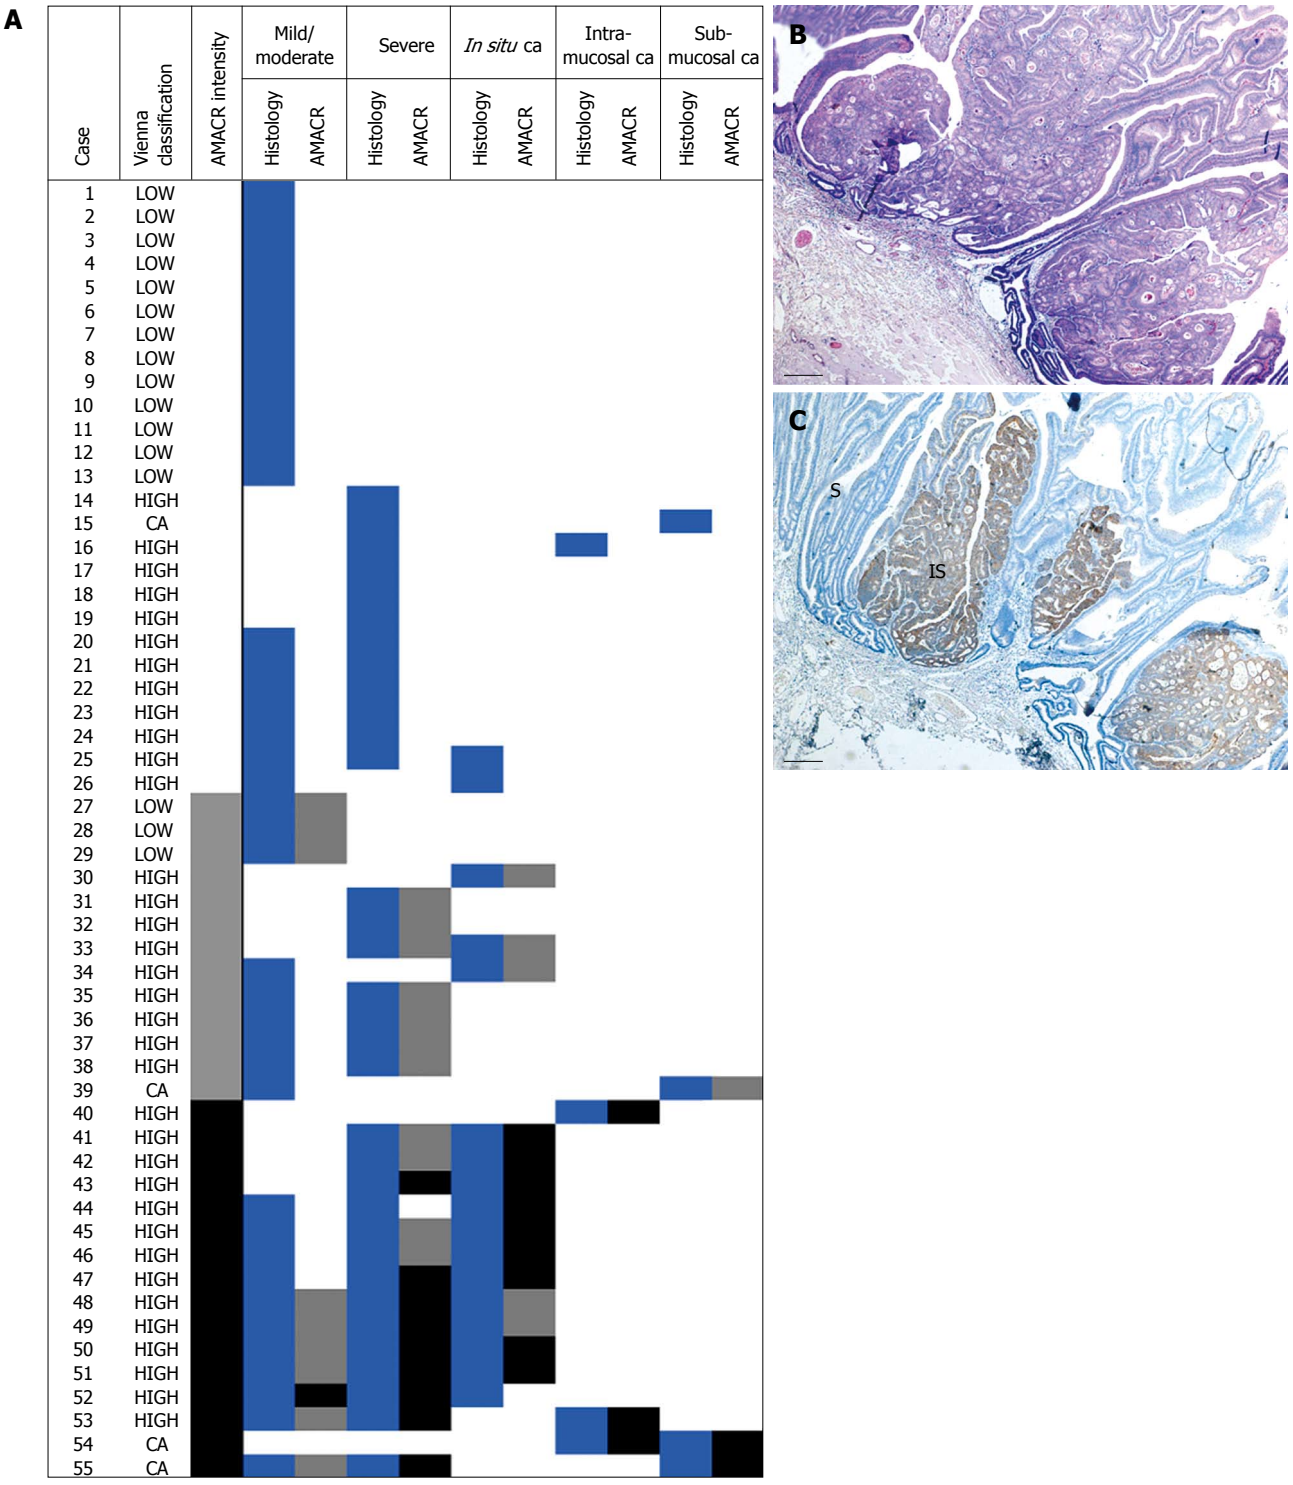

Figure 1 **α-methylacyl CoA racemase (AMACR) expression in colorectal adenomas is related to the grade of dysplasia.** A: Cumulative results from all dysplastic areas within each one of the 55 cases examined. Histology columns: white = absence, blue = presence of the indicated histological pattern. AMACR column: white = negative, grey = weak, black = strong staining; B and C: Case 44, as listed in A. In this adenoma with high grade dysplasia (HE staining), AMACR staining is restricted to the *in situ* component (IS) with severely dysplastic (S) adjacent glands showing negative or focal weak immunoreactivity. Bars: 100 microns.

play some role in the process of malignant transformation in the colon. What this role might be cannot be established by this study. As has also been suggested for AMACR in the prostate, it is uncertain whether its expression is directly involved in the process of malignant transformation or whether it is just an epiphenomenon triggered by the increased metabolic requirements of malignant cells[36].

Studies like the present one are performed to approach a basic question: How can molecular or genetic information help to stratify risk in patients with adenomatous polyps[33]. Currently, size ⩾ 1 cm, villous config-

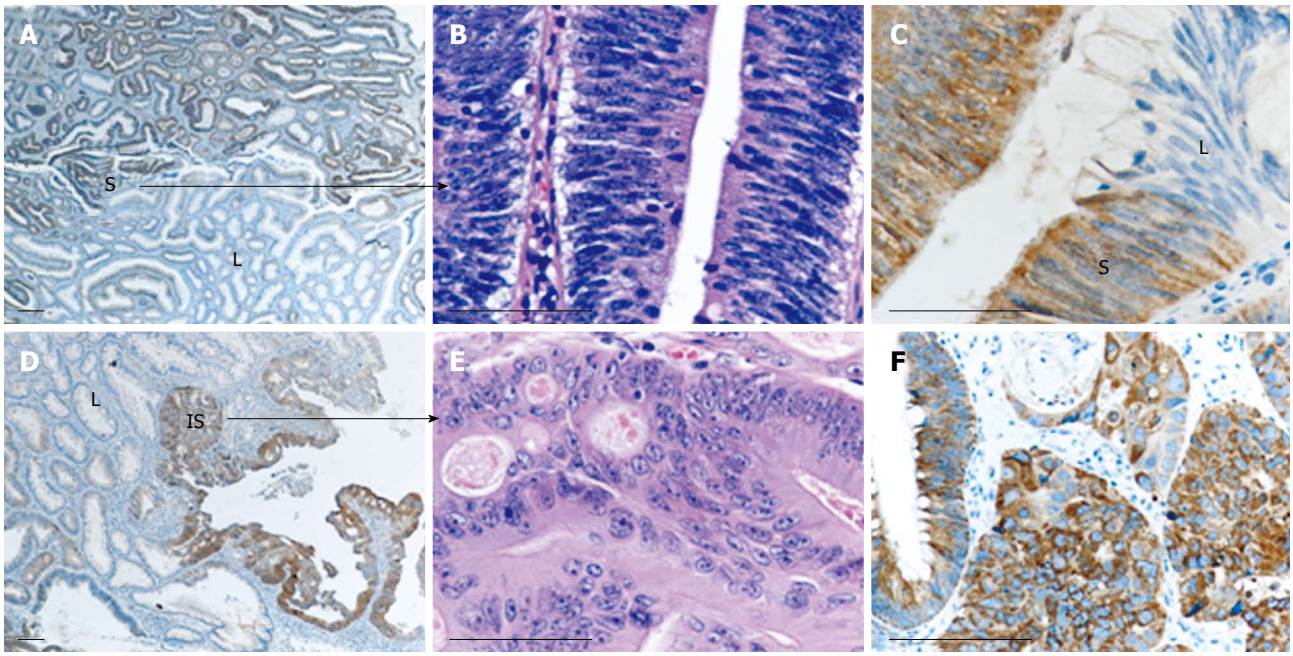

Figure 2 Heterogeneity of AMACR staining may be observed in different dysplastic areas within the same lesion. Case 47, as listed in Figure 1A, is shown. This case contained areas of mild/moderate [low-grade (L)] and severe (S) dysplasia, as well as carcinoma *in situ* (IS) elements. Severely dysplastic (A-C) and carcinoma *in situ* areas (D-F) are strongly positive for AMACR, while mild/moderate dysplastic areas are negative. Histological distinction between severe dysplasia and carcinoma *in situ* is apparent in B and E, respectively (HE staining). Bars: 100 microns.

uration and high grade dysplasia constitute the consensus criteria based on which an adenoma is characterized as "advanced" and patient surveillance is adjusted accordingly[18,31,33,34]. Based on these parameters, patients can be stratified at the time of colonoscopy into lower or higher risk groups for subsequent advanced neoplasia (adenomas with high grade dysplasia or cancer). However, debate on the clinical relevance of these factors continues to exist and many authors still address the need for more objective and standardized pathologic criteria[37-40]. As we show here, except for its association with the grade of dysplasia, AMACR expression in colonic adenomas is also related to two additional pathologic risk factors, i.e. size and villous configuration, a finding not previously reported. Hence, AMACR could be a candidate parameter for further evaluation as an additional risk factor for the development of subsequent advanced neoplasia. Large scale studies with long term patient follow-up would be required for the evaluation of any marker in this setting, since patients with adenoma seldom develop carcinoma within a period of 3 years[32].

Another observation that needs to be further evaluated is the significant difference in AMACR expression between severe dysplasia-like changes and carcinoma *in situ*-like changes, when these appear as independent lesions. Taking into account the drawbacks of our study (small sample size and lack of patient follow up), none of our findings directly raises any issues concerning the current guidelines for the reporting of dysplasia in colorectal adenomas that have been imposed by the need for simplicity and standardization. However as shown here a more detailed approach to the cytoarchitectural features of dysplasia in the context of observational studies might unravel meaningful and potentially useful associations.

COMMENTS

Background

α-methylacyl CoA racemase (AMACR) has been widely used in prostate pathology as an adjunct in the differential diagnosis of prostate cancer. Recently many papers have addressed the possible application of this biomarker in distinguishing low-grade from high-grade dysplasia in premalignant lesions of the gastrointestinal tract like Barrett's esophagus, Crohn's disease and ulcerative colitis.

Research frontiers

Although immunohistochemistry with AMACR in colorectal carcinoma has been extensively investigated, there are not yet any clear-cut conclusions regarding the expression of AMACR in sporadic colorectal adenomas in relation to histology. This is the first study to report associations between AMACR expression and cytoarchitectural features of colorectal polyps.

Innovations and breakthroughs

Recent studies have shown a positive association between AMACR expression and grade of dysplasia in inflammatory bowel disease and Barrett's esophagus with higher grade lesions showing strong staining at the immunohistochemical level. In this study, the authors report for the first time a significant association between AMACR expression and grade of dysplasia in sporadic colorectal adenomas, which may also be extended to other pathologic parameters like villousness and size.

Applications

AMACR may be considered as a candidate adjunct marker for further evaluation regarding risk stratification of patients undergoing colonoscopic surveillance.

Terminology

AMACR is a mitochondrial and peroxisomal enzyme implicated in the degradation of branched chained fatty acids and fatty acid derivatives. There are no conclusive results about the role of AMACR in carcinogenesis. However, multiple studies have addressed its potential use as a biomarker in cancer diagnostics.

Peer review

The study evaluate the expression of AMACR with polyps characteristics and suggested that it could be use as an additional risk factor for the assessment of colorectal adenoma.

Abstract

AIM: To investigate whether semi-vegetarian diet (SVD) has a preventive effect against relapse of Crohn's disease (CD) in patients who have achieved remission, who are a high-risk group for relapse.

METHODS: A prospective, single center, 2-year clinical trial was conducted. Twenty-two adult CD patients who achieved clinical remission either medically (n = 17) or surgically (n = 5) and consumed an SVD during hospitalization were advised to continue with an SVD and avoid known high-risk foods for inflammatory bowel disease. The primary endpoint was clinical relapse defined as the appearance of active symptoms of CD. Kaplan-Meier survival analysis was used to calculate the cumulative proportion of patients who had a relapse. A 2-year analysis of relapse rates of patients who followed an SVD and those who did not (an omnivorous diet group) was undertaken.

RESULTS: SVD was continued by 16 patients (compliance 73%). Remission was maintained in 15 of 16 patients (94%) in the SVD group *vs* two of six (33%) in the omnivorous group. Remission rate with SVD was 100% at 1 year and 92% at 2 years. SVD showed significant prevention in the time to relapse compared to that in the omnivorous group (P = 0.0003, log rank test). The concentration of C-reactive protein was normal at the final visit in more than half of the patients in remission who were taking an SVD, who maintained remission during the study (9/15; 60%), who terminated follow-up (8/12; 67%), and who completed 2 years follow-up (7/10; 70%). There was no untoward effect of SVD.

CONCLUSION: SVD was highly effective in preventing relapse in CD.

Lifestyle-related disease in Crohn's disease: Relapse prevention by a semi-vegetarian diet. *World J Gastroenterol* 2010; 16(20): 2484-2495 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i20/2484.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i20.2484

INTRODUCTION

The etiology of inflammatory bowel disease (IBD), which is a collective term for Crohn's disease (CD) and ulcerative colitis (UC), is unknown but is believed to be

multifactorial, whereby development of the disease in genetically susceptible subjects is triggered by environmental factors[1]. IBD is a complex polygenic disease in which the contribution of each gene to the onset of disease is small[2]. IBD incidence increases along with wealth[3,4]. The above two main features of IBD are exactly the same as those for other chronic diseases such as diabetes mellitus, coronary heart disease, and obesity in developed countries[5]. A large part of chronic diseases is related to lifestyle, including food and being sedentary. Some of the environmental factors that have been observed in association with IBD include cigarette smoking, the use of oral contraceptives, and appendectomy[3]. However, these environmental factors are thought to play only a mediating role in IBD. A real key environmental factor has not been identified. Consequently, there is no particular recommendation on lifestyle in guidelines except for smoking in CD[6-9].

Recent studies have clarified that the presence of gut indigenous microflora is a prerequisite for gut inflammation[10,11], and susceptible IBD genes identified are thought to play a role in recognition of microbial agents, immunoregulation, and inflammation[2]. Therefore, IBD is thought to result from an inappropriate response of the mucosal immune system to the intestinal microflora in a genetically susceptible individual[2]. An imbalance of gut microflora, a decrease in beneficial (preventive) bacteria, and an increase in potentially pathogenic bacteria, called dysbiosis, is observed in patients with IBD[12-14]. Dysbiosis can be a trigger for onset and relapse of IBD[15].

There is enough evidence to indicate that IBD is a diet-related disease. Epidemiology shows that IBD is prevalent in wealthy nations[3,4,16] where dietary westernization inevitably occurs[17,18]. Dietary westernization is characterized by increased consumption of animal protein, animal fat, and sugar, with decreased consumption of grains. A dietary study during dietary transition in Japan incriminated an increased intake of animal fat and animal protein in the increase in CD[19]. Pre-illness case-control studies, including those in Japan, have reported increased intake of sugar[20-23], fast foods, chocolate, and cola drinks in IBD[24,25], and a decrease in total fruit and vegetable fiber in CD[20,26]. Case-control studies in Japan are consistent; western foods including bread are a risk factor, whereas traditional Japanese foods are a preventive factor[27-29]. The same tendency has recently been reported in pediatric CD cases in Canada: a positive association with a western diet (meats, fatty foods, and desserts) and an inverse association with a prudent diet (vegetables, fruits, olive oil, grains, and nuts)[30]. Diets rich in animal protein and animal fat cause a decrease in beneficial bacteria in the intestine[31,32]. Probiotics that consist of beneficial bacteria can prevent and are effective against pouchitis, which is ileal inflammation after proctocolectomy in UC[33,34]. These pieces of evidence are consistent with the notion that a westernized diet is linked to an increase in IBD. Therefore, we regard IBD as a lifestyle-related disease that is mediated by mainly a westernized diet[35,36]. Consequently, if a suitable diet is identified and patients stick to the diet, we believe that the majority of IBD patients could be free from relapse without medication.

The conventional recommended diet for IBD is a low-residue diet[37]. A fear of irritating the bowel with dietary fiber has led to a low-residue diet. However, there is no evidence that such a diet is ideal for IBD. A low-residue diet that lacks non-digestible carbohydrates might accelerate the dysbiosis in IBD. Meals *per se* are thought to cause gut inflammation. Therefore, about half of the daily energy intake is provided by an elemental diet, which is a standard regimen in quiescent CD in Japan[38,39]. At present, it is unknown what kind of diet is suitable for IBD.

Therefore, we designed a diet that hopefully increases the number of beneficial bacteria. Limited foods are known to increase beneficial bacteria: green tea and unrefined brown rice[40,41]. However, most prebiotics are extracts of plants[42]. Therefore, we thought that a vegetarian diet would be suitable for IBD. Considering that excessive restriction in foods can be less acceptable, a semi-vegetarian diet (SVD) could be appropriate. Therefore, an SVD has been provided to IBD patients in our hospital since 2003[35,36]. SVD, which is rich in dietary fiber, is quite opposite to conventional low-residue diets in IBD[37].

The biggest problem in practice in IBD is a lack of a safe, long-lasting modality for relapse prevention. Relapse in CD is far more untenable than in UC[43]. The risk of relapse in CD is influenced by the interval of remission: a higher risk among patients with recently achieved remission than among patients in remission[44].

In this study, an SVD was provided throughout the induction phase in CD patients, or after intestinal surgery. After their discharge, they were immediately followed up in the IBD outpatient department. The aim of this study was to investigate whether an SVD has a preventive effect against relapse in high-risk patients who have recently achieved remission.

MATERIALS AND METHODS

Study design

This was a prospective clinical trial with 2 years follow-up to establish whether an SVD has a preventive effect against relapse in high-risk patients who have recently achieved remission. This study was approved by the Ethical Committee of Nakadori General Hospital and all patients gave written informed consent.

Subjects

SVD was first introduced in our institution in 2003, and it has been provided to all patients with CD. From April 2003 to December 2008, 25 active adult CD patients over 19 years old were admitted to the Division of Gastroenterology, Nakadori General Hospital, Akita, Japan.

F: Female; M: Male; EC: Enterocolitis; C: Colitis; E: Enteritis; R: Relapse; I: Initial onset; PO: Postoperative; CDAI: Crohn's disease activity index; CRP: C-reactive protein (normal range ≤ 0.3 mg/dL); SVD: Semi-vegetarian diet; CS: Colonoscopy; BE: Barium enema study; NT: Not tested.

Diagnosis of CD was made by established criteria[45]. Two patients did not achieve remission: one patient was referred to another hospital for surgery, and the other patient was discharged part way through treatment at his request. There were three smokers. Two of them accepted the doctor's advice and stopped smoking after admission. One patient resumed smoking again after discharge, and this patient was excluded from this study. Therefore, 22 patients who achieved clinical remission medically (n = 17, No. 1-17, Table 1) or surgically (n = 5, No. 18-22, Table 1) were included in this study. Clinical remission was defined as the disappearance of active symptoms of CD. Male patients predominated over female patients (14:8). Ages ranged from 19 to 77 years old (median: 26.5 years). The number of patients with enterocolitis, enteritis, and colitis was 11, 1, and 10, respectively. Fourteen patients had perianal fistulas and/or anal tags. Eleven patients with anal fistulas had draining pus. Disease duration of medically treated patients ranged from 1 to 74 mo (median: 8.0 mo). That of surgically treated patients was > 8 years except for case 19, who underwent surgery on his initial visit after 2 years with the disease. Two of the 22 patients underwent previous intestinal resection for CD. Thirteen cases were initial onset and nine were relapses. Crohn's disease activity index (CDAI)[46] on admission in medically treated patients ranged from 52 to 679 (median: 211). Five cases showed CDAI < 150, which is arbitrarily defined to be remission in many studies, but they were definitely suffering from active symptoms. Two cases showed very low CDAI, i.e. 88 in case 6 and 52 in case 13, but they had active symptoms: diarrhea for 2 mo and loose stools and lower abdominal pain for 3 mo, respectively. In surgically treated patients, CDAI score on transfer to our division after surgery was

Standard: A mixture of Japanese and western diet; BMI: Body mass index; Chol: Total serum cholesterol; ChE: Cholinesterase. Normal range: BMI: 18.5 kg/m^2 ≤- < 25.0 kg/m^2; Albmin: 3.8-5.2 g/dL; Chol: 120-220 mg/dL; ChE: 3200-6500 IU/mL; Hemoglobin: M: 13.8-17.5 g/dL, F: 12.0-15.1 g/dL.

determined. The details such as sex, age, clinical types by disease location, anal lesions, disease duration, initial onset or relapse, and C-reactive protein (CRP) concentration are shown in Table 1.

Medical induction of remission: The main medication was infliximab in all medically treated patients except for case 1. Case 1 was the earliest case in this study with mild symptoms and was treated with sulfasalazine 3 g/d. Metronidazole 750 mg/d was given after admission. Patients received liquid infusion of 1500 mL/d *via* a peripheral vein for about 1 wk, without meals. Meanwhile, morphological studies including colonoscopy or contrast barium enema study, enteroclysis, and esophagogastroduodenoscopy were performed to assess clinical types and stenosis. Laboratory data were also obtained. Then, infliximab (5 mg/kg body weight; Remicade, Centocor, Malvern, PA, USA) was infused over 3 h[47]. Infliximab was further infused at 2 and 6 wk according to the standard recommendation[47]. After about 1 mo of metronidazole administration, it was switched to mesalamine 1.5 g/d or sulfasalazine 2 g/d. After the third infusion of infliximab, patients were discharged. Iron (60 mg/d saccharated ferric oxide) was given to patients with moderately severe anemia, but none of patients received a blood transfusion. No steroid hormone, immunosuppressant, or antibiotic other than metronidazole was administered.

The CDAI score of medically treated patients was significantly decreased from 255 ± 169 (mean ± SD) on admission to 46 ± 24 at week 6 after the first infusion of infliximab, i.e. before the third infusion of infliximab (paired *t* test, $P < 0.0001$, Table 1). The concentration of CRP also significantly decreased from 4.0 ± 3.9 to 0.2 ± 0.3 mg/dL ($P = 0.001$). Morphological studies by colonoscopy and/or contrast barium enema study were performed before discharge in 15 patients (Table 1). Morphological remission was achieved in seven patients. Near remission was achieved in four patients in whom redness and/or a few small aphthoid lesions without ulcer were present. In three patients, active lesions were improved, but active lesions (ulcer) were still present. In case 1, there was no improvement in active lesions. Nutritional data in patients who showed hypoalbuminemia (< 3.8 g/dL, $n = 7$) or hypocholesterolemia (< 120 mg/dL, $n = 3$) on admission were improved to a normal level at week 6: from 3.2 ± 0.6 to 3.9 ± 0.6 g/dL ($P = 0.0086$) and from 99 ± 4 to 148 ± 31 mg/dL, respectively (Table 2). Low serum cholinesterase (< 3200 IU/L, $n = 5$) improved: from 1983 ± 855 to 3149 ± 1039 ($P = 0.0233$). There was little change in body mass index (BMI) at week 6 in patients who showed abnormally low levels (< 18.5 kg/m^2, $n = 5$) on admission: from 17.4 ± 0.2 to 17.5 ± 1.0. Anemia (male < 13.8 g/dL, female < 12.0 g/dL, $n = 11$) improved from 10.7 ± 2.0 to 12.3 ± 1.6 ($P = 0.0058$). Details of individual data are presented in Table 2.

Surgical induction of remission: Five patients, cases 18-22, who had recently undergone intestinal resection for intestinal obstruction, were transferred to our division

when they could take solid meals. This occurred on post-operative day 12-15 (Table 1). They took metronidazole 750 mg/d for about 1 mo along with meals[48].

Patients' dietary habits: Patients' dietary habits and lifestyles before onset or relapse of the disease were obtained immediately after admission, prior to providing information about the SVD, by means of a food-frequency questionnaire[49]. The questionnaire included 45 questions that covered almost all foods or food groups in Japan. There was a question about dietary type that listed six types: western, pro-western, standard/mixed, pro-Japanese, Japanese, and SVD. A definition of dietary types was not set. There was a variety of dietary patterns before the onset or relapse of CD: pro-western (n = 8), standard/mixed of western and Japanese diet (n = 6), pro-Japanese (n = 5), and Japanese (n = 2) (Table 2). Case 20 had a 2000 kcal/d polymeric diet without meals. None of our patients' dietary pattern was SVD or a western diet. Based on the questionnaire, a summarized table was made that showed both a patient's hitherto and future recommended lifestyle and dietary habits. Such a table created for case 8 is shown in Table 3. Recommended dietary habits were consistent with SVD in the following. This table was used by the dietitian when giving dietary guidance, and it was given to the patient by the chief investigator (Chiba M) during hospitalization.

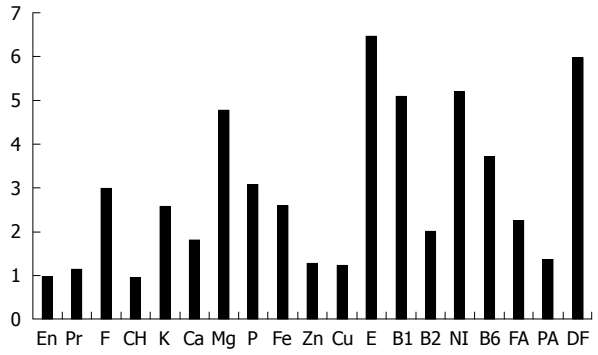

Figure 1 Nutritional elements of brown rice in comparison with white rice[50]. The amount of elements in 100 g of edible food is expressed in comparison with those in white rice, whose value is 1. Brown rice is richer in almost all elements in comparison. En: Energy; Pr: Protein; F: Fat; CH: Carbohydrate; E: Vitamin E; B1: Vitamin B1; B2: Vitamin B2; NI: Niacin; B6: Vitamin B6; FA: Folic acid; PA: Pantothenic acid; DF: Dietary fiber.

SVD: SVD was initiated on the same day as infusion of infliximab in medically treated patients. About 800 or 1100 kcal/d was given in the beginning, and calories were gradually increased to a maximum of about 30 kcal/kg standard body weight. White rice was served first for 2-5 d followed by mixed rice (70% white rice and 30% unrefined whole brown rice) for 2-5 d, and finally brown rice was served. Unrefined brown rice contains more vitamins and minerals than white rice[50] (Figure 1) and is reported to increase significantly beneficial bacteria compared to

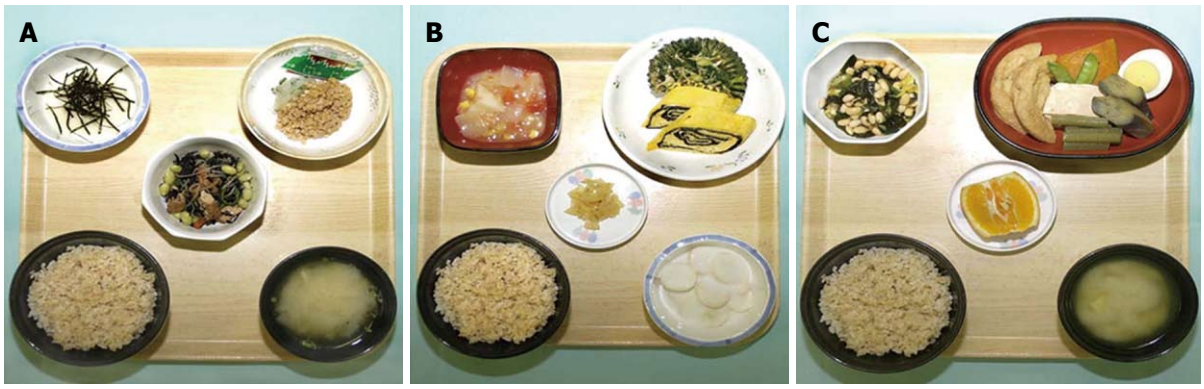

Figure 2 A sample of a 1700-kcal/d semi-vegetarian diet (SVD) for Crohn's disease (CD). From left to right, breakfast (A), lunch (B), and dinner (C). Boiled brown rice is seen at the bottom left of the tray and miso (fermented bean paste) soup is at the bottom right. Breakfast (A): Raw grated nagaimo (yam) and shredded toasted nori seaweed are at the top left; natto (fermented soybeans) and grated daikon (Japanese radish) are at the top right; and braised hijiki seaweed, nama-age (thick deep-fried beancurd), and edamame (young soybeans) are in the center; Lunch (B): Boiled potato, onion, and corn in tomato soup are at the top left; isomaki-tamago (dried nori seaweed inside egg roll) and boiled chrysanthemum with sesame dressing are at the top right; takuan (pickled radish) is in the center; and a mixture of banana and plain yoghurt is at the bottom right; Dinner (C): Boiled chingensai (qing gin cai), soybeans, and wakame seaweed with vinegar soy sauce dressing are at the top left; simmered ganmodoki (bean-curd-based mixture), tofu (bean curd), boiled egg, Japanese-variety eggplant, Japanese butterbur, Japanese-variety pumpkin, and snow peas are at the top right; and citrus fruit is in the center.

well-milled white rice[41]. Eggs and milk were used. In other words, our diet was a lacto-ovo-vegetarian diet[51]. Miso (fermented bean paste) soup, vegetables, fruits, legumes, potatoes, pickled vegetables, and plain yoghurt were served daily. Fish was served once a week and meat once every 2 wk, both at about a half the average amount. Patients were provided with several different 4-wk menus on a rotational basis. Figure 2 shows what an SVD looks like. Details of the contents of nutritional elements including minerals, vitamins, and fatty acids in an SVD are shown in Table 4. These figures were obtained by HOPE/COMETY-NT (Fujitsu, Tokyo, Japan). The rate of fat in total calories (18.6%) was < 20%, which is the lower limit of Dietary Reference Intakes for Japanese (DRI)[52]. The amounts of dietary fiber and iron in the SVD were above the DRI. Those of most of the other elements in the SVD were comparable to DRI (Table 4). Coarse tea was served along with the meal service. During hospitalization, foods other than the meal service were discouraged. Drinking of green tea was encouraged. Participant days of SVD ranged from 43 to 82 d (median: 49 d) in medically treated patients (Table 1). In surgically treated patients, they were shorter, about 3 wk. Case 22 was exceptionally long, 83 d, due to a postoperative complication of subcutaneous abscess formation. In all 22 cases, there were no adverse effects such as gaseous distress, abdominal discomfort, or diarrhea as a result of the SVD.

At the end of hospitalization, a qualified dietitian gave dietary guidance to the patient and the meal preparer. It included how to boil brown rice. The responsible doctor (Chiba M) also gave patients an SVD guide (Figure 3) and advised them to continue the diet after discharge. Foods that have been shown to be a risk factor for IBD in or outside Japan, including sweets[20-23,28-30], bread[27], cheese[27-29], margarine[27], fast foods, carbonated beverages, and juices[24,25,29], were discouraged. Healthy habits were encouraged: no smoking, regular physical activity, moderate or no use of alcohol, regularity of meals, and not eating between meals[53].

Follow-up study

Twenty-two patients who achieved remission either medically or surgically were followed up for 2 years. Medication was mesalamine or sulfasalazine (Table 5). None of

the patients took immunosuppressants such as azathioprine or 6-mercaptopurine. They visited the IBD outpatient department (responsible doctor: Chiba M) every 8 wk. Blood samples for measurement of CRP, complete blood counts, albumin, and transaminases were taken at each visit. The food-frequency questionnaire was obtained at month 3, at years 1 and 2, or when a patient relapsed. When remission was maintained for 1 year and a patient seemed to continue the SVD, medication was stopped if the patient so desired. Primary end point was clinical relapse that was defined as the appearance of active symptoms of CD that required treatment. Duration of remission was calculated as the number of days between discharge and the appearance of symptoms of relapse. Although the responsible doctor (Chiba M) similarly advised patients to continue the SVD, some patients did not follow the advice or abandoned it at some point. Relapse in 2 years was compared between two groups of patients: SVD group and the omnivorous diet group.

Assessment of dietary pattern in outpatients: Dietary pattern was classified into two groups: SVD and omnivorous diet. When the following two conditions were fulfilled, it was regarded as SVD in this study. One is that a patient follows the principle of SVD: daily intake of rice, vegetables, and fruits, and occasional intake of fish, meat, and other animal-based foods. The other one is that a patient refrains from foods reported as risk factors for IBD in or outside Japan as stated above[20-30]. A diet that did not fulfill these two conditions was regarded as an omnivorous diet.

Statistical analysis

Kaplan-Meier survival analysis was used to calculate the cumulative proportion of patients who had a relapse. Patients who stopped the treatment for any reason other than relapse were considered censored at the time of their last observation. Comparison of cumulative relapse rates between the SVD and omnivorous groups was tested by the log rank test. A P value of 0.05 or less was considered to indicate a statistically significant difference. Statistical analysis was performed using JMP 8 (SAS Institute Inc., Cary, NC, USA) software.

RESULTS

Eighteen patients terminated the follow-up: completion

Table 6 Maintenance therapy in Crohn's disease following induction of remission or response

PS: Prednisolone; AZA: Azathioprine; CD: Crohn's disease; TPN: Total parenteral hypernutrition; TEN: Total enteral nutrition; ED: Elemental diet.

of 2-year observation in 11, relapse in five, and early termination for other reason in two (moving and infliximab therapy for associated rheumatoid arthritis in one each). Four patients are ongoing (Table 5). Dietary types that patients marked in the food-frequency questionnaire during the follow-up study were judged appropriate by other foods or food groups marked. SVD was maintained by 16 patients but not by six (compliance 73%) (Table 5). There was no untoward effect of SVD. The reason for the discontinuance of SVD in six patients was not a detrimental effect of SVD but their preference for sweets, meat, and/or fish. Case 2 continued SVD for the first 3 mo but stopped thereafter. Cases 3 and 22 consumed vegetables and fruits only once a week and ate sweets frequently. Case 6 cooked and added meat to the SVD that was prepared by his mother. Case 9 had alcohol at supper every night and frequently ate fish and sweets. Case 15 consumed animal foods more often than the standard for an SVD.

Five patients relapsed. Four were medically treated and one was surgically treated. On the final study visit, they showed elevated CRP concentration and a CDAI of > 100 (Table 5). Seventeen patients maintained remission. Among them, 11 with normal CRP concentration showed almost normal values in other nutritional data (BMI, albumin, cholesterol, and cholinesterase) and hemoglobin. Their CDAI was extremely low. Meanwhile, most of the six patients with elevated CRP, although in remission, showed some abnormality in these indices. The details are shown in Table 5.

Among the 16 patients who continued with the SVD, 15 maintained remission and one relapsed (Table 5): the remission rate was 100% (16/16) at 1 year and 92% at 2 years (Figure 4 and Table 6). Among six patients who were on an omnivorous diet, two maintained remission and four relapsed (Table 5): the remission rate was 67% (4/6) at 1 year and 25% at 2 years (Figure 4 and Table 6). Life table analysis showed that the cumulative relapse rate

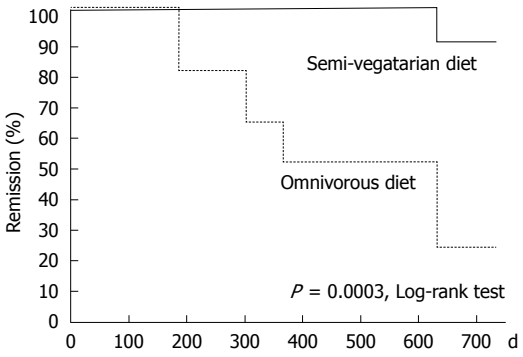

Figure 4 Life table estimate of maintaining remission with SVD or omnivorous diet.

at 2 years was significantly lower in the SVD group than in the omnivorous group (P = 0.0003) (Figure 4). The concentration of CRP was normal at the final visit in more than half of the patients in remission on an SVD; in those who maintained remission during the study (9/15; 60%); terminated follow-up (8/12; 67%), or completed 2 years follow-up (7/10; 70%).

DISCUSSION

We used mesalamine or sulfasalazine in the follow-up phase. Considering that the relapse-preventive effect of mesalamine or sulfasalazine is absent or modest at most[54], it is reasonable to conclude that the SVD protected patients from relapse but an omnivorous diet did not.

Azathioprine and 6-mercaptopurine are known to be effective and used for maintenance of remission in patients with steroid-dependent CD[6-9]. They are also used in the induction phase together with prednisolone and then used for maintenance. In such situations, Candy *et al*[55]

have reported that the remission rate at 1 year was 42% (placebo control, 7%) (Table 6). Recently, scheduled infliximab therapy every 8 wk has been shown to be effective as maintenance treatment in both adults and pediatric patients[56,57]. Remission rate at 1 year in adults was 25%-33% (placebo control, 11%) (Table 6)[56]. An elemental diet that consisted of about a half the daily energy intake has been shown recently to have a relapse-preventive effect in the Japanese study group: 26.9% relapse rate at 1 year (control free diet, 64.0%) (Table 6)[39]. Remission rates with the SVD in the present study were far better than those reported previously: 100% (16/16) remission rate at 1 year and 92% at 2 years. To the best of our knowledge, this is the best result in relapse prevention. Although our study population included mild cases, our excellent results cannot be explained solely by a difference in severity in study population, because even mild to moderate disease relapse rates are 60%-70% at 1 year (Table 6)[58]. More recently, scheduled infliximab therapy every 8 wk has been shown to be effective in postoperative patients: 80% remission rate at 1 year (placebo control, 58%) (Table 6)[59]. Successful scheduled maintenance therapy with infliximab, however, could encounter difficulty over longer periods due to a waning of efficacy, and side effects. In 2 years, more than half the patients need a shortening in the infliximab dosing interval and about 10% of patients need cessation of therapy[60]. Although the number of patients in our study was small, all four postoperative patients on the SVD maintained remission for 2 years (Table 5).

When we began thinking of IBD as a lifestyle-related disease mediated mainly by dietary westernization, we changed our modality of treatment to emphasize diet (Table 7). The menu of a conventional low-residue diet for IBD is shared by UC and CD. However, CD is apparently more tenacious than UC[43]. Therefore, the staple is refined white rice for UC and unrefined brown rice for CD. About 30 kcal/kg per day is provided in the current diet, while total calories were not individualized in the conventional diet. Dietary analysis is needed for dietary guidance in current practice (Table 7). In addition to diet, common health practices[53] are encouraged.

SVD is initiated after about 1 wk of fasting, on the same day as infliximab infusion. By this time, symptoms such as diarrhea, abdominal pain, and fever subside, and patients want to eat. SVD that contained a moderate amount of dietary fiber was not detrimental but useful for induction of remission of CD. It improved hypoalbuminemia, hypocholesterolemia, and anemia during hospitalization. Although clinical remission could be obtained by one or two infusions of infliximab, we believe that a certain period of time is needed for recovery of morphological changes in the intestine. Therefore, three infusions of infliximab in 6 wk[47] were given, not at the outpatient clinic but during hospitalization. This period of hospitalization was also useful for patients to become familiar with the SVD. Compliance with the SVD in outpatients in this study was about 75%, which indicates that an SVD could be applicable to the majority of CD patients. An SVD is completely natural and safe. There is no need to fear side effects, as with steroid hormones or immunosuppressants such as infliximab, azathioprine, 6-mercaptopurine, or methotrexate.

Table 7 Conventional and current diet in IBD at Nakadori General Hospital

	Conventional	Current
Diet	Low-residue diet	Semi-lactoovovegetarian diet
Menu	Common for UC and CD	SVD for UC (staple: white rice) SVD for RUC (staple: white rice 70%, brown rice 30%) SVD for CD (staple: brown rice)
Refrainment	Fiber-rich diet	Minced or processed meat, bread, fast foods, sweets, cola/soda, juices
Dairy products	Refrainment	Egg, milk: no refrainment Refrain from cheese/butter/margarine
Calories	2000 kcal/d	About 30 kcal/kg standard body weight/d
Dietary analysis	Absent	Food-frequency questionnaire
Dietary guidance	Absent	Guidance by doctor and registered dietitian

UC: Ulcerative colitis; RUC: Refractory ulcerative colitis.

Fifteen of 16 patients who continued the SVD were free from relapse in our study. In addition, more than half of the patients in remission showed normal CRP levels. CRP is a sensitive indicator for predicting relapse[61]. Judging from CRP levels, it seems that more than half of the patients who continue the SVD will be free from relapse as long as they maintain the diet. However, the rest of the patients in remission with elevated CRP might relapse in the long term, which seems a limitation of the SVD. Our study clearly shows that the dietary pattern influences the relapse rate in CD. Therefore, trials of the preventive effect of medications in CD should be designed in consideration of diet.

There have been trials for prevention of relapse in CD with diets or supplements. Excellent results with an exclusion diet of intolerant foods[62], an unrefined-carbohydrate, fiber-rich diet[63], or fish oil supplement[64] have not been reproduced in other studies[65-67]. Therefore, none of the dietary modifications has been widely accepted. Currently, manipulation of gut microflora with probiotics and/or prebiotics has emerged as an attractive therapeutic modality in IBD[11,15,33,34]. The rationale of an SVD, i.e. enhancement of beneficial bacteria in the gut, is the same as that of probiotics and prebiotics. There is a limitation to mere addition of probiotics, prebiotics or food stuffs and exclusion of potentially untoward food stuffs[65-68]. We believe that, not partial, but comprehensive food control is needed for patients who are genetically predisposed to IBD. Therefore, our SVD encourages consumption of grains, vegetables, and fruits, while limiting intake of animal foods that tend to decrease beneficial bacteria[31,32] and other foods reported to be risk factors for IBD[20-30]. However, no food item is prohibited.

Although we designed our SVD with gut bacterial flora in mind, both plant-only (vegan) and plant-based (lacto-ovo-vegetarian, semi-vegetarian) vegetarians are shown to have low rates of cancer, cardiovascular disease, obesity, and total mortality[51,69]. Plant-based diets are recommended for prevention of cancer and other lifestyle-related chronic diseases[70]. Therefore, SVD will not only be effective for gut inflammation, but also promote the general health of IBD patients.

Since we are aware that an SVD is effective for relapse prevention, we are concerned with rapid, safe and reliable induction of remission. This is now attainable by infliximab[47]. Therefore, we use infliximab as the first choice of therapy in all newly diagnosed active CD cases. So far, there has been no failure in induction of remission with infliximab (Chiba *et al*, article in preparation). Therefore, since the advent of infliximab and SVD, we feel that CD has been much more controllable than before.

In conclusion, this study shows that an SVD is safe and has a preventive effect against relapse of CD. Normal CRP levels are maintained in more than a half of the patients with an SVD. This supports our notion that IBD is a lifestyle-related disease that is mediated mainly by a westernized diet. The concept that IBD is a lifestyle-related disease is lacking in present practice. We believe that without introduction of this concept, a major breakthrough in the prevention of relapse in CD is not attainable. Whether gut microflora are indeed enriched in beneficial bacteria by an SVD needs to be clarified. Our new findings require verification in large, randomized, controlled clinical trials.

ACKNOWLEDGMENTS

The authors thank Mrs. Yohko Kinno and Miss Miki Yamada, registered dietitians, and other staff of the Dietary Division of Nakadori General Hospital for providing SVD.

COMMENTS

Background

Crohn's disease (CD) is a chronic disease of the intestine. The peak incidence is between the ages of 15 and 25 years. Remission is induced by drip infusion or elemental diet (amino-acid-based) without meals, by drugs such as prednisolone and infliximab, by resection of the involved intestine, or by a combination of these. The biggest problem in practice in CD is frequent relapse and difficulty in maintaining remission. At 1 year, the relapse rate is around 60%-70% and the remission rate is 25%-42%. A low-residue diet has been conventionally recommended without evidence of improving remission rates. Because meals inevitably cause relapse, the use of elemental diet is popular in countries like Japan.

Research frontiers

Although the etiology of CD is unknown, there is some evidence to indicate that it is a lifestyle-related disease that is mediated mainly by a westernized diet: increased consumption of animal protein, animal fat, and sugar, with decreased consumption of grains. Therefore, the authors designed a semi-vegetarian diet (SVD) which hopefully increases beneficial (preventive) bacteria in the intestine. In this study, the authors examined whether the SVD had a preventive effect against relapse in high-risk patients with CD who had recently achieved remission.

Innovations and breakthroughs

The SVD was highly effective in preventing relapse in CD. Remission rate with the SVD was 100% at 1 year and 92% at 2 years. This is the best result in relapse prevention. The concentration of C-reactive protein, an indicator of inflammation, was normal at the final visit in more than half of the patients on the SVD, which indicated that more than half of the patients who continue the SVD will be free from relapse as long as they maintain the diet.

Applications

SVDs can be provided anywhere in the world. Ulcerative colitis (UC) is another chronic inflammatory bowel disease that displays a less harsh clinical course than CD. An SVD can also be applied to UC.

Terminology

The SVD in this study was a lacto-ovo-vegetarian diet in which eggs and milk were used. Fish was served once a week and meat once every 2 wk, both at about half of the average amount.

Peer review

This is an excellent paper with clear scientific data in a clinical area of extreme importance.

Abstract

AIM: To compare the histopathologic features of intestinal tuberculosis (ITB) and Crohn's disease (CD) and to identify whether polymerase chain reaction for *Mycobacterium tuberculosis* (TB-PCR) would be helpful for differential diagnosis between ITB and CD.

METHODS: We selected 97 patients with established diagnoses (55 cases of ITB and 42 cases of CD) who underwent colonoscopic biopsies. Microscopic features of ITB and CD were reviewed, and eight pathologic parameters were evaluated. Nine cases of acid fast bacilli culture-positive specimens and 10 normal colonic tissue specimens were evaluated as the positive and negative control of the TB-PCR test, respectively. PCR assays were done using two commercial kits: kit <A> detected *IS6110* and *MPB64*, and kit <B> detected *IS6110* only; a manual in-house PCR method was also performed on formalin-fixed, paraffin-embedded colonoscopic biopsy specimens.

RESULTS: Statistically significant differences were noted between ITB and CD with regard histopathologic criteria: size of granulomas (P = 0.000), giant cells (P = 0.015), caseation necrosis (P = 0.003), confluent granulomas (P = 0.001), discrete granulomas (P = 0.000), and granulomas with lymphoid cuffs (P = 0.037). However, 29 cases (52.7%) of ITB showed less than five kinds of pathologic parameters, resulting in confusion with CD. The sensitivities and specificities of the TB-PCR test by kit <A>, kit <B>, and the in-house PCR method were 88.9% and 100%, 88.9% and 100%, and 66.7% and 100% in positive and negative controls, respectively. The PCR test done on endoscopic biopsy specimens of ITB and CD were significantly different with kit <A> (P = 0.000) and kit <B> (P = 0.000). The sensitivities and specificities of TB-PCR were 45.5% and 88.1%, 36.4% and 100%, and 5.8% and 100%, for kit <A> and kit <B> and in-house PCR method on endoscopic biopsy specimens. Among the 29 cases of histopathologically confusing CD, 10 cases assayed using kit <A> and 6 cases assayed using kit <B> were TB-PCR positive. A combination of histologic findings and TB-PCR testing led to an increase of diagnostic sensitivity and the increase (from 47.3% to 58.2) was statistically significant with kit <B> (P = 0.000).

CONCLUSION: The TB-PCR test combined with histopathologic factors appears to be a helpful technique in

formulating the differential diagnosis of ITB and CD in endoscopic biopsy samples.

INTRODUCTION

Tuberculosis (TB) is one of the most prevalent diseases in the world and a cause of significant mortality and morbidity in developing countries[1]. In Korea, the total number of newly developed TB patients was 19 652 in 2000, but the number was markedly increased to 34 123 in 2001 and 34 157 in 2008[2]. The resurgence of TB is, in part, due to the pandemic of human immunodeficiency virus infection[1,3,4]. The incidence of intestinal TB (ITB), one of the most common forms of extra-pulmonary TB, has been increasing in parallel with the overall resurgence of TB. Sometimes the diagnosis of ITB is very challenging to make, because of a close resemblance to Crohn's disease (CD) in clinical, radiological, endoscopic, and histological appearance[5,6]. This is especially true in Asia, where the incidence and prevalence of CD are also rising[7]. For this reason, definitive diagnosis of ITB and CD is increasingly important. In the case of ITB misdiagnosis, unnecessary anti-tuberculosis therapy poses a risk of toxicity and delays the treatment of CD. Conversely, treatment of ITB with steroids alone can lead to severe deterioration, or even death.

Pathologic features such as size and number of granulomas, giant cells, caseation necrosis, confluent granulomas, discrete granulomas, ulcers with bands of epithelioid histiocytes and granulomas with lymphoid cuffs are known to be important criteria for differentiating ITB and CD[8,9]. Several molecular techniques have been introduced in addition to histopathologic criteria for the detection of mycobacteria in histopathological specimens and for differentiating these two conditions[10-12]. Studies have shown that detection of the *IS6110* gene in *Mycobacterium tuberculosis* (*M. tuberculosis*) through an in-house method has high sensitivity and specificity[13,14], but the results are still controversial. Recently, many kinds of commercial kits have been developed using different targets to detect the *M. tuberculosis* genome, but their diagnostic accuracy has not been sufficiently examined in the literature. In this study, we compared the in-house PCR test, which detects the *IS6110* gene sequence, with two commercially available kits (represented as <A> and <B>) that have been used widely in Korea. Kit <A> detects both the *MPB64* and *IS6110* genes simultaneously, and kit <B> detects the *IS6110* gene sequence only. We reviewed the histopathological features of ITB and CD and performed PCR for *M. tuberculosis* (TB-PCR) in the endoscopic biopsy specimens to evaluate whether the histopathologic features and ITB-PCR would improve the differential diagnosis of these two diseases.

MATERIALS AND METHODS

Patient selection

We reviewed the records of patients who underwent endoscopic biopsies at Inha University Hospital, Incheon, South Korea, between 1996 and 2007 and determined their ITB and CD status. Before the study, an ethical committee approved the study protocol. A total of 334 cases which were pathologically suspicious for chronic colitis were selected. All the clinical data and hematoxylin- and eosin-stained sections were retrieved and reviewed. The definitive diagnosis of ITB or CD was based on clinical symptoms, colonoscopic findings, radiological investigation, pathological evaluation, response to antituberculous treatment, and follow-up data for more than 3 mo. A diagnosis of ITB was made when at least two of the following criteria were met: (1) demonstration of acid-fast bacilli on histologic examination of Ziehl-Neelsen stained sections; (2) positive *M. tuberculosis* culture; (3) radiologic, colonoscopic, and/or operative evidence of ITB with proven tuberculosis elsewhere; and (4) response to antituberculous therapy without subsequent recurrence in patients with radiologic, colonoscopic, and/or operative evidence of ITB. A diagnosis of CD was made when at least two of the following criteria were met: (1) clinical history of abdominal pain, malaise, diarrhea, and/or rectal bleeding; (2) endoscopic findings of mucosal cobblestoning, linear ulceration, skip areas, or perianal disease; (3) presence of enterocutaneous or entero-enteric fistulae and/or chronic perianal disease; and (4) resolution of symptoms and morphological (endoscopic and histological) features after corticosteroid and 5-ASA therapy. Ultimately, a total of 55 cases of ITB and 42 cases of CD were selected and the endoscopic biopsy specimens before medical therapy were used for this study.

Histopathological examination

Retrieved hematoxylin- and eosin-stained sections from ITB and CD patients were reviewed by two pathologists (Jin XJ and Kim JM). They evaluated the eight histopathologic parameters suggested by Pulimood *et al*[8,9]: size

of granuloma (small: < 200 μm, medium: 200-400 μm, large: > 400 μm), numbers of granulomas per biopsy piece, Langerhans giant cells, caseation necrosis (acellular pink areas of necrosis with karyorrhectic debris), confluent granulomas (merging of the adjacent boundaries of granulomas), discrete granulomas (well defined, majority of epithelioid histiocytes conforming to the shape of the granuloma), ulcers with bands of epithelioid histiocytes (conglomerate bands of epithelioid histiocytes lining the ulcer or ulcer slough), and perigranulomatous lymphoid cuffs (lymphoid aggregates surrounding granuloma). We divided the cases into four groups according to histopathologic parameters: group Ⅰ, showing caseation necrosis; group Ⅱ, showing more than four kinds of histopathologic parameters without caseation necrosis; group Ⅲ showing one to four kinds of histopathologic parameters without caseation necrosis; group Ⅳ, without any histopathologic parameters.

Positive and negative control samples for TB-PCR

Nine acid fast bacilli (AFB) culture-positive samples (3 from colon, 3 from bone, 2 from vertebrae, and 1 from a joint) and ten normal colonic mucosa samples obtained from disease-free resection margins of colectomy specimens resected due to colon cancer were used as the positive and negative controls for the TB-PCR test. All samples were open biopsy or resection specimens, enough in sample size and formalin-fixed and paraffin-embedded. DNA extraction and PCR tests were done according to the manual in-house PCR method and instructions of kits <A> and <B>, respectively.

Polymerase chain reaction

DNA extraction: The paraffin-embedded blocks for all samples used in this study were cut at 50 μm thickness and placed in a microcentrifuge tube. For the clinical sample, we used only one block containing one to eight pieces of intestinal mucosa revealing the most representative features of the disease. To prevent carry-over of DNA contamination, the microtome blade was changed after cutting each sample. For deparaffinizing, we added 1 mL xylene, vortexed vigorously, and centrifuged at 14000 r/min for 3 min at room temperature. The pellet was then washed with 100% ethanol twice and air-dried for 15 min at 37℃. Genomic DNA was extracted according to the manufacturer's protocol.

DNA amplification by PCR and detection: For each commercial kit, PCR was accomplished according to the manufacturer's protocols. Briefly, kit <A> was designed to detect the *IS6110* and *MPB64* genes of *M. tuberculosis* simultaneously. The first round of PCR was performed using 3 μL of genomic DNA in a total volume of 20 μL, in the presence of 1 × TB2 first primer, 3 μL of 8-MOP solution, and 1 × multiple master mix. PCR conditions included 35 cycles of 30 s at 95℃, 30 s at 60℃, and 30 s at 72℃. Nested PCR was performed using 3 μL of the first amplification mixture as the template in the same composition of PCR mixture without primer (TB2 second primer instead of TB2 first primer). PCR conditions included 25 cycles of 30 s at 95℃, 30 s at 62℃, and 30 s at 72℃. PCR product size was 520 base pairs (bp) for the internal control, 260 bp for the first PCR product, and 200 bp for the second PCR product. An internal control was used as a standard for success or failure. Kit <B> was designed to detect only the *IS6110* region of *M. tuberculosis*. The first round of PCR was performed using 4.5 μL of genomic DNA with 15.5 μL of first PCR master mix. PCR conditions included 35 cycles of 45 s at 95℃, 45 s at 68℃, and 30 s at 72℃. Nested PCR was performed using 1.5 μL of the first amplification mixture as the template with second PCR master mix. PCR conditions included 25 cycles of 45 s at 95℃, 45 s at 65℃, and 30 s at 72℃. PCR product size was 374 bp for the first PCR product and 158 bp for the second PCR product.

The in-house PCR method used in this study was designed to detect the *IS6110* region of *M. tuberculosis*. The first round of PCR was performed using 5 μL of genomic DNA in a total volume of 25 μL in the presence of 1 × Ex *Taq* buffer (10 mmol/L Tris-HCl, 50 mmol/L KCl, 2 mmol/L $MgCl_2$), 2 U Ex *Taq* DNA polymerase (TAKARA, Japan), and 10 pmol of each primer (KBN-1: 5'-GGATGGTCGCAGAGATCCBGC-3', KBN-2: 5'-CGATGCCCTCACGGTTCAGG-3'). PCR conditions were as follows: 35 cycles of 30 s at 95℃, 1 min at 60℃, and 1 min at 72℃, followed by a final extension step of 10 min at 72℃. For the second round of PCR, 1 μL of the first amplification mixture was used as the template in a total volume of 25 μL containing 10 pmol of each primer (KBN-3: 5'-GTCAGACGATTCGGAGTGG-3', KBN-4: 5'-TGATGATCGGCGATGAACCG-3'). PCR conditions were as follows: 35 cycles of 30 s at 95℃, 1 min at 60℃, and 1 min at 72℃, followed by a final extension step of 10 min at 72℃. PCR product size was 297 bp and was analyzed by gel electrophoresis on 2% agarose gels stained with ethidium bromide.

Statistical analysis

We used the R version 2.9.2 (A free software environment for statistical computing and graphics, Copyright 2009 The R Foundation for Statistical Computing, ISBN 3-9000051-07-0) for analyzing the histopathologic features and PCR results by χ^2 test and Fisher's exact test and for analyzing the increase of diagnostic sensitivity by Logistic regression analysis. *P* value less than 0.05 was considered statistically significant. The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated.

RESULTS

Clinicopathologic findings of ITB and CD

Out of a total of 97 cases, 55 cases were ITB, and 42 cases were CD. The mean ages of the ITB and CD patients were 39 and 27 years, respectively. The most common site of involvement for ITB was the right colon

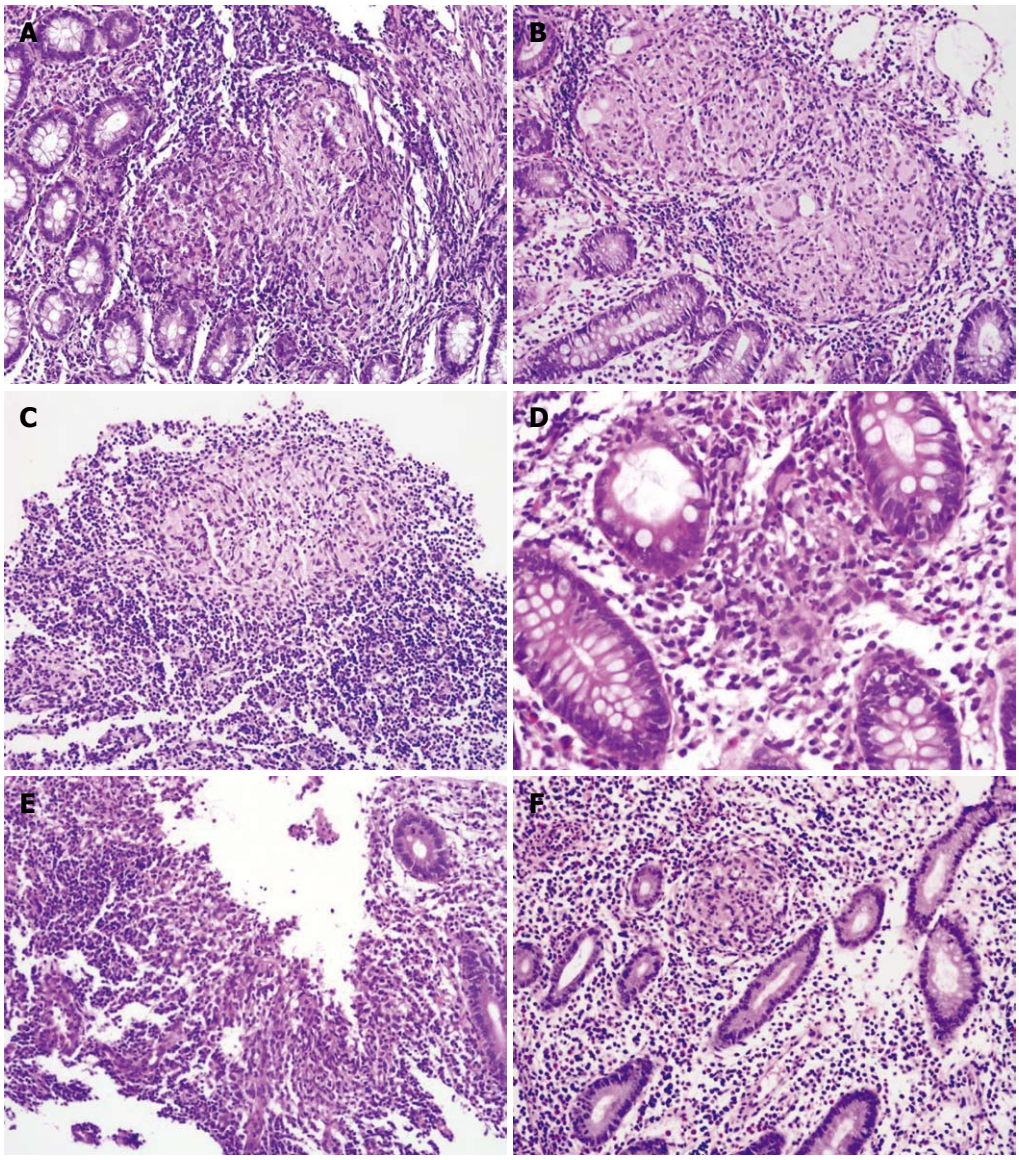

Figure 1 Histopathological parameters of intestinal tuberculosis (ITB) and Crohn's disease (CD). A: Confluent granuloma in ITB; B: Confluent granuloma with caseation necrosis and Langhans giant cells in ITB; C: Granuloma with lymphoid cuff in ITB; D: Vague granuloma in CD; E: Band of epithelioid histiocytes in ulcer base in ITB; F: Small granuloma in CD.

Table 1 Disease location of ITB and CD *n* (%)

Involving site	ITB	CD
Right colon	32 (58.2)	14 (33.3)
Left colon and rectum	4 (7.3)	4 (9.5)
Skip lesion or pancolitis	19 (34.6)	24 (57.1)

ITB: Intestinal tuberculosis; CD: Crohn's disease.

(58.2%), but many of the CD patients showed skip lesion or pancolitis (50.0%) (Table 1).

A summary of the histopathologic features is given in Figure 1 and Table 2. Granulomatous inflammation was seen in 52 cases (94.5%) of ITB and 25 cases (59.5%) of CD. The size and number of granulomas were larger in ITB than in CD ($P = 0.000$). Giant cells ($P = 0.015$), caseation necrosis ($P = 0.003$), confluent granulomas ($P = 0.001$), discrete granulomas ($P = 0.000$), and granuloma with lymphoid cuff ($P = 0.037$) were more frequently associated with ITB. Therefore, these histopathologic features were helpful in differentiating ITB and CD.

When all cases of ITB and CD were divided into four groups according to histopathologic parameters, almost all cases of group Ⅰ and Ⅱ were ITB patients except for one CD patient in group Ⅱ. However, more than half of the ITB patients (52.7%) and nearly all of the CD patients (98%) were in group Ⅲ or group Ⅳ (Table 3). Hence, groups Ⅰ and Ⅱ could be combined to form an "ITB group" although there was one case of CD. Groups Ⅲ and Ⅳ could be combined to form a "confusing group" because differential diagnosis between ITB and CD was difficult based on histopathologic parameters. According to this two-tiered classification, diagnostic sensitivity, specificity, PPV, and NPV were 47.3%, 98%, 96.3%, and 58.6%, respectively.

Table 2 Comparison of histopathologic parameters between ITB and CD *n* (%)

Histologic parameters	Cases		*P* value
	ITB (*n* = 52)	CD (*n* = 26)	
Size of granuloma			0.000
Small (< 200 μm)	6 (11.5)	13 (50.0)	
Medium (200-400 μm)	7 (13.5)	7 (26.9)	
Large (> 400 μm)	39 (75.0)	5 (19.2)	
Granuloma/piece > 1[1]	24 (46.2)	9 (34.6)	0.331
Giant cells	25 (45.5)	5 (19.2)	0.015
Caseation necrosis	14 (26.9)	0 (0.0)	0.003
Confluent granuloma	24 (46.2)	2 (7.8)	0.001
Discrete granuloma	30 (57.7)	3 (11.5)	0.000
Lymphoid cuff	31 (59.6)	9 (34.6)	0.037
Ulcer with histiocytes[2]	17 (30.9)	3 (11.5)	0.056

[1]More than one granuloma per biopsy piece; [2]Ulcer with band of epithelioid histiocytes.

Table 3 Classification of ITB and CD according to histopathologic parameters *n* (%)

Group	ITB (*n* = 55)	CD (*n* = 42)	Re-classification of ITB (*n* = 55)
Ⅰ	14 (25.5)	0 (0.0)	ITB group: 26 (47.3)
Ⅱ	12 (21.8)	1 (2.3)	
Ⅲ	23 (41.8)	15 (35.7)	Confusing group: 29 (52.7)
Ⅳ	6 (10.9)	26 (61.9)	

Group Ⅰ showing caseation necrosis; Group Ⅱ showing more than four kinds of histopathologic parameters without caseation necrosis; Group Ⅲ showing one to four kinds of histopathologic parameters without caseation necrosis; Group Ⅳ without any histopathologic parameters.

TB-PCR in positive and negative control

Among the 9 AFB culture-positive samples, 8 cases were identically TB-PCR positive based on analyses done with kit <A> and kit <B>. However, only 6 cases were TB-PCR positive by the in-house PCR method. Ten normal samples were all negative on three kinds of TB-PCR tests (Table 4).

TB-PCR in ITB and CD

When using kit <A>, 25 samples among 55 ITB cases were PCR positive (sensitivity 45.5%). In contrast, 37 samples among 42 CD cases were PCR negative (specificity 88.1%). When kit <B> was used, 20 samples were PCR positive among the ITB cases (sensitivity 36.4%), and all samples were PCR negative among the CD cases (specificity 100%). Both PCR tests were significantly different between ITB and CD ($P = 0.000$). Figure 2 demonstrates positive bands and negative results of PCR tests using kits <A> and <B>. The sensitivity of the in-house PCR method (5.5%) was much lower than that of either kit (Table 5).

Diagnostic value of TB-PCR in combination with histopathologic parameters

Among the ITB patients, group I showed the highest TB-PCR positivity, which gradually decreased in groups

Table 4 Results of TB-PCR in gold standard

	Positive control (*n* = 9)	Negative control (*n* = 10)	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Kit <A>	8	10	88.9	100	100	90.9
Kit <B>	8	10	88.9	100	100	90.9
In-house	6	10	66.7	100	100	71.4

TB-PCR: Polymerase chain reaction for *Mycobacterium tuberculosis*; PPV: Positive predictive value; NPV: Negative predictive value.

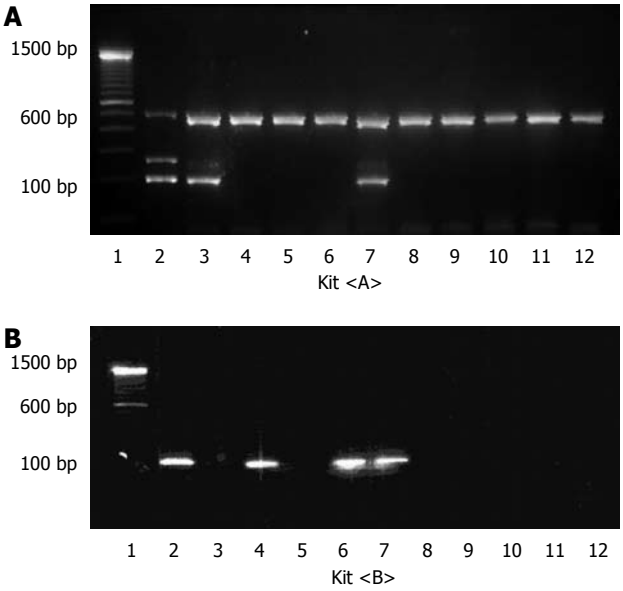

Figure 2 Polymerase chain reaction (PCR) product by kit <A> and kit <B>. A: Number 3 and 7 showing positive result by kit <A>; B: Number 2, 4, 6, 7 showing positive result by kit <B>.

Ⅱ, Ⅲ, and Ⅳ (Table 6). On two-tiered classification, the ITB cases belonging to the "ITB group" showed 57.7% (kit <A>) and 53.8% (kit <B>) TB-PCR positivity. In the "confusing group" there were 10 additional PCR-positive cases among the ITB cases based on kit <A> analysis, and 6 additional PCR-positive cases based on ITB analysis by kit <B>. The PCR positive cases in the "confusing group" of ITB could be reclassified as the "ITB group". The one CD case classified as group Ⅱ by histopathologic evaluation revealed negative TB-PCR. After a combination of histopathologic and PCR analyses with kit <B>, the diagnostic sensitivity of ITB was significantly increased ($P = 0.010$) to 65.5% (Table 7). Although the sensitivity of kit <A> was better than that of kit <B>, the diagnostic usefulness was not validated due to low specifity. The diagnostic sensitivity and specificity of histopathologic findings and adjuvant effect of TB-PCR is summarized in Table 7.

DISCUSSION

A number of reports have documented the characteristics of ITB[15-17] and CD[18-20], and some have also compared the histopathological features. Pulimood *et al*[8,9]

Table 5 Results of TB-PCR in ITB and CD

TB-PCR test	ITB (n = 55)		CD (n = 42)		Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	P value
	+	-	+	-					
Kit <A>	25	30	5	37	45.5	88.1	83.3	55.2	0.000
Kit <B>	20	35	0	42	36.4	100	100	54.5	0.000
In-house	3	52	0	42	5.5	100	100	44.7	0.256

Table 7 Comparison of diagnostic accuracy of ITB before and after combination of histopathology and TB-PCR

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	P value
Histopathology	47.3	100	100	59.2	
Combination with kit <A>	65.5	88.1	87.8	66.1	0.390
Combination with kit <B>	58.2	100	100	64.6	0.010
Combination with in-house PCR	49.1	100	100	60.0	0.320

evaluated several histological parameters in colonoscopic biopsies to distinguish between ITB and CD. They examined characteristics of granuloma such as size, number, confluence, caseation necrosis, location, and presence of microgranulomas, as well as ulceration pattern, focally enhanced colitis, and disruption of submucosa. They reported that all of these characteristics were significantly different between ITB and CD, but other factors, such as architectural alteration, chronic inflammation, and discontinuous inflammation, were not significantly different. In our study, the histopathological features that had been reported as favorable factors for ITB in the literature were also statistically significant in differentiating theses two diseases. More than a half of ITB cases (52.7%) showed less than five kinds of these histopathologic parameters confused with CD microscopically. Therefore, differential diagnosis of ITB and CD based on histopathologic features may be limited.

PCR detection of mycobacteria in histopathological specimens has been introduced as a rapid and useful technique for the diagnosis of pulmonary and extrapulmonary tuberculosis[13,21,22]. *IS6110* was originally described in 1990 as a 1.36 kb insertion sequence with extensive numerical and positional polymorphism, found only in the *M. tuberculosis* complex (MTBC). Many members of the MTBC contain multiple *IS6110* copies[23]. Because there are multiple copies of the *IS6110* insertion sequence in the MTBC, *IS6110* is an attractive target for PCR amplification. However, some MTBC strains do not contain the *IS6110* sequence[24], so false negative results may occur. Past studies have shown that detection of the *IS6110* gene in *M. tuberculosis* has variable sensitivity (30%-90%)[11,25-28] and specificity (60%-100%)[12,13,21,29].

MPB64 is a mycobacterial antigen specific to the *M. tuberculosis* complex. This antigen is secreted from *M. tuberculosis*, *Mycobacterium bovis* (*M. bovis*), and some strains of *M. bovis* BCG during bacterial growth[30,31]. In a study of pleural and meningeal tuberculosis, the sensitivity and specificity of nested-PCR using *MPB64* were 70% and 88%[32]. The study of Singh *et al*[33] used two PCRs targeting *IS6110* and *MPB64* and found that sensitivity is 77.8% better than PCR targeting *IS6110* only (48.2%).

The current study used conventional in-house PCR, which detects the *IS6110* gene sequence, along with two newly developed kits manufactured by <A> and <B>. Kit <A> detects the *MPB64* and *IS6110* genes simultaneously using the duplex nested PCR method, and kit <B> detects the *IS6110* gene sequence using only the nested PCR method. Among 9 positive control cases, 8 cases (88.9%) were PCR positive for both kits. The sensitivity of the in-house PCR test (66.7%) was lower than that of both kits. Ten negative control cases were all negative for three kinds of PCR test. The kits we used showed higher sensitivity and specificity than in-house PCR. The false negative rates of the kits were lower than in-house PCR test.

The PCR test performed on the endoscopic biopsy specimens showed a dramatic drop in sensitivity in both kits, as well as in the in-house method compared to the control samples. False negative results were probably due to paucibacilli. All samples were obtained from endoscopic biopsies, so the tissue samples were small in amount. *M. tuberculosis* would not be distributed evenly in the tissue, furthermore, each case tested for PCR was only a 50 μm thick sample from each paraffin block of endoscopic biopsy. Hence, some sections among the ITB samples might not have contained *M. tuberculosis*. The absence or only a few copies of *IS6110* gene sequence in a proportion of *M. tuberculosis*[34,35] may also bring about a false negative result.

The sensitivity of kit <A> was better than that of kit <B>. Twenty-five cases of ITB (45.5%) were posi-

tive by kit <A>, but 20 cases (36.4%) were positive by kit <B>. This suggests that the combined method could reduce false negativity in the samples without the *IS6110* sequence, as Singh *et al*[33] reported. However, five cases of CD were TB-PCR positive by kit <A>. Therefore, the specificity of kit <A> was not as good as that of kit <B> (100%). The false-positive results on the duplex method might be due to contamination or the influence of gene sequences on each other during the experiments.

The histopathologic findings were very informative in differentiating ITB and CD. However, more than half of all ITB cases (52.7%) and nearly all CD cases fell in the "confusing group". So, in order to increase diagnostic accuracy, it is better to interpret histopathologic features in conjunction with PCR results. Because of the high specificity of TB-PCR, we could ascertain ITB if the TB-PCR test was positive. The TB-PCR test could detect *M. tuberculosis* in 20.7%-34.5% of these gray zone ITB cases, and the diagnostic sensitivity of ITB was significantly increased ($P = 0.010$) from 47.3% to 58.2% with kit <B>, but the low sensitivity of the test in small biopsy pieces was problematic. Sufficient tissue sampling might improve results. Also, it is necessary to check the clinical features and endoscopic findings first.

In conclusion, kit <A> and kit <B> TB-PCR were more sensitive in detecting *M. tuberculosis* in endoscopic biopsy specimens when compared to the in-house PCR method. The TB-PCR test with kit <B> targeting *IS6100* combined with histopathologic examination appears to be a helpful technique in differentiating ITB and CD in endoscopic biopsy samples.

COMMENTS

Background

The incidence of intestinal tuberculosis (ITB) is increasing with resurgence of tuberculosis (TB). Because of similar clinical, endoscopic, radiological, and microscopic findings the differential diagnosis of ITB with Crohn's diseases (CD) is very difficult. Similar histopathological features of chronic colitis are seen in both ITB and CD but with some delicate differences. Recent studies have shown that polymerase chain reaction for *Mycobacterium tuberculosis* (TB-PCR) is useful for diagnosis of TB.

Research frontiers

Some characteristics of individual granulomas and some other histopathological features might be helpful for differential diagnosis between ITB and CD and TB-PCR targeting *IS6100* and/or *MPB64* is sensitive and specific for diagnosis of TB. But which and how many kinds of characteristic histopathological features may be helpful for differential diagnosis and whether combination with TB-PCR targeting *IS6100* and/or *MPB64* in endoscopic biopsy specimen may improve differential diagnosis are not well known.

Innovations and breakthroughs

In this study, the authors found that caseation necrosis and more than four kinds of histopathological features in an endoscopic biopsy specimen are very informative in differential diagnosis of ITB and CD and these histopathological features combined with TB-PCR can improve the differential diagnosis. Otherwise the commercial kits are more sensitive and specific in TB-PCR in endoscopic biopsy specimen than in-house TB-PCR.

Applications

By selecting and observing endoscopic biopsy specimens from patients of ITB and CD and comparing TB-PCR using commercial kits and in-house TB-PCR, this study is beneficial for the differential diagnosis between ITB and CD practically, and provides initial insight into a method of diagnosis of TB.

Peer review

This paper is very nicely written and makes a good contribution.

Abstract

AIM: To establish a model for prognosis assessment of extranodal follicular dendritic cell (FDC) sarcoma.

METHODS: Nine lesions were examined by routine and molecular approaches. Clinicopathological factors from the new cases and 97 reported cases were analyzed for their prognostic values.

RESULTS: The current lesions were found in five male and four female patients, located mainly in the head and neck area and averaging 7.2 cm in size. Six patients had recurrence or metastasis and three remained free of disease. The 106 patients (male/female ratio, 1.1:1) were aged from 9 to 82 years (median, 44 years). The tumor sizes ranged from 1.5 to 21 cm (mean, 7.4 cm). Abdominal/pelvic region was affected most frequently (43%). Surgical resection was performed in 100 patients, followed by radiation and/or chemotherapy in 35 of them. Follow-up data were available in 91 cases, covering a period of 3-324 mo (mean, 27 mo; median, 19 mo). Of the informative cases, 38 (42%) had recurrence or metastasis, and 12 (13%) died of the disease. These tumors were classified histologically into low- and high-grade lesions. A size $\geqslant$ 5 cm (P = 0.003), high-grade histology (P = 0.046) and a mitotic count $\geqslant$ 5/10 HPF (P = 0.013) were associated with tumor recurrence. The lesions were defined as low-, intermediate- and high-risk tumors, and their recurrence rates were 16%, 46% and 73%, and their mortality rates 0%, 4% and 45%, respectively.

CONCLUSION: Extranodal FDC tumors behave like soft tissue sarcomas. Their clinical outcomes are variable and can be evaluated according to their sizes and grades.

INTRODUCTION

Follicular dendritic cell (FDC) sarcoma was described by Monda *et al*[1] in 1986. It is considered to be derived from FDC, whose cell type normally forms a tight meshwork in the primary and secondary lymphoid follicles and participates in the immune system by interacting with B or T lymphocytes[2]. Epstein-Barr virus (EBV) infection was demonstrated in majority of the hepatic and splenic lesions and its causative effect has been proposed for the pathogenesis of the lesion[3-9], but the association is not evident in most of the tumors from other sites[10-13]. Majority of the tumors were found in lymph nodes. However, about one-third of the lesions were identified in extranodal sites. It was considered that extranodal FDC sarcoma occurred preferentially in the head and neck area[14].

FDC sarcoma is usually regarded as an indolent tumor with a tendency of local recurrence but a low risk of metastasis, behaving like a low-grade soft tissue sarcoma[2,15]. However, Perez-Ordonez *et al*[16] considered this tumor more aggressive through their observation of 13 cases. Because of the rarity of the tumor, assessment of its prognosis remains difficult, though intra-abdominal location, a high mitotic count (≥ 5/10 HPF), coagulative necrosis and marked cellular atypia were proposed to be predictors of an unfavorable outcome[3]. With more cases encountered in our pathological practice and reported from literatures, various morphologic and clinical representations were noticed. Clearly, histological grade of this malignancy remains to be defined and a model is needed to evaluate the recurrence risk of individual tumors within this category.

In this study, we presented our experience in nine cases of FDC sarcoma from northern China. In addition, clinicopathological features and corresponding data extracted from 97 reported cases were analyzed, with special respect to prognosis assessment of this disease.

MATERIALS AND METHODS

Samples and histological examination

As listed in Table 1, the tissue specimens were resected from nine patients in three medical centers, including the Fourth Military Medical University Tangdu Hospital in Xi'an (Cases 1 and 2), Chinese Academy of Medical Sciences Cancer Hospital in Beijing (Cases 3-6, 8 and 9) and the First Affiliated Hospital of Inner Mongolia Medical College in Huhehot (Case 7). These patients were admitted for a solid occupation in head and neck areas (n = 6), and thoracic and abdominal cavities (n = 3) from 2002 to 2009. Cases 1 and 2 had been described in a brief report[17], and follow-up data were complemented in the current study.

The formalin-fixed, paraffin-embedded tissue blocks were retrieved from the files. Sections of 4 μm in thickness were prepared and stained with hematoxylin and eosin (HE). Three pathologists (Su Q, Yang HY and Li L) reviewed the slides independently, and the diagnosis was confirmed by their histological and immunohistochemical phenotypes. As described previously[2], whorl, storiform and fascicular arrangements of spindle tumor cells were regarded as architectural features for typical lesions, while epithelioid and pleomorphic patterns were considered anaplastic phenotypes in this study. Other morphologic parameters, including mitotic activity, coagulative necrosis, nuclear atypia, distribution of infiltrating small lymphocytes and tumor sites, were also assessed. In addition, we also evaluated proportions of the typical tumor components, as described above, in each lesion.

Immunohistochemistry

Immunohistochemical reactions were performed on paraffin sections following deparaffinization, rehydration and antigen retrieval. The antigen retrieval was performed by heating in citrate (pH 6.0) or ethylene-diamine-tetraacetic acid (EDTA) buffer (pH 9.0; Table 2). In addition to routine markers for tumor diagnosis, such as pan-cytokeratins (CKs; AE1/AE3), epithelial membranous antigen (EMA), vimentin, desmin and smooth muscle-type actin (SMA), a panel of antibodies were applied to demonstrate histiocytic and dendritic cell linage differentiation, including those against CD68, S100 protein, CD21, CD23, CD35, CD1a and podoplanin (D2-40). Ki-67 antigen was detected to show proliferative activity of each lesion, and p53 protein accumulation was demonstrated by reaction with the antibody DO-7. After incubation with primary antibodies at room temperature for 1 h, the antigen-antibody reaction was demonstrated by a horseradish peroxidase (HRP)-labeled secondary antibody (EnVision™ Detection System, Dako A/S, Glostrup, Denmark) at room temperature for 15 min and visualized in a solution containing 0.5 mg/mL 3,3'-diaminobenzidine (DAB) and 0.01% hydrogen peroxide. Finally, the sections were counterstained slightly with hematoxylin and mounted in resin.

The expression levels were evaluated semiquantitatively according to the reaction intensities and percentages of immunoreactive cells, and expressed as strong (3+), moderate (2+), weak (+) and negative (-). Ki-67 antigen expression levels were assessed based on the number of positive cells/1000 nucleated tumor cells from randomly selected 5 high-power fields, and expressed as Ki-67 antigen-labeling indices (Ki-67-LI) in percentages. The p53 protein expression levels were evaluated by percentages of positive cells as described previously[18] and expressed as high (3+, > 30%), moderate (2+, 5%-30%), low (1+, < 5%) and absent (-, 0%).

In situ hybridization

In situ hybridization was performed in seven cases to demonstrate EBV-encoded RNA (EBER) molecules using a detection kit (Triplex International Biosciences Co. Ltd., Fuzhou, China) according to instructions of the manufacturer. Briefly, sections were treated with proteinase K following deparaffinization and rehydration. After denaturation for 90 min at 55℃, the sections were incubated with a digoxin-labeled DNA probe overnight at 37℃, and washed with phosphate-buffered saline. The hybridization signals were demonstrated by consecutive reactions with

Antibody suppliers: Dako, Glostrup, Denmark; Invitrogen Corporation, Carlsbad, CA, USA; NeoMarkers Inc., Fremont, CA, USA; Novacastro Laboratories Ltd., Newcastle upon Tyne, UK; Zeta Corporation, Sierra Madre, CA; Zymed Laboratories, San Diego, CA, USA. EMA: Epithelial membrane antigen; MAb: Mouse monoclonal antibody; PAb: Polyclonal antibody; SMA: Smooth muscle-type actin; MW-citrate: Microwaving for 8 min in citrate buffer (pH 6.0); AC-EDTA: Autoclaving for 100 s in EDTA buffer (pH 9.0).

a mouse monoclonal antibody against digoxin and the polymerized HRP-labeled anti-mouse immunoglobulin G, and visualized by incubation in a solution containing DAB and hydrogen peroxidase. Finally, the slides were counterstained slightly with hematoxylin and mounted with resin. A case of Hodgkin lymphoma, known to be positive for EBER, was used as a positive control. Yellow or brown staining of tumor cell nuclei was considered positive.

Amplification and sequencing of P53 gene

As most of the documented mutations of *P53* gene occur in its exons 5-8[19,20], these regions were examined for mutations by nested (for exons 6 and 7) or semi-nested polymerase-chain reaction (PCR; for exons 5 and 8). The primers used were adopted from literatures[21,22]. Their sequences were as follows: exon5s, 5'-TCTGTCTCCTTCCTCTTCCTA-3'; exon5as, 5'-AACCAGCCCTGTCGTCTCT-3'; exon6s, 5'-TTGCTCTTAGGTCTGGCCCC-3'; exon6as, 5'-CAGACCTCAGGCGGCTCATA-3'; exon7s, 5'-TTGCTCTTAGGTCTGGCCCC-3'; exon7as, 5'-GGGTCAGCGGCAAGCAGAGG-3'; exon8s, 5'-GACAAGGGTGGTTGGGAGTAGATG-3'; exon8as, 5'-GCAAGGAAAGGTGATAAAAGTGAA-3'. Selected tumor tissues were collected from serial paraffin sections of 10 μm in thickness. Following deparaffinization and rehydration, the tissues were digested by incubation with proteinase K (20 mg/mL) at 56℃ for 72 h. Genomic DNA was extracted with a kit (QIAamp DNA Mini Kit, Qiagen GmbH, Hiden, Germany) following instructions of the manufacturer. Primer pairs used for the first-round amplification of exons 5, 6, 7 and 8 were exon5s/exon6as, exon5s/exon7as, exon6s/exon8as and exon7s/exon8as, respectively. The reactions were in a mixture of 10 μL containing 100 ng of DNA templates, 0.8 μL of deoxynucleotide triphosphate (2.5 mmol/L each), 1 μL of 1 μmol/L sense and antisense primers each, 1 μL 10 × buffer (100 mmol/L Tris-HCl, pH 8.3, containing 500 mmol/L KCl and 20 mmol/L $MgCl_2$) and 0.5 U of *Taq* DNA polymerase (Takara Biotechnology Co., Ltd., Dalian, China). Amplification was conducted for 35 cycles (94℃, 40 s; 55℃, 40 s; 72℃, 40 s for exons 5 and 7; 1 min for exons 6 and 8) following the initial denaturation at 94℃ for 5 min. The final elongation was at 72℃ for 10 min. The second-round PCR was performed in a mixture of 50 μL containing 3 μL of products of the first-round reaction and 1 μL of 5 μmol/L sense and antisense inner premiers each. Primer pairs used for amplifying exons 5, 6, 7 and 8 were exon5s/5as, exon6s/6sa, exon7s/7as and exon8s/8as, respectively. The cycling conditions were the same as the first-round reaction. Amplification efficiency and specificity were visualized by electrophoresis on an agarose gel (2%), and the products of exons 5, 6, 7 and 8 migrated at positions of 196, 81, 234 and 277 bp, respectively. The products were subjected to direct sequencing using an automatic system (Prism 3100 Genetic Analyzer, Applied Biosystems, Foster, CA, USA) as described previously[22,23]. The sequences obtained were compared with those from Genbank (www.gdb.org).

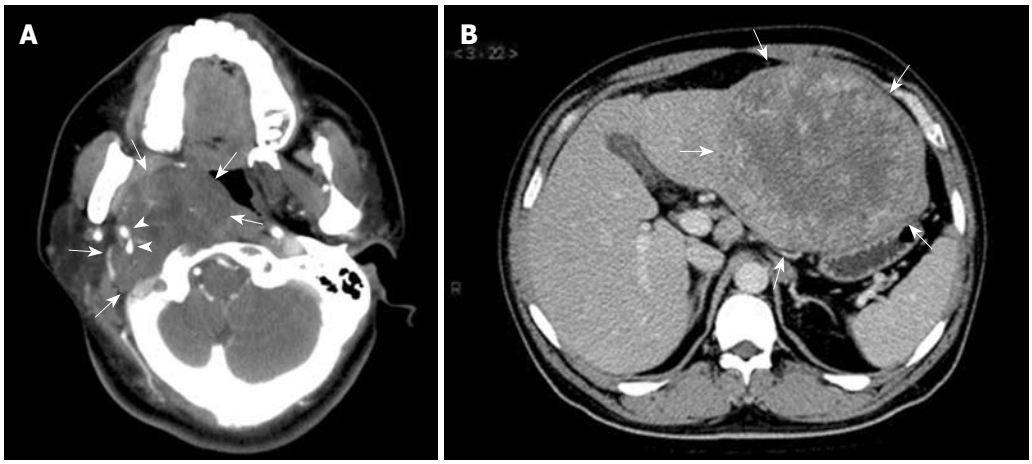

Figure 1 Radiological features of extranodal follicular dendritic cell (FDC) sarcoma shown by computed tomographic scan. A: Case 8, a tumor (arrows) at the right parapharyngeal space showing soft tissue-like density and an expansive growth pattern, with the internal and external carotid arteries (arrowheads) engulfed; B: Case 6, a well-circumscribed mass (arrows) at the left lobe of liver, showing irregular enhancement at its periphery.

Literature review

Search of literatures was performed using MEDLINE on PubMed (www.ncbi.nlm.nih.gov/pubmed) with the terms "follicular dendritic cell tumor" or "follicular dendritic cell sarcoma" combined with "extranodal". Articles published in Chinese journals were found by searches on Wanfangdata (www.wanfangdata.com.cn). References of the collected articles were also reviewed to identify other relevant publications. Efforts were made to identify cases that were reported more than once in different settings and only one entry with the most updated information was included for such cases. Nodal tumors were not included in this study.

Statistical analysis

Statistical analyses were carried out using the Software Packages for Social Science 13.0 for Windows (SPSS, Inc, Chicago, IL, USA). Survival of patients was assessed using the data obtained from both the current study and the literatures. Overall and recurrence-free survival rates were calculated and analyzed using the Kaplan-Meier method. Associations of different pathological factors with clinical outcomes were described by the Chi-square test. Fisher's exact test was also used when necessary. *P* values below 0.05 were considered significant.

RESULTS

Current cases

Ages of the nine patients (five men and four women) ranged from 23 to 63 years (median, 36 years). A local mass was the primary complaint in eight cases (Figure 1), and a sore throat was the first symptom in one patient (Case 2). Sizes of the tumors ranged from 2.0 to 15.0 cm as measured by the longitudinal dimension, averaging 7.2 cm. A diagnosis of FDC sarcoma was made in four of the nine cases following pathologic examination of the resected specimens. For Cases 1, 2, 3, 5 and 7, the resected lesions were misdiagnosed as granulomatous inflammation suspicious of tuberculosis, nasopharyngeal carcinoma (NPC), primitive neuroectodermal tumor (PNET), malignant peripheral nerve sheath tumor (MPNST) and malignant gastrointestinal stromal tumor (GIST), respectively. The diagnosis of FDC sarcoma was established by re-examination and immunohistochemistry with the delayed periods ranging from one to 66 mo. Their clinicopathological features are listed in Table 1. No precursor lesions were recorded in any of them.

Table 3 Histological features of low- and high-grade FDC sarcomas

Parameters	Low-grade phenotypes	High-grade phenotypes
Architectures	Nodular patterns in whorl, storiform and fascicular arrangement	Diffuse and sheet-like patterns
Cellular features	Spindle or blunt cells with mild nuclear atypia and a small nucleolus in > 90% of area	Epithelioid or pleomorphic cells with marked nuclear atypia and large nucleoli
Mitotic counts	< 5/10 HPF	⩾ 5/10 HPF
Ki-67-LI	< 10%	⩾ 10%
Necrosis	Absent	Frequently present
Lymphocyte infiltration	Sporadic and throughout the lesion	Focal or regional

Typically, the lesions were composed of spindle and ovoid tumor cells arranged in whorl, fascicular and storiform patterns, showing mild nuclear atypia and sparkled with small lymphocytes (Figure 2). Of the nine tumors, three (Cases 1, 5 and 6) were composed uniformly of the typical components, and one (Case 3) showed typical components in > 90% of the area and epithelioid appearance in small foci (Figure 3A). In the remaining five cases, large areas of epithelioid (Cases 2 and 8) and pleomorphic tumor cell components (Cases 4, 7-9), arranged in a diffuse or sheet-like pattern and with moderate to marked nuclear atypia, were also identified (Figure 3B-D). Sporadic small lymphocytes were present throughout tumor tissues in all the four typical cases (Figure 2), and this feature was less prominent (Figure 3B) or even absent (Figure 3C and D) in the rest five lesions. Focal coagulative necrosis was identified in six cases (Cases 2, 3, 5-8). The hepatic lesion (Case 6)

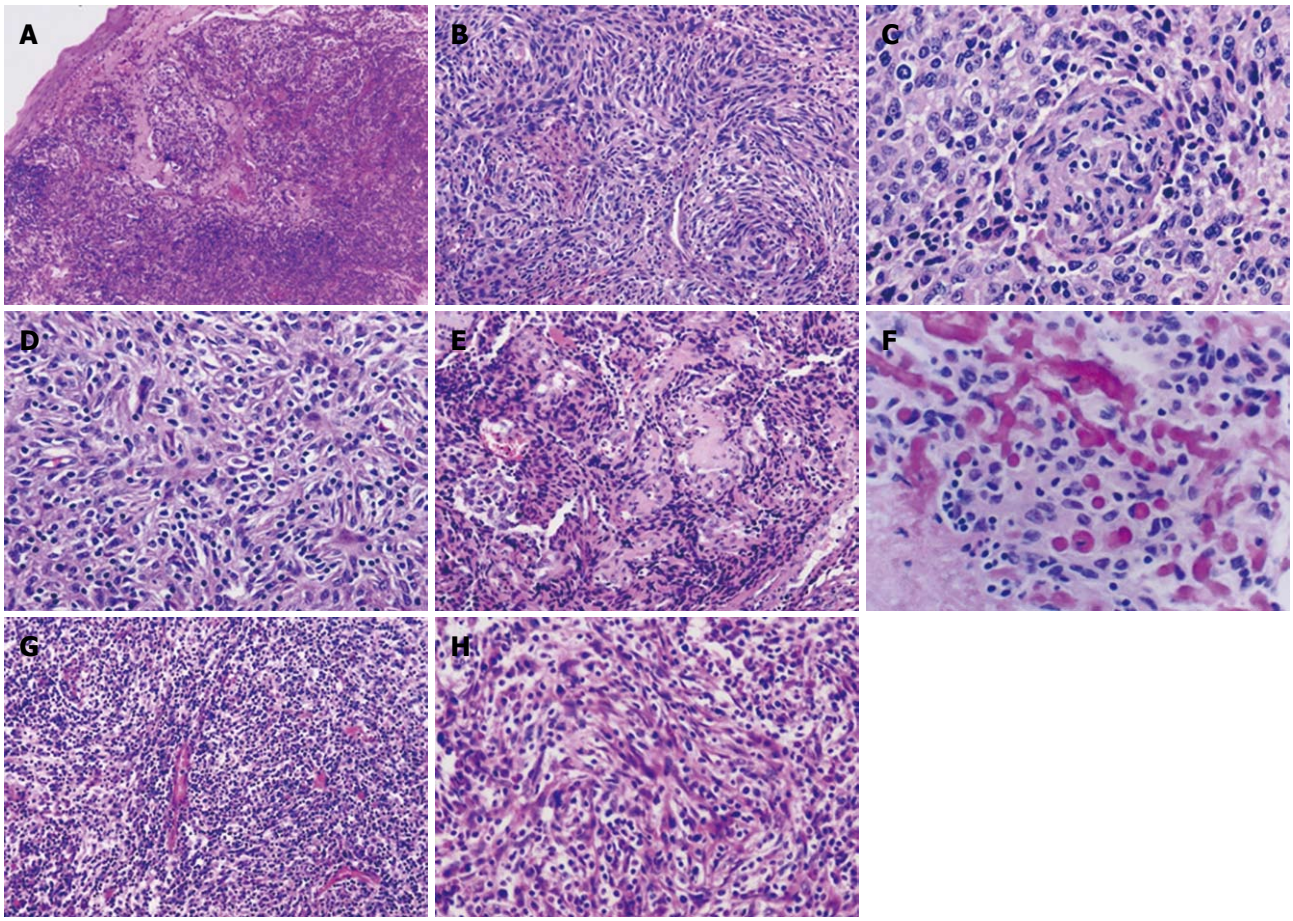

Figure 2 Typical features of follicular dendritic cell sarcoma of the conventional (A-F) and inflammatory pseudotumor-like types (G and H). Spindle and ovoid tumor cells, frequently growing in nodules as in Case 1 (A), arrange in whorl (Case 3, B and C) and storiform (Case 3, D) and fascicular patterns (Case 6, H), with sprinkling small lymphocytes throughout the former type of lesions and numerous plasma cells and lymphocytes in the latter. Perivascular sclerosis was noted in Case 3 (E), with foci of osteoid matrix deposition resembling osteosarcoma (F). HE: A, × 40; B, E and G, × 100; C, D, F and H, × 200.

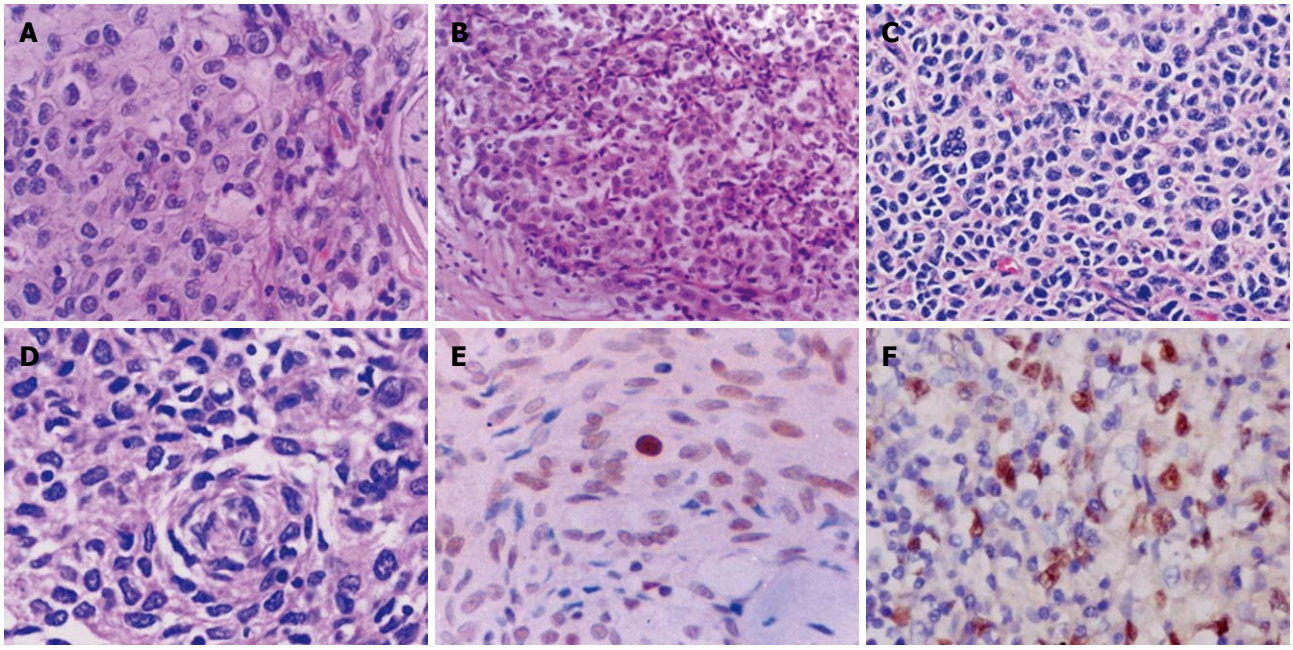

Figure 3 Atypical morphology of FDC sarcoma (A-D) and expression of p53 protein (E) and Epstein-Barr virus-encoded RNA (EBER) (F) in tumor cells. A-D: Epithelioid (A and B) and pleomorphic tumor cells (C and D) are arranged in a sheet-like or diffuse pattern. Lymphocyte infiltration is less prominent (A and B) or absent (C and D) in these areas. HE: A, C and D, × 400; B, × 200; E: Nuclear immunoreactivity for p53 protein in majority of tumor cells. S-P, × 400; F: *In situ* hybridization signal for EBER in tumor cells, × 400.

Table 4 Expression of lineage-specific and kinetic-associated molecules and EBV-encoded RNA (EBER) in nine FDC sarcomas (Cases 1-9)

Cases	CK	EMA	Vimentin	CD45	CD21	CD23	CD35	Podoplanin	CD68	S-100 protein	p53 protein[1]	Ki-67-LI (%)	EBER
1	-	1+	3+	-	3+	NT	1+	NT	NT	NT	3+	4	NT
2	-	-	NT	-	2+	NT	2+	NT	NT	-	2+	15	NT
3	-	1+	2+	-	2+	3+	-	3+	NT	-	2+	1	-
4	-	-	3+	-	3+	2+	2+	-	-	1+	2+	8	-
5	-	-	3+	-	2+	2+	3+	2+	1+	2+	2+	15	-
6	-	-	NT	-	1+	2+	-	-	1+	1+	-	10	+
7	-	-	2+	-	1+	3+	3+	-	-	-	2+	40	-
8	-	-	1+	-	3+	2+	-	2+	2+	1+	2+	20	-
9	-	-	2+	-	1+	2+	1+	-	-	-	2+	35	-

[1]Evaluated by the percentages of positive tumor cells, although majority of the positive cells showing weak nuclear immunoreactivity. Immunoreactivities expressed as strong (3+), moderate (2+), weak (1+) and negative (-); NT: Not tested.

was composed of spindle cells with mild nuclear atypia and numerous inflammatory cells including plasma cells, resembling an inflammatory pseudotumor (Figure 2G and H). In addition, neutrophils infiltration was observed in two lesions (Cases 3 and 8). In some tumor areas (Case 3), vascular proliferation was prominent with perivascular sclerosis (Figure 2E) and focal deposition of osteoid matrix mimicking osteosarcoma (Figure 2F).

As described above, the histology varies greatly among the lesions. It is conceivable to predict clinical outcomes using pathological parameters. According to our own data and proposals by other authors[3], we defined the criteria for low- and high-grade FDC sarcomas using six parameters. As shown in Table 3, the former four were found to be decisive and regarded as major factors for the grading. The lesions with typical architectural and cellular phenotypes, mitotic counts below 5/10 HPF and Ki-67-LI below 10%, as in Cases 1, 3, 5 and 6, were classified as low-grade tumors, and those with anaplastic morphology, mitotic counts up to 5/10 HPF and/or Ki-67-LI up to 10%, as in Cases 2, 4, 7-9, as high-grade tumors. The rest two parameters, including necrosis and loss or reduction of infiltrating lymphocytes, were found to be useful adjuvant factors, but not prerequisites for establishing a diagnosis of the high-grade lesion.

As listed in Table 4, all of the nine lesions were positive for vimentin and negative for CK and CD45. Weak immunoreactivity for EMA was observed in two cases. A diagnosis of FDC sarcoma was established by its immunohistochemical phenotypes including positivity for CD21 (9/9, 100%), CD23 (7/7, 100%) and CD35 (6/9, 67%). Podoplanin was detected in three (43%) of the seven cases. CD68 and S100 protein were detected in about half of the lesions, but their expression levels were low to moderate. Nuclear accumulation of p53 protein, albeit at relatively low levels, was observed in most of the tumor cells in eight (89%) of the nine lesions (Figure 3E). Amplification and sequencing were successful for *P53* exons 5-8 in one lesion (Case 9), and we failed to show any mutation. Ki-67-LI in these lesions was quite variable, ranging from 1% to 40%. *In situ* hybridization was performed in seven of the lesions for EBER, with positive signals demonstrated only in the hepatic lesion (Case 6, Figure 3F).

As the initial treatment, surgery was performed for all of the lesions, with the tumor masses completely removed in seven cases. In Cases 1 and 8, complete resection was not fulfilled because of the involvement of the internal carotid artery. Adjuvant treatment was given to six of the patients (Cases 1, 3-5, 8 and 9) after the operation. Radiation was administered in all the cases and chemotherapy in three cases (Cases 3, 5 and 8). The remaining three patients (Cases 2, 6 and 7) rejected any adjuvant treatment. Follow-up was carried out in all the cases for a period of 12-86 mo, with a median of 27 mo. As shown in Table 1, seven (78%) patients remained alive, four of them had recurrence or metastasis and three were alive without event, and two (22%) died of the tumor recurrence. Of the six cases with events, two recurred locally and four had distant metastases, with a disease-free period below 3 years.

Clinicopathologic features of extranodal FDC sarcomas

Data of 106 extranodal FDC sarcomas, including nine new cases (Table 1) and 97 from literatures (Table 5), were extracted and reviewed carefully. Of the patients, 56 were men and 50 were women, with a ratio of 1.1:1. Ages of the patients ranged from 9 to 82 years at diagnosis, with their mean being 46 years and median being 44 years. The tumors were identified at different anatomic regions. The abdominal and pelvic region was affected in 46 cases (43%), including 14 in the liver, 13 in abdominal/pelvic soft tissues, five in the spleen, and 14 at other organs including pancreas (n = 3), stomach (n = 3), colon and rectum (n = 3), appendix (n = 2), ampulla of Vater (n = 1), small intestine (n = 1) and adrenal (n = 1). Of the five splenic cases, two also showed liver involvement. These hepatic lesions were regarded as metastasis in this study. Head and neck were another common region for FDC sarcoma (38/106, 36%), with tonsils and parapharyngeal space affected most frequently. Fourteen (13%) of the lesions were identified from thoracic cavity, of which nine were located at mediastinum, three at lung, one at pleura and one at the chest wall. The less frequent sites included breast (n = 3), soft tissues at thigh (n = 2), dura mater (n = 1), groin (n = 1) and skin (n = 1). Tumor sizes ranged from 1.5 to 21 cm as described in longitudinal dimensions, with a mean of 7.4 cm. A broad spectrum of histological

LN: Lymph node; NA: Not available; Prog: Disease progression.

phenotypes were described, while the most helpful diagnostic features were the typical arrangement of spindle and ovoid tumor cells with eosinophilic cytoplasm, indistinct cytoplasmic borders and syncytial appearance, and presence of small lymphocytes in the tumor.

Morphologic information, indicative of the architectural and cellular anaplasia, was collected from the articles and re-evaluated carefully. Of the 63 informative cases, 37 (59%) were described as lesions with mild atypia, and 26 (41%) with moderate to severe cytological atypia throughout or in a certain area of the tumor. In the current study, these two groups were classified into low-grade and high-grade lesions, respectively. All of the tumors occurring in the liver resembled an inflammatory pseudotumor in morphology. Five of the eight informative cases were divided into low-grade group, and the other three into high-grade group due to identification of anaplastic components. Coagulative necrosis was recorded in 29 (45%) of the 64 informative cases. Mitotic counts were provided in 61 cases, with 31 (51%) up to 5/10 HPF. Ki-67-LI was calculated in 20 lesions, with 14 (70%) up to 10%. Preoperative tumor spreading was identified in 15 (23%) of the 66 informative cases through pathological examination of the resected samples, including local lymph node involvement in 11, distant metastasis to liver or peritoneal dissemination in three, and both nodal involvement and peritoneal spreading in one.

Management and clinical outcomes

One hundred and four patients received therapeutic procedures and two rejected any treatment. Of the patients, 100 (94%) were treated surgically to remove the tumor. Adjuvant treatment was administered in 35 cases, including radiation in 20, chemotherapy in 10 and both procedures in five. Chemotherapy was performed in most of the cases based on CHOP regimen including cyclophosphamide, adriamycin, vincristine and prednisone.

Follow-up data were available in 91 cases. The observation periods ranged from 3 to 324 mo, with a mean and a median of 27 and 19 mo, respectively. Overall, 38 patients (42%) had local recurrence and/or distant metastasis during the adjuvant treatment or surveillance period, with the events occurring within 36 mo in most (33/37, 89%) of the cases. Local recurrence occurred in 21 patients (23%) at a median of 12 mo after surgical removal (range, 3-31 mo). Distant metastases occurred in 19 patients (21%) at a median of 14 mo after operation (range, 4-324 mo). Metastatic sites included lung (n = 9), liver (n = 6), lymph node (n = 5), bone (n = 1), thorax (n = 1), ovary (n = 1) and kidney (n = 1). At the last follow-up, 12 patients (13%) died of the tumor, 25 (27%) were alive with disease, and 54 (59%) were alive with no evidence of disease. The 2-year and 5-year overall survival rates for the entire group were 82% and 79%, and their 2-year and 5-year disease-free survival rates were 57% and 32%, respectively (Figure 4).

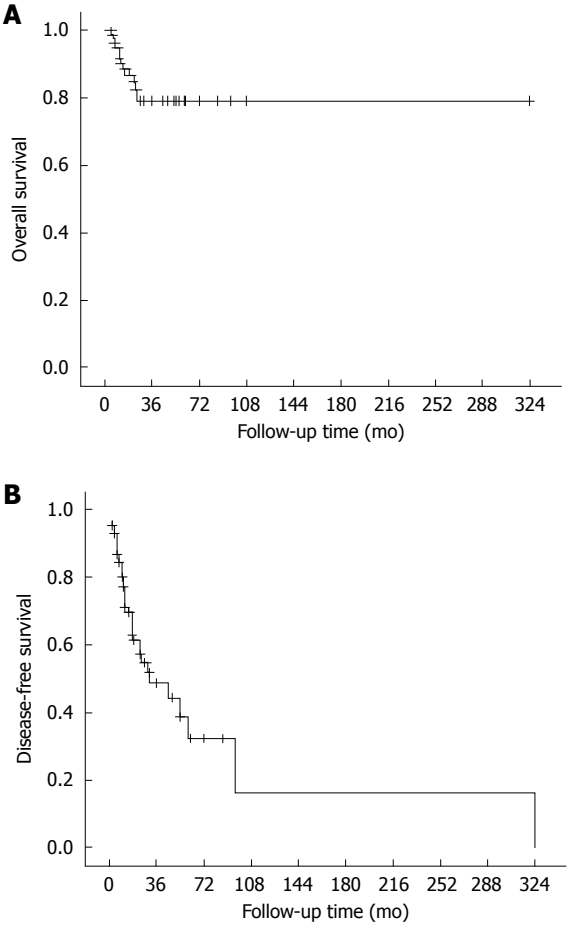

Figure 4 Overall (A) and disease-free survival curves (B) of FDC sarcoma. The results are based on follow-up data of 91 informative cases.

Prognostic factors

Associations between nine clinicopathological factors and recurrence risk were studied, and the results are summarized in Table 6. Of the 60 informative lesions, 25 (42%) were smaller than 5 cm and 34 (58%) were up to 5 cm in their longitudinal dimensions. Four (16%) of the smaller lesions relapsed (two with local recurrence and two with distant metastasis) and 19 (56%) of the larger lesions relapsed (nine with local recurrence and 10 with metastasis). The recurrence rate was markedly elevated with the increase of tumor size ($P = 0.003$). In addition, a mortality rate of 17% was observed for cases with the larger lesions, and none of the patients with smaller lesions died of the disease ($P = 0.036$).

For most of the lesions, as listed in Table 5, histological grades were assessed mainly according to descriptions on architectural features and cellular atypia from respective literatures. For this reason, tumor necrosis, mitotic activity and Ki-67-LI were evaluated separately in this study. Of the 63 informative cases, 37 (59%) were evaluated as low-grade and 26 (41%) as high-grade lesions. Twelve (32%) of the low-grade lesions relapsed (seven with local recurrence, four with metastasis and one with both local recurrence and metastasis) and 15 (58%) of the high-grade lesions relapsed (seven with local recurrence, seven with metastasis and one with both local recurrence and metastasis). The recurrence rate was higher in the latter group than in the former ($P = 0.046$). In addition, the high-grade lesions resulted in death in nine (35%) of the cases, while only one (3%) of the patients with low-grade lesions died of the disease, the mortality rate being closely associated with tumor grade ($P = 0.001$). Eighteen (58%) of the 31 lesions with a mitotic count ≥ 5/10 HPF relapsed, the frequency being higher than those with a count < 5/10 HPF (8/30, 27%, $P = 0.013$). The mortality rate (7/31, 23%) was also higher in the former group than in the latter (0/30, $P = 0.011$). According to the limited number of informative cases, increased Ki-67-LI (≥ 10%) appeared to indicate an unfavorable clinical outcome, but its impact failed to reach statistical significance ($P = 0.628$). The patients younger than 50 years tended to develop tumor recurrence more frequently (51%) than those over 50 years of age (31%), but without statistically significant difference ($P = 0.072$). Other factors, including gender, necrosis and therapeutic procedures following surgery, were not related to clinical outcomes ($P > 0.05$).

Table 6 Associations between clinicopathological parameters and recurrence risk in patients with extranodal FDC sarcoma

Pathologic parameters	Recurrence frequencies (%)	*P* values
Age (yr)		
< 50	26/51 (51)	0.072
≥ 50	11/35 (31)	
Gender		
Male	15/40 (38)	0.290
Female	22/46 (48)	
Size (cm)		
< 5	4/25 (16)	0.003
≥ 5	19/34 (56)	
Histological grades		
Low	12/37 (32)	0.046
High	15/26 (58)	
Mitotic counts		
< 5/10 HPF	8/30 (27)	0.013
≥ 5/10 HPF	18/31 (58)	
Ki-67-LI		
< 10%	2/6 (25)	0.628
≥ 10%	8/14 (57)	
Necrosis		
Absent	17/35 (49)	0.307
Present	13/29 (45)

Surgery alone	22/52 (42)	0.590
Surgery + adjuvant therapy	15/31 (48)	
Sites		
Abdominal/pelvic	18/37 (49)	0.372
Other sites	20/53 (38)	

The associations of tumor size, histological grade and mitoactivity with overall and disease-free survival are described in Figure 5. Among them, tumor size and histological grade were the most important factors, respectively, for tumor recurrence (Figure 5B) and disease-associated death (Figure 5C). Thus, a model was established for the recurrence risk assessment by combining the former two parameters. Recurrence rates of lesions smaller than 5 cm, the larger lesions (≥ 5 cm) with low-grade histology and those with high-grade histology were 16% (4/25), 46%

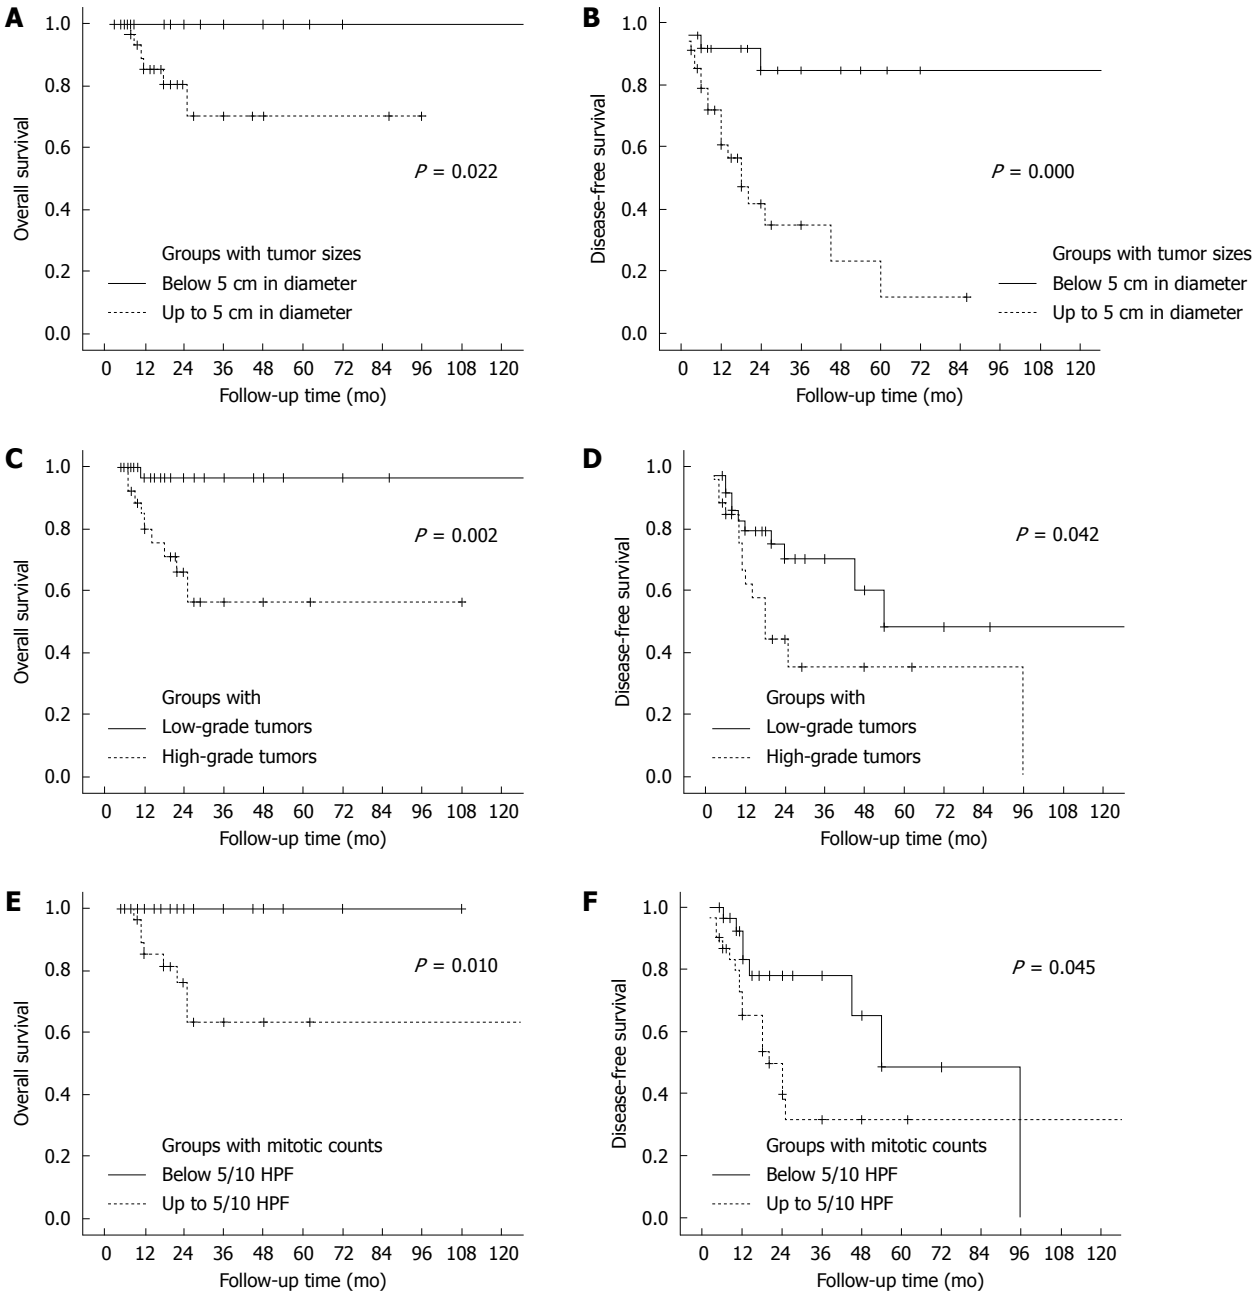

Figure 5 Overall (A, C and E) and disease-free survival curves (B, D and F) of patients with FDC sarcoma, showing data of 120 mo.

(11/24) and 73% (8/11), respectively, their difference being significant ($P = 0.000$). Based on the recurrence potential, these three groups of lesions were designated as low-, intermediate- and high-risk FDC sarcomas, respectively (Figure 6). A markedly higher mortality rate was also observed in cases with a high-risk tumor (45%) than in those with the low-risk (0%, $P = 0.001$) and intermediate-risk lesions (4%, $P = 0.006$). The low-risk group had a longer survival and the high-risk group had the most unfavorable clinical outcomes considering both the tumor recurrence and mortality (Figure 7).

During the follow-up period, 18 (49%) of the 37 informative lesions from abdominal and pelvic cavities recurred (20/53, 38%, $P = 0.302$). Of the 37 abdominal/pelvic lesions, 12 occurred in the liver and 25 were identified from other tissues. A lower recurrence risk (3/12, 25%) was observed in hepatic lesions than in the extrahepatic lesions (15/25, 60%, $P = 0.046$). A more favorable disease-free survival was also observed for the former group ($P = 0.004$). However, there was no significant difference between the hepatic (2/12, 17%) and extrahepatic groups (5/25, 20%) in mortality ($P = 0.372$, Figure 8). The size of the hepatic lesions (mean, 9.5 cm; range, 2-21 cm) was comparable to that of the extrahepatic lesions (mean, 10.4 cm; range, 1.5-16 cm, $P = 0.644$). Morphologically, all of the hepatic lesions belonged to the inflammatory pseudotumor-like variant, and most of the extrahepatic lesions were classified into conventional type. However, we failed to show a significant difference in frequency of occurrence of high-

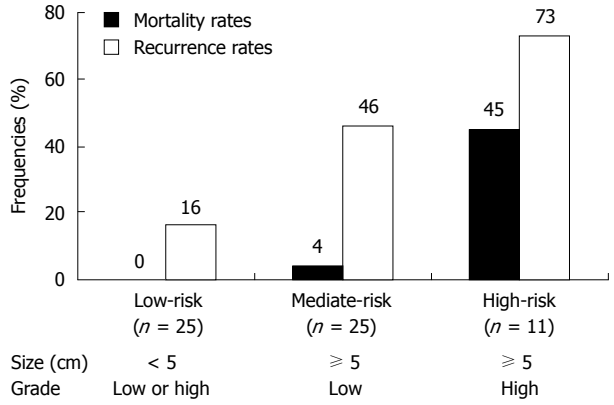

Figure 6 Definitions of low- (low-risk), intermediate- (mediate-risk) and high-risk groups (high-risk) of extranodal FDC sarcomas. Mortality rates: overall, $P = 0.000$; low-risk *vs* mediate-risk, $P = 1.000$; low-risk *vs* high-risk, $P = 0.001$; mediate-risk *vs* high-risk, $P = 0.006$; Recurrence rates: overall, $P = 0.001$; low-risk *vs* mediate-risk, $P = 0.032$; low-risk *vs* high-risk, $P = 0.002$; mediate-risk *vs* high-risk, $P = 0.167$.

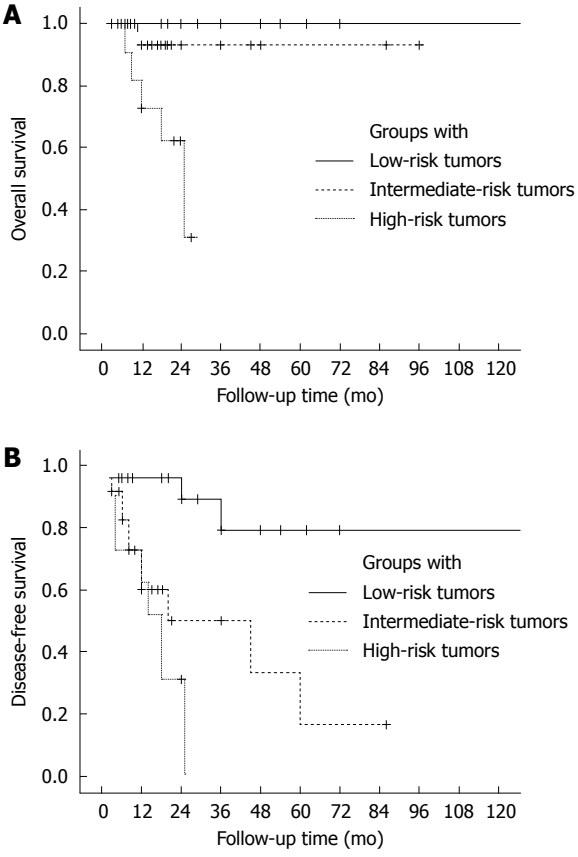

Figure 7 Overall (A) and disease-free survival curves (B) of patients with FDC sarcoma, estimated in groups with low-, intermediate- and high-risk tumors, showing data of 120 mo. A: Overall, $P = 0.000$; low-risk *vs* mediate-risk, $P = 0.273$; low-risk *vs* high-risk, $P = 0.000$; mediate-risk *vs* high-risk, $P = 0.017$; B: Overall, $P = 0.000$; low-risk *vs* mediate-risk, $P = 0.003$; low-risk *vs* high-risk, $P = 0.000$; mediate-risk *vs* high-risk, $P = 0.207$.

grade component between the hepatic (3/8, 38%) and extrahepatic lesions (7/18, 39%, $P = 1.000$).

The extrahepatic, abdominal/pelvic lesions were also compared with those occurring out of abdominal/pelvic cavity. Their recurrence rates were 60% (15/25) and 38%

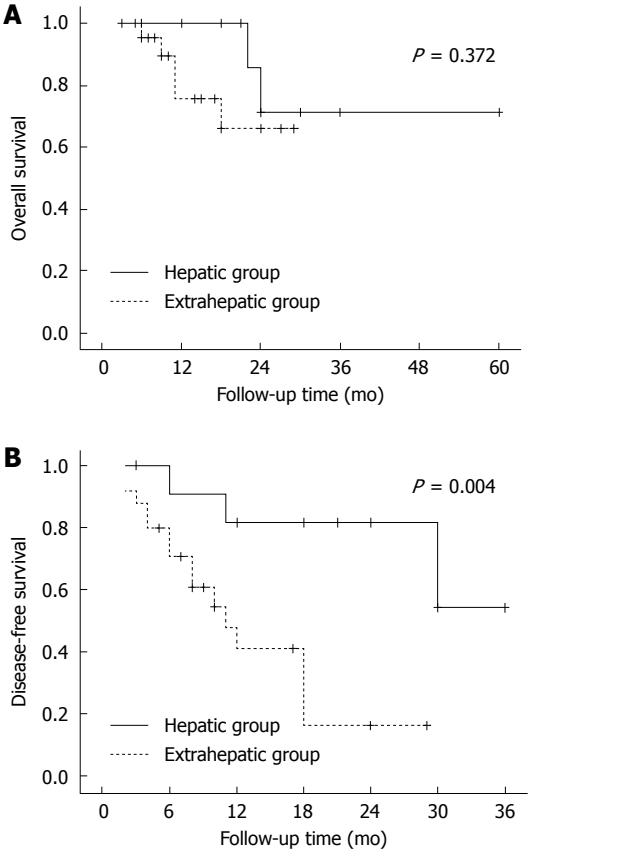

Figure 8 Overall (A) and disease-free survival curves (B) of abdominal/pelvic FDC sarcomas. The lesions are divided into hepatic and extrahepatic groups.

(20/53), respectively, with the former lesions recurring more frequently ($P = 0.000$) and earlier (Figure 9). The former cases tended to have a higher mortality rate (5/25, 20%) than the latter group (5/53, 6%), but without statistically significant difference ($P = 0.051$, Figure 9). These two groups also showed difference in their sizes, with the average of the former group (9.5 cm) being larger than that of the latter group (5.3 cm, $P = 0.003$). They were not significantly different in histological grade ($P = 0.204$), with high-grade phenotypes observed in 57% (26/46) of the former lesions and 39% (7/18) of the latter lesions.

DISCUSSION

FDC sarcoma may occur in extranodal tissues from a variety of anatomical sites, including head and neck, liver, spleen, gastrointestinal tract, soft tissue, skin, lung and breast[14]. As shown in this survey, abdominal/pelvic cavity and head/neck areas are affected more frequently, where 43% and 36% of extranodal FDC sarcomas were identified. It usually presents with a solitary tumor, typically composed of spindle and ovoid cells with scattered mature lymphocytes. However, there is a broad spectrum of morphologic variations in this tumor, some of which overlap with those of other neoplasms including ectopic meningioma, thymoma, myoepithelial tumor, inflammatory myofibroblastic tumor and GIST. In our series, osteoid component was found in a low-grade FDC sarcoma

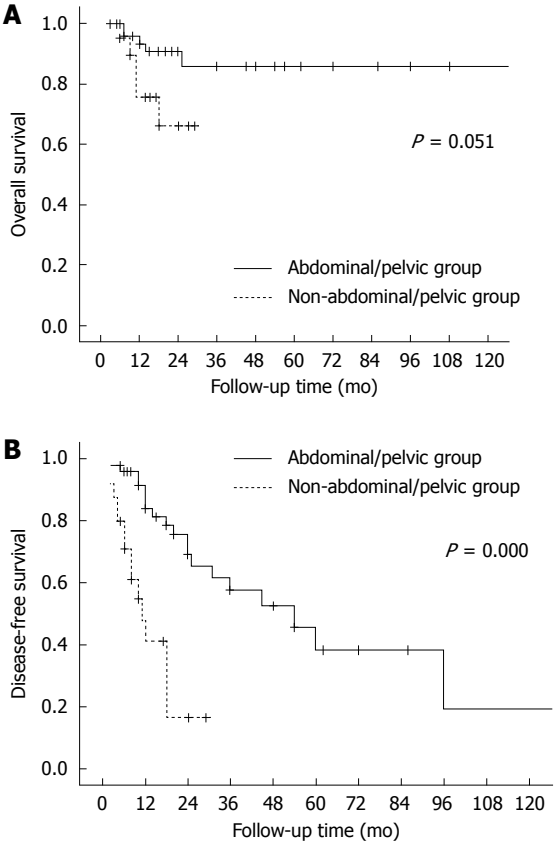

Figure 9 Overall (A) and disease-free survival curves (B) of patients with extrahepatic FDC sarcomas, showing data of 120 mo. The lesions are divided into abdominal/pelvic and non-abdominal/pelvic groups.

(Case 3). This is the first case showing presence of an osteosarcoma-like phenotype (Figure 2F). Misdiagnosis may occur when a pathologist is not aware of the tumor, as in Cases 1 and 2 of the current series (Table 1). The diagnosis can be established by immunohistochemical demonstration of CD21, CD23, CD35[70], podoplanin and clusterin expression[64,84,85].

FDC sarcoma is usually regarded as an indolent tumor with a tendency of local recurrence but a low risk of metastasis, behaving like a low-grade soft tissue sarcoma[15]. In a study of 13 cases, Perez-Ordonez *et al*[16] observed a substantial risk of metastases, prompting consideration of this malignancy to be of intermediate grade. An analysis by Shia *et al*[64] found that the 2- and 5-year recurrence-free survival rates were 62% and 27%, respectively. In our study, a total number of 106 extranodal cases were analyzed. The recurrence rate was 42%, including local recurrence in 23% and distant metastasis in 21% of the cases, and the mortality rates were 13% over the periods from 3 to 324 mo (mean, 27 mo; median, 19 mo). The 2-year and 5-year disease-free survival rates were 57% and 32%, and the 2-year and 5-year overall survival were 82% and 79%, respectively. It appears that extranodal FDC sarcomas, as a whole, are more aggressive than a low-grade soft tissue sarcoma.

As demonstrated in this study, pathologic representations of extranodal FDC sarcoma are variable among different cases. New approaches are needed to find most important prognostic factors relevant to their clinical outcomes. It has been proposed that intra-abdominal involvement, a high mitotic count (≥ 5/10 HPF), coagulative necrosis and marked cellular atypia are potentially helpful predictors of an unfavorable outcome[3]. In this study, nine clinicopathological parameters were analyzed, and large tumor size (≥ 5 cm in diameter), high-grade histology and high mitotic counts (≥ 5/10 HPF) were found to be closely associated with the clinical outcomes. The recurrence risk seemed to be increased in lesions with high Ki-67-LI, but the association showed no statistical significance. It needs to be clarified in future studies with a larger number of informative cases.

While some histological phenotypes, including cellular atypia, mitoactivity and coagulative tumor necrosis, were considered important parameters for prognosis assessment[3], a grading model remains to be established. Soriano *et al*[70] identified five high-grade lesions from 14 FDC sarcomas based on cellular atypia, but they failed to show its relevance of statistical significance to clinical outcomes. In this study, we examined nine new cases from northern China, extracted and reviewed data of 97 cases from literatures, and established histological criteria for low-grade and high-grade FDC sarcomas according to four major parameters including architectural alteration, cellular atypia, mitoactivity and/or Ki-67-LI (Table 3). Using this model, 63 informative cases were classified into low- (n = 37) and high-grade lesions (n = 26). Their recurrence rates were 32% and 58%, and their mortality rates were 3% and 35%, respectively. The results show a significant difference in their recurrence risks and mortality rates. Our data demonstrate that these two groups of lesions behave like low- and high-grade soft tissue sarcomas.

It should be noted that, for reported cases, histological grades were evaluated mainly according to two parameters (the architectural features and cellular atypia) in this study. Mitotic counts were not available for about half of the cases from literatures, and Ki-67-LI was provided in only 21 of the reported cases. For this reason, influence of mitoactivity on clinical outcomes was evaluated separately, with the recurrence rates of the mitotically indolent (< 5/10 HPF) and active lesions (≥ 5/10 HPF) determined to be 27% and 58%, respectively. It is expected that, with the assessment based on all of the six parameters including four major and two adjuvant factors (Table 3), the predicting power of our grading model for tumor recurrence risk would be stronger. This has been reflected in our own cases: the recurrence rates of the low- and high-grade lesions were 25% (1/4) and 100% (5/5), respectively.

Among the three parameters associated with clinical outcomes of extranodal FDC sarcoma, tumor size was shown to be most important. It appears that tumor size is a main factor for predicting its recurrence potential, and histological grade is closely associated with mortality rate mainly in patients with larger tumors (Figures 5 and 6). Considering the independent impact of the size to tumor behaviors and close association between mitoactivity and histological grade, we combined the size and grade fac-

tors, and proposed a model for recurrence risk assessment (Figure 6). By this model, FDC sarcomas were classified into low-, intermediate- and high-risk groups. Recurrence rates in the three groups were 16%, 46% and 73%, and the mortality rates were 0%, 4% and 45%, respectively. This will provide a convenient approach for diagnostic pathologists to predict the clinical outcomes of the tumor more accurately following its surgical resection or even with a biopsy. It should be noted that it is impossible to know exactly whether an FDC sarcoma developed from lymph node or extranodal tissues at advanced stages, as in some of the cases in this study. We believe that this model may also be applied for prognosis assessment of the FDC sarcomas which develop from lymph nodes.

Chan *et al*[3] pointed out that intra-abdominal location was associated with a higher recurrence rate. In this study, the recurrence rates of the intra-abdominal lesions and those from other sites were 49% and 38%, respectively, but their difference did not attain a statistical significance. Interestingly, a lower recurrence rate (25%) and a more favorable clinical course were observed in the hepatic lesions as compared with that of the extrahepatic, abdominal/pelvic tumors (60%). It seems to be true that, for extranodal FDC sarcomas of the conventional type, intra-abdominal lesions recur more frequently than those from other sites. The tumors of the former group were found to be larger at diagnosis (9.5 cm) than the latter lesions (5.3 cm). It is conceivable to ascribe their difference in clinical outcomes to their size difference, considering the fact that abdominal/pelvic FDC sarcomas are frequently concealed and diagnosed later compared with those from other sites including head, neck and some superficial areas.

While its pathogenesis has not been established, several factors were linked to development of FDC sarcoma. Some FDC sarcomas from lymph nodes appear to be associated with hyaline-vascular type Castleman disease[86], and similar changes were also noted in tissues surrounding some rare extranodal tumors[38,87,88]. Several reports have observed FDC proliferation and dysplastic changes in lymphoid tissues with Castleman disease where an FDC sarcoma develops[38,89-91], apparently supporting the hypothesis that FDC sarcoma develops from Castleman disease in a hyperplasia - dysplasia - neoplasia sequence[24]. However, the association was not evident in any lesion of our series.

There have been some data indicative of a link between persistent EBV infection and Castleman disease[92,93]. EBER signals were also demonstrated in some FDC sarcomas, particularly the hepatic and splenic lesions[4-9]. Most of these EBV-positive lesions contain numerous inflammatory cells, including plasma cells and lymphocytes, and dispersed tumor cells, thereby being described as inflammatory pseudotumor-like FDC sarcoma[94]. In this study, EBER was demonstrated in the hepatic inflammatory pseudotumor-like lesion (Case 6), but not in any of the six conventional FDC sarcomas examined. It appears to be true that inflammatory pseudotumor-like FDC sarcomas are related to EBV infection.

Clonal cell composition was described in an extranodal FDC sarcoma[17], but greater efforts are required to elucidate its genetic background and establish its molecular pathogenesis. Nuclear immunoreactivity for p53 protein was noticed fortuitously in a few cases[17,38]. In this series, eight extranodal FDC sarcomas without a background of Castleman disease were tested, and a low-level accumulation of p53 protein was observed in majority of tumor cells. Our data raises a possibility of involvement of the p53-mediated pathway during development or progression of FDC sarcoma. In addition, *P53* exons 5-8, where most of the *P53* gene mutations had been found[19,95], were examined in one of the lesions, but without any mutation demonstrated. Based on these data, we consider that the nuclear immunoreactivity may reflect accumulation of wild-type p53 protein. This phenomenon may be an adaptive reaction responsive to elevated mitotic activity and/or increased stress for cell survival, as observed in other cell types under neoplastic[96] and non-neoplastic conditions[18,97-99].

ACKNOWLEDGMENTS

The authors thank Dr. Ling Li and Dr. Hong-Tu Zhang for the helpful discussions, Dr. Lin Yang for her help in statistical analysis, Guo-Lian Wei, Xiu-Yun Liu, Xin-Hua Xue and Yong-Qiang Xie for their technical assistance.

COMMENTS

Background

Follicular dendritic cell (FDC) sarcoma is a rare tumor, occurring in lymph nodes and extranodal tissues. It is usually regarded as an indolent tumor with a tendency of local recurrence but a low risk of metastasis. With more cases encountered during pathological practice and reported from literatures, various morphologic and clinical representations were noticed. Because of the rarity of the tumor, assessment of its prognosis remains difficult. Clearly, histological grade of this malignancy remains to be defined and a model is needed to evaluate the recurrence risk of individual tumors within this category.

Research frontiers

While FDC sarcoma is regarded as an indolent tumor, like a low-grade soft tissue sarcoma, a broad spectrum of pathologic phenotypes and more aggressive clinical representations were noticed for this tumor type. Intra-abdominal involvement, elevated mitoactivity, coagulative necrosis and marked cellular atypia were considered potentially helpful predictors of an unfavorable outcome, but a grading model remains to be established. In this study, a total number of 106 extranodal FDC sarcomas, nine new cases and 97 from literatures, were analyzed, histological grades of this malignancy were defined and a model was established for recurrence risk assessment of the tumor.

Innovations and breakthroughs

In this study, data of 106 cases of extranodal FDC sarcoma were extracted and reviewed. Histological criteria for low-grade and high-grade FDC sarcomas were established according to four major parameters including architectural pattern, cellular atypia, mitoactivity and/or Ki-67-labeling index. Using this model, 63 informative cases were divided into low- (n = 37) and high-grade lesions (n = 26). Their recurrence rates were 32% and 58%, and the mortality rates were 3% and 35%, respectively. The results showed a significant difference in their recurrence risks and mortality rates. In addition, nine clinicopathological parameters were analyzed, and large tumor size ($\geqslant$ 5 cm in diameter), high-grade histology and elevated mitotic counts ($\geqslant$ 5/10 HPF) were found to be closely associated with the clinical outcomes. According to the tumor size and histological grade, a model was proposed for recurrence risk assessment. By this model, FDC sarcomas were classified into low-, intermediate- and high-risk groups, and their recurrence rates were 16%, 46% and 73%, and the mortality rates were 0%, 4% and 45%, respectively.

Applications

A grading approach was established for evaluating aggressiveness of extranodal FDC sarcomas, and the lesions were divided into low-grade and high-grade categories. According to the tumor size and histological grade, a model was proposed for recurrence risk assessment. This will provide a convenient procedure for diagnostic pathologists to predict the clinical outcomes of the tumor more accurately following its surgical resection or even with a biopsy. This model may also be applied to the prognosis assessment of the FDC sarcomas which develop from lymph nodes.

Peer review

It is a well written and important paper that likely represents the most thorough examination of a rare sarcoma. The authors are to be congratulated for an important work.

Abstract

AIM: To determine the rate and yield of repeat esophagogastroduodenoscopy (EGD) for dyspepsia in clinical practice, whether second opinions drive its use, and whether it is performed at the expense of colorectal cancer screening.

METHODS: We performed a retrospective cohort study of all patients who underwent repeat EGD for dyspepsia from 1996 to 2006 at the University of California, San Francisco endoscopy service.

RESULTS: Of 24780 EGDs, 5460 (22%) were performed for dyspepsia in 4873 patients. Of these, 451 patients (9.3%) underwent repeat EGD for dyspepsia at a median 1.7 (interquartile range, 0.8-3.1) years after initial EGD. Significant findings possibly related to dyspepsia were more likely at initial (29%) *vs* repeat EGD (18%) [odds ratio (OR), 1.45; 95% confidence interval (CI): 1.20-1.75, $P < 0.0001$], and at repeat EGD if the initial EGD had reported such findings (26%) than if it had not (14%) (OR, 1.32; 95% CI: 1.08-1.62, $P = 0.0015$). The same endoscopist performed the repeat and initial EGD in 77% of cases. Of patients aged 50 years or older, 286/311 (92%) underwent lower endoscopy.

CONCLUSION: Repeat EGD for dyspepsia occurred at a low but substantial rate, with lower yield than initial EGD. Optimizing endoscopy use remains a public health priority.

INTRODUCTION

Dyspepsia, which can be defined as chronic or recurrent pain or discomfort centered in the upper abdomen, is a highly prevalent condition, affecting approximately 20% of the population in Western countries[1-4]. The major causes of dyspepsia are peptic ulcer disease, gastroesophageal reflux disease, malignancy, and functional dyspepsia[5]. The evaluation and management of dyspepsia constitutes a significant clinical and economic burden[6-8].

Non-invasive strategies, including testing and treatment for *Helicobacter pylori*, are recommended for younger persons without alarm symptoms, while prompt esophagogastroduodenoscopy (EGD) is recommended for older persons and those with alarm symptoms[9-11]. An important aim has been to decrease the use of EGD, which is costly and reveals no abnormalities in the majority of patients with dyspepsia[5]. In randomized, controlled trials in multiple countries, non-invasive strategies for dyspepsia led to EGD within 1 year in 2%-50% of patients[12-17]. In these trials, 5%-25% of patients assigned to prompt EGD underwent repeat EGD within 1 year[13-15,17] reflecting the frequently persistent nature of dyspepsia, the difficulty in managing patients with functional dyspepsia[18,19], and the imperfect reassurance value of a normal endoscopy[20-22].

The rate and yield of repeat EGD for dyspepsia in clinical practice, outside of a controlled trial, is unknown. We performed a retrospective, observational study to determine the rate and yield of repeat EGD for dyspepsia in the endoscopy service of the University of California, San Francisco (UCSF), USA. We examined whether different endoscopists performed the initial and repeat EGDs in order to shed light on whether the performance of repeat EGD could be related to patients seeking a second opinion. Given the benefits of colorectal cancer screening, we determined the rate of lower endoscopy in patients undergoing repeat EGD for dyspepsia in order to explore whether endoscopic resources might have been used more optimally.

MATERIALS AND METHODS

Endoscopic databases and study population

The study was approved by the UCSF Committee on Human Research. The study sites were Moffitt-Long Hospital, a university tertiary care medical center that also serves as a community hospital for many patients, and Mount Zion Hospital and Clinics, an integral part of the University of California, San Francisco system that serves primary, secondary and tertiary care patients. Records were available for all endoscopic reports from February 1996 to June 2006 in an endoscopic database that serves both sites (Pentax EndoPRO, Version 6.5.2, copyright 1998-2005, Pentax Precision Instrument Co., Orangeburg, New York). We have used this database and methods similar to those of this study in previous investigations[23]. The source population for the study consisted of all patients undergoing any EGD at either site during the study period.

Search strategy, data collection, and definitions

The endoscopic database was searched systematically to identify all patients who underwent EGD for the evaluation of dyspepsia. Dyspepsia as an indication was defined as any of the following terms in the database's "Indications" field: "dyspepsia", "abdominal pain", "abdominal pain despite treatment", "abdominal pain suggesting organic disease", and "bloating". All patients who underwent at least 2 EGDs with an indication of dyspepsia during the study period were included. For all studies in which biopsies were performed because of suspected malignancy or Barrett's esophagus, histological diagnoses were confirmed by review of electronic pathology records.

Data were extracted from the endoscopy and pathology reports and entered into matrix format (Excel 2000, Microsoft, Redmond, WA, USA). Demographic data included gender and date of birth. Data characterizing the procedure included procedure date, physician, and procedure sequence for a given patient (first or second EGD, or subsequent EGDs). By definition, all procedures included dyspepsia as an indication. Additional indications were recorded and categorized as abnormal imaging study, anemia or gastrointestinal bleeding, anorexia and/or weight loss, dysphagia, gastroesophageal reflux disease symptoms, nausea and/or vomiting, follow-up of ulcer, follow-up of Barrett's esophagus, cirrhosis-related, diarrhea and miscellaneous. Findings at endoscopy were recorded and categorized as esophagitis, hiatal hernia, esophageal stricture, gastritis, gastric erosions, gastric ulcer, gastric polyps, duodenitis, duodenal erosions, duodenal ulcer, duodenal stricture, biopsy-proven malignancy, a new diagnosis of biopsy-confirmed Barrett's esophagus, and retained food suggesting gastroparesis. A significant finding possibly related to dyspepsia was defined as esophagitis, gastric or duodenal ulcer, or biopsy-proven malignancy. We also performed analyses with a less stringent definition of a significant finding that also included gastric or duodenal erosions.

An additional search was performed to identify which study patients had undergone a sigmoidoscopy or colonoscopy at any point during the study period. The purpose was to determine whether subjects had undergone procedures that could serve as endoscopy-based colorectal cancer screening.

Statistical analysis

Data were imported into SAS v9.1 (SAS Institute, Cary, NC) for analysis. Procedures were subgrouped into those that had dyspepsia as the exclusive indication and those that had dyspepsia and additional indications. Summary descriptive statistics for demographic descriptors, indications, and findings were calculated for the set of first (initial) EGDs, second (repeat) EGDs, and so on. Relatively few subjects underwent 4 or more EGDs.

Analyses specified *a priori* were performed. Endoscopic findings were compared between EGDs that included only dyspepsia as an indication and those that included dyspepsia and additional indications. Procedure dates were compared between initial and repeat EGDs for each subject in order to determine the time elapsed between procedures. Endoscopic findings were compared between initial and repeat EGDs in order to determine whether the rate of significant findings differed between these. Endoscopic findings at repeat EGD were compared between subjects who did and did not have

EGD: Esophagogastroduodenoscopy.

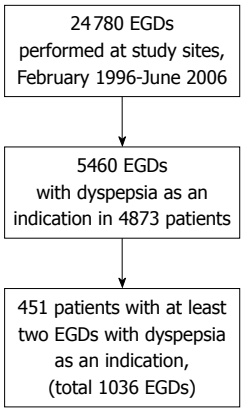

Figure 1 Study population. Starting with all esophagogastroduodenoscopies (EGDs) performed at the study sites during the study period, all EGDs with dyspepsia as an indication were identified, and patients who had undergone at least 2 EGDs with dyspepsia as an indication were selected.

significant findings at initial EGD. Endoscopists performing the initial and repeat EGD were compared to determine whether the same or a different endoscopist performed the procedures.

Continuous variables were compared with the Student's *t*-test, and means with SD are reported. Where appropriate, medians with interquartile ranges are reported. Proportions were compared with the χ^2 test and Mantel-Haenszel odds ratios (OR) with 95% confidence intervals (CI) are reported. Statistical significance was set at P $\alpha \leqslant 0.05$.

RESULTS

Study population

Figure 1 depicts the study population. During the study period, a total of 24780 EGDs were performed at the study sites. Of these, 5460 (22%) included dyspepsia as an indication for the procedure. These 5460 EGDs were performed in 4873 unique patients. A total of 451 of these patients (9.3% of all patients who underwent EGD for dyspepsia) underwent at least 2 EGDs with dyspepsia as an indication, with a total of 1036 EGDs performed with dyspepsia as an indication in this subgroup. The number of patients who underwent 3 or more EGDs with dyspepsia as an indication was 90 having 3 EGDs, 29 having 4 EGDs, 8 having 5 EGDs, 5 having 6 EGDs, 1 having 7 EGDs and 1 having 8 EGDs. Of the 5460 EGDs with dyspepsia as an indication, 585 (10.7%) were second or subsequent EGDs for dyspepsia.

Table 2 Indications for endoscopy *n* (%)

	Initial EGD (*n* = 451)	Repeat EGD (*n* = 451)
Dyspepsia	451 (100)	451 (100)
Dyspepsia	196 (44)	159 (35)
Abdominal pain	168 (37)	199 (44)
Abdominal pain despite treatment	115 (26)	103 (23)
Abdominal pain suggesting organic disease	10 (2)	17 (4)
Bloating	11 (2)	24 (5)
Additional Indications	196 (43)	198 (44)
Abnormal imaging study	1 (0.2)	2 (0.4)
Anemia or gastrointestinal bleeding	27 (6)	15 (3)
Anorexia and/or weight loss	17 (4)	16 (4)
Dysphagia	68 (15)	42 (9)
Gastroesophageal reflux disease symptoms	56 (12)	77 (17)
Nausea and/or vomiting	26 (6)	33 (7)
Follow-up of ulcer	9 (2)	5 (1)
Follow-up of Barrett's esophagus	5 (1)	8 (2)
Cirrhosis-related	1 (0.2)	1 (0.2)
Diarrhea	22 (5)	20 (4)
Miscellaneous[1]	12 (3)	16 (4)

[1]Includes planned dilation, evaluation for graft-versus-host disease, fever, postoperative evaluation, family history of malignancy, and "surveillance".

The demographic and procedure-related characteristics of the study patients are summarized in Table 1. The proportions of EGDs that included dyspepsia as an exclusive indication were nearly identical for the initial and repeat EGDs (56%-57%). Repeat EGD was performed a median of 1.7 (IQR, 0.8-3.1) years after the initial EGD.

Indications for initial and repeat EGD

The indications for the initial and repeat EGD for the patients are shown in Table 2. The distributions of indications classified as "dyspepsia" and those defined as additional indications were each similar for the initial and repeat EGDs.

Findings at initial and repeat EGD

The findings at the initial and repeat EGD for the patients are shown in Table 3. A minority of EGDs showed significant abnormalities. The proportion of EGDs showing a significant finding possibly related to dyspepsia was higher for the initial EGD (133/451, 29%) than for the repeat EGD (79/451, 18%) (OR, 1.45; 95% CI: 1.20-1.75, $P < 0.0001$). There was a higher rate of significant findings possibly related to dyspepsia on the repeat EGD if the initial EGD had reported such findings (35/133, 26%) than if it had not (44/318, 14%) (OR, 1.32; 95% CI: 1.08-1.62, $P = 0.0015$).

The 44 patients who had significant findings only at the repeat EGD had a mean age of 52 (± 23) years at initial EGD, a median time to repeat EGD of 1.8 (IQR, 0.7-4.1) years, and 28/44 (64%) were female. In 27 (61%) of these patients, dyspepsia was the only indication for repeat EGD, while indications in addition to dyspepsia

Table 3 Findings at endoscopy *n* (%)

	Initial EGD (*n* = 451)	Repeat EGD (*n* = 451)
Esophagitis	95 (21)	59 (13)
Hiatal hernia	160 (36)	172 (38)
Esophageal stricture	13 (3)	10 (2)
Gastritis	221 (49)	196 (43)
Gastric erosions	44 (10)	40 (9)
Gastric ulcer	31 (7)	14 (3)
Gastric polyps	21 (5)	21 (5)
Duodenitis	35 (8)	24 (5)
Duodenal erosions	6 (1)	3 (0.7)
Duodenal ulcer	13 (3)	8 (2)
Duodenal stricture	2 (0.5)	3 (0.7)
Retained food suggesting gastroparesis	2 (0.5)	8 (2)
Postoperative changes	11 (2)	18 (4)
Biopsy-proven malignancy	0 (0)	0 (0)
Biopsy-proven Barrett's esophagus (new diagnosis)	3 (0.7)	3 (0.7)
Significant finding possibly related to dyspepsia[1]	133 (29)[2]	79 (18)[2]

[1]Defined as esophagitis, gastric or duodenal ulcer, or biopsy-proven malignancy. The sum of these individual findings in the table is higher than this cumulative value because some patients had more than one individual finding; [2]Odds ratio, 1.45; 95% confidence interval: 1.20-1.75, $P < 0.0001$.

in the other 17 included bleeding, weight loss, nausea and vomiting, diarrhea, dysphagia, and gastroesophageal reflux symptoms. At repeat EGD, the findings were esophagitis in 31 (70%), gastric ulcer in 9 (20%), duodenal ulcer in 3 (7%), and esophagitis and gastric ulcer in 1 (2%). It is not possible to determine whether the findings at repeat EGD were missed at initial EGD.

For the initial EGD, the proportion of tests showing a significant finding possibly related to dyspepsia was higher for procedures with dyspepsia and additional indication(s) than for procedures with dyspepsia as the exclusive indication (36%, or 71/196 *vs* 24%, or 62/255; OR, 1.30; 95% CI: 1.06-1.59, $P = 0.006$). In contrast, for repeat EGD, the proportions of tests showing a significant finding possibly related to dyspepsia did not differ significantly between procedures with dyspepsia and additional indication(s) and procedures with dyspepsia as the exclusive indication (18%, or 36/198 *vs* 17%, or 43/253; OR, 1.04; 95% CI: 0.83-1.29, $P = 0.74$).

With a less stringent definition of a significant finding that also included gastric or duodenal erosions, the proportion of EGDs showing a significant finding possibly related to dyspepsia remained higher for initial EGD (172/451, 38%) than for repeat EGD (111/451, 25%) (OR, 1.40; 95% CI: 1.19-1.65, $P < 0.0001$). With this less stringent definition, there was a trend towards a higher rate of significant findings possibly related to dyspepsia on repeat EGD if initial EGD had reported such findings (51/172, 29%) than if it had not (60/279, 22%) (OR, 1.19; 95% CI: 0.99-1.44, $P = 0.051$).

Physician performing initial and repeat EGD

The repeat EGD was performed by the same physician who performed the initial EGD in 77% (346/451) of the cases.

Sigmoidoscopy or colonoscopy

Of the 451 study patients, 393 (87%) underwent either a sigmoidoscopy or colonoscopy. Among those aged 50 years or older, 286/311 (92%) underwent either a sigmoidoscopy or colonoscopy compared to 107/140 (76%) of those younger than 50 years (OR, 2.09; 95% CI: 1.59-2.75, $P < 0.0001$).

DISCUSSION

In our observational study, over 20% of all EGDs performed included dyspepsia as an indication. Of patients undergoing EGD with dyspepsia as an indication, approximately 9% underwent repeat EGDs for dyspepsia at a median 1.7 years after the initial EGD. This constituted a relatively small but still substantial fraction of endoscopic volume related to dyspepsia. The yield of repeat EGD for dyspepsia was modest, and lower than the yield of initial EGD. For initial EGD, the yield was higher for EGDs performed for dyspepsia and additional indications compared with dyspepsia exclusively. In the vast majority of cases, the repeat EGD was performed by the same endoscopist as the initial EGD, suggesting that the seeking of a second opinion was not a major driver in the rate of repeat EGD. Over 90% of patients aged 50 years or older who underwent repeat EGD for dyspepsia also underwent either sigmoidoscopy or colonoscopy, suggesting that repeat EGD was not undertaken at the expense of tests that can serve for colorectal cancer screening.

Because our study was not prospective and did not capture EGDs performed outside the UCSF endoscopy service, we could not compare our results directly with the rates of repeat EGD for dyspepsia observed in the randomized trials of competing management strategies for uninvestigated dyspepsia. Nonetheless, the fraction of patients undergoing repeat EGD for dyspepsia in our study was within the range of 5%-25% observed in those controlled trials at 1 year[13-15,17], and within the range of 9%-26% observed in follow-up at 6 to 7 years[24,25]. If some patients who underwent an initial EGD for dyspepsia in our study cohort then underwent repeat EGD for dyspepsia at another institution, or if the "initial EGD" for dyspepsia in our study was in reality a repeat EGD, then our results would underestimate the true rate of repeat EGD for dyspepsia. In our study, repeat EGD was performed a median of 1.7 (IQR, 0.8-3.1) years after the initial EGD. Longer-term follow-up of patients in randomized trials has shown that some patients undergo repeat EGD for dyspepsia years later, but most repeat EGDs were within the initial year of the studies[13,24,25].

It is well recognized that most EGDs performed for dyspepsia demonstrate no significant abnormality[5,13-17]. Thus, the relatively low yield in our study was not surprising. The yield at repeat EGD for dyspepsia

was lower than at initial EGD, a finding that might have been expected, but has not been demonstrated in clinical practice previously. Because our study design selected patients with repeat EGD for dyspepsia, the diagnostic yield at initial EGD might actually have been lower than in patients who did not undergo repeat EGD. For instance, no malignancies were diagnosed, but one could postulate that patients diagnosed with malignancy at initial EGD might be less likely to undergo repeat EGD with dyspepsia as an indication.

The management of patients with functional dyspepsia is challenging[18,19]. Patients may seek second opinions in search of underlying disease that may have been missed, or new treatments. We expected to find that a majority of repeat EGDs for dyspepsia had been performed by a different endoscopist than the initial EGDs, but this was not the case. If we failed to capture a significant fraction of all repeat EGDs for dyspepsia in our study patients because they occurred at other institutions, then the proportion of repeat *vs* initial EGDs performed by a different endoscopist would be higher. It is unlikely that the endoscopists in our study played the role of proceduralist instead of consultant, since open-access upper endoscopy is relatively rare in our endoscopy service. One may speculate that repeat EGD in patients with established care with a gastroenterologist could be driven in part by ongoing patient concern[20-22]. We could not address this issue directly in the current study.

With the growing national emphasis on colorectal cancer screening, the capacity and proper utilization of lower endoscopic services have been debated[26-28]. Because we expected that the yield of repeat EGD for dyspepsia would be low, we sought to investigate whether endoscopic services might have been applied better towards colorectal cancer screening in our study patients. We found that a very large majority of our patients also underwent lower endoscopy, at a rate much higher than national uptake rates for colorectal cancer screening[29]. This likely reflected a group of patients who had well established medical care and might in fact utilize more medical resources than the average, as reflected by a high rate of lower endoscopy even in patients younger than 50 years of age. The endoscopic capacity in our study sites is somewhat elastic, so that a repeat EGD for dyspepsia may not directly displace a screening lower endoscopy. We could not determine whether patients outside of our study cohort were denied access to lower endoscopy as a result of the repeat EGDs that were performed. If present at all, this effect would be small. However, this may be a more salient issue in other settings with more constrained resources and different incentive structures for endoscopists.

Our study has limitations. First, because it was a retrospective study without complete coverage of all of our patients' medical contacts, some repeat EGDs at other facilities might have been missed. However, our results accurately reflected the fraction of endoscopic services devoted to initial and repeat EGD for dyspepsia within our study sites. Second, we did not know whether patients whose EGDs were performed for abdominal pain fit the definition of dyspepsia, but we chose to include them because many endoscopists in our unit do no use the term dyspepsia in the indication field, and because we believe that when EGD is performed for abdominal pain it is likely that this pain is in the upper abdomen and can be categorized as dyspepsia. Third, we did not know the management strategies offered to patients, which could have affected the rate of repeat EGD. Fourth, our results may be generalizable to other endoscopy units with similar systems, patients and endoscopists as ours, but not necessarily to those in different practice settings. Fifth, we did not attempt to determine whether lower endoscopies were performed for diagnostic or screening purposes. However, for the purposes of determining resource use in this study, the distinction was not necessary. Finally, it is possible that some patients with abdominal pain and diarrhea had inflammatory bowel disease, and this might have contributed to the use of lower endoscopy, but diarrhea was an additional indication in only 5% of EGDs.

In conclusion, the rate of repeat EGD for dyspepsia in this study was relatively low but still substantial, and it may have underestimated the true rate because of possible repeat EGDs at other facilities. The diagnostic yield of repeat EGD for dyspepsia was modest, and lower than at initial EGD. Our findings do not support the hypothesis that repeat EGD for dyspepsia in our study sites was usually performed for a second opinion by a different endoscopist. Repeat EGD for dyspepsia in our study patients was not performed at the expense of age-appropriate colorectal cancer screening. Optimal allocation of endoscopic resources remains a public health priority.

COMMENTS

Background

Dyspepsia is a highly prevalent condition. Non-invasive strategies to evaluate dyspepsia are recommended for younger persons without alarm symptoms in large part to limit the use of esophagogastroduodenoscopy (EGD). In randomized, controlled trials, 5%-25% of patients assigned to prompt EGD to evaluate dyspepsia underwent repeat EGD within 1 year.

Research frontiers

The rate and yield of repeat EGD for dyspepsia in clinical practice is not known. The optimal use of endoscopic resources is a public healthy priority.

Innovations and breakthroughs

The authors performed a retrospective cohort study of all patients who underwent repeat EGD for dyspepsia from 1996 to 2006 at the University of California, San Francisco endoscopy service. They determined the rate and yield of repeat EGD for dyspepsia, whether second opinions drove its use, and whether endoscopic resource use might have been shifted to colorectal cancer screening.

Applications

Repeat EGD for dyspepsia occurred at a low but substantial rate, and the diagnostic yield was lower than at initial EGD. Because repeat EGD was not usually performed for a second opinion, it is likely that the physician who performed an initial EGD will face the decision as to whether to perform a repeat EGD. In our cohort, repeat EGD was not performed at the expense

of age-appropriate colorectal cancer screening. Nonetheless, optimal use of endoscopic capacity remains a public health priority.

Terminology

Dyspepsia can be defined as chronic or recurrent pain or discomfort centered in the upper.

Peer review

This is an interesting retrospective study to demonstrate the rate and yield of repeat EGD for dyspepsia.

Abstract

AIM: To evaluate retrospectively the efficacy of rituximab plus chemotherapy in gastric diffuse large B cell lymphoma (DLBCL).

METHODS: Sixty patients (median age: 58 years) with histologically confirmed gastric DLBCL treated at four Italian institutions between 2000 and 2007, were included in this analysis. Patients were selected by stage (Ⅰ-Ⅳ, Lugano staging system), European Cooperative Oncology Group performance status (0-2) and treatment strategies. Treatment strategies were chemotherapy alone (group A, *n* = 30) [scheduled as cyclophosphamide, doxorubicin, vincristine and prednisone (CHOP) and CHOP-like], and chemotherapy combined with rituximab (group B, *n* = 30). The primary end point of the study was complete response (CR) rate; the secondary end points were disease-free survival (DFS) at 5 years and overall survival (OS).

RESULTS: Median follow-up was 62 mo (range: 31-102 mo). We observed a significant difference between the two groups (A *vs* B) in terms of CR [76.6% (23/30) *vs* 100%, *P* = 0.04) and DFS at 5 years [73.3% (22/30) *vs* 100%, *P* = 0.03). To date, 19 group A (63.3%) patients are alive and 11 have died, while all group B patients are alive. No significant differences in toxicity were observed between the two groups.

CONCLUSION: Rituximab in combination with chemotherapy improves CR rate, DFS and OS. Further prospective trials are needed to confirm our results.

INTRODUCTION

Immunotherapy with rituximab, a chimeric monoclonal antibody against B-cell surface antigen CD20, is widely utilized in non-Hodgkin's lymphoma[1,2]. Rituximab in addition to cyclophosphamide, doxorubicin, vincristine and prednisone (CHOP) chemotherapy represents the gold standard for the treatment of nodal aggressive non-Hodgkin'a lymphoma, since it improves response rate, overall survival (OS) and event-free survival *vs* chemotherapy alone, with no increase in toxicity. These results were obtained in a phase Ⅲ randomized study (GELA) that included a population of 399 previously untreated elderly patients with diffuse large B cell lymphoma (DLBCL)[3].

Primary gastric non-Hodgkin's lymphoma (PGNHL) is the most common extranodal lymphoma, and represents 60%-75% of gastrointestinal lymphoma cases, with an incidence about of 1 per 100 000 in developed countries, which appears to be increasing. PGNHL is more common in men and in individuals aged > 50 years, with a maximum incidence in the seventh decade, but it may also occur in younger patients[4].

Clinical presentation includes a variety of symptoms such as weight loss, anorexia and abdominal pain, whereas gastric bleeding is uncommon. B lymphoma generalized symptoms are less common than in primary nodal lymphoma. All histological lymphoma categories are present, but the main ones are mucosa-associated lymphoid tissue (MALT) lymphoma (low and high grade) and DLBCL[5-7].

The relationship between *Helicobacter pylori* chronic infection and MALT is well known (about 90% of cases), but its role in gastric DLBCL is controversial[4]. Eradication therapy is an effective option for low-grade MALT lymphoma[8].

The CHOP schedule, as a standard treatment for nodal non-Hodgkin's lymphoma, has been utilized in several non-randomized studies and represents an effective option[9,10]. Rituximab and CHOP combination is also commonly utilized in the treatment of gastric DLBCL, but it has only been tested in a few studies[11,12].

Therefore, we carried out a retrospective study to evaluate the efficacy of rituximab in combination with chemotherapy in gastric DLBCL. To date, this study represents the largest analysis.

MATERIALS AND METHODS

In this retrospective study, we analyzed a group of non-gastrectomized patients with gastric DLBCL, who were treated at our four institutions between 2000 and 2007.

Patients

Sixty patients (42 men and 28 women) with a median age of 58 years received only systemic treatment. Performance status according to European Cooperative Oncology Group (ECOG) was 0-2. All patients presented with a histologically confirmed diagnosis of gastric DLBCL. Stages were between I and Ⅳ according to the Lugano staging system (Table 1), with primary localization in the stomach at the antrum (46.6%) and antrum-body (25%). B-symptoms were present in only 14% patients. β2 microglobulin was elevated in 60% of patients and lactate dehydrogenase was elevated in 85.0% (Table 2). The primary end point was the complete response (CR) rate. Secondary end points were disease-free survival (DFS) at 5 years and OS.

Table 1 Lugano staging of GI lymphomas

Stage Ⅰ: tumor confined to GI tract
Stage Ⅱ: tumor extending into abdomen from GI site
Ⅱ 1 = local nodal involvement
Ⅱ 2 = distant nodal involvement
Stage Ⅲ: penetration of serosa to involve adjacent organs or tissue
Stage Ⅳ: disseminated extranodal involvement, or supradiaphragmatic nodal involvement

GI: Gastrointestinal.

Table 2 Clinicopathological characteristics of 60 patients affected by gastric DLBCL

Clinicopathological characteristics	
Age (yr)	
Median	58
Range	19-76
Sex	
Male	42
Female	28
Performance status	
ECOG 0	0 (65%) (39/60)
ECOG 1	1 (28.3%) (17/60)

Ⅰ	28.3% (17/60)
Ⅱ	46.6% (28/60)
Ⅲ	16.6% (10/60)
Ⅳ	8.3% (5/60)
B symptoms	15% (9/60)

ECOG: European Cooperative Oncology Group; DLBCL: Diffuse large B cell lymphoma.

Treatment

We selected 60 cases from an archive of patients that had received chemotherapy plus immunotherapy or chemotherapy alone from 2000 to 2007. Thirty of these patients (group A) received only chemotherapy accord-

Table 3 Treatment response

Chemo-immunotherapy treatment	
No. of patients	
CHOP-like	30
CHOP-like and rituximab	30
Second or other lines	7.50%
No. of cycles	
Median	6 (3-24)
mean	8.3 (3-24)
Results	
Median follow-up	77 mo
CHOP-like	CR = 76.6%, DFS at 5 yr = 73.3%, OS = 63.3%
CHOP-like and rituximab	CR = 100%, DFS at 5 yr = 100%, OS = 100%

CHOP: Cyclophosphamide, doxorubicin, vincristine and prednisone; CR: Complete response; DFS: Disease-free survival; OS: Overall survival.

ing to CHOP or CHOP-like (MACOP-B) schedules. The CHOP schedule consisted of cyclophosphamide at 750 mg/m^2 on day 1, doxorubicin 50 mg/m^2 on day 1, vincristine 1.4 mg/m^2 up to a maximal dose of 2 mg on day 1, and prednisone 100 mg/d for 5 d, every 21 d. MACOP-B schedule consisted of methotrexate 100 mg/m^2 on day 1, adriamycin 35 mg/m^2 on day 1, cyclophosphamide 350 mg/m^2 on day 1, vincristine 1.4 mg/m^2 up to a maximal dose of 2 mg on day 1, prednisone 40 mg/m^2 on days 1-5, and bleomycin 10 mg/m^2, every 21 d. A group of 30 patients (group B) received rituximab (375 mg/m^2 administrated on day 1 of each cycle of CHOP or CHOP-like MACOP-B) (Table 3). Rituximab infusion was interrupted in the event of fever, chills, edema, congestion of the head and neck mucosa, hypotension or any other serious adverse event, and it was resumed when the event resolved. If the absolute neutrophil (granulocyte) count was < 1500/μL or the platelet count was 100000/μL, chemotherapy was halted for up to 1 wk, and treatment was stopped. The dose of rituximab was not modified, and rituximab was continued when CHOP was stopped. Treatment was stopped, however, if lymphoma progressed, if the patient declined to continue, or at the discretion of the physicians in cases of concurrent illness or adverse events.

Response to treatment and adverse events

Response to treatment was classified as CR, partial response (PR) or progressive disease (PD) according to the International Workshop criteria[13]. CR was defined as the disappearance of all lesions and radiological or biological abnormalities observed at diagnosis, and the absence of new lesions. PR was defined as regression of all measurable lesions by > 50%, disappearance of non-measurable lesions, and absence of new lesions. PD was defined as the appearance of new lesions, any growth of the initial lesions by > 25%, or growth of any measurable lesion that had regressed during treatment by > 50% from its smallest dimensions. All adverse events reported by the patient or observed by the investigator were collected and were graded according to the NCI toxicity criteria (CTCAE v3.0).

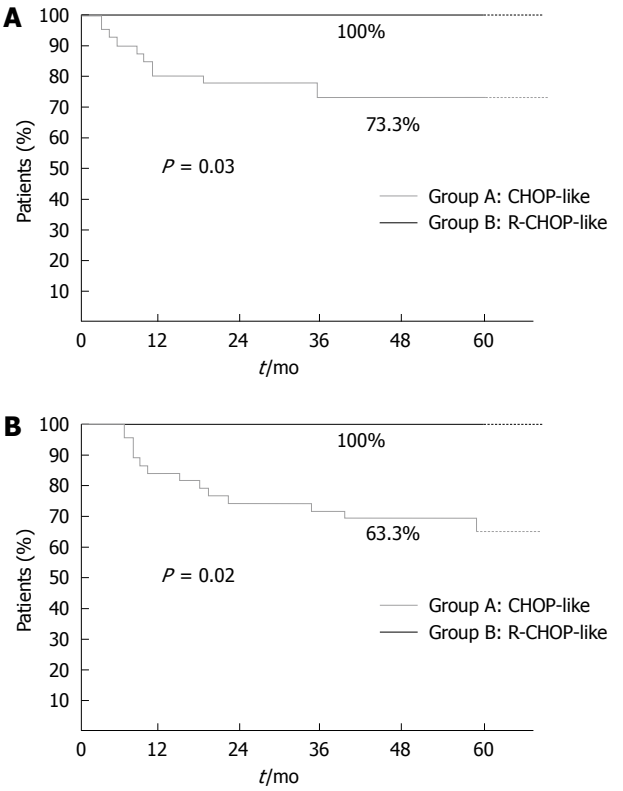

Figure 1 Disease-free survival (DFS) (A) and overall survival (OS) (B) curve. Group A: Cyclophosphamide, doxorubicin, vincristine and prednisone (CHOP); Group B: Rituximab plus chemotherapy.

Statistical analysis

Quantitative data were described by the median (range), and qualitative data were expressed as counts and percentages. Duration of the disease-free interval and OS were estimated according to the Kaplan-Meier method. Fisher's exact test was used to assess the significance of all correlations. Statistical significance was achieved if P was < 0.05. All reported P values were two-sided.

RESULTS

Treatment response

Median follow-up was 62 mo (range: 31-102 mo). No difference between the two groups was observed in term of stage, ECOG performance status and metastatic sites. Rituximab plus chemotherapy *vs* chemotherapy alone yielded a statistically significant advantage in terms of CR (100% *vs* 76.6%, P = 0.004), DFS at 5 years (100% *vs* 73.3%, P = 0.03) (Figure 1A) and OS (100% *vs* 63.3%, P = 0.02) (Figure 1B). We observed in group A, five patients with PR and two with PD. Only 7.5% of patients underwent a second or additional line of therapy (Table 3). To date, 19 group A patients are alive and 11 have died [nine due to lymphoma-related causes, one to brain metastatic melanoma, and one to hepatocarcinoma (hepatitis C virus-related)]. All patients in group B are alive.

Pain	1 (3.3)	1 (3.3)	0 (0)	2 (6.6)	1 (3.3)	0 (0)

Toxicity

The most common toxicities were grade 2/3 and 4 granulocytopenia (76.6% in group B and 73.3% in group A, $P > 0.05$) and recurrent infection (all grades) (43.2% in group B and 36.6% in group A, $P > 0.05$) (Table 4).

DISCUSSION

Our analysis is believed to be the first study to compare directly chemo-immunotherapy and chemotherapy alone in gastric non-Hodgkin's lymphoma. We demonstrated a statistically significant improvement with chemo-immunotherapy in terms of CR, DFS at 5 years and OS, without a significantly greater toxicity.

Rituximab was introduced as a treatment for prior nodal lymphoma at the end of the 1990s. A randomized phase Ⅲ trial (GELA group) has underlined the effectiveness of rituximab in prior nodal B cell lymphoma. Three hundred and ninety-nine previously untreated elderly patients (≥ 60 years) with stage Ⅱ-Ⅳ DLBCL were randomized to receive either standard CHOP or rituximab plus CHOP for eight cycles. CR rate was significantly higher in the group that received rituximab plus CHOP than in the group that received CHOP alone (76% *vs* 63%, $P = 0.005$), with a median follow-up of 2 years, DFS and OS times were significantly longer in the rituximab plus CHOP group ($P < 0.001$ and $P = 0.007$, respectively). Clinically relevant toxicity was not significantly greater with rituximab plus CHOP[3].

However, as far as we are aware, no previous studies have compared immunotherapy-chemotherapy with chemotherapy alone in gastric DLBCL.

A few studies have evaluated immuno-chemotherapy in gastric DLBCL. In one single-arm study, 15 patients were treated with rituximab plus chemotherapy. CR rate was 87% and PR rate was 13%. The CR rate was high in this study, as in our analysis, but there was no direct comparison with chemotherapy alone[11]. A phase Ⅱ trial of 42 patients with early-stage disease did not show any advantage of rituximab plus CHOP chemotherapy. A CR was obtained in 95% of cases, and relapses were observed in two[12]. The treatment did not achieve a statistically significant effect in terms of DFS at 5 years and OS at 5 years in comparison with the historical control[14].

Our results are in agreement with this previous study in term of CR, and confirmed that the chemotherapy-immunotherapy was more active than chemotherapy alone.

Our study had several limitations. First, it was a retrospective study with potential bias in the patients and methods. Second, chemotherapy was not the same in each group (the first patients were treated mainly with the MACOP-B schedule, while the more recent patients were treated mainly with the CHOP schedule).

In conclusion, our results are promising in terms of CR, DFS and safety. However, prospective randomized trials are needed to confirm these preliminary results.

COMMENTS

Background

Rituximab in addition to cyclophosphamide, doxorubicin, vincristine and prednisone (CHOP) chemotherapy represents the gold standard for the treatment of nodal aggressive non-Hodgkin's lymphoma.

Research frontiers

Rituximab and CHOP combination is also commonly utilized in the treatment of gastric diffuse large B cell lymphoma (DLBCL), but it has only been tested in a few studies. Therefore, the authors carried out a retrospective study to evaluate the efficacy of rituximab in combination with chemotherapy in gastric DLBCL.

Applications

To date, this study represents the largest analysis. The analysis represents the first study to compare directly chemo-immunotherapy and chemotherapy alone in gastric non-Hodgkin's lymphoma. The results are promising in terms of CR, DFS and safety. However, prospective randomized trials are needed to confirm these preliminary results.

Terminology

Rituximab is a chimeric monoclonal antibody against B-cell surface antigen CD20 and it is widely utilized in non-Hodgkin's lymphoma therapy. Primary gastric non-Hodgkin's lymphoma is the most common extranodal lymphoma, and represents 60%-75% of gastrointestinal lymphoma cases. The main histological types are mucosa-associated lymphoid tissue lymphoma (low and high grade) and DLBCL. The CHOP schedule consists of cyclophosphamide, doxorubicin, vincristine and prednisone.

Peer review

The study is interesting as it is the first to compare the two types of therapy in these gastric tumors.

Abstract

AIM: To describe a Polish population with nonalcoholic fatty liver disease (NAFLD) with regard to *HFE* gene mutations, as well as analyzing demographic and clinical data.

METHODS: Sixty-two consecutive patients with biopsy-proven NAFLD were included in the study. Demographic, clinical, and laboratory data were summarized in a database. C282Y and H63D mutations of the *HFE* gene were analyzed using polymerase chain reaction-restriction fragment lenght polymorphism.

RESULTS: The analyzed cohort consisted of 62 homogeneic Caucasian participants, 66.1% men and 33.9% women, with a median age of 48 years. The median body mass index was 29.05 kg/m^2. Hypercholesterolemia was observed in 74.2% of patients and hypertriglyceridemia in 32.2%; 16.1% had type 2 diabetes mellitus (DMt2). On liver biopsy, 22.6% of NAFLD patients were found to have severe fibrosis. There were no differences between frequencies of *HFE* gene mutations in subgroups of NAFLD patients with less and more severe liver fibrosis. Obesity, older age, female gender and DMt2 were associated with more advanced fibrosis in this Polish cohort, as well as higher glucose level, serum iron and transaminase aspartate aminotransferase/alanine aminotransferase ratio.

CONCLUSION: *HFE* mutations conferred no additional hepatic fibrosis risk in NAFLD, but higher serum iron was a risk factor for severe liver damage in NAFLD, regardless of *HFE* mutations.

INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is now the most common liver disease in Western countries, affecting up to a third of individuals. It covers a spectrum of liver problems including benign simple steatosis (fatty liver) and steatohepatitis [nonalcoholic steatohepatitis (NASH)] with hepatic injury, inflammation, and fibrosis, which can lead to cirrhosis, liver failure, and hepatocellular carcinoma[1]. NAFLD is strongly associated with metabolic syndrome and is now regarded as its liver manifestation. Hyperinsulinemia is a risk factor for the development of NASH. A moderate increase of iron stores is observed in NASH, and its presence may contribute to the development of insulin resistance (IR)[2,3].

Some studies have identified high ferritin level and/or increased prevalence of hyperferritinemia in patients with metabolic syndrome[4] or its single components[5]. Serum ferritin could be a marker of IR[6]. Increased ferritin levels, together with high transferrin saturation, are typical features of *HFE* hereditary hemochromatosis (HHC). However, hyperferritinemia with normal or slightly increased transferrin saturation has also been described in non-C282Y homozygotes with NASH and has been designated "IR hepatic iron overload syndrome" because of a frequent association with hepatic steatosis and metabolic abnormalities[7].

The mechanism determining the progression from fatty liver to steatohepatitis is still unclear, and there is a conflict of evidence regarding inheritance of the *HFE* gene mutation and the influence of hepatic iron deposition as cofactors for developing fibrosis in NAFLD. Family studies and inter-ethnic variations in susceptibility suggest that genetic factors may be important in determining disease risk or the clinical course of the disease. Thus, the aim of this study was to evaluate the frequency of the *HFE* gene polymorphisms C282Y and H63D in Polish patients with NAFLD with respect to demographic, clinical and laboratory data.

MATERIALS AND METHODS

Sixty-two consecutive patients with biopsy-proven NAFLD were included in the study between 2007 and 2009. Patients were recruited consecutively by means of liver biopsy. We analyzed only the patients with a negative history of alcohol intake; those consuming more than 20 g/d were excluded from the study. All patients tested negative for HBV antigen and anti-HCV antibodies. Those aged 40 years or less had their ceruloplasmin checked and confirmed to be normal. γ-globulins, immunoglobulins, and auto-antibodies were tested and imaging diagnostics were performed to exclude autoimmune hepatitis as well as primary biliary cirrhosis and primary sclerosing cholangitis. Advanced fibrosis in liver biopsy was defined as bridging fibrosis F3 and cirrhosis F4. Demographic and clinical data were summarized in a database.

HFE gene analysis was performed by polymerase chain reaction (PCR) amplification of total genomic DNA of two regions of the gene carrying the mutations C282Y and H63D. The PCR primers for amplifications of the C282Y locus were 5'-TCCGTCTTAGCTGAGTGGAACTACTACCCCCAGAACATCACC-3' and 5'-AGGCAGAATCGACTCACCTGGCTCTCATCAGTCACATACCC-3'. For detection of H63D, the sense primer sequence was 5'-ATGGTTAAGGCCTGTTGCTCTGTC-3' and the antisense primer sequence was 5'-CCCTTGCTGTGGTTGTGATTTTC-3'. PCR amplification was performed in a total volume of 12.5 μL containing 10 to 20 ng genomic DNA, 2.5 nmol of each deoxynucleotide triphosphate, 4 pmol of each primer, 1.5 mmol/L magnesium chloride, 1 × PCR buffer solution, and 0.3 U *Taq* polymerase (MBI Fermentas, Vilnius, Lithuania). PCR amplification consisted of initial denaturation for 3 min at 94℃, followed by 35 cycles of denaturation at 94℃ for 30 s, annealing at 56℃ for 30 s, and extension at 72℃ for 30 s. The terminal elongation was performed at 72℃ for 7 min.

PCR products were digested with *Rsa* I (MBI Fermentas, Vilnius, Lithuania) for detection of C284Y and with *Mbo* I (MBI Fermentas, Vilnius, Lithuania) for H63D. The G-to-A transition (aa282) creates a new *Rsa* I site, and a second *Rsa* I site in this fragment acts as internal control within the restriction fragment length polymorphism. The C-to-G transversion (aa63) results in loss of one of two *Mbo* I sites in the amplified product. DNA fragments generated after digestion were separated on 3% agarose gels.

Statistical analysis

The statistical analysis was performed using SPSS v 15.0. The independent-samples *t* test, preceded by Levene test for equality of variances test, was used to compare means in continuous data. Pearson χ^2 test was used to check the association with advanced fibrosis. The Pearson correlation coefficient and Spearman rho coefficient of correlation were also calculated. Multivariate logistic regression was used to determine the set of data independently correlated with advanced fibrosis.

RESULTS

The analyzed cohort consisted of 62 racially homogeneic Caucasian patients. There was a predominance of males over females (66.1% *vs* 33.9%). The median age of patients was 48 years (ranges, women: 30-75 years; men: 25-64 years). Body mass index (BMI) in women ranged from 21.32 to 39.3 kg/m^2 and in men from 21.9 to 37.7 kg/m^2. More than half of the analyzed group was obese (BMI > 30 kg/m^2 in 50.4%), and 38.1% of patients were overweight (25 kg/m^2 < BMI < 30 kg/m^2).

Table 1 Selected characteristics of patients with NAFLD

	Minimum	Median	Maximum	mean ± SD
Age (yr)	25	48	75	46.56 ± 11.91
Fe (10.56-228.3 μmol/L)	4.12	20.9	68.4	21.4 ± 9.79
Transferrin saturation (< 45%)	7.6	36	206	40.59 ± 30.46
Ferritin (629.2-7999.3 pmol/L)	629.2	5336.6	129584.4	9714.9 ± 18409.2
AST (< 38 IU/L)	16	45.5	275	57.44 ± 43.91
ALT (< 41 IU/L)	15	73	281	86.37 ± 57.35
AST/ALT ratio	0.36	0.62	2.43	0.79 ± 0.47
PLT (150-400 × 10^9/L)	93	218	376	224.98 ± 67.47
Albumin (34-48 g/L)	36.8	46.2	54.8	45.8 ± 4.0
Glycemia (3.89-5.83 mmol/L)	3.44	5.6	11.8	581.7 ± 1.27
BMI (19-25 kg/m^2)	21.2	29.05	39.3	29.10 ± 4.17
HOMA (> 1.8)	0.44	4	35.63	7.44 ± 9.25
HBA_{1c} (4.8%-5.9%)	4.99	5.76	9.76	6.20 ± 1.26

NAFLD: Nonalcoholic fatty liver disease; Fe: Iron; AST: Aspartate transaminase; ALT: Alanine transaminase; PLT: Platelet count; BMI: Body mass index; HOMA: Homeostatic model assessment; HBA_{1c}: Glycated hemoglobin.

Among co-morbidities, hypercholesterolemia (total cholesterol > 5.18 mmol/L) was present in 74.2% of patients; hypertriglyceridemia (> 2.03 mmol/L) in 32.2%; type 2 diabetes mellitus (DMt2) in 16.1%; and arterial hypertension in 21.0%. Selected demographic and clinical data are presented in Table 1.

Among the 62 participants, 14 patients (22.6%) had severe (F3-F4) fibrosis and 48 (77.4%) had no or mild fibrosis. Table 2 summarizes the clinical data related to NASH with no/mild (F0-F2) and advanced (F3-F4) fibrosis.

High serum aspartate aminotransferase/alanine aminotransferase ratio, and higher serum iron were strongly associated with advanced fibrosis (F3-F4). Lower levels of albumin were also indicators of more severe liver disease. There were no statistically significant interactions between gender and common co-morbidities and NAFLD, although a trend was observed in a subgroup of patients with F3-F4 fibrosis and female gender as well as DMt2. The Spearman's correlation coefficients showed higher age, higher BMI and presence of DMt2 as being associated with more advanced fibrosis. Multivariate logistic regression was provided and evidenced DMt2, higher age and female gender as good predictors of fibrosis F3-F4.

Table 3 shows the frequencies of the *HFE* gene mutations C282Y and H63D. There were no statistically significant differences between frequencies of mutated alleles in the subgroup of patients with NAFLD. The number of mutated alleles was too low to identify a Pearson correlation between lipids, iron, ferritin, and transferrin saturation or clinical course (i.e. severe fibrosis) and *HFE* gene mutations. However, a trend towards statistically significant correlations between at least one mutated allele of the H63D *HFE* gene and total cholesterol ($P = 0.034$) as well as LDL-cholesterol ($P = 0.020$) was observed in the group of NASH patients with F3-F4 fibrosis with the Pearson correlation coefficient.

Table 2 Comparison of selected clinical data between patients with fatty liver and no/mild and advanced fibrosis

	Fibrosis 0-2 (n = 48)	Fibrosis 3-4 (n = 14)	P value
Age (yr)	45 ± 12	51 ± 11	0.096
BMI (19-25 kg/m^2)	28.68 ± 3.85	30.64 ± 5.05	0.135
AST (< 38 IU/L)	51.27 ± 38.75	80.69 ± 55.27	0.091
ALT (< 41 IU/L)	89.10 ± 53.64	75.85 ± 71.39	0.462
AST/ALT ratio	0.65 ± 0.31	1.33 ± 0.55	0.001
PLT (150-400 × 10^9/L)	231.08 ± 66.51	201.54 ± 68.57	0.161
Glucose (3.89-5.83 mmol/L)	5.36 ± 0.74	7.08 ± 20.5	0.020
HOMA (> 1.8)	6.0 ± 8.4	13.1 ± 10.7	0.144
Fe (10.56-228.28 μmol/L)	19.9 ± 7.32	26.9 ± 15.0	0.028
Ferritin (629.2-7999.3 pmol/L)	742.2 ± 753.9	1934.4 ± 3914.3	0.362
Albumin (34-48 g/L)	4.64 ± 0.38	4.31 ± 0.37	0.017
HBA_{1c} (4.8%-5.9%)	5.92 ± 0.96	7.48 ± 1.78	0.121
Transferrin saturation (< 45%)	38.68 ± 30.88	49.06 ± 28.64	0.361

Table 3 Frequencies of C282Y and H63D *HFE* gene mutations in patients with NAFLD

HFE gene mutation	Fibrosis 0-2 (n = 48)	Fibrosis 3-4 (n = 14)
C282Y/C282Y	1	0
C282Y/W	1	0
H63D/H63D	3	0
H63D/W	11	3

DISCUSSION

NAFLD has become the most common liver disorder of our times. In about 15% of all NAFLD cases, steatosis may evolve into steatohepatitis, a mix of inflammation, hepatocellular injury and fibrosis, often resulting in cirrhosis and even hepatocellular carcinoma, but this process is not well understood[8]. The pathogenesis of NAFLD is often posited as the "double-hit" hypothesis, in which hepatocellular lipid accumulation is the first hit, followed by a second hit in which pro-inflammatory mediators and reactive oxygen species induce inflammation, hepatocellular injury, and fibrosis. Altered abundance and composition of liver tissue lipids may impair sinusoidal perfusion and modulate the microvascular inflammatory response[8]. On the other hand, in chronic liver disease, iron deposits are found in hepatocytes and in Kupffer/sinusoidal cells, leading to oxidative stress, cell toxicity, and genotoxicity[2]. Despite a number of reports supporting a hypothesis of an association among ferritin, iron overload, IR, and NAFLD, the mechanisms underlying this intricate and intriguing relationship remain unclear, but a likelihood is that IR, fatty acid accumula-

tion, and oxidation are the major determinants of serum ferritin levels[9].

The goal of this study was to describe a racially homogeneic cohort of Polish patients with NAFLD with respect to *HFE* gene mutations as well as their demographic, clinical, and laboratory data. The results of our study showed similar clinical and laboratory markers to those previously described as being associated with advanced fibrosis[1]. The Polish NAFLD population differs with regard to two points: our patients are less obese than the patients participating in Harrison *et al*[10] and Angulo *et al*[11] and only 16.1% of Polish patients in the current work had diabetes mellitus. In these two US studies - the largest cohort studies in NAFLD - the participants had higher BMI and DMt2 affected 35%[10] and 30%[11] of individuals, respectively.

The frequency of *HFE* gene mutations in the Polish NAFLD population is similar to the frequencies in a healthy Polish cohort[12] and other Central European countries[12] as well as in 119 Polish patients with alcoholic liver disease[13]. The first report about the connection between *HFE* gene mutations and NAFLD showed a positive correlation between levels of serum ferritin, iron, and transferrin saturation and the presence of the mutated allele, as well as between C282Y mutation and more severe fibrosis in a North American population[14]. The results of George *et al*[15] supported these findings, but subsequent larger series have not confirmed such an association[3,16-18]. The results of Chitturi *et al*[18] even brought into question the link between hepatic iron and liver fibrogenesis, and both Adams *et al*[16] and Bugianesi *et al*[3] in their series reported a lack of an association between hepatic steatosis and hepatic fibrosis in patients with HHC and iron overload. On the other hand, among patients homozygous for the C282Y *HFE* gene mutation, the degree of hepatic iron loading remains the dominant factor associated with liver fibrosis[16]. Serum ferritin is often raised in NAFLD patients[3,9] and has been associated with advanced fibrosis[18]. In our Polish cohort we also found the highest serum ferritin levels in the subgroup of NASH patients with F3-F4 fibrosis, although without statistical significance.

In the current study, higher levels of serum iron, as well as DMt2, were associated with severe liver fibrosis. There is a growing body of work showing that iron and glucose metabolism are interdependent and that an increased iron store may contribute to IR. Serum iron may contribute to IR *via* increased adipocyte lipolysis and impairment of glucose transport[19]. There is evidence from *in vitro* studies that iron can reduce binding of insulin to its receptor and reduce insulin receptor gene expression[20]. Valenti *et al*[21] showed that higher iron stores were associated with more advanced liver fibrosis.

The conflicting evidence regarding *HFE* gene mutation and NAFLD could be the result of the ethnic structure of a cohort study. The results from our study with a racially homogeneic Caucasian population showed no increased frequency of mutated alleles of the *HFE* gene in Polish NAFLD patients as well as no association between mutations and iron, ferritin, and transferrin saturation. In addition, no connection was found between *HFE* gene mutation and the clinical course of NAFLD, supporting the results of Bugianesi *et al*[3] and Yoneda *et al*[22]. An increased ferritin level is a marker of severe histological liver damage in some studies[3,9] and also in ours such a trend was observed. Together with the lack of an increased transferrin saturation and increased serum iron independently of *HFE* gene mutations, the results point strongly towards IR hepatic iron overload as a cause of progression in NAFLD. Data obtained in studies of NAFLD provide the possible mechanism of iron interfering with lipid metabolism[23] and thereby promoting hyperglycemia. There is a suggestion that the effect of iron on steatosis development may extend to other liver diseases[24].

Our study provides novel findings regarding *HFE* gene mutations and cholesterol levels. We found that in a subgroup of NASH patients with severe fibrosis, there were statistically significant correlations between the presence of at least one mutated allele of H63D and total cholesterol as well as LDL-cholesterol levels. Although H63D *HFE* gene mutations are quite common in the general population from the northern part of Europe, these results contrast with those of Pankow *et al*'s[25] US population-based study, but support our findings from a previous alcoholic liver disease study[13]. These novel results may be of value in explaining progressive liver fibrosis in at least some proportion of patients with NAFLD. Presence of *HFE* H63D mutation with elevated total and LDL cholesterol, together with increased iron levels, may lead to excessive free fatty acid oxidation with free oxygen radical formation, increased inflammation, and fibrogenesis. However, this novel aspect of NAFLD pathogenesis should be evaluated in a larger cohort of patients, because a previous study with Caucasians showed higher prevalence of the C282Y mutation in NAFLD[26]. In other studies, the frequencies of C282Y *HFE* gene mutation were similar in NAFLD patients and in the general population[27-29] and none of them found increased prevalence of H63D mutation in NAFLD.

In conclusion, this Polish population of patients with NAFLD was similar to populations described in the largest cohort studies from the United States, according to demographic and clinical data, although our patients were less obese and with no incidence of morbid obesity among them. The risk factors for advanced fibrosis in this Polish NAFLD cohort are also approximately similar to those previously reported. In addition, the frequency of *HFE* gene mutations was similar to that described for populations in Central-Eastern Europe, and neither the C282Y nor the H63D *HFE* gene mutations were associated with NAFLD pathogenesis in this cohort. Our study results also suggest a novel possible pathogenesis in some populations of NAFLD patients; however, these results should be validated in larger and racially heterogeneic populations of NAFLD patients.

COMMENTS

Background

Nonalcoholic fatty liver disease (NAFLD) is now the commonest liver disease, affecting up to a third of individuals. It includes a wide spectrum of liver diseases, ranging from pure steatosis to nonalcoholic steatohepatitis (NASH), and can eventually lead to liver cirrhosis, liver failure and hepatocelullar carcinoma. Identifying the biochemical markers and gene mutations leading to more severe liver damage in patients with NAFLD is crucial for evaluating their prognosis.

Research frontiers

There is conflicting evidence regarding inheritance of *HFE* gene mutations [hereditary hemochromatosis (HHC)] as a cofactor for development of more severe fibrosis in NAFLD patients. Although serum ferritin is an independent predictor of hepatic fibrosis, the mechanisms underlying the intricate and intriguing relationship with NAFLD are still unclear. The authors analyzed different biochemical and clinical parameters of sixty two patients with biopsy-proven NAFLD. *HFE* gene analysis was performed by polymerase chain reaction amplification of total genomic DNA of two regions of the *HFE* gene carrying the mutations C282Y and H63D.

Innovations and breakthroughs

Higher serum iron level is a predictor of more advanced fibrosis, in addition to the factors of obesity, older age, female gender and type 2 diabetes mellitus. This research provides novel findings regarding *HFE* gene mutations and cholesterol level. It was found that in a subgroup of NASH patients with severe fibrosis there were correlations between at least one mutated allele of H63D and total cholesterol as well as LDL-cholesterol levels.

Applications

These findings may be of value in the explanation of progressive liver fibrosis in at least some proportion of patients with NAFLD. Higher total and LDL cholesterol levels, together with increased iron levels, may lead to excessive free fatty acid oxidation with free oxygen radical formation, increased inflammation and fibrogenesis. However, this novel aspect of NAFLD pathogenesis should be evaluated in larger cohorts of patients.

Terminology

HFE gene mutation/HHC: An autosomal recessive genetic iron storage disorder, that usually results from defects in this gene. The mutation or polymorphism most commonly associated with hemochromatosis is C282Y. About 1/200 of people of Northern European origin have two copies of this variant; males are particularly at high risk of developing hemochromatosis. Organs commonly affected by hemochromatosis are the liver, heart and endocrine glands.

Peer review

The authors described a Polish population with NAFLD and tried to analyze the correlation of different biochemical and clinical parameters with the disease. This can be considered a very well-designed study.

Abstract

AIM: To investigate the efficiency of levobupivacaine in treating experimentally induced colitis in rats.

METHODS: Colitis was induced by trinitrobenzene sulfonic acid and ethanol in 30 rats under general anesthesia, and 10 rats were used as a sham group. Subsequent to induction of colitis, rats were divided into three groups; budesonide group received 0.1 mg/kg budesonide, levobupivacaine group received 10 mg/kg levobupivacaine and saline group received 1 mL saline solution *via* rectal route for 7 d. In the sham group, only routine rectal catheterization was performed without use of any material. At the end of 7 d, laparotomy and total colectomy were performed for histopathological examination in all rats and blood samples were drawn for measurement of tumor necrosis factor (TNF)-α and interleukin (IL)-6 following cardiac puncture. Macroscopic and microscopic evaluations of the specimens were performed by a pathologist blinded to group assignment of the rats.

RESULTS: Weight loss (P = 0.016) and macroscopic examination scores (P = 0.001) were significantly higher in saline group than others. Histopathological scoring was comparable between all colitis groups (P = 0.350). There was no significant difference in TNF-α levels and IL-6 levels (P = 0.150).

CONCLUSION: The significant improvement in macroscopic scores suggests that levobupivacaine may have topical anti-inflammatory effects in an experimental colitis model; however, this finding was not supported by microscopic findings.

INTRODUCTION

Inflammatory bowel disease (IBD), usually referring to

ulcerative colitis or Crohn's disease, has an unknown etiology[1]; however, some theories have been proposed. One of the key factors is the excessive immune response of the host[2], which has led to broad use of corticosteroids[3]. Potentially serious side effects of corticosteroids are the most important limiting factor[4]. The autonomic imbalance between sympathetic and parasympathetic nerves is anticipated as another etiological factor[5]. Adrenergic preponderance had been found to be associated with increased epithelial turnover and vasoconstriction resulting in mucosal injury[6]. The beneficial effects of nicotine on IBD support this theory[7].

Local anesthetics, particularly lidocaine, have inhibitory effects on hyperactive autonomic nerves and on host immune response[8-10]. When all these effects are put together, it is not surprising that local lidocaine was effective in the treatment of experimentally produced IBD[11]. Ropivacaine, another local anesthetic with longer acting time than lidocaine had a more pronounced protective effect on mucosal damage when it was topically applied to colonic mucosa in comparison to 5-amino salicylic acid (5-ASA)[12,13]. In this study, we investigated the potential of levobupivacaine, which is a novel, long lasting local anesthetic with less systemic side effects[14], in the treatment of experimentally induced IBD.

MATERIALS AND METHODS

All procedures in this study were approved by local animal ethics committee. The histopathological examinations and biochemical studies were performed, respectively in research laboratories of pathology and biochemistry at Uludag University School of Medicine.

Forty male Sprague-Dawley rats weighing 270 to 390 g were used in this study. The animals were kept in a restricted access room with controlled temperature and light cycle. All rats were housed in individual standard cages. *Ad libitum* standard pellet food and water were maintained for all animals to provide minimum stress.

Induction of colitis

At the day of induction all rats were anesthetized with intramuscular ketamine (8 mg/kg, Ketalar®, Pfizer Inc.) and xylazine (90 mg/kg, Ronpum®, Bayer AG). A 6F feeding tube was inserted rectally until the tip was 8 cm proximal to the anus. The mixture of 0.6 mL of trinitrobenzene sulfonic acid (TNBS) (5% w/v, 40 mg, Sigma Chemical Co., St. Louis, USA) and 0.25 mL of 50% ethanol was instilled into the lumen *via* a feeding tube. Finally, 0.5 mL of air was given to ensure that the whole mixture was instilled into the lumen of the colon.

There were four groups consisting of 10 rats for each: (1) Sham group: no colitis was induced; only rectal insertion of feeding tube was performed once a day from day 1 to day 7; (2) Budesonide group: rats were treated with daily rectal single dose of budesonide (0.1 mg/kg, Entocort® enema, AstraZeneca) *via* feeding tube for 7 d following the induction of colitis; (3) Levobupivacaine group: rats were treated with daily rectal single dose of levobupivacaine (10 mg/kg, Chirocaine®, Abbott) *via* feeding tube for 7 d following the induction of colitis; and (4) Saline group: rats were treated with daily rectal single dose of saline (1 mL, 0.9% NaCl) *via* feeding tube for 7 d following the induction of colitis.

All rectal tube applications were performed under anesthesia.

All rats were weighed daily during the study period. At the end of 7 d, laparotomy and total colectomy after inspection for adhesions were performed for all rats under general anesthesia. Finally, all rats were sacrificed by intra-cardiac puncture to get blood samples for interleukin (IL)-6 and tumor necrosis factor (TNF)-α analysis.

When tissue samples were obtained, macroscopic

TNF: Tumor necrosis factor; IL: Interleukin.

damage was scored on a scale of 0 to 13 modified from a description by Wang *et al*[15] (Table 1) by the same pathologist who was blinded to the group assignment of the rats. Later, the tissue samples were fixed with 10% formaldehyde solution. Tissue samples of 5 mm in length were taken from proximal, middle and distal segments of total colectomy specimens. All samples were embedded in paraffin wax and sections were taken and stained with hematoxylin-eosin (HE). All sections were evaluated by light microscopy and scored on a scale of 0 to 10 as described by Wang *et al*[15] (Table 2) in a blinded fashion by the same pathologist.

Serum IL-6 and TNF-α levels were analyzed with ELISA by using rat IL-6 and TNF-α kits (Invitrogen™ Rat Immunoassay Kit; Invitrogen Corporation, Carlsbad, California, USA).

Statistical analysis

The Statistical Package for Social Sciences version 11.5 (SPSS, Chicago, IL, USA) program was used for statistical analysis of data. All values were expressed as median (minimum-maximum). The Kruskal-Wallis test followed by the Mann-Whitney *U* test was used for statistical evaluation and $P < 0.05$ was accepted as the level of significance.

RESULTS

There was no significant weight difference between budesonide, levobupivacaine and sham groups; however the weight loss in the saline group was significantly higher than other groups ($P = 0.016$).

Macroscopic damage score was significantly higher in budesonide, levobupivacaine and saline groups when compared to sham group ($P = 0.001$). No significant difference was found between budesonide and levobupivacaine groups but macroscopic damage scores of these two groups were significantly lower than saline group (Budesonide *vs* Saline: $P = 0.001$; Levobupivacaine *vs* Saline: $P = 0.002$).

Various inflammatory cell accumulations and ulcerations were the common alterations observed by light microscopy in budesonide, levobupivacaine and saline groups as there was no granuloma formation or fibrosis.

Microscopic damage scores were significantly higher in budesonide, levobupivacaine and saline groups than sham group ($P = 0.014$). Although the levobupivacaine group had lower scores than the budesonide and saline groups, there was no statistical significance (Budesonide *vs* Levobupivacaine: $P = 0.436$; Saline *vs* Levobupivacaine: $P = 0.105$).

TNF-α levels did not show any significant difference among groups ($P = 0.152$). IL-6 levels in budesonide, levobupivacaine and saline groups were significantly increased when compared to sham group ($P = 0.040$). Levobupivacaine group had slightly lower IL-6 levels than budesonide and saline group, however, there was no significant difference (Levobupivacaine *vs* Saline: $P = 0.853$; Levobupivacaine *vs* Budesonide: $P = 0.247$).

These results are summarized in Table 3.

DISCUSSION

In this study, we investigated whether topical administration of levobupivacaine has an anti-inflammatory efficiency in an experimentally induced colitis model. While weight alterations and macroscopic examination scores suggested that levobupivacaine might have had anti-inflammatory effects on colitis, this suggestion was not supported by histopathological findings. Although the IL-6 levels increased secondary to induction of colitis as a proof of systemic inflammatory response, diminution of IL-6 levels after levobupivacaine administration was not significant.

Weight loss in the saline group was significantly higher when compared to levobupivacaine and budesonide or sham groups ($P = 0.016$). This might be as a result of "no treatment" as Martinsson *et al*[13] suggested. The significant weight loss in the saline group was probably due to a more serious inflammatory process than in levobupivacaine and budesonide groups. Macroscopic damage scores also supported this finding. Levobupivacaine and budesonide groups had significantly lower macroscopic damage scores than the saline group ($P = 0.001$). On the other hand, macroscopic damage scores of levobupivacaine and budesonide groups were significantly higher than the sham group ($P = 0.001$). Treatment with levobupivacaine or budesonide had equivalently improved the mucosal damage caused by colitis. Martinsson *et al*[13] suggested that ropivacaine had more protective effects than budesonide on the mucosa in a similar study. According to our findings, levobupivacaine had similar efficiency

with budesonide, which has been used in the treatment of clinical IBD[16]. Administration of levobupivacaine and budesonide diminished the inflammatory changes in our study, but this was not sufficient enough to draw back all the inflammatory process.

Microscopic damage scores did not show significant decreases in levobupivacaine and budesonide groups when compared to the saline group which suggests insufficient anti-inflammatory efficiency. However, we are not the only researchers who reported discordance between macroscopic and microscopic examination scores. Neither ropivacaine nor lidocaine administration decreased the microscopy scores even though they caused a significant decrease in macroscopic scores[13,17,18]. Maybe longer study periods are needed to examine the effects of topical local anesthetic treatment on IBD or maybe the microscopic scoring should be revisited.

TNF-α and IL-6 serum levels were measured to determine the systemic proofs of inflammatory response in our study. These cytokines act as proinflammatory factors in IBD and are usually related to severity of the disease[19]. In our study, IL-6 levels were significantly higher in levobupivacaine, budesonide and saline groups than in the sham group ($P = 0.040$). However, changes in TNF-α level did not show any significance. But it is known that TNF-α has a wide range in IBD and may sometimes not be detectable[19]. The IL-6 level in the levobupivacaine group was lower than budesonide and saline groups without statistical significance. It was reported that some local anesthetics such as lidocaine might affect the release of proinflammatory cytokines by membrane depolarization in epithelial cells[20]. The decrease of IL-6 levels in the levobupivacaine group made us think that levobupivacaine might have similar effects on cytokine levels as lidocaine. Further research might be focused on that finding.

In conclusion, despite the decrease in microscopic damage scores and IL-6 levels suggesting that topical administration of levobupivacaine might have some level of anti-inflammatory efficiency in an experimental colitis model, microscopic examination failed to support this finding. However, there may be individual differences in inflammatory response in IBD[21]. Further studies with larger groups and longer treatment periods might be beneficial in examining the potential therapeutic capacity of local anesthetics in the treatment of IBD.

COMMENTS

Background

Inflammatory bowel disease (IBD) affects many people all around the world. There are several drugs that are useful in reducing the symptoms but no definitive therapeutic agents have been defined. Local anesthetics might be useful in the treatment of IBD based on their actions that inhibit hyperactive autonomic nerves and host immune response which are key factors in the pathogenesis of IBD.

Research frontiers

Previous studies reported successful results with the local application of various local anesthetics on colonic mucosa even in comparison to conventional drugs that have been officially used in the treatment of IBD for decades.

Innovations and breakthroughs

There are various types of local anesthetics. Their action period and side effects that may be seen due to the possibility of getting into the systemic blood circulation from the areas they are applied may vary. In this study, different from the previous similar studies, the authors used levobupivacaine, which is a novel, long lasting local anesthetic with less systemic side effects.

Applications

Even though there may be some side effects if they are used in high doses or applied on very wide colonic mucosa, local anesthetics are much safer than the drugs that have been conventionally used in the treatment of IBD. Therefore, if successful results are reported with the use of local anesthetics in the treatment of IBD, a safe and cheap alternative might be defined.

Peer review

The manuscript is very interesting for the readers. In their study they explored the effect of levobupivacaine and budenosine in induced colitis. The authors analyzed macro and microscopically the resected specimen and measured the serum levels of tumor necrosis factor (TNF) and interleukin (IL)-6. It could be more interesting and support more of their results if the authors could perform immunohistochemistry detection for TNF and IL-6 in the samples.

Abstract

AIM: To evaluate the safety and efficacy of stapled transanal rectal resection (STARR), and to analyze the outcome of the patients 12-mo after the operation.

METHODS: From May 2007 to October 2008, 50 female patients with rectocele and/or rectal intussusception underwent STARR. The preoperative status, perioperative and postoperative complications at baseline, 3, 6 and 12-mo were assessed. Data were collected prospectively from standardized questionnaires for the assessment of constipation [constipation scoring system, Longo's obstructed defecation syndrome (ODS) score system, symptom severity score], patient satisfaction (visual analogue scale), and quality of life (Patient Assessment of Constipation-Quality of Life Questionnaire).

RESULTS: At a 12-mo follow-up, significant improvement in the constipation scoring system, ODS score system, symptom severity score, visual analog scale and quality of life ($P < 0.0001$) was observed. The symptoms of constipation improved in 90% of patients at 12 mo after surgery. The self-reported definitive outcome was excellent in 15 (30%) patients, fairly good in 8 (16%), good in 22 (44%), and poor in 5 (10%).

CONCLUSION: STARR can be performed safely without major morbidity. Moreover, the procedure seems to be effective for patients with obstructed defecation associated with symptomatic rectocele and rectal intussusception.

Stapled transanal rectal resection for obstructed defecation syndrome associated with rectocele and rectal intussusception. *World J Gastroenterol* 2010; 16(20): 2542-2548 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i20/2542.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i20.2542

INTRODUCTION

Obstructed defecation syndrome (ODS) is characterized by a spectrum of symptoms including difficult evacuation, excessive straining during defecation, sensation of incomplete evacuation, prolonged time to defecate, anal

pain, bleeding, and the use of external assistance to aid defecation. It has been estimated that approximately 20% of adult female population suffered from the syndrome[1,2]. The etiology of ODS is likely to be multifactorial, resulting from the interaction of functional and anatomic factors that influence the rectoanal evacuatory mechanism[3]. Furthermore, the most common clinical signs and pathophysiologic alterations associated with ODS are rectocele (RE) and rectal intussusception (RI)[4].

To date, a variety of surgical techniques including transvaginal, transperineal, transanal, and combined abdominal and vaginal approaches have been described for the treatment of ODS. However, there is no method achieving overall superiority because of different patterns of complications and high rate of recurrence. Based on the stapled hemorrhoidopexy procedure, Longo[5] proposed an alternative technique for patients with ODS caused by RE and RI called stapled transanal rectal resection (STARR). The novel technique is carried out sequentially using double circular stapler devices (PPH01, Ethicon Endo-Surgery), anteriorly and posteriorly, to restore normal rectal anatomy by strengthening rectovaginal septum and resecting redundant rectum.

STARR has been implemented rapidly and described as an effective cure for RE, RI, prolapsed hemorrhoids and even solitary rectal ulcer[6-9]. In addition, observations from several case series and multi-center trials have demonstrated a clinical benefit of the procedure in short-term follow-up[10-14]. Nevertheless, some unique and troublesome complications were also documented by a few case reports[15-18]. The current study was designed to determine the safety and efficacy of STARR in treatment of ODS related to symptomatic RE and RI, and to perform an analysis of outcomes of the patients 12 mo after surgery

MATERIALS AND METHODS

From May 2007 to October 2008, 50 female patients with ODS caused by RE and/or RI underwent STARR. Before the surgery, patients were asked about symptoms of constipation and previous histories of anorectal or gynecologic surgery. Apart from the comprehensive history, the presence and extension of any anatomical or functional abnormality were evaluated by means of a clinical examination and appropriate physiological investigations such as proctoscopy, colonoscopy, colonic transit time study, defecography and anorectal manometry. All the patients were operated on by the same surgical team, using the original techniques reported previously[6] without modifications. The protocol was approved by the ethical committee of our institution and all patients gave informed written consent.

Inclusion criteria

Patients with persistence of at least three specific symptoms of ODS (feeling of incomplete evacuation, prolonged painful straining, frequent calls to defecate, excessive toilet time, digital assistance, pelvic pain or pressure, rectal bleeding, soiling, or a feeling of prolapse). Additionally, conservative treatment with diet (1.5 L/d water, high-fiber diet), laxatives (10 g/d lactulose), enemas and/or physiotherapy had been tried in all patients without success. Moreover, there was radiologically-proven RE $\geqslant$ 3 cm, or RI < 4 cm on straining, or significant rectal barium trapping after defecation.

Exclusion criteria

Exclusion criteria were in accordance with the consensus statement published by the Pioneers group[4] and the consensus recommendations by Corman *et al*[19]. These included patients with good response to conservative treatment, slow transit constipation, enterocele, sigmoidocele, cystocele, genital prolapse, external rectal prolapse, pelvic floor dyssynergia, proctitis, active perineal infection, chronic diarrhoea, inflammatory bowel disease, neoplasia, anorectal stenosis and previous anterior resection with rectal anastomosis, and patients with anal incontinence (Cleveland Clinic Florida; Wexner Score > 7) and foreign material (such as mesh) adjacent to the rectum or with mental disorder. Furthermore, RE < 3 cm or RI $\geqslant$ 4 cm on straining was not considered straightforward candidates for the STARR procedure. Also excluded were those with general contraindications for surgery and those who declined surgical treatment.

Study design

All patients had detailed data on preoperative status, perioperative and postoperative complications. A clinical assessment was performed at baseline and at 3, 6, and 12 mo after surgery. The magnitude and degree of ODS were quantified by constipation scoring system (CSS)[20]. The validated CSS consists of eight items and the overall score ranges from 0 (normal) to 30 (severe constipation). In addition to CSS, the severity of disordered defecation was also quantified by Longo's ODS score system (Table 1) and the symptom severity (SS) score (Table 2). The summed global scores of ODS and SS range from 0-40 and 0-36, respectively, in which a higher score indicates more severe symptoms. Moreover, the index of patient satisfaction was evaluated by a visual analog scale (VAS: with a score from 0 to 10), and a higher score suggests an improvement in patient satisfaction with the surgery. Patient Assessment of Constipation-Quality of Life Questionnaire (PAC-QoL), a self-reported questionnaire, was used to measure the quality of life of patients[21,22]. The validated PAC-QoL is composed of 28 items grouped into four subscales: physical discomfort, psychosocial discomfort, worries and concerns, and satisfaction. The first three subscales were used to assess the patient dissatisfaction index, with an overall score ranging from 0 to 96 (where lower scores correspond to better quality of life). The satisfaction subscale includes four items with a global score ranging from 0 to 16, so that each patient's self-reported definitive outcome was defined as either poor (0-4), fairly good (5-8), good (9-12), or excellent (13-16)[23].

STARR: Stapled transanal rectal resection.

Surgical technique

Polyethylene glycol electrolyte solutions were given for preoperative bowel preparation, and patients received routine broad-spectrum antibiotics immediately after the induction of anesthesia. The operation was always performed under spinal anesthesia with the patient in a lithotomic position. According to recommendations for the performance of STARR[6], two circular PPH-01™ staplers (Ethicon Endo-Surgery) were used. Briefly, the anal canal was gently dilated, then the circular anal dilator (CAD33) introduced and secured with silk sutures. Three semi-circumferential purse-string sutures were positioned in the anterior rectum at approximately 1, 2, and 3 cm above the haemorrhoidal apex. The first PPH-01 stapler was inserted and the posterior rectal wall was protected with a spatula. The ends of sutures were delivered through the specific holes of the stapler, and tension was applied to prolapse the removed tissues into the stapler housing, making sure that the posterior vaginal wall had not been incorporated, the stapler was closed and fired. By the same procedure, two semi-circumferential purse-string sutures and a second PPH-01™ stapler were performed on the posterior rectal wall. Subsequent bleeding from the staple line was controlled with full-thickness 2-0 Vicryl™ stitches, and "posterior staple bridge" was divided with scissors.

Statistical analysis

Statistical analysis was performed using paired *t* test for continuous variables, and Wilcoxon's signed-rank test for quantitative variables. The total scores of CSS, ODS, SS, VAS and PAC-QoL were expressed as mean values with 95% confidence intervals (CI). A P value < 0.05 was considered statistically significant.

RESULTS

There were 50 female patients (median age, 53.7 years; range, 30-70 years). As shown in Table 3, 43 (86%) patients had experienced 1-5 vaginal deliveries, 13 (26%) had experienced at least one episiotomy, and 36 (72%) had undergone prior anorectal or gynecologic surgeries. All the patients had symptoms of outlet obstruction (Table 4). Median operating time was 28 min (range,

20-50 min). The mean vertical height of the resected specimen was 3.8 cm (range, 2.5-4.8 cm) anteriorly and 2.0 cm (range, 2.0-4.0 cm) posteriorly; the mean horizontal length was 5.9 cm (range, 4.6-7.2 cm) anteriorly and 4.4 cm (range, 3.2-5.3 cm) posteriorly. The only intraoperative incident was subsequent bleeding from the anastomotic ring, which occurred in 92% of cases and was secured with hemostatic stitches.

Early complications are summarized in Table 4. The most common morbidity after surgery was defecatory urgency, and the incidence was 42% during the first postoperative week. Bleeding occurred in 4 (8%) patients, but the symptom was minor and no further surgical intervention was required. Other recorded complications were acute incontinence to flatus (6%), acute urinary retention (4%), severe pain (4%) and anal fissure (2%). No staple line dehiscence, massive rectal hemorrhage, rectovaginal fistula, perianal sepsis and postoperative mortality occurred.

In addition, the postoperative complications were followed up for one year. As shown in Table 5, the frequency of defecatory urgency decreased dramatically with time and was 10% at 3-mo, 6% at 6-mo and merely 2% at 12-mo follow-up. Incontinence to flatus was a problem in only 1 (2%) elderly patient at a 3-mo follow-up. Moreover, the patient developed incontinence and remained unchanged during a 12-mo follow up. Another 2 (4%) cases had chronic pain during 3 mo after resection, whereas one resolved at a 6-mo follow-up. Forty-six (92%) patients had a clinical benefit at 3 mo, however, constipation recurred in one patient at 6 mo after the STARR procedure. At a follow-up of 12 mo, the symptoms of constipation improved in 45 (90%) patients. No rectal stenosis and rectal diverticulum occurred.

The variation of the CSS, ODS, SS and VAS scores are presented in Figure 1A-D. Overall, a significant reduction in CSS, ODS and SS scores was observed at 12 mo as compared with baseline [CSS score at baseline *vs* 12 mo: 15.58 (95% CI: 14.40-16.76) *vs* 5.68 (95% CI: 4.34-7.02); ODS score: 17.54 (95% CI: 16.13-18.95) *vs* 5.92 (95% CI: 4.31-7.53); SS score: 15.22 (95% CI: 13.91-16.53) *vs* 4.52 (95% CI: 3.29-5.75); $P < 0.0001$]. The differences indicated that patients undergoing STARR had an improvement in the symptoms of obstructed defecation. Additionally, the VAS score at 12 mo was more markedly increased than that at baseline [VAS score at baseline *vs* 12 mo: 4.07 (95% CI: 3.79-4.35) *vs* 7.59 (95% CI: 7.10-8.08), $P < 0.0001$]. The results were consistent with the improvement in CSS, ODS and SS scores, and suggested that patients undergoing STARR also had an obvious improvement of patient satisfaction. Summarized data from the individuals showed that the PAC-QoL score at 12 mo was significantly lower than that at baseline [PAC-QoL (dissatisfaction index) at baseline *vs* 12 mo: 47.78 (95% CI: 44.25-51.31) *vs* 8.14 (95% CI: 6.13-10.15), $P < 0.0001$]. Furthermore, the self-reported definitive outcome was excellent in 15 patients (30%), fairly good in 8 (16%), good in 22 (44%), and poor in 5 (10%). These observations demonstrated that most of the patients (90%) undergoing STARR had noticeable improvement in both the quality of life and the index of satisfaction.

DISCUSSION

ODS is an emerging and challenging clinical problem, the pathophysiology of which remains to be clearly defined. RE and RI, however, are the two most frequent anatomic defects associated with ODS. Although various surgical procedures have been described for the treatment of the syndrome, many of these are unsuitable for patients accompanied with RE and RI[24]. Notably, STARR has been demonstrated as an alternative operation and a relatively noninvasive surgical technique for ODS caused by RE and RI. The novel procedure aims to correct rectocele, resect internal prolapse, restore anatomy, correct rectal volume, and improve function[10]. Nevertheless, limited evidence has been available about the safety and short-term efficacy of STARR so far[23,25,26].

In our experience, STARR can be performed safely without major morbidity. The only intraoperative incident was subsequent bleeding from the staple line which happened in 92% of patients. Given that a full thickness segment of rectal wall was excised by the STARR staplers, the anastomotic ring should be meticulously checked and carefully secured with stitches whenever necessary. The current dada documented 4 (8%) cases with mild bleeding from the staple line postoperatively,

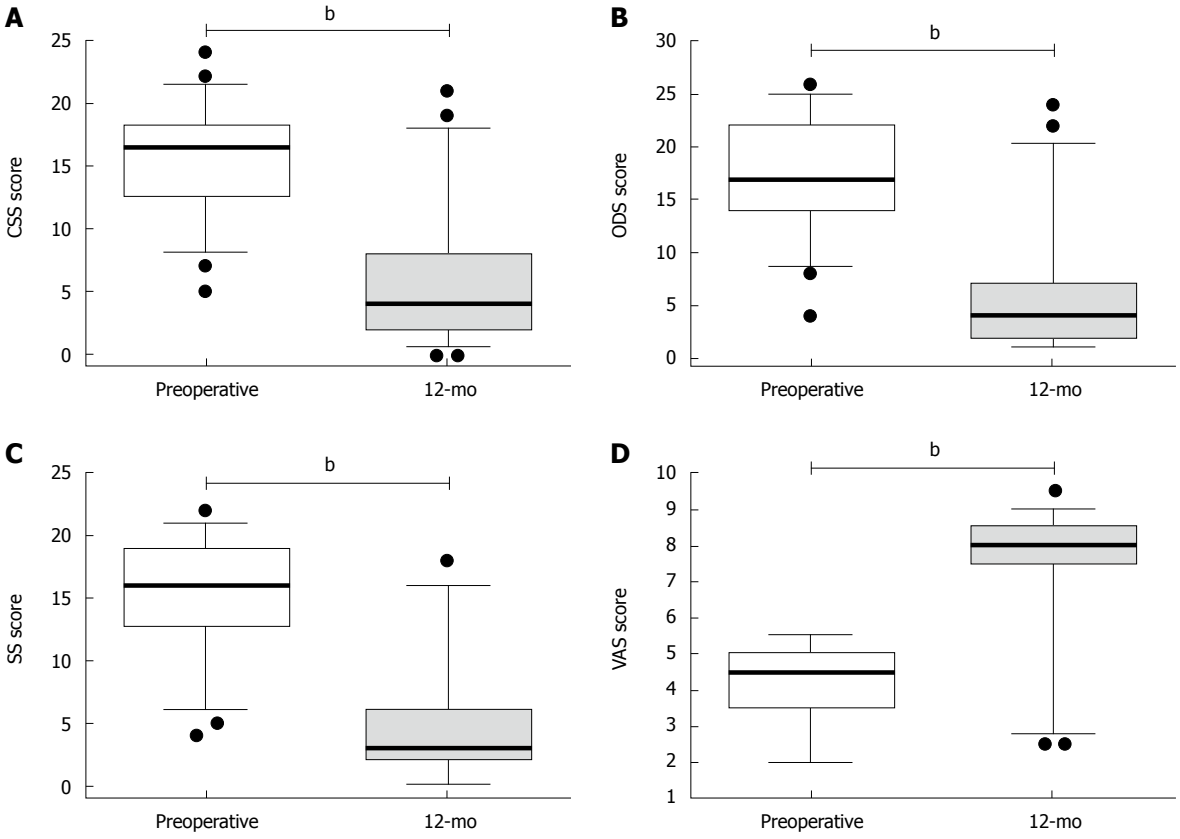

Figure 1 Comparison of scores at baseline and at a 12-mo follow-up. A: Comparison of constipation scoring system (CSS) scores; B: Comparison of Longo's obstructed defecation syndrome (ODS) scores; C: Comparison of symptom severity (SS) scores; D: Comparison of visual analog scale (VAS) scores. A significant reduction in the CSS, ODS, SS and VAS scores was observed at 12 mo after surgery as compared with baseline (paired *t* test , $^{b}P < 0.0001$).

but no one required further surgical intervention. Additionally, no severe complications associated with bleeding such as massive rectal hemorrhage and secondary anastomotic sepsis occurred in this study. Furthermore, no patient had recto-vaginal fistula. It may be because to a large extent, that much attention was paid to avoiding any entrapment of the posterior wall of vagina in the process of operation. Even though a few worrisome complications[15-18] including staple line dehiscence, rectal diverticulum, pelvic infection and even fulminating necrotizing pelvic fasciitis occurred following the STARR procedure in some studies, none of our patients developed any of the complications.

Accumulating evidences have shown that defecatory urgency was the most common complaint in the immediate and intermediate recovery periods after STARR[26,27]. Consistently, our data showed that the incidence was 42% during the first postoperative week and 10% at 3-mo, 6% at 6-mo and merely 2% at a 12-mo follow-up. The frequency was decreased dramatically with time, indicating that the complication was largely self-limited. Contrary to Titu's observations[27], the complaint was not present with an obviously regular rhythm and symptom-relieving period character in our patients. Although the exact etiopathogenesis of defecatory urgency is unclear, it may reflect the inflammatory response related to the staple line, presence of irritable rectum, and reduced rectal capacity or compliance. The incidence of incontinence to flatus was 6% during the first week after surgery, but was only 2% at a 3-mo follow-up. The marked improvement manifested that it may be a procedure-related complication caused by transient sphincteric impairment during instrumentation. Nevertheless, one elderly patient with postoperative defecatory urgency was concomitant with incontinence during a 12-mo follow-up. The potential relationship between defecatory urgency and incontinence need to be further elucidated.

Even though there is no acknowledged and standardized assessment to quantitate ODS, a dedicated score represents an essential tool, which can be used for the clinical staging of ODS for subsequent surgery and for the evaluation of therapeutic results[28]. Therefore, the validated CSS, Longo's ODS score system, SS score, VAS, and the validated PAC-QoL were used for clinical assessment in this study. Compared with the preoperative results, an evident reduction in the CSS, ODS and SS scores was exhibited at 12 mo after surgery. The variation demonstrated the efficacy of STARR in relieving symptoms of obstructed defecation. Furthermore, the significant differences between preoperative and postoperative mean total scores of VAS and PAC-QoL indicated an improvement in both the patient satisfaction index and the quality of life. At a 12-mo follow-up, it was noteworthy that the self-reported definitive outcome was excellent in 15 patients (30%), fairly

good in 8 (16%), good in 22 (44%), and poor in 5 (10%). The symptoms of constipation improved in 45 (90%) patients. However, a few studies have reported the limited effect of STARR for the treatment of ODS[15,16]. The different inclusion/exclusion criteria, the limited expertise of STARR surgery and the absence of routine surgical practice may account for the discrepant results. In addition, the long-term benefits warrant further investigations.

Intriguingly, the Contour Transtar stapler™ (Ethicon Endo-Surgery, Inc.) device has been introduced more recently as a modification of the STARR procedure[29,30]. Transtar has the potential benefit of being able to tailor the amount of rectal wall to be resected. Meurette *et al*[31] suggested that it would be wise to select the STARR procedure for a predominant "isolated" RE and the Transtar procedure for a high grade RI. Therefore, further research into this area is required to optimize patient selection, and the difference in function and efficacy between STARR and Transtar remains to be observed.

COMMENTS

Background

Obstructed defecation syndrome (ODS) is one of the most widespread clinical problems which frequently affect middle-aged females. Rectocoele (RE) and rectal intussusception (RI) are the two most common clinical signs and anatomic defects associated with ODS. Stapled transanal rectal resection (STARR) is a new procedure for obstructed defecation due to RE and RI.

Research frontiers

Previous studies have shown a clinical benefit of the STARR procedure for ODS related to RE and RI in short-term follow-up. However, limited effect and some serious complications were also described. In this study, the authors demonstrated that STARR seems to be safe and effective for selected patients presenting with ODS caused by RE and RI.

Innovations and breakthroughs

This is an original study taking place in a single centre that describes the safety and feasibility of STARR for the management of ODS due to symptomatic RE and RI. The study confirms that this technique can be performed safely without major morbidity. Furthermore, the symptoms of constipation relieved in 90% of patients with significant improvement in both the quality of life and the index of satisfaction at 12 mo after surgery.

Applications

Although the current study indicates a short-term clinical benefit, a longer follow-up should be made to establish the true value of STARR. Moreover, further studies are needed to optimize patient selection and compare the efficacy of this technique with that of other surgical procedures for patients with ODS.

Terminology

STARR is a relatively noninvasive surgical technique using double circular stapler devices to resect a full thickness segment of rectal wall. The novel procedure has been utilized for the treatment of RE, RI, prolapsed hemorrhoids, solitary rectal ulcer and even rectal tumor.

Peer review

This work is well planned and structured. The authors report good short-term results with the STARR procedure for obstructed defecation due to a RE or RI.

Abstract

AIM: To prospectively investigate the association between the *Xba* I polymorphisms of apolipoprotein B (*APOB*) gene and gallstone formation following gastrectomy.

METHODS: The study was conducted between January 2005 and December 2006. A total of 186 gastric cancer patients who had undergone radical gastrectomy were grouped according to *Xba* I polymorphisms of *APOB* gene (X^+X^- group, n = 24 and X^-X^- group, n = 162) and compared. The *Xba* I polymorphisms of *APOB* gene were detected by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP).

RESULTS: The incidence of gallstone was significantly higher in the X^+X^- group than in the X^-X^- group [54.2% *vs* 9.3%, RR = 5.85 (2.23-15.32), P < 0.001]. The serum levels of total cholesterol (TC) and low-density lipoprotein (LDL) were higher in the X^+X^- than in the X^-X^- group (4.02 ± 1.12 *vs* 3.48 ± 0.88, P = 0.004 before surgery and 3.88 ± 1.09 *vs* 3.40 ± 0.86, P = 0.008 after surgery). LDL was 2.21 ± 0.96 *vs* 1.89 ± 0.84 (P = 0.042) before surgery and 2.09 ± 0.95 *vs* 1.72 ± 0.85 (P = 0.029) after surgery in the two groups. No relationship was found between *Xba* I polymorphisms and gallbladder motility.

CONCLUSION: In Chinese patients after radical gastrectomy, X^+ allele of *APOB* gene is another risk factor for the development of gallstone besides the gallbladder motility disorder after surgery.

INTRODUCTION

The incidence of gallstones is higher in patients after radical gastrectomy than in the general population[1]. The current literature suggests that this higher incidence is related to gallbladder motility disorder after surgery resulting from severance of the vagus nerve, non-physiological reconstruction of the gastrointestinal tract and lymph node dissection[2-5]. However, it is also observed in clinical practice that following the same type of surgery on patients with the same stage of gastric cancer, some of them

do and the others do not develop gallstones. This suggests that besides gallbladder dysmotility, there are some possible inherent factors of gallstone formation after gastrectomy. In recent years, several studies have reported that polymorphisms in the apolipoprotein B (*APOB*) gene were associated with gallstone diseases[6,7]. Apolipoprotein B is a key protein in lipid metabolism. It plays an important role in the homeostasis of low-density lipoprotein (LDL) cholesterol in plasma serving as a ligand for receptor-mediated endocytosis of LDL. Several polymorphic forms of *APOB* alleles have been reported to be associated with disorders like coronary heart disease and non-insulin dependent diabetes mellitus[8]. The *APOB-Xba* I polymorphism has been found to be associated with increased serum lipids. Genetic polymorphisms in the *APOB* gene have also been reported to be associated with susceptibility to cholesterol gallstones[9]. However, the effects of *APOB-Xba* I gene polymorphism in patients who had undergone radical gastrectomy for gastric cancer without any previous history of cholelithiasis, abnormal gallbladders motility, diabetes, hyperlipidemia, hyperparathyroidism and other metabolic disorders is unknown. The present study prospectively investigated the association between the *Xba* I polymorphisms of *APOB* gene and gallstone formation after radical gastrectomy.

MATERIALS AND METHODS

Patients

The study enrolled 206 patients who underwent radical gastrectomy for gastric cancer in Zhongshan Hospital between January 2005 and December 2006. The inclusion criteria included age less than 60 years; biopsy proven gastric cancer; normal gallbladder motility; no gallstone or other hepatobiliary system diseases, no metabolic disorders and important organs dysfunction. To avoid biases, all patients were operated upon by the same surgical team with D2 dissection. Complete data were available for only 186 patients as 20 patients were lost to follow-up (3 patients in X^+X^- group and 17 patients in X^-X^- group). These patients were grouped according to *Xba* I polymorphisms of *APOB* gene. For analyzing the effects of *Xba* I polymorphisms, blood was also collected before and 6 mo after gastrectomy. The serum lipids, lipoproteins and apolipoproteins were determined. The levels of total cholesterol (TC), LDL and *APOB* were tested by biochemical autoanalyser (HITACHI7600). The gallbladder motility was examined by detecting gallbladder emptying fraction (GBEF) using nuclide imaging before and 6 mo after gastrectomy. Gallstone formation was determined by periodic ultrasonography after gastrectomy.

Informed consent was obtained from all patients, and the study was approved by the ethics committee of the hospital.

Determination of DNA polymorphism

Leukocyte genomic DNA was extracted from 5 mL of peripheral blood by TianGen Genetic DNA Kit (TianGen Biotech Co., Ltd.). The desired segments were amplified by PCR using the APOB *Xba* I protocols with the primers: 5'(5'GGAGACTATTCAGAAGCTAA3') and 3'(3'GAAGAGCCTGAAGACTGACT5'). The final amplification products were submitted to digestion with the restriction enzymes (*Xba* I) and the variations were visualized after electrophoresis on 1.5% agarose gel with ethidium bromide under ultra-violet light, followed by photographic documentation. PCR cycle for amplification of *APOB* gene was performed at 95℃ for 5 min followed by 95℃ for 45 s, annealing at 58℃ for 45 s and extension at 72℃ for 45 s in 33 cycles. A final extension was conducted for 10 min at 72℃. The products were digested by *Xba* I restriction enzyme at 37℃ for 12 h.

Statistical analysis

Data are expressed as the means ± SD. Means of age, body mass index (BMI), TC, LDL and *APOB* in different groups were compared using Student's t test. Gender, stage, types of gastrectomy and reconstruction were compared using χ^2 test. The differences between each genotype of *Xba* I polymorphisms and the incidence of gallstones were assessed by Fisher's exact test. Interaction between *Xba* I polymorphisms and gallbladder motility in the development of gallstone after gastrectomy was estimated by logistic regression analysis. SPSS statistical software, version 15.0 for Windows was used for all analyses. $P < 0.05$ was considered statistically significant.

RESULTS

Demographic data of X^+X^- group and X^-X^- group

The frequencies of X^+X^- and X^-X^- in 186 patients were 24 (13%) and 162 (87%), respectively. No genotype with X^+X^+ was detected in the study. Demographic data of X^+X^- group and X^-X^- groups are shown in Table 1. The median follow-up time was 28 mo (range: 24-32 mo). The mean age and BMI at the time of gastrectomy was 56.1 ± 8.2 years (range: 38-80 years) and 21.9 ± 1.8 kg/m^2 (range: 19.2-25.1 kg/m^2), respectively. With regard to type of gastrectomy, 7 (4%), 162 (87%), and 17 (9%) patients underwent a proximal, distal and total gastrectomy, respectively. Age and BMI did not differ significantly between the X^+X^- and X^-X^- groups. With respect to TMN stage, gallbladders motility after surgery, types of gastrectomy and reconstruction, there were no significant differences between the two groups (Table 1).

Gallstone formation after radical gastrectomy in X^+X^- and X^-X^- groups

Of the 186 patients, 28 (15.1%; 13 in X^+X^- group, 15 in X^-X^- group) developed gallstones with in a mean follow-up period of 28.4 ± 2.7 mo. The incidence of gallstone formation was significantly higher in the X^+X^- group than in the X^-X^- group (54.2% *vs* 9.3%, relative risk 5.85, 95% CI: 2.23-5.32, $P < 0.001$). The time period from gastrectomy to detection of the gallstones ranged from 6 to 32 mo with a median of 20 mo. The timing of gallstones formation showed no difference between the two groups

Table 1 Demographic data of 186 gastric cancer patients who underwent gastrectomy with D2 dissection in the X^+X^- and X^-X^- groups (mean ± SD) *n* (%)

GBEF before surgery	50.9% ± 12.5%	51.3% ± 10.3%	0.863
GBEF after surgery	30.3% ± 20.1%	29.6% ± 19.1%	0.868
Follow-up period after gastrectomy (mo)	28.3 ± 1.1	28.6 ± 1.2	0.249

n: Number of patients with gallstone; GBEF: Gallbladder emptying fraction.

(Table 2). For further analysis, whether interaction existed between *Xba* I polymorphisms and gallbladder motility in the development of gallstone after gastrectomy was estimated by logistic regression. As a result, no interaction effect of *Xba* I polymorphisms was found with gallbladder motility (Table 3). To analyze the higher incidence of gallstone in X^+X^- group, the serum concentrations of TC, LDL and APOB were compared between the two groups (Table 4). The serum levels of TC and LDL were significantly higher in X^+X^- group than in X^-X^- group both before and after surgery, but there was no statistical difference in APOB values between the two groups.

DISCUSSION

Formation of gallstones after radical gastrectomy is the result of a very complex interaction of various factors.

Table 3 Association of *Xba* I genotypes with gallstone after gastrectomy, stratified by gallbladder motility status

	Normal gallbladder motility[1]		Abnormal gallbladder motility[1]		Pinteraction
	Gallstone (+)	Gallstone (-)	Gallstone (+)	Gallstone (-)	
X^+X^- group	3	7	10	4	0.701
X^-X^- group	1	61	14	86	

[1]According to the GBEF (gallbladder emptying fraction), estimated by logistic regression analysis.

Table 4 Serum levels of TC, LDL and APOB in X^+X^- and X^-X^- groups (mean ± SD)

	X^+X^- group (*n* = 24)	X^-X^- group (*n* = 162)	*P* value
Total cholesterol (mmol/L)			
Before surgery	4.02 ± 1.12	3.48 ± 0.88	0.004
After surgery	3.88 ± 1.09	3.40 ± 0.86	0.008
Low-density lipoprotein (mmol/L)			
Before surgery	2.21 ± 0.96	1.89 ± 0.84	0.042
After surgery	2.09 ± 0.95	1.72 ± 0.85	0.029
Apolipoprotein B (μg/L)			
Before surgery	0.73 ± 0.15	0.70 ± 0.12	0.142
After surgery	0.72 ± 0.14	0.68 ± 0.12	0.072

TC: Total cholesterol; LDL: Low-density lipoprotein; APOB: Apolipoprotein B.

Destruction of neural structures, such as the vagal nerves, represents one well-known risk factor[2,10,11]. It is speculated that complete amputation of the vagal trunk with dissection of the esophagus (as in total gastrectomy) has a great influence on the contractile ability of the gallbladder. A previous experimental study showed that gastrectomy abolishes phasic contraction of the gallbladder, resulting in an absence of agitation of the gallbladder bile and mixing of gallbladder bile with fresh hepatic bile, increasing the propensity for salt precipitation and gallstone formation[12]. The type of reconstruction is also closely related to gallstone formation because the passage of food through the duodenum stimulates a variety of hormonal secretions such as cholecystokinin[13,14] and this hormone causes contraction of the gallbladder through the hormonal regulation system. It is postulated that exclusion of the duodenum leads to changes in the pattern of cholecystokinin secretion, resulting in decreased gallbladder contraction and an increased risk of gallstone formation[15].

Almost all previous studies have attributed gallstone formation to gallbladder motility disorder after radical gastrectomy. However, it is known from clinical experience that after the same type of surgery is performed on patients with the same stage of gastric cancer, some of them do and the others do not develop gallstones. In the present study, of 114 patients with abnormal gallbladder motility after surgery, 24 patients (21%) developed gallstones and the others did not. It suggests that the theory

of gallbladder motility disorder cannot completely explain gallstone formation after radical gastrectomy. The present study showed that the incidence of gallstone formation was significantly higher in the X^+X^- group than in the X^-X^- group (54.2% *vs* 9.3%), RR 5.85 (2.23-15.32), suggesting that the X^+X^- genotype may be another risk factor in gallstone formation after radical gastrectomy besides gallbladder motility disorder. Furthermore, we found that X^+X^- genotype had no interaction effect with gallbladder motility.

The *Xba* I RFLP-PCR in exon 26 of the *APOB* gene involves the 2488th nucleotide (ACC→ACT). The presence of thymine creates a restriction site for the *Xba* I enzyme characterizing the X^+ allele, whereas its absence determines the X^- allele. These are synonymous variations and so they do not affect the amino acid sequence of *APOB*[16,17]. Hegele *et al*[18] suggested that the allelic frequencies varied between races or within genetic subgroups of a single race. Caucasians have a much higher frequency of X^+ allele than Chinese. In our study, the frequency of X^+ allele in Chinese population was 13% similar to other regional reports and much lower than that reported in Caucasians, South Asians and Brazilians[8,19-21]. Law *et al*[22] and Rajput-Williams *et al*[23] also found a positive association between the X^+ allele and cholesterol concentration, whereas others did not demonstrate such correlation[24,25]. In the present study, we observed that in Chinese population, the serum levels of TC and LDL were significantly higher in X^+X^- group than in X^-X^- group both before and after gastrectomy, but no statistical difference was found in APOB values between the two groups. Since the X^+ and X^- variations are synonymous, the APOB concentration showed no difference between X^+X^- and X^-X^- groups. It is possible that the X^+ allele is in linkage disequilibrium with an unknown variation in the *APOB* gene or with a variation in another gene that influences the levels of TC and LDL, resulting in an increased saturation of bile cholesterol, leading to the gallstone formation[26,27].

In conclusion, the X^+ allele of *APOB* gene in Chinese patients is another important risk factor of gallstone formation after radical gastrectomy. Since this is the first report in a relatively small cohort, the findings should be validated in more independent studies.

COMMENTS

Background

The cause of higher incidence of gallstone after radical gastrectomy is very complex. Besides the gallbladder motility disorder, *Xba* I polymorphisms of apolipoprotein B (*APOB*) gene may be associated with gallstone development.

Research frontiers

APOB is a key protein in lipid metabolism. However, the effects of *APOB-Xba* I gene polymorphism on patients who underwent radical gastrectomy for gastric cancer are unknown. In this study, the authors demonstrate that X^+ allele of *APOB* gene is an important risk factor of gallstone formation after gastrectomy.

Innovations and breakthroughs

Previous studies have attributed higher incidence of gallstone after radical gastrectomy to gallbladder motility disorder. This is the first study to report the relationship between genetic factor (*APOB-Xba* I gene polymorphism) and gallstone formation in gastrectomized patients.

Applications

It is important to screen the high-risk group of gallstone in patients who underwent radical gastrectomy in order to prevent the gallstone formation after surgery.

Peer review

This is a small but interesting study with a reasonable rationale - examining whether a suspected genetic risk factor for gallstones increases the risk of gallstones after gastrectomy (which is a known major risk factor for gallstones). The authors indicated X allele of *APOB* gene is another risk factor for development of gallstone formation after radical gastrectomy. This present data is clear and interesting.

Abstract

AIM: To explore the expression and function of slug, a transcriptional repressor, in human intrahepatic cholangiocarcinoma (IHCC) and identify its role in IHCC progression.

METHODS: Expression of slug was detected in 36 cases of IHCC and 12 cases of normal intrahepatic bile ducts and liver parenchyma by immunohistochemistry. The patients were divided into low slug expression group (< 20% of carcinoma cells stained) and high slug expression group (≥ 20% of carcinoma cells stained). Slug expression was correlated with clinicopathological parameters of IHCC patients. The patients were defined as short-term survivors if their survival time was < 12 mo and as long-term survivors if their survival time was ≥ 12 mo.

RESULTS: Slug was not expressed in normal liver epithelium samples, lowly expressed in 15 tissue samples (10 -, 5 +) and highly expressed in 21 tissue samples (16 ++; 5 +++) from IHCC patients. The survival rate of patients with a low slug expression was 33.3% (n = 5) and 66.7% (n = 10), respectively. The survival rate of patients with a high slug expression was 61.9% (n = 13) and 38.1% (n = 8), respectively (P = 0.02). Lymph node metastasis was found in 4 (26.7%) out of the 15 patients with a low slug expression and in 14 (66.7%) out of the 21 patients with a high slug expression, respectively. The incidence rate of lymph node metastasis increased with the increasing slug expression level (P = 0.003), and higher in patients with a high slug expression than in those with a low slug expression. Slug expression did not significantly correlate with the tumor size and stage or histologic grade, or with the gender and age of patients.

CONCLUSION: Slug expression is a novel prognostic marker for IHCC with lymph node metastasis.

Clinicopathologic significance of slug expression in human intrahepatic cholangiocarcinoma. *World J Gastroenterol* 2010; 16(20): 2554-2557 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i20/2554.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i20.2554

INTRODUCTION

Intrahepatic cholangiocarcinoma (IHCC) is the second

most common liver cancer in adults, accounting for approximately 10% of all primary liver cancers[1,2]. Complete surgical resection is the only procedure for IHCC. The prognosis of IHCC is very poor because of its advanced stage when diagnosed and early metastasis. The prognostic factors for IHCC include curative resection, hepatitis B surface antigen (HBsAg), as well as tumor, node and metastasis (TNM) stage, tumor size, lymph node metastasis, perineural invasion, portal vein invasion, and intrahepatic metastasis[3-7].

Slug, a member of the snail family of transcription factors, plays a crucial role in regulation of epithelial-mesenchymal transition by suppressing several epithelial markers and adhesion molecules, including E-cadherin[8-12]. It has been shown that slug is overexpressed in breast, esophageal squamous cells, colorectal, gastric carcinomas and lung adenocarcinoma[13-17], accompanying increased lymph node metastasis. In this study, we investigated whether slug expression is correlated to the invasion and lymph node metastasis of IHCC and whether it is a significant prognostic factor after surgical resection.

MATERIALS AND METHODS

Patients and tissue samples

From October 1998 to December 2008, 36 IHCC patients (21 men and 15 women) at the age of 31-76 years (mean: 60 ± 9 years) underwent liver resection at the Second Department of General Surgery in Affiliated Hospital of Qingdao University (China). All the patients were histologically confirmed to have IHCC. Thirty-six patients underwent hepatectomy with lymph node dissection in 30, and common bile duct resection with biliary reconstruction in 18. Lymph node metastasis, lymphovascular invasion, and distant metastasis were detected in 18, 12, and 8 patients, respectively. Clinicopathologic parameters were recorded and compared.

Histologic examination

Resected specimens were cut along the largest diameter, fixed with formalin and embedded in paraffin. The sections were stained with hematoxylin and eosin (HE). Tumor diameter, bile duct spread type, vascular and lymphatic duct permeation of cancer cells, perineural invasion of cancer cells, and lymph node metastasis were observed and recorded.

Immunohistochemistry

Mouse monoclonal anti-slug antibodies diluted at 1:100 (Santa Cruz Biotechnology, Santa Cruz, CA, USA) and secondary antibodies to rabbit anti-mouse IgG (Bost, Wuhan, China) were used for immunostaining. Formalin-fixed and paraffin-embedded tissue blocks were cut into 4-μm thick sections. After deparaffinization and blocking of endogenous peroxidase with 0.3% hydrogen peroxide in methanol for 30 min, the sections were immersed in 10 mmol/L citrate buffer (pH 6.0), dried in a microwave oven for 25 min, and washed with 50 mmol/L Tris-buffered saline (TBS; pH 7.6). After preincubation with normal goat serum (DAKO, Hamburg, Germany), the sections were incubated with appropriate primary antibodies for 1 h at room temperature, washed with TBS, incubated with secondary antibodies (diluted at 1: 50) for 30 min, and washed again with TBS. Peroxidase reaction was visualized using 0.05% diaminobenzidine tetrahydrochloride (DAB) containing 0.01% hydrogen peroxide. The sections were counterstained with hematoxylin. IHC results were assessed with a scoring system as previously described[18].

Immunohistochemical staining was expressed as percentage of positively stained carcinoma cells. Slug expression in cytoplasm of cells was evaluated. The percentage of positively stained carcinoma cells was graded as -: < 5% of carcinoma cells stained, +: ≥ 5% - < 20% of carcinoma cells stained, ++: ≥ 20% - <50% of carcinoma cells stained, and +++: ≥ 50% of carcinoma cells stained. Additionally, the examined cases were divided into low slug expression group and high slug expression group for statistical analysis.

Statistical analysis

All statistical analyses were carried out using the SPSS 11.0 software (SPSS, Chicago, USA). Differences between slug expression in tumor and its adjacent nontumorous tissues were analyzed using paired Student's *t* test. Spearman bivariate correlation was used to determine positive or negative correlations between slug protein expression and clinicopathologic parameter of IHCC patients. Relation between slug protein expression and clinicopathologic parameters of IHCC patients was analyzed using the Pearson χ^2 test. $P < 0.05$ was considered statistically significant.

RESULTS

Histologic observation

Slug was detected in 26 of 36 tumor tissue samples (72.2%). Weak staining (+), moderate staining (++), and strong staining (+++) were found in 5, 16, and 5 tumor tissue samples, respectively. Slug was lowly expressed in 15 (- and +) tumor tissue samples and highly expressed in 26 (++ and +++) tumor tissue samples, respectively. The positive slug staining (≥ 5% of carcinoma cells stained) was observed in cytoplasm of carcinoma cells. Slug was not expressed in normal intrahepatic bile ducts or liver parenchyma of 12 normal epithelium tissue samples.

Relation between slug expression and clinicopathologic features

The relation between slug expression and clinicopathologic parameters of IHCC patients is summarized in Table 1. The percentages of distant metastasis, positive nodal metastasis, and positive lymphatic invasion were significantly higher in patients with a high slug expression than in those with a low slug expression, as were the percentages of recurrence in hematogenous and lymph nodes.

The expression rate of slug was 66.7% and 33.3% in patients with a long survival time (> 12 mo) and a short

⩾ 1	10	8	< 0.050

survival time (< 12 mo), respectively. A high slug expression was seen in 38.1% and 61.9% of long-term survivors and short-term survivors, respectively ($P = 0.04$, Table 1).

DISCUSSION

Slug (Snai2), a snail-related zinc-finger transcription factor, is critical for the normal development of neural crest-derived cells and loss-of-function. It has been shown that slug mutations contribute to pie baldism and Waardenburg syndrome type 2 in a dose-dependent manner and slug is aberrantly expressed in a number of tumors, thus contributing to tumorigenesis[19-22]. It has been reported that overexpression of slug plays a role in progression of many malignancies such as breast, colon, and gastric cancers[13,15,16]. Slug up-regulation correlates with deeper invasion, lymph node metastases, and stage of esophageal squamous cell carcinoma[14]. It was reported that slug up-regulation is significantly related with distant metastases and advanced pTNM stage of gastric carcinoma[16]. In this study, however, we were unable to find a significant association between slug up-regulation and lymph node metastases of IHCC.

In this study, the expression of slug protein was detected by immunohistochemistry in 26 (72.2%) out of 36 IHCC tissue samples, indicating that slug is expressed in IHCC. However, slug was not expressed in normal intrahepatic bile ducts or liver parenchyma.

The poor prognosis of IHCC patients with a high slug expression seemed to be related to the high incidence of lymph node metastases. Slug was closely correlated with lymph node invasion, lymphovascular invasion, and distant metastasis ($P < 0.005$). The patients with lymphatic invasion and distant metastasis had a high slug expression. Furthermore, the higher recurrence of lymph node metastasis in patients with a high slug expression also indicated that slug might play an important role in lymph node metastasis of IHCC. In various other cancers, such as breast cancer[13], and esophageal squamous cell carcinoma[14], slug is positively correlated with lymph node metastasis, also indicating that slug may play an important role in invasion of sinusoidal space and portal tract. Nevertheless, the precise mechanism underlying lymphatic duct invasion and lymph node metastasis has yet to be clarified. Another mechanism underlying the affinity of cancer cells for lymphatic tissue may also present. Therefore, it is necessary to determine the precise mechanism underlying lymph node metastasis of IHCC.

In this study, high slug expression was significantly related to a short survival time of IHCC patients and was an independent factor for poor prognosis of IHCC patients. The outcome after surgery was significantly poorer in patients with a high slug expression than in those with a low slug expression, suggesting that slug may be involved in the progression of IHCC and serve as a marker for predicting the malignancy of IHCC after surgery.

It has been shown that slug is expressed in several malignancies, such as breast and gastric cancer[13,16]. Slug expression is independently correlated with tumor invasiveness in breast cancer[13]. It has also been shown that slug is present in all infiltrating ductal carcinomas with lymph node metastases[16] and slug expression is inversely correlated with the differentiation of breast cancer[13]. In our experiment, no correlation was found between slug expression and tumor differentiation, which may be attributed to the limited number of cases.

In conclusion, slug is expressed in IHCC and is an independent indicator of poor prognosis. Slug can be sued as a marker for predicting the outcome of patients with IHCC after surgical resection. IHCC patients with positive slug expression should be followed up carefully.

COMMENTS

Background

The incidence of intrahepatic cholangiocarcinoma (IHCC) has been increasing in recent years. However, its cause remains largely unknown. Prognosis of IHCC is very poor because of early metastasis. Several recent studies have shown that slug is overexpressed in many cancers accompanying lymph node metastasis, which is related to shorter survival time of IHCC patients.

Research frontiers

In this study, slug was overexpressed, which is related to increased lymph node metastasis and shorter survival time of IHCC patients.

Innovations and breakthroughs

Recent reports have highlighted the importance of slug in carcinogenesis. Slug

is overexpressed in many cancers including IHCC, which is related to increased lymph node metastasis and shorter survival time of IHCC patients.

Applications

This study may foster a future strategy against IHCC by elucidating whether slug expression is correlated to invasion and lymph node metastasis of IHCC, and whether slug expression may be a significant prognostic factor after surgical resection.

Terminology

Slug, a member of the snail family of transcription factors, plays a crucial role in regulation of epithelial-mesenchymal transition by suppressing several epithelial markers and adhesion molecules, including E-cadherin.

Peer review

The results of this study support the use of novel biomarkers in diagnosis and treatment of IHCC. The histological identification of slug expression was carefully done and the conclusion is evidence-based.

Abstract

AIM: To evaluate the efficacy of high-dose proton pump inhibitors (PPIs) *vs* low-dose PPIs for patients with upper gastrointestinal bleeding.

METHODS: PubMed, Embase, the Cochrane Library, and Web of Science were searched to identify relevant randomized controlled trials (RCTs). Eligible trials were RCTs that compared high-dose PPI with low-dose PPI following endoscopic hemostasis. The primary endpoint was rebleeding; secondary endpoints were patient numbers that needed surgery, and mortality. The meta-analysis was performed with a fixed effects model or random effects model.

RESULTS: Nine eligible RCTs including 1342 patients were retrieved. The results showed that high-dose intravenous PPI was not superior to low-dose intravenous PPI in reducing rebleeding [odds ratio (OR) = 1.091, 95% confidential interval (CI): 0.777-1.532], need for surgery (OR = 1.522, 95% CI: 0.643-3.605) and mortality (OR = 1.022, 95% CI: 0.476-2.196). Subgroup analysis according to different region revealed no difference in rebleeding rate between Asian patients (OR = 0.831, 95% CI, 0.467-1.480) and European patients (OR = 1.263, 95% CI: 0.827-1.929).

CONCLUSION: Low-dose intravenous PPI can achieve the same efficacy as high-dose PPI following endoscopic hemostasis.

INTRODUCTION

Acute upper gastrointestinal bleeding is a prevalent and clinically significant condition[1]. The core management of these patients consists of resuscitation and endoscopic therapy, but rebleeding still occurs after initial control of the bleeding[2]. Currently, the combination of endoscopic

hemostasis and administration of proton pump inhibitors (PPIs) is the standard management, and two authoritative consensus guidelines have recommended the use of a high-dose PPI regimen (80 mg stat followed by an infusion of 8 mg/h for 72 h) following endoscopic hemostasis for high-risk peptic ulcer bleeding lesions[3,4]. The possible biological benefit of this high-dose regimen is to promote clot stability by sustaining the intragastric pH above 6[5,6]. However, when high-dose PPI is compared with a low-dose PPI regimen after primary endocopic hemostasis is achieved, some clinical trials[7-10] reported no differences in rebleeding rate and the need for surgery between the high- and low-dose regimens.

This meta-analysis aims to analyze trials of low-dose *vs* high-dose PPI after endoscopic hemostasis, and to determine whether low-dose PPI administration can produce the same effect as high-dose after endoscopic hemostasis. This study was performed according to the QUOROM (Quality of Reporting Of Meta-analysis) statement, and the QUOROM statement checklists were all answered as "Yes"[11].

MATERIALS AND METHODS

Literature search

A comprehensive literature search was performed to identify all randomized controlled trials (RCTs). Trials were identified by systematically searching the electronic databases PubMed, EMBASE, the Cochrane Library, and Web of Science in any language. The search was conducted using the following key words: omeprazole, lansoprazole, esomeprazole, pantoprazole, dexlansoprazole, rabeprazole, PPI, and bleeding. The last search was done in September 2009. In addition, an extensive manual search was also performed by using references from each retrieved study or review article.

Study selection

Trials were included using the following criteria: (1) RCT; (2) comparing high-dose with low-dose PPI following endoscopic hemostasis for acute upper non-variceal gastrointestinal bleeding; and (3) availability of adequate data (persistent or recurrent bleeding, need for surgery, or mortality). Subsequently, trials were excluded if the PPI treatment was initiated prior to endoscopic hemostasis. The study selection was done by two reviewers independently, and any difference of opinion was settled by discussion. Publications identified as duplicates were excluded, and when one study had substantial overlap in terms of author, institution or study period with another study, the one which was more recent and of better quality was included.

Regarding the definitions of high and low-dose PPIs, high-dose was not limited to the regimen of 80 mg iv bolus followed by an infusion of 8 mg/h for 72 h. In our study, dosage of PPI was considered high-dose if at least twice the low-dose of any of the PPIs was used during the 72 h following endoscopic hemostasis.

Qualitative assessment

The quality of the studies was assessed and graded by two reviewers independently according to criteria described in The Cochrane Handbook 5.0.1[12]. The criteria included: (1) sequence generation; (2) allocation concealment; (3) blinding of participants, personnel and outcome assessors; (4) incomplete outcome data; and (5) selective outcome reporting. Each criteria was categorized as "yes", "no", or "unclear", and the summary assessments of the risk of bias for each important outcome within and across studies was categorized as "low risk of bias", "unclear risk of bias" and "high risk of bias"[12].

Data extraction

Two reviewers independently extracted data by using a standardized form. If there was inconsistency, the original papers were retrieved and jointly investigated to resolve the disagreement. Data were extracted regarding the details of all therapeutic interventions, including the specific kind of PPI, the dose and administration method (oral, intermittent bolus, or continuous infusion). We also extracted the first author, publication year, patients age, sex ratio, region, numbers assigned to each group, numbers with comorbid conditions, the site of bleeding ulcer (duodenal, gastric or esophageal), signs of recent hemorrhage (spurting, oozing, non-bleeding vessel, and adherent clot). Our primary endpoint was persistent or recurrent ulcer bleeding, and secondary endpoints included patient numbers that needed surgery and mortality.

Statistical analysis

The pooled odds ratio (OR) and 95% confidence intervals (CI) were calculated from the original study data by using the Mantel-Haenszel method (fixed effects model) if no heterogeneity was detected throughout the studies[13]; in other words, if there was no variability among the studies in the meta-analysis because all the studies could be assumed to come from the same population. Statistical heterogeneity was assessed using the forest plot and inconsistency statistic (I^2). If any heterogeneity existed ($P < 0.1$, OR $I^2 > 50\%$), then use of the fixed effects model might have been invalid. Any heterogeneity was explored by subgroup analysis and by a sensitivity analysis done by excluding the studies which potentially biased the results. If the investigations of the cause of the heterogeneity showed that this was more appropriate, then the Der Simonian and Laird method (random effects model) was applied. A random effects model assumes that each study has a different underlying effect and this leads to wider confidence intervals than with the fixed effects model[13]. Egger's test was applied to determine the symmetry of the funnel plot, to identify any publication bias, $P < 0.05$ indicated bias, and $P > 0.05$ indicated no publication bias[14].

All data analyses were performed using the statistical software Stata 9.2 (Stata Co., College Station, Texas, USA).

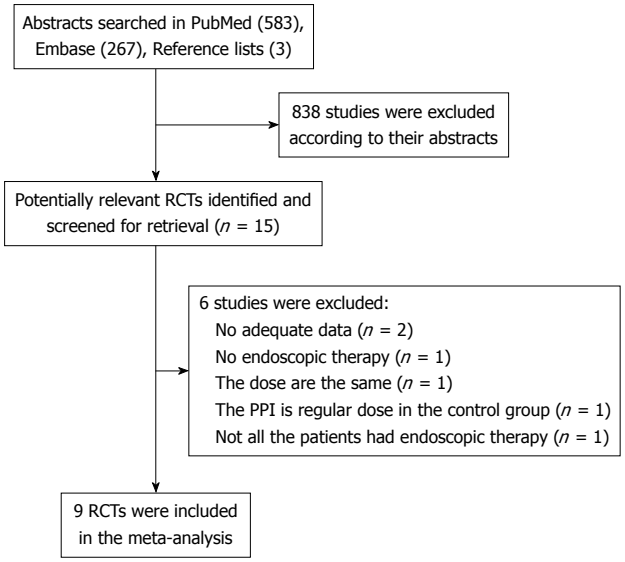

Figure 1 Flow chart of the literature search for this meta-analysis.

RESULTS

Searches of the PubMed and Embase databases identified 583 and 267 abstracts, respectively. After screening the titles and the abstracts, 12 studies from PubMed and Embase and their full texts were retrieved for further review[2,8,10,15-23], and 3 studies were found from reference lists[7,9,24]. Thus, in total, 15 studies were retrieved for further review. Two studies were excluded because no adequate data were available[18,22], one study was excluded because not all the patients received endoscopic therapy[20], one study was excluded because the total dose of PPI was the same across the different groups[23], one study was excluded because the PPI in the intravenous group was regular dose[15], one study was excluded because not all patients had endoscopic intervention[10]. Thus, 9 studies and 3 abstracts[7,9,24] were included in this meta-analysis. The flow chart of the literature search of this meta-analysis is shown in Figure 1.

The qualities of the included studies are shown in Table 1. Thus, 4 studies are at low risk of bias[16,17,21,22], 2 studies are at unclear risk of bias[9,19], and the other 3 studies are at high risk of bias[2,7,24], including two which could not be accessed as full texts. Thus, 4 studies' allocation sequence were adequately generated[2,8,16,17], 5 studies' allocation were adequately concealed[8,16,17,19,21], 3 studies' blinding of participants, personnel and outcome assessors were adequately carried out[8,16,21], 5 studies' incomplete outcome data were adequately addressed[8,16,17,19,21], 2 studies were free of other bias[16,17].

Patients were of European origin in 6 studies[7-9,16,17,24] and Asian in 3 studies[2,19,21]. Baseline characteristics and PPI regimens of the included studies are shown in Tables 2 and 3, respectively. Thus, 9 studies including 1342 patients were analyzed in this meta-analysis, and the mean number of patients per study was 149, ranging from 24 to 474. The mean age of patients was ⩾ 60 years in 6 studies, in the other three studies the age of the patients could not be ascertained. The number of patients who had gastric ulcers was 435, while that of duodenal ulcers was 600, included in the 6 studies from which adequate data could be extracted[2,8,16,17,19,21]. The PPI used in the included studies was omeprazole or pantoprazole. In fact, 4 studies used omeprazole[8,9,19,21], 3 studies used pantoprazole[2,7,17], while the other 2 studies used both drugs[16,24].

Rebleeding

Nine studies including 1342 patients evaluated the rate of rebleeding as an outcome measure; 666 patients in the high-dose group and 676 patients in the low-dose group. The summary OR for rebleeding was 1.091 (95% CI: 0.777-1.532, $P = 0.617$) suggesting the result was not statistically significant when comparing high-dose with low-dose PPI following endoscopic hemostasis in reducing the risk of rebleeding (Figure 2A). The χ^2 test for heterogeneity for the high-dose effect in rebleeding was not significant ($I^2 = 0.0\%$, $P = 0.498$). The subgroup analysis according to different region did not indicate any benefit in either European or Asian population with high-dose PPI regimen compared with low-dose regimen following endoscopic hemostasis; for Asian patients the summary OR was 0.831 (95% CI: 0.467-1.480, $P = 0.529$), while for European patients the summary OR was 1.263 (95% CI: 0.827-1.929, $P = 0.279$). No heterogeneity was detected in those two subgroup analyses, with *P*-values of 0.143 and 0.812, respectively. The summary OR for rebleeding from 4 studies using omeprazole[8,9,19,21] (OR = 0.926, 95% CI: 0.550-1.557) and for the remaining 5 studies using pantoprazole/omeprazole[2,7,16,17,24]

PPIs: Proton pump inhibitors; OME: Omeprazole; PAN: Pantoprazole.

(OR = 1.234, 95% CI: 0.786-1.936) did not differ in rebleeding rate. The summary OR for rebleeding from 5 studies[2,9,16,17,19] with endoscopic high-risk stigmata for rebleeding revealed no reduction in the high-dose PPI group (OR = 0.991, 95% CI: 0.628-1.565, P = 0.970). The summary OR for rebleeding from 4 studies[16,17,21,22] with low risk of bias revealed no reduction in the high-dose PPI group (OR = 1.479, 95% CI: 0.963-2.269, P = 0.999). When excluding the 3 abstracts, the summary OR for rebleeding from the remaining 6 studies revealed no reduction in the high-dose PPI group (OR = 1.130, 95% CI: 0.827-1.544, P = 0.335). In addition, the time-frame of rebleeding rate should be taken into consideration, because one study reported early rebleeding (within first 72 h)[17], two studies reported in-hospital occurrence of rebleeding[8,25], one study reported rebleeding before discharge and within 14 d[19], and 2 studies reported rebleeding within 30 d[21,26]; the time-frame of rebleeding was not reported in the remaining 3 studies[7,9,24].

Surgery

Seven studies[2,8,9,16,17,19,24] including 1225 patients evaluated the rate of surgery as an outcome measure; 532 patients in the high-dose group and 537 in the low-dose group. Thus, the need for surgery was reported in 2.3% of the patients treated with high-dose PPI, and in 1.5%

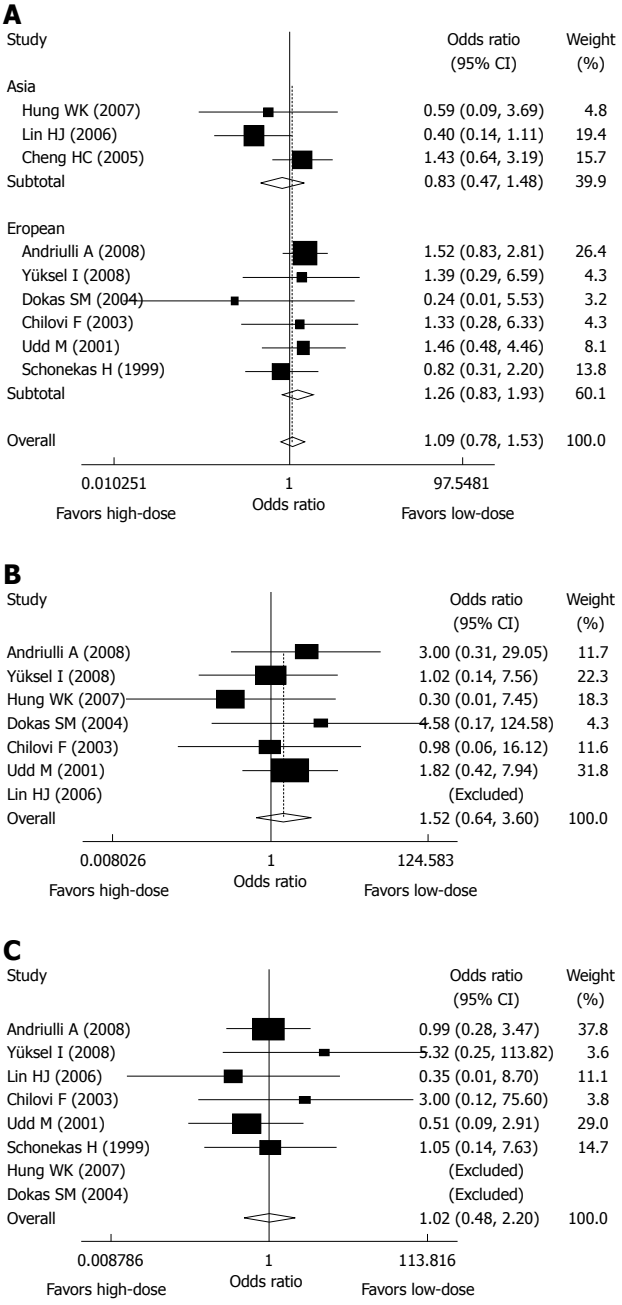

Figure 2 Meta-analysis results of randomized clinical trials comparing high-dose proton pump inhibitor (PPI) *vs* low-dose PPI in rebleeding (A), surgery (B) and mortality (C).

of the patients treated with low-dose PPI. The summary OR for surgery was 1.522 (95% CI: 0.643-3.605, P = 0.340), indicating the result was not statistically significant when comparing high-dose with low-dose PPI following endoscopic hemostasis in reducing the need for surgery (Figure 2B). The χ^2 test for heterogeneity for the high-dose effect in reducing the need for surgery was not significant (I^2 = 0.0%, P = 0.840). The summary OR for surgery from 5 studies[2,9,16,17,19] with endoscopic high-risk stigmata for rebleeding revealed no reduction in the high-dose PPI group (OR = 1.465, 95% CI: 0.461-4.655, P = 0.517). The summary OR for surgery from 4 studies[16,17,21,22] with low risk of bias revealed no reduction in the high-dose PPI group (OR = 1.760, 95% CI: 0.626-4.946, P = 0.780). When excluding the 2 abstracts, the summary OR for surgery from the remaining 5 studies revealed no reduction in the high-dose PPI group (OR = 1.422, 95% CI: 0.569-3.556, P = 0.676).

Mortality

Eight studies[2,7-9,16,17,19,24] including 1237 patients evaluated the rate of mortality as an outcome measure; 614 patients in the high-dose group and 623 patients in the low-dose group. Thus, mortality was reported in 2.0% of the patients treated with high-dose PPI, and in 1.9% of the patients treated with low-dose PPI. The summary OR for mortality was 1.022 (95% CI: 0.476-2.196, P = 0.955), indicating the result was not statistically significant comparing high-dose with low-dose PPI following endoscopic hemostasis in reducing overall mortality (Figure 2C). The χ^2 test for heterogeneity for the high-dose effect of affecting overall mortality was not significant (I^2 = 0.0%, P = 0.765). Six studies[2,8,9,16,17,19] reported causes of death, and rebleeding caused 8 deaths (4 in the high-dose PPI group and 4 in the low-dose group); the summary OR for rebleeding-related deaths was 1.008 (95% CI: 0.250-4.067, P = 0.991), suggesting no benefit with high-dose PPI therapy. No studies stated the time-frame of mortality rate clearly, so they were assumed to be in-hospital mortality rates.

Publication bias

The P-values from Egger's test in rebleeding, the need for surgery, and mortality were of 0.183, 0.674, and 0.488, respectively. Thus, no publication bias exists in this meta-analysis.

DISCUSSION

Rebleeding has remained the most important adverse prognostic factor contributing to morbidity and mortality after upper gastrointestinal hemorrhage[25]. Previous consensus groups have recommended that an intravenous bolus followed by continuous-infusion PPI is effective in decreasing rebleeding in patients who have undergone successful endoscopic therapy[4]. However, this recommendation of a high-dose of PPI is in conflict with some previous studies[7,16], which reported no difference in the magnitude of risk reduction between high-dose and low-dose regimens. Therefore, this meta-analysis set out to evaluate the efficacy of a high-dose PPI regimen *vs* a low-dose PPI regimen in reducing rebleeding, the need for surgery and the mortality rate following endoscopic hemostasis for upper gastrointestinal bleeding.

The findings of this meta-analysis suggest that a high-dose PPI regimen for patients who have undergone successful endoscopic therapy is not superior to a low-dose PPI regimen for the parameters of rebleeding (OR = 1.091, 95% CI: 0.777-1.532, P = 0.617), the need for surgery (OR = 1.522, 95% CI: 0.643-3.605, P = 0.340),

and mortality (OR = 1.022, 95% CI: 0.476-2.196, P = 0.955) and rebleeding-related deaths (OR = 1.008, 95% CI: 0.250-4.067). Also, no heterogeneity exists, suggesting that the studies for these endpoints were homogenous.

It has been hypothesized that the efficacy of a high-dose PPI regimen may vary depending on physiological measures, pharmacodynamic profiles (metabolism of proton-pump inhibitors through the cytochrome P4502C19 genetic polymorphism), and prevalence rates of *Helicobacter pylori* infection in different ethnicities[26], so subgroup analysis was carried out to determine whether low-dose PPI can have the same efficacy in patients from different regions. This subgroup analysis did not find any difference in rebleeding rate between Asian and European patients using a low-dose PPI regimen. However, the need for surgery and mortality cannot be assessed in this subgroup analysis due to limited studies. Thus, a low-dose PPI regimen can achieve the same efficacy in reducing rebleeding as a high-dose regimen in both Asian (OR = 0.831, 95% CI: 0.467-1.480, P = 0.529) and European patients (OR = 1.263, 95% CI: 0.827-1.929, P = 0.279). The endoscopic therapy technique was epinephrine injection, plus if indicated thermal or mechanical therapy, and this technique was applied in 5 studies[2,8,9,16,21]. This endoscopic therapy technique is practical and widely used in most hospitals, so the endoscopic therapy technique was homogenous across the included studies. In this present meta-analysis, four studies evaluated omeprazole, while the other 5 studies evaluated pantoprazole or both drugs together. Subgroup analysis according to different PPI showed similar results to those found in all 9 studies, so this effect of PPI seems to be a class effect.

This meta-analysis showed that the high-dose PPI regimen did not affect overall mortality (OR = 1.022, 95% CI: 0.476-2.196, P = 0.955) when compared with the low-dose PPI regimen. A total of 8 deaths were rebleeding-related (50% in the high-dose group and 50% in the low-dose group), and 11 deaths were non-ulcer deaths (45.5% in the high-dose group and 54.5% in the low-dose group). The data in this present meta-analysis indicated that the high-dose group had a similar mortality rate as the low-dose group independent of the outcome of comorbid diseases. However, this mortality result is not reliable, because it has been estimated that in order to detect clinically important effects on mortality, at least 1000 high-risk patients should be included in each of the treatment and control groups[27]; thus the number of high-risk patients included in this meta-analysis is not enough. Nonetheless, since high-dose regimens can produce similar reductions in rebleeding and need for surgery as low-dose regimens, maybe the effect of a high-dose PPI regimen on mortality is the same as a low-dose PPI regimen.

Summary improvements in transfusion requirements and duration of hospital stay have not been analyzed in this meta-analysis, because these improvements are of lesser clinical magnitude and are based on weaker source study methodology[28].

A previous meta-analysis revealed that PPI therapy is only efficacious for patients who had endoscopic high-risk stigmata for rebleeding[29]. In addition, subgroup analysis has shown that in this particular patient group, low-dose PPI is as effective as high-dose PPI. Future studies should stratify the management of patients according to low-, intermediate-, and high-risk endoscopic lesions with relevant strategies that include low-dose PPI regimens.

Cost-effectiveness analyses using decision modeling and direct costing from studies have demonstrated that the use of high-dose PPI following endoscopic hemostasis saves money for health care systems in most clinical scenarios[30,31]. Thus, if low-dose PPI is as effective as high-dose, it is assumed that this can result in savings in health care costs. The most recent randomized trials comparing the use of intravenous regular-dose omeprazole with oral rabeprazole revealed that these drugs are equally effective in preventing rebleeding in patients with high-risk bleeding peptic ulcers after successful endoscopic injection with epinephrine[15]. If intravenous PPIs could be replaced by oral PPIs, this could result in significant savings in healthcare resources[32]. This trial was performed in an Asian population, however, so additional data from randomized clinical trials comparing the use of intravenous PPIs with that of oral PPIs are required in western patient populations.

In this meta-analysis, the modality of endoscopic intervention and the type of PPI used have varied across studies. Regarding the claim that monotherapy with epinephrine is inferior to dual endoscopic therapies[33], published data are not consistent. Pharmacologic data indicate a class effect of PPI therapy as inhibitors of gastric secretion, and one study did find similar rebleeding rates in a comparative trial of omeprazole *vs* pantoprazole[24]. Therefore, the differences in practice patterns across different studies might constitute a particular strength of this meta-analysis, because it better approximates the real-life practice due to availability of different PPIs and endoscopic interventions in different hospitals. Thus, the differences in the modality of endoscopic intervention and the type of PPI would not have affected the overall validity of our findings.

There are some limitations in this meta-analysis: firstly, a total of nine studies were included, in which only four studies were at low risk of bias, and three studies could not be accessed as full texts, so the included studies are not quite adequate; secondly, although subgroup analysis revealed that the summary OR for rebleeding remained statistically stable (similar to summary OR obtained from 9 studies), it does not prove the stability of our results; thirdly, the time-frame of rebleeding rate varied between different studies, so the results for rebleeding should be interpreted with caution, and further subgroup analyses were not performed in this meta-analysis; fourthly, studies included in this meta-analysis were carried out with varying doses of PPI, different populations with different risks of rebleeding and varying proportions of associated comorbid diseases. It is inevitable

in clinical practice to encounter different patients, so this should not affect the overall validity of the findings.

In conclusion, a low-dose PPI regimen is as efficacious as a high-dose PPI regimen following endoscopic hemostasis in upper gastrointestinal bleeding patients, and this beneficial effect seems to be similar in both Asian and European patients. Future comparative trials are warranted to compare oral PPI with intravenous PPI following endoscopic hemostasis in western patient populations.

COMMENTS

Background

The combination of endoscopic hemostasis and the administration of proton pump inhibitors (PPIs) is the current standard management for upper gastrointestinal hemorrhage. A low-dose of PPIs may achieve the same efficacy as high-dose PPIs following endoscopic hemostasis.

Research frontiers

This meta-analysis investigated the rebleeding rate, the need for surgery and mortality outcomes in randomized controlled trials (up to 9 studies).

Innovations and breakthroughs

Compared with high-dose PPIs following endoscopic hemostasis, low-dose PPIs can achieve the same effect in reducing rebleeding, the need for surgery and mortality. This beneficial effect seems to be consistent in both Asian and European patients.

Applications

The study can be applied as guidance for using low-dose PPI regimens following endoscopic hemostasis for gastrointestinal bleeding.

Peer review

This is a good quality work on a subject of everlasting interest.

Abstract

The involvement of the small bowel in systemic forms of amyloidosis may be diffuse or very rarely focal. Some cases of focal amyloidomas of the duodenum and jejunum without extraintestinal manifestations have been reported. The focal amyloidomas consisted of extensive amyloid infiltration of the entire intestinal wall thickness. Radiological barium studies, ultrasound and computed tomography (CT) patterns of diffuse small bowel amyloidosis have been described: the signs are non-specific and may include small-bowel dilatation, symmetric bowel wall thickening, mesenteric infiltration, and mesenteric adenopathy. No data are available about the positron emission tomography (PET)/CT and magnetic resonance imaging (MRI) patterns of intestinal amyloidosis. We report two cases of small bowel amyloidosis: the former characterized by focal deposition of amyloid proteins exclusively within blood vessel walls of the terminal ileum, the latter characterized by diffuse intestinal involvement observed on MRI and PET/CT studies.

INTRODUCTION

Systemic amyloidosis is a rare disease characterized by the extracellular deposition of amyloid protein in one or more organs[1]. Involvement of the small bowel is frequent in systemic amyloidosis[2], and protein deposition

is mainly seen in the mucosa, the submucosal connective tissues, the muscularis propria and within blood vessel walls. The deposition of amyloid into the blood vessel walls causes bowel ischemia and muscle atrophy leading, eventually, to mucosal erosion or ulceration[3].

The involvement of small bowel may be diffuse or very rarely localized, presenting as focal amyloidoma[4-6]. Focal amyloidomas of the small bowel without extraintestinal manifestations are rare and typically present as multiple polypoid lesions or large amyloid tumors of the duodenum and jejunum[5-7].

To the best of our knowledge, a case of focal deposition of amyloid proteins exclusively within blood vessel walls of the terminal ileum has never been described in the literature.

Radiological barium studies, ultrasound (US) and computed tomography (CT) pattern of diffuse small bowel amyloidosis have been described: the signs are non-specific and may include small-bowel dilatation, symmetric bowel wall thickening, mesenteric infiltration, and mesenteric adenopathy[4,8,9].

On the contrary, the positron emission tomography (PET)/CT and magnetic resonance imaging (MRI) patterns of intestinal amyloidosis have never been described in the literature.

We report two cases of small bowel amyloidosis: the former characterized by focal deposition of amyloid proteins exclusively within blood vessel walls of the terminal ileum, the latter characterized by diffuse intestinal involvement observed on PET/CT and MRI studies.

CASE REPORT

Case 1

A 72-year-old woman with a medical history of hypertension and of multiple episodes of acute onset of abdominal pain accompanied by intestinal sub-occlusion presented in our hospital.

Two months before our observation, the patient had undergone conventional colonoscopy with retrograde ileoscopy, which disclosed mucosal ulcerations of the terminal ileum and of the ileo-cecal valve. The biopsy specimen showed active inflammatory infiltration without evidence of granulomas.

On admission the patient had acute abdominal pain and intestinal sub-occlusion. She was afebrile with stable vital signs. Findings on physical examination were significant for distended abdomen with discrete tenderness in the right iliac fossa.

Laboratory studies including complete blood count, serum electrolytes, liver function tests, coagulation and tumour markers were as follows (with normal values): hematocrit, 34% (37%-54%); haemoglobin, 11.5 g/dL (12-16); white blood cell count, 16 300 cells/mm^3 (4800-10 800); alkaline phosphatase, 117 U/L (35-104); γ-glutamyl transpeptidase, 81 U/L (5-36); albumin, 3.5 g/dL (3.6-5.2). The remaining values were unremarkable.

An US examination of the abdomen showed thickened (20 mm) hypoechoic walls of the terminal ileum with loss of parietal stratification and mild pseudoaneurysmal dilatation of the lumen. Moreover multiple ileo-cecal lymph nodes with a diameter ranging between 10 and 20 mm were disclosed.

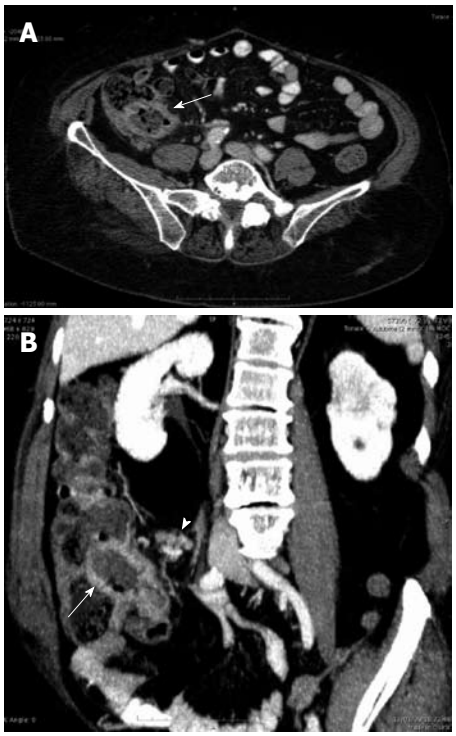

Figure 1 The axial computed tomography (CT) image (A) and the multiplanar reformatted (MPR) coronal oblique image (B) showed thickened walls of the terminal ileum with mild pseudoaneurysmal dilatation of the lumen (arrows) and multiple ileo-cecal lymph nodes (arrow head).

To better evaluate the US intestinal findings, a 64 multidetector CT scan of the abdomen and pelvis was performed 75 s after the intravenous bolus administration of 150 cc iodinated non ionic contrast agent. The CT images confirmed the findings of US (Figure 1A and B). The mesenteric vessels and the collateral branches were patent.

The US and CT findings suggested the following diagnostic hypothesis: an intestinal lymphoma, considering the pseudoaneurysmal dilatation of the intestinal lumen and the dimension of ileo-cecal lymph nodes or less probably a terminal ileitis. Features of intestinal ischemia were not present.

The patient underwent laparotomy with ileo-caecal resection. The biopsy specimen was consistent with a deposition of amyloid within blood vessels of the terminal ileum walls after staining with Congo red (Figure 2).

The patient was discharged from the hospital in a stable condition 5 d after surgery. Further workup showed (1) a monoclonal spike in the serum immunoelectrophoreses; (2) the immunoglobulin κ light-chain urine concentration was 71 mg/L (normal, < 10 mg/L) and the immunoglobulin λ light-chain urine concentration was 26 mg/L (normal, < 5 mg/L); and (3) 8% plasma cells in the bone marrow aspirate. There was no clinical, laboratory, or radiographic evidence of extraintestinal involvement of

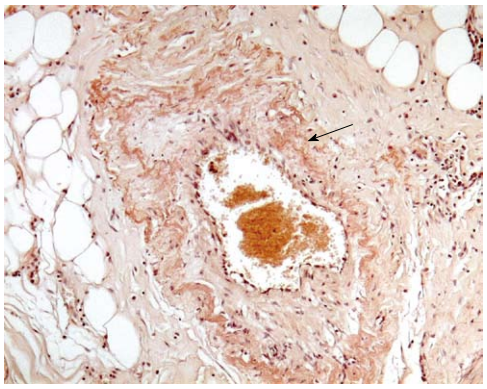

Figure 2 Intestinal amyloid ("congophilic") angiopathy. Amyloid in the intramural vessels of terminal ileum walls (arrow) takes the Congo red stains (× 270).

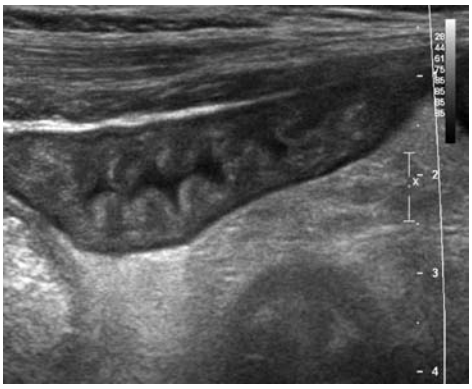

Figure 3 Ultrasound images. Thickened and stratified bowel walls with hypertrophy of the mucosal and sub-mucosal strata and increased number of folds due to amyloid deposition.

amyloidosis. These examinations suggested the diagnosis of primary systemic amyloidosis (AL) with focal intestinal manifestation.

Case 2

In March 2009, a 78-year-old man with a medical history of multiple myeloma and diabetes mellitus presented with diffuse abdominal pain, nausea, lack of appetite and diarrhoea. The patient had a recent episode of rectorrhage.

On admission the patient was afebrile with stable vital signs. Findings on physical examination were significant for moderately distended abdomen with mild diffuse tenderness.

On admission, laboratory studies including complete blood count, serum electrolytes, liver function tests, coagulation and tumour markers were as follows (with normal values): hematocrit, 27% (37%-54%); red blood cell count, 3 780 000 cells/mm^3 (4 200 000-5 600 000); haemoglobin, 8.4 g/dL (12-17.5); white blood cell count, 2333 cells/mm^3 (4800-10 800); glucose, 177 mg/dL (60-110); total protein, 5.6 g/dL (6.5-8.2); albumin, 3.3 g/dL (3.6-5.2). The remaining values were unremarkable.

Urinalysis showed 100 mg/dL of proteinuria. Serum immunoelectrophoreses showed a monoclonal spike. In the urine, the immunoglobulin λ light-chain concentration was 929 mg/L (normal, < 5 mg/L) and the immunoglobulin κ light-chain concentration was 37.8 mg/L (normal, < 10 mg/L).

An US examination of the abdomen showed thickened and stratified intestinal walls with hypertrophy of mucosal and sub-mucosal strata and increased number of plicae which were forming a polyp-like shape (Figure 3).

To better evaluate the US intestinal findings, an MRI of the small bowel previous gastro-intestinal preparation with 750 mL of polyethylene glycol solution as an oral contrast agent was performed using a 3.0 T MR device and the following acquisition protocol: axial and coronal T2-weighted half-Fourier single-shot turbo spin-echo sequences and true fast imaging in the steady-state precession sequences, fast low-angle shot T1-weighted sequences with fat suppression, followed by "spoiled" 3D T1-volume interpolated breath-hold examination acquired before and 70 s after intravenous administration of gadopentetate dimeglumine (0.1 mmol/kg).

The MR images showed diffuse intestinal wall symmetrical thickening with increased number and hypertrophy of the folds causing "jejunalization" of the ileum; wall stratification was not observed. After intravenous administration of contrast agent, diffuse enhancement of intestinal walls was observed (Figure 4A-C). The wall thickening associated with the increased number and hypertrophy of the folds suggested a malabsorption disease. The enhanced images did not show any sign indicative of a specific pathology. As a consequence it was not possible to perform a definitive diagnosis exclusively on the basis of MR findings.

Moreover, a PET/CT scan was performed to re-stage the multiple myeloma as requested by the haematologist. After a fast of 6 h prior to examination and previous normalization of the blood glucose levels with an oral hypoglycemic agent, PET/CT examination was carried out 60 min after intravenous administration of 370 MBq of 18FDG. The PET/CT images did not show a focal or diffuse increase in tracer uptake of small bowel walls (Figure 5).

Finally, the US, MRI and PET/CT findings suggested a malabsorption disease. As a result, considering that the patient was affected by myeloma, the diagnosis of primary systemic AL involving diffusely the gastro-intestinal tract was evaluated as the most probable. To test this diagnostic hypothesis we performed a biopsy of the rectal mucosa: the histological examination of the specimen disclosed diffuse infiltration by amyloid after staining with Congo red (Figure 6).

DISCUSSION

Focal amyloidomas of the duodenum and jejunum have been described as extensive amyloid deposits involving the entire wall thickness, with destruction of the mucosa and deep infiltration into the muscularis propria and with luminal narrowing of blood vessels[4-7].

The peculiarity of case report 1 is related to the focal deposition of amyloid proteins exclusively within intramural blood vessel walls of the terminal ileum. In our patient arteriolar amyloid deposition may have caused

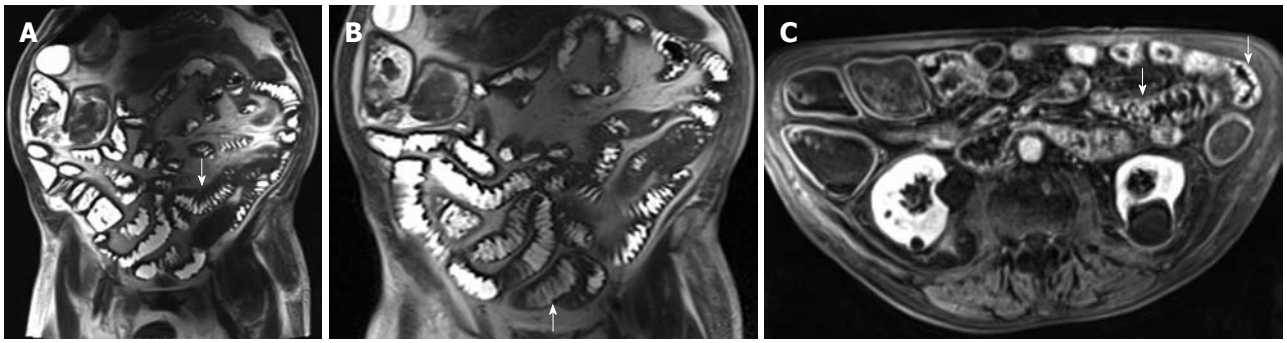

Figure 4 MRI changes of the small bowel. A and B: Coronal T2-weighted half-Fourier single-shot turbo spin-echo magnetic resonance images showed diffuse intestinal wall symmetrical thickening with increased number and hypertrophy of the folds (A, arrow) and "jejunalization" of the ileum (B, arrow); C: 3D T1-fast imaging in the steady-state precession after iv administration of contrast agent showed diffuse enhancement of intestinal walls (arrows).

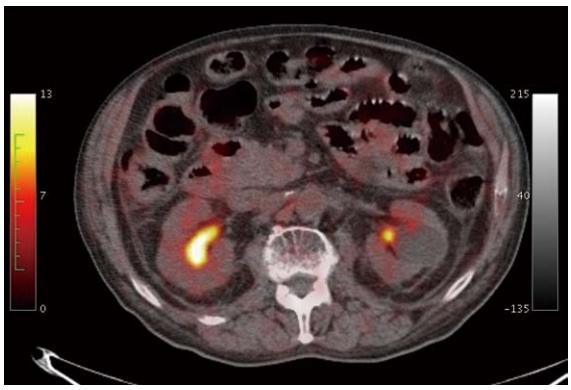

Figure 5 18FDG-positron emission tomography (PET)/CT images did not show focal or diffuse increase of the tracer uptake of small bowel walls.

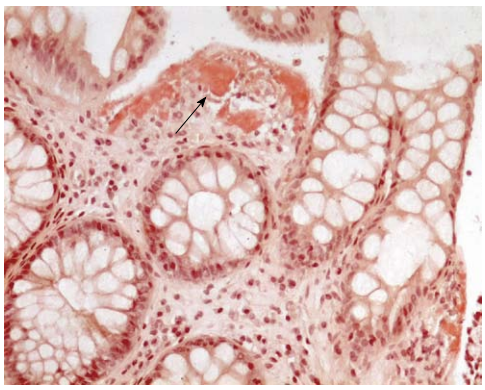

Figure 6 Colonic biopsy. Submucosal amyloid deposition (arrow) (Congo red stains, × 270).

ischemia, resulting pathologically in submucosal edema and mucosal erosion and ulceration and small bowel wall thickening, and clinically in acute onset of abdominal pain with intestinal sub-occlusion.

The thickened walls of the terminal ileum with mild pseudoaneurysmatic dilatation of the lumen associated to multiple ileo-cecal lymph nodes ranging between 10 and 20 mm suggested to us an intestinal lymphoma or less probably an atypical presentation of a terminal ileitis. The hypothesis of intestinal ischemia related to focal amyloid deposition was not evaluated.

Although a specific US or CT pattern has never been reported, the presence of a focal pseudoaneurysmal dilatation of the small bowel lumen associated to wall thickening may represent a radiological sign useful for considering intestinal amyloidosis in the differential diagnosis[4,8,9]. Amyloid may form deposits within the neural myenteric plexus, which determine the hypotonia of the gastro-intestinal wall and promote the pseudoaneurysmal dilatation[9]. On the contrary, the segmental bowel loop pseudoaneurysmal dilatation of intestinal lymphoma is highly suggestive of underlying celiac disease, likely as a reflection of the generalized hypotonia known to exist in the presence of this condition[10].

The diagnosis of localized intestinal amyloidosis is (1) potentially problematic because it is possible that the pathology may occur in the setting of subclinical extraintestinal disease or may represent an early manifestation of systemic amyloidosis; and (2) really crucial because the prognosis for patients with focal amyloidosis is generally good, whereas that for patients with systemic disease is usually poor[1]. Therefore, since the clinical presentation is often not specific and an abdominal CT scan may be required, it is important that radiologists consider the possible diagnosis of amyloidosis in the presence of focal pseudoaneurysmal dilatation of the small bowel lumen associated with wall thickening.

Case report 2 is the first describing the MRI findings of diffuse intestinal amyloidosis characterized by (1) wall symmetrical thickening with increased number and hypertrophy of the folds causing "jejunalization" of the ileum; (2) the absence of wall stratification; and (3) diffuse non-specific wall enhancement and the PET/CT findings characterized by the absence of a focal or diffuse increase of tracer uptake in diffuse thickened small bowel walls.

MRI signs, like the US and CT patterns, seem to be non-specific and are common to other malabsorption diseases, however they may suggest the clinician should consider diffuse intestinal amyloidosis in the differential diagnosis. On the other hand, the lack of pathological tracer uptake on PET/CT images is highly indicative of the absence of active inflammatory and/or neoplastic cells in the intestinal walls and represents a really important finding suggesting the storage nature of the disease char-

acterized by the intramural deposition of an amorphous substance such as amyloid. Considering that a PET/CT scan may be performed in the staging or restaging protocol of patients with multiple myeloma, the radiologist and the nuclear medicine physician should suggest the coexistence of primary systemic AL when they observe absence of pathological tracer uptake in a diffuse intestinal wall thickening.

In conclusion, since the clinical presentation of focal or diffuse intestinal amyloidosis is frequently non-specific and requires an US and/or CT and/or MRI scan and occasionally a PET/CT scan, it is important that radiologists become confident with imaging findings of intestinal amyloidosis in order to make a correct differential diagnosis allowing a proper diagnostic and therapeutic management.

Abstract

Intrahepatic clear cell cholangiocarcinoma is very rare - only 8 cases have been reported. A 56-year-old Japanese man with chronic hepatitis B infection was diagnosed with a 2.2 cm hepatocellular carcinoma on imaging, and hepatic segmentectomy was performed. Histopathologically, the tumor cells had copious clear cytoplasm and formed glandular structures or solid nests. These pathological findings suggested the tumor was a clear cell variant of intrahepatic cholangiocarcinoma. Particular stains and radiological images suggested that the cause of the clear cell change had been glycogen, not mucin nor lipid. On immunohistochemical staining, cytokeratin (CK) 7 and CK19 were positive, whereas CK20 was negative. Vimentin was detected on the cell membranes, and CD56 was focally positive. The patient was given adjuvant chemotherapy and is currently free from the tumor 7 mo postoperatively. Careful follow-up with adequate postoperative supplementary chemotherapy is necessary because the characteristics of this type of tumor are unknown.

INTRODUCTION

Intrahepatic cholangiocarcinoma (ICC) represents about 15% of primary liver cancers[1]. Several studies in recent years have suggested that chronic hepatitis increases the carcinogenesis of ICC, with particular relevance of hepatitis B virus infection[2,3]. Therefore, it is often difficult to preoperatively distinguish ICC from hepatocellular carcinoma (HCC), despite the high resolution of the latest imaging techniques[3].

In ICC, there is a quite rare variant, clear cell carcinoma[1,4-11]; until now, only 8 cases have been reported[4,7-11] (Table 1). The tumor is characterized by proliferation of the tumor cells with clear cytoplasm similar to renal clear cell carcinoma. The patients are in their 50 s or 60 s and no gender specificity has been found. The patients often have no underlying diseases. The background and risk factors of the ICC clear cell variant are unknown. Unlike

typical ICC, there is no report on the relevance of hepatitis. The prognosis is relatively good. The mechanism for the clear cell change has been speculated to involve glycogen[4,7], mucin[7-9], or lipid[4,7], but it remains unclear.

In this report, a case of intrahepatic clear cell cholangiocarcinoma with background chronic hepatitis B infection is presented. We discuss histopathological and radiological findings on the mechanism of clear cell change, and present a review of the literature.

CASE REPORT

A 56-year-old Japanese man who was found to have hepatic dysfunction on annual examination 3 years previously. He was diagnosed as having chronic hepatitis B (HBe-antigen (Ag)-positive and HBe-antibody (Ab)-negative). He was started on antiviral treatment with lamivudine {(-)-1-[(2R,5S)-2-hydroxymethyl-1,3-oxathiolan-5-yl]}. As the antiviral effect was not adequate, he was changed to a new drug, entecavir hydrate {9-[(1S,3R,4S)-4-hydroxy-3-(hydroxymethyl)-2-metylenecyclopentyl] guanine monohydrate cytosine}, to prevent tolerance emerging. As a result, HBV-DNA became negative, but the amplification signal of the virus remained detectable.

Follow-up abdominal ultrasonography 1 mo prior to surgery revealed a well-circumscribed, 2 cm mass with a halo at segment 7 (S7) of the liver. The tumor was diagnosed as HCC based on the findings of computed tomography (CT) and magnetic resonance imaging (MRI) of the abdomen. He was admitted to our hospital for surgery. At the time of admission, laboratory examination (Table 2) showed that α-fetoprotein (AFP) and protein induced by vitamin K antagonist or agonist (PIVKA)-Ⅱ were in the normal range, and liver function tests were mildly abnormal (Child-Pugh Class A). Both HBs-Ag and HBs-Ab were high.

CT showed a well circumscribed mass in the postero-superior S7 of the right lobe, measuring approximately 2 cm in diameter, with no calcification or fatty component (Figure 1A). After intravenous injection of iopamidol {N,N'-Bis [2-hydroxy-1-(hydroxymethyl)ethyl]-5-[(2S)-2-hydroxypropanoylamino]-2,4,6-triiodoisophthalamide} (total amount, 100 mL; injection rate, 3 mL/s), the lesion was well enhanced in the arterial phase (Figure 1B) and showed washout in the equilibrium phase (Figure 1C). Although the tumor margin was irregular without capsule-like enhancement, the internal enhancement pattern was consistent with classical HCC.

On MRI, the tumor was hypointense on T1-weighted imaging and hyperintense on T2-weighted imaging relative to the liver parenchyma (Figure 2A). Diffusion-weighted images showed that the lesions had very high intensity (Figure 2B). Opposed-phase images showed no signal intensity reduction compared with in-phase images (Figure 2C and D), indicating no fatty component in the tumor. The MRI were also consistent with HCC.

This tumor was diagnosed as an HCC from the imaging studies, and hepatectomy was performed. Based on the findings of intraoperative ultrasonography, the tumor was located close to the right hepatic vein, and subsegmental resection combined with the hepatic vein was performed. Macroscopically, the cut surface of the surgical specimen showed a yellowish-white, solid tumor, measuring 1.5 cm × 2.2 cm. Although the tumor margin was clear, there was no fibrous capsule. Neither hemorrhage nor large blood vessels were observed in the tumor. The outline margin with the surrounding liver was irregular, indicating cholangiocarcinoma (Figure 3).

Pathologically, cuboidal to columnar cells with copious clear cytoplasm proliferated in the ductal structures (Figure 4A). Most of the tumor showed a well-differentiated glandular pattern (Figure 4B), and there was an area showing a poorly differentiated component without conspicuous lumens and forming solid nests (Figure 4C).

The tumor cells showed a weak reaction to periodic acid Schiff (PAS) and were digested by diastase treatment (Figure 5A and B). Neither mucicarmine nor Alcian blue stained the tumor cells (Figure 5C and D).

Immunohistochemical staining showed positive reactions for cytokeratin (CK) 7, CK19, vimentin (cell membranes), CD56 (focally), and epithelial membrane antigen (EMA) (membranes of the luminal side) (Figure 6), and negative reactions for CK20, AFP, hepatocyte, and carcinoembryonic antigen (CEA) (Table 3).

Based on the histopathologic and immunohistochemical findings, the tumor was diagnosed as intrahepatic cholangiocarcinoma, clear cell variant. In the liver parenchyma, mild fatty change of hepatocytes, mild fibrosis and bridging of portal areas, and inflammatory infiltrates were observed.

Postoperatively, the patient was given adjuvant chemotherapy with tegafur-gimeracil-oteracil potassium {5-fluoro-1-[(2*RS*)-tetrahydrofuran-2-yl] uracil-5-chloro-2,4-dihydroxypyridine-monopotassium1,2,3,4-tetrahydro-2,4-dioxo-1,3,5-triazine-6-carboxylate} and is presently, 7 mo after surgery, free from tumor recurrence.

DISCUSSION

ICC is an epithelial malignancy that originates in the intrahepatic bile duct epithelium. Most ICCs are adenocarcinomas showing a tubular pattern, while some show cords or papillary structures[1]. Variants include adenosquamous carcinoma, sarcomatoid carcinoma, mucinous carcinoma, mucoepidermoid carcinoma, signet-ring cell carcinoma, and squamous carcinoma[1,4-6]. There is also a very rare variant, the clear cell variant[1,4-11].

Only 8 cases of the clear cell variant of ICC have been reported until now[4,7-11]. As the number of cases is very low, there is not a clear definition of histology and background disease. The reported background diseases were one case with diabetes mellitus and hypertension[8] and 2 cases with cholecystectomy[4] in the previous 8 reported cases. The present case had chronic hepatitis B as the background disease, that had not been reported.

The clear cell variant of ICC is characterized by tubular structures that consist of clear cells with copious clear cytoplasm, as well as a solid nest pattern[10] and papillary

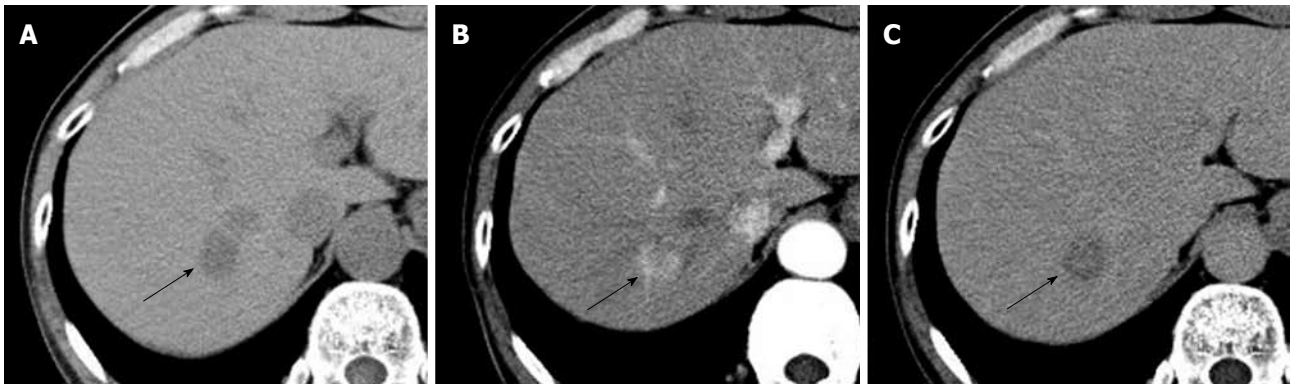

Figure 1 Findings of contrast enhanced computed tomography (CT) of the abdomen (arrows indicate the tumor). A: Plain CT shows a well-circumscribed mass in the posterosuperior S7 of the right lobe, measuring approximately 2 cm in diameter, with no calcification or fatty component; B: Enhanced CT of the arterial phase shows that it is well-enhanced; C: Enhanced CT of the equilibrium phase shows a washed-out image.

Table 1 Reported cases of intrahepatic cholangiocarcinoma clear cell variant

Yr	Age (yr)/sex	Location	Size (cm)	Hepatitis	Liver cirrhosis	Mechanism	Prognosis
1998[10]	64/F	Unknown	12	Unknown	Unknown	Unknown	Unknown
1998[11]	62/M	Right lobe	5	-	-	Unknown	Dead, 14 mo; no treatment
1998[7]	72/M	Left lobe	15	Unknown	Unknown	Lipid >> glycogen	Alive, 30 mo
1999[8]	50/M	S6	1.5	-	Unknown	Mucin	Alive, 12 mo
2001[9]	64/M	Right lobe	6	-	-	Unknown	Alive, 3 yr
2007[4]	51/M	S4a	9	Unknown	-	Lipid >> glycogen	Meta, 1 yr; dead, 3 yr
2007[4]	60/F	S5	4.5	Unknown	-	Lipid >> glycogen	Alive, 1 yr
2007[4]	58/F	S5	2.3	Unknown	-	Lipid >> glycogen	Alive
Present case	56/M	S7	2.2	HBV	-	Glycogen	Alive, 7 mo

M: Male; F: Female; S: Segment; meta: Metastasis.

Table 2 Serum data on admission

Item	Data	Normal values
HBs-Ag (C.O.I)	277.5	< 1.0
HBs-Ab (mIU/mL)	165.1	< 5.0
Anti-HCV-Ab (C.O.I)	0.1	< 1.0
α-fetoprotein (ng/mL)	3.6	≤ 7.0
PIVKA-Ⅱ (mAU/mL)	17.0	< 40.0
Carcinoembryonic antigen (ng/mL)	2.4	≤ 5.0
Total cholesterol (mg/dL)	181.0	128-25
Aspartate aminotransferase (IU/L)	28.0	13-33
Alanine aminotransferase (IU/L)	21.0	8-42
Alkaline phosphatase (IU/L)	198.0	115-359
Lactate dehydrogenase (IU/L)	207.0	119-229
γ-glutamyl transpeptidase (IU/L)	30.0	10-47

HBs-Ag: Hepatitis B surface antigen; HBs-Ab: Hepatitis B surface antibody; anti HCV-Ab: Anti hepatitis C virus antibody; PIVKA: Protein induced by vitamin K absence; C.O.I: Cut off index.

[1]Ki-67(MIB-1) index was estimated at the most frequent area. CAM: Cell adhesion molecule; CEA: Carcinoembryonic antigen; TTF-1: Thyroid transcription factor-1; CD: Cluster of differentiation.

pattern[9]. The neoplastic cells are medium sized with a vacuolated or clear cytoplasm and have distinct cell borders[4,7]. The nuclei of the clear cells are round to ovoid and hyperchromatic[9]. In the present case, most of the tumor showed a well-differentiated glandular pattern, though there were some areas showing a poorly differentiated component without conspicuous lumens and forming solid nests. The cells were of medium size in the glandular areas and were smaller in the solid areas.

The cause of the clear cell change is said to be glycogen, based on electron microscopy and diastase diges-

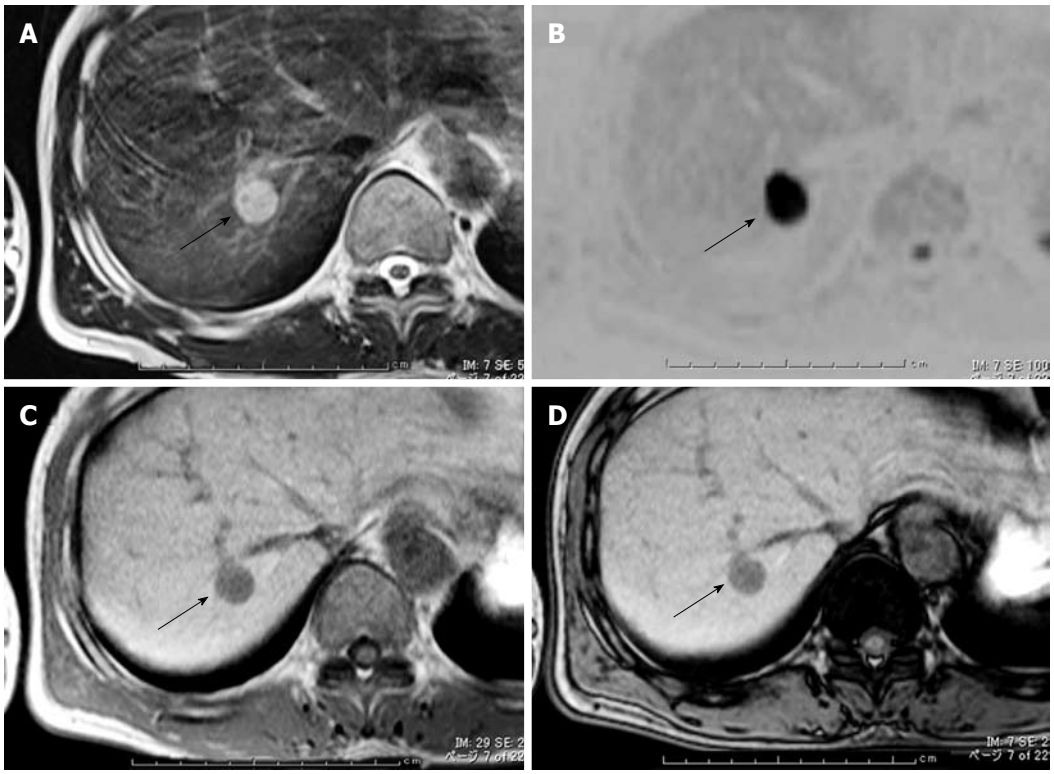

Figure 2 Findings of magnetic resonance imaging (arrows indicate the tumor). A: The T2-weighted image shows a hyperintense tumor; B: The inverse video of the diffusion-weighted image shows a markedly hyperintense signal; C: In-phase T1-weighted image shows a hypointense signal; D: Opposed-phase T1-weighted image shows no signal intensity reduction compared with Figure 2C.

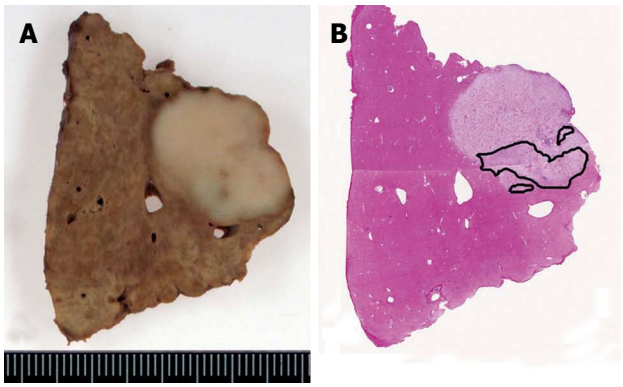

Figure 3 Tumor images. A: Photograph of the cut surface of the tumor fixed in formalin shows a yellowish-white, solid tumor, measuring 1.5 cm × 2.2 cm. Although the tumor margin is clear, there is no fibrous capsule. Neither bleeding nor blood vessels inside the tumor are observed. The outline margin with the surrounding liver is irregular; B: Scanning image. The tumor consists of clear cells. The margin is clear. The area surrounded by the black line is the poorly differentiated area.

tion[4,7], mucin, based on positive staining with either mucicarmine or Alcian blue[4,7,9], and lipid, based on electron microscopy[4,7]. These cases may represent the same disease entity only because they show similar clear changes, despite having different causes. In the present case, mucin did not stain, the radiological findings did not support a fatty component[12], and only PAS with diastase suggested glycogen.

Immunohistochemically, tumor cells were CK7-positive[4,7-9,11] and CK20-negative[4,7-9], and both HepPar1[4,9] and AFP-negative[4,7,8,11]. CD56-positivity was reported recently by Haas *et al*[4], who argued that the reactivity was related to the clear cell change. However, ICCs with hepatitis B or C were also reported to be CD56-positive[13,14]. Therefore, it is uncertain whether the background is responsible for CD56 reactivity. As CD56 had not been determined in the reports before Haas *et al*[4], the reactivity for CD56 may be a new feature of clear cell ICC. The expression of vimentin usually relates to mesenchymal cells, though some epithelial tumors such as renal cell carcinoma (RCC), some ICCs[14], and some clear cell ICCs were seen in previous[4] cases and in the present case.

The clear cell variant of ICC should be distinguished from clear cell HCC and metastatic clear cell carcinomas arising from extrahepatic organs, especially RCC. Positivity for CK7 and negativity for CK20 correspond to cholangiocarcinoma[15]. Hepatocyte negativity, AFP-negativity, and formation of tubular structures can rule out HCC[4,7-9,11]. Lack of detection of mucin and small gland formation may be similar to cholangiolocellular carcinoma. Cholangiolocellular carcinomas can be differentiated in that they usually show numerous nodules composed of cells smaller than normal hepatocytes[16,17] and are negative for vimentin and CD56[14]. The differential diagnosis from RCC is achieved by detailed examination of the kidneys and negative staining for vimentin, CD10, and S-100 protein[4,7,9,10]. The present case was CD10- and S-100 protein-negative and vimentin-positive, but reactivity for vimentin

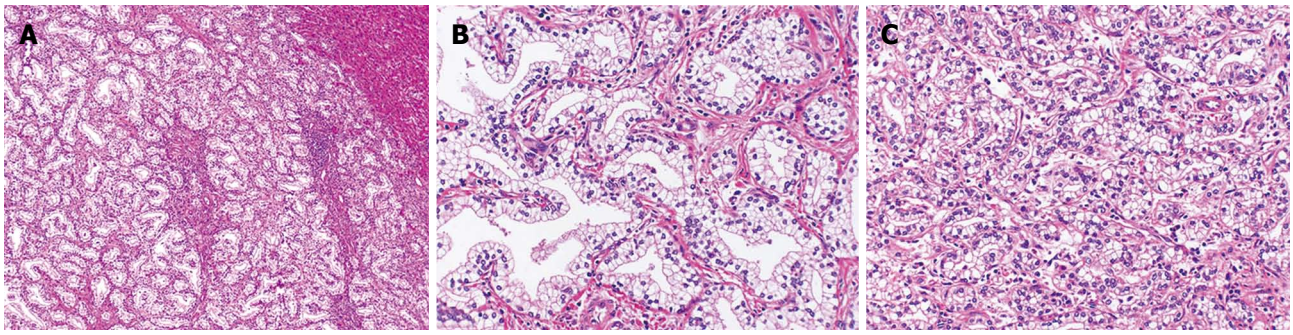

Figure 4 Pathological findings (hematoxylin-eosin). A: Clear tumor cells proliferate in a tubular shape. The pushing margin is irregular (× 40); B: Area of well-differentiated duct formation. The tumor cells have copious clear cytoplasm (× 200); C: The poorly differentiated area shows solid proliferation (× 200).

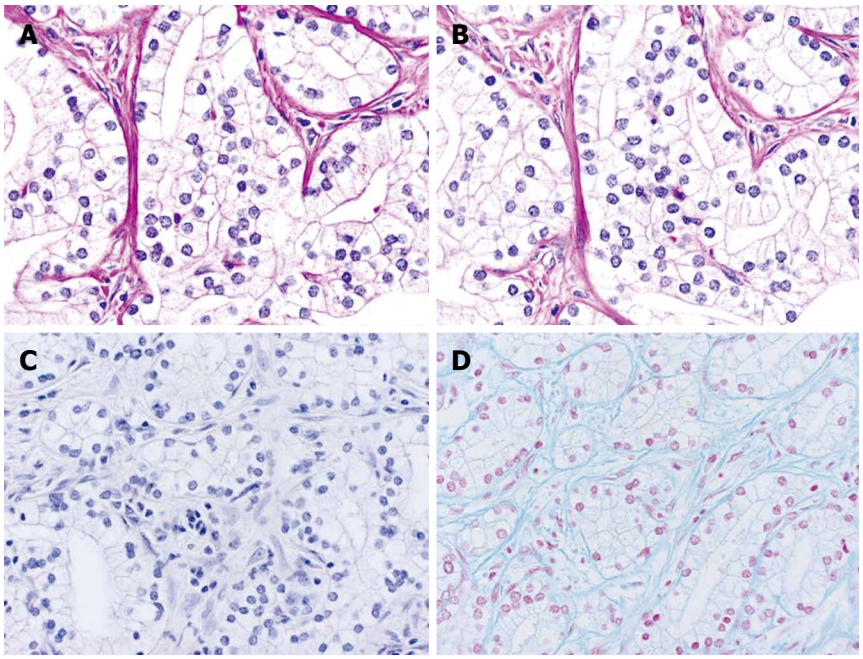

Figure 5 Particular stains (× 400). A: The tumor cells show a weak reaction for periodic acid Schiff (PAS) stain; B: PAS stain is slightly digested by diastase treatment; C: Mucicarmine is negative; D: Alcian blue is negative.

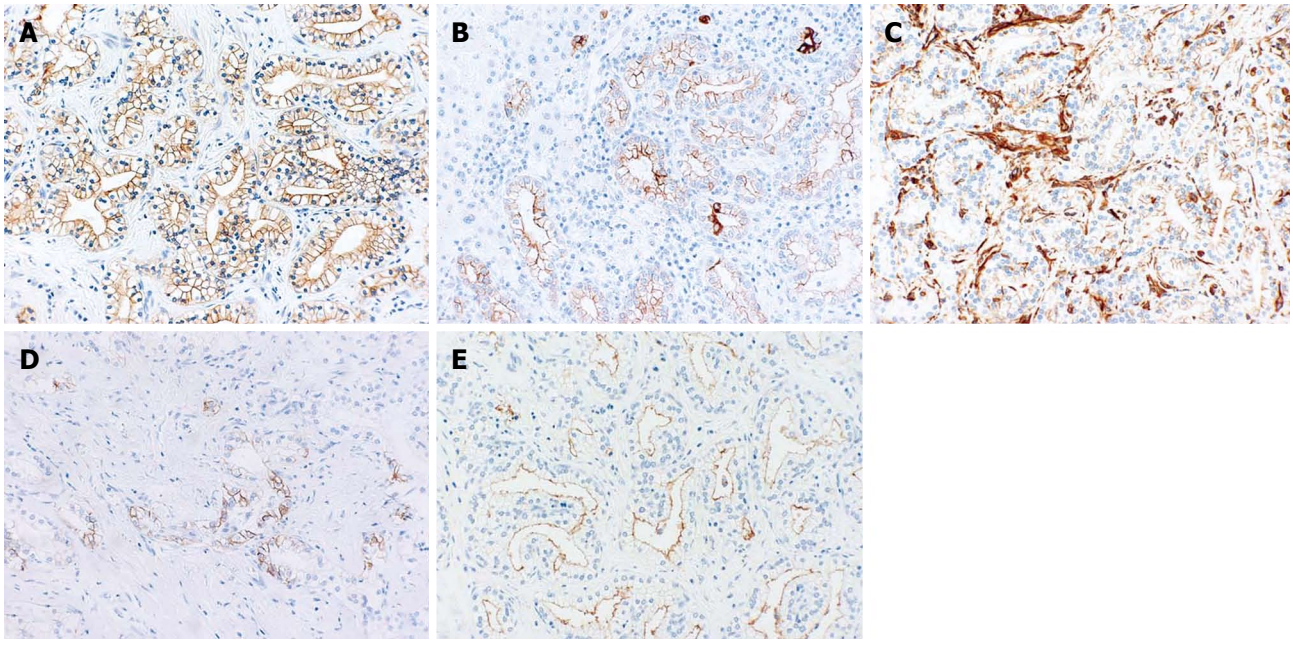

Figure 6 Immunohistochemical staining (× 200). A: Cytokeratin (CK) 7 is positive; B: CK19 is positive; C: Vimentin is positive; D: CD56 is focally positive; E: Epithelial membrane antigen (EMA) is positive at the membrane of the luminal side.

in ICC has also been reported[4,14]. In addition, there were no abnormalities in the kidneys in careful radiological examination. Clear cell carcinoma of the gastrointestinal tract can be differentiated by detailed examination and histopathological findings.

Benign clear cell tumors of the bile ducts have seldom been reported except for 3 cases of atypical bile duct adenoma, clear cell type[9]. Immunohistochemically, they showed similar reactivity to their malignant counterpart, i.e. positivity for CK7, CEA, EMA and p53 and negativity for CK20. The only reported differential point was positivity rate of Ki-67 (MIB-1) of under 10% for bile duct adenomas and of over 50% for ICCs[9]. However, the ICC clear cell variant has also been reported to show positivity of less than 5%[4]. Thus, the conclusion has not been ascertained. Bile duct adenoma is said to be under 1 cm in diameter, located under the capsules and have less irregularity of the nuclei[1]. The present case showed Ki-67 positivity of under 10%. However, the size was 2.2 cm and it was located deep in the parenchyma apart from the capsule, with the nuclei showing irregularity, indicating a diagnosis of carcinoma.

ICC is said to have a poor prognosis[2,14] because of its tendency to be diagnosed at a late stage and the absence of effective treatment[3]. While the ICC clear cell variant has been reported to have a good prognosis[4,7-9], except for one death with metastasis after hepatic resection[4], and one case that had not been operated on because of underlying diseases and died 14 mo later[11]. In this case, the patient is currently free from disease, and the medication for chronic hepatitis B and the postoperative chemotherapy has been continued. Because the number of cases is very low, there is no evidence for the use of chemotherapy. Therefore, careful follow-up with sufficient postoperative supplementary chemotherapy is necessary to achieve longer survival.

Ma LS. Mourning for renowned pharmacologist Professor Geng-Tao Liu. *World J Gastroenterol* 2010; 16(20): 2577-2578 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i20/2577.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i20.2577

Figure 1 Geng-Tao Liu, Professor, Department of Pharmacology, Institute of Materia Medica, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing 100050, China

At 22:08 h on February 27, 2010, Professor Geng-Tao Liu, a renowned pharmacologist affiliated with the Department of Pharmacology, Institute of Materia Medica, Chinese Academy of Medical Sciences, Beijing, an academician of the Chinese Academy of Engineering, a doctoral tutor, and a member of *World Journal of Gastroenterology* (*WJG*) Editorial Board, passed away at Peking Union Medical College Hospital, at the age of 77 years (Figure 1).

Professor Liu was born in 1932 in Shuangfeng, Hunan Province. He graduated from Hunan Medical College in 1956 and then started his research career in the Department of Pharmacology, Institute of Materia Medica, Chinese Academy of Medical Sciences. He was elected a member of the 6-8th Council of Chinese Pharmacological Society.

During his research career, Professor Liu successfully developed two novel anti-hepatitis drugs: dimethyl diphenyl bicarboxylate and bicyclol. He also made great contributions to the understanding of the pharmacology of *Schisandra*, *Ganoderma lucidum,* and *Salvia miltiorrhiza*.

Professor Liu successfully developed Ganoderma Spore Powder Injection that has been used in China for over 30 years to treat a variety of neuromuscular ailments. To evaluate the pharmacological effects of Ganoderma lucidum, Professor Liu created two unique animal models: one for dermatomyositis and the other for elevated serum aldolase, which provide a basis for a scientific explanation of the therapeutic effects of Ganoderma lucidum against dermatomyositis. He also found that several schizandrins, particularly schisanhenol, have potent antioxidant activity.

Professor Liu published over 200 papers and was granted multiple patents. He is the editor-in-chief of "*Contemporary Pharmacology*" and the editor of "*Pharmacology of Traditional Chinese Herbs and Drug Innovation*". He was a member of the editorial board of 12 domestic and foreign academic journals. He was awarded nine scientific or technological prizes in China, such as "National Invention Award", "Scientific and Technological Progress Award of the Ministry of Health", and "Beijing Municipal Scientific and Technological Progress Award". Professor Liu also won the titles of "National Young and Middle-aged Experts with Outstanding Contributions",

"Capital May 1st Labor Medal", and "Beijing Municipal Outstanding Teacher". Having tutored more than 40 postgraduates, Professor Liu enjoyed a great reputation in the field of pharmacology.

Professor Liu took time out of his busy schedule to review six *WJG* articles and made a great contribution to *WJG*. Now, he has left us forever! We are deeply saddened by his passing and will turn our grief into strength to continue our efforts to establish *WJG* as one of the leading journals. Professor Liu, may you rest in peace.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in tahe field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Abstract

Nonalcoholic fatty liver disease (NAFLD) is a common clinical condition which is associated with metabolic syndrome in 70% of cases. Inappropriate dietary fat intake, excessive intake of soft drinks, insulin resistance and increased oxidative stress combine to increase free fatty acid delivery to the liver, and increased hepatic triglyceride accumulation contributes to fatty liver. Regular soft drinks have high fructose corn syrup which contains basic sugar building blocks, fructose 55% and glucose 45%. Soft drinks are the leading source of added sugar worldwide, and have been linked to obesity, diabetes, and metabolic syndrome. The consumption of soft drinks can increase the prevalence of NAFLD independently of metabolic syndrome. During regular soft drinks consumption, fat accumulates in the liver by the primary effect of fructose which increases lipogenesis, and in the case of diet soft drinks, by the additional contribution of aspartame sweetener and caramel colorant which are rich in advanced glycation end products that potentially increase insulin resistance and inflammation. This review emphasizes some hard facts about soft drinks, reviews fructose metabolism, and explains how fructose contributes to the development of obesity, diabetes, metabolic syndrome, and NAFLD.

INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a significant health problem affecting 20%-30% of the adult population[1]. NAFLD can progress to nonalcoholic steatohepatitis (NASH), a fatty liver with hepatitis. This form of liver injury carries a 20%-50% risk for progressive fibrosis, 30% risk for cirrhosis, and 5% risk for hepato- cellular carcinoma[2-4]. Although the mechanisms underlying dis-

ease progression remain unclear, insulin resistance and obesity-related inflammation are thought to play a key role, along with possible genetic, dietary and lifestyle factors. The rising incidence of obesity in today's generation is associated with many health complications in addition to NAFLD[5,6]. These include cardiovascular diseases, diabetes, hyperlipidemia, and hypertension. This constellation is recognized as metabolic syndrome. 70% of patients with fatty liver have metabolic syndrome and 30% of patients with metabolic syndrome have fatty liver[7] (Figure 1).

A global change in dietary habits has occurred over the last few decades resulting from the introduction of sweeteners such as fructose and sucrose by the food industries. For example, regular soft drinks (SD) and fruit drinks, major sources of high fructose corn syrup (HFCS) or sugar, have increased from 3.9% of the total energy intake in 1977 to 9.2% of the total energy intake in 2001[8].

Worldwide, SD are the leading cause of added sugar. Recent evidence suggests an association between the intake of sugar sweetened SD and the risk of obesity and diabetes resulting from large amounts of HFCS used in their manufacture, which raises blood glucose similar to sucrose[9]. In addition, diet SD contain aspartame sweetener and caramel coloring, which are rich in advanced glycation end products that potentially increase insulin resistance and inflammation[10,11].

Human studies and animal models suggest that dietary factors can affect fatty infiltration and lipid peroxidation in various types of liver disease including NAFLD[12,13]. More recently, increased ingestion of SD was found to be linked to NAFLD[14] independent of metabolic syndrome, with NAFLD patients consuming 5 times the amount of carbohydrates from SD as compared to healthy persons[15] (Figure 2 and Table 1). Individuals consuming > 1 soft drink daily showed a higher prevalence of metabolic syndrome than those consuming < 1 soft drink per day[16].

This review emphasizes some hard facts about SD, reviews fructose metabolism, and explains how fructose contributes to the development of obesity, diabetes, metabolic syndrome, and NAFLD.

SOFT DRINKS

The term SD more commonly known as soda, soda pop, pop, Coke™, Pepsi™ or tonic, refers to a nonalcoholic beverage that is usually carbonated. Two types of SD are used; regular SD which are sweetened with sugar (fructose) and diet SD which are sweetened with non-caloric sweeteners (aspartame). Up to the 1980s, SD contained most of their food energy in the form of refined cane sugar or corn syrup. Today, HFCS is used almost exclusively as a sweetener in the United States and in other countries because of its lower cost. The calories and sugar content in various soft drinks are shown in Table 2.

Added sweeteners in regular SD are an important component of our diet, representing 318 kcal of dietary intake, or 16% of all calorie intake[17]. HFCS made by enzymatic isomerization of glucose to fructose was introduced as HFCS-42 (42% fructose) and HFCS-55 (55% fructose) in 1967 and 1977, respectively, and opened a new frontier for the sweetener and SD industries.

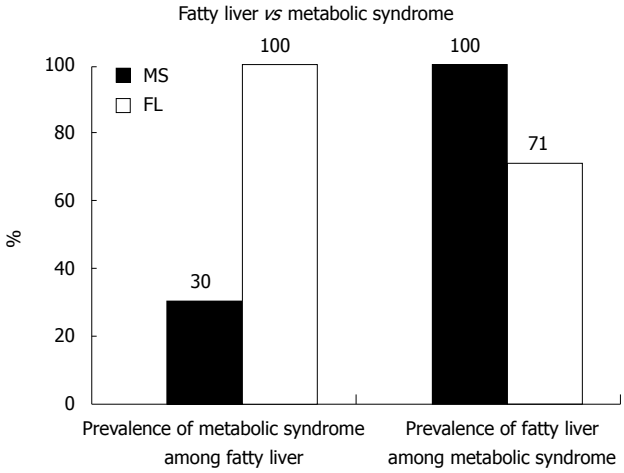

Figure 1 Prevalence of fatty liver among metabolic syndrome and prevalence of metabolic syndrome among fatty liver. MS: Metabolic syndrome; FL: Fatty liver. Alberti, Circulation (2009). $P < 0.001$.

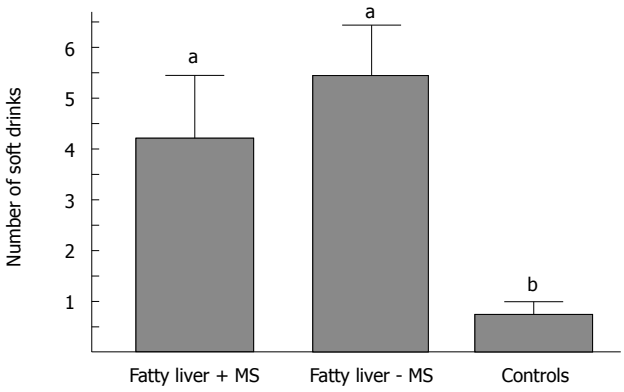

Figure 2 Daily amount of soft drinks consumption in nonalcoholic fatty liver disease (NAFLD) patients with (n = 31) or without metabolic syndrome (n = 29) and in controls (n = 30). [a]$P < 0.07$; fatty liver without metabolic syndrome *vs* fatty liver with metabolic syndrome, [b]$P < 0.001$ between fatty liver subgroups and controls[14,15].

Table 1 Soft drink consumption linked with NAFLD

Dietary constituents	Controls (n = 30)	NAFLD (n = 31)	P value
Total energy intake (kcal)	2200 ± 600	2300 ± 500	0.300
Added sugar (g/d)	33.6 ± 12.6	75.6 ± 8.4	0.001
Percent of added sugar from soft drinks	8%	43%	0.001

NAFLD: Nonalcoholic fatty liver disease.

Aspartame and caramel (colorant) are also used as sweeteners in the beverage industry mainly in diet SD[18]. Aspartame is an amino-acid compound that is about 160 times sweeter than sugar. Aspartame is absorbed from the intestine and metabolized by the liver to form phenylalanine, aspartic acid and methanol. Aspartame can contribute to weight gain, obesity, insulin resistance, and type 2

Table 2 Calories and sugar content in different soft drinks

Soft drinks: calorie content (number of calories)				Soft drinks: sugar content (numbers of teaspoons of sugar)

diabetes mellitus[18]. Recently, Brown *et al*[19] showed that artificial sweeteners may trigger the secretion of glucagon-like peptide (GLP)-1 by the digestive tract, and thereby curb appetite and calorie intake.

Caramel is made by the carefully controlled heat treatment of carbohydrates, generally in the presence of acids and alkalis, in a process called caramelization. Soft drinks contain caramel coloring, which is rich in advanced glycation end products which increase insulin resistance and inflammation[9,10]. The FDA has established 200 mg of caramel per kg body weight as an acceptable daily intake.

High fructose diets have induced fatty liver in rats and ducks[20]. Such diets have also caused increases in hepatic lipid peroxidation and activation of inflammatory pathways in the liver of rats[21]. The inborn error of metabolism known as hereditary fructose intolerance, a rare disease which results from a deficiency in the fructose metabolizing enzyme, aldolase B, has demonstrated that fructose consumption can cause progressive liver disease in humans[22].

The extent to which excessive fructose might contribute to the high prevalence of NAFLD in Western societies has not been systematically investigated. It has been shown that consumption of SD is linked to obesity and results in an increased risk of metabolic syndrome. Individuals consuming > 1 soft drink per day had a higher prevalence of metabolic syndrome than those consuming < 1 drink per day[16].

METABOLISM OF FRUCTOSE

Fructose is a simple sugar with a chemical formula ($C_6H_{12}O_6$) similar to that of glucose. Fructose differs from glucose by the presence of a keto group attached to carbon 2 of the molecule, while glucose has an aldehyde group at carbon 1. In the diet, fructose is consumed in various amounts with fruits, honey, beverages sweetened with HFCS/sucrose and as a constituent of sucrose, the most common sugar (a disaccharide composed of fructose through a 1-4 glycoside bond) (Table 2).

Absorption of fructose from the intestine into the portal blood is aided by glucose transporter-5 at the brush border and basolateral membranes of the jejunum. This route of absorption results in massive fructose uptake by the liver. Fructose is phosphorylated by fructokinase, forming fructose-1-phosphate, which can then be converted to several three-carbon molecules, including glyceraldehydes, dihydroxyacetone phosphate and glyceraldehyde-3-phosphate (Figure 3). Some of these 3 carbon molecules can be converted to glucose through gluconeogenesis, or they can be used to generate other products such as triglyceride (TG).

The second metabolism of fructose, i.e. the extrahepatic metabolism that bypasses fructokinase, allows the carbons from fructose to enter glycolysis downstream of this enzyme. The 3 carbon molecules can eventually be used for the synthesis of glycerol and fatty acids, which through esterification can form TGs.

The concentration of fructose in fasting blood of healthy humans is typically 1 mg/dL or less. After oral administration of fructose load in doses ranging from approximately 18 g (0.25 g/kg of body weight) to 100 g, the mean plasma or serum fructose concentration increased in a dose-dependant manner, to values ranging from 4.5-13.0 mg/dL and peak fructose concentrations were seen 30-60 min after fructose ingestion. A 20-ounce soft drink containing 32.6 g of fructose would therefore be expected to increase the fasting serum fructose concentration by approximately four-fold[23,24]. Fructose is 7 times more likely than glucose to form advanced glycation end products (AGEs). Fructose does not suppress ghrelin and does not stimulate insulin or leptin[23,24]. Some key molecular features involved in the metabolism of fructose include the roles of cellular signaling molecules including nuclear factor-κB (NF-κB), tumor necrosis factor-α (TNF-α), c-Jun amino terminal kinase 1 (JNK-1), protein tyrosine phosphatase-1B (PTP-1B), phosphatase and tensin homolog deleted on chromosome ten (PTEN), liver X receptor (LXR), farnesoid X receptor (FXR), and sterol regulatory element-binding protein-1c (SREBP-1c)[25]. Fructose activates JNK-1, which causes hepatic inflammation and increased insulin receptor substrate-1 (IRS-1). Fructose induces lipogenesis *via* upregulation of SREBP-1c and CHREBP, thereby increasing the hepatic pool of free fatty acids[25].

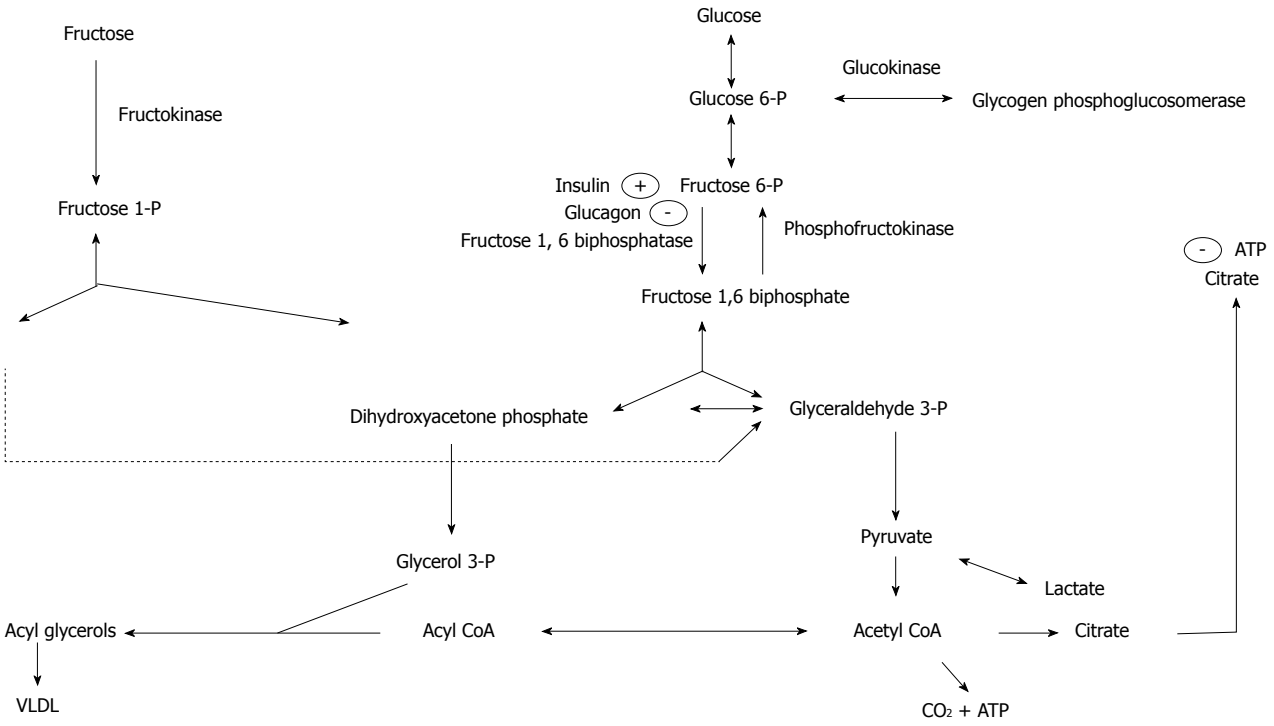

Figure 3 Fructose metabolism in the liver. Hepatic fructose metabolism begins with phosphorylation of fructokinase. Fructose carbon enters the glycolytic pathway at the triose phosphate level. Thus, fructose bypasses the major control point by which glucose carbon enters glycolysis. This allows fructose to serve as an unregulated source of glycerol-3-phosphate and acetyl-CoA for hepatic lipogenesis.

PATHOPHYSIOLOGY OF NAFLD

The "two hits" hypothesis proposed by Day *et al*[26] remains the prevailing pathophysiological theory. According to the authors, the first "hit" describes a net retention of lipids within hepatocytes, mostly in the form of TGs, and is a prerequisite for the development of NAFLD. A continuous delivery of free fatty acids to the liver from splanchnic lipolysis of visceral fat (60%) or from increased ingestion of fatty food (10%), combined with peripheral insulin resistance, and *de novo* lipogenesis (30%) results in excessive fat accumulation and an increased liver concentration of TG and cholesterol esters. High blood TG concentration in the form of very low density lipoprotein (VLDL) tends to accompany this condition and induces cholesterol ester transfer protein activity, resulting in an increased transfer of TG from VLDL to high density lipoprotein (HDL) and a subsequent increase in HDL clearance and decreased HDL concentration which leads in the end to liver steatosis[27].

The progression of steatosis to steatohepatitis (NASH) is associated with other factors ("second hit"), such as lipotoxicity, inflammation, oxidative stress and insulin resistance[26]. Consumption of SD may act as a first or as a second hit in the pathogenesis of NAFLD. Recently, it has been suggested that cholesterol metabolism may have a role in the accumulation of liver fat and that inflammation may be the first hit followed by TG accumulation as a second hit (www.easl.eu/bologna 2009).

FRUCTOSE AND INSULIN RESISTANCE

Fructose consumption increases postprandial TG concentrations within 24 h[28,29], which suggests that postprandial hypertriglyceridemia is the earliest metabolic perturbation associated with fructose consumption. The most likely mechanism for postprandial hypertriglyceridemia is increased hepatic de-novo lipogenesis (DNL), which in turn upregulates VLDL production and secretion[30].

Fructose consumption can promote hepatic lipogenesis primarily because the liver is the main site of fructose metabolism; secondly, entry of fructose into glycolysis *via* fructose-1-phosphate bypasses the main rate controlling step of glycolysis catalyzed by phosphofructokinase, thus providing unregulated amounts of the lipogenic substrates acetyl-CoA and glycerol-3-phosphate[30]; thirdly, fructose can activate sterol receptor element binding protein-1c (SREBP-1c) independently of insulin, which then activates fat genes involved in DNL[31,32].

Recently, Stanphone demonstrated that consuming fructose-sweetened beverages, not glucose-sweetened beverages increases DNL, promotes dyslipidemia, decreases insulin sensitivity and increases visceral adiposity in overweight and obese adults[33,34] (Figure 4).

One study of lean women found that 4 d of over feeding with a sucrose-sweetened (glucose + fructose) drink increased DNL by 200%-300%[35]. Another feeding study showed that 2 d of high fructose intake (30% of kcal/d, consumed as sweetened beverage at every meal)

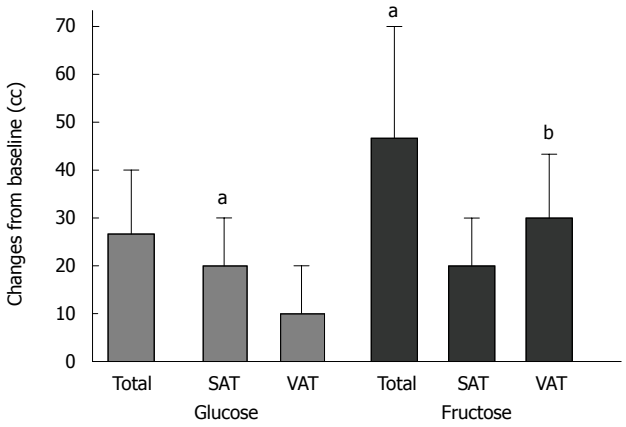

Figure 4 Changes in total abdominal adipose tissue, superficial adipose tissues (SAT), and visceral adipose tissue (VAT) volume after consuming glucose- or fructose-sweetened beverages for 10 wk. $^{a}P < 0.05$, $^{b}P < 0.01$, 10 wk *vs* 0 wk; paired Student's *t* test. Glucose, $n = 14$; Fructose, $n = 17$. Data represent mean ± SE (Stanhope, *J Clin Invest*, 2009).

resulted in decreased postprandial glucose concentration and insulin response and prolonged alimentary lipemia in women[29]. A recent clinical study indicates that NAFLD patients have a higher intake of SD and meat and a tendency towards a lower intake of fish rich in omega-3[36].

FRUCTOSE AND DIABETES MELLITUS

Lipotoxicity can promote insulin resistance in type 3 diabetes mellitus by accelerating pancreatic β-cell failure. Elevated plasma free fatty acids are associated with the progression from pre diabetes (impaired fasting glucose IFG, impaired glucose tolerance IGT) to type 2 diabetes mellitus[37]. The presence of diabetes mellitus in patients with NASH have significant clinical implications, as NASH appears to follow a more aggressive course in the presence of hyperglycemia, placing a growing number of diabetic patients at risk of progressive liver disease[37]. In short-term studies in humans, fructose ingestion had no deleterious effect on glucose metabolism. In studies lasting 3-8 d, substitution of sucrose or starch with fructose improved glycemic control in patients with type 1 or type 2 diabetes mellitus. Similarly, no adverse effects of fructose feeding on glycemic control were seen in studies lasting 1-3 mo. In a series of patients with diet controlled type 2 diabetes, substitution of sucrose by fructose (13% of calories) for three months had no significant effect on fasting plasma glucose levels or postprandial plasma glucose and insulin responses[37].

Long-term fructose consumption may promote the development of diabetes, even though fructose usually has no adverse effects on glucose tolerance in the short- and intermediate term. In rats, long-term feeding of moderate amounts of fructose (15% of the diet by weight) resulted in impaired glucose tolerance[38], and high-fructose diets (72% by weight) resulted in the development of diabetes mellitus and diffuse glomerulosclerosis[39,40].

The association between consumption of sugar-sweetened beverages and risk of type 2 diabetes was assessed in an eight-year prospective study of 51 603 women participating in the Nurses' Health Study Ⅱ[41]. After adjustment for potential confounders, women consuming one or more sugar-sweetened soft drink daily had a relative risk (RR) of type 2 diabetes of 1.83 ($P < 0.001$) compared with those who consumed > 1 of these beverages per month. The results were attenuated after further adjustment for body mass index and caloric intake, but remained statistically significant (RR = 1.32, $P < 0.04$). Consumption of fruit punch was associated with a similar increase in diabetes risk.

FRUCTOSE AND OBESITY

The association between HFCS consumption and obesity is due in part to metabolic changes induced by fructose or HFCS, rather than merely to an increase in total energy intake[41]. In baboon studies, consumption of sucrose compared with glucose promoted the development of abdominal obesity, suggesting that the fructose moiety of sucrose was responsible for the increase in abdominal fat[42,43]. In addition, some strains of mice showed an increase in visceral fat accumulation when fed a high-fructose diet[44]. Although it has long been suspected that SD contribute at least in part to the obesity epidemic, only in recent years have large epidemiologic studies begun to investigate the relation between SD consumption and long-term weight gain. Obesity among children has increased dramatically during the past two decades and is approaching epidemic proportions[45,46]. Various environmental, genetic and social factors relating to diet have been associated with obesity in children[47-50].

The results of the study by Dubois *et al*[51] indicated that regular sugar-sweetened beverage consumption, especially between meals, may put children at greater risk for obesity in childhood. Because there is a positive association between the consumption of sugar-sweetened beverages and body weight among preschool-aged children, they advise that parents should limit the quantity of such sweetened beverages consumed during preschool years[51]. In the FIELD trial, 644 British schoolchildren (ages 7-11 years) were randomly assigned to a control group or to an education program designed to reduce their consumption of carbonated drinks (both sweetened and unsweetened). The mean consumption of carbonated drinks decreased by 50 mL/d in the intervention group and increased by 16.7 mL/d in the control group (mean difference 0.7, 95% confidence interval 0.1 to 1.3). After 12 mo, the approximate percentage of overweight and obese children had increased in the control group from 20% to 27.5%, compared with a decrease in the intervention group from 20% to 19.8% (mean difference 7.7%, 2.2% to 13.1%)[52].

FRUCTOSE AND NAFLD

Risk factors for NAFLD include obesity, type 2 diabetes, insulin resistance and hypertriglyceridemia. Of note,

each of these risk factors can occur as a result of excessive fructose consumption. Recently we have shown that[14,15] SD consumption is linked with fatty liver independently by metabolic syndrome diagnosis.

High-fructose diets have induced fatty liver in rats[53] and ducks[54], such diets have also caused increases in hepatic lipid peroxidation[55] and activation of inflammatory pathways in the liver of rats[21].

Fructose is lipogenic and stimulates TG synthesis[31]. Splanchnic perfusion studies demonstrate that fructose produces higher rates of TG secretion from the liver than equimolar amounts of glucose[56]. The long-term administration of fructose to rats results in hepatic macro- and micro vesicular steatosis with a 198% increase in hepatic TGs and an 89% increase in hepatic cholesterol concentration[57]. Furthermore, the administration of a diet with 25% of the total energy as sucrose (which contains 50% fructose) resulted in a rise in hepatic aminotransferases (ALT and AST) levels within 18 d[58,59]. Indeed, total fructose intake averages approximately 12% of the total energy intake and may increase to 15% in some subgroups in the US population[22].

Animals maintained on a chronic high fructose diet develop elevated non-esterified fatty acids (NEFAs) and hyperinsulinemia at the expense of glycemic control[39]. This is not surprising, as fructose-induced metabolic dyslipidemia is usually accompanied by whole body insulin resistance[60] and reduced hepatic insulin sensitivity[61].

A potential mechanism by which fructose may cause liver injury is shown in Figure 5. The metabolism of fructose is distinct from glucose. Before converging with the glycolytic pathway, initial fructose metabolism involves phosphorylation of fructose to fructose-1-phosphate by fructokinase (ketohexokinase, KHK) using the substrate ATP. Unlike glucokinase, the phosphorylation of fructose by fructokinase is specific for fructose and not rate limited. The high activity of fructokinase in phosphorylating fructose to fructose-1-phosphate in the liver, can result in hepatic ATP depletion[22]. Indeed, fructose has been shown to cause ATP depletion in humans[62,63], and recovery from fructose-induced ATP depletion was found to be delayed in subjects with NALFD in studies that used phosphorus-1 magnetic resonance spectroscopy to assess hepatic metabolism[63,64]. In some respects, fructose-induced ATP depletion resembles hepatic ischemia[65]. In rats, fructose administration increases hepatic lipid peroxidation and activation of inflammatory pathways[21,55]. Cirillo *et al*[66] found that incubation of endothelial cells or renal tubular cells with postprandial concentrations of fructose reduces intracellular ATP and activates proinflammatory and prooxidative responses. Therefore, high fructose consumption may contribute to NAFLD pathogenesis because fructose-induced ATP depletion promotes hepatic necroinflammation. Moreover, fructose promotes insulin resistance, lipid peroxidation, dyslipidemia, increased arterial blood pressure, increased AGEs, and increased hepatic inflammation[66].

Ouyang *et al*[67] found that subjects with NAFLD have a significantly greater intake of sweetened beverages by history, representing a 2-fold greater intake than the mean intake in both controls and in population-based studies. Their second finding was that the key initiating enzyme in fructose metabolism, KHK (ketohexokinase), was also increased 2-fold in the liver biopsies of these patients compared to controls[67]. The increase in KHK levels is consistent with the known effect of fructose to upregulate KHK in the liver of rats[68,69].

Patients on a high fructose or sucrose diet show a greater uric acid response to a bolus of fructose[70,71] consistent with the upregulation of KHK activity. Finally, uric acid levels can predict the development of NAFLD[72]. There is also increasing evidence that the rise in uric acid may also have a potential role in causing features of the metabolic syndrome[73], in part by the ability of uric acid to deplete endothelial nitric oxide levels[74] and by activating adipocytes[68]. What does fructose become in our liver? Fructose becomes free fatty acids (the building blocks of all lipids), becomes VLDL lipoproteins and TGs (the nasty lipids most associated with cardio- vascular disease), and becomes uric acid (oxidative stress, vascular inflammation, Figure 5).

FRUCTOSE AND METABOLIC SYNDROME

Reaven noted that several risk factors (e.g. dyslipidemia, hypertension and hyperglycemia) are commonly clustered together[75]. This clustering he called Syndrome X, and he recognized it as a multiplex risk factor for cardiovascular disease (CVD). Other researchers use the term metabolic syndrome for this clustering of metabolic risk factors. ATP Ⅲ used this alternative term[76]. Beyond CVD and type 2 diabetes, individuals with metabolic syndrome are susceptible to other conditions, notably polycystic ovary syndrome, fatty liver, cholesterol gallstones, asthma, sleep disturbances, some forms of cancer, and is associated with a proinflammatory/prothrombotic state that include elevated levels of C-reactive protein, endothelial dysfunction, hyperfibrinogenemia, increased platelet aggregation, increased levels of plasminogen activator, elevated uric acid levels, microalbuminuria, and a shift toward small, dense particles of low-density lipoprotein[77].

The major characteristics of metabolic syndrome include insulin resistance, abdominal obesity, elevated blood pressure, and lipid abnormalities (i.e. elevated levels of TGs and low levels of HDL cholesterol).

The role of fructose in insulin resistance, hyperglycemia, and obesity that constitute important elements of the metabolic syndrome were discussed above[77].

Visceral adipose tissue and dyslipidemia induced by fructose/sucrose consumption play a major role in the development and progression of metabolic syndrome. The main role of adipose tissue is to take up excess fatty acids provided by the diet and to store them in the form

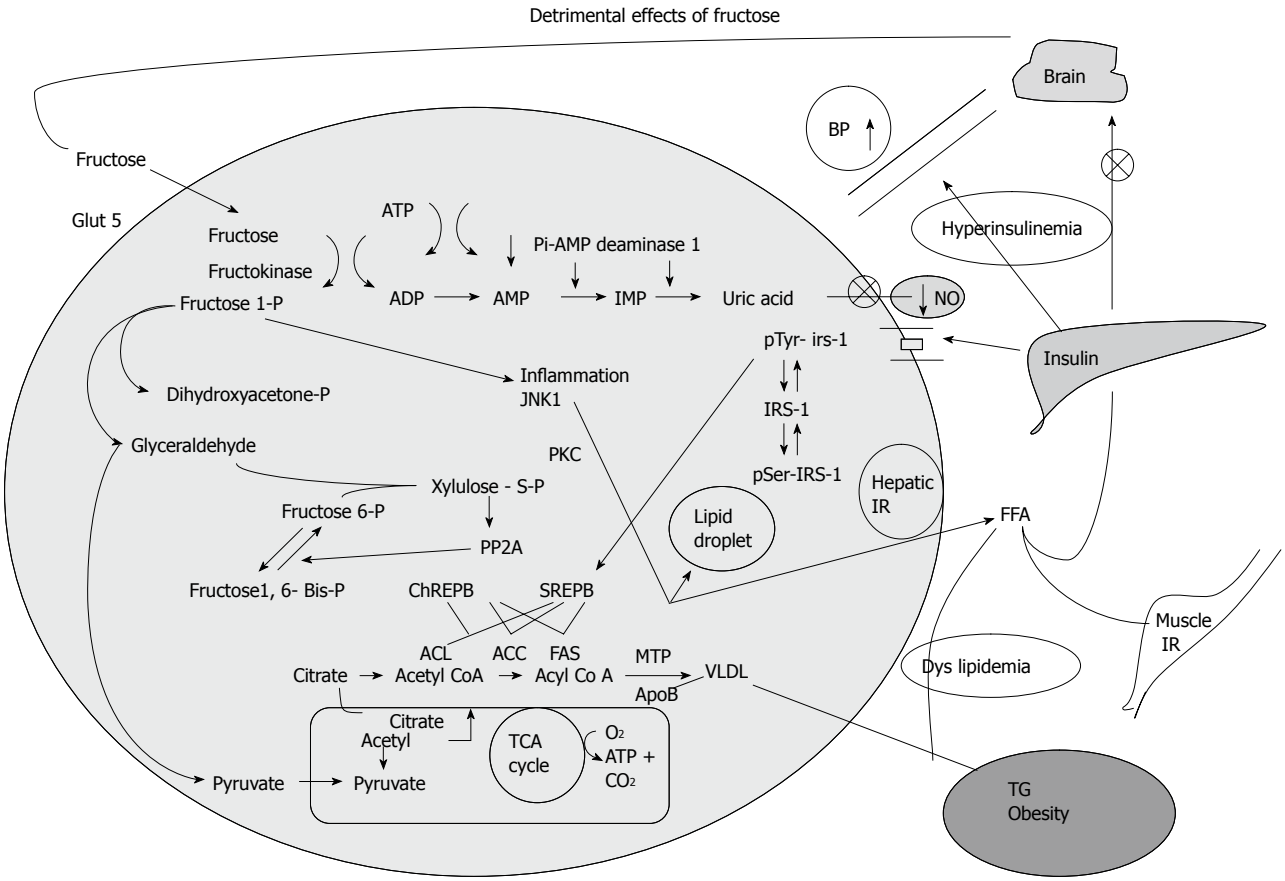

Figure 5 Mechanisms of detrimental effects of fructose.

of TGs to be used as an energy supply for the body in times of starvation, however, adipose tissue has a limited capacity to store fat. This maximum capacity may be reached in states of obesity, resulting in an impaired ability of adipose tissue to acquire dietary fatty acids and, therefore, increased levels of fatty acids are found in the circulation[77].

Signaling abnormalities in adipocytes can also trigger lipolysis of TG stores and the efflux of fatty acids into the bloodstream, augmenting the problem. The presence of high levels of NEFAs in the bloodstream is proposed to function as a key mechanistic link between obesity and insulin resistance, type 2 diabetes, and metabolic dyslipidemia. Eventually, these NEFAs may be taken up ectopically by non-adipose tissues such as the liver and skeletal muscle, where they may be stored as TG or diacylglycerol and interfere with metabolic pathways such as the response to insulin, contributing to insulin resistance and the metabolic syndrome[78].

Differences exist in the metabolic properties of the various sites of adipose tissue. Visceral or abdominal fat stores are believed to pose a greater risk for the development of insulin resistance and the metabolic syndrome than subcutaneous fat stores. Reasons for this include reduced responsiveness of visceral fat to the anti-lipolytic effects of insulin (due to lower expression and activity of hormone sensitive lipase, reduced tyrosine phosphorylation of the insulin receptor, decreased IRS-1 expression, and increased PTP-1B activity); greater responsiveness of visceral fat to the lipolysis-inducing effects of catecholamines; and decreased uptake and acylation of fatty acids compared with subcutaneous fat, all of which result in amplification of NEFA levels in the blood[79]. Visceral fat is also located conveniently for these NEFAs to enter the portal circulation for direct delivery to the liver, where they pose a risk to hepatic insulin responsiveness.

Fructose consumption can induce perturbations in cell signaling and inflammatory cascades in insulin-sensitive tissues[25]. The contribution of fructose/sucrose in dyslipidemia was discussed above. Consuming such large amounts of fructose/sucrose can lead to the development of a complete metabolic syndrome by increasing plasma TGs and altering hepatic glucose homeostasis, gaining weight, and decreasing insulin sensitivity.

CONCLUSION

The use of sweeteners has increased considerably worldwide and soft drink beverages seem to be a major contributor for obesity, diabetes mellitus, hyperlipidemia, insulin resistance, hypertension, metabolic syndrome, and cardiovascular disease. In this review we sought to focus attention on the impact of soft drinks on the accumulation of fat in the liver. This has significant clinical implications, as

the presence of NAFLD correlates strongly with diabetes, cardiovascular disease and diffuse atherosclerosis.

Abstract

Clinical presentation at diagnosis and disease course of both Crohn's disease (CD) and ulcerative colitis are heterogeneous and variable over time. Since most patients have a relapsing course and most CD patients develop complications (e.g. stricture and/or perforation), much emphasis has been placed in the recent years on the determination of important predictive factors. The identification of these factors may eventually lead to a more personalized, tailored therapy. In this TOPIC HIGHLIGHT series, we provide an update on the available literature regarding important clinical, endoscopic, fecal, serological/routine laboratory and genetic factors. Our aim is to assist clinicians in the everyday practical decision-making when choosing the treatment strategy for their patients suffering from inflammatory bowel diseases.

In this TOPIC HIGHLIGHT series, we provide an update on the available literature regarding important clinical, endoscopic, fecal, serological/routine laboratory and genetic factors (Table 1) that may be used for the prediction of the disease course in inflammatory bowel diseases (IBD)[1]. Our aim is to assist clinicians in the everyday practical decision-making when choosing the treatment strategy for their patients suffering from IBD.

We focus first on clinical and endoscopic variables by Louis *et al*[2] and Allez *et al*[3] that were found to be important medium and long-term markers in the prediction of complicated disease course in IBD. The phenotypic classification of Crohn's disease (CD) plays an important role in determining the treatment, and may assist in predicting the likely clinical course of disease. Using the Vienna classification system, it has been shown in clinic-based cohorts that there can be a significant change in disease behavior over time, whereas disease location remains relatively stable[4,5]. In addition, factors, e.g. young age at onset or pediatric presentation, early steroid use, ileal disease, presence of perianal disease, mucosal healing or smoking were identified as an important risk factor for developing disabling disease or major abdominal surgery[6-10]. Fewer factors are available in ulcerative colitis. One of the important factors is disease extent, identified by previous studies and also a recent 10-year population-based inception cohort study[7].

A second group of markers that will be discussed in details are biomarkers. Biomarkers can be divided into long-term markers (e.g. genetics and serology) influencing the clinical phenotype and short-term markers that may be used for the prediction of flares. Genetic (e.g. nucleotide oligomerization domain, NOD2)/caspase activation recruitment domain (CARD15) and serology markers, discussed by Vermeire *et al*[8] and Dubinsky *et al*[9], may be important in the prediction of long term evolution of disease phenotype and need for surgery in CD or they might also be used to predict the efficacy and/or side effects of medical therapy. However, various geographical differences may exist at least for genetic

Table 1 Predictors for long and short term disease course in inflammatory bowel diseases

Markers
Disabling/complicated disease in CD
Young age at onset (pediatric or < 40 yr)
Small bowel disease
Stricturing
Perianal disease
Weight loss > 5 kg
Steroid need for the first flare at diagnosis
Early immunosupression and/or biological therapy (protective?)
NOD2/CARD15
rs1363670 near IL12B
ASCA, glycans
Surgery in CD/colectomy in UC
Young age at onset (pediatric or < 40 yr)
Small bowel disease
Stricturing or penetratingat diagnosis
Early immunosupression and/or biological therapy (protective?)
Deep ulcers at endoscopy
ASCA, glycans
Extensive disease in UC
Smoking (protective) in UC
Clinical relapse
CRP, ESR
Calprotectin
Complete or partial mucosal healing (protective)

NOD2/CARD15: Nucleotide oligomerization domain2/caspase activation recruitment domain15; ASCA: Anti-*Saccharomyces cerevisiae* antibodies; CRP: C reactive protein; ESR: Erythrocyte sedimentation rate; UC: Ulcerative colitis; CD: Crohn's disease.

markers. Finally, we focus on the predictive power of serum, fecal and mucosal markers, which were used by Scaldaferri *et al*[10] to identify relapses and/or disease progression.

The search for clinical, laboratory, and molecular markers to define and predict disease outcome in common diseases has moved rapidly forward with the help of modern technologies and vigorous collection of clinical data. However, many questions remain unanswered. We believe that this issue will be of strong interest not only for IBD specialists, but also for gastroenterologists, since our ultimate goal is to identify individual patient profiles, including clinical, laboratory and molecular markers, which will hopefully allow us to choose the most appropriate management in terms of therapy and intensity of follow-up.

Abstract

During the course of the disease, most patients with Crohn's disease (CD) may eventually develop a stricturing or a perforating complication, and a significant number of patients with both CD and ulcerative colitis will undergo surgery. In recent years, research has focused on the determination of factors important in the prediction of disease course in inflammatory bowel diseases to improve stratification of patients, identify individual patient profiles, including clinical, laboratory and molecular markers, which hopefully will allow physicians to choose the most appropriate management in terms of therapy and intensity of follow-up. This review summarizes the available evidence on clinical, endoscopic variables and biomarkers in the prediction of short and long-term outcome in patients with inflammatory bowel diseases.

INTRODUCTION

Inflammatory bowel disease (IBD) is a multifactorial disease with probable genetic heterogeneity[1]. In addition, several environmental risk factors (e.g. diet, smoking, measles or appendectomy) may contribute to its pathogenesis. During the past decades, the incidence pattern of various forms of IBD has changed significantly[2], showing some common but also quite distinct characteristics for the different variations of the disorder.

The phenotypic classification of Crohn's disease (CD) plays an important role in determining the treatment, and may assist in predicting the likely clinical course of disease[3]. In 2005, the Montreal revision of the Vienna classification system was introduced[4]. Using the Vienna classification system, it has been shown in clinic-based cohorts that there can be a significant change in disease behavior over time, whereas disease location remains relatively stable[3,5]. Since the early introduction of immunomodulators and/or biologicals might be justified in patients at risk for disease progression, so it is important to identify these patients as soon as possible. Much emphasis has been placed in recent years on the determination of important predictive factors. In this review, the authors try to highlight some of the clinical, endoscopic variables and biomarkers that are important in the prediction of disease course in IBD (Table 1).

CLINICAL, ENVIRONMENTAL, AND ENDOSCOPIC FACTORS

Clinical and endoscopic variables are important medium

Table 1 Possible use of predictors for long and short term disease course in inflammatory bowel diseases

	Marker name	Clinical outcome
Clinical markers	Young age at onset (pediatric or < 40 yr)	Disabling disease
	Small bowel disease	
	Stricturing	
	Perianal disease weight loss > 5 kg	
	Steroid need for the first flare at diagnosis	
	Early immunosupression and/or biological therapy (protective?)	
	Young age at onset (pediatric or < 40 yr)	Surgery
	Small bowel disease	
	Stricturing or penetrating at diagnosis	
	Early immunosupression and/or biological therapy (protective?)	
	Extensive disease	Colectomy in UC
	Younger age at onset (< 50 yr)	
	Smoking (protective)	
Genetic markers	NOD2/CARD15	Disease location/behavior/surgery in CD
	rs1363670 near IL12B	Disease behavior
	TPMT	Azathioprine toxicity
Serology markers	ASCA, glycans	Complicated disease, surgeries
Biomarkers	CRP	Clinical flares
	ESR	
	Calprotectin	
Endoscopy markers	Complete or partial mucosal healing (protective)	Clinical flares and surgery

NOD2/CARD15: Nucleotide oligomerization domain2/caspase activation recruitment domain15; TPMT: Thiopurine S-methyltransferase; ASCA: Anti-*Saccharomyces cerevisiae* antibodies; CRP: C reactive protein; ESR: Erythrocyte sedimentation rate; CD: Crohn's disease; UC: Ulcerative colitis.

and long-term markers in the prediction of complicated disease course in IBD. A young age at onset or pediatric presentation is an important risk factor for developing complicated disease behavior, and even disease extension in a large proportion of patients, as reported in a recent French population based-cohort study[6,7].

In CD, an initial need for steroid use (OR: 3.1, 95% CI: 2.2-4.4), an age below 40 years (OR: 2.1, 95% CI: 1.3-3.6), and the presence of perianal disease (OR: 1.8, 95% CI: 1.2-2.8) were associated with the development of disabling disease in the study by Beaugerie *et al*[8]. The positive predictive value of disabling disease in patients with 2 and 3 predictive factors of disabling disease was 0.91 and 0.93, respectively. More recently, authors from New Zealand[3] have shown that > 70% percent of CD patients had inflammatory disease at diagnosis, with the proportion of patients with complicated disease increasing over time. Progression towards complicated disease was more rapid in those with small bowel than colonic disease location, ($P < 0.001$), and perianal disease was a significant predictor of change in CD behavior [hazard ratio (HR): 1.62, $P < 0.001$]. Similarly, perianal lesions, the need for steroids to treat the first flare and ileocolonic location, but not age below 40 years were confirmed as predictive markers for developing disabling disease (according to the predefined criteria) at 5 years[9]. In the same study, stricturing behaviour (HR: 2.11, 95% CI: 1.39-3.20) and weight loss (> 5 kg) (HR: 1.67, 95% CI: 1.14-2.45) at diagnosis were independently associated with the time to development of severe disease. In addition, small bowel location and stricturing disease were predictors for surgery in a long term follow-up study[10]. Finally, terminal ileal location ($P < 0.001$), stricturing ($P = 0.004$), penetrating behavior ($P < 0.001$), and age younger than 40 years ($P = 0.03$) at diagnosis were independent risk factors for subsequent surgery in a prospective 10-year follow-up study by the IBSEN group[11].

An important environmental factor that may possibly be important in determining changes in disease behavior in CD is smoking. In CD, smoking was reported to be associated with disease location: most, but not all, studies report a higher prevalence of ileal disease and a lower prevalence of colonic involvement in smokers[12,13]. A recent review[13] and previous data have demonstrated that smoking, when measured up to the time-point of disease behavior classification, was associated more frequently with complicated disease, penetrating intestinal complications[12,14,15], and greater likelihood to progress to complicated disease, as defined by the development of strictures or fistulae[13], and a higher relapse rate[16]. In addition, the risk of surgery as well as the risk for further resections during disease course was also noted to be higher in smokers in some studies[12,17] and in a recent meta-analysis[18]. The need for steroids and immunosuppressants was found to be higher in smokers compared to non-smokers[19]. In a recent paper by Aldhous *et al*[20] using the Montreal classification, the harmful effect of smoking was only partially confirmed. Although current smoking was associated with less colonic disease, smoking habits at diagnosis were not associated with time to development of stricturing disease, internal penetrating disease, perianal penetrating disease, or time to first surgery.

In one study by Cosnes *et al*[21], immunosuppressive therapy was found to neutralize the effect of smoking on the need for surgery. The importance of an early aggressive medical strategy in determining long term disease phenotype is further supported by a recent Hungarian study[22,23] where the authors have reported that early aza-

thioprine (AZA)/biological therapy reduced the risk for disease behavior change and delayed the time to the first operation in CD in both smokers and non-smokers. The most convincing data to support a benefit from early use of AZA however, comes from the pediatric literature[24], where in a randomized controlled trial in 55 children, the early use of 6-mercaptopurine (6-MP) was associated with a significantly lower relapse rate (only 9%) compared with 47% in controls ($P = 0.007$). Moreover, the duration of steroid use was shorter ($P < 0.001$) and the cumulative steroid dose was lower at 6, 12, and 18 mo ($P < 0.01$).

In addition, in a recent withdrawal study by the Groupe D'Etude Thérapeutique Des Affections Inflammatoires Du Tube Digestif (GETAID) group[25], authors have provided evidence for a benefit of long term AZA therapy beyond 5 years in patients with prolonged clinical remission. Finally, in a recent controlled randomized prospective trial[26], AZA administered for 12 mo together with metronidazole for 3 mo was more effective in preventing endoscopic postoperative recurrence assessed at 12 mo, compared to metronidazole alone in patients previously only minimally exposed to AZA.

Fewer factors are available in ulcerative colitis (UC). One of the important factors is disease extent, identified by previous studies and also a recent 10 years population-based inception cohort study[27]. In the same study, an age at the time of diagnosis > 50 years was associated with reduced hazard ratio (0.28) for subsequent colectomy. In addition, one-fifth (69/288) of patients with proctitis or left-sided colitis had progressed to extensive colitis. In contrast, pediatric UC was more aggressive. Disease course was characterized by disease extension in 49% of patients during in a 6.5 years population-based cohort study[7]. A delay in diagnosis of more than 6 mo and a family history of IBD were associated with an increased risk of disease extension, with odds ratios of 5.0 (1.2-21.5) and 11.8 (1.3-111.3), respectively. The cumulative rate of colectomy was 8% at 1 year, 15% at 3 years, and 20% at 5 years. Of note, however, surgical rates have shown a wide geographical variation with significantly lower rates reported from the Mediterranean region and Eastern Europe in earlier studies[22,28].

Furthermore, in contrast to CD, smokers with adult UC have been reported to run a more benign disease course compared to non-smokers[29]. Flare-ups, hospitalization rates, the need for oral steroids, and colectomy rates, were reported to be lower, while age at onset was older in smokers compared to non-smokers, though not in all studies. Relapse rates were lower in patients who began smoking after the diagnosis of UC was made. In concordance, in a recent Europe-wide population-based cohort[30], the relapse rate was lower (HR: 0.8, 95% CI: 0.6-0.9) in smokers compared to non-smokers, while being higher in women. In addition, in a meta-analysis of several large series with a total of 1489 UC patients, the risk for colectomy was lower (OR: 0.57, 95% CI: 0.38-0.85) in current smokers compared to non-smokers[31].

Finally, it is still unclear whether mucosal healing prevents the development of complications, although its importance was investigated in several studies using heterogeneous definitions. A well-known example is the study by Allez *et al*[32] where severe endoscopic activity was associated with an increased risk for colectomy in CD after 1, 3 and 8 years of follow-up. This was only partially confirmed in a more recent population-based follow-up study by the IBSEN group, where mucosal healing at 1 year in UC was associated with a lower subsequent colectomy risk, but mucosal healing in CD was not a significant predictor for resective surgery at 5 years, but the risk of future steroid use was decreased[33]. Similarly, in a very recent follow-up report the beneficial effect of early complete mucosal healing was confirmed in early CD. Complete mucosal healing in patients with early-stage CD was associated with significantly higher steroid-free remission rates 4 years after the start of the therapy[34]. Similarly, mucosal healing at 6 mo following the start of scheduled infliximab maintenance therapy was associated with lower need for major abdominal surgery during follow-up in a study from the Leuven group[35].

BIOMARKERS

Biomarkers can be divided into long-term markers (e.g. genetics and serology) influencing the clinical phenotype and short-term markers that may be used for the prediction of flares.

In 2001, the identification of nucleotide oligomerization domain2 (NOD2)/caspase activation recruitment domain15 (CARD15) on chromosome 16 in the IBD1 region, as a candidate gene for CD[36,37], has stimulated further research focusing on novel genetic determinants of susceptibility and phenotype in IBD. The presence of a NOD2/CARD15 mutation increases the risk for CD by 1.4-4.3-fold in heterozygous patients and 17.6-44.0-fold in homozygous and compound heterozygous patients. Of importance, reports exist of homozygous individuals who are disease-free. However, various geographical differences were noted. A much lower prevalence of these mutations was reported in, for example African American, Chinese and Japanese[38] populations. NOD2/CARD15 is a good example for case-control phenotype-genotype correlations, since in earlier studies the three common NOD2/CARD15 mutations were associated with ileal disease and fibrostenosing behavior. On the contrary, in colonic and fistulizing disease, they were relatively less frequent[39,40]. There are many controversial findings, such as the association between the OCTN TC risk haplotype and penetrating disease (OR: 1.474, 95% CI: 1.028-2.114, $P = 0.035$) in one study[41] or non-fistulizing non-fibrostenotic disease (OR: 1.57), colonic disease (OR: 1.31), an earlier age at the onset of disease, and reduced need for surgery (OR: 1.38) in another[42], or the association between the presence of DLG5 R30Q variant and steroid refractory disease that could not be confirmed yet[43]. Finally, in a recent study by Weersma *et al*[44] the same type of statistical analysis was performed in a little more complex genetic dataset by using both novel markers (e.g. ATG16L1,

IL23R) and earlier (NOD2, IBD5 and DLG5) genetic markers. In this study, patients with CD with a more severe disease course, surgeries or an age of onset below 40 years had more risk alleles compared to non-stricturing, nonpenetrating behaviour (P = 0.0008), no operations (P = 0.02) or age at onset greater then 40 years (P = 0.028). However, the association became insignificant after a longer disease duration, confirming that many other factors (e.g. clinical variables, disease phenotype at diagnosis, medical therapy) contribute to the long term evolution of disease phenotype.

Although in some of these studies the authors corrected their findings for disease duration using logistic regression, these are all static correlations between phenotype and genotype. In 2009, we finally observed new examples of genotype-phenotype association scans, where the authors have performed a complete follow-up of the patients and so the association between time-dependent clinical outcomes and genotype could be more preciously evaluated in multivariate analysis using Cox regression. Moreover, the authors realized that clinical parameters should also be included in the complex testing. A fine example of how this should be performed was recently published by the Leuven group[45]. Of course, the presentation of the results is now much more complex. For example, homozygosity for the rs1363670 G-allele in a gene encoding a hypothetical protein near the *IL12B* gene was independently associated with stricturing disease behavior and with shorter time to strictures, especially in patients with ileal involvement, or alternatively male patients carrying at least one rs12704036 T-allele in a gene desert had the shortest time to non-perianal fistula. This landmark study with its complex analysis is, however, bringing genetics closer to being used in routine clinical practice.

Genetic markers may also be used to predict the efficacy and/or side effects of medical therapy, that is pharmacogenetics. This use is also expected to be complex and include certain clinical predictors. The importance of using conventional genetic testing might be highlighted by the well-known thiopurine S-methyltransferase (TPMT) genotype/activity testing. TPMT limits the production of 6-TGNs by converting 6-MP to 6-thioruric acid and 6-methylmercaptopurine[46], which may lead to myelotoxicity. Population studies have shown that the distribution of TPMT activity is trimodal: 0.3%-0.5% of the population has low to absent activity (TPMTL/TPMTL), around 10% have intermediate activity (TPMTL/TPMTH), and approximately 90% inherit normal to high enzyme activity (TPMTH/TPMTH)[46]. In this regard, a correlation between the TPMT genotype and enzyme activity has been proven. Approximately 5% of the white population carries one or more variant TPMT alleles, with more than ten variant alleles reported[47]. The functional consequences of alleles *2, *2A, *3B, and *3C, accounting together for more than 90% of mutant alleles, have been extensively characterized. Nevertheless, it is clear that there are many other causes of myelotoxicity. This was accurately demonstrated by Colombel *et al*[48], who found that only 27% of patients had a documented low TPMT activity. Other confounding genetic and environmental factors include, for instance, the patient's age, renal function, AZA formulation, coadministration of mesalazine (a reversible TPMT inhibitor) and allopurinol (XO inhibitor). Thus, the determination of TPMT activity is not an exclusive test to rely on. It may only be helpful in identifying a certain group of high risk patients but as the negative predictive value is rather low, it is not beneficial in ruling out possible side effects. Also, as the prevalence of double carriage of variant TPMT alleles is as low as 1/300, continuous monitoring of red blood cell counts remains mandatory in clinical practice. A different approach was recently reported by the Leuven group[49]. The authors analysed gene expression signatures in the mucosa of patients with UC and were able to identify predictive panels of genes for (non-)response to infliximab. Further studies of the pathways involved should allow a better understanding of the mechanisms of resistance to infliximab therapy in UC.

Similarly, serological markers represent medium to long term markers of disease phenotype and progression. The phenotype and disease course of CD are associated with the presence and extent of the serologic response targeted against various microbial antigens. In patients with conventional anti-*Saccharomyces cerevisiae* antibodies (ASCA$^+$, IgG and/or IgA) or atypical perinuclear antineutrophil cytoplasmic antibodies (P-ANCA) phenotype, small bowel involvement (with or without colonic disease) is more typical than the pure colonic disease (60%-80% *vs* 30%-45%)[50,51]. ASCA positivity predicts a more aggressive disease course with a higher rate of complications. ASCAs have been associated with stricturing and penetrating disease and a higher risk of small bowel resection[51,52]. Some studies also suggest that ASCA positivity is associated with an earlier onset of disease. The presence of anti-OmpC in adult CD patients is associated with an increased prevalence of the penetrating form only[53], while in children, both the penetrating and stenosing forms[54] are more frequent. Moreover, antibody positivity may lead to a more aggressive course of disease and a higher risk for surgical interventions. Like ASCA and anti-OmpC, anti-I2 also appears to be associated with an increased risk for complications in adult CD patients. It is an independent risk factor for the development of the stenosing form and the need for surgical interventions[54]. Recent research has shown that the anti-CBir1 antibody is associated with ileal involvement in adult CD patients independently from other serological markers, and it predisposes for the development of both stenosing and penetrating forms[55]. Interestingly anti-Cbir1 was more frequent in young children with CD (age: 0-7 years)[56]. In a very recent study, an association was also reported between the presence of pancreatic autoantibodies and perforating perianal disease, arthritis, ocular, and cutaneous manifestations[57]. In addition to qualitative correlations, quantitative correlations with serological responses are also present. The number of antibodies produced against microbial anti-

gens in CD also showed a positive correlation with the severity of the disease course[51].

Similarly, the presence and magnitude of the more newly developed antiglycan antibodies (including the most recent anti-laminarin and anti-chitin markers) in CD was associated with a more aggressive disease phenotype in CD, as well as a younger age at onset, ileal involvement, stricturing/penetrating disease behavior, and risk for surgery[58-60]. In the latter study, gASCA IgG and ASCA IgG were comparable for the diagnosis and determination of disease phenotype in CD; however, each test recognized an additional patient population that was missed by the other, indicating a partially complementary role. The differentiation between colon only CD and UC was also better[58,61].

In prospective pediatric cohorts Dubinsky *et al*[54], found that the presence and magnitude of immune responses to microbial antigens (ASCA, anti-OmpC, anti-I2 and anti-CBir1) are significantly associated with more aggressive disease phenotype. The risk of developing penetrating and/or stricturing CD was increased in those individuals with immune response against all four microbial antigens compared to seronegative cases. Moreover, they demonstrated that the time to develop a disease complication during the 18 mo of follow-up period is significantly faster in those children who have a serologic response against at least one antigen, recently confirmed by the same group in a much larger IBD population[62].

In addition, the occurrence of atypical P-ANCA in UC is associated with a characteristic clinical appearance and represents a distinct subgroup, which is often characterized by specific human leucocyte antigen markers. These patients have a higher probability of developing a severe left-sided UC that is more resistant to treatment than the usual case. The disease has a more aggressive course requiring surgery earlier in the course of the disease[63]. The presence of atypical P-ANCA identifies a subgroup of CD patients characterized by "UC-like" colitis; the inflammation usually involves the left side of the colon and the response to therapy is generally good. The atypical P-ANCA in CD patients is associated with a later age of onset and a relatively smaller incidence of complications, such as stricture and/or perforation[64].

Of note however, one should be aware of the fact that the serology profile is not a stable phenotype; seroreactivity may change during the course of follow-up. This is at least suggested by studies done in patients with celiac disease where seropositivity was lost several months after the introduction of a gluten free diet[65].

IBD follows an alternating disease course and both CD and UC are characterized by periods of remission and relapse. However, disease flare-ups occur in a random way and are often unpredictable. Based on the half-life and changes over time serum laboratory and fecal markers may be best used for the prediction of short or medium term relapses. Erythrocyte sedimentation rate (ESR) and C reactive protein (CRP) are traditional non-specific markers of inflammation. In addition, a number of neutrophil-derived proteins present in stool samples have been studied, including fecal lactoferrin, lysozyme, elastase, myeloperoxidase, and calprotectin.

ESR is defined as the rate at which erythrocytes migrate through the plasma. Inevitably, ESR will depend on the plasma concentration and on the number and size of the erythrocytes. Conditions such as anemia, polycythemia, and thalassemia affect ESR. Compared with CRP, ESR will peak much less rapidly and may also take several days to decrease, even if the patient's clinical condition or the inflammation is ameliorated. Although CRP is non-specifically upregulated in most inflammatory diseases, including IBD, there is remarkable heterogeneity in the CRP response between CD and UC. Whereas CD is associated with a strong CRP response, UC has only a modest or no CRP response in both adult and children IBD populations[66]. This is an important fact to keep in mind when using CRP in clinical practice. There is no good explanation for this heterogeneity.

In general, patients with severe disease more often have abnormal inflammatory markers, compared with patients without or with only a low-grade inflammation. This has been shown in one of the early studies by Fagan *et al*[67], both CRP and ESR correlated well with disease activity, yet the correlation was better for CRP. In addition, the correlation of laboratory markers with disease activity has been shown to be much stronger for CD than for UC. However, a wide range of CRP values was observed and no clear cut-off values exist between mild to moderate (10-50 mg/L), moderate to severe (50-80 mg/L), and severe disease (> 80 mg/L). Therefore, the comparison of individual CRP values with previous values in any given patient is of great clinical importance. In addition, CRP showed acceptable correlation with endoscopic and histological activity in CD[68]. For UC, again, this correlation was weaker. In contrast, more recent data from Australia suggested that a subgroup of patients with active ileal disease, low body mass index, and previous ileocecal resection was characterized by low CRP[69].

In CD, a number of studies have investigated a panel of laboratory markers in predicting clinical relapse. Later, Boirivant *et al*[70] prospectively followed 101 outpatients with CD. Half of the patients had an elevated CRP value and this correlated well with clinical activity. Approximately one-third of CD patients presented with active disease despite normal CRP and one-third had high CRP levels but clinically inactive disease. The likelihood of relapse after 2 years was higher in the patients with an increased CRP compared with those who had a normal CRP value. More recently, the GETAID group[71] proposed a simple biological score for predicting short-term relapse in CD. Multivariate analysis selected two markers predictive of relapse: CRP > 20 mg/L and an ESR > 15 mm/h. The relative risk of short-term relapse for patients with a positive score compared to those with a negative score was 8.0 (95% CI: 2.8-22.9). The score's sensitivity and specificity was 89% and 43%, respectively, with a negative predictive value of 97%, suggesting that normal CRP and ESR could almost certainly rule out a relapse in the next 6 wk. Much less data exist on the value of laboratory mark-

ers in assessing disease course and outcome in UC. The well known, prospective study from Oxford evaluated 49 severe UC patients treated with hydrocortisone and/or cyclosporine (n = 49). On day 3, a daily stool frequency of > 8 or 3-8 with increased CRP (> 45 mg/L) predicted with 85% certainty the need for colectomy[72]. Only one relatively small study investigated the role of hs-CRP in IBD[73]. Ninety CD, 70 UC patients, and 160 controls were investigated. The coefficient of correlation between hs-CRP and the disease activity score was weak but similar in both UC (0.26) and CD (0.36).

Finally, a recent population based study by the IBSEN group has demonstrated[74] that CRP at diagnosis or during follow-up was able to predict medium term outcome as measured by the need for colectomy or resective surgery. In patients with UC with extensive colitis, CRP levels above 23 mg/L at diagnosis predicted an increased risk of surgery (OR: 4.8, 95% CI: 1.5-15.1) during the first 5 years of follow-up. In patients with UC, CRP levels above 10 mg/L after one year predicted an increased risk of surgery during the subsequent 4 years (OR 3.0, 95% CI: 1.1-7.8). A significant association between CRP levels at diagnosis and risk of surgery was also found in patients with CD with terminal ileitis (L1), where the risk increased when CRP levels were above 53 mg/L in this subgroup (OR 6.0, 95% CI: 1.1-31.9).

A change in CRP following therapy serves as a good parameter in assessing the effectiveness of the drug on the underlying inflammation. A decrease in CRP, in response to therapy, is objective evidence that the drug has a beneficial effect on intestinal inflammation, even in patients with small changes in their symptoms. On the other hand, persistently raised CRP indicates therapeutic failure in controlling mucosal inflammation. This was clearly demonstrated by the different response rates to anti-TNF antibodies in patients with CD. In some studies, a high baseline (5-10 mg/L) CRP value before the start of therapy was associated with a higher response compared to patients with lower CRP[75,76]. These findings raise the question of whether CRP should be included in patient selection for future clinical trials, at least for selected drugs. Furthermore, high CRP (> 20 mg/L) was found to be an independent predictor for relapse after AZA withdrawal in patients on AZA therapy for longer than 42 and 63 mo[25,77].

Fecal calprotectin was also shown to predict relapse in CD. Calprotectin, a 36 kDa calcium- and zinc-binding protein, is probably the most promising marker for various reasons. In contrast with other neutrophil markers, calprotectin represents 60% of cytosolic proteins in granulocytes. The presence of calprotectin in feces can therefore be seen as directly proportional to neutrophil migration to the gastrointestinal tract. Fecal calprotectin is a very stable marker (stable for more than 1 wk at room temperature) and is resistant to degradation, making it an attractive option. Other neutrophil protein markers, include fecal lactoferrin, polymorphonuclear-elastase, and S100 A12. They are also more specific to intestinal rather than systemic inflammation, but their clinical role has been less extensively evaluated in IBD.

In the study by Tibble *et al*[78], calprotectin levels of 50 μg/g or more predicted a 13-fold increased risk for relapse. In another study[79], 38 CD and 41 UC patients were investigated. All patients were in remission for a mean duration of 5 mo. A baseline level of calprotectin of 150 μg/g or more was predictive for a relapse in the next year. Although sensitivity was high for both CD (87%) and UC (89%), specificity was much lower in the case of CD (43%) compared to UC (82%). Similarly, in a recent study, fecal calprotectin and lactoferrin were able to differentiate organic colorectal disease and were associated with active disease at endoscopy, both in UC (78% and 75%, respectively) and in CD (87% and 82%, respectively)[80]; however, specificity was low overall. It is thus difficult to define cut-off values based on these studies. In addition to serum markers, fecal calprotectin also correlates well with endoscopic and histological activity in patients with UC and CD, and elevated calprotectin levels normalize once the inflammation has resolved in both adults and children[81,82].

Lastly, calprotectin, at a cut-off value of 200 mg/L, at 3 mo post-surgery, was useful in predicting endoscopic post-surgical recurrence in asymptomatic patients with a sensitivity of 63% and a specificity of 75%[83].

CONCLUSION

In conclusion, the search for clinical, laboratory, and molecular markers to define and predict disease outcome in common diseases has moved rapidly forward with the help of modern technologies and vigorous collection of clinical data. However, many questions remain unanswered. Nevertheless, research should be encouraged because, as physicians treating patients with IBD, our ultimate goal is to have at our disposal a complex individual patient profile, including clinical, laboratory and molecular markers around the time of diagnosis which will hopefully allow us to choose the most appropriate management in terms of therapy, intensity of follow-up and frequency of various investigations.

Abstract

While therapeutic strategies able to change the natural history of the disease are developing, it is of major importance to have available predictive factors for aggressive disease to try and target these therapeutic strategies. Clinical predictors have probably been the most broadly studied. In both Crohn's disease (CD) and ulcerative colitis (UC), age at diagnosis, disease location and smoking habit are currently the strongest predictors of disease course. A younger age at onset is associated with more aggressive disease both in CD and UC. Disease location in CD is associated with different types of complications: surgery and recurrence in upper gastrointestinal and proximal small bowel disease; and surgery in distal small bowel disease and peri-anal lesions in rectal disease. In UC, extensive colitis is clearly been associated with more severe disease. Finally, active smoking globally increases disease severity in CD but decreases it in UC. Besides these important factors, others may predispose to some specific disease evolution and complications, and are also reviewed in the present paper.

INTRODUCTION

The clinical course of the disease varies greatly among patients with inflammatory bowel diseases (IBD). It usually follows a pattern of more or less frequent relapses of variable duration interspersed with remission periods, but some patients may experience progressive decrease and even disappearance of disease activity over time, while others may have chronic active disease without remission periods. Furthermore, the natural history of IBD progressively leads to the development of complications in approximately two-thirds of Crohn's disease (CD) patients[1,2] and less than one-third of ulcerative colitis (UC) patients[3,4]. In CD, the main complications are the development of fibrotic strictures that lead to intestinal obstruction and the development of intra-abdominal and peri-anal fistulae and abscesses. In UC, the main complications are fulminant colitis that leads to emergency colectomy and the development of colorectal cancer.

To be able to predict the course and complications of IBD has become particularly important since drugs able to change the natural history of the disease have become available: this is particularly the case for anti-tumor necrosis factor treatment[5,6] but probably also, albeit to a

lesser extent, immunosuppressive treatment if it is used early enough[7].

Among other markers that can help clinicians to predict disease course in IBD, demographic and clinical characteristics are important because they are probably the easiest to use. The value of clinical parameters has been studied for the prediction of various types of disease outcomes, including the development of complications, need for surgery, or more elaborate definitions of disabling or severe disease.

CD

The variable course of CD has been well described in several Scandinavian population-based studies[8,9]. In particular, four subtypes have been described: 1, severe flare at diagnosis but with rapid decrease and disappearance of disease activity; 2, mild activity at the beginning with secondary progressive worsening of the disease; 3, recurrent flares interspersed with periods of full remission; and 4, chronic active disease with fluctuating but constant disease activity. In a recent population-based Norwegian study, types 1, 2, 3 and 4 affected 43%, 3%, 32% and 19%, respectively[9]. To date, no clinical predictive factor has been associated with these different profiles of disease evolution. More numerous studies have been devoted to the search for predictive factors of disease complications.

The characteristic of CD that is associated most strikingly with the course of the disease is disease location. Terminal ileal location has been very strongly associated with the risk of stricture and internal penetrating behavior in several independent studies[10,11]. Hence, it has also been associated with the risk of surgery[12,13]. Proximal small bowel and upper gastro-intestinal tract location (category L4 in the Montreal classification) has been associated in a European population-based study with the risk of recurrence[14]. In a recent Asian study, it was also associated with the risk of surgery[15]. Colonic disease, and particularly rectal disease, is associated with the development of peri-anal disease, and such a complication develops in 12% of patients with ileal disease, 41% of those with colonic disease, and 92% of those with rectal disease[16].

The behavior of the disease at diagnosis can also influence the course of the disease, since a fibro-stenosing or a perforating phenotype is already the sign of the presence of complications. By itself, a particular phenotype may necessitate surgery or the use of immunosuppressive drugs. Beyond this, the predictive value of the phenotype at diagnosis is more difficult to imagine. One of the reasons is that the phenotype of CD is a dynamic process, and after 10 years, almost 50% of the patients with an inflammatory phenotype at diagnosis develop fibro-stenosing or perforating complications that affect the course of the disease[1]. However, it must be remembered that, if only a minority of CD patients remain complication-free over time (30% at 10 years and < 20% at 20 years), among those developing complications, these will occur with a variable delay after diagnosis. This can be interpreted as a different inclination to develop such complications, that is, patients who have already developed complications at diagnosis are the most prone to develop such complications. This difference may then influence the course of the disease.

The presence at diagnosis of peri-anal lesions, is associated with a more frequent use of immunosuppressive treatment[17,18], poor mid-term outcome[19], and increased risk of surgical resection and postoperative recurrence[20]. A stricture or intra-abdominal penetrating lesion is associated with an increased risk of surgery[12,18]. Other studies have also shown that abdominal penetrating lesion at the time of first surgery is associated with more rapid recurrence and is an indicator of further surgery[21].

More recently, some studies have been performed in an attempt to define predictive factors for the development of disabling or severe disease over time. In a large cohort study that used retrospective analysis and prospective validation, the need for surgery, immunosuppressive treatment, biological agents, and hospitalization, demonstrated that peri-anal disease, together with young age at diagnosis and the need for steroids to treat the first flare, were factors associated with disabling chronic disease[22]. In a further study, these factors were partly confirmed, particularly the presence of peri-anal disease at diagnosis[23]. Furthermore, the presence of a stricture or penetrating disease at diagnosis, and peri-anal disease together with weight loss, fever and increased platelet count, were associated with development of severe disease, which was defined by surgical resection of two small bowel segments (or at least 70 cm) or any colonic segment, complex peri-anal disease, or definitive stoma[23]. However in a European population-based study, a stricture or penetrating behavior at diagnosis was not associated with recurrence after the first flare, need for surgery[14], or increased mortality[24].

Young age at onset is also associated with greater disease severity, particularly with the risk of disabling disease[22,23]. However, in contrast, older age at onset is associated with a slight increase in mortality[24].

As indicated earlier, weight loss at diagnosis is associated with more severe disease that is characterized by development of non-reversible tissue damage[23]. Obesity has been associated in a recent study with a more rapid need for surgery, which indicates a more aggressive disease in these such patients[25].

Finally, active smoking is associated with disease activity[26], as well as with the development of strictures and fistula complications[10,11,27]. In a recent study, low levels of smoking increased disease activity and hospitalization, but not the need for surgery[28].

UC

Disease course also varies greatly among patients with UC. In a recent population-based study from Norway, nearly one-fifth of the patients experienced no significant relapse over 10 years after diagnosis, while about half of

the patients had quiescent disease over the past 5 years[29]. In UC, disease location is associated most strikingly with disease course. In particular, extensive colitis is associated with increased risk of colectomy[30] and colon cancer[31], as well as a slight increase in mortality[32]. Colectomy rate reached 35% in extensive colitis, while it was < 20% in left-sided colitis and < 10% in proctitis[30]. The same is true for the risk of colon cancer, which reached 45% after 30 years of the disease in one early historic study, while it was around 30% in left-sided colitis and 10% in proctitis[31]. These risks have been shown to be much lower in most recent studies. It has gone down to 5%-10% for cancer, probably due to sustained control of inflammation and perhaps surveillance, but still with an increased risk in extensive colitis[33,34]. Likewise, in a recent population-based European study, the global risk of colectomy was 8.7% over 10 years[4].

In a recent study, patients with distal colitis were at increased risk of disease extension if they were younger at diagnosis or if they had sclerosing cholangitis[35]. Furthermore after disease extension, these patients were at increased risk of more aggressive disease with resistance to treatment. In another recent pediatric study, disease extension was strongly associated with risk of colectomy[36]. It was also the case, albeit to a lesser extent, for extra-intestinal manifestations.

In a recent Norwegian population-based study, age > 50 years at diagnosis was associated with decreased risk of colectomy[29].

Finally, smoking is associated with a less aggressive disease course in UC[37,38]. In a recent study from Hungary, it even decreased the risk of colectomy[39].

CONCLUSION

Clinical presentation markedly influences disease course in CD and UC. It probably currently represents the strongest predictor for further disease evolution and complications. In both CD and UC, the clinical and demographic characteristics most constantly associated with disease course are age at diagnosis, disease location, and smoking. Younger age at onset is associated with a more severe course in both diseases. In CD, proximal small bowel and upper gastrointestinal tract location is associated with risk of recurrence and surgery; small bowel disease with risk of surgery; and colonic disease, and particularly rectal disease, is associated with increased risk of peri-anal lesions. In UC, extensive colitis is associated with increased risk of colorectal cancer and colectomy. Finally, smoking globally decreases disease severity in UC while it increases severity in CD.

Abstract

The search for biologic markers that can assess the natural history and perhaps predict the course of individual's disease including response to treatments over time has become an important focus of inflammatory bowel disease research. The knowledge of an individual's prognosis can help physicians and patients make important management decisions and aid communication on risk and benefits of disease and treatment.

INTRODUCTION

The ideal serological and laboratory marker should be able to identify individuals at risk for the disease and should be disease specific. Moreover it should be able to detect disease activity and monitor the effect of treatment; and finally it should have a predictive value towards relapse or recurrence of the disease. Predicting disease course however has now been expanded beyond just disease recurrence, but perhaps more importantly to include predictors of disease complications including surgery. This topic highlight will focus on the prognostic role of serological and laboratory markers and the importance of phenotype stratification in inflammatory bowel disease (IBD) patients.

SEROLOGICAL IMMUNE MARKERS

The search for the underlying trigger of the abnormal intestinal inflammatory reaction characteristic of IBD has led to the discovery of antibodies present specifically in the blood of patients with Crohn's disease and/or ulcerative colitis (UC)[1-6]. Perinuclear anti-neutrophil antibody (pANCA) is noted for its association with UC or a UC like phenotype[7-13]. Anti-*Saccharomyces cerevisiae* antibody (ASCA) is another important antibody marker that is present in the blood of individuals with IBD[7-9]. ASCA is part of the family of anti-glycan (carbohydrate) antibodies. Other anti-glycan antibodies, antibodies against laminaribioside (ALCA) and chitobioside (ACCA) have been studied in IBD[14]. In addition to the anti-glycan antibodies, 3 additional markers representative of microbial driven immune responses have been identified; antibodies to the *Escherichia coli* (*E. coli*) outer-membrane porin C (OmpC), the *Pseudomonas fluorescens* CD related protein [anti-CD related bacterial sequence (I2)] and the CBir1 flagellin[15,16]. As seen with the genetic and clinical heterogeneity of CD, studies have shown immune response (immune phenotype) heterogeneity exists among

CD patients. Landers *et al*[15] analyzed immune response heterogeneity in 330 patients and demonstrated that CD patients could be clustered into 4 distinct groups depending on their immune response patterns to microbial or auto-antigens. One cluster was ASCA, a second was antibodies to OmpC and I2, the third pANCA and the fourth was low or no immune response to any tested antigens. Immune reactivity to CBir1 may further define CD phenotypes in that anti-CBir1 expression is present in 40%-44% of pANCA positive CD patients *vs* only 4% in pANCA positive UC patients. This difference may denote a unique etiopathogenic mechanism of disease that helps to further stratify patients based on immunogenetic phenotypes.

Vasiliauskas *et al*[17] introduced the notion of immune response stratification when he first reported that high ASCA levels were found to be associated with fibrostenosing (FS) and internal-penetrating (IP) disease as well as the need for small bowel surgery. Another cross sectional study demonstrated that patients who were ASCA IgA or IgG positive were 8.5 times and 5.5 times more likely to undergo early surgery (within 3 years of diagnosis) than ASCA IgA or IgG negative patients[18]. Mow *et al*[19] examined the association of multiple immune responses and disease phenotype. Reactivity to OmpC was independently associated with IP disease, while reactivity to anti-I2 was independently associated with FS disease and the need for surgery. Both the presence and magnitude of the immune response was associated with more aggressive disease behaviors. A similar study in a Scottish CD cohort reported that the cumulative reactivity to ASCA, I2 and OmpC was associated with small bowel complications[20]. Antibodies to CBir1 were examined in a later study and were found to be independently associated with small bowel disease, IP and FS disease[16]. Xue *et al*[21] demonstrated that reactivity to ASCA, OmpC and CBir1 was associated with early disease onset, FS and IP disease and the need for surgery. The presence and magnitude of the serological response to anti-glycan antibodies were found to be associated with complicated disease, disease duration, and need for surgery[22]. Subsequently, increasing amount and level of antibody responses toward gASCA, ALCA, ACCA, AMCA, and OmpC were found to be associated with more complicated disease behavior ($P < 0.0001$) and need for surgery in CD ($P = 0.023$) in an eastern European IBD cohort[23].

More recent pediatric cohort studies suggest that these markers are present in patients before a complication occurs and thus predictive of disease progression from uncomplicated to complicated disease state. Desir *et al*[24] demonstrated that baseline ASCA reactivity was associated with a more relapsing course in a pediatric CD cohort (OR = 2.9; 95% CI: 1.33-6.35). A multi-center study examined the association of ASCA, anti-I2, anti-OmpC, and anti-CBir1 reactivity with disease course in close to 800 pediatric CD patients[25]. The frequency of development of disease complications (IP and or FS) increased in parallel with reactivity to increasing numbers of antigens. The odds ratio for the development of IP disease was 5.0 and 9.5 for children with reactivity to 2 and 3 antigens, respectively. Furthermore, survival analysis demonstrated that reactivity to at least one microbial antigen was associated with the development of surgery faster as compared to patients negative for all markers suggesting that these markers may predict more aggressive disease behaviors. Amre *et al*[26] also studied a cohort of pediatric CD patients who had sera drawn at diagnosis and were studied for the subsequent development of complications of their disease. Survival analysis revealed that the time to first complication was more rapid for ASCA positive patients than those who were ASCA negative. Moreover the relative risk (RR) of a recurrent complication (RR = 3.68) and needs for an additional surgery (RR = 1.95) was significantly higher in ASCA positive patients. As compared to the positive association between ASCA, antibodies to OmpC, I2 and CBir1 and disease complication, pANCA has been shown to be associated with a more benign, UC-like disease course and negatively associated with small bowel complicating disease[17,27]. High pre-colectomy levels of pANCA (> 100 EU/mL) have been prospectively shown to be associated with the development chronic pouchitis all IBD patients undergoing IPAA[28]. More recently, the same group reported that anti-CBir1 may accelerate the development of chronic pouchitis in the face of high pANCA levels[29]. Melmed demonstrated that ASCA positivity and a family history of Crohn's disease was most predictive of CD of the pouch after IPAA[30]. This information may not change the need for colectomy but the surgical procedure chosen and the post operative management would certainly be impacted by this prognostic information.

FECAL CALPROTECTIN AND C-REACTIVE PROTEIN

Other biomarkers such as fecal calprotectin and C-reactive protein (CRP) have been examined as non invasive tools to predict disease course but with a focus on relapse or disease recurrence. Calprotectin is an abundant neutrophil protein found in both plasma and stool that is markedly elevated in infectious and inflammatory conditions including IBD. Calprotectin constitutes approximately 5% of the total protein and 60% of the cytosolic protein in human neutrophils[31]. Plasma calprotectin has been shown to increase 5 to 40 fold in infectious and inflammatory conditions[32] and fecal calprotectin concentration is approximately six times that of normal plasma[33]. The clinical course of most patients with IBD is typically marked by periods of remission with intermittent relapses. Because the timing of these relapses can be unpredictable, clinical symptoms more so than invasive tests are used to monitor disease activity. Most IBD relapses, however, come to medical attention after the inflammatory response has become well-established and clinical symptoms are worsening. Given that fecal calprotectin has been shown to correlate well with endoscopic and

histologic intestinal inflammation, its use as a predictor of relapse in patients with quiescent IBD has been examined. Tibble *et al*[34] studied 43 patients with CD and 37 patients with UC in clinical remission for 1-4 mo as determined by clinical disease activity indices and Harvey Bradshaw index. These patients had fecal calprotectin measurements at baseline and were then followed for 1 year. Approximately half of the patients in each group relapsed during the 12 mo follow up period. The sensitivity and specificity of calprotectin for predicting relapse within the year in all patients with IBD were 90% and 83%, respectively by using a cut off of 50 mg/L. This cut off was associated with a 13-fold increased risk of relapse. These values were similar when patients with CD or UC were examined separately. Costa *et al*[35] found nearly identical sensitivity and specificity of calprotectin for predicting relapse in UC, but their specificity of calprotectin in CD was 43%, markedly lower than the 83% reported by Tibble *et al*[34] noted above. This large discrepancy may be explained by the fact that their study used a different assay and a lower cut-off of fecal calprotectin (150 μg/g, corresponding to 30 mg/L). A more recent study prospectively evaluated 97 patients with UC and 65 with CD in clinical remission for at least 6 mo[36]. The cutoff level was set at 130 mg/kg of feces. Patients were followed up for 1 year after the test or until relapse. Fecal calprotectin was positive in 44 UC patients and 26 of them relapsed within a year, while 11 of 53 UC patients with a negative calprotectin relapsed within the year. Thirty CD patients had a positive calprotectin and 13 of them relapsed within a year, as did 7 of the 35 with a negative test result. A significant correlation emerged between a positive calprotectin and the probability of relapse in UC patients ($P = 0.000$). In CD patients, only cases of colonic CD showed a significant correlation between a positive calprotectin test and the probability of relapse, such that 6 colonic CD patients were positive for the calprotectin test and 4 relapsed ($P = 0.02$). A subsequent multicenter study demonstrated that fecal calprotectin concentrations in patients who suffered a relapse were higher than in nonrelapsing patients $P < 0.001$)[37]. Relapse risk was higher in patients having high (> 150 μg/g) calprotectin concentrations (30% *vs* 7.8%, $P < 0.001$). The area under the receiver operating characteristic curve to predict relapse using calprotectin determination was 0.73 (0.69 for UC and 0.77 for CD). Better results were obtained when only colonic CD disease or only relapses during the first 3 mo were considered (100% sensitivity).

CRP is one of the most important acute phase proteins in humans. Under normal circumstances CRP is produced by hepatocytes in low quantities but following an inflammatory stimulus, hepatocytes rapidly increase production of CRP under the influence of interleukin (IL)-6, tumour necrosis factor α, and IL-1β. CRP has a short half life (19 h) compared with other acute phase proteins and will therefore rise early after the onset of inflammation and rapidly decrease after the stimulus is resolved. Although CRP is upregulated in most inflammatory diseases, including IBD, CD is associated with a strong CRP response and UC only a modest and sometimes absent CRP response[38,39]. Moreover not all IBD patients mount a CRP response, even in CD and this must be kept in mind when measuring inflammatory markers in individual patients. It is unclear if this is due to differences in cytokine levels such as IL-6 or due to mucosal *vs* transmural disease differences among UC and CD or is genetically driven[40-43]. CRP has been shown to be a good marker for predicting disease course and outcome in a number of diseases with cardiovascular disease and poor outcome after myocardial infarction as well as in multiple myeloma[44-47]. Boirivant *et al*[48] prospectively followed 101 CD outpatients with 50% having raised CRP which correlated well with disease activity. However, 1/3 of patients presented with active disease despite normal CRP and 1/3 had raised CRP but reported inactive disease. The likelihood of relapse after 2 years was higher in CD patients with an increased CRP compared with patients with normal CRP. Perhaps the best study to date on the predictability of CRP and other biomarkers was reported by the GETAID group who prospectively followed 71 CD patients with medically induced remission and measured laboratory markers (full blood count, CRP, ESR, α1 antitrypsin, orosomucoid) every 6 wk[49]. In total, 38 patients relapsed after a median follow up of 31 wk. In the end only two laboratory markers were predictive of relapse: CRP (20 mg/L) and ESR (15 mm). Patients with both markers positive had an 8 fold increased risk for relapse with a negative predictive value of 97%, suggesting that normal CRP and ESR has a very high probability of ruling out relapse in the preceding 6 wk. There are fewer studies examining the role of these markers in predicting UC recurrence or outcome. One study evaluated 49 severe hospitalized UC patients treated with steroids and/or cyclosporine. On day 3, a stool frequency of > 8/d or 3-8 stools/d plus an increased CRP (0.45 mg/L) predicted with 85% certainty the need for colectomy[50].

CONCLUSION

Research has fostered a novel approach to understanding the intricate relationship between genetic and clinical expression of disease. Serum immune markers hold the most promise in helping researchers better comprehend disease heterogeneity and natural history. Although our current gold standard diagnostic tests do not possess this capability, prospective research studies now suggest that IBD-specific genetic and antibody markers may serve as predictors of an individual's disease course. Although promising at predicting disease recurrence, larger studies are needed with more frequent biomarker testing as this may allow for early detection of active, perhaps sub clinical inflammation which may alter treatment decisions. Their role as non-invasive predictors of post-operative recurrence is currently under investigation and will be of interest to help guide post-operative maintenance strategies.

Abstract

The clinical course of Crohn's disease and ulcerative colitis is highly variable between patients, and this has therapeutic implications. A number of clinical features have been identified, which predict a mild or more severe outcome. However, several of these are subjective and/or not persistent over time. With the progress in genetics research in inflammatory bowel disease (IBD), genetic markers are increasingly being proposed to improve stratification of patients. Genetics have the major advantage of being stable over time and not prone to subjective interpretation. Nevertheless, none of the genetic variants associated with particular outcomes have shown sufficient sensitivity or specificity to have been implemented in daily management. Along the same line of thinking, pharmacogenetics or the study of association between variability in drug response and genetic variation has also received more attention as part of the endeavor for personalized medicine. The ultimate goal in this area of medicine is to adapt medication to a patient's specific genetic background and therefore improve on efficacy and safety rates. Although pharmacogenetic studies have been performed for all classes of drugs applied in IBD, few have generated consistent findings or have been replicated. The only genetic test approved for clinical practice is thiopurine S-methyltransferase testing prior to starting treatment with thiopurine analogues. The other reported associations have suffered from lack of confirmation or still need replication efforts. Nevertheless, the importance and necessity of pharmacogenetic studies will increase further as more therapeutic classes are being developed.

INTRODUCTION

The search for molecular markers to predict outcome in inflammatory bowel disease (IBD), has received much interest in the past years and is moving forward rapidly with the help of modern technologies. The recently completed and pivotal SONIC study as well as the Benelux Step-up/Top-down trial in Crohn's disease (CD) illustrated that treatment with biological agents early in the disease course results in higher steroid-free remission and mucosal healing rates, and impacts positively on the necessity of surgical resections[1,2]. However, from a clinical perspective, not all patients require thiopurine analogues and/or biological therapies. In addition, these

agents are not free from adverse events, including opportunistic infections and lymphomas. Predictors of a mild or complicated disease course would therefore help to select patients for a particular therapy.

GENETIC MARKERS TO PREDICT DISEASE COURSE

Compared to clinical parameters or serologic markers, genetic markers are more appealing for risk stratification as they are present long before the onset of the disease and before any environmental factor plays a role. In contrast to serologic factors, genetic factors are stable and are unaffected by disease flares. Moreover, as several studies have correlated microbial seroreactivity with genetic mutations in pattern recognition receptors, genetic markers may well prove to be superior[3,4]. Despite a large number of confirmed genetic variants in the susceptibility to CD and ulcerative colitis (UC), only very few have so far been proven to influence outcome. The presence of NOD2/CARD15 variants has been associated with a more rapid onset of stenosing small bowel disease and need for ileocecal resections[5-7]. In a Dutch tertiary multicentre cohort, Weersma *et al*[8] described a more severe disease phenotype, a higher need for surgery and a younger age at onset of CD with an increasing number of risk alleles and genotypes (NOD2, IBD5, DLG5, ATG16L1, IL23R). We studied whether the recently identified susceptibility genes for CD and their variants could improve stratification of patients, when applied together with other subphenotypes[9]. In a cohort of 875 CD patients with a median follow-up time of 14 years, homozygosity for the rs1363670 G-allele in a gene encoding a hypothetical protein near the *IL12B* gene was independently associated with a stricturing disease behavior with an odds ratio (OR) of 5.48 [95% confidence interval (CI), 1.60-18.83, $P = 0.007$] and furthermore with a shorter time to onset of these strictures ($P = 0.01$), and this was especially the case in patients with ileal involvement ($P = 0.0002$) (Figure 1). In the same cohort, male patients carrying a T-allele at rs12704036 T had the shortest time to development of non-perianal fistula. Presence of a C-allele at the CDKAL1 rs6908425 single nucleotide polymorphism (SNP) and absence of NOD2 variants were both independently associated with development of perianal fistula, particularly when colonic involvement and active smoking were present (Figure 2). Despite their potential promise, genetic markers will most likely never fully predict evolution of disease, because of the incomplete penetrance, their modest to low frequency and the role of other (environmental) factors in shaping the disease. The place of genetic markers in predicting disease outcome more realistically lies in their integration with other molecular markers, clinical data and environmental triggers (Figure 3).

GENETIC MARKERS TO PREDICT THERAPY OUTCOME

Prediction of response to therapy is as accurate as prediction of disease course, and will become even more important as more therapeutic classes are being developed. The success of genetic markers in predicting outcome to CD or UC therapy has been limited, in contrast to other fields such as oncology, where molecular markers have demonstrated clinical utility in predicting response to chemotherapy. The response to cetuximab, a monoclonal antibody to epidermal growth factor receptor in metastatic colorectal cancer is influenced by the KRAS mutation status, as the benefit of cetuximab seems limited to patients with KRAS wild-type tumors[10]. Likewise, germline mutations may also correlate with clinical outcome to chemotherapy. A subanalysis of a large phase Ⅲ study with bevacizumab (Avastin), a humanized monoclonal antibody to vascular endothelial growth factor (VEGF), in metastatic pancreatic cancer, showed that overall survival and progression-free survival were influenced by SNPs in the tyrosine kinase domain of the VEGF receptor-1[11]. As in almost all human diseases necessitating medical therapy, a variable response is also observed for most drugs used in IBD. Between 20% and 30% of patients are refractory to any given medication despite optimal dose and duration. Besides the response, side effects and toxicity are also variable. These factors are of course not all explained by genetics. Disease duration, severity, behavior (inflammatory or stenosing) and concomitant therapies may all influence the response to a drug. Among the genetic factors, genetic variations in drug metabolizing enzymes and target proteins, and also heterogeneity in the patient's genetic background will account for the variable response. Genetic polymorphisms in drug metabolizing enzymes will affect active drug concentrations and this, together with genetic polymorphisms of drug sensitivity (drug receptor genetic variants), will ultimately lead to heterogeneity in drug effects[12].

There are several reasons why pharmacogenetic research in IBD has witnessed only modest success: identifying molecular markers which influence the response to a drug is more difficult than, for instance, the study of genetic markers that influence toxicity. Side effects are usually easy to define and identify, in contrast to efficacy scores, which are often less well defined. In addition, and as already explained, treatment response in a heterogenic

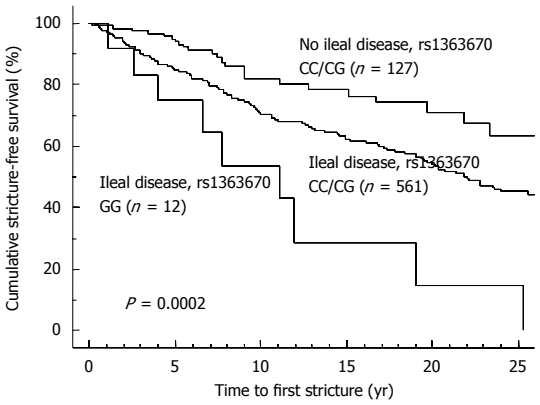

Figure 1 Time to onset of stricture formation in Crohn's disease patients.

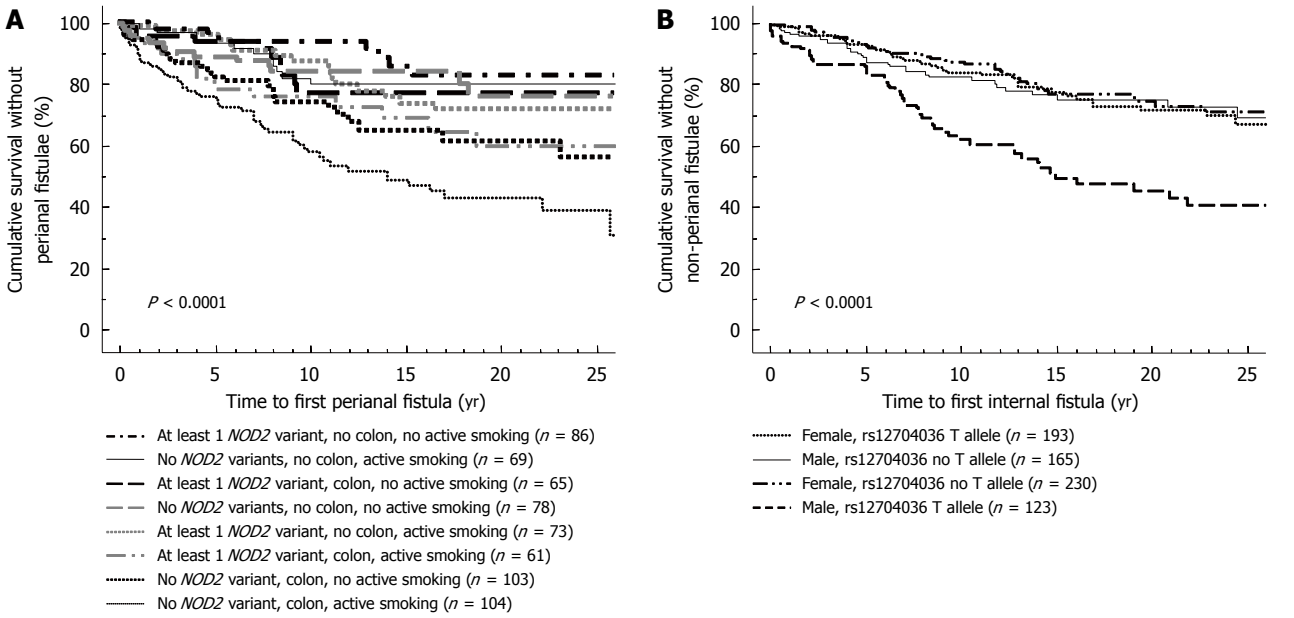

Figure 2 Stratification of patients with respect to development of perianal (A) or internal (B) penetrating disease.

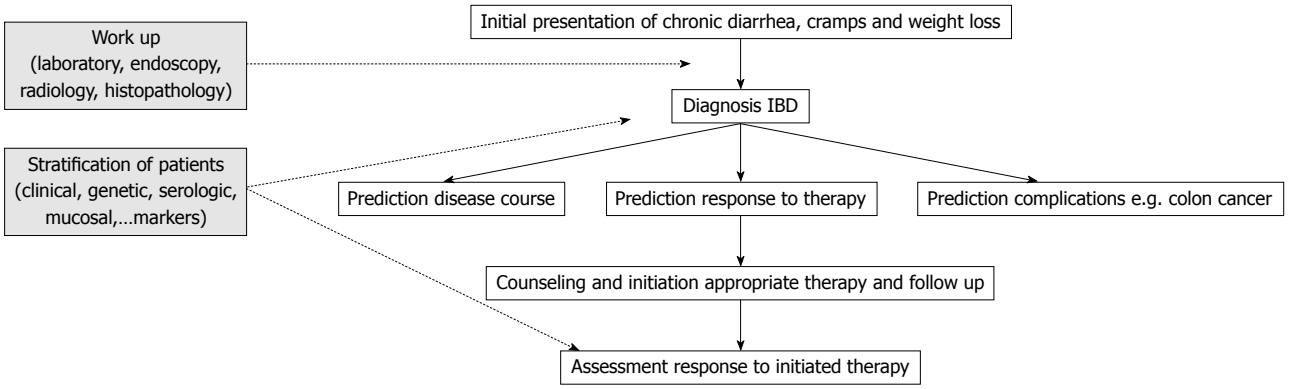

Figure 3 Implementation of genetic markers in management of inflammatory bowel disease (IBD).

disease like IBD is influenced by many factors such as disease duration, behavior and severity. Finally, besides polymorphisms in specific drug metabolizing enzymes or target proteins, heterogeneity in the patient's genetic background can also influence the response to treatment.

Since there are no or very little studies on genetic predictive factors for drugs such as methotrexate, cyclosporin, and tacrolimus, we focus in this overview on azathioprine and infliximab, on which most research has been conducted.

The only class of drugs where genetic testing for response prediction is useful and recommended are the thiopurine analogues. Azathioprine is metabolized by the enzyme thiopurine methyl transferase (TPMT), and the activity of this enzyme is under genetic control[13]. Mutations in the *TPMT* gene result in lower TPMT enzyme activity and this is associated with an increased risk for hematopoietic toxicity. In clinical practice, genotyping the most common TPMT variants or measuring TPMT enzyme activity can be carried out. Both techniques have advantages, and which technique is used is in part dependent on the availability. TPMT enzyme activity is measured in red blood cells with a radiochemical or high-performance liquid chromatography assay. The results can be influenced by blood transfusions but also other drugs may interfere with the TPMT enzyme activity (e.g. diuretics, 5-aminosalicylic acid). TPMT enzyme activity will identify patients with high TPMT activity that metabolize 6-mercaptopurine (6-MP) to 6-methyl-MP and therefore may be resistant to treatment with thiopurine drugs. Genotyping is an easier method, but genotypes do not fully correlate with the enzyme activity, especially in the case of wild-type (some patients will have reduced TPMT activity) or heterozygous (some will have a normal TPMT activity) individuals[14-17]. Therefore, measuring TPMT enzyme activity will give a more accurate picture. In patients in whom TPMT testing is performed, azathioprine or 6-MP can be initiated at normal doses (2.5 and 1.5 mg/kg, respectively) in the case of a wild-type genotype or normal TPMT enzyme activity. When TPMT activity is intermediate or when pa-

tients are heterozygous for the common TPMT variants, a dose reduction of 50% is recommended. Finally, low or absent TPMT activity and/or compound heterozygous/homozygous mutant patients should not be initiated on azathioprine or 6-MP given the high risk of myelotoxicity. Socioeconomic analyses showed that TPMT phenotyping or genotyping was cost effective[18]. However, hematologic toxicity can also develop in patients with a normal TPMT activity and this is the reason why monitoring of blood counts and liver transaminases remains necessary in all patients, as long as they are taking this drug.

Apart from TPMT, mutations in the *ITPA* gene (inosine triphosphate pyrophosphatase) have also been studied with respect to azathioprine toxicity. ITPAse deficiency would result in the accumulation of the potentially toxic 6-thio-ITP. Although some studies reported an association between the ITPA 94C>A deficiency-associated allele and azathioprine toxicity, other studies could not confirm this[19-21].

Corticosteroids (CS) are effective as induction therapy in moderate to severe active UC and CD. The long term outcome data look less promising, however, as European as well as North American studies showed that 25%-30% of patients became steroid-dependent and 20% steroid-resistant within 1 year[22,23]. CS are potent inhibitors of T cell activation and cytokine secretion and mediate their antiinflammatory effect through binding the intracellular glucocorticoid (GC) receptor (GRα). A homodimer of 2 activated GRs is translocated to the nucleus and this complex then binds to specific DNA sequences and controls the expression of target genes [e.g. inhibition of the *activator protein-1* (*AP-1*) gene and induction of the *IκBα* gene]. Several mechanisms have been proposed for the resistance to CS. Overexpression of the *MDR1* (multidrug resistance) gene and subsequent elevated p-glycoprotein-mediated efflux of the drug was the first[24]. Altered functions of the GR and an excessive synthesis of pro-inflammatory cytokines have also been suggested. Steroid-resistant asthma patients do not respond to high doses of inhaled CS but develop Cushingoid side effects. In these patients reduced peripheral T lymphocyte GR binding affinity and abnormalities of GR-AP-1 interaction and increased expression of GRβ (a truncated splice variant of the normal isoform GRα) are observed. GRβ is unable to activate steroid-responsive genes. Honda *et al*[25] reported GRβ mRNA expression in 83% of the patients with steroid-resistant UC compared to only 9% in steroid-responsive patients, and 10% in healthy controls and chronic active CD patients. These results were confirmed in a recent study from Japan, where the authors looked at the frequency of GRα and β positive cells in colonic biopsies of GC-sensitive (n = 6) and GC-resistant (n = 8) UC patients[26]. They also found that there were significantly more GRβ-positive cells in the GC-resistant group than in the GC-sensitive and the control groups. Whereas GRα mRNA was expressed in all UC patients, GRβ mRNA was expressed in only 1 patient in the GC-sensitive group and in 7 patients in the

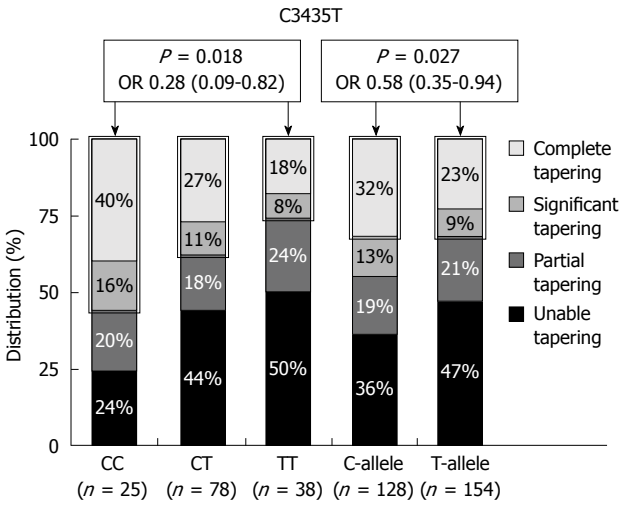

Figure 4 Distribution (%) of C3435T MDR1 genotypes and alleles with respect to glucocorticosteroid tapering in patients under azathioprine maintenance therapy[27].

GC-resistant group. Interestingly, the Foxp3+ cell count was also significantly higher in the GC-sensitive group.

The *MDR1* gene encodes for the drug efflux pump P-glycoprotein-170 (Pgp-170) and is expressed on the surface of lymphocytes and intestinal epithelial cells. Pgp and MDR expression were shown to be significantly higher in CD and UC patients requiring surgery due to failure of medical therapy[24]. MDR1 knockout mice spontaneously develop colitis and the MDR1 gene maps to the IBD susceptibility locus on chromosome 7 making it an excellent functional and positional candidate gene for susceptibility to IBD, and associations between C3435T and UC and G2677C/T and IBD have been described[27,28]. The MDR1 3435 TT genotype was especially associated with extensive UC. An association between steroid refractoriness and the 3435 TT genotype can therefore be the result of an extensive more severe disease phenotype in UC, but the TT genotype is associated with lower expression of MDR1 and Pgp170. Potocnik *et al*[29] reported an association between particular SNPs in introns 13 and 16 of the *MDR1* gene and CS-refractory CD and UC. The C3435T SNP in exon 26 was, on the other hand, associated with significant or complete CS tapering in a cohort studied from Leuven (Figure 4)[30]. Several other associations with SNPs in the *TNF* (tumor necrosis factor) gene and the macrophage *MIF* (migration inhibitory factor) gene and CS dependency or sensitivity have also been reported[31,32]. What is clearly needed from reviewing the literature on this topic, are trials in patient cohorts treated with fixed doses of CS and followed with well defined response criteria. Instead of looking for candidate genes, mucosal expression studies looking at differences between responsive and resistant patients may pave the way.

The use of monoclonal antibodies to TNF has greatly improved the quality of life of patients suffering from IBD but this therapy is expensive and not free from side effects. Although more than 75% of patients in general

respond to infliximab or adalimumab, resistance is seen in a subset of patients. If early response could be accurately predicted, management could be optimized.

Early studies looking at genetic variants with respect to anti-TNF outcome focused logically on the TNF and TNF receptor pathway. Specific mutations in these genes were studied but results were either negative, or positive results could not be confirmed in larger cohorts[33-35]. Since nuclear factor-κB signaling and TNFα levels are lower in cells carrying a CD-associated CARD15 variant it was also hypothesized that patients carrying a mutation in the CARD15 gene might respond differently to treatment with a TNF blocking agent. No significant associations were found also here in 3 independent cohorts of patients, including the ACCENT study cohort[36,37].

One of the mechanisms of action of infliximab is induction of apoptosis of monocytes and T lymphocytes[38,39]. It was therefore postulated that failure to induce apoptosis would be associated with lack of efficacy. In a small pilot study from Amsterdam, 14 patients were given infliximab and underwent endoscopy and 99mTc-annexin V single photon emission computer tomography scanning before and 24 h after infliximab administration (5 mg/kg)[40]. There was a clear and significant uptake of annexin V in the responders, whereas no such uptake was seen in the non-responders. This study showed that molecular markers may assist in predicting the outcome of anti-TNF treatment. Therefore, as the efficacy of infliximab is partly the result of the ability to induce apoptosis of activated T lymphocytes, we analyzed the effect of polymorphisms in apoptotic genes on outcome[41]. In luminal CD, there was a response rate of 74.7% in patients with the Fas ligand -843 CC/CT genotype compared with a response rate of 38.1% in patients with the TT genotype (OR, 0.11; 95% CI: 0.08-0.56, $P < 0.01$). The poorer outcome in patients carrying FasL-843T could be overcome by concomitant use of azathioprine. Patients with the caspase-9 93 TT genotype all responded, in contrast with 66.7% of patients with the CC and CT genotypes (OR, 1.50; 95% CI: 1.34-1.68, $P = 0.04$).

Also polymorphisms in the *Fcγ receptor 3A* gene, binding the Fc portion of the immunoglobulin have been studied, building on the hypothesis that infliximab leads to complement activation and antibody-dependent cellular cytotoxicity. The FcγRIIIa receptor 158V allotype displays a higher affinity for IgG1 and an increased ADCC and influences the therapeutic response to rituximab, an anti-CD20 IgG1 used in the treatment of non-Hodgkin lymphomas[42]. Similarly, Louis *et al*[43] showed an association between FCGR3A-158 and biological and possibly clinical response to infliximab in CD. However, this association could not be confirmed in a subset of 344 patients from the large and well-defined ACCENT 1 cohort of 573 patients[44]. There was however again a trend towards a greater decrease in C-reactive protein after infliximab in V/V homozygotes as compared with V/F heterozygotes and F/F homozygotes (-79.4, -76.5, and -64.3%, respectively, at week 6, $P = 0.085$; one-tailed $P = 0.043$). This finding has no immediate clinical impact but may enhance the understanding of the complex mechanisms of action of anti-TNF agents in CD.

More recently, microarray technology has been applied to advance our understanding on the reasons for (non)response to this class of agents. This technology enables measurement of the expression of thousands of genes simultaneously. In order to identify predictive gene profiles, we studied mucosal gene expression using the genome-wide Affymetrix HGU133 Plus 2.0 arrays in infliximab-naive CD and UC patients[45]. By comparing pre-treatment colonic mucosal expression profiles of responders with non-responders, we found that expression of IL-13Rα2 separated IBD responders from non-responders with 100% sensitivity and 91.3% specificity. The interleukin receptor, IL-13Rα2 has raised a lot of interest lately because of its involvement in fibrogenesis. IL-13 is a critical regulator of a Th2 response and is the key cytokine in parasite immunity and in the generation of an allergic response. IL-13 can bind to IL-13Rα1 with low affinity, causing downstream STAT6 activation. Alternately, IL-13 together with TNF-α can induce IL-13Rα2 expression and IL-13 can bind it with high affinity. This interaction leads to activation of the TGF-β1 promoter 20. It has been shown in a mouse model of colitis, that the initial Th1 response subsides after 3 wk and is followed by an IL-23/IL-25 response with IL-17 and IL-13 production, TGFβ1 production and the onset of fibrosis. If IL-13 signaling through this receptor is blocked by administration of soluble IL-13Rα2-Fc, or by administration of IL-13Rα2-specific small interfering RNA, TGF-β1 is not produced and fibrosis does not occur. Therefore, IL13Rα1 deserves further study.

Finally, for drugs such as methotrexate, cyclosporin, and tacrolimus, which are used less often in IBD, no or very few studies on genetic predictive factors have been conducted.

CONCLUSION

As physicians treating patients with IBD, the goal is to have at our disposal a molecular (serum, DNA, tissue-based) profile of our patient which will allow the most appropriate management (What is the most likely course of disease? Which is the most appropriate therapy with highest chances of success? Which should be the intensity of follow up?…). At the moment, only TPMT testing prior to start of thiopurine analogues has shown clinical applicability, but does not replace blood monitoring during treatment. Other reported genetic associations for the different therapeutic classes in IBD have not (yet) shown consistent or robust results. Studies looking at mucosal gene expression profiles could reveal novel pathways of (non)response. What is needed in pharmacogenetic and other predictive studies to advance the field are patients treated with standardized doses of the drug and fixed endpoints and criteria for response. The setting of a clinical trial may well be the preferred method for this and

attempts to collect DNA from these patients should be enforced.

Abstract

Inflammatory bowel diseases (IBDs) are chronic inflammatory disorders of the bowel, including ulcerative colitis and Crohn's disease. A single etiology has not been identified, but rather the pathogenesis of IBD is very complex and involves several major and minor contributors, employing different inflammatory pathways which have different roles in different patients. Although new and powerful medical treatments are available, many are biological drugs or immunosuppressants, which are associated with significant side effects and elevated costs. As a result, the need for predicting disease course and response to therapy is essential. Major attempts have been made at identifying clinical characteristics, concurrent medical therapy, and serological and genetic markers as predictors of response to biological agents. Only few reports exist on how mucosal/tissue markers are able to predict clinical behavior of the disease or its response to therapy. The aim of this paper therefore is to review the little information available regarding tissue markers as predictors of response to therapy, and reevaluate the role of tissue factors associated with disease severity, which can eventually be ranked as "tissue factor predictors". Five main categories are assessed, including mucosal cytokines and chemokines, adhesion molecules and markers of activation, immune and non-immune cells, and other mucosal components. Improvement in the design and specificity of clinical studies are mandatory to be able to classify tissue markers as predictors of disease course and response to specific therapy, obtain the goal of achieving "personalized pathogenesis-oriented therapy" in IBD.

INTRODUCTION

During the past decade, major insights into the pathogenesis of inflammatory bowel disease (IBD) have been achieved, and investigators generally agree that factors including the external environment, genetic makeup, intestinal microbial flora, and immune system are all involved and functionally integrated in the generation of

the chronic intestinal inflammatory reaction that characterizes IBD[1].

Among all factors, those considered to contribute mainly to IBD pathogenesis are genetics, along with mucosal immunity. New insights in mucosal immunity have allowed for the introduction of biological agents, which have led to great changes in clinical management of IBD, as well as the course of the disease.

Biological drugs block key molecules that are involved in the induction and maintenance of intestinal chronic inflammation through several pathways, differently represented among patients. However, although considered pathogenesis-oriented drugs, a lot still needs to be done in order to achieve "personalized pathogenesis-oriented therapy" in IBD. The complex pathogenesis that involves several major and minor contributors, involves different inflammatory pathways that can have diverse roles in different patients.

These components should be taken into consideration, when choosing from the variety of emerging therapies available for IBD patients, especially biological agents and immunosuppressants. These potent treatments may be associated with significant side effects, in particular serious infections and increased risk of malignancy. In addition, they might not be needed for the subgroup of patients destined to have a more benign course. Their high cost also requires optimal treatment-to-patient adjustment.

As a consequence, there is a pressing need to differentiate between patients who may have more aggressive phenotypes from those with a potentially more benign course[2], with the use of markers that are capable of predicting therapeutic responses.

Major attempts regarding the prediction of therapeutic efficacy have been made on clinical characteristics (e.g. smoking is associated with lower response rates[3]), concurrent medical therapy, serological markers (anti-Saccharomyces cerevisiae antibody and anti-neutrophil cytoplasmic antibody[4-6], outer membrane porin C, CBir1-flagellin, antibodies against I2 protein and the anti-glycan antibodies) and genetic markers[2]. All the above markers have been assessed for their response to anti-tumor necrosis factor (TNF)-α therapy. Emerging evidence, mostly related to the capacity of biological agents to induce mucosal healing, has suggested that mechanisms related to mucosal disease/healing are helpful in completing the scenario of predictors of specific therapy in IBD.

However, how mucosal and tissue inflammatory pathways can influence or predict the disease remains largely unknown, therefore making both prediction of disease course and clinical management of IBD a challenging task.

In fact, only few reports exist on how mucosal/tissue markers can predict clinical response, mostly related to infliximab treatment (summarized in Table 1 and briefly reported below).

Arijs *et al*[7] have shown that mucosal extracts that overexpress five genes, which encode osteoprotegerin (TNFRSF11B), stanniocalcin-1, prostaglandin-endoperoxide synthase 2, interleukin (IL)-13 receptor α 2 and IL-11, predict response to infliximab therapy with 89% accuracy in patients with refractory ulcerative colitis (UC). Notably, those genes encode for proteins involved in signaling in the adaptive immune response, inflammation and TNF-α pathways.

Another study from Van den Brande *et al*[8] has suggested that higher levels of apoptosis in the intestinal mucosa, as shown by 99mTc-annexin V uptake SPECT-CT images comparing before and after infliximab infusion, correlated with clinical response to infliximab in active Crohn's disease (CD) patients.

Schmidt *et al*[9] have demonstrated that, in 19 steroid-refractory CD patients treated with infliximab or cyclophosphamide, lower mucosal TNF-α concentration predicted long-term remission with a sensitivity of 100% and a specificity of 87.5%.

Similar to the study mentioned above, Olsen *et al*[10] have reported that an inverse association between pre-treatment TNF-α expression levels and clinical/endoscopic remission following infliximab treatment exists in UC patients with moderate to severe disease activity. In the same study, neither age, sex, steroid therapy, immunosuppression, pancolitis, endoscopic sub-score, disease duration, C-reactive protein, IL-4, IL-10 nor interferon (IFN) predicted mucosal or clinical remission.

Arsenescu *et al*[11] have revealed that, in a cohort of 69 CD patients, those with low levels of RelA subunit of nuclear factor (NF)-κB, A20 (a negative regulator of NF-κB), polymeric immunoglobulin receptor (pIgR), TNF-α and IL-8, had moderate to severe disease and poor responses to immunosuppressive and anti-TNF-α therapy, while patients characterized by low expression of RelA, A20, and pIgR, normal TNF-α and elevated IL-8, had acute inflammation that responded well to therapy.

Few reports are available on tissue factors as predictors of response to corticosteroids. Ishiguro[12] have found a higher protein level of IL-6 and TNF-α in biopsies from patients with intractable disease who were receiving corticosteroids compared to those with non-intractable disease receiving corticosteroids; these findings have not been confirmed in other studies[13].

Alternately, Raddatz *et al*[14] have found that, in patients with IBD, glucocorticosteroid receptor (GR) expression was not different from controls, although it was decreased in biopsies from UC patients who were non-responsive to glucocorticosteroids. In those patients, the inhibitory subtype GRb was expressed 100-1000 times less than GRa. On the contrary intercellular adhesion molecule-1 (ICAM-1) mRNA expression, although elevated in biopsies from UC patients with active disease, was no different in responders or patients with impaired response[14].

Another study has shown by univariate analysis that, in a total population of 561 UC patients evaluated with a median follow-up of 21.4 years since disease onset, mean histological inflammation and steroid use were predictors of colectomy[15].

Moving to tissue markers as predictors of disease

relapse, Yamamoto *et al*[16] have shown by multivariate analysis that higher rectal mucosal IL-8 level, younger age, and greater number of prior relapses were independent significant risk factors for future relapse in patients with quiescent UC. In the same study, IL-1, IL-6 and TNF-α levels in the rectal mucosa were not associated with relapse.

In light of these experiments, the aim of this paper is to review the role of tissue factors associated with disease severity, which may eventually be ranked as predictors of disease course and response to specific therapy. A schematic representation of the five proposed main categories of mucosal biomarkers, including mucosal cytokines and chemokines, adhesion molecules and markers of activation, immune and non-immune cells, and other mucosal components, is shown in Figure 1.

MUCOSAL CYTOKINES AND CHEMOKINES

Alterations in the production of many cytokines have been described in patients with active IBD[17]. Although the significance of these findings in the pathogenesis of IBD remains a controversial issue, as it is unclear whether they are primary or secondary defects in the regulation of the intestinal immune system, they can be considered as markers in the differentiation of groups of patients.

In active IBD, a disturbed balance between regulatory and effector cells has been described, which mainly involves effector T cells (Th1 and Th2) and regulatory T cells (Tregs, Th3). CD is associated with a Th1 T-cell cytokine profile, including IFN-γ, TNF-α and IL-12[18], whereas UC is associated with a modified Th2 type response cytokine profile including IL-15 and IL-10[18]. In addition, these findings have been recently complemented by the discovery of the IL-23/IL-17 axis that is part of the effector T cell immunological response, and seems to be involved in IBD. Levels of expression of IL-23 and IL-17 are increased in patients with active IBD[19].

TNF-α, IL-1, IL-6

IL-1 and TNF-α share a multitude of pro-inflammatory properties and are crucial in the amplification of mucosal inflammation in IBD. Both cytokines, primarily secreted by monocytes and macrophages, activate intestinal macrophages, neutrophils, fibroblasts, and smooth-muscle cells, inducing them to secrete prostaglandins, proteases, and other soluble mediators of inflammation and injury, as well as other chemotactic cytokines[20].

TNF-α is increased in the colorectal mucosa and stools of both forms of IBD[21,22], and correlates with a higher endoscopic inflammation score[23]. TNF-α is significantly increased in the non-inflamed mucosa of CD patients compared to controls[13,21], as well as in organ culture taken from macroscopically normal mucosa[24].

Other studies[13,22] have shown that several cytokines other than TNF-α are also upregulated in the intestinal mucosa of active IBD patients, including IL-1 and IL-6.

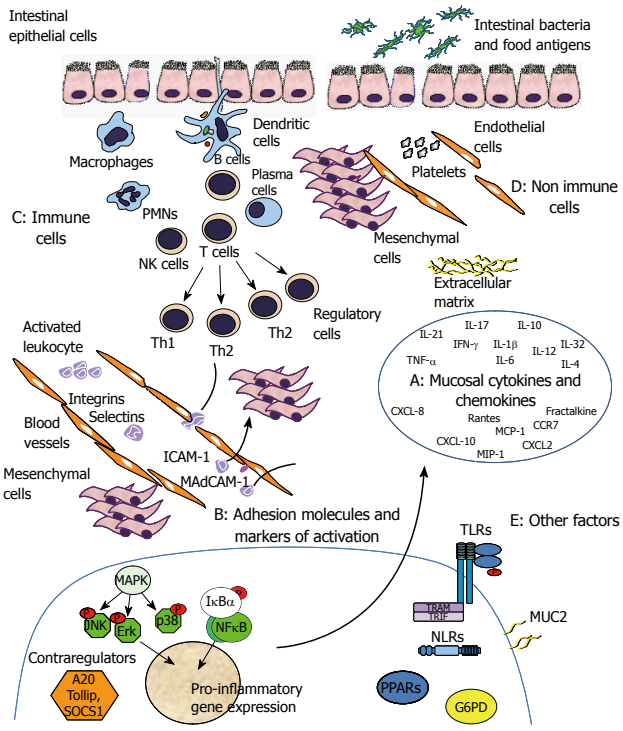

Figure 1 Mucosal biomarkers in inflammatory bowel disease (IBD). Based on available data from IBD pathogenesis, there are five major categories of mucosal biomarkers which can be assessed as predictors of disease severity and also response to therapy. A: Mucosal cytokines and chemochines [tumor necrosis factor (TNF)-α, interleukin (IL)-6, CXCL-2, *etc.*]; B: Adhesion molecules (MadCAM, ICAM-1, *etc.*) and intracellular markers of activation [mitogen-activated protein kinase (MAPK), nuclear factor (NF)-κB, A20, *etc.*]; C: Immune cells (dendritic cells, monocytes, macrophages, lymphocytes, NK, plasma cells, *etc.*); D: Non immune cells (endothelial cells, mesenchymal cells, platelets, *etc.*); E: Other factors [toll-like receptors (TLRs), NLRs, mucin (MUC), G6PD, *etc.*].

In addition TNF-α, IL-1β and IL-6 mRNA expression is increased compared to controls, with IL-6 being particularly high in the inflamed mucosa.

IL-4

IL-4 seems to play a crucial role in the Th2 response. One study has found that IL-4 is expressed in most biopsies from UC patients but not in CD[25], whereas others have not found any association between IL-4 levels and any form of IBD[13,26], probably due to technical issues[27].

IL-10

IL-10 is an anti-inflammatory cytokine produced by T cells, which inhibits the production of IL-1, IL-6 and TNF-α. Although a polymerase chain reaction (PCR)-based qualitative study on IL-10 in IBD has revealed that IL-10 is less frequently detected in UC compared to controls and CD[25], other studies have reported elevated mucosal IL-10 expression in UC and CD[28,29] or in UC alone[13,30,31].

IFN-γ

IFN-γ is elevated in all genetic animal models of IBD and is crucial in the development of Th1 responses.

Table 1 Studies assessing tissue markers as predictors of disease severity or drug response

Target	Techniques	Use	Ref.
Osteoprotegerin, STC1, PTGS2, IL13Rα2 and IL11	Microarray and PCR on mucosal extract	Predict response to IFX in UC	Arijs *et al*[7]
TNF-α levels and IL8, IL18	PCR and Immunohistochemistry on mucosal biopsies, ELISA on organ culture	Clinical/endoscopic remission in UC, response to corticosteroids, response to therapy in CD	Olsen *et al*[10] Ishiguro *et al*[12] Arsenescu *et al*[11] Schmidt *et al*[9]
RelA, A20, pIgR	PCR and Immunohistochemistry on mucosal biopsies	Severe disease and poor responses to immunosuppressive and anti-TNF-α therapy in 69 CD patients	Arsenescu *et al*[11]
GR expression	RT-PCR on mucosal biopsies	Decreased in biopsies from UC patients non responsive to glucocorticosteroids	Raddatz *et al*[14]
Mean histological inflammation and steroid use	Histology on colon biopsies	For univariate analysis, were predictors of colectomy in 561 patients UC	Hefti *et al*[15]
Mucosal IL-8 level	ELISA on mucosal biopsies culture	In multivariate analysis, independent risk factors for future relapse in patients with quiescent UC	Yamamoto *et al*[16]

GR: Glucocorticosteroid receptor; UC: Ulcerative colitis; CD: Crohn's disease; TNF: Tumor necrosis factor; IL: Interleukin; pIgR: Polymeric immunoglobulin receptor; ELISA: Enzyme-linked immunosorbent assay; RT-PCR: Reverse transcriptase polymerase chain reaction; IFX: Infliximab.

Mucosal IFN-γ expression is elevated in clinically active CD[32] but not in UC[33-35], which supports the theory that an imbalance in cytokine expression occurs in UC and CD; however, other studies have not reported such differences between UC and CD patients[36,37].

Other mucosal cytokines and chemokines

Other cytokines in the intestinal mucosa that are associated with active IBD include IL-21, IL-18, IL-8, monocyte chemotactic protein (MCP)-1, RANTES, epithelial neutrophil activating protein 78 (ENA-78), and IL-32[38].

Western blotting analysis of biopsies from patients with IBD and controls has demonstrated that IL-21 (a cytokine involved in the Th17 response) is overproduced in the inflamed intestine of patients with CD, in comparison to patients with UC and normal controls[39].

IL-18 is upregulated in intestinal mucosal cells of patients with IBD[40], and animal models have shown to benefit from anti-IL-18 antibody therapy with reduced severity in colitis[41].

In the proximal and distal regions of the colonic mucosa of UC patients, there was a greater than 10-fold increase in IL-8 levels compared to control subjects. A 3-5-fold increase in leukotriene B4 levels was observed along with a significant increase in myeloperoxidase levels throughout the colonic mucosa in patients with UC[42].

Other studies have reported elevated levels of MCP-1 and MCP-3, ENA-78, macrophage inflammatory proteins 1a and 1b, IFN inducible protein 10, stromal cell derived factor 1, and fractalkine[43-49].

Of particular interest is the demonstration that RANTES expression is not only increased in human IBD, but also plays a crucial role in the transition of acute to chronic disease in experimental models of colitis. In addition, RANTES triggers leukocyte adhesion to the inflamed intestinal microvasculature[50-52].

Furthermore, Kawashima *et al*[53] have observed a significant increase in CCR7 receptor only in CD and not in UC patients or healthy subjects. These observations are consistent with the reported increase in CC ligand expression in CD.

Studies assessing mucosal cytokine/chemokine panels

Several studies have attempted to explore the possibility of detecting tissue factors as predictors of disease severity by combining the analysis of different components simultaneously. However, none of these approaches has been validated and none are used for clinical purposes.

Real-time PCR quantification of CXCL8, CXCL10, calgranulin B and CXCL2 in colonic biopsies correlated with clinical activity index and endoscopic activity index in 27 UC patients, which suggests the use of these molecules as biomarkers and objective tools in clinical trials for the evaluation of anti-inflammatory and immunomodulatory regimens[54].

Another study with real-time PCR analysis (some confirmed by western blotting and enzyme-linked immunosorbent assay) of biopsy specimens from patients with UC and CD has shown increased expression levels of IFN-γ, TNF-α, IL-6, IL-15, IL-18, and IL-23 in affected and unaffected areas of IBD mucosa, compared to those found in healthy controls. Conversely, IL-1β, IL-6, IL-12, and IL-27 levels were higher in affected areas compared to unaffected ones in UC mucosa, but not in CD. A correlation between cytokine mRNA levels and inducible nitric oxide synthase and granzyme B has been observed[43].

ADHESION MOLECULES AND MARKERS OF ACTIVATION

Lymphocyte infiltration into the intestinal tract in IBD is mostly mediated by the interaction between α4β7 integrin expressed on lymphocytes and its specific ligand, mucosal vascular addressin CAM-1 (MAdCAM-1), which is expressed on the endothelial cells of the microvasculature in the inflamed intestinal tissue. Integrins form a large family of transmembrane proteins that are required for leukocyte-endothelium interaction, as well as cell-cell

interactions in the intestinal mucosa. These molecules together with the NF responsible for the signaling transduction pathway, such as NF-κB and mitogen-activated protein kinase (MAPK), are particularly abundant in the inflamed mucosa in UC and CD.

In one study[55], MAdCAM-1-expressing venules were more abundant in CD than in UC, whereas E-selectin was equally expressed in both diseases. Furthermore, CD was characterized by the presence of MAdCAM-1-expressing venules deep into the intestinal tissue, mainly localized in lymphoid aggregates.

Another group has reported[56] increased endothelial ICAM-1 expression in areas with dense lymphocyte infiltration, and areas close to crypt abscesses and ulcerations in the intestinal mucosa of active IBD patients. Ulcerations were covered by a continuous layer of macrophages and epithelial cells expressing ICAM-1.

We have reported previously[57] CD40 overexpression on mucosal endothelium in CD patients, which was reduced markedly after infliximab treatment, and reached a level similar to that seen in the normal mucosa of control subjects. In the same study, we reported vascular cell adhesion molecule-1 overexpression in the intestinal microvasculature of CD patients, which also disappeared after infliximab treatment.

Nikolaus *et al*[58] have shown that CD patients that relapse after induction of remission following infliximab administration, are characterized by increased TNF-α secretory capacity and mucosal nuclear NF-κB p65 before reactivation of clinical symptoms. Conversely, extended downregulation of nuclear concentrations of colonic mucosal NF-κB p65 is associated with sustained induction of remission.

Our group has reported increased phosphorylation of all three MAPKs (p38, extracellular signal-regulated kinase and Jun N-terminal kinase) in the microvasculature and mesenchymal cells of bowel preparations from patients with CD and UC, compared to controls and non-inflamed IBD mucosa[59]. In the same study, activation of these major signal transduction pathways was associated, *in vitro*, with increased production of inflammatory cytokines, as well as increased leukocyte adhesiveness to intestinal endothelial cells and fibroblasts.

IMMUNE CELLS

The uncontrolled inflammatory reaction in IBD is most likely the result of the interplay between genetic deficiencies in the innate immune system and an exaggerated T-cell-driven adaptive immune response[20].

IL-17-positive cells have been detected by immunohistochemical staining in the inflamed mucosa of CD and UC patients[60]. A recent study has confirmed the presence of Th17 cells in CD mucosa but the authors also found a previously unreported subset of mucosal T cells that share features with Th1 and Th17 cells (i.e. cells concomitantly producing IFN-γ and IL-17)[61].

Abnormalities in Tregs in human IBD have been described but are unclear because of the few inconclusive studies reported so far. It has been reported that, in the course of active UC and CD, the number of circulating Tregs is decreased compared to controls[62-64], but these differences do not persist during remission, which suggests that, in active IBD, Tregs migrate to the inflamed gut. In fact, paralleling the clinical activity of the disease, the number of Tregs during UC and CD has been reported to increase in the intestinal lamina propria and mesenteric lymph nodes[62,63,65-67]. One study from Japan has found that the relative proportion of CD4+CD25+ Tregs is significantly increased in patients with active IBD[68], whereas a German study has demonstrated that the frequency of CD4+CD25+ Tregs varies according to IBD activity[62]. In the latter study, Tregs were functional, but their number was reduced in the peripheral circulation and only moderately expanded in the inflamed mucosa.

Neutrophils and monocytic cells also play an important role in the pathogenesis of IBD and in the maintenance of active inflammation. Recently[69], infliximab has been reported to decrease histological disease activity in Crohn's ileocolitis, by lowering the number of neutrophils and mononuclear cells in intestinal mucosal biopsies. Furthermore, the number of lamina propria mononuclear cells is also reduced because of a global reduction in CD4(+) and CD8(+) T lymphocytes and CD68(+) monocytes.

Mucosal dendritic cells (DCs), the main antigen-presenting cells in the gut, display an activated phenotype in IBD tissues, which is indicative of their involvement in the local chronic inflammatory reaction. In particular, they have been shown to express elevated levels of CD40 in mucosal extracts from UC and CD patients. These levels decrease after patients are treated with anti-TNF-α[70]. Another group[71] has reported an imbalance in intestinal DC subpopulations in a group of pediatric CD patients that underwent surgical bowel resection, following different therapies. In particular, immature DCs (CD11c+CD83-CD68-DC-SIGN+) were only found in non-inflamed control colonic tissue, whereas mature (CD11c+CD83+CD68+DC-SIGN+) DCs were markedly reduced (60% and 30%) in CD tissue samples compared to controls. In addition, tissue samples from CD patients undergoing corticosteroid therapy display marked depletion of DCs compared to tissue from untreated patients or those treated with other drugs. Colonic tissue with severe inflammation shows reduced numbers of CD11c+ and CD83+ DCs in the lamina propria and submucosal compartments, with a concomitant increase in DCs in the muscularis, compared to moderately inflamed and non-inflamed CD tissue[71].

Active CD is also associated with an increased number of macrophages in the ileal and colonic mucosa. A recent study[72] has shown increased numbers of macrophages expressing the scavenger receptor CD163 in colonic mucosa of CD patients concomitantly affected by spondyloarthritis. Macrophages or DCs that express RANK (receptor activator of NF-κB ligand), CD68 and S100

protein are increased in the colon of CD patients, particularly in inflamed areas compared to normal colon[73].

NON-IMMUNE CELLS

Other important cell types that participate in the chronic inflammatory response of IBD, include epithelial, mesenchymal and endothelial cells, and platelets, which exert many of the functions traditionally attributed to classical immune cells, such as cytokine production or expression of major histocompatibility complex class Ⅱ antigens[18].

Immunohistochemical studies have shown that intestinal epithelial cells (IECs) inappropriately express the class Ⅱ antigen HLA-DR in actively inflamed mucosa of UC and CD patients[74]. More recently, IBD IECs have been reported to inappropriately express members of the B7 family of costimulatory molecules[56], a finding that suggests alterations in B7-ICOS costimulatory pathways in IBD.

Other studies have shown that, in IECs, expression of toll-like receptor (TLR)3 is significantly downregulated in active CD but not in UC, whereas TLR4 is strongly upregulated in both CD and UC[75]. In the mucosa of patients with postcolectomy active pouchitis, expression of TLR2 and TLR4 is also strongly upregulated[76]. In addition, patients with CD show a reduced content of defensins in the affected ileum, and this reduction is independent from the degree of mucosal inflammation[77].

The involvement of fibroblasts in IBD traditionally has been viewed as being restricted to the production of extracellular matrix components and the pathogenesis of a common and serious complication, such as intestinal fibrosis[78]. However, fibroblasts are also involved in gut injury because they represent a major source of matrix metalloproteinases (MMPs), a family of proteolytic enzymes that are directly responsible for the tissue destruction that occurs during inflammation.

In the course of IBD, upregulation of MMPs occurs in the intestinal tissue, and this increase is lowered significantly by the anti-TNF-α antibody infliximab. These observations have been confirmed by the work of Meijer *et al*[79]. They have reported increased expression of MMP and tissue inhibitor of metalloproteinase (TIMP) in the intestinal mucosa from patients with IBD, compared with control samples. Furthermore, infliximab downregulated expression of MMP-1, -3 and -9 but not TIMP-1 and -2, depending on genotype.

Wang *et al*[80] have confirmed these findings. They have shown that mRNA and protein expression of MMP-1 and TNF-α in the ulcerated and inflamed colon mucosa of patients with UC is significantly higher than that in non-inflamed mucosa of normal controls. Furthermore, the expression of MMP-1 and TNF-α in the ulcerated area is significantly higher than that in the inflamed area of patients with UC.

Endothelial cells play an essential role in inflammation as a result of their central gatekeeper function, which controls the quality and quantity of leukocytes that transmigrate from the vasculature into the interstitial space. This process is complex and is mediated by a number of molecules, including cytokines, chemokines and adhesion molecules.

Bardin *et al*[81] have shown that, in active disease, high expression of CD146 is observed on endothelial cells in intestinal biopsies from patients with CD and UC. In addition, there is a decrease in the soluble form of CD146 in relation to active disease and extent of CD and UC. Lower levels of soluble CD31 have also been detected in UC, but not in CD. This suggests CD146 as a novel marker of the endothelial intercellular junction, which reflects endothelial remodeling more effectively than soluble CD31 does.

Angiogenesis has been suggested to play an integral part in IBD pathology[82]. Vascular endothelial growth factor (VEGF) has long been considered to play a central specific role in angiogenesis. Our group has reported[82] increased microvessel density in IBD mucosa, with an increase in αVβ3 expression on new mucosal vessels. These observations are associated with increased mucosal levels of VEGF, which in turn are able to induce increased angiogenesis in corneal and chorioallantoic membrane assays. Other groups[83] have confirmed our findings, and have shown increased VEGF expression in CD and UC compared to controls. Furthermore, immunohistochemical staining for CD146 is also higher in both forms of IBD, as well as CD34 expression, which indicates a possible role of angiogenesis in the pathogenesis of IBD.

Endothelial junction adhesion molecules, such as CD146, recently have been suggested to play a role in angiogenesis. CD34 is expressed on the vascular endothelium, and is upregulated in IBD.

In active CD and UC, a loss in the expression of endothelial EPCR (the receptor for protein C) and thrombomodulin has been reported, therefore impairing the activated protein C pathway in the intestinal microvasculature[84].

OTHER MUCOSAL COMPONENTS

A positive correlation has been found between mucosal levels of total lactate dehydrogenase (LDH) isoenzyme M monomers and LDH 5 monomers for each of the histological subgroups of UC, while glucose-6-phosphate dehydrogenase activity seems to be independent of inflammatory changes[85].

Peroxisome proliferator-activated receptors (PPARs) are members of the nuclear hormone receptor superfamily of transcription factors whose activities are regulated by high affinity binding of small lipophilic ligands such as steroid hormones. PAR2 methylation status in rectal mucosa has been shown to correlate with more severe disease phenotypes of UC[86].

Mucin 2 (MUC2) precursor biosynthesis and total MUC2 levels are significantly decreased in UC patients with active inflammation, compared to controls. In contrast, both these parameters returned to control values

during remission from inflammation, which demonstrates that colonic biosynthesis and total amounts of MUC2 vary according to disease activity. However, *MUC2* mRNA levels are similar in all patients and are independent of disease activity, which indicates that these variations in MUC2 synthesis are regulated post-transcriptionally[87].

Immunohistochemical analysis[88] of cryostat sections, using polyclonal and monoclonal antibodies specific for TLR2, TLR4 and CD14, have shown a significant increase in TLR2 expression in the terminal ileum of patients with inactive and active UC compared with controls. Significant upregulation of TLR4 expression relative to controls has been found in the terminal ileum and rectum of UC patients in remission and in the terminal ileum of CD patients with active disease. CD14 expression is upregulated in the terminal ileum of patients with active and inactive CD. It is also upregulated in the cecum of UC patients in remission and with active disease, and in the rectum of patients with active UC.

CONCLUSION

The identification of tissue markers, together with other predictors, is crucial for clinical assessment and management of IBD. Although several attempts have been made, it is clear that more efforts should be made in creating a wider analysis, which involves more IBD centers and patients. To achieve this, a prospective observational study to identify precursors for each subgroup of patients is necessary. More consistent data from immunohistochemistry or western blotting of cytokines on mucosal extracts are needed. Interesting data also can be derived from tissue indicators of activation, such as NF-κB, MAPK or markers of other pathways, which are also involved in IBD pathogenesis. Finally identifying whether an immune or non-immune cell type is involved in mucosal inflammation through specific markers of activation/function, also represents another important aspect to be addressed by further research.

In conclusion, we must admit that, to date, despite great potential, no tissue factor can be considered as a predictor of disease progression or response to therapy in everyday clinical practice devoted to the management of patients with IBD.

Abstract

Endoscopy provides a direct evaluation of mucosal lesions in inflammatory bowel disease (IBD), permitting the description of elementary lesions, their surface extent and severity. The severity of mucosal lesions directly reflects disease activity and may help to identify an aggressive behavior of the disease. Several studies have recently pointed out the potential role of endoscopy in the prediction of IBD outcome. Indeed, severe endoscopic lesions in Crohn's disease (CD) patients, defined by deep and extensive ulcerations on at least one part of the colon, are associated with an increased risk of penetrating complication and surgery. Severe endoscopic lesions during severe attacks of ulcerative colitis (UC) are associated with an increased risk of colectomy in the short and long term. Severity of postoperative recurrence in CD may help to predict the risk of clinical relapse and need for further surgery. Achievement of mucosal healing, which can be obtained by administration of several types of drugs, is associated with a better outcome, less surgery and hospitalization. This review focuses on the assessment of endoscopic severity in CD and UC and on the impact of endoscopic severity on disease outcome. More specifically, we discuss how endoscopy can be used at different stages of IBD to predict the disease course and/or to adapt treatment strategies.

INTRODUCTION

The management of inflammatory bowel diseases (IBD) has dramatically changed over the last decade. Progress has been supported by the increasing size of the therapeutic arsenal, the introduction of biologics providing more alternative options in patients with severe diseases, and new concepts as to how and when treatments should be used. Immunosuppressants and biologics are classically used following a step-up approach in patients with refractory disease, who are unresponsive to conventional therapies or are steroid-dependent. Beyond their high efficacy in induction and maintenance of remission, it has been demonstrated that anti-tumor necrosis factor (TNF) therapies can close fistulae and heal mucosal lesions, and reduce rates of hospitalization and surgery[1]. Several recent studies suggest that early intervention with combination therapy may modify the long-term course of Crohn's disease (CD)[2-4]. However, these strategies should

not be used in all patients, but only in selected patients with severe diseases and/or with features predicting a poor prognosis[1]. Good predictors of IBD outcome are still lacking in our daily practice. Studies performed with regard to prediction have mainly focused on clinical and biological parameters. Endoscopy has been rarely investigated as a predictor of the clinical course of IBD. However, there is now growing evidence that morphological examination, including endoscopy, may help to identify among IBD patients those who should be treated with more intensive treatments. Furthermore, as demonstrated in a recent study assessing early intervention with combination of infliximab and azathioprine in CD, endoscopy may help to select patients who will obtain the best results with early intervention[2].

Endoscopy allows the examination of mucosal lesions in IBD[5,6]. The severity of mucosal lesions directly reflects the activity of the disease and may thus be considered as an indication of an aggressive behavior of the disease. In this article, we review aspects of assessment of endoscopic severity in CD and ulcerative colitis (UC) and discuss their role in predicting the course of these diseases and their impact on decisions regarding medical strategies.

ASSESSMENT OF ENDOSCOPIC SEVERITY IN CD

Endoscopic scores of severity in CD

A number of mucosal characteristics may be observed at endoscopy in CD, such as erythema, swelling, nodularity, strictures, aphtoid ulcerations and ulcers of variable size and depth. The severity of ileocolonic lesions can be quantified by validated endoscopic indices of disease activity. The CD endoscopic index of severity (CDEIS) is based on the recognition of elementary lesions (non-ulcerated lesions, superficial and deep ulcerations), associated with the appreciation of their surface in five segments (ileum, right colon, transverse, left colon and sigmoid, and rectum)[7,8]. A simplified index, the simple endoscopic score for CD (SES-CD), has been proposed and correlates well with the CDEIS[9]. The CDEIS is considered as the gold standard for quantifying endoscopic severity, but is often regarded as not easy to use. It requires a specific training for the estimation of ulcerated or diseased mucosal surfaces.

These scores can be used to assess endoscopic severity during active phases of the disease, and they may also be used to assess changes induced by medical treatments. Several studies on mucosal healing have been performed in CD. However, there is no validated definition of mucosal healing in CD[10]. The ideal definition is absence of ulcerated lesions. However, this definition may be excessively strict. For example, a patient who had deep and extensive ulcerations at index colonoscopy and who healed almost all lesions but still had one aphtous ulcer would not be considered as achieving complete mucosal healing. For this reason, we think that mucosal healing should be evaluated through validated scores on endoscopic severity.

Severe endoscopic lesions in CD

It is widely accepted that severity of colonic lesions in CD relies on the extent in depth and in surface of the mucosal damage. Recognition of these lesions by an endoscopist may be seen as subjective. However, it appears that diagnosis of severe endoscopic lesions may not be difficult. A previous interobserver variation study targeted on evaluation of ileocolonoscopic lesions in CD[11] has shown that deep ulcerations and estimation of ulcerated surface were among the most reproducible endoscopic items. Such lesions were also selected by multivariate analysis for the construction of the CDEIS[7].

Nahon *et al*[12] demonstrated that colonoscopy accurately predicts the anatomical severity of colonic CD attacks. In this retrospective study of 78 patients operated for colonic CD resistant to medical treatment, criteria of severity in colectomy specimens were defined as either deep ulcerations eroding the muscle layer, or mucosal detachments, or ulcerations limited to the submucosa but extending to more than one third of one defined colonic segment (right, transverse, left colon). Three endoscopic criteria of severity were defined: (1) deep ulcerations eroding the muscle layer; (2) deep ulcerations not eroding the muscle layer but involving more than one third of the mucosal area; and (3) mucosal detachment at the edge of ulcerations. Evaluation of endoscopic severity correlated well with findings on colectomy specimens. At least one of these criteria was found in 95% of patients with severe anatomic lesions on colectomy specimens. The extent of ulcerations at colonoscopy was correlated to the results of colectomy specimen examination ($P < 0.001$). Of note, usual clinical and biological severity criteria were not different in patients with severe colonic lesions or without. This study further demonstrates that colonoscopy can accurately assess anatomical severity of colonic CD.

THE ROLE OF ENDOSCOPY IN PREDICTING THE COURSE IN CD

Severe endoscopic lesions predict a more aggressive outcome with increased rates of complications and surgery in CD

Early studies by the Groupe d'Etudes Thérapeutiques des Affections Inflammatoires du Tube Digestif (GETAID) have shown that endoscopic pattern severity (assessed by the CDEIS) correlated poorly with clinical (assessed by the CDAI) and biological activity (assessed by C-reactive protein measurement)[8]. Furthermore, clinical improvement is not always associated with healing of mucosal lesions in CD. Indeed, clinical remission obtained with steroids is associated with mucosal healing in only one third of CD patients[11]. Moreover, the degree of endoscopic improvement in patients with prednisolone-induced clinical remission did not predict

the subsequent clinical course in terms of steroid weaning, or occurrence of relapse[13].

However, endoscopic severity may still have an impact on the long term course of the disease. We have shown in a retrospective study that patients with CD exhibiting deep and extensive ulcerations at colonoscopy have a more aggressive clinical course with an increased rate of penetrating complications and surgery[14]. Among the 102 patients included, 53 had severe endoscopic lesions at index colonoscopy, defined as extensive and deep ulcerations covering more than 10% of the mucosal area of at least one segment of the colon. During the follow-up (median 52 mo), 37 patients underwent colonic resection. Patients with severe endoscopic lesions needed significantly more colonic resections than patients without severe lesions (relative risk 5.43, 95% CI: 2.64-11.18)[14]. Six patients had penetrating complications during the follow-up. All had severe endoscopic lesions at index colonoscopy, performed in most of them several years before. These data suggest that a subset of CD patients have a more aggressive disease, characterized by severe endoscopic lesions in the ileocolon during symptomatic phases, and a higher risk of surgery and penetrating complications[14].

Mucosal healing and long term outcome in CD

In clinical trials, the efficacy of therapies in CD is usually assessed by improvement in clinical activity (defined by a decrease of the CDAI). Assessment of endoscopic improvement was not usually performed until recently in clinical trials assessing the efficacy of drugs in CD. The main reason for this was that steroid-induced clinical remission is not associated with mucosal healing in two-thirds of CD patients. Furthermore, endoscopic remission obtained with steroids does not correlate with the risk of relapse after steroid withdrawal. However, there is growing evidence that mucosal healing during therapy is a sign of a good efficacy of a drug[10,15]. Data from the IBSEN cohort strongly suggests that mucosal healing predicts a generally favorable outcome of disease based on all types of treatment strategies (except corticosteroids) and is related to treatment efficacy, reduced frequency of surgery and hospitalizations[16].

Moreover, it is now clearly demonstrated that mucosal healing can be achieved with azathioprine and anti-TNF[17-21]. Rates of mucosal healing under azathioprine vary among studies, probably due to differences in the timing of endoscopy and the population analyzed. In a randomized controlled trial performed in steroid-dependent CD patients, Mantzaris *et al*[22] have recently shown that azathioprine was superior to budesonide in inducing mucosal healing at 1 year; complete or near complete healing was achieved in 83% of azathioprine-treated patients compared with only 24% of budesonide-treated patients ($P < 0.0001$). In a GETAID study, long lasting remission ($\geq$ 42 mo) maintained with azathioprine was associated with a complete mucosal healing (CDEIS = 0) in only 36% of CD patients[23]. In the SONIC study, which concerned CD patients naïve to immunosuppressants and biologics, only 15.6% of patients treated with azathioprine achieved mucosal healing at week 26[2].

In the endoscopic substudy of the ACCENT I study, patients treated with scheduled maintenance therapy with infliximab had superior rates of mucosal healing, and those who maintained complete mucosal healing over 1 year had a lower rate (but the difference was not significant) of hospitalizations and surgeries[24,25]. A study of mucosal healing in a cohort of CD patients under long-term treatment with infliximab was recently reported[26]. In this study from the Leuven group, 214 patients had a colonoscopy before and a second one within months after starting infliximab. Mucosal healing (complete or partial) was observed in 68% of the 183 initial responders. Mucosal healing was associated with a significantly lower need for major abdominal surgery during long-term follow-up (14.1% major surgeries in patients with mucosal healing *vs* 38.4% in patients without mucosal healing, $P < 0.0001$). Interestingly, partial mucosal healing had the same favorable impact as complete mucosal healing.

Several studies suggest that immunosuppressants and anti-TNF therapy may be more effective when given early in the course of the disease. Two studies have been recently performed in CD patients naïve to immunosuppressants and biologics, including "top-down strategy" which refers to early introduction of immunosuppressive or biologic therapies. In the SONIC study, infliximab therapy was superior to azathioprine in inducing mucosal healing at week 26 (30.1% *vs* 15.6%), but inferior to infliximab plus azathioprine combination therapy[2]. D'Haens *et al*[3] compared a top-down strategy to a more classical step-up strategy. Top-down strategy, which consisted of early induction with infliximab and maintenance with azathioprine, resulted in mucosal healing in 19/26 of patients (73%) at week 104. In the other arm (step-up strategy), mucosal healing was significantly less frequent (7/23 patients, 30%). This difference may have an impact in the long term. Indeed, when mucosal healing was achieved at 2 years (SES-CD score at 0), 70% of the patients (17/24) were in stable clinical remission during the following 2 years as compared to only 6 of the 22 (27%) who had mucosal lesions (SES-CD score above 0)[4]. Fifteen of the 17 patients with mucosal healing at year 2 maintained in remission without further infliximab infusions during the following 2 years. Mucosal healing obtained with immunosuppressants or anti-TNF agents was also associated with a decreased risk of surgery in the long term. Altogether these data would suggest checking endoscopic response in patients treated with immunosuppressants or anti-TNF. However, this attitude would make sense only if we are ready to optimize or switch to another treatment those patients who have no mucosal healing. Another question which is raised by recent studies is whether partial mucosal healing is sufficient to modify the disease outcome with decreased risk of hospitalizations, surgery and complications.

A further question is whether mucosal healing under a therapy is associated with a decreased risk of relapse after

discontinuation of this therapy. In a placebo-controlled study of the GETAID, presence of ulcerations at ileocolonoscopy before withdrawal of azathioprine was not predictive of the risk of relapse[23]. A recent study from the GETAID assessed the risk of relapse after infliximab discontinuation in patients in remission on combined maintenance therapy, who continued the immunosuppressant (azathioprine or methotrexate). Mucosal healing was among the factors strongly associated with a decreased risk of relapse[27].

Endoscopy in predicting relapses of CD after surgery

CD patients who have "curative" ileal resection and ileocolonic anastomosis are exposed to a high risk of postoperative recurrence[28]. Rutgeerts *et al*[29] demonstrated in 1990 that ileocolonoscopy performed within 1 year of surgery may predict the risk of clinical recurrence. Eighty-nine patients treated by ileal resection for CD were included in this prospective cohort follow-up to study the natural course of early postoperative lesions. Within 1 year of surgery, ileocolonoscopy detected recurrent lesions in the neo-terminal ileum in 73% of the patients, although only 20% had a clinical relapse. The rate of clinical relapse was 34% at 3 years. A score was devised to assess the severity of recurrent endoscopic lesions. The course of the disease was best predicted by the severity of the early postoperative lesions, as observed at ileocolonoscopy, on the anastomosis and/or on the neo-terminal ileum. Indeed, patients with less severe endoscopic lesions according to Rutgeerts' score (less than 5 aphtoid ulcers at anastomosis site), have a lower risk of clinical recurrence risk at 9% compared with 100% risk at 4 years for patients with more severe endoscopic recurrence (Rutgeerts' score i2 or greater). This score is widely used in clinical practice, and ECCO guidelines state that ileocolonoscopy should be the gold standard in the diagnosis of postoperative recurrence by defining the presence and severity of morphologic recurrence and predicting the clinical course. Ileocolonoscopy is recommended within the first year after surgery where decisions of postoperative treatment may be affected[30].

ASSESSMENT OF ENDOSCOPIC SEVERITY IN UC

Endoscopic scores of severity in UC

Nine different scores have been proposed to measure endoscopic severity in UC. Some of these scores focus on the severity of bleeding, but most of them rely on the recognition of elementary lesions such as abnormal vascular pattern, granularity, friability, bleeding and ulcers[10].

Endoscopic severity in severe attacks of UC

Carbonnel *et al*[31] demonstrated that total colonoscopy is feasible in 86% of cases in severe UC (73/85). In this study, endoscopy accurately identified severe endoscopic lesions (extensive deep ulcerations). Eighty-five consecutive patients with attacks of UC were reviewed. Extensive deep colonic ulcerations were diagnosed in 46 of them. No complication related to colonoscopy occurred except for one colonic dilatation. Forty-three of the 46 patients with severe endoscopic colitis underwent surgery. Extensive ulcerations reaching at least the circular muscle layer were found on pathological examination and were confirmed in 42/43[31]. Because of potential risks of complications, some rules have to be applied when performing colonoscopy in patients presenting severe attacks of UC, including pre-radiological examination to exclude megacolon, minimal insufflations, and when severe lesions are detected, the examination can be stopped as further examination has no additional prognostic value.

THE ROLE OF ENDOSCOPY IN PREDICTING THE COURSE OF UC

Patients with severe endoscopic lesions during severe attacks of UC have an increased risk of colectomy

Among patients hospitalized for a severe attack of UC, the presence of extensive and deep ulcerations at colonoscopy is associated with an increased risk of colectomy on that admission[31]. In their study performed in the prebiologic era, Carbonnel *et al*[31] showed that colectomy was performed in 43 of the 46 patients who presented severe endoscopic lesions (93%) as compared to 10/39 (26%) of those without such lesions (OR 41). In another study performed in severe UC patients, severe endoscopic lesions at colonoscopy were significantly more frequent in non-responders to medical treatment (91%) compared with responders (34%) (OR > 20)[32].

The colonoscopies performed during severe attacks of UC have also an impact on the long term outcome, with an increased rate of surgery in the long term in patients who exhibit extensive and deep ulcerations at index colonoscopy[33].

Mucosal healing and outcome in UC

Mucosal healing is classically assessed in patients treated for UC. However, there is no consensus on the definition of mucosal healing in UC[10]. The International Organization of IBD proposed the following definition: absence of friability, blood, erosions and ulcers in all visualized segments of the gut mucosa. According to this definition, disappearance of the normal vascular pattern is compatible with mucosal healing.

Mucosal healing may be obtained with several types of drugs[10,34]. It has been shown that it can be obtained with 5-aminosalicylates (5-ASA), steroids, azathioprine or methotrexate, and infliximab. Mucosal healing has been assessed in recent trials with different formulations of 5-ASA. In the ASCEND studies, evaluating different dosages of a delayed-released oral mesalazine in patients with mild or moderate UC, complete remission (including endoscopic remission) ranged between 18% and 25% at

week 6[35,36]. Truelove *et al*[37] demonstrated in 1954 that mucosal healing can be obtained with a high-dose of oral steroids in 30% of patients at week 6 compared with 10% in patients who received placebo ($P = 0.02$). In a recent review, it was considered that corticosteroids induce mucosal healing in 12%-41% of patients with UC, depending on the method of administration and the medication[10]. Some data suggest that mucosal healing may also be obtained with azathioprine or methotrexate[38,39]. Anti-TNF agents probably induce mucosal healing more rapidly. In ACT 1 and ACT 2, patients with refractory moderate-to-severe UC received placebo or infliximab intravenously[40]. Induction therapy with infliximab resulted in mucosal healing at week 8 in 61% of patients (148/242) compared with 32% (79/244) in the placebo groups ($P < 0.001$)[40]. At week 54 (ACT 1), scheduled maintenance therapy with infliximab resulted in mucosal healing in 45.5% (55/121) of patients compared with 18.2% (22/121) in the placebo group ($P < 0.001$).

Data from several studies suggest that mucosal healing may be associated with a better outcome in UC, more specifically a decreased risk of relapse. Reduced relapse rates have been demonstrated in UC patients who achieved mucosal healing with steroids. In a study published in 1966, Wright *et al*[41] found that 40% of patients who achieved mucosal healing with oral and rectal steroids did not relapse during 1 year of follow up as compared to 18% of those who still had lesions. In the ACT1 and 2 studies on infliximab maintenance in patients with moderately to severely active UC, 48.3% of the patients who achieved mucosal healing at week 8 were in remission at week 30 as compared to only 9.5% of those who did not achieve mucosal healing[39].

Mucosal healing may also be associated with reduced risk of surgery in UC. In the IBSEN population-based study, UC patients who achieved mucosal healing at 1 year (whatever the treatment) had a decreased risk of colectomy at 5 years (2% *vs* 7%, $P = 0.02$)[16]. A study performed in the Leuven cohort of UC patients treated with infliximab showed that colectomy was more frequent in patients who did not achieve mucosal healing at week 4 or 10 (Mayo endoscopic subscore greater than 1)[42]. In ACT1 and 2, it was shown that patients treated with infliximab were less likely to undergo colectomy through 54 wk than those receiving placebo[43]. However, data on the relationship between mucosal healing and risk of colectomy are not available in these studies.

Finally, there is a clear relationship between the grade and chronicity of inflammation in the colon and the risk of colorectal cancer. Better control of inflammation, as demonstrated with mucosal healing, may be associated with decreased risk of colorectal cancer.

PERSPECTIVES

There is growing evidence that morphological evaluation of lesions may provide help in the selection of IBD patients who should be treated more intensively. Endoscopy may help to select patients who will better respond to a therapy and those who should be treated because of exposure to an increased risk of complication and surgery. Assessment of mucosal healing should be increasingly performed in the future. However, it is not yet proven that patients not achieving mucosal healing should be treated more intensively. As endoscopy may be difficult to repeat in these patients, surrogate markers such as calprotectin or C-reactive protein levels, provided they are closely related to the presence of severe lesions, could be increasingly used.

Another limit of endoscopy relies on the fact that only mucosal aspects can be assessed by endoscopy. Radiological techniques, including ultrasonography, CT scan or MRI, can also describe the wall and identify penetrating and stricturing complications. Recent studies with MRI suggest that this technique could be proposed to assess severity of mucosal and parietal disease[44].

CONCLUSION

Endoscopy, which allows a direct assessment of severity and extent of mucosal lesions, may help in the management of IBD. In patients with active IBD, endoscopy may help to select patients who should receive early and active therapies and this is for two reasons. First, severe endoscopic lesions may predict a poor outcome with increased risk of colectomy and complications. Second, patients with no lesions gain no benefit in receiving active treatments with potential risks. In treated IBD patients, mucosal healing is associated with a better outcome, with decreased risks of relapse and major surgery. Assessment of mucosal healing may help to characterize the response to treatments and in decisions of optimal strategies.

Abstract

Heme oxygenase-1 (HO-1) system catabolizes heme into three products: carbon monoxide, biliverdin/bilirubin and free iron. It is involved in many physiological and pathophysiological processes. A great deal of data has demonstrated the roles of HO-1 in the formation, growth and metastasis of tumors. The interest in this system by investigators involved in gastrointestinal tumors is fairly recent, and few papers on HO-1 have touched upon this subject. This review focuses on the current understanding of the physiological significance of HO-1 induction and its possible roles in the gastrointestinal tumors studied to date. The implications for possible therapeutic manipulation of HO-1 in gastrointestinal tumors are also discussed.

INTRODUCTION

Heme oxygenase (HO) plays an important role in regulating the intracellular heme level by cleaving heme into carbon monoxide (CO), biliverdin and free iron[1]. Three HO isoforms have been identified to date: HO-1, HO-2, and HO-3, among which the isoforms 1 and 2 are the best known. HO-2 is constitutively and most highly expressed in neuronal tissues contributing to cell homeostasis, whereas HO-1, also referred to as heat shock protein-32 (Hsp32), is an inducible enzyme and relatively lowly expressed in most tissues[2]. HO-3, which is described in the rat brain, has no activity and is not expressed in humans[3].

HO-1 and HO-2 are different gene products. Unlike the constitutively expressed HO-2, HO-1 is exquisitely sensitive, not only to heavy metals[4], but to all kinds of stimuli and agents that cause oxidative stress and pathological conditions, including ischemia[5], hemorrhagic shock[6], heat shock[7], hypoxia[8], UVA radiation[9], reactive oxygen species (ROS)[10]. In fact, there is no other enzyme to date that is affected by so many stimuli of diverse nature as HO-1[2].

HO-1 is involved in many pathophysiological processes, ranging from Alzheimer's disease to cancer. The interest in this system by investigators involved in gas-

trointestinal tumors is fairly recent, and few reports on HO-1 have focused on this subject.

HO-DERIVANTS AND THEIR EFFECTS

All products of HO activity are now suspected to be biologically active, in which metabolic pathway is involved in a wide variety of physiological and pathophysiological processes[11]. Almost all CO produced *in vivo* comes from the degradation of heme by HO. Depending on the cell type, CO can activate one or both key signaling pathways in numerous physiological and pathophysiological conditions (Figure 1). One of the pathways is soluble guanylate cyclase (sGC)/cyclic guanosine monophosphate (cGMP), which has been implicated in mediating the effects of CO on vascular contractility, the inhibition of smooth muscle proliferation, neurotransmission[12,13] and preventing apoptosis in endothelial cells[14] and fibroblasts[15]. Another one is p38 mitogen-activated protein kinase (MAPK) pathway, through which CO can mediate the anti-inflammatory actions in a large measure[16-18]. Moreover, Chin *et al*[19] recently pointed out that CO has played an additional novel role as a host defense molecule agent against microbes (bactericidal agent).

HO-1 catalyzes the rate-limiting step in heme degradation to biliverdin. Biliverdin is, in turn, converted into bilirubin by biliverdin reductase at the expense of NADPH. Biliverdin and bilirubin are potent antioxidants[20,21]. Several studies have demonstrated that the administration of biliverdin and/or bilirubin is potently cytoprotective in a variety of pathophysiological events, including ischemia-reperfusion injury, transplant rejection and inflammatory bowel disease[22-25]. In addition, bilirubin is also known to modulate immune effector functions and suppress inflammatory response[26].

Fe^{2+}, which is also a product of heme degradation, upregulates an iron-transporter pump that removes intracellular Fe^{2+} from the cell[27] and induces the expression of ferritin, a iron binding protein[28]. Expression of ferritin is originally reported to protect endothelial cell against oxidant damage *in vitro*[28]. In addition, over-expression of H-ferritin (heavy chain ferritin) has also been shown to protect cultured endothelial cells from undergoing apoptosis and protect livers from transplant-associated ischemia-reperfusion injury[29]. Although the roles of the iron and ferritin in the overall cytoprotective effect of HO-1 are not clear, presumably both contribute in a crucial manner to the overall anti-oxidant effect following increased HO-1 expression in a variety of situations[30].

EXPRESSION OF HO-1 IN GASTROINTESTINAL TUMORS

Expression of HO-1 is usually increased in tumors, compared with surrounding healthy tissues, which was shown in oral squamous cell carcinoma[31], pancreatic cancer[32] and hepatoma[33]. There have been few published reports in gastrointestinal tumors and only one paper to date has investigated HO-1 expression in gastrointestinal tumors.

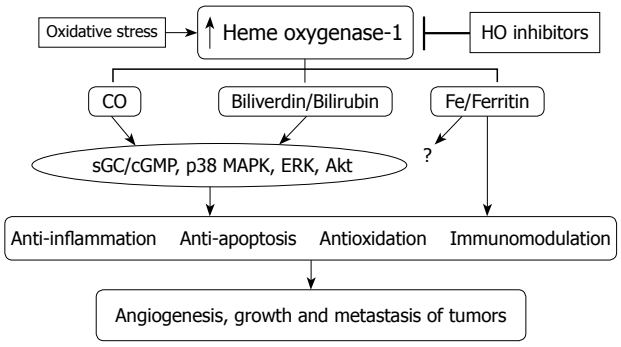

Figure 1 Schematic demonstration of mechanism underlying the biological actions of HO-1 pathway in tumors. HO-1: Heme oxygenase-1; CO: Carbon monoxide; sGC/cGMP: Soluble guanylate cyclase/cyclic guanosine monophosphate; MAPK: Mitogen-activated protein kinase.

The study investigates the expression of HO-1 in human colon tumor. Focal HO-1 expression in colorectal cancer and colonic adenoma was found to be 41.8% (23/55) and 36.8% (7/19), respectively[34]. Of importance, HO-1 in gastrointestinal tumors can be further upregulated in response to chemotherapy[35] and photodynamic therapy[36].

HO-1 PROMOTER POLYMORPHISM

HO-1 is known as an oxidative stress responsive protein that is upregulated by multiple stimuli, which has been proposed to provide an important cellular response that protects cells against oxidative damage. However, humans differ quantitatively in their ability to mount an HO-1 response. The association between the HO-1 genotype and various gastrointestinal tumors has been studied. Lo *et al*[37] examined the correlation between the HO-1 gene promoter polymorphism and the clinicopathological characteristics, along with the risk of gastric cancer. Their findings suggest that the long (GT)n repeat of HO-1 gene promoter was associated with a higher frequency of gastric adenocarcinoma, and the medium (GT)n repeat might possess a protective effect against gastric adenocarcinoma with a lower frequency of lymphovascular invasion in tumors. Additionally, the (GT)n-repeat promoter polymorphism was investigated in gastrointestinal stromal tumors (GIST) by Vashist *et al*[38]. They found that Short GTn allele (SGTn) was significantly associated with metastasis, higher tumor recurrence rates and high-risk GIST. Furthermore, SGTn allele carriers had significantly shorter disease-free and overall survival[38]. Moreover, a higher promoter activity genotype of the HO-1 gene was associated with increased risk in women with gastric cancer[39]. In gastrointestinal tumors, a potential impact of the (GT)n repeat polymorphism has been demonstrated, which might be considered as a potential prognostic marker to allocate patients to different risk groups and customize therapy and follow-up.

HO-1 AND CYTOPROTECTION AND APOPTOSIS

The gastrointestinal tract is lined by a simple epithelium

that undergoes constant renewal involving cell division, differentiation and cell death, in which HO-1 plays a major role in the regulation of the cell cycle/apoptosis, oxidative stress, inflammation, development of colon cancer[40]. Many studies have convincingly shown that HO-1 is a cytoprotective and antiapoptotic enzyme in gastrointestinal tumor cells exposed to diverse stimuli (Figure 1). It has been demonstrated that HO-1 is involved in the pathogenesis of human gastric cancer. Antiapoptotic effects of HO-1 in gastric cancer cells are independent of p53 status in a p38 MAPK- and ERK-mediated pathway with elevated caspase inhibitory protein-2 (c-IAP2) and decreased caspase-3 activity[41], in which nuclear factor-κB is implicated. The pathway of HO-1 was also investigated in HT29 human colon cancer cells by Park *et al*[42]. Another study also demonstrated that HO-1 induction resulted in resistance to apoptosis in a human colon cancer cell line, Caco-2, whose effects were independent of p38, but were mediated *via* Akt pathway[43]. In a similar study, Kim *et al*[44] reported that administration of Zerumbone (ZER) effectively suppressed mouse colon carcinogenesis through multiple modulation of growth, apoptosis and inflammation. Ohyama *et al*[45] examined the cytotoxicity of a crude extract from Vitex agnus-castus fruits (Vitex extract) in gastric signet ring carcinoma (KATO-III) cells. They found that cell apoptosis may be attributed to the inhibition of HO-1. It can be supposed that cytoprotective action of HO-1 can be mediated by the following factors: (a) decreased intracellular pro-oxidant levels; (b) increased bilirubin levels; and (c) elevated CO production[46]. On the contrary, flavonoids- (Vitex extract) induced apoptosis is caused through the induction of HO-1 in human colon carcinoma cell line, COLO 201[35]. The relationship between HO-1 and apoptosis remains to be clarified.

HO-1 AND TUMOR GROWTH AND METASTASIS

Apart from the cytoprotective action, HO-1 is commonly regarded as a potent proangiogenic enzyme. Angiogenesis is critical not only for tumor growth but also for metastasis. Thus, proangiogenic action of HO-1 may further support tumor progression[47]. Bussolati *et al*[48] reported that vascular endothelial growth factor (VEGF) induced prolonged HO-1 expression and activity in human endothelial cells and HO-1 inhibition abrogated VEGF-driven angiogenesis. Overexpression of HO-1 in pancreatic cancer cells[49] and melanoma cells[50] increased the occurrence of metastasis, while inhibition of HO activity completely inhibited the occurrence of metastasis[49]. In contrast, some authors have demonstrated that inhibition of the HO pathway by zinc deuteroporphyrin 2,4-bis glycol (ZnDPBG) in colon carcinoma had no effect on metastasis to the lung and even increases metastasis to the liver[51]. Furthermore, the rate of lymphatic tumor invasion was significantly lower in colorectal cancer samples expressing HO-1[34]. Thus, the mechanism of HO-1 in the metastatic potential of cancer cells is not recognized and it may depend on the type of cancer or other still not defined factors.

HO-1 AS A POTENTIAL THERAPEUTIC TARGET

Studies of the role of HO-1 seem to be important not only for better understanding of tumor growth regulation but also for clinical practice. HO-1 is often upregulated in gastrointestinal tumors[34], its expression is further increased in response to the different types of therapies such as photodynamic therapy[52,53] and pyrrolidine dithiocarbamate[54]. Since HO-1 may protect tumor cells against oxidative stress and can be regarded as an enzyme facilitating tumor progression, administration of HO-1 inhibitors might be effective for the treatment of gastrointestinal tumors. It has been demonstrated that pegylated zinc protoporphyrin, a potent HO inhibitor, administered *in vitro* induced apoptosis of human colon carcinoma SW480 cells and inhibited growth of murine colon carcinoma *in vivo*[55]. However, the growth, invasion and metastasis of tumors are a highly complex and multistep process, the mechanisms responsible for HO-1 in gastrointestinal tumors remain to be elucidated.

CONCLUSION

HO-1 system may play an important role in different pathophysiological conditions, in which pharmacologic modulation of HO-1 system may represent an effective and cooperative strategy to facilitate tumor growth and metastasis, although the exact effects can depend on the type of disease. Therefore, down-regulating the HO-1 system by pharmacological or genetic means will be a new therapeutic approach in the management of gastrointestinal tumors. A comprehensive understanding of the underlying mechanisms for the observed effects of HO-1 and its products will be necessary before their use can be evaluated in clinical applications for the prevention and/or treatment of human diseases such as gastrointestinal tumors.

Abstract

AIM: To investigate the efficacy of Viusid, a nutritional supplement, as an antioxidant and an immunomodulator in patients with chronic hepatitis C.

METHODS: Sixty patients with chronic hepatitis C who were non-responders to standard antiviral treatment were randomly assigned to receive Viusid (3 sachets daily, n = 30) or placebo (n = 30) for 24 wk. The primary outcome was the change in serum malondialdehyde and 4-hydroxyalkenals (lipid peroxidation products). Secondary outcomes were changes in serum tumor necrosis factor-α (TNF-α), interferon-γ (IFN-γ) and interleukin-10 (IL-10).

RESULTS: Statistically significant reductions in serum 4-hydroxyalkenals and malondialdehyde levels were observed in both groups in comparison with pretreatment values, but the patients who received Viusid showed a more marked reduction as compared with the control group (P = 0.001). TNF-α levels significantly increased from 6.9 to 16.2 pg/mL (P < 0.01) in the patients who received placebo in comparison with almost unchanged levels, from 6.6 to 7.1 pg/mL (P = 0.26), in the patients treated with Viusid (P = 0.001). In addition, IL-10 levels were markedly increased in the patients treated with Viusid (from 2.6 to 8.3 pg/mL, P = 0.04) in contrast to the patients assigned to placebo (from 2.8 to 4.1 pg/mL, P = 0.09) (P = 0.01). Likewise, the administration of Viusid markedly increased mean IFN-γ levels from 1.92 to 2.89 pg/mL (P < 0.001) in comparison with a reduction in mean levels from 1.80 to 1.68 pg/mL (P = 0.70) in the placebo group (P < 0.0001). Viusid administration was well tolerated.

CONCLUSION: Our results indicate that treatment with Viusid leads to a notable improvement of oxidative stress and immunological parameters in patients with chronic hepatitis C.

INTRODUCTION

Hepatitis C virus (HCV) infection is one of the most important causes of chronic liver disease leading to cirrhosis and hepatocellular carcinoma (HCC)[1]. Peginterferon plus ribavirin is the only therapeutic alternative with proven efficacy in patients with chronic hepatitis C (CHC)[2]. Unfortunately, sustained virological response is achieved in only approximately 50% of the patients. HCV protease and polymerase inhibitors have been evaluated recently, but the increased rate of adverse events and discontinuations reported during the trials may possibly preclude their use in clinical practice[3,4].

The exact pathogenesis of liver injury and fibrosis has not been fully elucidated. Previous studies have found increased oxidative damage in patients chronically infected with HCV[5,6]. These findings have been supported by increased levels of lipid peroxidation (LPO) products (such as malondialdehyde and hydroxynonenal), an overabundance of reactive oxygen species, elevated superoxide dismutase (SOD) activity and reduced levels of glutathione (GSH) in serum or erythrocytes of patients with CHC compared with healthy controls[5-9].

Similarly, cytokine dysregulation is thought to play a crucial role in the persistence of viral infection and as a key mediator in the inflammatory and fibrogenic processes of patients with HCV infection[10].

Studies have shown that increased production of interferon-γ (IFN-γ) is strongly associated with spontaneous resolution of HCV infection compared with scant production in patients with persistent infection[11,12]. Likewise, it has been reported that patients with chronic HCV infection show enhanced serum interleukin (IL)-10 concentration[13,14]; however, long-term IL-10 therapy to treat chronically HCV-infected patients leads to a significant improvement of inflammation and fibrosis[15].

Several studies have suggested a positive association between increased serum tumor necrosis factor-α (TNF-α), IL-1 and -6 levels, and the degree of hepatic inflammation and fibrosis in patients with CHC[16,17].

This provides a rationale for studies using antioxidant and immunomodulatory agents; however, trials involving these agents have not clearly demonstrated their potential benefits, in part due to the limitations of non-randomized studies with small sample size, lack of dependable end points, and poor understanding of the role of different antioxidants in CHC[18-23].

There is an obvious need for the continuous development of new treatment strategies for CHC. Thus, the administration of compounds with antioxidant and immunomodulatory properties could be a plausible strategy to halt the natural course of the disease, particularly in patients with poor response to antiviral therapy. Viusid, a nutritional supplement, contains different molecules (ascorbic acid, zinc, and glycyrrhizic acid) with recognized antioxidant properties (Table 1)[24-26]. Its different chemical compounds are activated through a molecular activation principle that strongly increases their biological activity without modifying their physical structure. Recently, Vilar Gomez *et al*[27] reported that the addition of Viusid to the conventional interferon/ribavirin therapy was associated with significant histologic and biochemical improvements, especially in patients without sustained virological response. They suggested that the Viusid-related effect on histologic features, especially fibrosis, appears to be associated with antioxidant and/or immunomodulatory properties. All of these effects could modulate the histologic pattern of CHC, especially inflammation and fibrosis, in an attempt to halt disease progression. Therefore, we conducted a randomized double-blind and placebo-controlled study to evaluate whether Viusid may have a beneficial effect on oxidative stress and cytokine parameters in patients with chronic hepatitis C.

MATERIALS AND METHODS

Patients

We recruited 60 patients with chronic hepatitis C diagnosis at a tertiary care center (National Institute of Gastroenterology, Havana, Cuba).

Inclusion criteria included male and female patients of 18 to 65 years of age who had a positive test for anti-HCV antibody, HCV RNA detectable in serum by polymerase chain reaction (PCR), persistently elevated ALT at least on two occasions, liver biopsy consistent with chronic hepatitis, non-responders to previous treatment with peginterferon plus ribavirin, and absence of significant alcohol ingestion (weekly ethanol consumption of more than 40 g).

Exclusion criteria included presence of any other form of liver disease, positive screening for viral hepatitis A and B and human immunodeficiency virus (HIV), pregnancy or lactation, decompensated cirrhosis, concomitant disease with reduced life expectancy, severe psychiatric conditions, drug dependence, evidence of liver cancer at entry into the study on the basis of ultrasonography and α-fetoprotein levels less than 50 ng/L, and refusal to participate in the study.

Ethics

The study was conducted in compliance with the Declaration of Helsinki and approved by the ethics committee and the institutional review board of the National Institute of Gastroenterology. All patients provided written

Table 1 Ingredients of Viusid

Malic acid	0.666 g	Ascorbic acid	0.020 g
Glycyrrhizic acid	0.033 g	Folic acid	66 mcg
Glucosamine	0.666 g	Cyanocobalamine	0.3 mcg
Arginine	0.666 g	Zinc sulfate	0.005 g
Glycine	0.333 g	Pyridoxal	0.6 mg
Calcium pantothenate	0.002 g		

informed consent for participation. The trial had been registered at ClinicalTrials.gov (NCT00778843).

Study design

After initial evaluation, all patients who met the eligibility criteria were consecutively enrolled in the study. They were randomly assigned to receive: Viusid (3 sachets daily, $n = 30$) or placebo (3 sachets daily, $n = 30$) for 24 wk. Viusid was provided by Catalysis, S.L. (Madrid, Spain).

Randomization was conducted by allocation into blocks of 4 (block randomization). It was performed by a health worker experienced in randomization techniques who was not involved in the evaluation or treatment of the participants. The physicians, study coordinators, and patients did not have access to the randomization scheme.

The patients, investigators, and study coordinators were blinded as to the treatment administered. Catalysis, Spain provided Viusid and placebo sachets. There was no difference in appearance, smell or flavor between Viusid and placebo.

All patients were evaluated at baseline and at monthly intervals by an experienced hepatologist who strongly encouraged the subjects to accomplish the treatment.

Clinical assessment, including body weight, liver tests, glucose, creatinine, and hemoglobin determinations, along with compliance with the study medication (verified through sachet count) and adverse events, was determined at baseline and/or at monthly intervals during the 24 wk of the study.

The HCV-RNA level was quantified by PCR assay (Amplicor Monitor HCV v. 2.0; Roche Molecular Systems; lower limit of detection, 600 IU/mL). HCV genotyping was performed by reverse hybridization (Inno-LiPA HCV; Innogenetics, Ghent, Belgium). Liver biopsy was performed at least 6 mo before the inclusion in the study and histological results were classified by a single local pathologist according to Ishak score. Liver biopsies were also performed after conclusion of the antiviral treatment.

Laboratory method

Venous blood samples were collected after an overnight fast; 7 mL of blood was drawn into tubes containing EDTA. Plasma was obtained by centrifugation (4000 *g* for 15 min at 4℃) and frozen at -70℃ until assayed. After separation of the plasma, the buffy coat was removed and the packed cells washed three times with cold isotonic saline. Then, a known volume of erythrocytes was lysed with cold distilled water (1:4) and stored in a refrigerator at 4℃ for 15 min, and the cell debris was removed by centrifugation. The erythrocyte lysates were stored at -70℃ until assayed. In general, all samples were analyzed in duplicate.

Oxidative stress determination: Blood for oxidative stress determination was drawn at baseline and every two months up to study conclusion.

The blood oxidative stress status was evaluated by assaying nine parameters: plasma lipid peroxidation products (malondialdehyde and 4-hydroxyalkenals), advanced oxidation protein products, and antioxidant defense systems (glutathione peroxidase, Cu/Zn superoxide dismutase, catalase, glutathione reductase, glutathione, and myeloperoxidase).

Erythrocyte catalase, glutathione reductase, and glutathione peroxidase activities were determined with BIOXYTECH® CAT-520™, BIOXYTECH® GR-340™ and BIOXYTECH® GPx-340™ (OXIS Research, Portland, USA), respectively. Their values were expressed as units per milligram of hemoglobin.

SOD in erythrocytes was measured by the Fulbert method[28], based on the capacity of SOD to inhibit the reduction of ferricytochrome C by the xanthine/xanthine oxidase system. A standard curve was prepared using commercially available SOD (Sigma-Aldrich). Reaction development was monitored spectrophotometrically at 405 nm. One SOD unit is defined as the amount of enzyme that inhibits cytochrome C reduction by 50% under the respective conditions; activity is expressed per hemoglobin.

LPO measurement was performed using the BIOXYTECH® LPO-586™ kit (OXIS Research, Portland, USA) and was based on the reaction of a chromogenic reagent (N-methyl-2-phenylindole) with malondialdehyde (MDA) and 4-hydroxyalkenals at 45℃.

Determination of advanced oxidation protein products (AOPP) was based on spectrophotometric detection according to the method described by Witko-Sarsat[29]. Briefly, 200 μL of plasma [diluted 1:5 with phosphate buffered saline (PBS)], 200 μL of chloramine-T (0-100 μmol/L) for calibration, and 200 μL of PBS as blank were applied on a microtiter plate. 10 μL of 1.16 mol/L potassium iodide and 20 μL of acetic acid were added to each well, and absorbance at 340 nm was measured immediately. Concentration of AOPP was expressed in chloramine units (μmol/L).

GSH concentration was measured by the method of Sedlak and Lindsay, in which 5,5'-dithiobis-(2-nitrobenzoic acid) reacting with sulfhydryl groups yields 2-nitro-5-mercaptobenzoic acid with maximal absorbance at 412 nm[30]. Glutathione (Sigma-Aldrich) was used to generate the standard curves.

Serum myeloperoxidase (MPO) concentration was measured using a high-sensitivity, quantitative sandwich enzyme immunoassay (OXIS Research, Portland, USA). In this assay, the lowest detection limit of MPO is 1.02 ng/mL.

Serum cytokine determinations: Blood for cytokine measurement was drawn at baseline and every two months up to study conclusion.

Serum cytokine levels (IL-1α, IL-1β, IL-2, IL-6, IL-10,

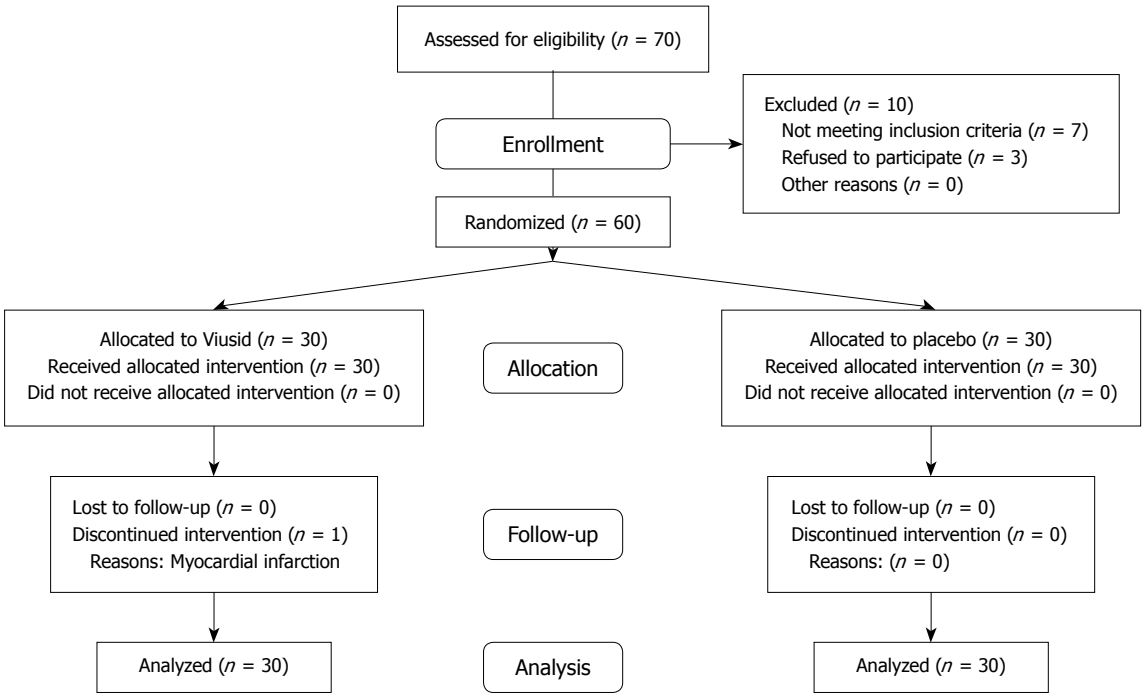

Figure 1 Flow of participants through the study.

IL-12; TNF-α, TNF-β, IFN-γ, cathepsin L, and GM-CSF) were measured using commercial sandwich-type ELISA kits following the procedure recommended by the manufacturers (Bender MedSystem, Vienna, Austria). Detection limits were as follows: 1.1 pg/mL for IL-1α, 0.3 pg/mL for IL-1β, 9.9 pg/mL for IL-2, 0.92 pg/mL for IL-6, 1.0 pg/mL for IL-10, 2.1 pg/mL for IL-12; 2.3 pg/mL for TNF-α, 4.6 pg/mL for TNF-β, 0.99 pg/mL for IFN-γ, 1.71 ng/mL for cathepsin L, and 2.9 pg/mL for GM-CSF.

Outcomes

The primary outcome was the change in serum MDA and 4-hydroxyalkenals (lipid peroxidation products). Secondary outcomes were changes in serum TNF-α, IL-10 and IFN-γ. Change was the difference between measurements obtained at baseline and at the end of treatment (24 wk).

Statistical analysis

The baseline characteristics were summarized as percentages for categorical variables and as mean ± SE for continuous variables. The χ^2 test was applied to categorical variables. The two-sample *t*-test was used to compare means, and the Mann-Whitney *U*-test if they were not normally distributed. Outcome measurements included all patients who were randomized and received at least one dose of study medication (intention-to-treat analysis). The Wilcoxon signed-rank tests were used to compare changes between the baseline and post-treatment measurements, and the Wilcoxon rank-sum tests were used for treatment group comparisons. The safety analysis included all treated patients who had at least one safety evaluation after baseline.

The study was designed to have a statistical power of 80% to detect an absolute difference of 28% in the changes of serum MDA and 4-hydroxyalkenals (28% in the group with Viusid versus 0% in the placebo group). Considering a type I error of 0.05 and a type II error of 0.20, 30 patients per arm were needed to reach statistical significance.

All confidence intervals, significance tests, and resulting *P* values were two-sided, with an alpha level of 0.05.

Statistical analyses were performed using SPSS Inc. for Windows, release 15, Chicago, IL.

RESULTS

A total of 60 patients were recruited at a tertiary center (National Institute of Gastroenterology, Havana, Cuba) between October 2008 and May 2009. The flow of participants through the trial is presented in Figure 1. All randomized patients received at least one dose of the study medication; 1 subject assigned to Viusid did not complete the study and the reason for discontinuation was a myocardial infarction in week 16 of the study. No patient was lost during the follow-up period and no patient received co-interventions during the trial that could have affected the outcomes.

All patients who underwent random allocation were analyzed for outcomes according to original group assignment (intention-to-treat analysis).

Baseline characteristics were comparable across the two groups (Table 2). The majority of the patients in the Viusid group were female; however, there was no statistical difference in comparison with the placebo group. All patients were non-responders to previous antiviral therapy with peginterferon plus ribavirin and infected with genotype 1, and more than half of the patients had a viral load of over 600 000 IU/mL (75%).

Table 2 Baseline characteristics

Variable	Viusid (n = 30)	Placebo (n = 30)	P value[1]

[1]P values are for the comparison between Viusid and placebo; Plus-minus values are mean ± SE of mean; For all laboratory measures and for continuous demographics: P value Mann-Whitney U-test; Proportions: Percentage, P value χ^2. HCV: Hepatitis C virus; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; IL: Interleukin; IFN: Interferon; TNF: Tumor necrosis factor; GM-CSF: Granulocyte-macrophage colony-stimulating factor; MDA: Malondialdehyde; Cu/Zn SOD: Copper/Zinc superoxide dismutase; CAT: Catalase; GR: Glutathione reductase; GPx: Glutathione peroxidase; GSH: Glutathione; MPO: Myeloperoxidase; AOPP: Advanced oxidation protein products.

Oxidative stress markers

Lipid peroxidation products (primary end point): There were significant mean reductions from baseline to 6 mo in MDA and 4-hydroxyalkenals in each group of treatment (Table 3). However, the administration of Viusid markedly reduced the mean MDA level from 0.97 to 0.29 μmol/L with a mean improvement of 0.68 (95% CI: 0.50-0.84) *vs* 1.12 to 0.76 μmol/L with a mean improvement of 0.36 (95% CI: 0.11-0.62) for placebo (P = 0.001) in comparison with baseline values (Figure 2A). Similarly, significant changes in the mean of serum 4-hydroxyalkenals occurred in the patients assigned to Viusid (1.76 to 0.53 μmol/L), with a mean difference of 1.22 (95% CI: 0.97-1.45), as compared with the patients treated with placebo (1.92 to 1.39 μmol/L), with a mean difference of 0.53 (95% CI: 0.43-1.17) (Figure 2B).

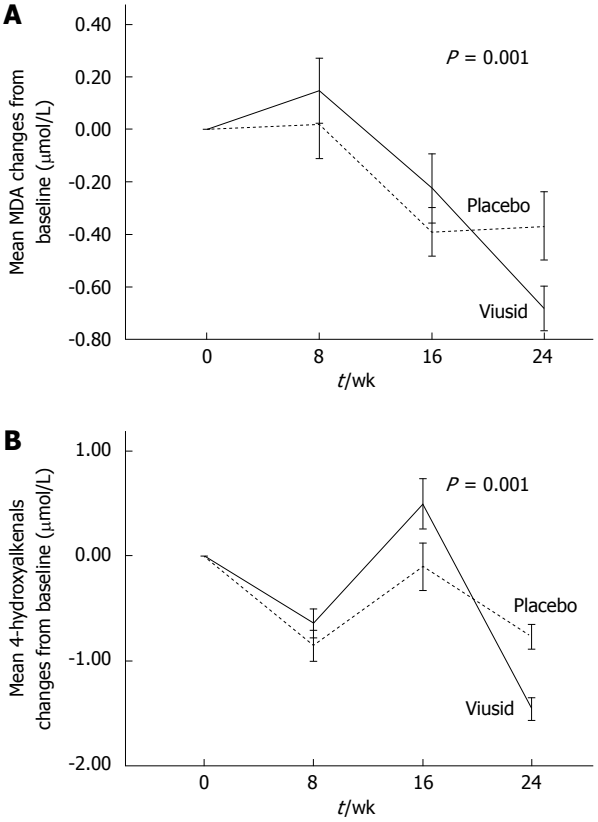

Figure 2 Change in mean serum malondialdehyde (MDA) (A) and serum 4-hydroxyalkenals (B) levels during the treatment period. Error bars indicate SE. P value for the comparison of the Viusid and the control group at 24 wk. A comparative analysis was performed using Wilcoxon rank-sum test.

Antioxidant defense system markers: Surprisingly, significant reductions in erythrocyte Cu/Zn SOD, CAT, GR, and serum GSH and MPO were observed in both groups of treatment in comparison with pretreatment values; however, no significant difference was observed between groups (Table 3).

Advanced oxidation protein products: Serum AOPP concentrations remained unchanged for the patients who received Viusid or placebo as compared with baseline values (Table 3).

Serum cytokines

Serum cytokine results are summarized in Table 4.

TNF-α levels (secondary outcome) significantly increased from 6.9 to 16.2 pg/mL (P < 0.01) in the patients treated with placebo in comparison with almost unchanged levels (6.6 to 7.1 pg/mL, P = 0.26) in the patients treated with Viusid (P = 0.001) (Figure 3A). Similarly, the administration of Viusid markedly increased the mean IFN-γ level (secondary outcome) from 1.92 to 2.89 pg/mL (P < 0.001) in comparison with re-

[1]P values are for the comparison between groups (change from baseline). Plus-minus values are mean ± SE of mean; Continuous parameters were analyzed using the Wilcoxon signed-ranks test and the Wilcoxon rank-sum tests were used for treatment group comparisons.

duced mean levels from 1.80 to 1.68 pg/mL (P = 0.70) in the placebo group (P < 0.0001) (Figure 3B).

Likewise, IL-1α levels slightly decreased from 3.26 to 2.61 pg/mL (P = 0.04) in the patients who received Viusid, as compared with a significant increase from 3.09 to 6.62 pg/mL (P = 0.04) in subjects assigned to placebo (Figure 3C). In addition, IL-10 levels were markedly increased in the patients treated with Viusid (from 2.6 to 8.3 pg/mL, P = 0.04) in contrast to the patients assigned to placebo (from 2.8 to 4.1 pg/mL, P = 0.09) (P = 0.01) (Figure 3D).

Unexpectedly, significant reductions in the mean serum level of IL-1β, IL-2, TNF-β, and cathepsin L were recorded in all patients at 24 wk of treatment in comparison with baseline; however, no significant difference was observed between the groups.

Serum IL-6, IL-12, and GM-CSF concentrations remained unchanged in the patients who received Viusid or placebo as compared with baseline values.

Biochemical results

At 24 wk of treatment, γ-glutamyltransferase (GGT) levels were considerably reduced in comparison with baseline values (Table 5). GGT levels were reduced by 44% (from 72.7 to 40.8 IU/L, P = 0.001) in patients receiving Viusid, as compared with 12% (from 84.1 to 74.4 IU/L, P = 0.56) in the patients assigned to placebo (P = 0.002). Uric acid levels slightly decreased by 23% (from 257 to 198 mmol/L, P = 0.01) in patients receiving Viusid, as compared with 3% (from 276 to 267 mmol/L, P = 0.66) in subjects assigned to placebo.

In both groups, aminotransferase levels were unaffected in comparison with pretreatment values (Table 5).

Safety analysis

Headache and diarrhea were reported in one subject who received Viusid. No laboratory adverse event was reported with the use of Viusid. There was no incidence of discontinuation or dose modification of Viusid secondary to adverse events.

DISCUSSION

Encouraging effects of Viusid on liver histology have been reported in patients with chronic hepatitis C and nonalcoholic fatty liver disease[27,31]; however, pathophysiologic mechanisms for explaining these effects remain unknown. There is a potential hepatoprotective

TNF-α: Tumor necrosis factor-α; IFN-γ: Interferon-γ; IL-1α: Interleukin-1α; IL-10: Interleukin-10.

mechanism in the chemical composition of Viusid that could be explained by the anti-inflammatory and antioxidant properties of its different molecules, such as zinc, glycyrrhizin acid, and ascorbic acid[24-26]. Thus, the aim of this study was to investigate the role of Viusid as an antioxidant and an immunomodulator in patients with CHC who have failed previous antiviral treatment.

Several studies have demonstrated increased production of MDA in CHC, which is an indirect marker for oxidative stress (lipid peroxidation), and its levels have been associated with moderate-to-severe inflammation and fibrosis compared with those patients who had milder disease, suggesting higher oxidative stress with advanced stage of the disease[32,33].

We found that MDA and 4-hydroxyalkenal levels were significantly reduced in the serum of the patients treated with Viusid as compared with placebo, indicating an important effect on lipid peroxidation products. Recent evidence shows that increased lipid peroxidation products, such as 4-hydroxynonenal, play a decisive role

in stellate cell activation and fibrosis progression[34]. Increased 4-hydroxynonenal levels upregulate procollagen and tissue inhibitor of metalloproteinase-1 gene expression. Matrix metalloproteinase-1 plays an important role in degrading collagen; therefore, the inhibition of this enzyme could increase fibrosis. Thus, this provides a putative mechanism to explain in part the effect of Viusid on fibrosis reduction in patients with CHC[27]. Therefore, these results support the rationale for further studies in other forms of liver disease such as alcoholic liver disease and nonalcoholic fatty liver disease.

Encouraging antioxidant effects of ascorbic acid and zinc have been reported recently. Ascorbic acid and zinc supplementation have been associated with a significant reduction of LPO products[35,36].

Surprisingly, a marked reduction of serum antioxidant defense system markers was seen in the whole group during treatment, maybe reflecting the "regression towards the mean" phenomenon, a placebo-induced effect, or poor maintenance of the redox homeostasis status.

Imbalanced Th1- and Th2-type response has been postulated to play an important role in influencing both the persistence of HCV infection and the extent of liver damage[10,37,38]. In this context, IFN-γ and IL-12 are Th1-type cytokines, which are critical in the development of T-cell-mediated immunity, paramount for viral clearance. Thus, an increased production of serum IFN-γ has been strongly linked to self-limited HCV infection[11,12]. Our data suggest an increased production of IFN-γ in the patients treated with Viusid when compared with baseline, maybe suggesting a reestablishment of the T-cell-mediated immunity *via* Th1-type response; however, the underlying mechanisms by which Viusid is able to induce IFN-γ are still poorly understood. On the other hand, IL-10 is a Th2-type response cytokine with a suppressive effect on the generation of Th1-type response cytokines (IFN-γ and IL-12), which have recognized anti-inflammatory and slight proviral effects[13-15]. Our data show that serum IL-10 levels were markedly increased with the administration of Viusid in spite of simultaneously increasing serum IFN-γ levels. IL-10 is known to suppress the secretion of pro-inflammatory cytokines, such as TNF-α, IFN-γ, and IL-12[15,39,40]. In contrast, administration of neutralizing monoclonal antibodies to anti-IL-10 enhances *in vitro* IFN-γ production in HCV patients[41], suggesting that IL-10 levels differ widely between individuals, possibly due to polymorphisms in the promoter region of the *IL-10* gene[42].

Recent data support the hypothesis that long-term IL-10 therapy to treat chronically HCV-infected patients leads to significant histological improvement of inflammation and fibrosis[15].

Our data suggest that increased serum IL-10 levels could be a significant finding to explain the effect of Viusid on histological features (inflammation and fibrosis) in patients with CHC and non-alcoholic fatty liver disease (NAFLD)[27,31].

Recent studies have indicated that glycyrrhizin, an aqueous extract of licorice root and the main ingredient of Viusid, can induce a significant production of IL-10 by liver dendritic cells in concanavalin A-induced hepatitis in mice[43].

Our findings also show that a short course of Viusid slightly reduces IL-1α and stabilizes TNF-α concentrations in patients with CHC. These are markers of inflammation and fibrosis that are elevated in HCV-infected subjects compared with healthy controls[16,17,38]; therefore, their reduction or stabilization could be associated with histological improvement, in particular inflammation and fibrosis.

Viusid has chemical ingredients with recognized immune regulatory properties that would explain in part the effect on cytokine secretion. Zinc supplementation has demonstrated that it can significantly increase IFN-γ and IL-10 secretion and reduce IL-1 and TNF-α secretion in patients with chronic inflammatory diseases[44].

GGT has been regarded as a biomarker of hepatobiliary disease and alcohol consumption/abuse[45]. In addition to liver disease, GGT has been associated with high all-cause mortality, cardiovascular disease incidence and death, and cancer incidence and death[46,47]. Accumulating experimental evidence suggests that GGT is a key mediator in the mechanisms of oxidative stress. GGT-mediated oxidative stress has been reported capable of inducing lipid oxidation, oxidation of protein thiols, alterations of the normal protein phosphorylation patterns, and biological effects such as the activation of transcription factors[48].

In the current study, we found that serum GGT levels were significantly reduced in the patients treated with Viusid in comparison with unchanged levels in the patients assigned to placebo. The mechanism that explains the contribution of Viusid to GGT reduction has not been fully elucidated and further studies are needed to evaluate the clinical impact of long-term Viusid administration in patients with other forms of chronic liver disease, cardiovascular disease, metabolic syndrome, and cancer.

On the other hand, the administration of Viusid did not improve aminotransferase levels during the 24 wk of treatment. In contrast to what has been suggested in two recently published papers[33,37], Viusid without supportive therapy such as antiviral therapy or lifestyle modification for CHC and NAFLD, respectively, is unable to induce improvement in aminotransferase levels, regardless of its proven and significant antioxidant and immunomodulatory capability. Further studies must evaluate higher doses and long-term administration of Viusid to determine its effect on aminotransferase levels in patients with chronic liver diseases.

The main strength of this study is the presence of a concurrent placebo control group allowing adequate comparison between control and experimental groups for outcome measures. A possible weakness of our study is that patients were treated for 24 wk only, and it remains unclear whether some parameters related to oxidative stress and immunological status can be improved beyond 24 wk.

In conclusion, our data suggest that Viusid improves oxidative stress through reduction of lipid peroxidation products and that it has an immunomodulatory

effect on cytokine secretion *via* increased production of IFN-γ and IL-10, decreased production of IL-1α, and stabilized TNF-α secretion in patients with CHC who have failed previous antiviral treatment. Our findings also highlight the limitations in our understanding of the complex mechanism of the host immune response and its interaction with pro-oxidant/antioxidant status.

COMMENTS

Background

The pathogenesis of chronic hepatitis C (CHC) is associated with severe oxidative stress and non-selective immunological disturbance that lead to necroinflammation and the progression of fibrosis. Several trials have suggested that antioxidant and immunostimulant therapies may have a beneficial effect. Two previous clinical studies have reported that the Viusid-related effect on histologic features, especially fibrosis, appears to be associated with antioxidant and/or immunomodulatory properties. However, the putative mechanism of action of Viusid is unknown.

Research frontiers

Peginterferon plus ribavirin is the only therapeutic alternative with proven efficacy in patients with CHC. Unfortunately, sustained virological response is achieved in only approximately 50% of patients. Viusid is a nutritional supplement with documented effects on histological parameters (steatosis, inflammation and fibrosis) in patients with CHC and nonalcoholic fatty liver diseases. It contains different molecules (ascorbic acid, zinc, and glycyrrhizic acid) with recognized antioxidant and immunomodulatory properties. However, is necessary to confirm whether Viusid may have a beneficial effect on oxidative stress and cytokine parameters in patients with CHC.

Innovations and breakthroughs

Recent studies have suggested that the Viusid-related effect on histologic features, especially fibrosis, appears to be associated with antioxidant and/or immunomodulatory properties. All of these effects could modulate the histologic pattern of CHC, especially inflammation and fibrosis, in an attempt to halt disease progression. The identification of the molecular mechanisms of action of Viusid as an immunomodulatory and/or antioxidant product in patients with CHC could support a new strategy of treatment in patients who have failed previous antiviral treatment.

Applications

In current clinical practice, there are no available strategies of treatment for patients with CHC who have failed previous antiviral treatment. Therefore, there is an obvious need for the continuous development of new treatment strategies for CHC. Thus, the administration of compounds with antioxidant and immunomodulatory properties such as Viusid could be a plausible strategy to halt the natural course of the disease, particularly in patients with poor response to antiviral therapy. Further studies are needed to evaluate the clinical impact of the administration of Viusid in patients with end-stage liver disease secondary to CHC.

Terminology

Viusid is a nutritional supplement. It contains different molecules (ascorbic acid, zinc, and glycyrrhizic acid) with recognized antioxidant and immunomodulatory properties. The different compounds in the supplement are activated through a molecular activation principle which strongly increases their biological activity without modifying their structure. With this method the molecules are treated under a determined electric field during a time span calculated beforehand and under certain specific conditions for each kind of molecule.

Peer review

In this report, the authors reported the results of a randomized double-blind and placebo-controlled study to evaluate the effect of Viusid on oxidative stress and cytokine parameters in patients with chronic hepatitis C who had been non-responders to previous antiviral therapy with peginterferon plus ribavirin and infected with genotype 1.

Abstract

AIM: To evaluate the prophylactic properties of integrin CD18-βA peptide in a murine model of abdominal polymicrobial peritonitis and sepsis.

METHODS: Bacterial sepsis was induced in Institute of Cancer Research (ICR) mice by cecal ligation and puncture (CLP) surgery. Inflicted mice were then injected with either sterile saline or CD18-βA peptide intraperitoneally at 2 h after surgery, and were sacrificed at 12 and 24 h after surgery. Blood samples were immediately collected, and analyzed for endotoxin activity and tumor necrosis factor (TNF)-α and interleukin (IL)-6. Lungs and liver were studied for CD45+ leukocyte and CD3 mRNA content. Pulmonary expression of intercellular adhesion molecule (ICAM)-1, vascular cell adhesion molecule (VCAM) and E-selectin was also determined.

RESULTS: Intraperitoneal injection of CD18-βA peptide significantly suppressed circulating endotoxin activity ($P < 0.01$) at 24 h, as well as serum levels of TNF-α ($P < 0.05$ at 12 and 24 h) and IL-6 ($P < 0.01$ at 12 h, $P < 0.05$ at 24 h) in CLP-inflicted mice. CD18-βA peptide also abrogated leukocyte infiltration into liver and lungs as unveiled by reduced CD45+ leukocyte and CD3 mRNA contents. Furthermore, the peptide significantly reduced pulmonary expression of VCAM ($P < 0.01$ at 12 h, $P < 0.001$ at 24 h), E-selectin ($P < 0.01$ at 12 and 24 h), and ICAM-1 ($P < 0.01$ at 12 h, $P < 0.001$ at 24 h). These actions of CD18-βA peptide collectively protected septic mice against lethality ($P < 0.01$).

CONCLUSION: CD18-βA peptide is a potent endotoxin antagonist that can protect surgical patients against sepsis-associated lethality.

INTRODUCTION

Endotoxin [or lipopolysaccharide (LPS)] was first identified by Richard Pfeiffer from the late log phase culture of *Vibrio cholerae*, of which the heat inactivated bacterial

lysates could induce septic shock and death in experimental animals[1,2]. In clinical settings, circulating endotoxin acts as a pivotal initiator in the pathogenesis of bacterial sepsis and signals front-line immune host cells to trigger the "cytokine storm", resulting in systemic inflammatory response syndrome (SIRS)[3]. Given that the deleterious SIRS goes unchecked, patients may develop and die from acute respiratory distress, shock, and multiple organ dysfunction. Severely ill patients in surgical wards and intensive care units are at risk from sepsis-associated death, despite the use of broad-spectrum antibiotics, corticosteroids, and other new drugs like drotrecogin alfa[4]. To resolve the stringent clinical situation, many experimental therapeutics like cultured bone marrow stromal cells[5], cholinergic agonists[6] and lysophosphatidylcholine[7] have emerged as potential therapeutics. Studies on their therapeutic efficacies however still remain in pre-clinical stages.

Our previous finding has identified that leukocyte integrin CD18 βA peptide is able to bind bacterial LPS and to alleviate the pro-inflammatory responses in LPS-stimulated Jurkat cells[8]. In the present study, we evaluated the potential prophylactic use of CD18-βA peptide in a murine model of cecal ligation and puncture (CLP) that resembles abdominal polymicrobial peritonitis and sepsis in humans[9].

MATERIALS AND METHODS

CD18-βA peptide

We designed the CD18-βA peptide basing on the residues 266-318 of CD18 of leukocyte β2 integrins. We cloned the cDNA fragment into pET43.1B vector (Novagen, San Diego, CA, USA), expressed recombinant CD18-βA peptide in *E. coli.* BL21 (DE3) (Novagen), and subsequently purified the resulting protein using ion mobilized affinity chromatography following our published procedure[8,10]. Before we injected CD18-βA peptide into mice, we dialyzed the peptide against sterile phosphate buffered saline. We verified the purity using electrophoresis, and measured the concentration of CD18-βA peptide as described[11].

Polymicrobial CLP peritonitis model in mice

We obtained male Institute of Cancer Research (ICR) mice (30 g in weight) from the AAALAC-accredited Laboratory Animal Unit of the University of Hong Kong (Pokfulam, Hong Kong), and divided them randomly into three experimental groups of equal size. We then maintained all mice in a vivarium on a 12-h light/dark cycle at 21℃. Mice had ad libitum access to a sterilized animal chow and water. We performed all experimental procedures on mice in accordance with the ethical guidelines set forth by the University's Committee on Using Live Animals for Teaching and Research.

We performed CLP as previously described[5] in ICR mice. We anaesthetized mice with an intraperitoneal injection of 50 mg/kg sodium pentobarbital (Nembutal, Rhone Merieux, Pinkenba, QLD, Australia), and opened the anterior abdomen by a 15 mm midline incision. Afterwards, we ligated the exposed cecum non-obstructively with surgical silk, punctured it twice with a 19-gauge needle, and then replaced it back to the peritoneal cavity. For sham-operated mice, we opened the abdomen, but the cecum was neither ligated nor punctured. Finally, we completed CLP surgery by closing the abdomen wall with nylon sutures, and gave no analgesics and antibiotics to mice. At 2 h after the completion of CLP surgery, we injected 0.1 mL sterile saline intraperitoneally into 12 mice, and 0.8 mg/kg CD18-βA peptide (this optimal dosage was prior determined in a pilot study ranging from 0.6-1.2 mg/kg) to another 12 mice. An additional injection of sterile saline or CD18-βA peptide, respectively, was given to mice at 14 h after the completion of CLP surgery. We gave no treatment to the sham-operated mice throughout the experiment. We killed six mice from each of the three experimental groups at 12 and 24 h after CLP. Therefore, mice that were sacrificed at 12 and 24 h received one and two injections of CD18-βA peptide, respectively. We collected blood from the interior vena cava, and harvested lung and liver. We obtained serum from the collected blood by centrifugation at 3000 rpm for 10 min at 4℃. For each harvested lung and liver, we minced it into two pieces that were formalin-fixed and snap-frozen separately.

Survival study

We studied the survival of septic mice receiving different treatments after CLP in another group of ICR mice (n = 8 in each experimental group, in total 24 mice). We performed CLP as previously described, and injected mice intraperitoneally with either sterile saline or CD18-βA peptide at 2, 12 and 24 h after closure of abdomen. Sterile saline was used as a control according to our earlier studies and reported procedures[5,7,12]. We assessed survival after CLP continually for 48 h, and regarded mice that still remained alive beyond the observation period as survivors. Survival data were analyzed using the Kaplan-Meier module in GraphPad Prism (GraphPad Software Inc., La Jolla, CA, USA).

Limulus amoebocyte lysate assay of endotoxin activity

We determined the endotoxin activity in circulation using the Limulus amoebocyte lysate (LAL) pyrochrome kit (Associates of Cape Cod Inc, East Falmouth, MA, USA) as previously described[13,14]. All buffers for the LAL assay were prepared using endotoxin-free water according to manufacturer's instructions. We measured the resulting signal spectrophotometrically at 540 nm using a microtiter plate reader (Molecular Devices, Sunnyvale, CA, USA), and each sample was done in triplicate. We finally determined the endotoxin activity from the measured signals using a standard curve with a dynamic range from 0 to 0.623 Endotoxin Units (EU)/mL.

Tumor necrosis factor-α and interleukin-6 enzyme-linked immunosorbent assay

We measured the serum level of tumor necrosis factor (TNF)-α and interleukin (IL)-6 of mice using commercially available enzyme-linked immunosorbent assay kits

that were purchased from Dakewe (Shenzhen, China) and eBioscience (San Diego, CA, USA), respectively, in accordance with instructions previously reported[15,16].

Immunohistochemistry

We followed our published procedures to perform all immunohistochemical staining[17,18]. To study the CD45+ leukocyte content in lungs and liver of mice, we stained tissue paraffin sections with 10 μg/mL monoclonal antibody against CD45 (Santa Cruz Biotechnology, Santa Cruz, CA, USA) as described[19]. We stained lung tissues with 20 μg/mL monoclonal antibody against VCAM (20 μg/mL; BD Biosciences, San Jose, CA, USA) and 20 μg/mL monoclonal antibody against E-selectin (BD Biosciences) to study pulmonary expression of the two adhesion molecules. We incubated tissue sections with respective antibodies at 4℃ overnight. After washing, we added a horseradish peroxidase-conjugated secondary antibody (Invitrogen, Carlsbad, CA, USA). We visualized the resulting signals with a liquid DAB substrate kit (Invitrogen), and thereafter, we counterstained tissue sections with hematoxylin (Vector Laboratories, Burlingame, CA, USA).

Real-time polymerase chain reaction

We measured the level of CD3 mRNA in lung and liver of mice after CLP using real-time polymerase chain reaction (PCR). This method provides robust and quantitative measurement on tissue infiltration of inflammatory leukocytes[20]. To study the expression of ICAM-1, VCAM, and E-selectin in lungs, we measured their mRNA levels. We performed RNA extraction, first-strand cDNA synthesis, and real-time PCR in ABI PRISM 7700 sequence detector system (Applied Biosystems Inc., Forest Hill, CA, USA) as previously described[21-23].

Statistical analysis

We performed all statistical analysis using the GraphPad Prism (GraphPad Software Inc.); group means of the study parameters were compared by one-way ANOVA, and P values < 0.05 were considered to indicate statistical significance.

RESULTS

Survival of septic mice

Diagnosis of bacterial sepsis in most clinical scenarios is always delayed, therefore in this study we injected mice intraperitoneally with CD18-βA peptide (0.8 mg/kg) (or sterile saline) at 12-h intervals beginning two hours after the CLP surgery. We first looked at the survival rates after CLP surgery in saline- and CD18-βA peptide-treated mice. A statistically significant ($P < 0.01$) improvement in the survival of mice injected CD18-βA peptide intraperitoneally was noted (Figure 1A); about 40% of mice survived over the 48 h post-operative observation period, and remained alive thereafter despite discontinuation of therapy. In contrast, mice that received saline all died within the 36 post-operative hour period.

Endotoxicity and pro-inflammatory cytokines in circulation

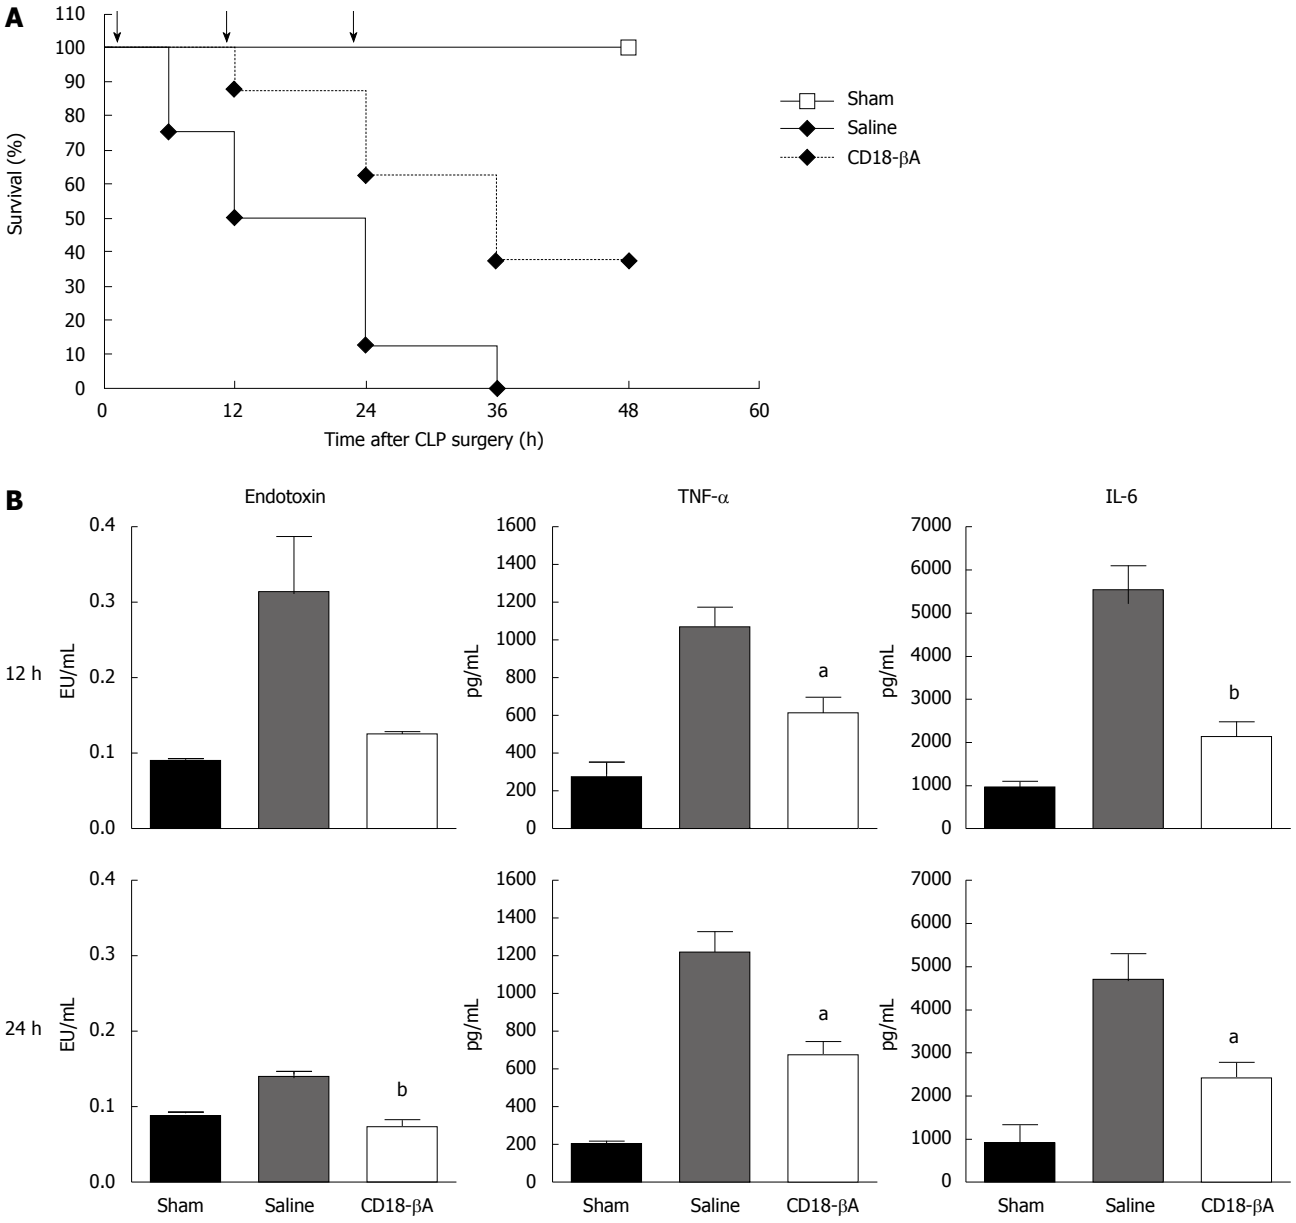
We next investigated whether the beneficial effect of CD18-βA peptide on the survival of septic mice was associated with reductions in endotoxin activity in circulation. To this end, we measured both biological activity of endotoxin and serum levels of TNF-α and IL-6 after we sacrificed mice at 12 and 24 h after CLP surgery and collected blood samples at the interior vena cava. Mice inflicted with CLP surgery showed up-regulation of the circulating endotoxin activity and TNF-α and IL-6 levels in serum samples, which could be remarkably modulated by treatment with CD18-βA peptide but not with saline control (Figure 1B). Intraperitoneal injection of CD18-βA peptide achieved a statistically significant reduction in circulating endotoxin activity ($P < 0.01$) at 24 h, as well as serum levels of TNF-α ($P < 0.05$ at 12 and 24 h) and IL-6 ($P < 0.01$ at 12 h, $P < 0.05$ at 24 h).

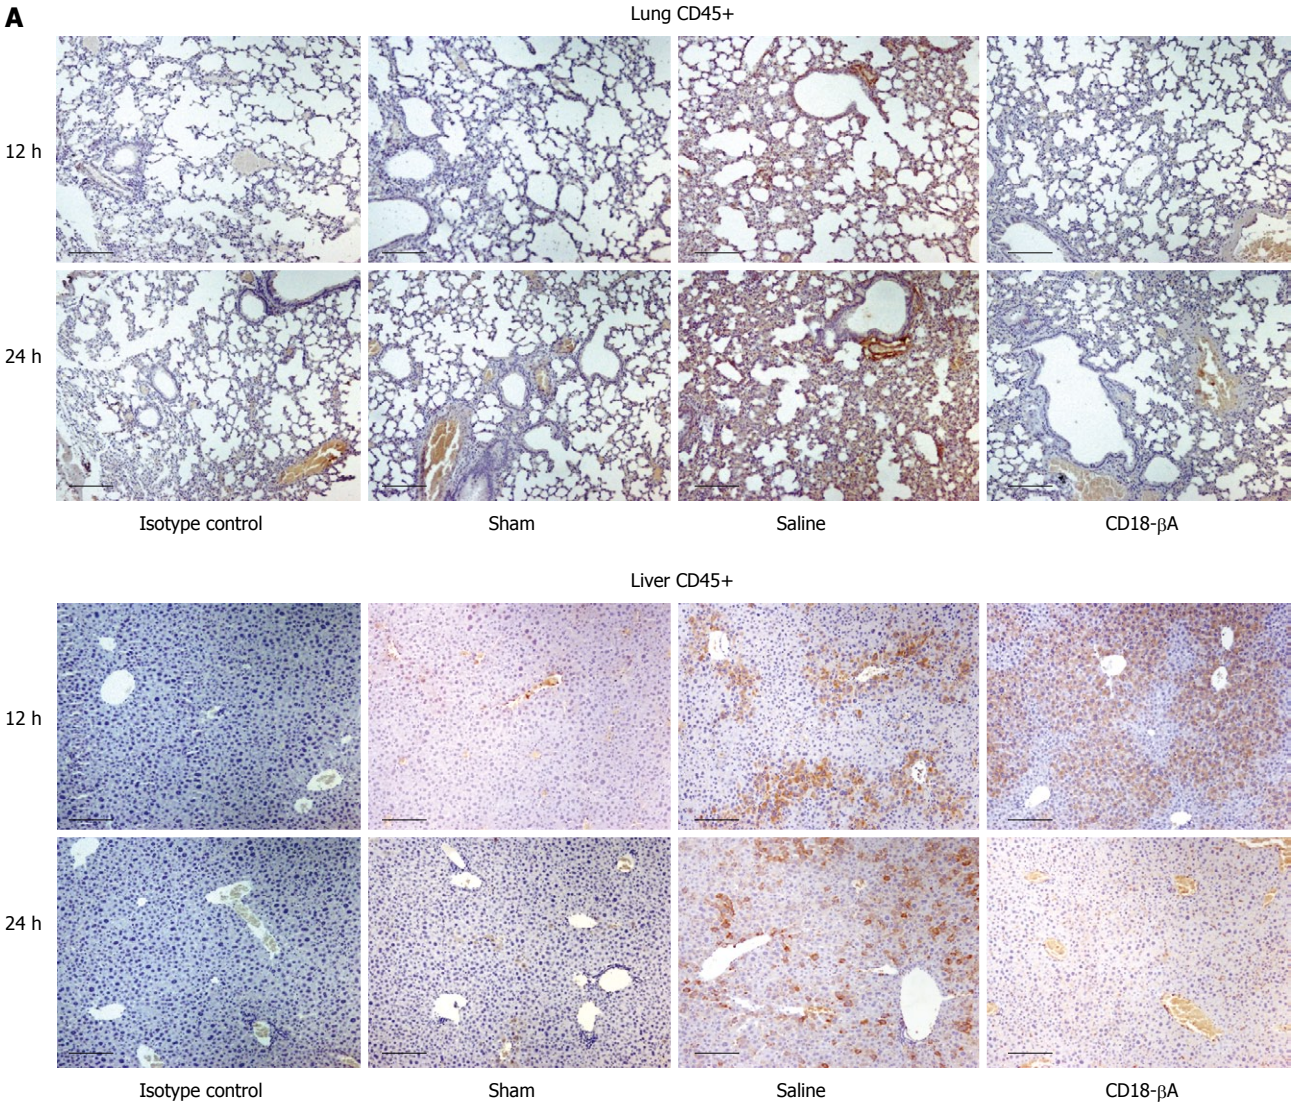
CD45+ leukocyte and CD3 mRNA contents in lungs and liver

In view of the fact that infiltrating leukocytes usually injure tissues, we first studied histologically the effect of CD18-βA peptide on CD45+ leukocyte infiltration in lungs and liver of septic mice (Figure 2A). Intense CD45 reactivity was detected in the lungs and liver organs from the placebo group. Strikingly, a bolus of CD18-βA peptide injection drastically diminished CD45+ cells in liver, and almost completely eradicated the CD45+ signals in lungs. Further to confirm this observation, we measured the level of CD3 mRNA that is expressed by infiltrating leukocytes using real-time PCR (Figure 2B). Compared to the sham control, CD3 mRNA levels of lungs and liver were up-regulated by over 10-20 fold by CLP surgery, and these elevations were reduced significantly by treatment with the CD18-βA peptide ($P < 0.05$). Taken together, we suggest that CD18-βA peptide can be used to prevent leukocyte infiltration in bacterial sepsis.

ICAM-1, VCAM and E-selectin expression in lungs

Adhesion molecules facilitate leukocyte trafficking, and are implicated in mediating organ injuries[24]. To study the effect of CD18-βA peptide on adhesion molecule expression, we first determined the pulmonary expression of VCAM and E-selectin by immunohistochemistry (Figure 2C). Intense immunoreactivity toward VCAM and E-selectin was detected in lung paraffin sections prepared from saline-treated septic mice, whereas the corresponding immunoreactivities were markedly diminished from the CD18-βA peptide-treated mice. Expression of ICAM-1, VCAM, and E-selectin mRNA in lungs has also been determined by real-time PCR. Similarly, mRNA levels of the three adhesion molecules surged in lungs of saline-treated septic mice, whereas such elevations were significantly suppressed after CD18-βA peptide treatment: VCAM ($P < 0.01$ at 12 h, $P < 0.001$ at 24 h), E-selectin ($P < 0.01$ at 12 and 24 h), and ICAM-1 ($P < 0.01$ at 12 h, $P < 0.001$ at 24 h) (Figure 2C).





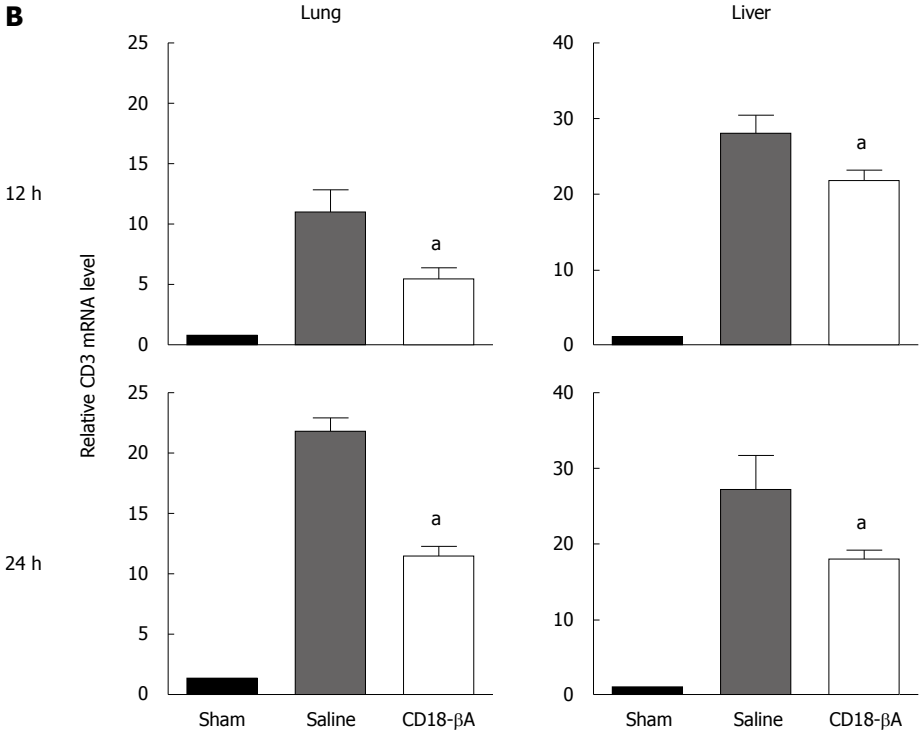


Figure 1 CD18-βA peptide protects mice against cecal ligation and puncture (CLP)-induced lethality and inflammatory responses. A: Mice were injected with either sterile saline or CD18-βA peptide intraperitoneally at 12 h intervals beginning 2 h after CLP (as indicated by arrows), and were monitored continually over 48 h. There was statistically significant improvement in survival of septic shock mice that received CD18-βA injection ($P < 0.01$), compared to those that received saline. n = 8 for each experimental groups; B: Measurement of endotoxin activity and tumor necrosis factor (TNF)-α and interleukin (IL)-6 levels in blood circulation. Injection of CD18-βA peptide achieved significant reductions in endotoxin activity at 24 h, and reductions in TNF-α and IL-6 at 12 and 24 h after CLP. 12 h, n = 5 and 24 h, n = 6 for each experimental group. [a]$P < 0.05$, [b]$P < 0.01$ *vs* saline group (one-way ANOVA). Error bars represent mean ± SD.

DISCUSSION

We illustrated in a stringent murine model of bacterial sepsis that CD18-βA peptide was able to neutralize circulating endotoxin, to reduce serum TNF-α and IL-6 levels, to inhibit leukocyte infiltrating into lungs and liver, and to suppress endotoxin-induced adhesion molecule expression. All these protective actions of CD18-βA peptide might contribute to survival benefits of the animals in the sepsis model.

We found the protection of CD18-βA peptide on septic mice was in some ways impressive. Notably, CD18-βA peptide still afforded protection on septic mice even when it was administered after onset of bacterial sepsis. This is in contrast to many other therapeutic interventions that are incapable of halting the already-initiated super-inflammatory responses in surgical patients. In view of this, CD18-βA peptide can serve as an adjunctive therapeutic particularly for patients who are being challenged by high concentration of endotoxin, which usually results with a delayed diagnosis of bacterial sepsis. One of the possible underlying mechanisms for the effective endotoxin neutralization could be attributed to the presence of an amphipathic helix motif (VGQLAHKLAENNIQPIFA) at the C-terminal end (Figure 3). Such structural moiety favors endotoxin binding and neutralization of

Figure 2 CD18-βA peptide inhibits CD45+ leukocyte infiltration into lung and liver in CLP-induced mice. A: CD45+ leukocyte content in lung and liver after CLP was visualized by immunohistochemistry. Images are representative of $n = 6$ for each experimental group. Scale bar, 80 μmol/L; B: Real-time polymerase chain reaction (PCR) analysis of CD3 mRNA level in lungs and liver, normalized to β-actin, at 12 and 24 h after CLP. Significant reductions in CD3 mRNA contents were observed in lungs and liver of septic mice that have been treated with CD18-βA peptide. $^{a}P < 0.05$ *vs* saline group (one-way ANOVA); C: Pulmonary expression of adhesion molecules was studied using immunohistochemistry and real-time PCR. Lung sections were stained with VCAM and E-selectin antibody, and images are representative of $n = 6$ for each experimental group. Scale bars, 80 μm. Real-time PCR was employed to study mRNA expression of ICAM-1, VCAM, and E-selectin in lungs. Significant reductions in adhesion molecule mRNA contents were observed in lungs of septic mice that were treated with CD18-βA peptide. $^{b}P < 0.01$, $^{d}P < 0.001$ *vs* saline group (one-way ANOVA). For all real-time PCR study, $n = 6$ for each experimental group at 12 and 24 h. Error bars represent mean ± SD.

endotoxicity[25]. In addition, we have previously shown that the positively charged residues (e.g. arginine, lysine) along the CD18-βA peptide are contributing to the effective binding to LPS of various bacterial strains[8].

We showed CD18-βA peptide is an effective agent to suppress the "cytokine storm" in bacterial sepsis, given that the peptide significantly reduced TNF-α and IL-6 levels in the circulation of septic mice. This aspect of CD18-βA peptide is essential to sepsis treatment because pro-inflammatory cytokines can stimulate phagocytes to release reactive oxygen species, increasing vascular permeability and leading to organ injury[26]. In fact, therapeutic agents like anti-cytokine antibodies and receptor antagonists that are aiming to abolish cytokine functions have long been developed. Unfortunately, none of these agents proved efficacious in protecting sepsis patients[27,28], apparently because of the redundancy of cytokine functions. Unlike these therapeutic agents, use of CD18-βA peptide can circumvent this problem because in our recent study, we have shown CD18-βA peptide could down-modulate the NF-κB-mediated signaling that is central to the release of many pro-inflammatory cytokines.

The clinical utility of CD18-βA peptide as a sepsis therapeutic is further enhanced by its ability to inhibit leukocyte infiltration into lungs and liver, given that leukocyte-mediated injury on these two organs cause the high mortality rate of sepsis patients[29,30]. The inhibition is likely attributed to the suppression of adhesion molecules in lungs. In addition to this mechanism, it was apparent that CD18-βA peptide could block the integrin binding sites on adhesion molecules (e.g. ICAM-1) because CD18-βA peptide is homologous to the CD18 antigen of leukocyte β2 integrins. Indeed, this hypothesis is supported by our early study showing that a recombinant CD18 subunit could inhibit the binding of leukocytes to immobilized adhesion molecules (Luk JM, unpublished observation). We also hypothesized that CD18-βA peptide could antagonize direct activation of leukocytes by bacterial endotoxin as our recent study has illustrated that CD18-βA peptide could prevent the sensing of Jurkat cells by bacterial LPS *in vitro*[8].

Furthermore, a recent *in vivo* animal study of necrotizing enterocolitis has readily demonstrated the potential therapeutic efficacy of CD18-βA peptide against LPS-induced proinflammatory reactions[31]. In that study, rat intestine was distended and then challenged by bacterial LPS, culminating in profound TNF-α release from immune cells, intense leukocyte influx into the intestine, and severe intestinal tissue damage. CD18-βA peptide was able to neutralize the LPS endotoxicity and modulate the above-mentioned deleterious immune responses.

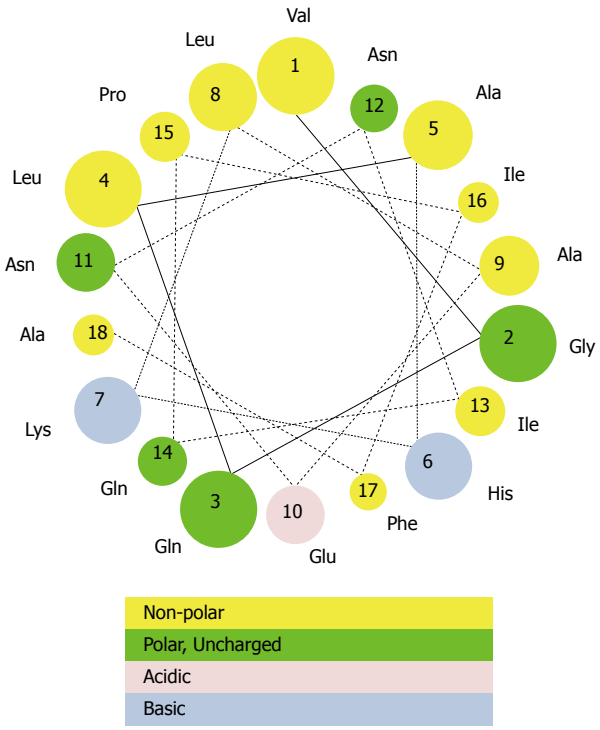

Figure 3 A predicted model of the amphipathic helix sequence at CD18-βA that binds bacterial endotoxin. Shown is the polypeptide sequence of the CD18-βA domain of leukocyte β2 integrin, and the two LPS-binding sites are colored green and red. CD18-βA peptide is derived from the red binding site. The underlined portion of CD18-βA peptide demonstrates a feature of the amphipathic helix, as revealed by the helical wheel diagram.

In summary, CD18-βA peptide is a promising therapeutic for intervention of bacterial sepsis. Unlike anti-LPS antibodies that failed to protect septic patients because of their inability to inhibit pro-inflammatory cytokine releases from immune cells[32], CD18-βA peptide can halt the deleterious "cytokine storm" in bacterial sepsis. To further assess the therapeutic efficacy of CD18-βA peptide, we are going to study the protective action in a porcine model of endotoxemia[33].

for critical review and professional editing of the manuscript. The use of CD18-βA peptide in treating sepsis has been filed for US patent (application 61/080,558) and PCT Patent Application No. PCT/CN2009/000791.

COMMENTS

Background

Patients severely infected with Gram-negative bacteria can die of endotoxemia and sepsis. Indeed, despite the emergence of broad-spectrum antibiotics, corticosteroids, and advanced surgical resuscitative supports, sepsis remains one of the leading causes of death in intensive care units. In this context, many experimental therapeutic agents have been developed over the last few decades. Disappointingly, only a few of these agents were shown to improve survival, and nearly none of them could halt the unchecked inflammatory response of sepsis.

Research frontiers

CD18-βA peptide is a novel endotoxin antagonistic peptide derived from a lipopolysaccharide (LPS)-binding site of leukocyte integrins, and was found able to suppress the stimulation of LPS on leukocytes *in vitro*. The present work is the first published data concerning the use of CD18-βA peptide in the treatment of mice with polymicrobial peritonitis.

Innovations and breakthroughs

The key pathogenesis of sepsis is the super-inflammatory response (or "cytokines storm") that can ultimately lead to multiple organ failure and inevitably death. To date, clinical uses of corticosteroids and antibiotics, and experimental uses of cytokine antibodies all fail to halt the deleterious immunological cascades. In this study, CD18-βA peptide was shown to antagonize endotoxicity in circulation, preventing the pro-inflammatory "cytokines storm" from initiation. This mitigation of the inflammatory response reduced the influx of leukocytes from the bloodstream into lungs and liver, protecting both organs from leukocyte-mediated damage. All these beneficial effects of CD18-βA peptide collectively protected septic mice against death.

Applications

The indication of CD18-βA peptide as a potent endotoxin antagonist promises to be an effective therapeutic agent to alleviate the deleterious superinflammatory responses in patients with acute septic conditions.

Terminology

Polymicrobial peritonitis model is a clinically relevant model that resembles sepsis resulting from endotoxemia. Endotoxin (e.g. LPS) is a structural component of the Gram-negative bacteria cell wall, and once been liberated to circulation, can stimulate the innate immunity to release pro-inflammatory cytokines, culminating in systemic inflammatory response syndrome and sepsis.

Peer review

This is a paper that evaluates the prophylactic properties of integrin CD18, and the results are very important. The authors show integrin CD18 suppressed circulating endotoxin activity and levels of tumor necrosis factor-α and interleukin-6.

Abstract

AIM: To investigate the effects of blueberry on hepatic fibrosis and *NF-E2-related factor 2* (*Nrf2*) transcription factor in rats.

METHODS: Forty-five male Sprague-Dawley rats were randomly divided into control group (A); CCl_4-induced hepatic fibrosis group (B); blueberry prevention group (C); Dan-shao-hua-xian capsule (DSHX) prevention group (D); and blueberry + DSHX prevention group (E). Liver fibrosis was induced in rats by subcutaneous injection of CCl_4 and a high-lipid/low-protein diet for 8 wk (except the control group). The level of hyaluronic acid (HA) and alanine aminotransferase (ALT) in serum was examined. The activity of superoxide dismutase (SOD), glutathione-S-transferase (GST) and malondialdehyde (MDA) in liver homogenates was determined. The degree of hepatic fibrosis was evaluated by hematoxylin and eosin and Masson staining. Expression of *Nrf2* and NADPH quinone oxidoreductase 1 (Nqo1) was detected by real-time reversed transcribed-polymerase chain reaction, immunohistochemical techniques, and western blotting.

RESULTS: Compared with group B, liver indices, levels of serum HA and ALT of groups C, D and E were reduced (liver indices: 0.038 ± 0.008, 0.036 ± 0.007, 0.036 ± 0.005 *vs* 0.054 ± 0.009, $P < 0.05$; HA: 502.33 ± 110.57 ng/mL, 524.25 ± 255.42 ng/mL, 499.25 ± 198.10 ng/mL *vs* 828.50 ± 237.83 ng/mL, $P < 0.05$; ALT: 149.44 ± 16.51 U/L, 136.88 ± 10.07 U/L, 127.38 ± 11.03 U/L *vs* 203.25 ± 31.62 U/L, $P < 0.05$), and SOD level was significantly higher, but MDA level was lower, in liver homogenates (SOD: 1.36 ± 0.09 U/mg, 1.42 ± 0.13 U/mg, 1.50 ± 0.15 U/mg *vs* 1.08 ± 0.19 U/mg, $P < 0.05$; MDA: 0.294 ± 0.026 nmol/mg, 0.285 ± 0.025 nmol/mg, 0.284 ± 0.028 nmol/mg *vs* 0.335 ± 0.056 nmol/mg, $P < 0.05$). Meanwhile, the stage of hepatic fibrosis was significantly weakened ($P < 0.05$). Compared with group A, the activity of GST liver homogenates and expression levels of *Nrf2* and Nqo1 in group B were elevated ($P < 0.05$). The expression level of *Nrf2* and Nqo1 in groups C, D, and E were increased as compared with group B, but the difference was not significant.

CONCLUSION: Blueberry has preventive and protective effects on CCl_4-induced hepatic fibrosis by reducing hepatocyte injury and lipid peroxidation. However, these effects may not be related to the activation of *Nrf2* during long-term of CCl_4.

Wang YP, Cheng ML, Zhang BF, Mu M, Wu J. Effects of

blueberry on hepatic fibrosis and transcription factor *Nrf2* in rats. *World J Gastroenterol* 2010; 16(21): 2657-2663 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i21/2657.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i21.2657

INTRODUCTION

Hepatic fibrosis is a common result of chronic injury to the liver[1]. Oxidative stress has recently been recognized as a fundamental factor in the pathological changes observed in various liver diseases[2,3]. Oxidative stress can cause excessive damage to hepatocytes through lipid peroxidation and protein alkylation[4,5]. *NF-E2-related factor 2* (*Nrf2*) is an important transcription factor that regulates antioxidative stress reactions. NADPH quinone oxidoreductase 1 (Nqo1) and glutathione-S-transferase (GST) are the major phase-Ⅱ detoxification enzymes controlled by *Nrf2*[6,7].

Blueberries are flowering plants that belong to *Vaccinium* spp. of the family *Ericaceae*. The Human Nutrition Research Center (Mayer, USA) has performed a series of intensive studies of blueberries. These studies have indicated that blueberries contain anthocyanins, polyphenols and flavonoids, and appear to have the highest antioxidant capacity among the common fruits and vegetables[8,9]. Blueberries may also affect chronic disease through anti-inflammatory and antitumor mechanisms[10,11].

The focus of the present study was to examine the effect of blueberry on hepatic fibrosis and detoxification enzyme systems in rats.

MATERIALS AND METHODS

Ethical approval of the study protocol

All animal studies complied with the Animal Care and Use Guidelines of Guiyang Medical College (Guiyang, China).

Reagents and animal treatments

Forty-five male Sprague-Dawley rats (200 ± 20 g) were obtained from the Experimental Animal Center of Guiyang Medical College [Approval number SCXK (Guizhou) 2002-0001]. Rats were randomly divided into five groups of nine: control group (A); CCl_4-induced hepatic fibrosis group (B); blueberry prevention group (C); Danshao-hua-xian capsule (DSHX) prevention group (D); and blueberry + DSHX prevention group (E).

Except in the control group, liver fibrosis was induced in each group by a complex method[12]. Rats in groups B-E received subcutaneous injections of 40% CCl_4 solution (mixture of pure CCl_4 and peanut oil) and 0.3 mL/100 g twice a week for 8 wk (the first dose was 40% CCl_4 0.4 mL/100 g). Rats were fed a high-lipid/low-protein diet (79.5% corn farina, 20% fat, and 0.5% cholesterol) each day. Rats in group A were fed only a normal diet. At the same time, blueberry juice (1.5 g/100 g per day, *po*, "Rabbiteye Blueberry"; Blueberry production field of Ma-Jiang, Guizhou, China) was processed. Samples were stored at -20℃ until use, and homogenized to prepare blueberry juice (1 mL blueberry juice contained about 2 g of dried blueberries). DSHX (1.0 g/kg per day, *po*; lot number 20081011; DSHX capsules composed of five Chinese herbal medicines, Tetrandrine, *Radix Salviae Miltiorrhizae*, *Radix Paeoniae Rubra*, *Astragalus Membranaceus* and *Ginkgo leaf*; Guiyang Pharmaceutical Company, Guizhou, China) and blueberry juice + DSHX (1.5 g/100 g + 1.0 g/kg, *po*, daily) were given to rats in groups C-E. After 8 wk, there were eight survivors in groups A, B, D and E, and nine in group C.

Rats were killed to collect blood and livers (rats were weighed before killing). The wet liver was weighed. The same part of each liver was removed and fixed in 10% neutral formalin; the remaining portion of liver was stored at -80℃ until use. Rat serum was centrifuged (1500 r/min for 15 min at room temperature) and stored at -80℃ until use.

Histopathology

After fixation in 10% formalin for 24 h, samples were embedded in paraffin. Samples were then cut into 5-μm pieces and mounted on slides. They were stained with hematoxylin and eosin (HE) for histopathological examination, and with fibrosis-specific Masson stain for evaluation of the degree of liver fibrosis[13].

Calculation of the liver index

The liver index was calculated according to the formula[12]: (liver weight/rat weight) × 100%.

Measurement of levels of hyaluronic acid and alanine aminotransferase

Concentrations of hyaluronic acid (HA) (lot number 20090501, Shanghai Institute of Naval Medicine, Shanghai, China) and alanine aminotransferase (ALT) were measured by radioimmunoassay (RIA) or by an automatic biochemical analytic instrument (Siemens Advia 1650, Bensheim, Germany).

Measurement of levels of superoxide dismutase, glutathione-S-transferase and malondialdehyde in liver homogenates

Liver homogenates were prepared. Superoxide dismutase (SOD) content was determined by the xanthine oxidase method; malondialdehyde (MDA) content was tested by the thiobarbituric acid method; and GST content examined by the dinitrobenzene combination method, according to the manufacturer's instructions (lot numbers 20090521, 20090522, and 20090522, respectively; Jiancheng Biologic Co., Nanjing, China).

Real-time reverse transcriptase-polymerase chain reaction analyses

Total RNA was extracted from liver tissues with Trizol reagent (lot number 13827390; Invitrogen, Carlsbad, CA, USA) and purified. This was followed by reverse transcription (lot number 00033699; Fermentas, MBI, Burling-

[a]$P < 0.05$ *vs* group A; [c]$P < 0.05$ *vs* group B. HA: Hyaluronic acid; ALT: Alanine aminotransferase; SOD: Superoxide dismutase; MDA: Malondialdehyde; GST: Glutathione-S-transferase.

ton, ON, Canada) with Moloney murine leukemia virus (MMuLV) reverse transcriptase and oligo (dT)$_{18}$ primers. polymerase chain reaction (PCR) primers were supplied by Dr. Jie Liu (American National Cancer Institute at the National Institute of Environmental Health Sciences (NC, USA) (Table 1). The SYBR Green DNA PCR kit (lot number 0804104; Applied Biosystems, Foster City, CA, USA) was used for real-time reverse transcriptase (RT)-PCR analyses. The cycle time (C_t) values of the genes of interest were first normalized with β-actin from the same sample. Relative differences between groups calculated and expressed as relative increases, setting the control as 100%.

Immunohistochemical analysis

After de-paraffinization, rehydration, and antigen unmasking by heat treatment, histological sections were placed in 3% H_2O_2 for 10 min. They were then incubated with anti-*Nrf2* (lot number K2008; Santa Cruz Biotechnology, Santa Cruz, CA, USA) and anti-Nqo1 (lot number B1508; Santa Cruz Biotechnology) antibody (1:100) overnight at 4℃. Samples were then processed using an EnVision kit (lot number 10N1775A; Dako, Denmark) according to the manufacturer's protocols. PBS was used as the negative control. Yellow material in the cytolymph/nucleus was considered to be a positive cell. Five microscopic fields (× 400 magnification) were randomly chosen per slice, and the number of cells per field counted.

Western blotting

Protein in the total and cytoplasm were extracted using the Bradford method quantified using kits (lot numbers 090310 and 090401; Nanjing Kaiji Biological Engineering Research Institute, Beijing, China). Forty micrograms of total extract (*Nrf2*)/cytoplasm extract (Nqo1) were boiled in an equal volume of 2 × SDS electrophoresis sample buffer for 5 min before 12% SDS-PAGE. After electrophoresis, proteins were transferred to polyvinylidene fluoride membranes (lot number K7KN9080G; Millipore, Billerica, MA, USA). Membranes were blocked with 5% fat-free dry milk-TBST buffer for 1 h at room temperature, and then washed in TBST buffer. Membranes were incubated with a 1:1000 dilution of primary antibody of *Nrf2* and Nqo1 overnight. On the second day, membranes were washed, followed by incubation with a 1:5000 dilution of horseradish peroxidase secondary antibody (lot numbers D2409 and G1009; Santa Cruz Biotechnology) for 1 h. Transferred proteins were visualized with an electrochemiluminescence detection kit (lot number 09065A2; Millipore) and short exposure of the membrane to X-ray films. β-actin (lot number 028K4826; Sigma-Aldrich, St. Louis, MO, USA) was used as an internal reference.

Statistical analysis

Data analyses were carried out using SPSS 11.5 software (Chicago, IL, USA). Quantitative data were expressed as mean ± SD and subjected to one-way analysis of variance. Ordinal data were analyzed by Ridit analysis. $P < 0.05$ was considered significant.

RESULTS

Effect of blueberry on the liver index and serum concentrations of HA and ALT

The liver index and serum concentrations of HA and ALT in group B increased greatly compared with those in group A ($P < 0.05$). Compared with group B, the liver index and serum concentration of HA and ALT in groups C-E were clearly reduced ($P < 0.05$) (Table 2).

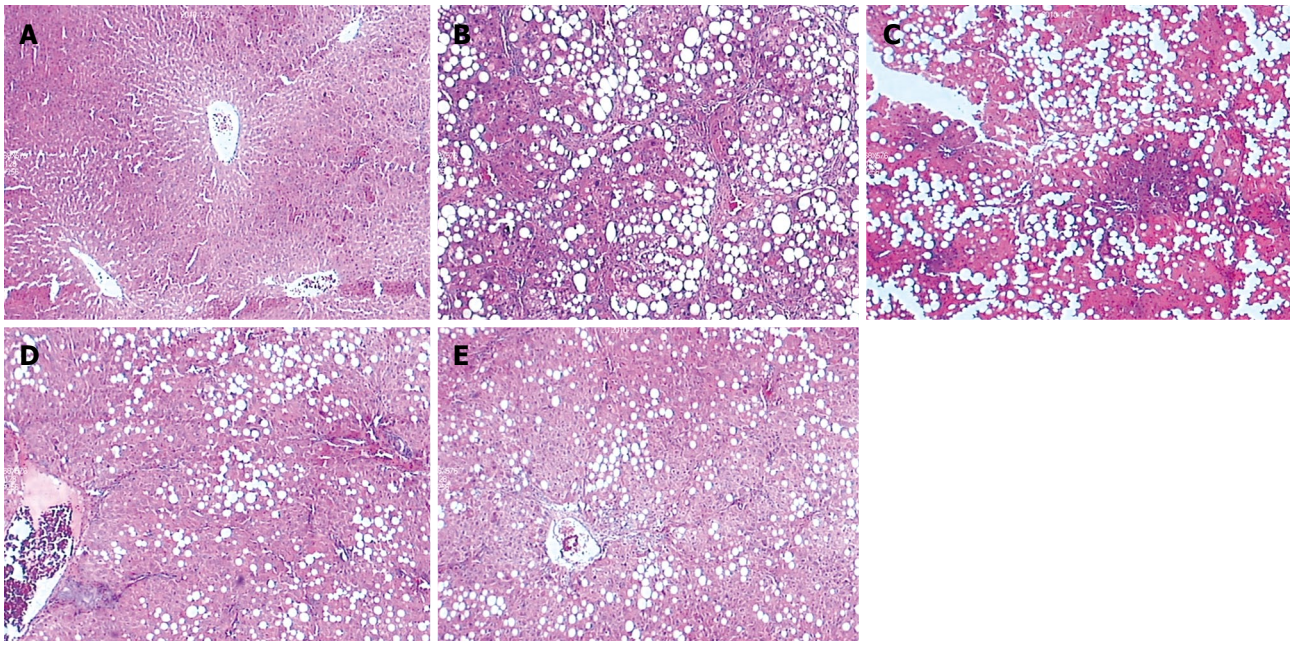

Figure 1 Liver tissue in each group of rats (HE staining, × 40 magnification). A: Light microscopy showing normal liver tissue in the control group; B: Marked fibrosis in the model group; C-E: Pathological change in the treatment group was milder compared with that in the model group.

Table 3 Degree of hepatic fibrosis in each group of rats

Group	*n*	Degree of hepatic fibrosis							Mean rank
		0	1	2	3	4	5	6	
A	8	5	3	0	0	0	0	0	4.5
B	8	0	0	0	0	1	6	1	34.25[a]
C	9	0	0	3	2	2	2	0	23.00[a,c]

E	8	0	0	4	1	2	1	0	20.63[a,c]

[a]$P < 0.05$ *vs* group A; [c]$P < 0.05$ *vs* group B.

Effect of blueberry on levels of SOD, MDA and GST in liver homogenates

The level of SOD in liver homogenates was significantly higher and that of MDA significantly lower in groups C-E compared with those in group B ($P < 0.05$) (Table 2). The level of GST was significantly higher in group B than that in group A ($P < 0.05$). The activity of GST in groups C-E was increased as compared with group B, but the differences were not significant.

Effects of blueberry on the degree of hepatic fibrosis

After HE and Masson staining, hepatocytes in group A had a radial array with the central vein, and regenerating collagen fibers were absent. The lobular structure of group-B hepatocytes was destroyed, and the hepatic plates were disordered with diffuse, fatty degeneration. Collagen fibers expanded into the hepatic parenchyma, and fibrous septa surrounding and separating the normal lobules formed. Pseudolobules were observed in a few samples, and numerous inflammatory cells infiltrated in the portal area and fibrous septa. The degree of hepatic fibrosis in group B was significantly more compared with that in group A ($P < 0.05$).

The hepatic fibrosis in groups C-E was alleviated; the fibrous septa were thinner than those in group B ($P < 0.05$). Diffuse fatty degeneration in hepatocytes was found in some samples. Bridging fibrosis, a few inflammatory cells infiltrated into the portal area, fibrous septa, and pseudolobules were also found in some samples. More detailed information about the degree of hepatic fibrosis in each group is shown in Table 3 and Figure 1.

Effect of blueberry on gene and protein expression of Nrf2 and Nqo1

Real-time RT-PCR showed that *Nrf2* and Nqo1 mRNA expression was significantly higher in group B than group A ($P < 0.05$); and expression of *Nrf2* and Nqo1 mRNA in groups C-E was increased as compared with group B, but the differences were not significant. Immunohistochemical and western blotting assays showed similar protein expression of *Nrf2* and Nqo1 (Table 4 and Figures 2-4).

DISCUSSION

The present work demonstrated that blueberry has a therapeutic effect on CCl_4-induced hepatic fibrosis in rats. There was no difference in therapeutic effect among the blueberry, DSHX, and blueberry + DSHX groups. DSHX is a mixed preparation composed of five traditional Chinese herbal medicines. We have previously reported that DSHX is effective in preventing hepatic fibrosis[12,14,15].

Reactive oxygen species and oxidative stress have an important role in the development of hepatic fibrosis. A central role in the defense against oxidative stress has been attributed to the transcription factor *Nrf2*, which

A: Few cytolymph-positive cells in the control group; B-E: More cytolymph-positive cells in the model group and each treatment group compared with the control group.

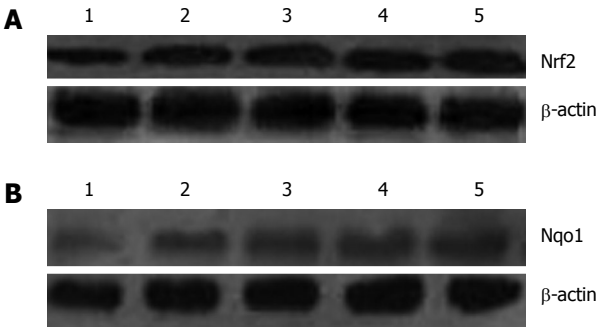

Figure 4 Expression of Nrf2 (A) and Nqo1 (B) protein assessed by Western blotting. Lane 1: Control group; Lane 2: Model group; Lane 3: Blueberry prevention group; Lane 4: DSHX prevention group; Lane 5: Blueberry + DSHX prevention group. The molecular weight of Nrf2 is 57 kDa, the molecular weight of Nqo1 is 31 kDa.

belongs to the basic region-leucine zipper family. In health[16], *Nrf2* localizes in the cytoplasm, where it interacts with the actin-binding protein Kelch-like ECH associating protein 1 (Keap1), and is rapidly degraded by the ubiquitin-proteasome pathway. Signals from reactive oxygen species or electrophilic insults target the *Nrf2*-Keap1 complex, which dissociates *Nrf2* from Keap1. Stabilized *Nrf2* then translocates to the nuclei, and promotes the expression of many antioxidant proteins and phase-Ⅱ detoxifying enzymes such as Nqo1, GST and heme oxygenase-1 (HO-1)[17,18]. Activation of *Nrf2* may be a novel strategy to prevent or ameliorate toxin-induced liver injury and fibrosis[17]. Curcumin has been shown to attenuate dimethylnitrosamine-induced liver injury in rats through *Nrf2*-mediated induction of HO-1[19]. Aleksunes *et al*[20] have proposed that *Nrf2* is crucial for cytoprotection by coordinately activating detoxification genes and preventing the pathogenesis of liver disease.

Blueberry is a small round berry and has high cellular antioxidant activity. Increasing fruit consumption is a logical strategy to increase antioxidant intake and reduce oxidative stress[21]. Studies have suggested that fractions from blueberries may alter phase-Ⅱ detoxification enzymes in cell culture[22]. Boateng *et al*[23] and Reen *et al*[24] have reported significant increases in the activity of phase-Ⅱ enzymes GST-α and NADPH quinine reductase in rats after supplementation with freeze-dried berries. Blueberry and probiotics exert protective effects on acute liver injury induced by d-galactosamine and lipopolysaccharide. They reduce the injury to hepatocytes (including inflammation and secretion of pro-inflammatory cytokines), improve barrier functions, and have antioxidant activity[25]. Proanthocyanidin isolated from blueberry leaves may be used against hepatitis C virus by inhibiting viral replication[26].

Our previous work has showed that blueberries can increase the level of mRNA expression of *Nrf2*, Nqo1, and HO-1 in rat liver if given orally for 21 d, and have good protective effects against acute hepatic injury in rats[27,28]. Blueberries can also increase expression of *Nrf2* and HO-1 in primary hepatic stellate cells (data not shown). The present study tested the hypothesis that blueberries may have preventive protective effects on CCl_4-induced hepatic fibrosis, and that these effects may be related to the activation of phase-Ⅱ enzymes in rat livers.

We found that, in the prevention groups, liver weight and serum levels of HA and ALT were significantly reduced, and liver fibrosis was alleviated. The level of SOD in liver homogenates increased and MDA level decreased. These results indicated that blueberry had certain therapeutic effects on CCl_4-induced hepatic fibrosis in rats through inhibition of liver inflammation and lipid peroxidation. There was no statistically significant difference in therapeutic effect among the blueberry, DSHX and blueberry +DSHX groups, which indicates that blueberry and DSHX did not act in synergy.

Compared with the normal group, GST activity and expression of *Nrf2* and Nqo1 were increased in the model group ($P < 0.05$). GST activity and expression of *Nrf2* and Nqo1 were also increased in the blueberry, DSHX and blueberry + DSHX groups compared with the model group (particularly in the blueberry and blueberry + DSHX group), but these increases were not significant at the concentrations of blueberry used ($P > 0.05$).

In summary, in the present study, blueberries possessed a therapeutic effect on CCl_4-induced hepatic fibrosis in rats through inhibiting liver inflammation and lipid peroxidation, and may be not related to the induction of phase-Ⅱ enzymes through the activation of *Nrf2* in rat liver during long-term of CCl_4. More detailed study is needed.

ACKNOWLEDGMENTS

The authors thank Dr. Jie Liu for his help in the experimental research.

COMMENTS

Background

Conventional drugs used in the treatment of liver diseases inevitably have side effects. An increasing number of natural substances have been studied to explore if they have protective effects on the liver. Blueberries have unique effects on human retinal, brain and tumor cells, but reports about the effects of blueberries on liver diseases are lacking.

Research frontiers

Reactive oxygen species and oxidative stress have an important role in the development of hepatic fibrosis. Blueberries have high cellular antioxidant activity. Recent reports have suggested that proanthocyanidin isolated from blueberry leaves can be used against hepatitis C virus by inhibiting viral replication.

Innovations and breakthroughs

The present study showed that blueberries have therapeutic effects on CCl_4-induced hepatic fibrosis in rats, through inhibition of liver inflammation and lipid peroxidation. This protective effect may not be related to the activation of NF-E2-related factor 2 in rat livers.

Applications

Increasing consumption of blueberries is a reasonable strategy to increase antioxidant intake, and may lead to a reduced risk of hepatic disease.

Peer review

The authors present some data from their research on the effectiveness of blueberries on liver fibrosis induced in laboratory animals. Readers of the journal may find it interesting to read the data.

Abstract

AIM: To investigate the frequency, etiology, and current management strategies for diarrhea in newborn.

METHODS: Retrospective, nationwide study involving 5801 subjects observed in neonatal intensive care units during 3 years. The main anamnesis and demographic characteristics, etiology and characteristics of diarrhea, nutritional and therapeutic management, clinical outcomes were evaluated.

RESULTS: Thirty-nine cases of diarrhea (36 acute, 3 chronic) were identified. The occurrence rate of diarrhea was 6.72 per 1000 hospitalized newborn. Etiology was defined in 29 of 39 newborn (74.3%): food allergy (20.5%), gastrointestinal infections (17.9%), antibiotic-associated diarrhea (12.8%), congenital defects of ion transport (5.1%), withdrawal syndrome (5.1%), Hirschsprung's disease (2.5%), parenteral diarrhea (2.5%), cystic fibrosis (2.5%), and metabolic disorders (2.5%). Three patients died due to complications related to diarrhea (7.7%). In 19 of 39 patients (48.7%), rehydration was performed exclusively by the enteral route.

CONCLUSION: Diarrhea in neonates is a challenging clinical condition due to the possible heterogeneous etiologies and severe outcomes. Specific guidelines are advocated in order to optimize management of diarrhea in this particular setting.

INTRODUCTION

Diarrhea and neonatal age are two major factors responsible for pediatric mortality worldwide[1,2]. The neonate has increased susceptibility to complications related to diarrhea due to immaturity of the systems that regulate fluid homeostasis and immunologic response[3]. Early diagnosis and timely treatment are crucial because diarrhea in neonates may rapidly lead to life-threatening dehydration and malnutrition[4,5]. Clinical and epidemiologic studies defining severity and etiology are needed in order

to improve diagnostic and therapeutic approaches for neonatal diarrhea. Starting with these considerations, the Working Group on Intestinal Infections of the Italian Society of Pediatric Gastroenterology, Hepatology and Nutrition (SIGENP), on behalf of the Italian Society of Neonatology (SIN), designed a nationwide study aimed at investigating the frequency, etiology, clinical features, nutritional management, therapeutic approach, and outcomes of diarrhea observed in hospitalized neonates.

MATERIALS AND METHODS

A multicenter, retrospective study was planned. The study design and aims were presented and discussed during two meetings of the SIGENP and the SIN. We invited the participation of the chiefs of neonatal intensive care units (NICUs) of urban children's hospitals, university medical centers or large community hospitals, observing at least 100 newborns per year and having the following diagnostic facilities: determination of fecal electrolyte concentrations, full microbiological examination, food allergy tests, gastrointestinal endoscopy and histology, metabolic tests and genetic counselling. The neonatologists operating in the participating centers were invited to review the data of 3 consecutive years (i.e. 2000-2002). Inclusion criteria were: (1) age at hospitalization $\leqslant$ 28 d; (2) gestational age at birth $\geqslant$ 24 wk; (3) clinical chart and hospital records available for review; and (4) presence of diarrhea, defined on the basis of increased frequency and watery consistency of stools along with dehydration. This definition, which was adopted in a previous study of neonates[4], is in accordance with the traditional definition employed in pediatric gastroenterology[6] and to the more recent guidelines for the management of acute gastroenteritis of the European Society for Pediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN)/European Society for Paediatric Infectious Diseases (ESPID)[7]. Data were recorded in a specific reporting form made up of 5 sections: (1) demographic characteristics: sex, gestational age, birth weight, age at hospitalization and at diarrhea onset; (2) anamnesis: intrauterine growth restriction, polyhydramnios, risk for allergy according to American Academy of Pediatrics (AAP) guidelines[8], familiarity for chronic diseases including diarrhea, surgery, diet before diarrhea onset; (3) characteristics of diarrhea: number of bowel movements, stool consistency, presence of blood and mucus in the stools, severity of dehydration, complications, development of chronic diseases, diarrhea duration and presence of other intestinal or extra-intestinal symptoms; (4) etiology of diarrhea; and (5) nutritional and therapeutic management, clinical outcomes.

To better define the study population and to establish the diarrhea occurrence rate, the number of hospital admissions and the main demographic characteristics of all subjects observed during the study period, in each participating NICU, were also evaluated. Diarrhea was classified as acute or chronic if it lasted < 14 d or > 14 d, respectively, according to the definition of the World Health Organization[9,10]. The study protocol was approved by the Ethics Committee of our institution. No competing interest was declared by the investigators involved in the study.

Statistical analysis

Patients were classified according to the duration of diarrhea into the acute and chronic groups. For continuous variables, the *t*-test for equality of means was used. For categorical variables, the χ^2 test and Fisher's exact test were used. Possible correlations between the duration of diarrhea and gestational age, birth weight, sex, number of bowel movements, antibiotic use, age at diagnosis and severity of dehydration were investigated by linear regression analysis. The level of significance for all statistical tests was 2-sided $P < 0.05$. Statistical analysis was performed using SPSS software (Version 14.0 for Windows, SPSS Inc., Chicago, IL, USA).

RESULTS

Sixteen NICUs were invited to participate in the study and 7 accepted. The clinical charts of 5801 cases were reviewed, and 39 cases of diarrhea were reported. The occurrence rate of diarrhea was estimated at 6.72 per 1000 hospitalized newborn. The number of cases observed during the study period was: 12 in the first, 14 in the second and 13 in the third year of the study. Diarrhea was the main cause of hospital admission in 14 of 39 subjects (35.9%). Diarrhea was classified as acute in 36 patients (92.3%) and chronic in 3 neonates (7.7%). The etiology of diarrhea was identified in 29 of 39 patients (74.3%) (Table 1).

A diagnosis of cow's milk allergy (CMA) was reported in 8 cases. Five of these cases were considered to be at risk for allergic diseases according to the AAP definitions[8]. In patients with CMA, diarrhea was associated with eczema or vomiting in 6 and in 5 subjects, respectively. Specific IgE titers against milk proteins were positive in 6 of 8 patients (> 5.0 kU/L)[11]. In each case of CMA, the diagnosis was confirmed by observation when an antigen elimination diet with an extensively hydrolyzed casein formula (Nutramigen®, Mead-Johnson Nutritionals, Italy) resulted in symptomatic improvement, and the reintroduction of cow's milk after 4 wk caused symptoms to reappear. An open food challenge was performed in 5 of 8 subjects during hospitalization in consultation with a pediatric allergy specialist, and in 3 of 8 patients after discharge, in a tertiary Center of Pediatric Gastroenterology and Food Allergy.

Seven patients were classified as having intestinal infection according to the results of microbiological analysis. The microorganisms responsible for diarrhea are reported in Table 1. One patient initially classified as having gastrointestinal infection had a familial history of immunodeficiency and a clinical course characterized by growth delay, recurrent opportunistic infections, lymphopenia, associated with defective cellular and humoral immune responses. In this case, molecular analysis

confirmed the clinical diagnosis of adenosine deaminase deficiency (OMIM 608958)[12].

Five babies presented with antibiotic-associated diarrhea. The microbiological analysis, including the search for *Clostridium difficile*, was negative in all these subjects.

According to clinical findings and the results of molecular analysis, two patients received a diagnosis of congenital diarrheal disorders (OMIM 251850): one with glucose-galactose malabsorption (OMIM 182380); and one with congenital chloride diarrhea (OMIM 214700)[13].

Neonatal withdrawal syndrome-induced diarrhea was reported in 2 subjects from mothers with a history of drug abuse (heroin and methadone) during pregnancy[14]. One case of Hirschsprung's disease was diagnosed according to the clinical history (no passage of meconium in the first 72 h of life, bloating of the abdomen) and the results of diagnostic tests, including rectal manometry, barium enema, and rectal biopsy[15]. This patient had diarrhea as a consequence of severe enterocolitis requiring broad-spectrum antibiotic therapy. Parenteral diarrhea induced by extra-intestinal infection caused by *Klebsiella pneumonia*-induced urinary infection was reported in one full-term baby during the first week of life. In this patient, diarrhea started before antibiotic treatment, all microbiological evaluations on stools were negative, and diarrhea improved rapidly when the urinary infection disappeared. For one subject with a familial history of cystic fibrosis (CF), intrauterine growth retardation, and chronic diarrhea, a final diagnosis of CF was achieved by a sweat test and was confirmed by the identification of a CFTR ΔF508 mutation, at the age of 4 mo[16]. A urea defect cycle was diagnosed in one patient by the presence of diarrhea together with metabolic acidosis, hyperammoniemia and protein load intolerance[17].

The main anamnestic and demographic characteristics of the neonates with diarrhea are shown in Table 2. Symptoms associated with diarrhea are reported in Table 3. The

Table 3 Main associated symptoms in the study population *n* (%)

	Acute	Chronic
Number of patients	36	3
Gastrointestinal		
Vomiting	18 (50.0)	1 (33.3)
Mucus in the stools	13 (36.1)	1 (33.3)
Blood in the stools	9 (25.0)	-
Abdominal distension	24 (66.7)	2 (66.7)
Systemic		
Fever	4 (11.1)	-
Hypovolemia[a]	1 (2.8)	1 (33.3)
Eczema	7 (19.4)	-
Seizures[a]	3 (8.3)	1 (33.3)

[a]$P < 0.05$.

neonates affected by diarrhea of unknown origin showed a birth weight significantly lower (1920 g, IQR 1418 g) than subjects with an established etiologic diagnosis (2870 g, IQR 705 g) ($P < 0.040$). The mean number of bowel movements per day was 7.4 (95% CI: 7.0-7.8) without differences between acute and chronic diarrhea. The mean number of daily bowel movements was not influenced by etiology. The mean duration of diarrhea was similar for full term (9.08 d, 95% CI: 4.7-13.4) and preterm neonates (4.7 d, 95% CI: 3.9-5.6, $P = 0.953$). Linear regression analysis using a stepwise method demonstrated that diarrhea duration had a negative relationship with age at symptom onset (B -0.80; Beta -0.48; $P = 0.005$). In contrast, birth weight, sex, gestational age, antibiotic use, severity of dehydration, rehydration or re-feeding strategies, and consumption of breast milk did not correlate with duration of diarrhea.

Data on dehydration and rehydration strategies are reported in Table 4. As a re-feeding strategy in patients with acute diarrhea, an extensive casein hydrolyzed formula (Nutramigen®, Mead-Johnson Nutritionals, Italy) was administered to all subjects with a suspected diagnosis of CMA, and in only 6 of 31 of the remaining subjects (19.3%). Nine of 39 subjects with diarrhea were fed breast milk, 3 received breast milk exclusively at diarrhea

Table 4 Severity of dehydration, modalities of rehydration and clinical outcomes *n* (%)

onset. After diarrhea onset, breast milk was continued in 3 subjects, temporally withdrawn (24 h) in 2, and definitively suspended in 4 of 9 newborn.

The clinical outcomes of diarrhea are reported in Table 4. Three deaths were reported among the 39 subjects (7.7%). Patients affected by adenosine deaminase deficiency, CF, and Hirschsprung's disease died due to complications related to fatal systemic infections at 1, 12 and 7 mo of life, respectively.

DISCUSSION

This is the first systematic study describing diarrhea in patients hospitalized in the NICU in an industrialized country and outside outbreak conditions. The results of our investigation showed that, in this particular setting, diarrhea is a relatively uncommon but insidious condition underlying a broad spectrum of illnesses. The list of diseases and mechanisms responsible for diarrhea in neonates is large and the number of possible etiologies is higher when compared to older pediatric patients[7,13,18,19]. In recent years, new diseases have been described (i.e. enteric anendocrinosis), and more accurate knowledge about neonatal enteropathies has been obtained[5,20]. The pathophysiology of these conditions is extremely variable and requires a complex diagnostic work up in order to rapidly adopt adequate therapy. We believe that all these steps should be performed as a result of tight collaboration between the neonatologist, pediatric gastroenterologist, immunologist, geneticist, and nutritionist. The most common etiology identified in our patients was food allergy (FA). Recently, the International Study of Asthma and Allergies in Childhood reported an increase in allergic disease prevalence occurring in the younger pediatric age group[21]. 20.5% of neonates in our population had FA-related diarrhea, and none were adherent to the recommendations of the AAP for primary prevention of FA[8]. These data highlight the importance of a high index of suspicion for FA in neonates presenting with diarrhea, and the application of preventive strategies[8,22,23]. The most frequent infective etiology was *Rotavirus,* which represents the leading cause of infectious diarrhea in childhood[24]. All patients acquired *Rotavirus* infection during hospitalization. Considering that *Rotavirus* is implicated in up to 50% of nosocomial pediatric diarrheal episodes, our data further support the importance of accurate surveillance against the spread of infection in the NICU[24].

In this study we reported the lack of a univocal rehydration and re-feeding strategy for hospitalized newborn with diarrhea, indicating the necessity for further prospective studies to optimize therapeutic approaches. The vast majority of newborn patients with diarrhea were rehydrated by the enteral route and received enteral feeding within 4-6 h, without complications. Despite the fact that it is difficult to assess the efficacy of rehydration and re-feeding strategies in patients with such different disorders, our results suggest that the therapeutic strategies for diarrhea which are commonly adopted in older subjects, could also be successfully used in newborn hospitalized in the NICU. This is of particular importance because the available guidelines for diarrhea management are mainly focused on older pediatric patients[7,25,26].

To conclude, despite the limits derived from the retrospective design, our study showed that neonatal diarrheal diseases are challenging clinical conditions due to their heterogeneous etiologies and possible severe outcomes. We believe that this study will help neonatologists to prevent diarrhea from becoming a severe clinical condition, and to recognize and correctly manage rare chronic cases who need the assistance of a specialized team dedicated to their long-term treatment. Specific guidelines for the management of diarrheal disorders in neonates are advocated.

ACKNOWLEDGMENTS

COMMENTS

Background

Diarrhea represents a major condition responsible for pediatric mortality worldwide. The onset of neonatal diarrhea may rapidly lead to life threatening dehydration and malnutrition. Thus, early diagnosis and timely treatment are both crucial in the management of diarrhea in neonates. Clinical and epidemiologic studies defining severity and etiology are needed in order to improve diagnostic and therapeutic approaches for the management of neonatal diarrhea.

Research frontiers

This study showed that neonatal diarrheal diseases are challenging clinical conditions due to their heterogeneous etiology and possible severe outcomes. The list of diseases and mechanisms responsible for diarrhea in neonates is large and the number of possible etiologies is higher compared with older pediatric patients. Specific guidelines for the management of diarrheal disorders in neonates are advocated.

Innovations and breakthroughs

This is the first systematic study describing diarrhea in patients hospitalized in the neonatal intensive care unit in an industrialized country and outside outbreak conditions. The results of the authors' investigation showed that, in this particular setting, diarrhea is a relatively uncommon but insidious condition underlying a broad spectrum of illnesses.

Applications

This research opens the way for new investigations in the area of diarrheal diseases with neonatal onset. The authors believe that these studies will help neonatologists to prevent diarrhea from becoming a severe clinical condition, and to recognize and correctly manage rare chronic cases who need the assistance of a specialized team dedicated to their long-term treatment.

Terminology

A neonatal intensive care unit, usually abbreviated to NICU, is a unit of a hospital specializing in the care of ill or premature newborn infants.

Peer review

This well-written informative and innovative manuscript convincingly shows that neonatal diarrheal diseases are challenging clinical conditions because of the heterogeneous etiology and possible severe outcomes. This study will help neonatologists to prevent diarrhea from becoming a severe clinical condition.

Abstract

AIM: To retrospectively analyze the fields of application, diagnostic yields and findings of OMOM capsule endoscopy in Chinese patients.

METHODS: A database including 2400 Chinese patients who received OMOM capsule endoscopy in 27 endoscopy centers in China was retrieved from the Jianshan Science and Technology Ltd. OMOM capsule endoscopy database. The patient's age, gender, fields of application, the potentially relevant findings, pyloric transit time (PTT), small bowel transit time (SBTT), and complete small-bowel examination rate (CSER) were recorded and analyzed.

RESULTS: Two thousand four hundred patients aged 9-91 years (mean, 49 years), of whom 1510 were males (62.9%), underwent 2400 OMOM capsule endoscopy procedures. One thousand two hundred and thirty two (51.3%) were referred with obscure gastrointestinal bleeding (OGIB), 642 (26.8%) with abdominal pain, and 223 (9.3%) with chronic diarrhea. The overall diagnostic yield was 47.7% (1144/2400). The diagnostic yield of OMOM capsule endoscopy in OGIB subgroup was much higher than in the non-OGIB subgroup (62.4% *vs* 32.1%, $P < 0.001$). The most common findings of the small bowel in Chinese patients with OGIB were arteriovenous malformation (28.1%) and tumors (18.9%). There was no significant difference in the diagnostic yield between the male and female patients with OGIB. However, the diagnostic yield in patients aged more than 60 was higher than in patients aged less than 60 (69.8% *vs* 58.9%, $P < 0.001$). The median PTT was 41 min (range: 1-544 min) and the mean SBTT was 247.2 ± 88.9 min. The overall CSER was 86.8%.

CONCLUSION: The OMOM capsule endoscopy is a valuable tool for small bowel evaluation with good overall diagnostic yield and CSER.

Fields of applications, diagnostic yields and findings of OMOM capsule endoscopy in 2400 Chinese patients. *World J Gastroenterol* 2010; 16(21): 2669-2676 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i21/2669.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i21.2669

INTRODUCTION

Examination of the small bowel represented a challenge for physicians due to its length and inaccessibility before the capsule endoscope and double balloon enteroscope

were introduced. On the other hand, radiologic techniques are relatively insensitive for diminutive, flat, infiltrative or inflammatory lesions of the small bowel. The capsule endoscope has been developed for direct and complete examination of the small bowel in a safe, non-invasive and well-tolerated manner and it has become the main method in the diagnosis of suspected diseases of the small bowel[1,2]. Today there are several different types of capsule endoscope systems in use. The M2A or PillCam capsule endoscope (Given Imaging, Israel) is the first wireless endoscopy system, which was approved by the Food and Drug Administration in August 2001. It has been also the most widely used capsule endoscope system with over 750 000 capsule ingestions worldwide[3-5]. Another less well known wireless capsule endoscope system, the OMOM capsule endoscope, developed by Jianshan Science and Technology (Group) Co., Ltd., Chongqing, China, has been widely used in China and some areas of Southeast Asian and European countries. It was approved by the State Food and Drug Administration of the People's Republic of China in March, 2004. About 60 000 OMOM capsules have been ingested since 2004[6]. However, there are few published studies with large sample size that summarize the experience of its clinical application. In this study we reported the fields of application, diagnostic yields, findings, pyloric transit time (PTT), small bowel transit time (SBTT), and complete small-bowel examination rate (CSER) of OMOM capsule endoscopy in 2400 Chinese patients.

MATERIALS AND METHODS

Database and patients

A database including 2400 cases was retrospectively retrieved from the Jianshan Science and Technology Ltd. OMOM capsule endoscopy database. The 2400 cases were performed at 27 endoscopy centers that used the OMOM capsule system in China.

Obscure gastrointestinal bleeding (OGIB) is defined as documented bleeding from the gastrointestinal tract with no etiology identified after upper endoscopy and colonoscopy. Each patient's age, gender, filed date of application, the potentially relevant findings, PTT (defined as the recorded time of the first image of duodenum), and SBTT (defined as the time from the first duodenal image to the time of the first cecal image for patients in whom the capsule reached the cecum and the time from the first duodenal image to the time of the last small-bowel image for patients in whom the capsule did not reach the cecum) were recorded and analyzed. Complete small-bowel examination was considered when the cecum was visualized during capsule endoscopy. The CSER was defined as the percentage of patients with complete small-bowel examination.

The OMOM imaging system

The OMOM capsule endoscopy system consists of four main parts: a smart capsule, an image recorder jacket, a portable real-time monitor, and a computer workstation. The OMOM capsule has an outer diameter of 13 mm and length of 27.9 mm and it weighs 6 g. Pictures are generally taken at a rate of 2 frames/s, though the rate can be changed during the study, a unique feature of this capsule endoscope system. There are 14 receiver elements placed close to the surface of the abdomen and waist in the recorder jacket. The duration of the battery of the OMOM capsule is about 8 h, similar to the PillCam small bowel capsule. The OMOM capsule endoscope transmits the acquired images *via* a digital radio frequency communication channel to the recorder jacket. A real-time monitor allows the endoscopist to view progression of the capsule and even to send various commands to the OMOM capsule through the workstation. The image format (VGA: 640 × 480; QVGA: 320 × 240), sampling frequency (capture rate of 2 fps, 1 fps or 0.5 fps), flash intensity (1-31 levels), exposure controlling (auto or manual), white balance (auto or manual), and the conditions of capsule (sleep or wakeup) can be adjusted through these commands. The workstation reading can be done at 1, 2, 4, 6, 8, or 15 frames per screen.

Statistical analysis

Quantitative data were summarized by mean ± SD or as medians with ranges, and analyzed by the *t*-test if they were normally distributed, or by the Wilcoxon rank-sum test if they were not normally distributed. Categorical data were presented as a frequency (percentage) and analyzed by a χ^2 test. SPSS 13.0 software for Windows (SPSS Inc., Chicago, Illinois, USA) was used for the statistical analyses. A P value of < 0.05 was considered statistically significant.

RESULTS

Age, gender and fields of application

Two thousand four hundred patients aged 9 to 91 years (mean, 49 years), of whom 1510 were males (62.9%), underwent 2400 OMOM capsule endoscopy procedures. 1232 (51.3%) cases were performed for OGIB, 642 (26.8%) for abdominal pain, and 223 (9.3%) for chronic diarrhea. Other fields of application included health examination (103, 4.3%), suspected Crohn's disease (52, 2.2%), and iron deficiency anemia (34, 1.4%) (Table 1).

Diagnostic yields

OMOM capsule endoscopies were negative in 1256 patients, and the overall diagnostic yield in the 2400 Chinese patients was 47.7%. OMOM capsule endoscopies were negative in 463 patients with OGIB and 793 patients with non-OGIB, respectively. The diagnostic yield of OMOM capsules in the OGIB subgroup was greater than in the non-OGIB subgroup (62.4% *vs* 32.1%, $P < 0.001$). In patients with abdominal pain and chronic diarrhea, the diagnostic yields were 39.4%, and 14.3%, respectively, and both were lower than that of patients with OGIB (both $P < 0.001$) (Table 2).

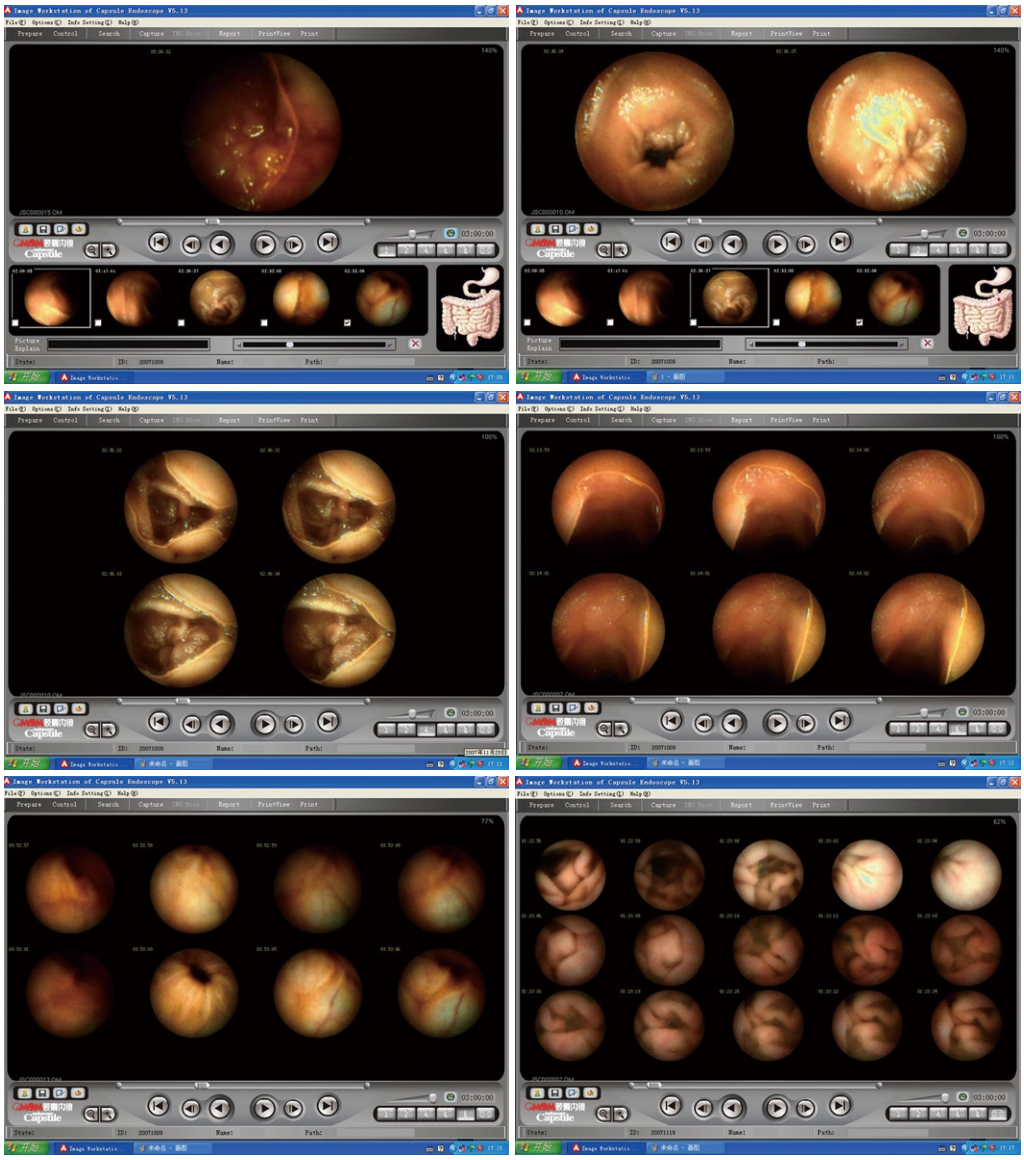

Figure 1 OMOM image workstation interfaces (1, 2, 4, 6, 8, or 15 frames per screen).

Table 1 Fields of application for OMOM capsule endoscopy in Chinese patients

Fields of application	*n* (%)
Obscure gastrointestinal bleeding	1232 (51.3)
Abdominal pain	642 (26.8)
Chronic diarrhea	223 (9.3)
Health examination	103 (4.3)
Suspected Crohn's disease	52 (2.2)
Iron deficiency anemia	34 (1.4)
Suspected tumors	25 (1.0)
Unexplained weight loss	19 (0.8)
Small intestinal polyposis	10 (0.4)
Ileus	10 (0.4)
Others	50 (2.0)
Total	2400 (100.0)

Findings in small bowel

Arteriovenous malformations were the most common finding, comprising 28.1% of 1144 patients with positive capsule endoscopy. The other common findings in the small bowel included tumor (216, 18.9%), polyp (119, 10.4%) and Crohn's disease (90, 7.9%). Small bowel parasites were also frequently found in 43 patients [*hookworm*, 26 (2.3%) and *lumbricoides*, 16 (1.4%)]. Celiac disease was rare in Chinese patients, accounting for only 0.6% (7) of the patients with positive capsule endoscopy (Figure 1).

In 1232 patients with OGIB, 769 potentially relevant lesions of the small bowel were seen on OMOM capsule endoscopy. The most common finding was arteriovenous malformations, which was seen in 313 patients (40.7%). The second most common finding in patients with OGIB was small intestinal tumors (201, 26.1%). The other common findings included small bowel ulcer (41, 5.3%), and polyps (24, 3.1%). Fifty seven patients (7.4%) had small intestinal active bleeding during the OMOM capsule endoscopy examinations. *Hookworm* and diverticulum were also causes for OGIB, and were seen in 26 (3.4%) and 18 (2.3%) patients. Interestingly,

[b]$P < 0.001$, diagnostic yield, age > 60 years *vs* age ⩽ 60 years.

duodenal ulcers were found in 38 (4.9%) patients with OGIB by OMOM capsule endoscopy. There was no significantly difference in the diagnostic yield between male and female patients with OGIB. However, the diagnostic yield in patients aged more than 60 was higher than patients aged less than 60 (69.8% *vs* 58.9%, $P < 0.001$). The proportions of arteriovenous malformations and small bowel tumors were not significantly different between the male and female patients, and the young and old patients (Table 3).

In 1168 patients with non-OGIB, only 375 lesions of small bowel were found (32.1%). The most common finding was polyps (95, 25.3%). Other common findings in the small bowel included Crohn's disease (67, 17.9%), mucosal erosions (63, 16.8%), and ulcer (48, 12.8%).

Table 4 Small bowel findings on OMOM capsule endoscopy in Chinese patients with abdominal pain and chronic diarrhea *n* (%)

	Abdominal pain subgroup	Chronic diarrhea subgroup
Sum	642 (100.0)	223 (100.0)

Lumbricoides	10 (4.0)	1 (3.1)
Tumor	4 (1.6)	1 (3.1)
Diverticulum	1 (0.4)	0 (0.0)
Celiac diseases	1 (0.4)	6 (18.8)
Others	10 (4.0)	3 (9.4)

In 642 patients with abdominal pain, 253 small intestinal lesions were found. Polyps, mucosal erosions, and ulcers were the most common findings, and were seen in 66, 60, and 39 patients, respectively. Eighteen patients with duodenal ulcer were also diagnosed on capsule endoscopy. Only four small intestinal tumors were found in those patients. In 223 patients with chronic diarrhea, only 32 (14.3%) small intestinal lesions were found. Polyps, celiac disease, and Crohn's disease were seen in 15, 6, and 4 patients, respectively. In 103 subjects who received capsule endoscopy for the purpose of health examination, only 27 lesions were found (23.6%). Moreover, 15 lesions outside the small bowel were found. Small bowel polyp, diverticulum, mucosal erosion, and tumor were found in 7, 2, 2, and 1 subjects, respectively (Tables 4 and 5). Figure 2 showed some representative small bowel images captured by the OMOM capsule endoscope.

PTT, SBTT and CSER

PTT and SBTT were recorded in 1876 and 1420 patients, respectively. The SBTT was normal distributed, while PTT was not. The median PTT was 41 min (ranging 1-544 min). The mean SBTT of the 1420 patients was 247.2 ± 88.9 min, ranging from 27 to 720 min. There was no statistically significant difference between the male and female patients in the median PTT [40 (1-544) min *vs* 41.5 (2-465) min, $P = 0.155$] and mean SBTT (246.6 ± 89.7 min *vs* 248.3 ± 87.5 min, $P = 0.720$). In the patients aged over 60, the median PTT was shorter, while mean SBTT was longer than patients aged less than 60 [32.5 (2-474) min *vs* 43.0 (1-544) min, $P = 0.004$; 258.9 ± 87.2 min *vs* 245.1 ± 89.1 min, $P = 0.034$]. PTT was shorter in patients with OGIB [40 (1-474) min *vs* 43 (1-544) min, $P < 0.001$], while SBTT was a little longer (252.9 ± 92.5 min *vs* 241.3 ± 84.8 min, $P = 0.014$) than patients without OGIB.

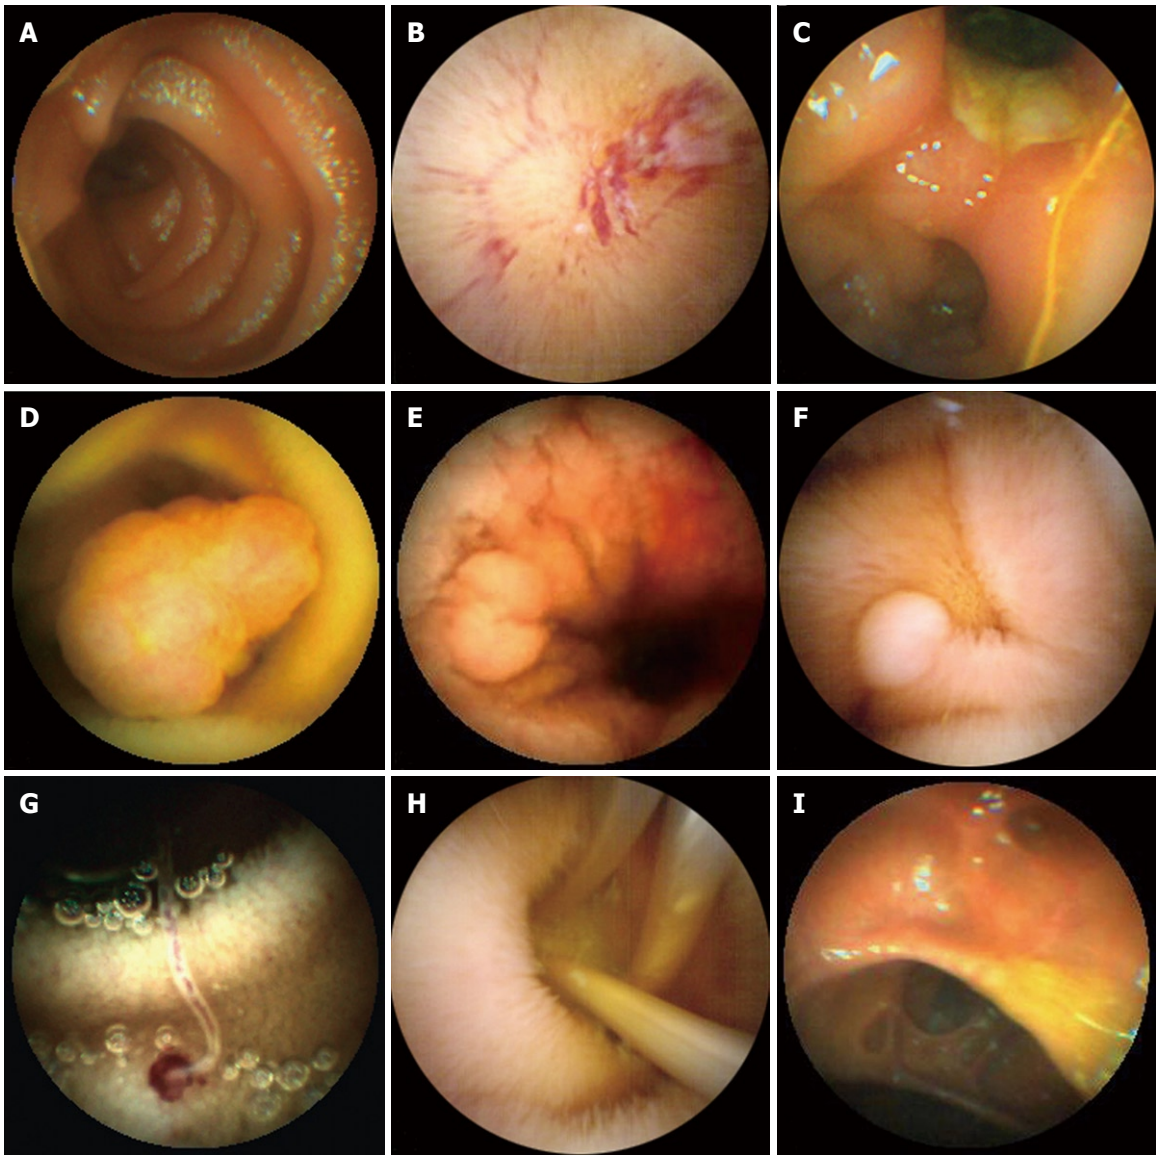

Figure 2 Small bowel images captured by the OMOM capsule endoscope. A: Normal small bowel mucosa; B: Angiectasias; C: Ulcer; D: Tumor; E: Crohn's disease; F: Polyp; G: *Hookworm*; H: *Lumbricoides*; I: Multiple diverticulum.

Table 5 Findings on OMOM capsule endoscopy in subjects for health examination *n* (%)

Findings	*n* (%)
Sum	103 (100.0)
Negative	76 (73.8)
Positive	27 (26.2)
Small intestinal polyp	7 (25.9)
Colonic polyp	4 (14.8)
Reflux esophagitis	3 (11.1)
Diverticula of colon	2 (7.4)
Duodenal ulcer	2 (7.4)
Small intestinal diverticula	2 (7.4)
Small intestinal mucosal erosion	2 (7.4)
Colonic ulcer	1 (3.7)
Duodenal diverticulum	1 (3.7)
Esophagopolypus	1 (3.7)
Gastric polyp	1 (3.7)
Small intestinal tumor	1 (3.7)

Two thousand and eighty two capsules reached cecums, and 318 capsules failed to reach cecums during the entire recording procedure. The overall CSER was 86.8%. In 318 patients with incomplete small-bowel examination, capsule endoscopies were negative in 140 patients. Crohn's disease (n = 41, 23.0%) and small bowel tumor (n = 40, 22.5%) were frequently found in the remaining 178 patients. Other findings included arteriovenous malformation and, ulcer. CSER was not significantly different between males (1321/1510, 87.5%) and females (761/890, 85.5%) (P = 0.171). CSER in patients aged over 60 was significantly lower than patients aged less than 60 (81.1% *vs* 87.9%, $P < 0.001$).

DISCUSSION

This was the first large report on a new wireless capsule

endoscopy system, OMOM, developed by Jianshan Science and Technology Ltd., Chongqing, China. Our study has showed that OMOM capsule endoscopy is a valuable tool for small bowel evaluation with good overall diagnostic yield and CSER. The diagnostic yield in the OGIB subgroup was much higher than in the non-OGIB subgroup. Arteriovenous malformations and tumors of the small bowel were the most common causes in Chinese patients with OGIB.

The OMOM capsule is widely used in China and some areas of Asian and European countries. The OMOM capsule is slightly larger and heavier than the Given Imaging PillCam small bowel capsule. The duration of the battery of the OMOM capsule is about 8 h, similar to the PillCam small bowel capsule. Two unique features of the OMOM capsule system are real-time viewing and workstation-to-capsule command controlling capabilities[7]. However, there has been no reported comparison in the literature of the diagnostic yields of the two different capsule endoscope systems. The details and comparison with the available other capsule (i.e. PillCam), including the cost comparision, are shown in Table 6.

The most common applications for capsule endoscopy include evaluation for OGIB - including iron deficiency anemia, suspected Crohn's disease, suspected small intestinal tumors and surveillance in patients with polyposis syndromes, suspected or refractory malabsorptive syndromes (e.g. celiac disease)[3]. There is not yet consensus on indicated applications of capsule endoscopy from the Chinese Society of Digestive Endoscopy. In this study, though the most common indication for OMOM capsule endoscopy in Chinese patients was OGIB, many patients with abdominal pain and chronic diarrhea, even some healthy individuals, underwent OMOM capsule endoscopy. The study by Fry *et al*[8] suggested that capsule endoscopy had a low yield for evaluation of abdominal pain or chronic diarrhea and cannot be recommended as a first-line test without further study. Our study also found that the diagnostic yields by OMOM capsules in those patients were very low. Though the yields were a little higher than previous studies[8,9], it is unknown whether the findings of the small bowel in those patients were the potential relevant causes of abdominal pain or chronic diarrhea. Moreover, in the 103 patients who underwent health examination by OMOM capsule endoscopy, only 12 lesions of the small bowel were found. Strict patient selection on the basis of such symptoms or signs was the key to increasing the yield of capsule endoscopy. Small bowel capsule endoscopy is not recommended as a tool for health examination.

The yield of capsule endoscopy in OGIB in published reports ranges from 30% to 92%, depending on the definition of positive findings and the type of bleeding investigated[10]. In our study with more than 2000 cases that underwent OMOM capsule endoscopy, the data showed that overall yield of the OMOM capsule was nearly 50% in this patient group. This yield was similar to previous studies on PillCam small bowel capsule endoscopy[11]. The yield of the OMOM capsule endoscope in the OGIB subgroup was 62.4%, and was comparable with other published series using PillCam small bowel capsule endoscopy[12-15]. However, not all endoscopy centers in China had push enteroscopy and the database did not include the information on all investigations before capsule endoscopy. We also found the yield in the OGIB subgroup was greater than that in the non-OGIB subgroup, again suggesting that OGIB is the most important indication for capsule endoscopy and the OMOM capsule system probably has similar performance characteristics as those of the PillCam capsule system. Furthermore, we found that there was no significantly difference in the diagnostic yield between male and female patients with OGIB. We also found that the diagnostic yield in patients aged more than 60 was higher than patients aged less than 60. The proportions of arteriovenous malformations and small bowel tumors were not significantly different between young and old patients, which was different with the previous results by Papadopoulos *et al*[16]. Papadopoulos *et al*[16] found that older patients had significantly less erosions and normal studies, but they had more angiodysplasias. Our study showed that, in Chinese patients, the causes of OGIB were not significantly different between male and female patients, and young and old patients.

It is reported that arteriovenous malformations of the small bowel comprise over 60% of the lesions found on capsule endoscopy[12]. However, the percentage of arteriovenous malformations in this study was much lower than previous studies[14,17]. The second most common finding in Chinese patients with OGIB was small bowel tumors. Another Chinese study on double balloon enteroscopy also showed that the most common abnormalities in Chinese patients with OGIB were small bowel tumors (39.1%) and angioectasia (30.4%)[18]. The data suggested that the spectrum of causes of small bowel bleeding might be different between Chinese people and

Western countries populations. Interestingly, *hookworm* was seen in 26 Chinese patients with OGIB, comprising 3.4% of the positive findings in patients with OGIB. We also found that there were only six published case reports on *hookworm*-induced small intestinal bleeding on capsule endoscopy to date[19-24], and four out of six articles were from Asia. *Hookworm* infestation rate in Asian patients is probably higher than Western patients, but to prove this, further larger study is needed.

The incidence of Crohn's disease in Chinese population is increasing[25]. A bibliometrics study also suggested that the incidence and prevalence rates of Crohn's disease were still lower than those in Western and other industrialized Asian countries, but these rates have been increasing rapidly[26]. In a prior study, capsule endoscopy yielded a diagnosis of Crohn's disease only in a very small percentage of the patients (0% to 4%)[27]. In the present study, 90 patients with Crohn's disease were diagnosed by OMOM capsule endoscopy, suggesting that this disease is probably no longer uncommon in Chinese people.

Celiac disease is a gluten-dependent enteropathy, characterized by chronic small bowel inflammation and mucosal atrophy. Celiac disease is a common medical condition with an estimated prevalence of 1:100 in the general Western population[28]. Abdominal pain, chronic diarrhea, growth failure and malabsorption are its typical clinical presentation[29]. Preliminary reports suggest that capsule endoscopy could represent an attractive and non-invasive diagnostic tool in patients with suspected celiac disease[30,31]. However, our study showed that the prevalence of celiac disease in the Chinese patients who underwent capsule endoscopy was very low (7/2400, 0.3%). Up till now, there is no study which has reported on the prevalence of celiac disease in a general Eastern population.

Although the PTT and SBTT were not recorded in all 2400 patients, we found those values were similar to previous studies used Given Imaging capsule endoscopy[32]. The overall CSER of OMOM capsule endoscopy was 86.8%, which was a little higher than Given Imaging capsule endoscopy (83.5%)[33]. Previous studies[34,35] have shown that the real-time viewer of the Olympus Endocapsule is very useful for determining a need for detecting gastric transit abnormalities and necessary intervention. The real-time viewer of OMOM capsule endoscopy may help to secure the passage of the capsule endoscope into the small bowel and hence increase the rate of complete small bowel examination. Many centers in China use the real-time viewer of the OMOM capsule endoscopy system and the CSER can be increased in some patients, but real-time viewing is sometime time-consuming, and some patients cannot wait for long in the endoscopy center.

Though the sample size was large, there were some limitations in our study. Firstly, many Chinese capsule endoscopists reported mucosal erosions of the small bowel, but further definitive categorization of such lesions was not clear. Secondly, the follow-up results of patients with positive findings by OMOM capsule were unknown; the positive findings of Crohn's disease, celiac disease and tumor were not confirmed by biopsy, and the diagnostic yield may be overestimated.

In conclusion, this was the largest report on clinical application of the OMOM capsule endoscope system in Chinese patients. OMOM capsule endoscopy is a valuable tool for small bowel evaluation with good overall diagnostic yield and CSER. The yield in OGIB subgroup was much higher than in the non-OGIB subgroup. Arteriovenous malformations and tumors of small bowel were the most common causes in Chinese patients with OGIB.

ACKNOWLEDGMENTS

The authors thank the Jianshan Science and Technology (Group) Co., Ltd., Chongqing, China for providing the data of OMOM capsule endoscopy.

COMMENTS

Background

The OMOM capsule endoscope, developed by Jianshan Science and Technology (Group) Co., Ltd., Chongqing, China, has been widely used in China and some areas of Southeast Asian and European countries. However, there are few published studies with large sample size that summarize the experience of its clinical application.

Research frontiers

The capsule endoscope has been developed for direct and complete examination of the small bowel in a safe, noninvasive and well-tolerated manner; and it has become the main method in the diagnosis of suspected diseases of the small bowel.

Innovations and breakthroughs

This was the first large report on a new wireless capsule endoscopy system, OMOM, developed by Jianshan Science and Technology Ltd., Chongqing, China. This study has showed that OMOM capsule endoscopy is a valuable tool for small bowel evaluation with good overall diagnostic yield and complete small-bowel examination rate (CSER). The diagnostic yield in the obscure gastrointestinal bleeding (OGIB) subgroup was much higher than in the non-OGIB subgroup. Arteriovenous malformations and tumors of the small bowel were the most common causes in Chinese patients with OGIB.

Applications

OMOM capsule endoscopy is a valuable tool for small bowel evaluation with good overall diagnostic yield and CSER.

Terminology

Pyloric transit time: the recorded time of the first image of duodenum; small bowel transit time: the time from the first duodenal image to the time of the first cecal image for patients in whom the capsule reached the cecum and the time from the first duodenal image to the time of the last small-bowel image for patients in whom the capsule did not reach the cecum; CSER: the percentage of patients with complete small-bowel examination; OGIB: documented bleeding from the gastrointestinal tract with no etiology identified after upper endoscopy and colonoscopy.

Peer review

It is a nice paper about the use of a locally manufactured capsule. The authors should mention that this is a retrospective study. A bit more of the details and a comparison with the available other capsules (Pillcam) should be made. A cost comparison is also important.

Abstract

AIM: To analyze the clinical and imaging features of the small intestinal lipomas and to evaluate the diagnostic value of multi-slice computed tomography (CT) enterography.

METHODS: Fourteen cases (one had two intestinal lesions) of surgically confirmed lipomas of the small intestine were retrospectively analyzed. The location, size, clinical and radiological aspects were discussed.

RESULTS: Twelve patients presented with abdominal pain, of whom three complained of paroxysmal colic. Melena or bloody stools was mentioned in five cases. One lesion was detected incidentally during routine physical examination. One lesion was found unexpectedly during the preoperational evaluation for cholecystitis. Examination of the abdomen revealed palpable masses in four cases. Precontrast CT scan showed round or oval well-defined hypo-intense intraluminal masses with the attenuation ranging from -130 HU to -60 HU. On contrast enhancement CT scan, no striking enhancement was seen.

CONCLUSION: The small intestinal lipomas are rare and difficult to diagnose merely based on clinical manifestations, while the characteristic features at small intestinal CT enterography can help establish reliable prospective diagnoses.

INTRODUCTION

Primary small intestinal tumors are uncommon, which account for about 1% of all gastrointestinal tumors, and primary lipomas of the small intestine are rare[1-5]. Preoperative diagnosis is usually indeterminate only based on clinical manifestations due to the overlap of symptoms and signs with other intestinal tumors. Benign tumors in the small intestine do not have a characteristic computed tomography (CT) appearance and, in most instances,

cannot be differentiated from malignant lesions, but lipomas can be definitively diagnosed by the recognition of fat attenuation within the mass[1]. To the best of our knowledge, only case reports of small bowel lipoma were presented in the literature[1-4]. Herein we present 15 surgically confirmed small intestinal lipomas and analyze retrospectively their clinical, pathological and imaging findings, especially multi-slice CT enterography.

MATERIALS AND METHODS

General data

The institutional review board approved this retrospective study and waived the need to obtain patient consent. Fourteen patients (one had two intestinal lesions) treated at three hospitals (Sir Run Run Shaw Hospital; First Affiliated Hospital, Zhejiang University School of Medicine and Zhejiang Provincial People's Hospital, China) from May 1994 to June 2009 were enrolled. All patients (four women and ten men; age range, 19-82 years; mean age, 63.2 years) with pathologically confirmed lipoma underwent 16-detector row CT enterography before surgery.

Clinical manifestations

Melena or bloody stools was mentioned in five cases. Fecal occult blood test was positive in nine cases and negative in the other five cases. No significant abnormality was found in blood biochemical tests. Twelve patients presented with abdominal pain, three of them complained of paroxysmal colic and were subsequently found to have intestinal obstruction secondary to intussusception. They denied vomiting, fever, or chills. One lesion was detected incidentally during routine physical examination. One lesion was found unexpectedly during the preoperational investigation for cholecystitis. Physical examination of the abdomen revealed palpable masses in four cases.

RESULTS

Fourteen patients had confirmed small intestinal lipomas (Figures 1-3), including one who had two intestinal lesions. Four of the 15 tumors occurred in the duodenum, three in the jejunum, and eight in the ileum (Figures 1-3).

The size of the lesions ranged from 2 cm × 1.5 cm × 1.1 cm to 6.3 cm × 4.5 cm × 2 cm (mean, 3.9 cm × 2.8 cm × 2.3 cm). The tumors were round or oval (Figures 1-3) and three were pedunculated in shape.

Precontrast CT scan showed round or oval well-circumscribed hypo-intense intraluminal masses with the attenuation ranging from -130 HU to -60 HU (Figure 2). Eleven of the 15 tumors were homogeneous, while the remaining four were heterogeneous with several streak septa. No enhancement after intravenous contrast material administration (Figures 1-3) was found in all the lesions, except the streak septa which was enhanced minimally. Small intestinal CT enterography demonstrated the typical "target" appearance (Figure 1) as intestinal intussusception in three cases. Except one of the three patients with intussusception, all other 13 patients had a definitive preoperative diagnosis of lipomas by the CT enterography, which were confirmed by subsequent surgical pathology.

At laparotomy, a jejunojejunal or ileoileac intussusception (Figures 1 and 3) was present in three cases. One patient had two separated submucosal lipomas. All tumors were defined to originate from the submucosal layer. Grossly they had a clear margin and yellow section surface. Microscopically (Figure 1D), they were composed of mature adipose cells, nine tumors had overlying necrosis and ulceration, and four showed inflammatory fibrous hyperplasia with septa formation extending in the adipose tissue.

DISCUSSION

Tumors of small intestine account for only 1%-2% of all gastrointestinal tumors, and benign tumors account for approximately 30% of all small intestinal tumors[6]. Gastrointestinal stromal tumors are the most common symptomatic benign tumors of the small bowel, while the lipomas are rare benign tumors, representing 2.6% of non-malignant tumors of the intestinal tract[2].

Pathology

Lipomas are often single submucosal intraluminal masses, with intensely yellow color in the mucosa because of the underlying accumulated fat. They usually appear as a capsulated round or oval yellowish mass protruding into the intestinal lumen. Sometimes there is overlying ulceration of the mucosa[7-10].

Clinical manifestations

Small bowel lipomas tend to occur in the elderly, and the sixth to seventh decades of life are considered to be the most risky period[3,11,12]. Jejunum and ileum, especially the terminal ileum, are common locations. Eleven of the 15 lesions arose from jejunoileum and the mean age of the patients was 63.2 years in this study, which was consistent with those previously reported. Patients may be completely asymptomatic with small lipomas (< 1 cm), which are usually detected incidentally. Larger tumors may produce symptoms as follows.

Paroxysmal abdominal pain: About 75% patients present with abdominal pain in different degree. Twelve of the 14 patients in this study complained of abdominal pain and 3 suffered from severe colic due to intussusception. Tumor traction, peristalsis disorder, intestinal obstruction, tumor necrosis or secondary infection may result in abdominal pain while the intestinal obstruction due to lipomas is usually characterized clinically by recurrent severe abdominal pain with increased bowel sound and locally palpable round or oval masses. Lesions greater than 4cm in diameter have a greater likelihood of introducing bowel intussusception, and submucosal or subserosal lipomas also tend to cause intussusception[7,13-15]. Large subserosal tumors are prone to result in intestinal compression and volvulus.

Hemorrhage of digestive tract: Approximately 25% of

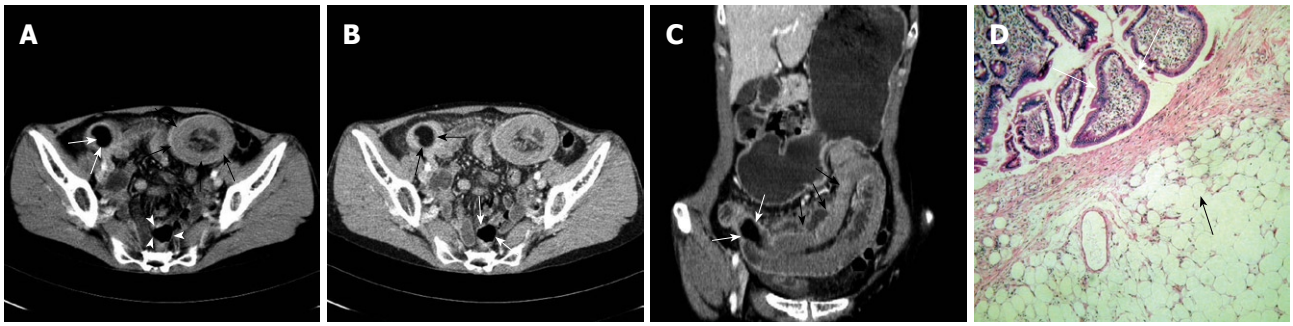

Figure 1 A lipoma of the ileum in a 56-year-old woman. A: Intussusception (black arrows) secondary to a lipoma. On transverse enhanced computed tomography (CT) scan, a well-defined hypo-attenuating mass (white arrows) is revealed with no enhancement, but it is difficult to differentiate the tumor from the intraluminal gas (arrowheads); B: The same level image with Figure 1A. It is easy to differentiate the lipoma (black arrows) from the intraluminal gas (white arrows) with regulated image windows; C: Small intestinal two-dimensional (2D) CT enterography shows ileoileac intussusception (white arrows) secondary to a lipoma (black arrows); D: Photomicrograph reveals the lipoma (black arrow) in the submucosal layer, the intestinal normal mucous membrane is also seen (white arrows) (HE, × 40).

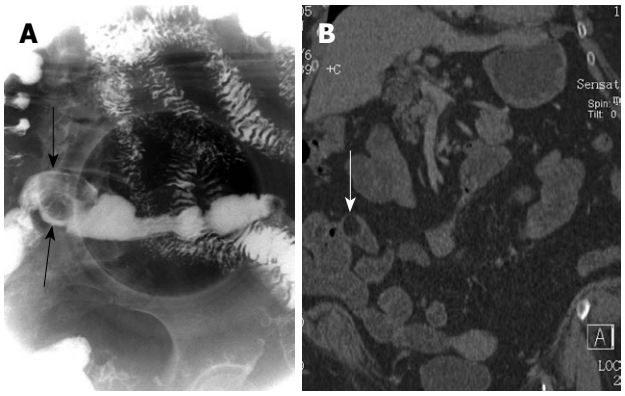

Figure 2 A lipoma of the ileum in a 70-year-old woman. A: Gastrointestinal barium examination shows an oval well-circumscribed intraluminal mass in the ileum (black arrows); B: Small intestinal 2D CT enterography reveals oval well-circumscribed hypo-intense (-89 HU) intraluminal mass (white arrow) in the ileum.

Figure 3 A lipoma of the ileum in a 59-year-old woman. Small intestinal 2D CT enterography showing intussusception secondary to a lipoma (white arrow).

patients with benign intestinal neoplasm have alimentary tract hemorrhage. Small bowel lipomas usually cause lower gastrointestinal hemorrhage, and lipomas arising from duodenum may cause upper gastrointestinal hemorrhage and symptoms like peptic ulcer. Some of the bleeding is intermittent, some is continuous in small amount or only presents as microscopically positive fecal occult blood. Melena or bloody stools was mentioned in five cases and fecal occult blood test was positive in nine cases in this study.

Abdominal masses: Large lipomas may be palpable as soft, lobulated and movable abdominal masses without tenderness. Of the 4 patients who had palpable masses in this study, three were ill-defined with tenderness, possibly due to the intestinal intussusception.

Other reported clinical symptoms include nausea, vomiting, constipation, diarrhea and abdominal distention. Pedunculated submucosal lipomas may ablate spontaneously and discharged from anus when there are volvulus and necrosis.

Diagnosis

Preoperative diagnosis of the small intestinal lipomas is mainly established by means of endoscopic and radiologic evaluations. The duodenal lipomas are endoscopically characterized by: (1) "tenting sign", implying that the mucosa can be pulled from the lesion with biopsy forceps on endoscopy; and (2) "cushion sign", implying spongy consistency of the lesion when indented with biopsy forceps and yellowish change of the mucosa from normal pink appearance for the compression of the vessels, representing the underlying lipoma[16].

The diagnosis of the jejunoileal lipomas mainly depends on the imaging modalities as follows.

The role of abdominal conventional radiographs for the evaluation of lipomas is limited. Mechanic intestinal obstruction or low density of the lipid is occasionally seen[17]. Abdominal X-ray films of two patients in our series revealed small bowel obstruction but failed to suggest the primary disease.

Double-contrast barium study, especially small bowel enema, may be helpful for the lipomas evaluation. The tumor commonly presents as round, oval or lobulated well-circumscribed intraluminal filling defect (Figure 2A), with so-called "squeeze sign" in which the shape of the mass changes as a consequence of peristalsis or manual pressure[3]. Some pedunculated tumors are movable and may change their locations in response to position or palpitation. There is also so-called "bull's-eye sign" signifying a niche formation in the radiolucent filling defect due to ulceration. The intestinal peristalsis remains normal and the mucosa is intact. However, barium study still has limitations in many aspects including: (1) overlap of the

intestinal loops, which makes unsatisfactory display and may result in misdiagnosis; (2) difficult differentiation from other tumors which also present as filling defects; (3) disability to detect small lipomas; and (4) contraindication in patients accompanying intestinal obstruction or intussusception.

Ultrasound may detect large lipomas of the small intestine as hyper- or hypo-echoic masses, or irregular sausage-shaped masses, of which the inner central part is hyper-echoic and the peripheral area is hypo-echoic representing intestinal intussusception[15,17]. However, the role of ultrasound is also limited greatly because of the noise interference caused by the intraluminal gas. Ultrasound examination of the two cases of our series both failed to establish a correct diagnosis.

Abdominal CT scans are considered to be the most definitive diagnostic measure of recognizing small bowel lipomas[1,3,11,15]. With the fast volume scan technique of multiple spiral CT, reformation in any dimensions is feasible, and the quality of the reformatted images is almost as same as the axial ones, which ensures a good overall observation. The finding of lipid attenuation (-100 to -50 HU) is vital to the diagnosis of a lipoma[17,18]. CT examination revealed lipid-attenuated (-130 to -60 HU) intraluminal masses in all patients of our series (Figure 2B), the location and range of the tumors and the accompanying intussusception were also displayed clearly and directly on the two-dimensional (2D) CT enterography (Figure 1C and Figure 3), which helped establish a correct prospective diagnosis. For the other misdiagnosed cases, postoperational recognization of the reformatted CT images with regulated windows still retrospectively showed the tumor existence. It is important to stress that adequate oral contrast media is necessary for filling the small bowel and optimal windows is also needed to avoid mistaking lipomas for intraluminal gas. Observation of the images reformatted in multiple dimensions is helpful in differentiation lipomas from invaginated mesenteric fat when there is an intestinal intussusception.

The role of MR imaging in the evaluation of small bowel lesions is limited due to the lack of effective intestinal contrast media and the presence of motion artifact caused by relatively long scanning time and intestinal peristalsis. With new MR machine, advanced fast scan techniques, fat-saturation imaging and gadolinium chelates application, the resolution of MR images has improved, the clinical and research application on intestinal diseases has increased over recent years, nevertheless there are still few reports in the literature about MR imaging of small bowel lipomas[19,20].

Clinical manifestation is not specific for this rare entity, imaging modalities are helpful for revealing small bowel lipomas, especially the characteristic features at multi-slice CT enterography can be used by the radiologists to establish a definitive diagnosis before operation for most cases. In the instances of secondary intestinal intussusception or obstruction, the primary lesion of a lipoma should be carefully searched out.

COMMENTS

Background

Lipomas are benign tumors and may arise from any anatomic location, subcutaneous tissue is the most common site, while lipomas of the alimentary tract especially of the small intestine are rare entities. According to the authors of this paper, only case reports of small bowel lipoma have been presented in the literature.

Research frontiers

Primary small bowel tumors are uncommon, which account for about 1% of all gastrointestinal tumors, and primary lipomas of the small intestine are rare. Preoperative diagnosis is usually indeterminate only based on clinical manifestations due to the overlap of symptoms and signs with other intestinal tumors. Benign tumors in the small intestine do not have a characteristic computed tomography (CT) appearance and, in most instances, cannot be differentiated from malignant lesions, but lipomas can be definitively diagnosed by the recognition of fat attenuation within the mass.

Innovations and breakthroughs

The authors presented 15 surgically confirmed small intestinal lipomas and analyzed retrospectively their clinical, pathological and imaging findings, especially multi-slice CT enterography.

Applications

Clinical manifestation is not specific for the small intestinal lipomas, imaging modalities are helpful for revealing small bowel lipomas, especially the multi-slice CT enterography which can be used by the radiologists to establish a definitive diagnosis before operation for most cases.

Terminology

Small bowel lipomas tend to occur in the elderly, and the sixth to seventh decades of life are considered to be the most risky period. Multi-slice CT enterography (MCTE): MCTE is a new non-invasive procedure that uses very fast CT scanning combined with liquid intake to obtain detailed images of the abdomen. CT enterography has several advantages over conventional bowel imaging: it shows the entire thickness of the bowel wall; it is able to image all of the long loops of the small intestine; and it can also evaluate surrounding mesentery and fat tissues. CT enterography has also become an important alternative to traditional fluoroscopy in the assessment of other small bowel disorders such as celiac sprue and small bowel neoplasms.

Peer review

The authors present 15 surgically confirmed small intestinal lipomas and analyze retrospectively their clinical, pathological and imaging findings.

Abstract

AIM: To retrospectively investigate microsurgical hepatic artery (HA) reconstruction and management of hepatic thrombosis in adult-to-adult living donor liver transplantation (A-A LDLT).

METHODS: From January 2001 to September 2009, 182 recipients with end-stage liver disease underwent A-A LDLT. Ten of these patients received dual grafts. The 157 men and 25 women had an age range of 18 to 68 years (mean age, 42 years). Microsurgical techniques and running sutures with back-wall first techniques were performed in all arterial reconstructions under surgical loupes (3.5 ×) by a group of vascular surgeons. Intimal dissections were resolved by interposition of the great saphenous vein (GSV) between the donor right hepatic artery (RHA) and recipient common HA (3 cases) or abdominal aorta (AA) (2 cases), by interposition of cryopreserved iliac vessels between the donor RHA and recipient AA (2 cases).

RESULTS: In the 58 incipient patients in this series, hepatic arterial thrombosis (HAT) was encountered in 4 patients, and was not observed in 124 consecutive cases (total 192 grafts, major incidence, 2.08%). All cases of HAT were suspected by routine color Doppler ultrasonographic examination and confirmed by contrast-enhanced ultrasound and hepatic angiography. Of these cases of HAT, two occurred on the 1st and 7th d, respectively, following A-A LDLT, and were immediately revascularized with GSV between the graft and recipient AA. HAT in one patient occurred on the 46th postoperative day with no symptoms, and the remaining case of HAT occurred on the 3rd d following A-A LDLT, and was cured by thrombolytic therapy combined with an anticoagulant but died of multiorgan failure on the 36th d after A-A LDLT. No deaths were related to HAT.

CONCLUSION: Applying microsurgical techniques and selecting an appropriate anastomotic artery for HA reconstruction are crucial in reducing the high risk of HAT during A-A LDLT.

INTRODUCTION

In the face of a constant shortage of cadaveric livers and the increasing size of the transplantation waiting list, living donor liver transplantation (LDLT) has become an accepted therapy for many patients with end-stage liver disease. However, despite improvements in LDLT, vascular complications related to the small diameter of the vessels in the partial liver graft and complex arterial reconstruction remain an important cause of morbidity and mortality[1-3]. Hepatic artery thrombosis (HAT), which is the most common vascular complication after LDLT, can result in graft loss associated with septic hepatic infarction and bile duct ischemia[4,5]. The incidence of HAT after LDLT varies widely, with a reported frequency of 4%-25%[6-10].

Retransplantation used to be an option for the treatment of HAT[11]. However, retransplantation is limited by both organ availability and the patient's condition. Urgent revascularization with thrombectomy or revision of anastomosis with thrombectomy has been successful in some patients with an early diagnosis[8,9]. Color Doppler ultrasonography[12] and contrast-enhanced ultrasound (CEUS)[13] have provided an accurate noninvasive method for the detection of HAT before nonreversible ischemic damage of the graft occurs.

The application of microsurgical techniques in arterial reconstruction has helped overcome the high risk of HAT following liver transplantation, and the effectiveness of this method has been demonstrated in numerous reports[14-17]. Because of the short donor hepatic artery (HA) stump which is small in diameter and vessel size discrepancy between the graft and recipient hepatic arteries, reconstruction of hepatic arteries is a challenge to surgeons in LDLT.

To outline our experience in hepatic reconstruction and the management of HAT after adult-to-adult living donor liver transplantation (A-A LDLT), the clinical data of patients with end-stage liver disease who underwent A-A LDLT at our center, were retrospectively reviewed.

MATERIALS AND METHODS

Recipients

From January 2001 to September 2009, we performed 182 consecutive A-A LDLTs in adult recipients with a mean age of 42 years (157 men and 25 women, aged 18 to 69 years) suffering from end-stage liver disease. Informed consent from both donor and recipient and the approval of the Ethics Committee of West China Hospital of Sichuan University were obtained. Of these cases, 10 recipients underwent dual graft liver transplantation.

FIF: Fulminant liver failure; DI IBS: Diffuse ischemic intrahepatic biliary stenosis; MELD: Model for end-stage liver disease.

In addition to dual graft A-A LDLT, 170 recipients received right grafts (right lobe without MHV, 160; right lobe with MHV, 10), 2 recipients received left grafts (extended left lateral segment, 1; left lobe without MHV, 1). The pre-transplant condition of the recipients was evaluated by the modified model for end-stage liver disease scores which has been documented to better predict the prognosis of patients[18]. The details of recipients and the diagnostic indications for A-A LDLT are summarized in Table 1. All these patients underwent emergency A-A LDLT.

Donors

There were 190 donors, including 110 men and 80 women, with an age range of 19-65 years (mean age, 35 years). Details of the dual donors are described in Table 2. The donors and recipients were blood group identical in 151 cases and compatible in 31 cases. All donors in this group voluntarily donated part of their liver following informed consent.

Preoperative evaluation of donors and recipients

Physical examination and retrospective analysis of both donors' and recipients' medical records were performed before surgery. Hepatitis, syphilis, HIV, Epstein-Barr virus, cytomegalovirus, and tuberculosis infection constituted ineligibility as a potential donor. We did not use routine HA angiography to study the tracks and variations of the HA, but used computed tomographic arteriography (CTA) instead. The volume of the total

liver and right lobe were evaluated and calculated with 3-dimensional computed tomography. Graft mass to recipient body weight ratio (GRWR) of 0.8%[20] or graft volume to recipient standard liver volume ratio of 40%[21] and donor remnant liver volume of 35%[22] were required for recipient and donor safety assurance.

Donor surgery and back table

The detailed surgical technique was as previously reported[23]. The partial graft liver was harvested without vascular flow occlusion and without graft manipulation to maintain graft viability. The HA and portal vein (PV) were individually exposed and carefully divided, during hilar dissection. In right grafts, the right hepatic artery (RHA) was identified and isolated to the right side of the hepatic duct. In left grafts, the proper hepatic artery (PHA) was isolated up to the bifurcation of the left hepatic artery (LHA) and the RHA. We preserved the length of the arteries as much as possible and cut the RHA or LHA with sharp scissors or a microvascular appliance to avoid injury to the arterial intima and intimal dissection.

All grafts were placed into a container filled with 4℃ University of Wisconsin (UW) solution, then removed to the back table. On the back table, we perfused the grafts from the PV with UW solution, rinsed the biliary tracts and flushed arterial ducts with heparin solution. All procedures mentioned below were performed by vascular surgeons. Plasty of the hepatic vein and PV was performed to make a single orifice for each. We anastomosed the great saphenous vein (GSV) from the recipient or cryopreserved vessels to the crassitude tributaries of the MHV (diameter, > 5 mm). We inspected the graft arteries to detect whether intimal injures and dissection existed. When the graft arterial stump was shorter than 1 cm, we anastomosed the inverse GSV from the recipient to the graft arterial stump to prolong the stump and interposed the GSV between the graft artery and recipient artery. The graft HA including the origins of multiple tiny arteries was reshaped to achieve a single orifice of adequate diameter at the back table.

Recipient surgery

The procedure was performed following the routine procedures of our hospital[24,25]. All recipient hepatic arteries were isolated toward their insertion sites into the hepatic parenchyma. After removal of the recipient liver, the stump of the recipient HA was meticulously preserved for as long as possible. The implanted graft was reperfused after reconstructing both the hepatic and PVs. Thereafter, one group of vascular surgeons performed all the microvascular reconstructions of the HA. Hepatic arterial reconstruction was performed using microvascular techniques with (3.5 ×) surgical loupes, after adoption of systemic anticoagulation (heparin, 62.5 U/kg, intravenous, 5 min before anastomosis). Low dose heparin did not cause any remarkable adverse effects in our study. We used running 8-0 or 9-0 monofilament polypropylene (Prolene; Ethicon Inc.) sutures for the HA anastomosis depending on the arterial diameter. During running sutures, the assistant vascular surgeon persistently and delicately stretched the stitch to ensure intimal eversion, and the vascular surgeon could see the arterial lumen after each stitch. According to the amount of inflow, stump location and matching of diameters, the most appropriate inflow artery was selected. In all cases, end-to-end vessel anastomosis was carried out between the recipient and graft HA, and the back wall-first microsurgical anastomosis technique which avoided vessel twisting during suturing was applied. In the case of a hepatic graft with multiple stumps, we tried to reconstruct all of the stumps. The dominant HA was reconstructed first. If there was sufficient back bleeding, the other arterial stumps were ligated. If there was only weak back bleeding, we always reconstructed the stumps. The patency of the arterial anastomosis was evaluated by intraoperative Doppler ultrasonography.

In dual graft patients, the RHA of the graft was anastomosed to the RHA of the recipient to reconstruct the RHA. Finally, the living or cadaveric left lateral segment was orthotopically implanted to the left lobe position of the recipient, followed sequentially by end-to-end anastomosis. The primary candidates of the recipient HAs for reconstruction were the RHA, LHA, and PHA. There were 192 anastomoses in all A-A LDLTs. Details of the recipient arteries are described in Table 3. The caliber difference between the graft artery and the recipient artery was resolved by cutting the smaller artery obliquely. Because of recipient HAs intimal dissection, these arteries were not suitable for HA reconstructions, and interposition bypass using GSV was performed between the donor RHA and recipient common hepatic artery (CHA) in 3 cases. Bypass was performed between the donor RHA and recipient abdominal aorta (AA) using GSV in 2 patients and cryopreserved cadaveric iliac vessels in 2 cases. The gastroduodenal artery was not ligated to increase the blood flow through the anastomosis. Administration of alprostadil (20 μg) to maintain artery patency was used in all cases after the completion of hepatic arterial reconstruction.

Table 3 Details of hepatic arteries (n = 192)

	n (%)
RHA	62 (32.29)
LHA	20 (10.42)
PHA	90 (46.88)
CHA	14 (7.29)
Aberrant RHA[1]	2 (1.04)
AA	4 (2.08)

[1]Aberrant right hepatic artery arising from superior mesenteric artery. Diameter of graft: mean (range), 1.91 (1.5-2.5) mm; diameter of recipient: mean (range), 2.12 (1.5-3.5) mm. RHA: Right hepatic artery; LHA: Left hepatic artery; PHA: Proper hepatic artery; CHA: Common hepatic artery; AA: Abdominal aorta.

Postoperative management and follow-up

All patients received immunosuppressive therapy including cyclosporine or tacrolimus. All patients underwent Doppler ultrasonography every 12 h during the first postoperative week and daily during the second postoperative week to confirm HA patency. The diagnosis of HAT after A-A LDLT was based on clinical presentation, color Doppler ultrasonography findings, and HA arteriography. If elevated hepatic enzymes, cholestasis, bile leakage, or high fever in the absence of acute rejection were detected, color Doppler ultrasonography, CTA, or conventional HA angiography was performed to establish the diagnosis in turn. If hepatic arterial inflow was not observed by color Doppler ultrasonography, CUES examination was performed in these cases[12].

RESULTS

Donor outcome

There were no donor deaths, and the hospitalization period ranged from 7 to 30 d (mean 10 d). Only 4 donors had the following complications: portal venous thrombosis in 1 case who underwent second thrombectomy and leakage was mended with a patch of GSV; transient chyle leakage in 1 case, which healed after symptomatic treatment; subphrenic effusion in 1 case which was cured by surgical drainage; and pleural effusion, healed after repeated thoracic cavity puncture.

Recipient outcome

In this series, HAT occurred in 4 cases of 192 grafts after A-A LDLT (2.08%). All thromboses occurred in the 58 incipient patients (63 grafts) with an incidence of 6.34%. Thereafter, HAT did not occur in 124 consecutive cases. HAT was suspected in 14 patients without arterial inflow by routine color Doppler ultrasonographic examination and confirmed in 4 patients by CEUS and HA angiography. These results are shown in Table 4. HAT occurred in 2 recipients on the 1st and 7th d following A-A LDLT, both of which were revascularized with GSV between the donor RHA and recipient AA immediately after thrombectomy. These patients were discharged with good liver function. The third HAT occurred on the 3rd d after A-A LDLT, and urgent administration of thrombolytic therapy combined with anticoagulant treatment was performed and coagulation status was monitored. Despite recovering HA inflow detected by color Doppler ultrasonography with good liver function, the patient died on postoperative day 36 with multiorgan failure (MOF). The fourth HAT occurred on the 46th postoperative day, however, no ischemia-related complication was observed during the follow-up period. No special treatment for this patient was performed because liver function test results and general condition were good.

DISCUSSION

Hepatic arterial reconstruction, which is critical to successful outcome, is one of the most difficult procedures in A-A LDLT. Currently, many scholars emphasize the importance of microvascular techniques for hepatic arterial reconstruction in LDLT to overcome the risk of HAT[14-17]. When comparing microsurgical techniques with conventional methods, the use of microsurgical techniques in HA reconstruction can result in a lower incidence of HAT compared with conventional procedures[17].

Despite the improvements in surgical techniques, a liver graft with a fine HA less than 2 mm in diameter is regarded as a contraindication for LDLT because of the high risk of HAT[15]. As shown in Table 3, the mean diameter of graft arteries and recipient arteries were equal to or less than 2 mm. In our study, all anastomoses were carried out by a group of vascular surgeons, including two experts in vascular surgery and two assistants, using atraumatic microvascular techniques during the reconstructions. Only 4 cases of HAT in recipients occurred which were in the 58 incipient patients following A-A LDLT. As we accumulated experience in microsurgical hepatic arterial reconstructions, no further cases of HAT occurred in 124 consecutive cases following A-A LDLT. On the basis of our experience in LDLT, the key points in HA reconstruction included: (1) selecting a reciprocal stump location for arterial reconstruction: a thicker arterial stump in the recipient was chosen for the first anastomosis. In 58 incipient cases, the primary candidates for the first anastomosis were the RHA and LHA, which are often small in diameter. To increase the blood flow through the anastomosis, a thicker arterial stump in the recipient, close to the donor stump, was used as the first option for anastomosis in the subsequent 124 cases. In order to expand the anastomotic stoma, the caliber discrepancy between the recipient and graft HA was resolved by cutting the smaller arterial end obliquely to change the effective caliber which was twice as wide as the diameter of the smaller vessel. Thereafter, the incidence of HAT decreased markedly. Other methods such as the fish-mouth method, funnelization method, or end-to-side anastomosis were not used in this study; (2) utilizing back wall-first anastomosis technique. Run-

[1]HAT occurred in right hepatic artery. HAT: Hepatic arterial thrombosis; A-A LDLT: Adult-to-adult living donor liver transplantation.

ning microsutures were placed in the back wall of the artery first without turning over the vessel. Compared with conventional sutures, running sutures can avoid repeatedly tied and twisting vessels, both of which can injure fragile intima. Running sutures were employed in all HA reconstruction procedures with a low incidence of HAT (2.08%) in our study. Controversially, another report suggested that interrupted sutures may be a better choice for HA anastomosis with a lower incidence of HAT than continuous sutures[26]; and (3) treating intimal dissection of recipient HA. In our study, direct end-to-end anastomosis between the recipient and graft HA was employed in most procedures of A-A LDLT. In the case of intimal dissection, recipient HA is not suitable for hepatic arterial reconstruction. Several methods of revascularization have been reported, including application of recipient splenic or right gastroepiploic artery[27-29], interposition of a vessel graft between the CHA and graft artery[30,31], or between the AA and the graft artery[32]. Despite several reports[4,33] suggesting that interposition of a vessel graft increased the risk of HAT, interposition of GSV was performed between the graft RHA and recipient CHA in 3 cases, and bypass was performed between the graft RHA and recipient AA using GSV in 2 patients and cryopreserved cadaveric iliac vessels in 2 cases. No HAT occurred in the interposition cases. These cases provided a safe and effective approach for the management of intimal dissection. On account of a relatively small sample size in this study, further research is needed.

HAT is the most common vascular complication. Due to irreversible ischemic damage of hepatocytes and bile duct epithelial cells, HAT can cause devastating complications with a high mortality of 50%, including bile leakage, hepatic necrosis, graft loss, and sepsis[4,5]. Several factors were suggested to cause HAT after LDLT: technical problems[34-36], anatomic variation[37], hypercoagulable state[38], severe intraoperative hypotension[38], long cold ischemic time[39], occlusion of HA outflow owing to hepatic congestion[10], and systemic infection[10]. Diagnosis can be suggested by Duplex ultrasonography[12], and confirmed by angiography[40] or CEUS[13]. In our study, among the 14 cases without arterial inflow at routine color Doppler ultrasonographic examinations, CEUS showed 4 cases of HAT that were confirmed by HA angiography which is the gold standard for diagnosing HAT.

In the case of early HAT, several methods[8,9,11], including retransplantation, urgent revascularization, or revision of anastomosis, have been performed to avoid irreversible damage of the allograft. In our study, two recipients underwent urgent revascularization immediately after HAT was confirmed on the 1st and 7th d after A-A LDLT, and were subsequently cured with satisfactory liver function. One HAT patient received thrombolytic and anticoagulant therapy with monitoring of coagulation status, and thereafter HA inflow returned to normal, however, this patient died of MOF on the 36th d after A-A LDLT. Thrombolytic therapy and anticoagulant therapy for HAT should be carried out cautiously due to the potential risk of hemorrhage. Late HAT, which occurs after the first postoperative month, can be well tolerated, and portal flow can support the liver until the collateral circulation has developed[41]. No special treatment for the patient in our study with late HAT was performed because liver function test results and general condition were good. However, long-term results of late HAT patients will require further research.

In conclusion, selecting an appropriate anastomotic artery and applying microvascular techniques for HA reconstruction are crucial to reduce the high risk of HAT during A-A LDLT. The principles of HA reconstruction will be followed in our future clinical procedures which include: a settled group of vascular surgeons, running sutures with intimal eversion, sufficient large caliber of the stoma and atraumatic manipulation. Running sutures may be a reliable alternative for anastomosis of small diameter HAs with a low incidence of HAT following A-A LDLT. Nevertheless, randomized prospective controlled studies should be performed to validate these results.

COMMENTS

Background

Hepatic artery thrombosis (HAT), which is the most common vascular complication after living donor liver transplantation (LDLT), can result in graft loss and devastating consequences. Surgical techniques are suggested to an important factor in causing HAT. Despite improvements in surgical techniques, arterial reconstruction in LDLT has a high risk of thrombosis.

Research frontiers

Although microsurgical techniques in arterial reconstruction has helped overcome the high risk of HAT, because of the short donor hepatic artery (HA) stump, which is small in diameter, and vessel size discrepancy between the graft and recipient hepatic arteries, reconstruction of hepatic arteries is a challenge to surgeons in LDLT. The incidence of HAT after LDLT varies widely from 4%-25%.

Innovations and breakthroughs

With atraumatic microsurgical techniques, the reconstruction of HA was accomplished in 182 recipients (192 grafts) of adult-to-adult LDLT performed

from January 2001 to September 2009 by a settled group of vascular surgeons. Interposition of the great saphenous vein or cryopreserved vessel between the recipient and graft was performed for the treatment of 7 intimal dissections of recipient hepatic arteries. Both back-wall first techniques and running sutures with intimal eversion were employed in all anastomoses, and a good outcome with a low incidence of HAT (2.08%), was achieved.

Applications

Besides the use of microsurgical techniques, reconstruction of the HA by settled surgeons in LDLT provides an approach for decreasing the incidence of HAT. Based on our study results, running sutures can be used in the anastomoses of hepatic arteries of small diameter.

Peer review

This is a retrospective analysis of HA thrombosis after living donor liver transplantation.

Abstract

Incarceration rarely complicates the chronically progressive form of the full thickness rectal prolapse. Even more rarely, it becomes strangulated, necessitating emergency surgery. We describe an extremely rare case of incarcerated acute rectal prolapse, without a relevant previous history or symptoms of predisposing pathology. The patient underwent emergency perineal proctosigmoidectomy, the Altemeier operation, combined with diverting loop sigmoid colostomy. The postoperative course was quite uneventful with an excellent final result after colostomy closure. The successful treatment of this patient illustrates the value of the Altemeier procedure in the difficult and unusual case scenario of bowel incarceration.

INTRODUCTION

Rectal prolapse (RP) is a rare anorectal disease with underestimated incidence, affecting both children and adults. Although known and described as early as 1500 BC[1], there is still uncertainty concerning its clinical definition, course and pathophysiology which justifies the numerous therapeutic modalities and operations proposed.

Three different clinical entities may coexist or be combined and inclusively called RP: the mucosal prolapse (partial or pseudoprolapse), the internal prolapse (rectal intussusception) and the full thickness RP (complete or true)[2]. The mucosal prolapse concerns the protrusion of the rectal mucosa usually as a result of a lesion such as hemorrhoids or polyps. Internal intussusception may be a full thickness or a partial wall disorder but the prolapsed tissue does not pass beyond the anal canal. Lastly, full thickness RP is a complete protrusion of the rectum (and/or the sigmoid) with its entire wall through the anus. Its course is usually progressive; initially it is reducible spontaneously, later manually and is finally irreducible. In any stage it may be complicated by incarceration and strangulation.

We describe a case of a young male patient presenting with acute, incarcerated large RP who was successfully managed by perineal proctosigmoidectomy (Altemeier procedure) combined with diverting sigmoid loop colostomy.

CASE REPORT

A previously fit, healthy and normal weight (body mass index, 27.8) 37-year-old Albanian male presented to our emergency department with a large, incarcerated RP resulting from intense straining 10 h before admission (Figure 1). Another episode of RP with easy manual reduction at the age of 10 years was vaguely mentioned in the patient's history. Neither chronic constipation, nor a relevant family history was reported. On clinical examination, the patient had a normal temperature and was hemodynamically stable and normal. Abdominal examination revealed mild tenderness in the lower abdomen while the laboratory investigation showed mild leucocytosis with left shift. As the bowel was not obviously necrotic, conservative measures were applied in order to permit repositioning of the bowel. Unfortunately, sedation, placing of the patient in the Trendelenburg position and topical application of warm compresses and 20% mannitol, all were unsuccessful and the patient was taken to the operating room after 4 h of ineffective efforts.

Under general anesthesia, a dilute epinephrine solution was injected 2-3 cm proximal to the dentate line and the rectal wall was incised across its full thickness at this level. The vessels of the mesorectum and mesosigmoid were carefully ligated, the prolapsed rectosigmoid was resected and a hand-sewn interrupted coloanal anastomosis in 2 layers was created. In addition, a loop sigmoid colostomy for a protective and fixing purpose was constructed. The patient's postoperative course was quite uneventful and the patient was discharged on the 10th postoperative day. Histological stained sections revealed severe ischemic alterations. The vessels of the bowel wall were found either dilated or thrombosed while the mucosa had multiple regions of necrosis and ulceration.

Six months later, the patient was readmitted for colostomy closure after physiologic examination with anal manometry, which was normal. However, a preoperative colonoscopy showed intense inflammatory changes at the anastomotic suture line, due to incompletely absorbed suture material plus a remnant rectal colitis. Short term conservative treatment with enemas and suppositories of mesalamine was successfully applied for a 20-d period. Both revision colonoscopy and barium enema, performed 1 mo later, were normal and the colostomy was closed without further complications. Ever since, and for an 8 mo period, the patient has been well.

DISCUSSION

There is still some debate about the exact pathophysiologic mechanism of RP. The prevailing theories are those of sliding herniation and progressive internal intussusception. Chronic or, less frequently, acute abdominal straining is present in most cases[3]. In addition, both pathologies coexist with different anatomical and physiological features (patulous anus, incontinence) and common predisposing factors (straining, constipation)[4]. The most usual form of RP is the chronic course of the disorder which permits selective use of investigative tools like sigmoidoscopy, videoproctography or, more rarely, physiologic studies such as anal manometry. It is evident that all diagnostic efforts are practically omitted in the rare scenario of incarcerated or strangulated RP, where urgent surgical treatment becomes a priority[5].

Figure 1 Patient with a large, incarcerated rectal prolapse in the operating room.

A wide spectrum of operative procedures are available mainly for elective cases[6]. They are categorized as resective, fixative or a combination of both in order to achieve 2 goals: anatomical repositioning of the bowel and improvement of the function of the anorectal complex. The approach may be either abdominal or perineal. The selection of the appropriate procedure primarily depends on the patient's clinical data adjusted to the operator's experience and personal preference[7].

Abdominal approaches are performed in patients fit enough to tolerate laparotomy as these seem to result in lower recurrence rates[8], perhaps with the exception of young men who cannot afford the increased risk of impotence and infertility from an abdominal operation[9]. In elective cases, rectopexy, using fixing material (mesh, sutures, clips), is the most popular operation with good results concerning recurrence[10,11]. The fixation to the presacral fascia can be done either anteriorly (Ripstein) or posteriorly. However, when constipation dominates symptomatology, usually with coexistence of a redundant sigmoid, an anterior resection alone or in combination with rectopexy is usually preferred[12]. In the modern era of surgery, the above operations can be accomplished laparoscopically with minimal morbidity and mortality[13].

When the prolapse cannot be manually reduced, a few techniques may help the bowel return to its anatomic position. Sedation, Trendelenburg position of the patient and topical application of salt and sucrose may decrease bowel edema and enable reduction[9,14]. Even the use of an elastic compression wrap has been practiced[15]. However, when the prolapsed bowel is incarcerated or strangulated and cannot return to its anatomic position by the measures described above, the situation becomes a surgical emergency, as was the case with our patient. Jeopardizing the bowel's viability should be avoided as gangrene significantly increases morbidity and mortality and thus, an urgent surgical intervention is

always indicated[16,17]. The operation of choice is perineal proctosigmoidectomy with or without colostomy[16]. Ramanujam *et al*[17] described 8 cases of acute incarcerated RP during a 9-year period, where perineal rectosigmoidectomy was performed. All were women over the age of 75 and 2 (25%) developed postoperative anastomotic leak with pelvic peritonitis requiring diverting colostomy.

Our male patient, with acute presentation of incarcerated RP, underwent emergency perineal resection as the only alternative to remove the ischemic bowel. Goligher states that irreducibility with gangrene remains one of the few indications for rectosigmoidectomy (perineal) at the present time[18]. Furthermore, in recent years, there has been a trend towards offering elective perineal rectosigmoidectomy in healthier younger patients especially in males[8]. The abdominal approaches carry an increased risk of impotence and infertility when comparing to the perineal ones[9]. Unfortunately, the recurrence rate after the Altemeier operation is not negligible. There have been historical reports of a recurrence rate of up to 58%[19]. More recent studies refer to much lower rates (3%-16%), which are still high when compared to the abdominal approaches[8,20]. In addition, restoration of continence following the operation is also unpredictable as it may result in increased soiling and frequency of defecation[8]. Therefore, the addition of levatorplasty to perineal rectosigmoidectomy has been suggested in order to achieve better results[8].

A transabdominal construction of a sigmoid loop colostomy was added aiming to protect the "difficult" hand sewn anastomosis from the fecal stream. The excessive bowel edema due to incarceration made the operator consider the anastomosis unsafe. In addition, colostomy might also have a fixing function, but, on the other hand, carries various risks and complications[21]. The inflammatory changes and remnant colitis seen in this patient's colonoscopy were rather minor and they were successfully dealt with by pharmacologic means.

In conclusion, a rare case of incarcerated and strangulated RP in a young adult is described in our case report. The patient's successful treatment with perineal proctosigmoidectomy highlights the value of the Altemeier procedure in this emergency situation.

Abstract

Pancreatic tumors with combined exocrine and endocrine features are rare. Most reported cases are classified as mixed exocrine and endocrine carcinoma of the pancreas. We report the first case of solitary concomitant endocrine tumor and ductal adenocarcinoma of the pancreas. A 58-year-old patient was admitted for uncontrolled diabetes mellitus and body weight loss. The tumor was fortuitously discovered in the pancreatic tail after a tumor survey panel. Grossly, the solitary tumor had a central fibrous band that clearly divided it into two parts. On microscopic examination, the tumor contained both endocrine and exocrine components distinctly separated by the central fibrous band. The exocrine part showed a poorly-differentiated adenocarcinoma. The endocrine part was strongly immunoreactive to chromogranin, synaptophysin and glucagon. We reviewed the literature on pancreatic tumors with combined exocrine and endocrine features. A simple classification for this group of neoplasms is suggested, including five types: amphicrine, mixed, collision, solitary concomitant and multiple concomitant.

INTRODUCTION

Pancreatic tumors, categorized according to exocrine and endocrine origin, are classified into ductal, acinar or endocrine types by morphological and immunohistochemical studies. Pancreatic endocrine tumor (PET) is uncommon and represents only 1%-2% of all pancreatic tumors[1]. Pancreatic exocrine tumor is rarely associated with pancreatic endocrine tumor[2]. Most reported cases are mixed ductal-endocrine carcinoma, mixed acinar-endocrine carcinoma and mixed ductal-acinar-endocrine carcinoma[2-7]. These reported cases are classified accord-

ing to World Health Organization (WHO) criteria[8], in which mixed exocrine and endocrine carcinoma is defined as carcinoma containing intimately intermixed exocrine and endocrine components, and each component comprises at least one-third of the tumor tissue. By this definition, a solitary concomitant pancreatic tumor with distinctly separated exocrine and endocrine components cannot be classified as mixed exocrine and endocrine carcinoma. Here, we report a case of solitary concomitant endocrine tumor and ductal adenocarcinoma of the pancreas. This type of pancreatic tumor is especially rare and, to the best of our knowledge, has never been reported in the English literature.

CASE REPORT

A 58-year-old Chinese male was admitted to the endocrinology and metabolism ward in July 2009 for poorly controlled hyperglycemia, which was refractory to an oral hypoglycemic agent. He had a history of diabetes mellitus (DM), hypertension and chronic renal insufficiency for more than 4 years and had been receiving regular follow-up at the outpatient clinic of this hospital. On admission, laboratory test (Table 1) revealed that his blood glucose was 561 mg/dL. Physical examination showed no skin rash or oral lesions. While he was hospitalized, daily high-dose insulin injection with Novomix 60 U/d was necessary to control his blood glucose level. The patient also complained of losing 10 kg of body weight in the prior two months. Therefore, he asked for a tumor marker examination. A tumor survey panel revealed an elevated carbohydrate antigen 19-9 (CA19-9) of 195 U/mL (normal, 0-37 U/mL) incidentally. Abdominal computed tomography (CT) demonstrated a 3.7 cm × 2.1 cm tumor in the pancreatic tail (Figure 1) and unremarkable adrenal glands bilaterally. Whole body positron emission tomography showed moderately increased accumulation of fluorine-18 fluorodeoxyglucose (F-18 FDG) in the pancreatic tail with standard uptake values of 3.3 (initial) and 4.5 (delayed). No increased uptake in other organs or sites was identified. Thyroid ultrasound showed no focal lesion. The patient received distal pancreatectomy and splenectomy under the impression of pancreatic tail carcinoma. Neither liver metastasis nor peritoneal seeding was found during surgery. The postoperative course was uneventful. Initially, only an oral hypoglycemic agent was prescribed for controlling DM when the patient was discharged from the hospital. However, because hyperglycemia (268 mg/dL) and elevated glycosylated hemoglobulin HbA1c (8.1%) were found at follow-up in the outpatient clinic, insulin injection with Novomix 28 U/d was represcribed. The patient moved to another city for family support and admitted there one month after operation. Therefore we lost the follow-up of him.

Grossly, the surgical specimen consisted of pancreatic tail tissue, 10 cm × 4 cm × 3.5 cm, and unremarkable spleen tissue (146 gm). A well-circumscribed gray-brown nodular mass, 3.8 cm × 3.2 cm × 2.2 cm, was found in

Figure 1 Computed tomography (CT) scan demonstrating a 3.7 cm × 2.1 cm tumor (arrow) in pancreatic tail.

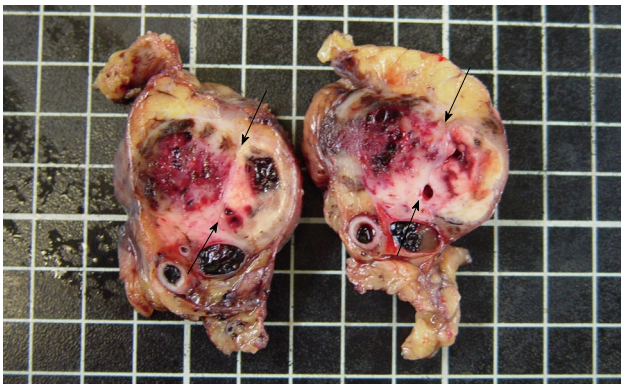

Figure 2 Gross examination showing a well-circumscribed tumor with a central fibrous band (arrows) separating the right exocrine and the left endocrine parts.

the pancreatic parenchyma. On serial cuts, the nodular mass clearly showed a red-brown, hemorrhagic, centrally necrotic heterogenous part and a gray-white, focally hemorrhagic solid part (Figure 2). A thin fibrous band was present between these two parts. No gross invasion to spleen, large vessels or resection margins was found.

The microscopic sections showed pancreatic tissue with a partially encapsulated tumor composed of two distinctly separated, exocrine and endocrine components (Figure 3A). The two components did not grow into each other and were completely separated by a small band of fibrous tissue and some residual, atrophic, benign exocrine glands. The endocrine part, up to 1.8 cm in diameter and occupying more than 40% of the pancreatic tumor, was well-circumscribed, completely enclosed by fibrous tissue and composed of uniform tumor cells containing small, round, monotonous nuclei and pale or mildly acidophilic cytoplasm (Figure 3B). These cells were arranged in gyriform or trabecullar patterns divided by slender fibrous connective tissue and rich vascular stroma. Neither mitotic figures nor cellular atypia was found. No evidence of necrosis, extrapancreatic spread or vascular invasion was present. Mucin and congo red stains were negative. On immunohistochemical (IHC) staining, the tumor cells were diffusely and strongly

Table 1 Laboratory data on admission

CBC and DC		Biochemistry data		Tumor marker	
WBC	13460/mm^3	Glucose	561 mg/dL	CA19-9	195 U/mL
RBC	5.11 × 10^6/mm^3	Albumin	2.7 g/dL	AFP	6.38 ng/mL
Hemoglobin	15.2 g/dL	Sodium	136 mmol/dL	CEA	2.01 ng/mL
Hematocrit	44.9%	Potassium	3.25 mmol/dL	PSA	1.90 ng/mL
Neutrophil	79.0%	BUN	48 mg/dL		
Lymphocyte	16.1%	Creatinine	1.6 mg/dL		
Monocyte	3.9%	Calcium	2.08 mmol/L		
Eosinophil	0.7%	Triglyceride	133 mg/dL		
Basophil	0.3%	Cholesterol	85 mg/dL		
Platelet	32.7 × 10^4/mm^3				

Normal values: CA19-9: 0-37 U/mL; AFP: 0-10 ng/mL; CEA: 0-7 ng/mL; PSA: 0-4 ng/mL. CBC and DC: Complete blood cell count and differential count; WBC: White blood cell count; RBC: Red blood cell count; BUN: Blood urea nitrogen; CA19-9: Carbohydrate antigen 19-9; AFP: α-fetoprotein; CEA: Carcinoembryonic antigen; PSA: Prostate-specific antigen.

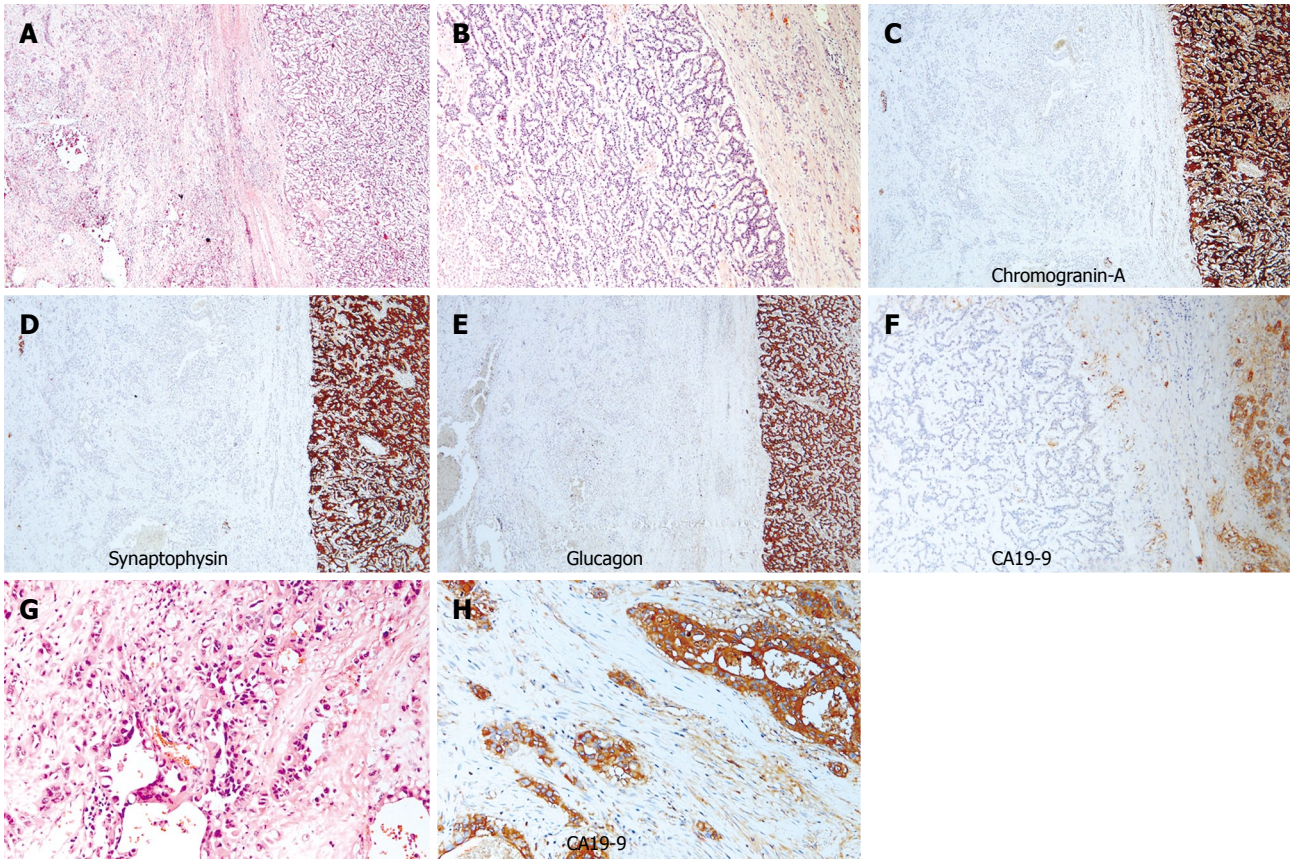

Figure 3 Microscopic features of solitary concomitant endocrine tumor and ductal adenocarcinoma of pancreas. A: Low-power view showing ductal adenocarcinoma (left) and endocrine tumor (right) with a fibrous band (central) clearly demarcating the two components (HE × 40); B: Pancreatic endocrine tumor composed of monotonous small, round tumor cells arranged in gyriform or trabecular patterns, marginated by a fibrous wall (right) (HE × 100); C-E: Pancreatic endocrine tumor (right) showing positive expression while ductal adenocarcinoma (left) showing negative expression of chromogranin A, synaptophysin and glucagon (IHC × 40); F: Pancreatic endocrine tumor (left) showing negative expression while residual benign pancreatic glands (right) showing positive expression of carbohydrate antigen 19-9 (CA19-9) (IHC × 100); G and H: Higher magnifications of ductal adenocarcinoma showing bizarre pleomorphic glands (HE × 200) and immunoreactive to CA19-9 (IHC × 200).

positive for chromogranin A (Figure 3C), synaptophysin (Figure 3D) and glucagon (Figure 3E). No expression of CA19-9 (Figure 3F), p53, Bcl-2, insulin, gastrin, vasointestinal peptide was demonstrated in the tumor. Ki-67 + cells were less than 0.5%. The exocrine component, a poorly-differentiated ductal adenocarcinoma, showed bizarre and hyperchromatic cells containing pleomorphic darkly staining nuclei, some mitoses and pale or acidophilic cytoplasm (Figure 3G). Scattered anaplastic nuclei were also found. These tumor cells were arranged in dilated ductal structures, small glands, cellular files or single cells, with large areas of necrosis and hemorrhage.

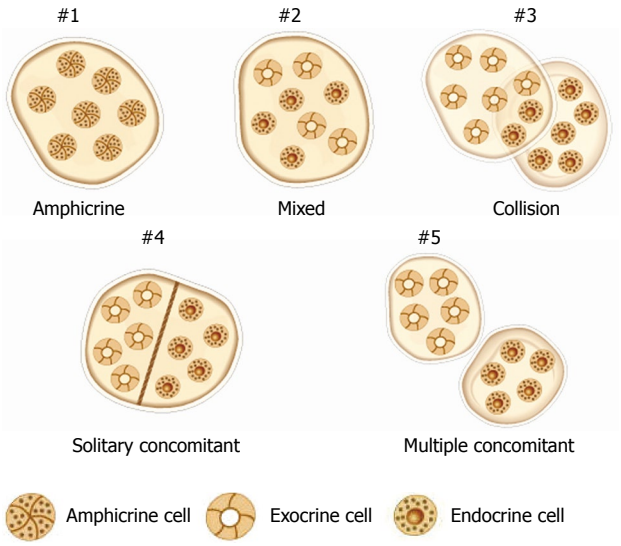

Figure 4 Five types of pancreatic neoplasm with combined exocrine and endocrine features.

The exocrine component showed focal invasion of peripancreatic soft tissue. The spleen and 9 peripancreatic lymph nodes were free of tumor. Mucin secretion was demonstrated by mucicarmine and periodic acid-Schiff with diastase stains. On immunohistochemical staining, this component was strongly positive for CA19-9 (Figure 3H), and negative for chromogranin A (Figure 3C), synaptophysin (Figure 3D), glucagon (Figure 3E), insulin, gastrin, vasointestinal peptide and Bcl-2. Ki-67 + cells were more than 25%. More than 55% of the ductal adenocarcinoma had strong intranuclear accumulation of p53 protein. In this case, the exocrine and endocrine components were clearly separated and different from each other in the single tumor. No collision or intermixing area could be found. With no other endocrine manifestations and focal lesion found in the thyroid and adrenal glands, MEN type 1 was not considered. Finally, a solitary concomitant endocrine tumor and ductal adenocarcinoma of the pancreas was diagnosed.

DISCUSSION

To the best of our knowledge, this is the first case of solitary concomitant PET and ductal adenocarcinoma of the pancreas reported in the English literature. Ballas *et al*[9] reported a case of mixed exocrine-endocrine tumor of the pancreas showing two distinct populations of tumor cells. Most parts of these two components were separated but focally showed a collision type of growth, with two different components growing into one another. Goh and colleagues[10] reported three cases of concomitant intraductal papillary mucinous neoplasm (IPMN) of the pancreas and pancreatic endocrine neoplasm. The sizes of the endocrine part were small (2, 5 and 8 mm) and well-circumscribed, isolated and nonfunctional. However, the morphology of all three exocrine components was not indicative of classical invasive ductal carcinoma as the present one.

Many reports have discussed the histogenesis of the association between exocrine and endocrine neoplasms of the pancreas[2,3,11,12]. Leteurtre *et al*[3] reported a case of mixed ductal-endocrine carcinoma of the pancreas and supported the hypothesis of a common endodermal histogenesis for ductal and endocrine cells. Chatelain and colleagues[2] also suggested that these tumors probably arise from a totipotent endodermal cell distributed in the pancreatic ducts and islets. Marrache *et al*[11] presented 6 patients with associated IPMN and PET, and suggested that these tumors may arise from a common progenitor cell or due to differentiation from one cell type to the other. Morikane *et al*[12] presented a small glucagonoma of the pancreas with evident ductular and tubular structures and supported the hypothesis that pancreatic endocrine tumors originate in the ductular epithelium. In the report of Cho *et al*[13], the tumor cells of a mixed acinar-endocrine carcinoma of the pancreas showed amphicrine differentiation, with one cell type harboring both exocrine and endocrine markers simultaneously, indicating that a close histogenetic relationship exists between pancreatic exocrine and endocrine cells. Pour *et al*[14] concluded that pancreatic cancer derives from pancreatic stem cells distributed within ductal trees and islets. According to the previous literature, it seems reasonable to hypothesize that associated exocrine and endocrine neoplasms of the pancreas arise from totipotent pancreatic stem cells, which reside in the pancreatic duct and islets. Under certain stimulation, the stem cells differentiate and give rise to exocrine and endocrine primitive cells. The exocrine primitive cells further differentiate into ductal and acinar cells. According to the proposed differentiation pathway, we hypothesize that the amphicrine type arises from early stem cells that proliferate into a neoplasm before differentiating into endocrine and exocrine cells (Figure 4). Thus, the amphicrine type, as in the case reported by Cho *et al*[13], contains only one cell type that has both exocrine and endocrine features. When the stem cells begin to differentiate into primitive exocrine and endocrine cells, three types of histological patterns may occur: mixed, collision and solitary concomitant. In the mixed type, the exocrine and endocrine cells are intimately intermixed together. Most reported cases of mixed exocrine and endocrine tumor of the pancreas are examples of this type[2-7]. The collision type, as in the case reported by Ballas *et al*[9], shows the endocrine part at one end and the exocrine part at the other end, with an intermixed central zone. The solitary concomitant type, first presented in our case, shows a single tumor composed of distinctly separate exocrine and endocrine components, with a dividing fibrous band found between the two parts. The last type is a multiple concomitant type that contains isolated exocrine and endocrine tumors simultaneously. The three cases reported by Goh *et al*[10] can be classified as the early ones of this latter type.

Because the present tumor contained both pancre-

atic endocrine tumor and exocrine carcinoma, we tried to consider these two parts together when discussing the prognosis of this patient. No evidence of metastasis was found at abdominal CT, whole body positron emission tomography scan and during surgery. The size of the present endocrine tumor was 1.8 cm. The microscopic features showed scarce mitoses and less than 0.5% Ki-67+ cells. Neither extrapancreatic spread nor vascular invasion was identified. According to criteria of the WHO Committee for Histological Typing of Endocrine Tumors, the present endocrine tumor was classified as a well-differentiated endocrine tumor with benign behavior[1]. In the previous literature and papers presenting cases of mixed exocrine and endocrine carcinoma, the authors suggested that the prognosis depends mainly on the stage of ductal carcinoma[2,8,9]. We cannot be certain that the prognosis of our case depends on the ductal carcinoma component because this is not a case of mixed exocrine and endocrine carcinoma of the pancreas as previously presented. Further study with more cases is necessary.

Chatelain *et al*[2] presented a case of mixed ductal-pancreatic polypeptide-cell carcinoma of the pancreas. In their study, the endocrine cells were not immunoreactive to p53 and Bcl-2, but the exocrine ductal cells were stained strongly positive, suggesting that over-expression of p53 and Bcl-2 plays a major role in neoplastic progression of the ductal component. We performed p53 and Bcl-2 immunostains in the present case. The endocrine part was negative for p53 and more than 55% of exocrine neoplastic cells showed strong intranuclear accumulation. However, both the endocrine and exocrine parts were negative for Bcl-2. The role of p53 and Bcl-2 in tumor histogenesis still needs further investigation.

Glucagonomas are rare and only represent about 10% of all functioning pancreatic tumors[15-17]. Cases without typical symptoms usually remain undiagnosed, resulting in long-term medical waste, and mental and physical suffering of the patients[18,19]. In our case, the patient only presented with DM and body weight loss and did not satisfy the criteria of glucagonoma syndrome. However, it was not certain whether the alpha-cell tumor plays a role in the manifestation of DM or not. In a recent study of pancreatic cancer-associated DM, Pannala *et al*[20] concluded that pancreatic cancer is a powerful diagnostic state and new-onset DM is likely induced by the tumor. Under this viewpoint, the adenocarcinoma of our case may be closely related to the poor control of DM, especially because the patient did not develop glucagonoma syndrome. In short, we suggest that, in cases of type Ⅱ DM occurring in middle-aged patients, the development of uncontrolled hyperglycemia should raise clinical suspicion of glucagonoma and/or pancreatic cancer. In this situation, further survey including pancreatic hormones and tumor marker profile is suggested.

In conclusion, combined pancreatic endocrine and exocrine tumors are rare. We have reported the first case of solitary concomitant pancreatic endocrine tumor and ductal adenocarcinoma. We suggest a classification system of tumor histogenesis for this group of tumors, including amphicrine, mixed, collision, solitary concomitant and multiple concomitant. Further investigation of more cases of this rare entity is still necessary.

Abstract

Inflammatory myofibroblastic tumor (IMT) is an uncommon benign neoplasm with locally aggressive behavior but malignant change is rare. We report an unusual case of pelvic-abdominal inflammatory myofibroblastic tumor with malignant transformation in a 14-year-old boy presenting with abdominal pain and 9 kg body weight loss in one month. Computed tomography revealed a huge pelvi-abdominal mass (30 cm), possibly originating from the pelvic extraperitoneal space, protruding into the abdomen leading to upward displacement of the bowel loops, downward displacement of the urinary bladder, massive central necrosis, a well-enhanced peripheral solid component with prominent peritumoral vascularity. Subsequent examination confirmed the computed tomographic findings. Histopathologic examination revealed proliferative epitheloid and spindle cells, inflammatory cell infiltration and high mitotic counts. Immunohistochemistry was strongly positive for anaplastic lymphoma kinase and revealed a high proliferative index (ki-67 = 40%). DNA sequencing and electronic microscopy further confirmed the primitive fibroblastic cell phenotype of the tumor and a final diagnosis of inflammatory myofibroblastic tumor with malignant transformation was established. Rapid tumor recurrence was noted 20 d after radical tumor resection. To our knowledge, this is the largest documented case of IMT in a pediatric patient and the first report of IMT with malignant transformation originating from the pelvic extraperitoneal space.

INTRODUCTION

Inflammatory myofibroblastic tumor (IMT) is an uncommon benign neoplasm with locally aggressive behavior and a tendency to recur[1-10]. An IMT is commonly found

in the lung as an asymptomatic solitary lung mass detected on chest radiography[1-3]. Extrapulmonary IMT can occur in nearly every site in the body but is most commonly found in the mesentery and omentum, orbit, and gastrointestinal and genitourinary tracts[1-4]. IMT of the retroperitoneum is unusual[3-6]. On rare occasions, IMT may exhibit malignant transformation or may evolve into lymphoreticular malignancy[2,3,7]. Herein, we describe an extremely unusual case of IMT with malignant transformation originating from the pelvic extraperitoneal space in a pediatric patient.

CASE REPORT

A previously healthy 14-year-old boy presented with abdominal pain and fullness with body weight loss of 9 kg in one month. A physical examination revealed slightly pale conjunctiva, a 23 cm × 33 cm fixed pelvi-abdominal mass and engorged superficial veins on the abdominal wall. Laboratory investigations showed that hemoglobin was 11.8 g/dL and the leukocyte count was 13.3 × 10^9/L with eosinophilia (eosinophil count 17.8%), and an elevated C-reactive protein level (77.7 mg/L). Computed tomography (CT) showed a huge pelvi-abdominal mass (30 cm), possibly originating from the pelvic extraperitoneal space, protruding into the abdomen with upward displacement of the bowel loops, downward displacement of the urinary bladder, massive central necrosis, and a well-enhanced peripheral solid component with prominent peritumoral vascularity (Figure 1A-C). Based on such CT features, the surgeons were notified for cautious surgical dissection of the extraperitoneal space as well as the possibility of massive bleeding and the need for blood transfusions during the operation. The initial impression included mesenteric fibromatosis, IMT, gastro-intestinal stromal tumor or mesenteric sarcoma. During surgery, CT findings were confirmed and prominent peritumoral vascularity was encountered resulting in a blood loss of 3900 mL during radical tumor resection and necessitated transfusion of packed red blood cells (6 units) and fresh-frozen plasma (4 units). The gross specimen was a slightly lobulated mass with an uneven peripheral solid component and massive central necrosis (Figure 1D). Histopathologic examination revealed predominantly epitheloid and spindle cells, prominent staghorn vascular channels, inflammatory cell infiltration and high mitotic counts (14/10-high-power-field) (Figure 1E). Immunohistochemistry was strongly positive for anaplastic lymphoma kinase (ALK) and revealed a high proliferative index (ki-67 = 40%) but was negative for desmin, HHF-35, Fli-1, CD31, CD34, CD117, S-100, chromogranin A, synaptophysin, and P-53. Real-time polymerization chain reaction assay revealed strong expression of TPM3-ALK fusion transcript and DNA sequencing revealed ALK fusion gene breakpoint at TPM3 Exon 8 to ALK Exon 21. Electron microscopy of the spindle cells revealed lack of subplasmalemal thin actin filament and microtendon in fibronexa on the cell surface confirming primitive fibroblastic cell phenotype. A final diagnosis of IMT with malignant transformation was established. The patient recovered uneventfully and was discharged 10 d after surgery. Unfortunately, a recurrent palpable mass was noted over the lower abdomen 20 d after discharge. He refused further treatment and died 6 mo later.

DISCUSSION

IMT has been reported as a quasineoplastic lesion histopathologically characterized by proliferation of myofibroblastic spindle cells and inflammatory cells. Most cases of IMT are found in the lung, orbit, mesentery and omentum, and gastrointestinal and genitourinary tracts[1-4]. IMT arising from uncommon locations including the liver, spleen, head and neck, central nervous system, heart, appendix and superficial soft tissue has also been documented[2-8]. Excluding urinary tract lesions, retroperitoneal IMT is unusual and only 10 cases have been described[3-6]. To our knowledge, this is the first reported case of IMT in the pelvic extraperitoneal perivesical space.

The etiology of IMT is contentious and whether it is a post-inflammatory process or a true neoplasm remains controversial[2-8]. Proponents for post-inflammatory or immunologic processes advocate the association of IMT and infectious agents such as mycobacteria, corynebacteria, the Epstein-Barr virus and human herpes virus, as well prior histories of surgery, trauma, and steroid usage[2-5]. In contrast, proponents for neoplasm emphasize the aggressive behavior, cytogenetic clonality, involvement of specific chromosome region 2p23 and the possibility of distant metastasis[5-8]. In this particular case, there was no definite evidence of related infection, a traumatic episode or prior steroid usage. On the other hand, histopathologic and immunohistochemical features such as high mitotic counts, positive ALK and a high proliferative index as well as the rapid recurrence after initial radical resection were supportive of the neoplastic nature of IMT.

The sizes of reported IMT ranged from 0.4 cm to 40 cm[1-10]. An intraabominal IMT is usually larger and the largest reported IMT (40 cm) occurred in the liver of a 29 year-old man[9]. Our patient had the largest reported IMT among pediatric patients. The clinical presentation varies depending on the anatomical location of the lesion[1-10]. As demonstrated in our patient, patients with abdominal IMT usually present with abdominal pain, palpable mass, and body weight loss. Occasionally, features of inflammation such as fever, an elevated erythrocyte sedimentation rate and a markedly elevated leukocyte count (> 80 × 10^9/L) are encountered[10].

The CT appearance of abdominal IMT is variable. The mass may be iso- or hypodense to muscle on unenhanced scans with variable enhancement patterns including homogeneous, heterogeneous, peripheral and delayed central filling patterns[1,4-10]. As seen in our patient, central necrosis may occur in a large abdominal IMT and the differential diagnosis of a large abdominal mass with central necrosis encompasses giant neurilemmoma, gastrointestinal stromal tumor and fibromatosis[11-13]. A giant abdominal neurogenic tumor in a patient without

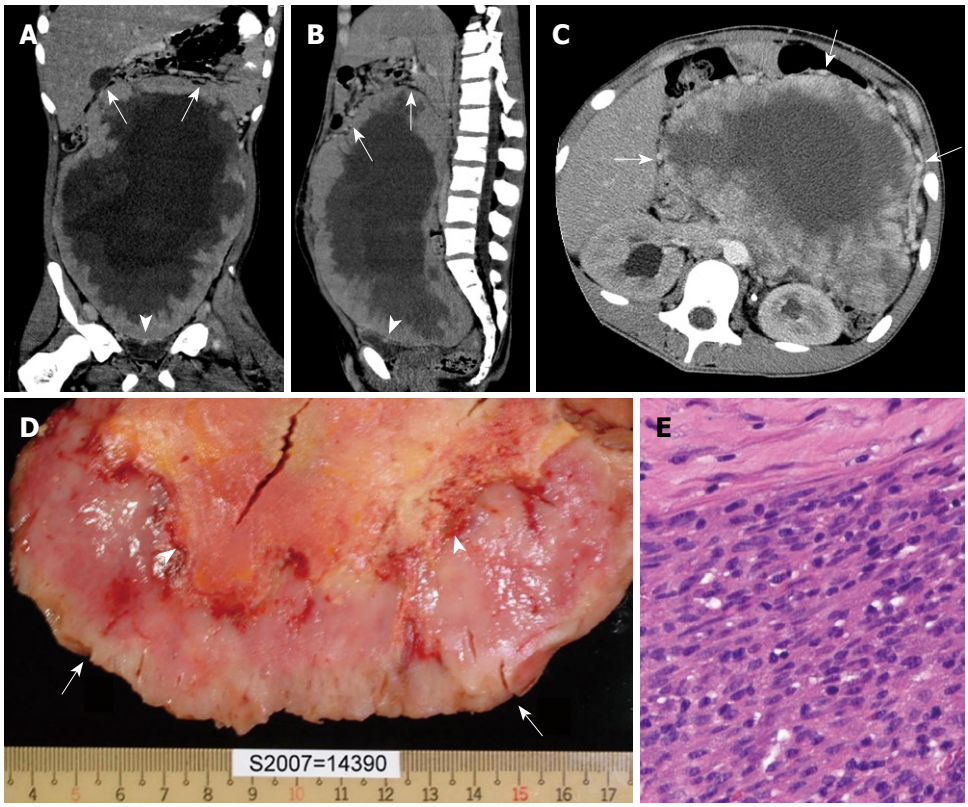

Figure 1 Malignant inflammatory myofibroblastic tumor in a 14-year-old with a history of abdominal pain and body weight loss. A, B: Coronal (A) and sagittal (B) computed tomography (CT) images reveal a huge pelvi-abdominal mass with an uneven peripheral solid component and massive central necrosis, with upward displacement of the bowel loops (arrows) and downward compression on the urinary bladder (arrowheads), highly suggestive of an extraperitoneal tumor originating from the perivesical space; C: Axial CT image at the level of the kidney clearly demonstrates prominent vessels around the tumor (arrows); D: The cut-surface of the gross specimen reveals an uneven peripheral solid component (arrows) and massive central necrosis (arrowheads); E: Photomicrograph shows proliferation of spindle tumor cells in the peripheral solid part (HE stain, original magnification × 200).

von Recklinghausen's disease was unusual and the lack of direct involvement of the gastrointestinal tract rendered gastrointestinal stromal tumor less likely[11,12]. CT demonstration of prominent peritumoral vascularity was suggestive of prominent regional inflammatory changes, supporting the diagnosis of IMT rather than fibromatosis[13]. In this particular case, coronal and sagittal reconstructed CT images clearly depicted the mass effect with upward displacement of the bowel loops and downward displacement of the urinary bladder, implying that the tumor might be extraperitoneally located. This information was helpful for preoperative planning, advocating cautious dissection of the extraperioneal spaces during surgery. In addition, surgeons were forewarned of the possibility of massive bleeding during tumor resection and the necessity for blood transfusion. Although CT may offer suggestive features of this unusual tumor, the definite diagnosis relies on detailed histopathologic and immunohistochemical evaluations[2-10]. ALK is an oncoprotein which essentially serves as a surrogate marker of chromosome rearrangement of 2p23 in IMT. Real-time polymerization chain reaction assay revealed strong expression of TPM3-ALK fusion transcript in our patient and in addition, DNA sequencing revealed ALK fusion gene breakpoint at TPM3 Exon 8 to ALK Exon 21 allowing further confirmation of IMT[14]. Chemotherapy, radiotherapy, and even immunomodulation have not been reported consistently effective against this aggressive tumor[7,8]. Radical resection remains the treatment of choice for patients with IMT and is adequate in most circumscribed tumors. However, mesenteric or retroperitoneal origin of the tumor, large tumor (> 8 cm), multinodular or ill-defined tumor morphology and incomplete tumor resection of IMT are factors associated with higher recurrence rates (17%-37%)[2-6,10]. In this particular patient, despite radical tumor resection being accomplished, rapid tumor recurrence was noted in 20 d and fatality in 6 mo, further confirming the highly malignant nature of the mass. In retrospect, the presence of abundant peritumoral vascularity demonstrated on CT was suggestive of high metabolic demand of the tumor which might be a clue to potential malignant change.

In summary, this report documents the first known case of pelvic extraperitoneal IMT with malignant transformation in a pediatric patient. In light of this case, IMT should be considered in the differential diagnosis of pelvi-abdominal mass with large central necrosis and the presence of prominent peritumoral vascularity may also be a clue of high metabolic demand and even malignant transformation.

Abstract

Acute cholecystitis is not a common complication of gastrectomy. Its clinical presentations and management strategies in old patients have not been well described in available literature. This report describes the clinical features, management strategies, and treatment outcome of acute cholecystitis immediately after gastrectomy. Acute cholecystitis immediately after gastrectomy in old patients has different clinical presentations, such as fever and high plasma C-reaction protein level. Abdominal computed tomography (CT) scan and ultrasonography showed acute cholecystitis in our cases, which was treated with antibiotics and ultrasound-guided percutaneous transhepatic gallbladder drainage (PTGD). The results indicate that abdominal CT scan and ultrasonography can effectively diagnose acute cholecystitis after gastrectomy, which can be effectively treated with antibiotics and PTGD.

INTRODUCTION

Radical gastrectomy is the main procedure for advanced gastric carcinoma. Acute cholecystitis following radical gastrectomy has been rarely reported[1], although bile stasis and gallbladder ischemia may occur after vagotomy and gastrohepatic ligament dissection[2]. Compared with acute cholecystitis in the general population, acute cholecystitis immediately after radical gastrectomy, a clinical situation not well-recognized in old patients, is characterized by a delayed diagnosis and a high mortality rate. In this paper, we report its clinical features, management strategies, and treatment outcomes of 3 old patients.

CASE REPORT

Case 1

A 64-year-old Chinese female patient presented with upper abdominal discomfort and a 10 kg weight loss for 10 mo. Gastroscopy revealed an ulcerated tumor at the gastric antrum. Biopsy demonstrated a poorly- differentiated adenocarcinoma with no metastasis. This patient had no history of gallstones and cholecystitis. Preoperative computed tomography (CT) displayed a normal gallbladder (Figure 1A). Six days after distal gastrectomy, D_2 lymphadenectomy and Billroth Ⅱ reconstruction, she received enteral nutrition via a transnasal jejunal feeding tube. The patient had slight right abdominal and left shoulder pain but no fever and chilly on day 9 after operation. Physical examination showed right upper quad-

Figure 1 Computed tomography (CT) scan showing normal gallbladder before operation (A), thickened gallbladder wall and biliary sludge deposition on day 12 after operation (B), and normal gallbladder wall 7 mo after operation (C).

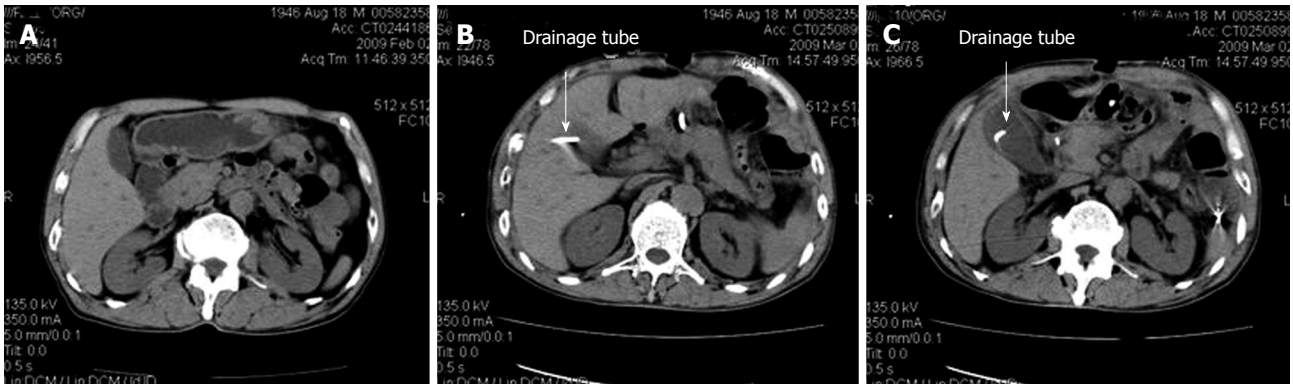

Figure 2 CT scan displaying normal gallbladder before operation (A), thickened gallbladder wall on day 16 after operation (B, C).

rant abdominal tenderness and muscle tension, but no rebound tenderness and Murphy's sign. Laboratory test showed normal white blood cells (WBC) and neutrophils in peripheral blood, as well as normal amylase level and liver function. Abdominal ultrasound and CT scan on day 12 after operation demonstrated thickened gallbladder wall and biliary sludge deposition (Figure 1B). She was given intravenous antibiotics on day 12 after operation for 24 d. Her symptoms disappeared on day 24 after treatment with antibiotics. The patient was discharged 50 d after gastrectomy. Abdominal CT scan displayed a normal gallbladder (Figure 1C) without abdominal pain 7 mo after gastrectomy.

Case 2

A 76-year-old Chinese male patient presented with melena for 6 mo. Gastroscopy showed an ulcerated tumor at the gastric antrum and biopsy demonstrated a moderately-differentiated adenocarcinoma with no metastasis. The patient had no history of gallstones and cholecystitis. Preoperative CT scan displayed a normal gallbladder (Figure 2A). Four days after distal gastrectomy, D_2 lymphadenectomy and Billroth Ⅱ reconstruction, he received enteral nutrition via a transnasal jejunal feeding tube. The patient developed high fever (39.4℃) and septic shock without abdominal pain on day 14 after operation. His plasma C-reaction protein (CRP) level was increased to 82.3 mg/L with normal WBC and neutrophils in peripheral blood as well as normal amylase level and liver function. Peripheral blood culture was positive for *Escherichia coli*. He received intravenous antibiotics on day 14 after operation for 6 d, but his body temperature did not become normal. Abdominal BUS and CT scan on day 15 after operation revealed thickened rough gallbladder wall (Figure 2B), and bile culture demonstrated *Escherichia coli*. Three days after ultrasound-guided percutaneous transhepatic gallbladder drainage (PTGD), his temperature returned to normal. He was discharged 30 d after gastrectomy.

Case 3

A 64-year-old Chinese male patient presented with abdominal pain for 1 year. Gastroscopy showed a cardiac ulcerated tumor and biopsy demonstrated a poorly-differentiated adenocarcinoma with no metastasis. The patient had no history of gallstones and cholecystitis. Preoperative CT and BUS displayed a normal gallbladder. Four days after total gastrectomy, D_2 lymphadenectomy and Roux-en-Y reconstruction, the patient received enteral nutrition via a transnasal jejunal feeding tube and developed severe right upper abdominal pain on day 14 after operation. Physical examination showed severe right upper abdominal tenderness. His body temperature was 38.8℃ and plasma C-reaction protein (CRP) level was increased

to 57.6 mg/L. The number of WBC in peripheral blood was 10.4 × 10^9/L with 82.1% of neutrophils. Abdominal BUS demonstrated thickened gallbladder wall with biliary sludge deposition on day 14 after operation and he underwent ultrasound-guided PTGD. Bile culture demonstrated *Escherichia coli*. His symptoms disappeared and body temperature decreased to 37.6℃ on day 15 after operation. He was discharged 22 d after gastrectomy.

DISCUSSION

Acute cholecystitis immediately after radical gastrectomy has been rarely reported[3-5]. Although its pathogenesis is still unclear, it may result from ischemia of gallbladder and biliary stasis, impaired contractile motility of gallbladder after gastrectomy and vagotomy, digestive tract reconstruction, and long-time preoperative fasting[2-4]. Its clinical features are inconsistent with those of acute cholecystitis in general population. Since the symptoms of acute cholecystitis in old patients appear on days 9-14 after gastroectomy, its diagnosis is often delayed and physical findings may be confused with other postoperative complications, such as duodenal stump leakage, postanastomotic leakage, abdominal cavity infection and incisional discomfort. Acute cholecystitis immediately after radical gastrectomy differs significantly from that in general population. The majority of old acute cholecystitis patients have right upper quadrant pain, fever, leukocytosis, and high plasma CRP. Severe bacterial infection may be an exclusive sign of acute cholecystitis immediately after radical gastrectomy in old patients. Case 2 had bacteremia and septic shock but no abdominal pain and tenderness. Abdominal CT and BUS scan confirmed acute cholecystitis immediately after radical gastrectomy by revealing a thickened gallbladder wall, gallstones or gallbladder sludge, pericholecystic fluid and inflammation. In case 1, acute cholecystitis immediately after radical gastrectomy was confused with incisional discomfort, which was diagnosed by abdominal CT and BUS scan on day 3 after operation. It was reported that cholecystectomy, cholecystostomy, ultrasound-guided percutaneous drainage or percutaneous transhepatic gallbladder drainage are the treatment modalities for acute cholecystitis immediately after radical gastrectomy. However, these treatment modalities are still controversial because their efficiency and safety have not been well evaluated. The mortality rate of patients with acute cholecystitis immediately after radical gastrectomy is over 20%[1]. According to our experience with the 3 cases, ultrasound-guided PTGD should be considered for patients with acute cholecystitis immediately after gastrectomy. When physical findings and/or laboratory test reveal postoperative infection, abdominal CT and BUS scan should be performed to diagnose acute cholecystitis immediately after gastrectomy. Ultrasoun-guided PTGD, as a minimal invasive surgical approach, is an efficient and safe method for acute cholecystitis immediately after gastrectomy in old patients.

Abstract

As a complement to standard laparoscopic surgery and a safe alternative to natural orifice transluminal endoscopic surgery, single incision laparoscopic surgery is gaining popularity. There are expensive ports, disposable hand instruments and flexible endoscopes that have been suggested to do this surgery and would increase the cost of operation. For a simple surgery like laparoscopic cholecystectomy, these extras are not needed and the surgery can be performed using standard ports, instruments and telescopes. Triangular port insertion and use of instruments by the "chop stick method" are recommended to successfully do the procedure as we have done in our so far small series of 40 cases.

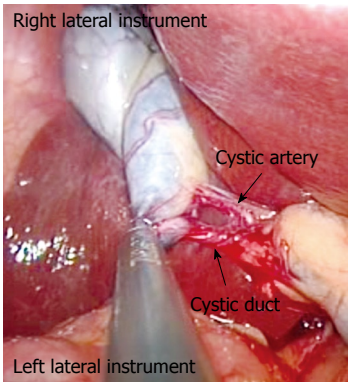

Figure 1 Instrument position while Calot's triangle is defined.

TO THE EDITOR

I read with great interest the article by Hirano *et al*[1] published in issue 2, volume 16 of *World J Gastroenterol* 2010. The use of loop is a good method for retraction without perforating the gall bladder. The method would increase safety of the procedure, but in purist terms, makes it a double incision laparoscopy (DILS).

We have done 40 single incision laparoscopic surgeries using conventional trocars, instruments and telescope. This is to avoid the increase in cost that is inevitable if we were to use two reticulating instruments and the more expensive semi flexible laparoscope or special ports[2].

By inserting the trocars in a triangular manner with a 10 mm telescope inserted from the top port, we are able to reduce sword fighting of instruments. The lower 5 mm ports are manipulated by the "chop stick method" developed by us to ensure that they do not clash. A 30° telescope, 5 mm in diameter, is introduced from the lower left cannula at the time when the 10 mm clip applier is introduced from the top cannula. The clips are only applied when a large window is made in the Calot's triangle (Figure 1).

After the first 20 cases, the instrument clashing, air leak,

and duration of surgery have reduced. This goes to show that there is a learning curve in this procedure[3] during which the main problems are of instrument clash and air leak.

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in tahe field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page,

Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Beijing Baishideng BioMed Scientific Co., Ltd, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www. clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by International Committee of Medical Journal Editors, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g., Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g., Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no more than 256 words) and structured abstracts (no more than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no more than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections. AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…; MATERIALS AND METHODS (no more than 140 words); RESULTS (no more than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case

report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version includes manuscript and high-resolution image figures. The author should re-submit the revised manuscript online, along with printed high-resolution color or black and white photos; Copyright transfer letter, and responses to the reviewers, and science news are sent to us *via* email.

Editorial Office

World Journal of Gastroenterology
Editorial Department: Room 903, Building D,
Ocean International Center,
No. 62 Dongsihuan Zhonglu,
Chaoyang District, Beijing 100025, China
E-mail: wjg@wjgnet.com
http://www.wjgnet.com
Telephone: +86-10-5908-0039
Fax: +86-10-85381893

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

Authors of accepted articles must pay a publication fee.
EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

AIM AND SCOPE		*World Journal of Gastroenterology* (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, DOI: 10.3748) is a weekly, open-access, peer-reviewed journal supported by an editorial board of 1096 experts in gastroenterology and hepatology from 60 countries. The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Abstract

Supported by the "Special Fund for Key Academic Journals" of the National Natural Science Foundation of China, *World Journal of Gastroenterology* (*WJG*) has become a high-impact international clinical medical journal due to the great efforts of Professor Lian-Sheng Ma, Editor-in-Chief, and his team over several years. Now, *WJG* has successfully achieved a high degree of internationalization and sets a good example for other Chinese academic journals.

Key words: China; Academic journals; Internationalization

Peer reviewer: Emmet B Keeffe, MD, Professor, Chief of Hepatology, Medical Director, Liver Transplant Program, Program Director, Gastroenterology Fellowship, Stanford University Medical Center, 750 Welch Road, Suite 210, Palo Alto, CA 94304, United States

Zu GA. *WJG* sets an example of internationalization for other Chinese academic journals. *World J Gastroenterol* 2010; 16(22): 2707-2709 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i22/2707.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i22.2707

CREATIVE PEOPLE DESERVE APPLAUSE

During the application period for the "Special Fund for Key Academic Journals" of the National Natural Science Foundation of China (NSFC) in early 2002, I came to know Professor Lian-Sheng Ma and *World Journal of Gastroenterology* (*WJG*), which he created. Since then, I have had close contact with him. As a successful entrepreneur and pharmacologist, he has devoted himself to the creation of academic journals by applying his past successful experience in the pharmaceutical industry to the academic publishing field. This shift carried a great personal risk but it has worked out well for the Chinese academic publishing industry. Professor Ma is always willing to listen to and incorporate other people's opinions and suggestions, and can thereby, provide creative ideas. He likes making friends and therefore keeps close contact with a number of government employees, scientists and publishers. During regular telephone or face-to-face conversations, Professor Ma often pushes me to give an in-depth opinion on the feasibility of his ideas. When *WJG* was initially supported by the NSFC "Special Fund for Key Academic Journals" in 2002, it was published bimonthly. Within a few years, *WJG* has become a weekly journal. Such rapid development has far exceeded my expectations and is a marvel in the Chinese academic publishing industry. For this reason, I have full confidence in the rapid development of Chinese academic journals in the next few years.

According to the traditional view, the basic conditions for Professor Ma to create international English-language medical journals are not very good. However, he is very good at exploiting the strengths of the journals to compensate for their inadequacies. For this reason, he can adeptly manage the overall operation of the journal and perform better than many other scientists and pub-

lishers. More importantly, he is not merely satisfied with issuing orders for the management of the journal operation. Instead, he always becomes personally involved in specific affairs, and therefore, has total control over the journal. He always participates in every aspect of journal production, whether the editing process or the design of the online version, constantly poses questions and suggests modifications, and immediately takes action. He not only has goals and ideas but also can find solutions to any problems that are encountered. These aspects constitute the basis for his success.

I was particularly touched by what Professor Ma did during the summer of 2003 while the severe acute respiratory syndrome epidemic was raging in Beijing. While many institutions came to a semi-standstill, Professor Ma launched the online version of *WJG* during that period. The overall outlook of online *WJG* is impressive and comparable to that of some world-renowned journals. At the beginning, thousands of visitors came to the site per day. Now, this figure has grown to tens of thousands, and *WJG* has become a leader among Chinese academic journals. Professor Ma's work style and creative spirit have rarely been seen in traditional Chinese publishers, because he has closely linked his personal interests (economic interests and social image) to the development of *WJG*.

The success of *WJG* has brought a fresh outlook to the Chinese academic publishing industry. Professor Ma should feel proud of his contributions, which have been made at a time when China is still not open to publishing privately funded academic journals. I hope that more successful and courageous Chinese entrepreneurs will become involved in the Chinese academic publishing industry; an area that remains to be developed, and one that can provide tremendous opportunities.

A JOURNAL REFLECTS A TYPE OF CULTURE

A journal not only reflects the experience and background of its editors/publishers, but also displays their unique personality and personal and cultural tastes. The readers can discover something beyond the contents of a journal. I have a habit of browsing world-renowned journals to capture changes in the overall trend and style of mainstream journals. I also look through *WJG*, from which I can glimpse inside Professor Ma's inner world and mind, and appreciate his efforts towards realizing his ambition to make *WJG* an excellent international journal.

With China's accession to the World Trade Organization and continuous rapid economic growth, its international status has been greatly improved. In recent years, a large number of foreign publishers and distributors have set up representative offices in China or have established cooperation with Chinese printers or publishers. I have had contact with more than 10 foreign publishers and therefore understand their primary intention and purpose. On many occasions, I have warned the publishers of journals supported by the NSFC Special Fund for Key Academic Journals to develop such cooperation with prudence. *WJG* Press was not the first domestic publisher to establish cooperation with well-known foreign publishers, but it was the first that dared to discontinue such cooperation. In this way, Professor Ma seeks internationalization of *WJG* not to further his own reputation, but rather that of the journal.

The development of *WJG* over these years has not been smooth, and has had many difficulties. We have always been concerned about the overall situation of NSFC-funded journals, especially those like *WJG* that have incurred much controversy. Between 2004 and 2005, the self-citation rate of *WJG* was 20%, which exceeded the ISI standard, and this resulted in *WJG* being removed from Science Citation Index (SCI). To combat these arguments, Professor Zuo-Yan Zhu, the NSFC Vice President, pointed out at a meeting in January 2003 that the goal of Chinese academic journals should be to achieve internationalization, to be included in SCI, and to be a leader among international journals in the same field. There are many ways to achieve these goals. However, the most fundamental way is to improve the quality of the journals. Although many approaches are available to improve the impact factor of a journal in a short period, there is no doubt that a high-impact journal can be created only after its scientific quality is raised.

As mentioned above, in 2004, *WJG* drew wide criticism because of a high self-citation rate. I sensed that Professor Ma underwent tremendous pressure during that period. However, it is pleasing to know that he did not make any excuses or avoid problems, but spent a lot of time to establish the reasons for this and make improvements. Fortunately, these lessons have led to the subsequent rapid development of *WJG*.

Ms. Emilie Marcus, Editor-in-Chief of *Cell*, pointed out in a forum in 2006 that the presence of high-impact articles depends on strong inputs of financial and human resources. These words are easier said than done. How is financial investment achieved? Where should the funds be invested? How are talented scientists recruited and utilized? Coincidentally, in recent years, *WJG* has been practicing the above sentiments. This shows that great minds think alike.

Looking back on modern technological developments worldwide, it can be seen that the progress of all renowned journals has not been smooth, but full of ups and downs. To create a world-renowned journal, the sponsor has to spend a lot of time and effort, sometimes even for several generations. Such journals are more respected and their publishing model is worthy of being passed on to others. The history of *Science*, which was created by Thomas Edison, spans 125 years, while that of British *Nature* and *The Lancet* (created by the Wakely family) spans 137 and 183 years, respectively. Although these journals are not run by governments, they enjoy a great reputation worldwide. I believe that Professor Ma could have the confidence and courage to make *WJG* a world-renowned journal.

PRACTICAL EXPERIENCE OBTAINED DURING *WJG* DEVELOPMENT HAS GREAT SIGNIFICANCE

At the last meeting of the *WJG* working group, I mentioned that the reform of state-owned enterprises could provide a reference for the successful operation of academic journals. Here, I would like to discuss the implications of the rise of the Chinese Communist Party (CCP) for the reform of Chinese academic journals.

In recent years, many entrepreneurs in China have been keen to read about the developmental history of the CCP, to gain a better insight into business management. As the world's largest political party (with nearly 70 million members), the CCP has been in existence for 85 years and has ruled China for more than half a century. What are the fundamental reasons for its sustainability? This question has attracted the interest of many domestic and foreign politicians and entrepreneurs. The rapid growth of China's national economy since 1979 has led state-owned enterprises into a new era of development. All enterprises are in competition with their rivals for the throne. The rise of new outstanding enterprises is often coupled with the fall of some previously successful companies. The rapid turnover of businesses has become a feature of the development of the Chinese economy. Survival is the main theme of business management in our times.

Ten years ago, entrepreneurs might have been successful merely by having the courage to go into business. In more recent times, however, the survival of enterprises has been more dependent on management rather than luck or back-door dealing. For this reason, entrepreneurs have been anxious to seek better management approaches: some have learned from the West, some from Confucianism, and others from the developmental history of the CCP.

Western management style has its own advantages, but it may not be suitable for Chinese enterprises. Although Chinese entrepreneurs hope to derive the essence from Western management style, they tend to spend a lot of time dealing with superficial matters. The Western business community has a history of 200 years and is very mature. Many excellent Western academic journals also date back for more than a century. A mature business environment provides Western academic journals with a sound management system. In contrast, the development of Chinese academic journals has occurred mainly after 1976. As a result of market, cultural and policy differences, there is no appropriate management system available for Chinese academic journals. This developmental stage provides a better opportunity for publishers to display their talents.

In terms of business management, an important criterion for entrepreneurs to judge the feasibility of a management theory is whether it is practical (in relation to the situation in China). The core issue with which entrepreneurs are concerned is how to realize Western management style in China. The ultimate goal of businesses is to achieve a profit, therefore, they advocate the same laws as the CCP: survival of the fittest and natural selection. How to guarantee basic living conditions is their common primary goal in response to external challenges. The development of enterprise management has about 100 years of history. As a result, various types of business management theories have been proposed. Despite diversity, their fundamental purpose is to answer the same question: how is efficiency improved? The CCP can organize many citizens in a fairly orderly manner and has an extremely high level of organization that is universally acknowledged. High efficiency and strong executive power are its biggest features.

The operation of academic journals has its own laws. If an academic journal is not run in accordance with market or economic rules, but managed in a very superficial manner, the journal will not be successful. *WJG* is aiming to implement Western management style in China by obeying market and economic rules. The success of *WJG* will make a significant contribution to Chinese scientific and cultural development. I hope Professor Ma can keep a diary to record his management practice, which could be a great asset to later generations.

Our generation, which is involved in the reform of China's academic journals, should not overlook the development of *WJG*, because its preliminary success has been achieved by overcoming many obstacles and fighting against the inherent snobbishness of the traditional publishing industry that has existed in China for decades. I am very pleased that some of my ideas for creating outstanding international academic journals have been adopted and gradually realized by Professor Ma. I am also happy that *WJG* sets an example of internationalization for other Chinese academic journals.

Abstract

Spices and herbal remedies have been used since ancient times to treat a variety of disorders. It has been experimentally demonstrated that spices, herbs, and their extracts possess antimicrobial, anti-inflammatory, antirheumatic, lipid-lowering, hepatoprotective, nephroprotective, antimutagenic and anticancer activities, besides their gastroprotective and anti-ulcer activities. Despite a number of reports on the toxicity of herbs and spices, they are generally accepted as safer alternatives to conventional therapy against gastric ulcers. To this end, it is also believed, that excessive consumption of spices may favor the pathogenesis of gastric and duodenal ulcer and some studies have substantiated this common perception. Based on various *in vivo* experiments and clinical studies, on the effects of spices and herbs on gastric ulcers, it has indeed been shown that certain spices do possess remarkable anti-ulcer properties mediated by antisecretory, cytoprotective, antioxidant, and anti-*Helicobacter pylori* effects and mechanisms regulated by nitric oxide, prostaglandins, non-protein sulfhydryl molecules and epidermal growth factor expression. Accordingly, their consumption may attenuate and help prevent peptic ulcer disease. In the present review, the beneficial effects of spices and herbal nutritive components on the gastric mucosa are discussed against the paradigm of their deleterious potential.

INTRODUCTION

Herbs and spices are considered as an important additive to food in several parts of the world. They enhance aroma, piquancy, and impart flavor to food. For long, they have been regarded as the essential component of eastern cuisine and have also been adopted into western diets. Since ancient times, spices and herbs have also been used in traditional treatment of a number of diseases. Nowadays, several experimental studies and, to a lesser extent, clinical trials have also emphasized the role of herbs in the treatment of a variety of disorders[1-4]. Several herbs and herbal extracts have been shown to possess antibacterial properties[5-7]. For instance, onion, garlic, ginger, pepper and mustard have demonstrated antimicrobial activity against several types of bacteria[8]. Tayel and El-Tras have recently reported a potent antibacterial activity of cinnamon and clove against several bacterial strains[9]. Some spices possess antifungal activity[10,11]. Beside their antifungal activity, herbs have also shown vermicidal, nematocidal and molluscicidal potential[12-15]. In addition, gingerol, the active ingredient of ginger, and eugenol have shown anti-inflammatory

and antirheumatic activity[16]. More recent studies have also demonstrated anti-inflammatory and antirheumatic properties of herbs[17-19]. Furthermore, gingerol and curcumin have also shown lipid-lowering potential in experimental animals[20-22] as well as in clinical trials[23,24].

In addition, many studies have especially endorsed the experimental evidence of folkloric utilization of spices to treat gastrointestinal disorders, without gastric mucosal toxicity. Also clinical, video-endoscopic studies conducted by Graham *et al*[25] have shown an adaptive cytoprotection. Furthermore, several experimental studies have also demonstrated cytoprotective activity of herbs[26-29].

On the other hand, some spices are considered to be toxic to the gastric mucosa and may potentiate or induce gastric injuries. Gastric mucosal toxicity induced by some spices in experimental animals is related to their oxidative constituents such as phenylpropenes, safroles, methyl eugenol, 1'-hydroxyestragole, myristicin and elemicin[30,31]. Meyers *et al*[32] have reported deleterious effect of red pepper and black pepper on the stomach. Both have induced a significant enhancement in parietal secretion, pepsin secretion, and potassium loss, as well as a dose-dependent gastric cell exfoliation and mucosal microbleeding, which are comparable to those induced by aspirin. Other studies have also reported epigastric pain and dyspepsia. The mechanism of epigastric pain and dyspepsia induced by red and black pepper is not well-defined. However, it is believed to be a consequence of inhibition of gastric surface hydrophobicity, enhancement of surface wettability and activation of intramucosal pain receptors[33]. Some spices may stimulate acid secretion and have deleterious effects on the gastric mucosal lining. Intragastric perfusion of albino rats with aqueous extracts of red pepper, fennel, omum/ajwain, cardamom, black pepper, cumin and coriander have stimulated a cholinergic response, and/or *via* other mechanism(s) have induced acid secretion with a respectively declining order. In injured stomach, cumin and coriander increase gastric secretion, and red pepper has an inhibitory effect[34].

Herbs in general are believed to be safe, and several studies have found them to be non-detrimental and beneficial to gastric mucosa and have cytoprotective properties[25,28]. In addition to their anti-ulcerogenic activity, it has been reported that spices contain protective factors that possess anticancer potential[35-37]. The ulcerogenic and/or anti-ulcerogenic activity of herbs is likely to be due to the oxidative and anti oxidative action of their different phytoconstituents. The prominent mechanism of protective action is mediated by their antioxidant activity and the ability to scavenge reactive oxygen species (ROS). A variety of herbs such as clove, cinnamon, oregano, black pepper, turmeric, ginger and polygonum species are known to contain phytoconstituents with anti-oxidative potential[38-46]. Antioxidative constituents of herbs are summarized in the Table 1.

The beneficial effects of herbs and plant extracts in the prevention of gastric injury have been indicated in several experimental studies. For example, various extracts of *Mammea americana* have significantly reduced the ulcer index and demonstrated a cytoprotective effect in experimentally induced ulcers[47]. Further pharmacological and histopathological studies have demonstrated significant protection against ethanol-induced ulcers in rats by extracts of roots of *Asphodelus aestivus* and *Cichorium intybus*, herbs of *Equisetum palustre* and *Viscum album ssp.* album and fruits of *Laurus*[48].

Clinical studies have also confirmed the gastric protection conferred by herbs. In a clinical study of 98 outpatients with chronic gastritis, who were randomly divided into a group treated with herbal pairs and a control group treated with *Banxia Xiexin Tang*, effectiveness was significantly higher in the treated group. The treatment has improved therapeutic effects, and minimized the adverse effects of gastritis[49]. In another clinical study, 103 patients with duodenal ulcer received phytotherapy in the form of infusions and concoctions of medicinal plants. This resulted in ulcer scarring and a decrease in relapse[50]. Furthermore, in a study of 170 patients with duodenal ulcer and gastroduodenitis treated with herbal combinations alone or with addition of antacids, pain and dyspeptic symptoms disappeared in > 85% of both treatment groups, with a similar rate of endoscopic healing[51]. Hence, agents that possess antioxidative activity are expected to play a major role in the treatment of peptic ulcer disease.

EXPERIMENTAL INDUCTION OF ULCERS

Various noxious chemical agents are used to induce acute experimental gastric ulceration. Indomethacin and necrotizing agents including 80% ethanol, 0.2 mol/L NaOH, 25% NaCl are commonly used. Pyloric ligation is applied in antisecretory studies[52-56]. Other universally accepted experimental ulcer models include stress induced by swimming[55], aspirin[56], ethanol/HCl, acetylsalicylic acid, cold-restraint[57] and hypothermic restraint[54]. In addition, gastric ulcers have also been induced by serosal application of acetic acid[58].

FACTORS INVOLVED IN ULCER HEALING

Acid and other noxious agents such as bile acids, non-steroidal anti-inflammatory drugs (NSAIDs) and ethanol enhance the presence of mucosal barrier disruption, H^+ back diffusion and ulcer susceptibility. Adequate mucosal flow and secretion of bicarbonate with formation of an alkaline buffer layer at the epithelial surface, is considered as a first line of mucosal defense. Prostaglandins (PGs) are involved in the ulcer healing process. Growth factors, some gut hormones (e.g. gastrin and cholecystokinin) and melatonin promote ulcer healing through generation of cyclooxygenase-2 (COX-2) and release of PGE2 in the ulcer margin[59,60]. Similar action is achieved by application of antisecretory doses of exogenous PG[61]. In addition to PGs, many other factors including growth factors, nitric oxide or calcitonin gene-related peptide, as well as some gut hormones such as gastrin and cholecystokinin, leptin,

Table 1 Antioxidant constituents of herbs

Antioxidant constituents	Herb	Ref.
Pimentol, biflorin	Clove, allspice	[38]
Phenolic constituents: phenolic acids, phenolic diterpenes, flavonoids, and volatile oils, phenolic volatile oils	Many herbs including clove, cinnamon and oregano	[39]
Piperine	Black pepper	[40]
Curcumin, methoxy phenols, dehydrogingerdione, bakuchiol	Turmeric, from Indian spices, ginger, *Psoralea corylifolia*	[41]
Phenolic compounds: flavonoids, phenolic acids and their derivatives, tannins, stilbenes, and anthraquinones	Polygonum species, spring onion, broccoli, orange, carrot and ginger	[42]
Phenolic diterpenes	*Rosmarinus officinalis* and *Salvia officinalis*	[43]
Phenolic, flavonoid, chlorogenic acid and neochlorogenic acid	Andean spice Sanicula graveolens (Apiaceae)	[44]
Phenylpropanoids (phenolic compounds)	Human diet, spices, aromas, essential oils, propolis and traditional medicine	[45]
Polyphenolic	*Piper umbellatum, Piper nigrum, Piper guineense*	[46]

ghrelin and gastrin-releasing peptide, are involved in gastroprotection. The protective action of gut hormones has been attributed to the release of PG or activation of sensory nerves[62].

MECHANISMS OF PROTECTION RENDERED BY SPICES AND HERBS

The mechanism of herb-induced gastroprotection varies according to the nature and chemical constituents of the herbs. Three main functions including antisecretory, cytoprotective and antioxidant activities, isolated or in combination, are responsible for gastric mucosal protection.

Antisecretory activity

Several herbs and plants extracts have shown an anti-ulcer effect mainly due to their potent antisecretory action, which could be related to their flavonoid content. In experimental animals, *Cissus quadrangularis* extract and *Maytenus ilicifolia* have been shown to inhibit gastric secretions and ulcer index[63,64]. Similarly, phytosphingosine hydrochloride has been shown to have antisecretory and anti-ulcer effects in animals with pyloric ligation[65]. Methanolic extract of *Momordica charantia* prevents development of peptic ulcer and promotes healing of ulcers induced by acetic acid. Antisecretory studies in pylorus-ligated rats have demonstrated a significant reduction in acidity, pepsin content and ulcer index. On the other hand, the extract also amplifies the gastric mucosal content[66]. A variety of herbs and plant extracts including standardized aqueous extract of *Cecropia glaziovii Sneth* (Cecropiaceae)[67], alkaloid extract and 2-phenylquinoline obtained from the bark of *Galipea longiflora* (*Rutaceae*)[68] and *Landolphia owariensis* extracts[69] have exhibited an anti-ulcer effect.

The inhibition of gastric acid and pepsin output in rats with intact or deactivated sensory nerves treated parenterally with capsaicin could contribute to the capsaicin-induced gastroprotection against acid-dependent mucosal lesions[70].

Cytoprotective activity

In pylorus-ligated rats, methanolic extract of *M. charantia L.* fruit protects against peptic ulcer and promotes ulcer healing *via* enhancing the gastric mucosal content and antisecretory activity in stress-, ethanol-, indomethacin- and cysteamine-induced ulcers[66]. In both ethanol- and indomethacin-induced experimental ulcers, pretreatment with isopulegol, a monoterpene present in essential oils of several aromatic plants, has resulted in significant gastroprotective action, which is apparently mediated through its endogenous PGs and antioxidative properties[71]. Moreover, Weikang (WK) decoction significantly protects against ethanol-induced gastric mucosal injury. This activity is mediated by enhancement of epidermal growth factor (EGF) content in gastric juice, nitric oxide (NO) in gastric tissue, PGE2 and superoxide dismutase (SOD) in plasma, inhibition of malondialdehyde (MDA) and endothelin in plasma, and an increase in mucosal thickness[72]. In swim- and ethanol-stress-induced ulcers, extract of ginger rhizome (*Zingiber officinale*) normalizes antioxidant enzymes and protects against oxidative and gastric mucin damage[55]. The gastroprotective effect of *Vanillosmopsis arborea* bark essential oil is likely mediated by α2-receptor activation[73], whereas the anti-ulcerogenic effect of *Solanum torvum Swartz* (Solanaceae) aqueous and methanol extracts is probably due to cytoprotective mechanisms[74]. Cytoprotective action of total carotenoid and astaxanthin esters depends on their mucin-related protective action as well as enhancing antioxidants enzymes level and H^+, K^+-ATPase inhibitory activity[75]. Synthesis of cytoprotective PGs, increased resistance of gastric mucosa, and inhibition of leukotriene synthesis are possibly responsible for gastroprotection induced by boswellic acids (from *Boswellia*)[57].

In various ulcer models in mice, the gastroprotective activity of *G. longiflora* (Rutaceae) is related to an increase in gastric mucus content and antisecretory activity. Additionally, NO is involved in mucosal protection, which could be attributed to their alkaloids, particularly 2-phenylquinoline[68]. Pretreatment of albino rats with aqueous extract orally once daily for 2 wk significantly inhibited HCl/ethanol-induced ulcers and enhanced gastric mucus production. Additionally, it displayed antisecretory activity in pylorus-ligated rats. The results indicate that the leaf extracts of *Landolphia* possess anti-ulcer properties[69].

A new flavonoid derivative, DA-6034, also prevents ulcers induced by ethanol, aspirin, indomethacin, stress, and acetic acid, and enhances endogenous PGE2 syn-

thesis and mucus content in the gel layer of the gastric mucosa. Promotion of the gastric defensive systems is the likely cause of its gastroprotective activities[56].

Antioxidative activity

Oxidants are implicated in the pathophysiology of various diseases, including peptic ulcer disease, and antioxidants may therefore contribute to their prevention and treatment. NSAIDs account for some of the most commonly used drugs worldwide and may activate the oxidative process. For instance, treatment with indomethacin induces neutrophil activation with release of ROS and microvascular injuries, which is considered as the prime event in gastric mucosal damage[76]. Therefore, investigators have continued to search for agents with antioxidative properties, which prevent or at least reduce ROS-induced mucosal damage. Such agents include isopulegol, which has shown significant gastroprotective effects in ethanol- and indomethacin-induced ulcer models. Gastroprotective action is probably mediated by its antioxidative properties, synthesis of endogenous PGs and K^+ (ATP) channel opening[71]. Other herbs with antioxidative actions include carotenoid and astaxanthin esters, the herb collection Korniozil, and ginger rhizome. For instance, total carotenoid and astaxanthin esters have experimentally protected gastric mucin and increased levels of the antioxidant enzymes catalase, SOD, and glutathione peroxidase in gastric homogenate[75]. In addition, Korniozil also protects against experimentally induced stress ulcers, with enhancement of gastric mucous coat regeneration, along with restoration of lipid peroxidation and antioxidative system function[77]. Ginger rhizome extract has shown gastroprotective activity in animals with swim- and ethanol-stress-induced ulcers. This activity is based on gastric mucin generation, restoration of antioxidant enzymes and inhibition of *Helicobacter pylori* (*H. pylori*) growth[55].

The gastroprotective effect of *Cissus sicyoides* extract administered orally in rodents treated with various ulcerogenic agents is also due to its antioxidative properties, increase of NO and SH groups, with enhancement of mucosal defense mechanisms and microcirculatory response. Therefore, the authors have supported its use for gastric ulcer treatment[78].

Studies on piperine have demonstrated an antioxidative effect *in vitro*, lipid peroxide inhibition *in vivo*, and enhancement of the bioavailability of phytochemicals. The protective activity of piperine is linked to its antioxidative action and ability to inhibit ROS[40]. Thymoquinone, the active constituent of *Nigella sativa*, has been shown to protect against gastric mucosal damage induced by ethanol. These effects can be ascribed to improvement in the antioxidant status, increased serum levels of serum glutathione, SOD, inhibition of radical oxygen species, and increased mucin content of the gastric mucosa[29,79].

Other activities: PG-herb interaction

PG synthesis is important for gastric mucosal protection. PG has been used as an antisecretory drug to treat peptic ulcer disease. However, the use of a sufficient therapeutic dose is associated with adverse effects, which limits its use, especially after the introduction of antisecretory drugs such as H2-receptor antagonists and proton pump inhibitors. Several studies on herbs and plant extracts that activate PG synthesis have emphasized their role in gastroprotection and healing of gastric mucosal injuries. Silva *et al*[71] have reported a significant dose-related protective effect of isopulegol, a monoterpene that is obtained from essential oils of several aromatic plants, against indomethacin- and ethanol-induced ulcers. This protective action is probably mediated by endogenous PGs, K^+ (ATP) channel opening, and antioxidant properties. Similarly, Alqasoumi *et al*[54] have reported a PG and/or antisecretory, as well as antioxidant-mediated gastroprotective activity of Rocket extract. Boswellic acid, a triterpenoid used clinically to treat arthritis, has exhibited a mucosal protective action through PG synthesis stimulation and leukotriene synthesis inhibition[57]. Endogenous PGs and PG EP1 receptors have an important role in the adaptive protection and functional responses in mice treated with sodium taurocholate[80]. The active ingredient of chilli, capsaicin, which is believed to be ulcerogenic, on the contrary, prevents ulcer formation through its antisecretory action, as well as stimulation of mucus, alkali secretions and mucosal microcirculation. In addition, capsaicin stimulates afferent neurons in the stomach and transmits signals to the central nervous system, which trigger an anti-inflammatory response and gastroprotection[81]. Treatment with small doses of topical capsaicin protects the gastric mucosa from damage by strong irritants[69].

PGs have been found to reduce enhanced duodenal mucosal permeability induced by hydrochloric acid[82]. In acute injury, small bowel mucosa function recovers with the restitution of epithelium, which is believed to be pivotal for epithelial repair, and occurs only in the presence of PG-mediated paracellular space closure[83]. Hatazawa *et al*[84] have studied the role of PGs/COX in the healing of indomethacin-induced small-intestinal ulcers in rats. They have reported ulcer healing by endogenous PGs, which is mediated by PG EP4 receptors, and involvement of COX-2 in the early stage and COX-1 in the late stage of healing. Bacterial lipopolysaccharide is involved in gastric mucosal protection in rats, *via* activation of COX and endogenous PG genes[85]. In rats, *Teucrium polium* has demonstrated protection against indomethacin-induced gastric ulcer through PG synthesis, EGF receptor (EGFR) expression and modulation of mucin secretion, besides its antioxidative activity, and it lack of toxicity[86].

EGF and effect of herbs

Ulcer preventive activity of herbs in experimentally induced gastric injury is thought to be mediated through their antisecretory and antioxidative properties, as well as PG generation. Various factors are involved in mucosal defense and repair, including gastrin, parietal cells and tumor necrosis factor (TNF)-α. Gastrin and parietal cells play an important role in the regulation of mucosal proliferation in response to gastric injury and inflammation[87]. Similarly, TNF-α, which is released during gastric mucosal

injury, also contributes to epithelial cell repair in the gastric mucosa *via* its receptor and activation of the PG pathway[88]. EGF and other growth factors are also pivotal for the process of mucosal healing. EGF and transforming growth factor (TGF)-α have a common receptor (EGFR). They promote ulcer healing through enhancement of cell proliferation, overexpression of growth factors, inhibition of gastric secretion and enhancement of blood flow at the ulcer margin[89]. Treatment with EGF significantly induces extracellular signal-regulated kinase (ERK) activity, COX-2 and PGE2 generation, and cell proliferation. The EGF-induced proliferation of gastric epithelial cells is probably mediated by the ERK/COX-2 pathway[90]. Gastric mucosa regeneration, with cell proliferation, migration, tissue injury repair and ulcer healing are controlled by activation of EGFR. Although TGF-α acts under normal circumstances and following acute injury, EGF acts mainly during the healing process of chronic ulcers. Both TGF-α and EGF, and other growth factors including basic fibroblast growth factor (bFGF) and vascular endothelial growth factor (VEGF), promote restoration of connective tissue and angiogenesis in injured gastric mucosa. Further growth factors involved in regeneration include keratinocyte growth factor, hepatocyte growth factor and trefoil peptides[91]. Regeneration of injured human gastric epithelial monolayers has been promoted by EGFR-dependent phosphoinositide 3-kinase activation[92].

Besides its role in gastric inflammation and injury, EGF plays an important role in the regulation of cancer growth. Phosphorylation of EGFR and inhibition of heparin-binding EGF-like growth factor (HB-EGF) carboxyl-terminal fragment (CTF), and HB-EGF-CTF nuclear translocation are considered crucial in inhibitory regulation of cancer cell growth[93]. Overexpression of EGF has often been found in gastric cancer. Growth factors alter the localization of tight-junction-associated proteins such as ZO-1 and occludin[94]. Baek *et al*[95] have also reported EGF overexpression and urokinase plasminogen activator receptor in human gastric cancers. In epithelial and mesenchymal cells, EGF binds to tyrosine kinase receptor and promotes malignant formation as well as tissue repair[96].

Herb-induced growth factor enhancement may support treatment strategies for gastric ulcer and cancer. Capsaicin-sensitive nerves contribute to healing of acetic-acid-induced chronic gastric ulcer through stimulation of EGF expression in salivary glands, serum and gastric mucosa[97]. Weitongning herb increases EGF and NO content in ulcer scars, which improves ulcer healing and reduces recurrence[98]. Also, in ethanol-induced gastric mucosal injury, WK decoction has shown a significant gastroprotective effect that is mediated by increased levels of NO in gastric tissue, PGI2 and SOD in plasma, and EGF in gastric juice[72]. Mexican tea herb and pilular adina herb have also demonstrated protection of gastric mucosa through stimulation of NO and EGF secretion and enhancement of EGFR expression[99]. Wang *et al*[100] have also reported increased expression of EGF and EGFR mRNA in experimental gastric ulcer in rats treated with Kuiyangping, with possible promotion of ulcer healing and decreased ulcer recurrence. *Angelica* and *Chuanxiong* spices given to rats with myocardial infarction may affect VEGF expression and promote endothelial cell proliferation[101]. This angiogenic effect may also be applied to the formation of new vessels in granulation tissue and restitution of injured gastric mucosa.

Through their effect on EGF, herbs may prove beneficial in the management of cancer. Constituents of ginger have inhibited EGF-induced cell transformation[102]. Inhibition of EGFR tyrosine kinase proliferation and invasion of gastric cancer cells has also been achieved by curcumin[103]. Molecular therapies that target growth factors EGF and VEGF and their receptors have shown promise against hepatocellular carcinoma in the absence of beneficial effects of chemotherapy[104]. Recent data combining EGFR and VEGF inhibitors have suggested the superiority of targeting multiple pathways rather than a single pathway[105]. The anticancer potential of curcumin has been demonstrated by inhibition of EGF-induced upregulation of aquaporin and ovarian cancer cell migration[106].

Role of NO mediation by herbs

Tsai *et al*[107] have evaluated the effect of some spices on NO overproduction generated by inducible NO synthase (iNOS), which is implicated in disease development. Rosemary, tarragon, oregano, basil, marjoram, allspice, and thyme have demonstrated poor to moderate activity. In contrast, cinnamon has excellent ability to scavenge NO. NO-scavenging activity of herbs is probably related to their high content of phenolic compounds, which scavenge NO or suppress iNOS. In another study, pretreatment with NOS inhibitor attenuated the gastroprotective effect induced by polyalthic acid[108]. Moreover, plant-extract-induced gastroprotection is probably related to the enhancing effect on NOS inhibitor expression, gastric microcirculation and release of NO[109]. Participation of NO, PGs and SH compounds may explain the anti-ulcerogenic action of diterpenoid from *Croton reflexifolius*[108].

Non-protein-SH compounds and herbal involvement

Non-protein (NP)-SH compounds contribute to gastric mucosal defense. Depletion of NP-SH alters mucosal integrity. *Commiphora opobalsamum* (L.) Engl. (Balessan) protects against various models of experimental gastric ulcers in rats. It has been shown to protect in a dose-dependent manner against mucus and NP-SH depletion with a large margin of safety[52]. Methanolic *C. sicyoides* extract given orally to rodents has been shown to inhibit experimental gastric injuries induced by necrotizing agents, *via* participation of NP-SH compounds and NO, and enhancement of the defense system[78]. Maintaining adequate gastric mucus concentration and NP-SH levels is essential for gastric mucosa integrity and function. Other herbs and plant extracts also have the ability to preserve the defense system of the gastric mucosa. For instance, pretreatment with *Ginkgo biloba* extract has been shown to inhibit, in a dose-dependent manner, ethanol-induced NP-SH compound production, depletion of gastric wall mucus con-

centration, and lipid peroxidation, and preserve mucosal function[110]. Similarly, anise aqueous suspension, and rocket and anise have significantly replenished ethanol-induced gastric wall mucus concentration and NP-SH depletion in experimental studies[54,111].

H. pylori bactericidal activity of herbs

The association between *H. pylori* and peptic ulcer disease is well-established and eradication is pivotal for ulcer healing and minimizing the relapse rate. Although the eradication rate of currently used regimens ranges between 80% and 90%, the problem of developing resistance is emerging. A number of investigators have evaluated the effect of herbs and plant extracts on *H. pylori*. Methylene chloride cinnamon extract has also shown an inhibitory effect on the free urease of *H. pylori*[112]. Also curcumin and its methanolic extract have inhibited the growth of all strains of *H. pylori in vitro*[113]. In addition, gingerol, a polyphenolic constitute of ginger root, has also demonstrated inhibitory activity on CagA+ strains of *H. pylori*[114]. Moreover, eugenol and cinnamaldehyde prevented growth of *H. pylori* obtained from human gastric tissue, and inhibited the growth of all 30 tested *H. pylori* strains, with a lack of resistance[115]. In a declining order, turmeric, cumin, ginger, chilli, borage, black caraway, oregano and liquorice have demonstrated partial bactericidal activity against *H. pylori*. *H. pylori* adhesion to the stomach has been inhibited by extracts of turmeric, borage and parsley[116]. Zaidi *et al*[117] have reported that > 50% of 50 commonly used Pakistani medicinal plants have inhibited the growth of eight *H. pylori* strains. *Curcuma amada* Roxb., *Mallotus philippines* (Lam) Muell., *Myrisctica fragrans* Houtt., and *Psoralea corylifolia* L aqueous-ethanol extracts have demonstrated a potent anti-*H. pylori* activity and *Mal. philippines* (Lam) Muell. has exhibited potent bactericidal activity.

SAFETY AND TOXICITY OF SPICES

The majority of experimental studies have reported a lack or low levels of toxicity for most spices. However, there are many case reports, and *in vivo* and *in vitro* toxicological studies that have demonstrated the toxicity of certain herbs and their constituents[118]. Some investigators have reported hepatotoxicity of curcumin and its derivatives[119], as well as turmeric and its ethanolic extract in vulnerable mice[120]. Longer treatment with high turmeric dose has been associated with a significant decline in body weight gain and alterations in liver weight[121]. In contrast, chronic treatment with *Foeniculum vulgare* ethanolic extracts of fruit and *Ruta chalepensis* aerial parts have resulted in a significant weight gain in male mice[122]. Changes in liver, spleen, lung or reproductive organs, along with a significant increase in sperm count and motility, and decreased hemoglobin have been reported in *Cinnamon zeylanicum*, *Piper longum* and *R. chalepensis*-treated animals[122,123]. In an experimental model, piperine (10 and 20 mg/kg) decreased mating performance and fertility. Five days post-mating, oral treatment induced considerable anti-implantation activity. In addition, intrauterine injection of piperine has caused loss of implants. However, piperine treatment has not produced any histopathological effect in the ovaries and uterus at the cellular level[124]. Although initial reports on the safety of black pepper and its active ingredient piperine were controversial, the current literature has established its safety in animals. Moreover, piperine has shown antimutagenic and antitumor activities. Curcumin administered at higher doses has resulted in nuclear, genome and more extensive mitochondrial damage in human hepatoma G2 cells, mediated by the elevated concentration of ROS and lipid peroxidation. Curcumin also has caused genotoxicity in PC12 cells and has induced suicidal death of normal erythrocytes[125-127]. At elevated concentrations, thymoquinone may be genotoxic and cytotoxic, induce programmed cell death in erythrocytes, and cause glutathione depletion and liver damage[128,129].

CONCLUSION

It continues to be debatable whether spices and herbal xenobiotics are beneficial to gastric mucosal damage, and whether their toxicity outweighs any benefits. It is, however, clear that the consumption of certain common spices in food and the intake of herbal supplements may help the fight against peptic ulcer disease in humans. This review provides insights into the future use of herb- and spice-based drugs as alternative treatments for gastric ulcer. Dietary and nutritional practices in the oriental region and the consumption of spices in moderate quantities may be of benefit for the prevention of gastric ulcer. The review suggests the need for further investigations into the benefit of herbal xenobiotics and spices on the gastric mucosa, with in-depth *in vivo* studies, sustained clinical trials and cohort analyses. There is enough evidence to conclude that spices have a beneficial effect on gastric ulcers, despite various reports of their toxicity.

Abstract

The gastrointestinal (GI) tract is a common site of bleeding that may lead to iron deficiency anemia (IDA). Treatment of IDA depends on severity and acuity of patients' signs and symptoms. While red blood cell transfusions may be required in hemodynamically unstable patients, transfusions should be avoided in chronically anemic patients due to their potential side effects and cost. Iron studies need to be performed after episodes of GI bleeding and stores need to be replenished before anemia develops. Oral iron preparations are efficacious but poorly tolerated due to non-absorbed iron-mediated GI side effects. However, oral iron dose may be reduced with no effect on its efficacy while decreasing side effects and patient discontinuation rates. Parenteral iron therapy replenishes iron stores quicker and is better tolerated than oral therapy. Serious hypersensitive reactions are very rare with new intravenous preparations. While data on worsening of inflammatory bowel disease (IBD) activity by oral iron therapy are not conclusive, parenteral iron therapy still seems to be advantageous in the treatment of IDA in patients with IBD, because oral iron may not be sufficient to overcome the chronic blood loss and GI side effects of oral iron which may mimic IBD exacerbation. Finally, we believe the choice of oral *vs* parenteral iron therapy in patients with IBD should primarily depend on acuity and severity of patients' signs and symptoms.

INTRODUCTION

Iron deficiency anemia (IDA) is a consequence of depletion of body iron stores due to decreased iron uptake or increased iron loss/use. Body iron content is imposed by controlling its entrance into the body through the gastrointestinal (GI) system rather than by controlling its excretion. GI diseases are among the most common etiologies of IDA because the GI tract is a common site of blood loss and GI diseases may cause malabsorption of iron. Treatment of IDA may be especially cumbersome in patients with GI diseases due to relatively poor tolerability of oral iron preparations and decreased GI iron absorption. The goal of this review is to increase awareness of parenteral iron therapies in the treatment of IDA associated with GI diseases, particularly inflammatory bowel diseases (IBDs).

IRON DEFICIENCY ANEMIA

Clinical findings

Iron deficiency causes anemia through impaired heme synthesis in maturing erythrocyte precursors. In addition to typical symptoms of anemia, patients may present with pica (appetite for bizarre foods), atrophy of upper GI mucosa (glossitis, stomatitis, achlorhydria), and spooning of the nails (koilonychia). Achlorhydria may further worsen anemia by decreasing iron absorption through the GI tract. IDA is also associated with cervical esophageal webs (Plummer-Vinson syndrome), especially in elderly women[1]. Furthermore, a high prevalence of iron deficiency with or without anemia has been reported among patients with restless legs syndrome[2].

Etiology

The etiology of IDA can be broadly categorized into two: increased iron loss/use (acute/chronic blood loss, menses, blood donation, rapid growth during childhood, pregnancy) and decreased iron uptake (inadequate diet, malabsorption due to GI disease or surgery). Common etiologies of IDA stemming from GI diseases are shown in Table 1. Any hemorrhagic lesion within the GI tract may result in blood loss and iron deficiency. IDA is often the first sign of an occult GI malignancy, celiac disease, and gastritis[3,4].

Diagnosis

Although patients with IDA generally present with microcytic, hypochromic anemia, early IDA has normocytic, normochromic indices. Reticulocyte count (corresponding to red cell production) and ferritin level (corresponding to stored iron amount) are typically low in uncomplicated IDA. Serum iron levels are not helpful by themselves because they vary with time of the day[5] and due to various systemic insults. Serum ferritin concentration is an excellent indicator of body iron stores, however, ferritin is an acute phase reactant and its level may be elevated in chronic inflammatory states. Virtually all patients with serum ferritin concentrations less than 15 ng/mL are iron deficient, with a sensitivity and specificity of 59% and 99%, respectively[6]. A cutoff limit of 30 ng/mL may increase its sensitivity to 92%[7]. Transferrin iron binding capacity (ratio of iron-unbound transferrin to total transferrin) is a helpful marker in the diagnosis of IDA and is generally lower than 16% in patients with IDA. Several conditions may complicate the diagnosis of IDA such as infections, malignancies, chronic renal failure, and inflammatory conditions by falsely elevating ferritin levels. Newer assays such as soluble transferrin receptor level and reticulocyte hemoglobin (Hb) content may be helpful, although lack of reliable standards prevented these assays from becoming a routinely available test in clinical practice[8]. Although examination of the bone marrow is considered to be the best method for evaluation of body iron status, it is invasive, expensive, and operator-dependent. In addition, recent papers questioned its accuracy[9].

TREATMENT

Keeping the diverse etiology of IDA in mind, clinicians should not consider it as a simple ailment or deficiency but a sign of a potentially life-threatening disease. Therefore, the mainstay of IDA management should be identification and correction of the underlying pathology. The search for etiology should start with history, primarily directed to assess blood loss from the GI tract and due to obstetrical causes. Potentially curable GI malignancies can be found more commonly using colonoscopy than upper endoscopy[10]. However, the overall prevalence of upper GI lesions is higher than that of lower GI lesions in patients with IDA[11,12]. The initial diagnostic test (colonoscopy *vs* upper endoscopy) can be chosen based on findings in the history.

Red blood cell transfusions are required in hemodynamically unstable patients primarily due to acute GI bleeding. On the other hand, transfusions should be avoided in chronically anemic, hemodynamically stable patients without cardiac or pulmonary comorbidities unless the Hb level is < 7 g/dL[13] due to the potentially life-threatening side effects of transfusions as well as their cost. In case of urgency, anemia can be corrected rapidly with parenteral iron therapy in patients with uncomplicated IDA.

Furthermore, iron studies should be performed after GI bleeding resolves even in non-anemic patients since frequent bleeding may deplete body iron stores without causing explicit anemia. Iron is essential for all cells in the body; and iron replacement in non-anemic but iron deficient patients may improve quality of life[14] and cognitive function[15]; may also delay/prevent the development of IDA in patients with frequent episodes of GI bleeding such as those with IBD and angiodysplasias. Clinicians should take side effects of oral iron therapy and the frequency of patients' bleeding episodes into consideration when deciding on iron supplementation in non-anemic iron deficient patients.

Oral iron replacement

Iron stores can be replenished through oral and parenteral therapy. In asymptomatic and mildly symptomatic patients with IDA, oral iron replacement therapy has been the mainstay therapy. Various iron salts have been used, ferrous sulfate being the most common. Use of oral iron is primarily limited by its GI side effects that are mediated by non-absorbed iron. Although newer preparations were claimed to have less side effects, ferrous sulfate is still the most commonly used oral iron preparation. Accordingly, no difference in efficacy and side effect profile were found between ferrous sulfate, ferrous gluconate, and ferrous fumarate in a randomized, double blind study[16]. However, controlled-release iron preparations and polysaccharide-iron complexes were found to have fewer GI side effects than ferrous sulfate in a few randomized trials[17,18].

Ferrous sulfate is 20% elemental iron so that a 325 mg tablet contains 65 mg iron. Although conventional wisdom

Table 1 Causes of iron deficiency anemia stemming from the GI tract

Decreased iron uptake	Increased iron loss (bleeding into GI tract)
Celiac sprue	Esophagus (esophagitis and cancer)
Giardiasis	Stomach (ulcer, gastritis, cancer, vascular lesions)
Achlorhydria (due to atrophic gastritis, *H. pylori* infection…)	Small bowel (vascular lesions)
Gastrojejunostomy and other surgical techniques bypassing the duodenum where iron absorption is maximal	Large bowel (cancer, angioectasias, adenoma, colitis)
Short bowel syndrome	

GI: Gastrointestinal; *H. pylori*: *Helicobacter pylori*.

Table 2 Pros and cons of parenteral iron over oral iron therapy

Pros
Assured repletion of iron stores regardless of factors affecting iron absorption
Rapid reversal of iron deficiency
Certain or at least assessable adherence to therapy
Infrequent side effects
One-time administration (FeCarb and LMWID)
Cons
Rare lethal drug-related adverse events
Expensive
Requires facilities/staff for administration
Simply taking tablets may be more convenient for some patients

FeCarb: Ferric carboxymaltose; LMWID: Low-molecular weight iron dextran.

dictates administration of 200 mg elemental iron daily for correction of IDA, there is no rationale for using such a high dose of oral iron. Iron absorption from the GI tract is highly efficient but saturable[19]. Accordingly, Rimon *et al*[20] demonstrated that oral iron preparations at doses as low as 15 mg/d could be used to correct iron deficiency.

To avoid GI side effects and consequent non-compliance, oral iron should be started at a low dose once daily after meals then the dose can be increased at the clinician's discretion. If well tolerated, patients should attempt to take iron preparations on an empty stomach to increase iron absorption. Within 7-14 d of therapy, an increase in reticulocyte count would be expected and within 2 mo Hb level should return to normal. Oral iron replacement should be continued to replenish iron stores, usually for an additional 4 to 6 mo after Hb normalization.

Parenteral iron replacement

The parenteral route should be used for iron replacement in patients who cannot be treated adequately with oral iron supplements due to severe GI side effects, inadequate absorption, and anemia that requires urgent correction. Many clinicians have been reluctant to use parenteral iron formulations due to the infrequent, random, but rarely lethal hypersensitive reactions to high molecular weight iron dextran (HMWID) infusions. However, the incidence of severe adverse effects is lower with low molecular weight iron dextran (LMWID) and newer parenteral iron complexes. Rates of life threatening adverse drug events were reported as 0.6, 0.9, 3.3, and 11.3 per million doses of iron sucrose, iron gluconate, LMWID, and HMWID, respectively[21]. The pros and cons of parenteral over oral iron replacement are listed in Table 2.

All parenteral iron complexes consist of a ferric iron core and a stabilizing carbohydrate shell. Table 3 demonstrates the selected characteristics, administration guidelines, and side effect profiles of four parenteral iron complexes[22,23]. Following parenteral administration, the iron-carbohydrate complex is separated by the reticuloendothelial system and iron is gradually released into the circulation combining with transferrin for transport to the liver, spleen, and bone marrow. Parenteral iron is administered at a dose to restore the total iron deficit (TID) in the body. The TID is traditionally calculated by Ganzoni's formula[24]: (2.4 × body weight (kg) × [target Hb (g/dL) - observed Hb (g/dL)] + 500 mg (iron depot). However, this formula may underestimate the iron depot in males which is estimated to be 700-900 mg[25].

Iron gluconate and iron sucrose are weaker complexes than iron dextran and ferric carboxymaltose (FeCarb). Therefore, iron is released into circulation quicker and becomes readily available for erythropoiesis[26]. While early release of iron may cause a quicker response in Hb levels, it increases the risk of acute adverse events because non-bound labile iron may cause transient capillary leak syndrome leading to nausea, hypotension, tachycardia, dyspnea, and edema mimicking anaphylaxis[27]. Hence, iron gluconate and iron sucrose have lower maximal recommended single doses.

Due to the higher incidence of anaphylactic reactions associated with iron dextran, a test dose of 25 mg as slow intravenous (IV) push is required before LMWID administration. On the other hand, LMWID can be administered at higher doses enabling physicians to administer the total iron dose at one infusion. Furthermore, LMWID is less expensive compared to the other parenteral iron complexes. Iron dextran can also be administered intramuscularly, however, this is not recommended due to the incomplete absorption from the injection site and pain on injection.

FeCarb is a novel parenteral iron complex with a favorable side effect profile that can be applied at single doses up to 1000 mg per week at a high infusion speed (1000 mg IV over 15 min)[28]. However, the safety information on FeCarb is not mature and various phase Ⅲ trials are underway evaluating its efficacy and safety. As of December 2009, FeCarb has not been approved by the USA Food and Drug Administration.

Table 3 Selected characteristics and dosage guidelines of parenteral iron complexes

	LMWID	Iron gluconate	Iron sucrose	FeCarb
Concentration	50 mg/mL (2 mL vial)	12.5 mg/mL (5 mL ampule)	20 mg/mL (5 mL vial)	50 mg/mL (2 mL vial)
IV injection dose	100 mg over 2-5 min	125 mg over 10 min	100 mg over 5 min	100 mg over 2 min
Direct iron donation to transferrin	1-2	5-6	4-5	1-2
Test dose required	Yes, 25 mg slow IV push	No	No	No
Maximal single dose for IV infusion	Not limited	125	500	1000
Total dose infusion	Yes, in NS over 1-6 h	No	No	No
Pregnancy category	C	B	B	N/A
Life threatening ADEs (per 10^6 doses)	3.3	0.9	0.6	N/A

LMWID: Low molecular weight iron dextran; IV: Intravenous; ADE: Adverse drug event; NS: Normal saline; N/A: Not available.

Table 4 Clinical studies comparing parenteral and oral iron therapy

Author	Intervention	Study method	*n*	Efficacy	*P*
Schröder *et al*[33]	Elemental iron 100-200 mg/d × 6 wk	Randomized	24	[1]RR: 53%	0.85
	Iron sucrose 7 mg/kg × one dose then 200 mg once-twice/wk × 5 wk		22	[1]RR: 55%	
Erichsen *et al*[34]	Elemental iron 120 mg/d × 14 d	Crossover trial with a washout period of > 6 wk	17	Mean increase in Hb: 0.2	< 0.05
	Iron sucrose 200 mg on days 1, 5, 10		17	Mean increase in Hb: 0.7	
Kulnigg *et al*[28]	Elemental iron 200 mg/d × 12 wk	2:1 (FeCarb:oral) randomization	136	Median increase in Hb: 2.8	NS
	FeCarb 1000 mg (max) weekly (× 1-3 wk)		60	Median increase in Hb: 3.7	
Gisbert *et al*[35]	Elemental iron 106 mg/d × 3-6 mo	Hb ≥ 10.0 g/dL	78	[2]RR: 89%	NS
	Iron sucrose 200 mg twice/wk × 3-6 mo	Hb < 10.0 g/dL	22	[2]RR: 77%	
Lindgren *et al*[36]	Elemental iron 200 mg/d × 20 wk	Randomized	46	[1]RR: 47%	0.07
	Iron sucrose 200 mg weekly until calculated dose reached		45	[1]RR: 66%

IRON DEFICIENCY IN INFLAMMATORY BOWEL DISEASE

IDA in IBD requires further attention because of its complex etiology and the current debate on its treatment. Anemia is thought to be the most common extraintestinal manifestation of IBD with a prevalence of 6%-74% in different study populations (higher in hospitalized patients)[29]. Anemia in IBD is multifactorial in origin and is frequently due to the combination of iron deficiency (primary cause) and anemia of chronic disease (ACD). In some cases, anemia may be drug induced (mesalazine, sulfasalazine, azathioprine, mercaptopurine) or due to folate/vitamin B12 deficiency. Iron deficiency in IBD is primarily caused by chronic blood loss through the GI tract, however, decreased iron absorption may also play a role in patients with Crohn's disease affecting the proximal small bowel. The prevalence of iron deficiency in IBD ranges from 36% to 90% depending on the definition of iron deficiency and cohort selection[30-32].

The frequent mixture of IDA and ACD in patients with IBD creates a diagnostic dilemma. Chronic inflammation increases serum ferritin and decreases serum transferrin level. As a result, the sensitivities of ferritin and iron saturation for IDA are decreased in patients with IBD. In addition to serum ferritin level and iron saturation, clinicians may use novel tests such as soluble transferrin level or a therapeutic trial of iron replacement therapy in anemic IBD patients.

The current debate on treatment of IDA in patients with IBD centers on the choice of the iron replacement route. The advantages of parenteral over oral iron replacement are thought to be:

Parenteral therapy may be more efficacious than oral supplementation because of low iron absorption from the GI tract in patients with IBD and lower compliance to the oral therapy. However, currently available data are not sufficient to reach such a conclusion. A few studies comparing the efficacy of oral and parenteral iron therapy have been published with conflicting results[28,33-36] (Table 4). Although Lindgren *et al*[36] recently concluded that IV iron therapy was more efficacious in the treatment of IDA in IBD after an intent-to-treat analysis, this study was confounded by a high discontinuation rate in the oral therapy arm (11 of 46 patients).

Persistent blood loss may exceed the capacity of intestinal absorption of iron in some patients[37]. The maximal iron absorption from intestines depends primarily on the level of body iron store and iron intake. Iron-deficient patients receiving 100 mg elemental iron/d can absorb at most 25-37.5 mg iron/d[38,39]. Since whole blood contains 0.5 mg elemental iron/mL[40], oral iron therapy may replace the iron lost in 50-75 mL of blood in the best circumstances. Therefore, clinicians should not expect oral iron therapy to correct IDA and replenish body iron stores in patients losing more than 20-30 mL blood daily. Consequently, parenteral therapy may be more useful in patients with moderate-severe active IBD.

Parenteral therapy causes an earlier increase in Hb levels[28,34]. For that reason, it is more valuable in situations where rapid correction of anemia is required such as in hemodynamically stable patients with moderately severe symptoms of anemia or those requiring an elective procedure within a few weeks.

Oral iron therapy has a high incidence of GI side effects such as epigastric pain and diarrhea that lead to discontinuation of therapy in up to 21% of patients[29]. Additionally, it is extremely difficult to differentiate these side effects from IBD exacerbation. Blackened stools by non-absorbed iron may also mimic melena and lead to unnecessary tests. On the other hand, lower doses of iron may be better tolerated and as efficacious as higher doses. Gisbert *et al*[35] recently reported a discontinuation rate of 5% and normalization of Hb concentration in 89% of IBD patients treated with 106 mg of oral elemental iron daily.

In addition to its GI side effects, oral iron may worsen IBD as a result of non-absorbed iron-mediated toxic reactive oxygen species. Accordingly, oral iron therapy was demonstrated to worsen disease activity in several rodent models at doses 100- to 1000-fold higher than the therapeutic iron dose[41-44]. In the only animal study in which the clinically therapeutic dose in humans was used, oral iron was found to increase histologic colitis scores in DSS-induced colitis in rats[45]. Furthermore, oral iron therapy was found to worsen IBD activity indices in one clinical study[34] while it improved or had no effect in other studies[35,36,46]. Irrespectively, disease activity questionnaires in IBD patients being treated with oral iron may not reflect the true disease activity but may be confounded with the GI side effects of iron.

On the other hand, oral iron therapy is less expensive, does not require additional infusion staff and infusion facilities, does not have life-threatening side effects, and may be more convenient for some patients because of logistics. We believe parenteral iron therapy is still advantageous over oral therapy in patients with IBD due to a quicker response, efficacy in severe cases, and the GI side effects of oral therapy.

Another pressing issue on iron replacement is the duration of therapy. Kulnigg *et al*[47] recently reported that anemia recurred within 10 mo of therapy cessation in 50% of anemic IBD patients whose Hb levels had normalized after IV iron sucrose and erythropoietin therapy, indicating a need for continuous iron maintenance therapy. In addition, patients with a ferritin level > 400 mg/dL at the end of replacement therapy had a longer period until they become iron deficient. Therefore, after replenishing TID, clinicians may opt to continue iron therapy at a less frequent maintenance dose or to switch to low-dose oral therapy.

Today, the widely recommended indications for use of IV iron in IBD patients with IDA are: severe anemia (defined as Hb level < 10 g/dL), need of quick recovery, intolerance to oral iron, and failure of oral iron. We agree with all of these indications with the exception of setting a definite Hb threshold. Considering the multifactorial etiology of anemia in IBD and the widely different tolerances of people to anemia, we believe that the choice of the iron administration route should primarily depend on the severity and acuity of patients' signs and symptoms. Concentrating only on the Hb level and overlooking the factors that may affect patients' tolerance to anemia such as age, cardiac and pulmonary comorbidities may blur the bigger picture and lead to over- or under-treatment. We believe symptoms such as dyspnea on mild exertion, tachycardia, severe fatigue, and ongoing gross blood loss from the GI tract should urge the clinicians to recommend first-line parenteral iron therapy to their patients with IBD and IDA.

CONCLUSION

GI diseases are one of the most common etiologies of IDA. Iron replacement should be initiated in patients with IDA and iron deficient non-anemic patients with recurrent episodes of GI bleeding. Novel parenteral iron preparations are safer than high molecular weight iron dextran and are more useful in patients with IBD primarily due to GI side effects of oral iron therapy. Finally, regardless of the route, iron therapy needs to be continued until iron stores are completely replenished. The need for maintenance therapy should be assessed in prospective trials.

Abstract

Molecularly targeted agents have dramatically impacted the management of several cancers. Targeting KIT has led to a new treatment paradigm in gastrointestinal stromal tumors (GISTs). KIT is a cell surface receptor with tyrosine kinases that, upon binding of its ligand, stem cell factor, activates various signaling pathways. Imatinib and sunitinib, both tyrosine kinase inhibitors directed to KIT, were approved for first- and second-line treatment of metastatic and unresectable GISTs. In this article, we will review the molecular pathogenesis of GISTs followed by a discussion of imatinib and sunitinib's role in the treatment of GISTs. Finally, we will introduce novel therapeutic options for imatinib- and sunitinib-resistant GISTs.

INTRODUCTION

The gastrointestinal stromal tumor (GIST) is the most common (80%) mesenchymal neoplasm of the gastrointestinal tract[1] and represents about 5% of all sarcomas[2]. The annual incidence of GISTs is estimated to be 14.5 per million and prevalence 129 per million[3], with as many as 6000 new cases per year in the United States[4].

GISTs represent a morphological and biological gamut from incidentally discovered, < 1 cm nodules of benign appearance to large sarcomas, although all GISTs are currently accepted as potentially malignant. GISTs most commonly involve the stomach (50%) and small bowel (25%) (Figure 1); however, they may occur anywhere in the GI tract including the mesentery and omentum[5,6]. Approximately half of the patients present with metastatic disease and nearly two-thirds of those have liver metastases. Extra-abdominal and lymph node metastases at presentation are rare, obviating the need for lymph node dissection unless they are directly involved[2].

Until the 1980s, stromal tumors arising from gastrointestinal tract were classified as various entities such as leiomyosarcoma, leiomyoblastoma and bizarre leiomyoma. With the advent of immunohistochemistry, it was realized

that these tumors lacked immunophenotypic characteristics of smooth muscle. Mazur and Clark showed that a proportion of these tumors stained positively for S-100 and suggested the myenteric nervous system as the cells of origin, introducing the more generic term, "stromal tumor"[7]. In 1998, Hirota and colleagues demonstrated that almost all GISTs expressed KIT and had activating c-kit mutations. They also showed that interstitial cells of Cajal (ICC) were positive for both KIT and CD34 suggesting ICC as the cells of origin of GISTs[8].

KIT

KIT encoded by the c-*Kit* gene (mapped to chromosome 4q12) belongs to the type Ⅲ receptor tyrosine kinase family and is structurally similar to platelet-derived growth factor receptors (PDGFRs), colony-stimulating factor-1 receptor, and fms-like tyrosine kinase-3 (FLT-3)[9,10]. KIT consists of an extracellular (EC) domain with 5 immunoglobulin-like loops, a transmembrane region, and a cytoplasmic domain with juxtamembrane (JM) region and a split tyrosine kinase (TK) domain. The latter is divided into an adenosine triphosphate (ATP) binding region (TK1) and a phosphotransferase region (TK2) by a hydrophilic kinase insert (KI) (Figure 2).

Normally, KIT is activated by stem cell factor. Ligand binding to the EC domain results in the dimerization of receptors and phosphorylation of tyrosine in the cytoplasmic TK domains. This leads to a phosphorylation cascade and activation of signal transduction pathways including Ras/MAP kinase, Rac/Rho-JNK, PI3K/AKT and SFK/STAT signaling networks[11]. Signaling by KIT plays an important role in erythropoesis, lymphopoesis, mast cell development and function, megakaryopoesis, gametogenesis and melanogenesis.

KIT is expressed in more than 95% of GISTs, including tumors with wild-type KIT and most PDGFR-A mutant GISTs. However, in the latter group, KIT expression may be weaker. KIT mutation in GISTs does not cause KIT expression, but modifies KIT function[12]. About 65%-85% of GISTs have KIT mutations[13-15]. Based on the location, these mutations could be divided into 2 categories: mutations of the receptor regulatory domain (EC and JM) and mutations of the enzymatic domain (TK1 and TK2)[16]. Most involve the JM domain (exon 11) and consist mostly of deletions or point mutations. Mutations in the JM domain affect KIT's autoregulatory function and promote spontaneous kinase activation[17]. Exon 9 (EC domain) mutations are the second most common mutations followed by exon 13 (TK1 domain) and exon 17 (TK2 domain) mutations.

In approximately 10% of GISTs, no c-kit mutations are found even when the whole coding region is examined. In 2003, Heinrich *et al*[18] and Hirota *et al*[19] found gain-of-function mutations of the *PDGFR-A* gene in about half of the GISTs lacking c-kit mutations. A majority of PDGFR-A mutations affect the TK2 domain (exon 18). These mutations change the activation loop, which regulates the ATP-binding pocket and leads to kinase activation[6]. Activated PDGFR-A activates the same signaling pathways that KIT activates, leading to GIST.

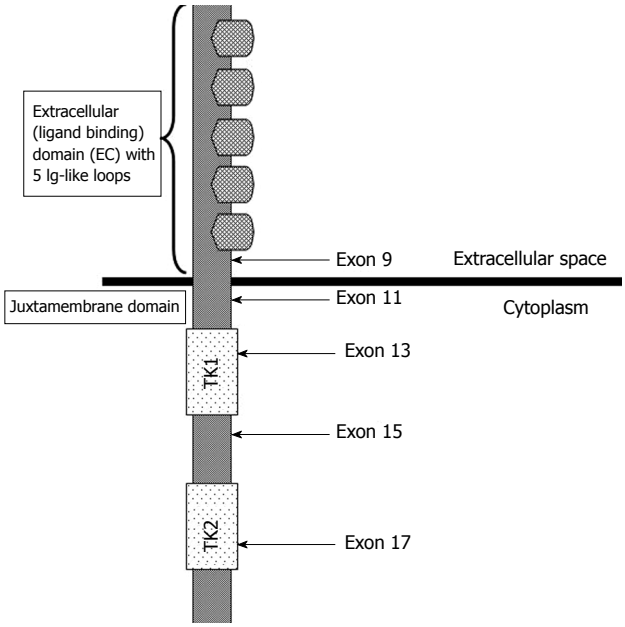

Figure 2 KIT structure and localization of common KIT mutations. Ig: Immunoglobulin.

IMATINIB

Imatinib mesylate (henceforth referred to as imatinib) is a small-molecule TK inhibitor. It works by binding to ATP binding sites of KIT, PDGFR-A, and bcr-abl fusion product, consequently inhibiting their activity[20].

Imatinib is rapidly absorbed in the GI tract, reaching maximum plasma concentrations 2-4 h after oral intake. Absolute bioavailability of imatinib is 98% and food does not affect its absorption[21]. Imatinib is metabolized mainly by the cytochrome P450 (CYP) 3A4 enzymes in the liver, with minor contributions from other CYP enzymes and is eliminated mainly via the feces, mostly in the form of metabolites[22]. As a result of intrinsic variability of CYP enzyme activity, there is a high inter-patient variability for imatinib exposure. Accordingly, imatinib trough levels at

day 29 were recently reported to be associated with clinical outcome[23]. Concomitant administration of CYP3A4 inhibitors (e.g. ketoconazole) may increase and CYP3A4 inducers (e.g. rifampin) may decrease imatinib systemic exposure. Conversely, imatinib may inhibit the metabolism of CYP3A4 substrates (e.g. simvastatin), thereby increasing their exposure. Imatinib may also increase systemic exposure to paracetamol by inhibiting its O-glucuronidation[21,24].

In May 2001, the US Food and Drug Administration (FDA) approved imatinib for chronic myelogenous leukemia (CML) based on excellent responses as first- and second-line treatments[25]. Following demonstration of its activity against KIT and successful treatment of a patient with a GIST[26], imatinib was evaluated in an open label, randomized, multicenter trial. Of 147 patients with unresectable or metastatic GISTs who were randomly assigned to receive either 400 or 600 mg imatinib daily, 79 (54%) had a partial response and 41 (28%) had stable disease. None of the patients had a complete response. There were no significant differences in the rate or duration of responses between the 2 dose levels of imatinib that were tested. The estimated 1-year overall survival rate was 88% for all patients[27]. As a result of this study, the FDA approved the use of imatinib in advanced GISTs in 2002. Recently, a long-term follow-up analysis of the same trial demonstrated that median duration of response was 27 mo and median overall survival was 58 mo[28].

In the same phase Ⅱ trial, the 18F-fluoro-2-deoxy-D-glucose uptake in the tumors was found to be decreased markedly from baseline as early as 24 h after a single dose of imatinib. The median time to an objective response was 13 wk[27]. Accordingly, in the Euro-Australasian phase Ⅲ trial, the median time to best response was 15 wk, with most responses occurring within the first 9 mo. However, best responses were occasionally observed after as long as 2 years of treatment suggesting that responses to imatinib can be seen late in the treatment[29].

Blay *et al*[30] investigated whether imatinib could be stopped after 1 year in patients who responded to imatinib and concluded that treatment with imatinib should continue until disease progression, patient intolerance or refusal. In this study, 58 patients with advanced GISTs were randomized to continuous and intermittent treatment arms. Twenty-six (81%) of the 32 patients in the intermittent arm had progressed and were restarted on imatinib. Of these 26 patients, 24 had a response or stable disease after imatinib was restarted. At the time of the final analysis, there was no difference in overall survival between continuous and intermittent treatment arms[30].

Adjuvant and neoadjuvant therapy with imatinib

Imatinib showed promising results in adjuvant therapy of GISTs. However, there is an ongoing debate on the duration, dose, and the selection of patients for adjuvant imatinib therapy. It is assumed that GIST patients with a relatively high risk of recurrence would benefit the most from adjuvant treatment. Several models were constructed to estimate the recurrence risk of resected GISTs.

Table 1 Risk stratification of primary GISTs

Tumor feature		Risk of tumor progression	
Mitotic index	Size (cm)	Stomach	Small bowel[1]
< 5/50 HPF	≤ 2	Very low	Very low
	> 2 ≤ 5	Very low	Low
	> 5 ≤ 10	Low	Moderate
	> 10	Moderate	High
≥ 5/50 HPF	≤ 2	Very low	Moderate
	> 2 ≤ 5	Moderate	High
	> 5 ≤ 10	High	High
	> 10	High	High

Modified from Hornick *et al*[33] Copyrighted permission from Elsevier Inc. [1]GISTs arising from other sites should probably be stratified as small bowel tumors. GISTs: Gastrointestinal stromal tumors; HPF: High power fields.

Parameters commonly used were tumor size and mitotic rate[4,31]. Based on the reports of a higher recurrence risk of small bowel GISTs compared to gastric ones[32], a new risk stratification model incorporating tumor location was proposed[12,33] (Table 1). In addition to estimation of the recurrence risk, in the near future, mutation analyses from tumor specimens may help practitioners to select different agents according to different genotypes, customize both the duration and the dose of imatinib or other effective agents in the adjuvant setting.

After a phase Ⅱ trial (ACOSOG Z9000) demonstrated high tolerability and promising efficacy in high risk (tumor size > 10 cm, tumor rupture, or multifocal disease) GIST patients[34,35], a phase Ⅲ trial (ACOSOG Z9001) was initiated to compare 400 mg imatinib daily for 1 year with placebo in patients with KIT-expressing GISTs measuring at least 3 cm that were grossly resected. Accrual to the trial was halted early because of the better relapse-free survival (RFS) in the treatment arm in the interim analysis, and these results were presented at the 2007 ASCO meeting leading the FDA to approve imatinib for adjuvant treatment of GISTs in the USA[36]. Final results showed a 1-year RFS of 97% and 83% in imatinib and placebo arms, respectively, with a hazard ratio (HR) of 0.35 (95% confidence interval, 0.22-0.53)[37]. However, the risk reduction in patients with a tumor diameter between 3 and 6 cm was nearly zero. Secondly, there was no difference in overall survival between the 2 groups. It remains unclear whether imatinib prevents GIST recurrence or merely delays it. While 2 phase Ⅱ trials from Korea and China confirmed the improved RFS in intermediate- and high-risk GIST patients treated with imatinib in an adjuvant setting[38,39], 2 other phase Ⅲ trials are still ongoing: EORTC 62024 comparing imatinib for 2 years *vs* placebo, and SSG XVⅢ/AIO trial comparing imatinib for 3 years *vs* 1 year. Long-term follow-up results will be needed to demonstrate the adjuvant treatment effect on overall survival, the subsets of patients that would benefit, and the optimal duration of the treatment. Table 2 demonstrates the adjuvant/neoadjuvant trials registered by the National Cancer Institute (USA).

On the neoadjuvant side, early results from the phase Ⅱ RTOG 0132 trial established the feasibility of the ap-

Table 2 Adjuvant and neoadjuvant trials of imatinib in patients with GISTs

Trial	Accrual	Eligibility	Therapy (*n*)	End points
Phase Ⅱ study of adjuvant imatinib mesylate in patients with completely resected high-risk primary GIST (ACOSOG-Z9000)	Closed	Diameter > 10 cm or tumor rupture or multifocal	Imatinib 400 mg daily for 1 year (107)	2-year OS: 97%, 2-year RFS: 73%[33]
Phase Ⅲ randomized study of adjuvant imatinib mesylate in patients with resected primary GIST (ACOSOG-Z9001)	Closed	Diameter > 3 cm	Imatinib 400 mg daily for 1 year (359) Placebo (354)	1-year RFS: 98%[36] 1-year RFS: 83%
EORTC soft tissue and bone sarcoma group (EORTC-62024) randomized phase Ⅲ trial	Closed	Diameter > 5 cm or mitotic rate > 5/50 HPF	Imatinib 400 mg daily for 2 years Observation (Total projected 750)	Primary: OS Secondary: RFS and safety
Scandinavian sarcoma group trial SSGXVⅢ	Closed	Diameter > 10 cm or mitotic rate > 10/50 HPF or > 5 cm and > 5/50 HPF or tumor rupture	Imatinib 400 mg daily for 36 mo Imatinib 400 mg daily for 12 mo (Total projected 280)	Primary: RFS Secondary: OS, safety
Phase Ⅱ study of neoadjuvant and adjuvant imatinib mesylate in patients with primary or recurrent potentially resectable malignant GIST (RTOG-S0132)	Closed	Locally advanced or metastatic/recurrent	Imatinib 600 mg daily for 6-8 wk followed by debulking/resection (52)	2-year PFS: 80%, objective response rate: 6%, R0 resection in 65%[39]
Five year adjuvant imatinib mesylate in GIST (Phase Ⅱ)	Open	Diameter > 2 cm and mitotic rate > 5/50 HPF or non-gastric GIST > 5 cm	Imatinib 400 mg daily for 5 years (Projected 133)	Primary: Time to recurrence Secondary: Safety
Phase Ⅱ study of neoadjuvant imatinib mesylate in patients with locally advanced gastrointestinal stromal tumor (Germany/Austria)	Open	Locally advanced, KIT expressing, histologically confirmed GIST	Imatinib 400 mg daily/*BID* (Projected 40)	Primary: ORR Secondary: R0-resectability and organ-preserving resectability

OS: Overall survival; RFS: Relapse-free survival; PFS: Progression-free survival.

proach in locally advanced and metastatic GIST patients[40]. Fiore *et al*[41] recently reported that all of the 15 patients who received preoperative imatinib benefited from neoadjuvant treatment: one patient had a complete response; 3 patients who were initially considered to have unresectable disease underwent complete resection; 7 patients with initial indication for extensive surgery were more conservatively operated on; 4 patients initially deemed at high perioperative risk underwent safe surgery[41]. For patients that do not have access to the ongoing neoadjuvant trials (Table 2), we consider preoperative imatinib as an option for those with unresectable GISTs or in whom surgical morbidity would be improved by reducing the size of the tumor preoperatively. Positron emission tomography (PET) scans within 2-4 wk of therapy could be a predictive test separating responding from resistant patients. Non-responding patients, if surgically resectable, would be taken to surgery. Patients that are not surgical candidates could be considered for second-line therapy.

Toxicity

Almost all patients in clinical trials with imatinib experienced adverse events; however, most of the events were mild or mild to moderate. Patients treated with 800 mg/d imatinib had more grade 3 or above side effects compared to those treated with 400 mg/d in both phase Ⅲ trials comparing 2 different doses. Most common grade 3-4 side effects in these 2 phase Ⅲ trials were anemia, granulocytopenia, fatigue, fluid retention, muscle pain, and gastrointestinal symptoms[29,42]. In the Euro-Australasian trial, dose reductions and treatment interruptions, mostly because of toxic effects, were found to be more likely to occur in patients who received imatinib 400 mg twice daily. Additionally, side effects were mostly recorded during the first 8 wk of treatment[43].

Fluid retention due to imatinib is generally mild, most frequently affects the periorbital region, and can be seen in 70%-80% of patients treated with imatinib. It responds well to intermittent low dose thiazide diuretics. On the other hand, muscle cramps can be seen in up to 40% of patients and can be very troublesome as a result of their long-term course. There are anecdotal reports of patients responding to magnesium/calcium supplements[44], quinine[45], and chlordiazepoxide[46]. Hypophosphatemia can also be seen with imatinib use, and routine monitoring of phosphate levels has been suggested[47]. In 2006, 10 individuals were reported to develop severe heart failure after receiving imatinib[48]. However, whether imatinib causes cardiac toxicity in GIST patients is still unclear. Multiple randomized studies failed to show excess cardiotoxicity in patients treated with imatinib postoperatively[37,49]. Tumor hemorrhage is a life-threatening toxicity for which patients with large, bulky tumors have a higher risk. Therefore, hemoglobin levels should be monitored upon starting GIST patients on imatinib.

Imatinib resistance

The advent of imatinib had completely changed the management and survival of patients with GISTs. However, imatinib resistance, both primary and secondary, is still a

Table 3 Prevalence of c-kit and PDGFR-A mutations and clinical responses in advanced GISTs to imatinib and sunitinib correlated with mutational status

Genotype	Prevalence[59-61]	Clinical benefit from imatinib[15,58,59]	Clinical benefit from sunitinib[58]1
KIT exon 9 mutation (%)	5-14	74-81	60
KIT exon 11 mutation (%)	57-69	83-93	35
KIT exon 13 mutation (%)	< 5	60-100 (few cases)	65
KIT exon 17 mutation (%)	< 5	75-80 (few cases)

Both wild-type (%)	5-10	33-73	55

Clinical benefit is defined as complete, partial response or stable disease. [1]In imatinib-resistant GIST.

significant problem. In the Euro-Australasian phase Ⅲ trial, 12% of patients exhibited initial resistance to imatinib[29]. Furthermore, more than 40% of patients who were initially responsive to imatinib developed late resistance after a median follow-up of 25 mo.

Several different mechanisms of imatinib resistance were identified in the literature: (1) KIT or PDGFRA mutations resulting in intrinsic target resistance; (2) genomic amplification leading to target overexpression; and (3) alternate oncoprotein activation supplanting target expression[24,50,51]. During imatinib treatment, resistance often develops as a result of secondary mutations, primarily in the kinase domains of KIT or PDGFR-A[52-54]. One of the frequent secondary kinase domain mutations, V654A mutation, is intrinsically imatinib-resistant[55].

Depending on the mechanism of the resistance, a higher dose of imatinib may be considered in patients with GISTs resistant to 400 mg/d imatinib. The effect of increasing the dose of imatinib to 800 mg daily in advanced GIST patients was assessed in 2 phase Ⅲ trials. In the Euro-Australasian trial of 946 patients, Verweji *et al*[29] reported that although there was no difference in response rates between daily and twice daily 400 mg dosing, progression-free survival was significantly better in patients who received the higher dose. On the other hand, the results of the phase Ⅲ trial in North America did not reveal any difference between daily and twice daily 400 mg dosing in response rates, progression-free and overall survival. However, 31% of patients who progressed on 400 mg daily dosing and crossed over to 400 mg twice daily dosing had a partial response or stable disease suggesting that in a subset of patients increasing the imatinib dose may overcome the resistance to imatinib[42].

In the North American phase Ⅲ trial, patients with exon 11 mutations had a better response rate, time to progression and overall survival compared to those with exon 9 mutations and the wild-type *c-kit* gene. Although the survival rates of exon 9, exon 11 or wild-type GISTs were not affected by imatinib dose, the response rate for patients with an exon 9 mutation was significantly higher in those who were treated with a higher dose of imatinib (67% *vs* 17%, $P = 0.02$)[56]. Furthermore, in a meta-analysis of 2 phase Ⅲ trials, 800 mg/d imatinib was found to be associated with a significantly better progression-free survival in patients with the exon 9 mutation (median progression-free survival: 1.6 year *vs* 0.5 year; HR, 0.58, $P = 0.017$)[57]. Table 3 demonstrates the prevalence and response rates of mutations in different exons of *KIT* and *PDGFR-A* genes derived from 3 different clinical trials[15,58,59], population[60] and institution based studies[61]. Lasota *et al*[62] had published a detailed review on the role of *c-kit* and *PDGFR-A* gene mutations on GIST therapy[62].

SUNITINIB

Sunitinib malate, an oral multitargeted inhibitor of KIT, PDGFRs, vascular endothelial growth factor receptors (VEGFR), FLT3 and RET receptor TKs, is FDA approved for treatment of imatinib-resistant GISTs and of advanced renal cell carcinoma. In addition to its antitumor effect through inhibition of KIT and PDGFR, sunitinib may have an antiangiogenic effect on GISTs through inhibition of VEGFR[63].

In a phase Ⅰ/Ⅱ trial, sunitinib at different dosages and schedules was administered to 97 GIST patients with imatinib resistance (96%) or intolerance (4%). In phase Ⅰ, sunitinib 50 mg/d for 4 wk followed by 2 wk off treatment was chosen for further development. Overall, 73% of patients experienced stable disease which lasted > 6 mo and 7% achieved a partial response. The median overall survival was 19 mo[64].

The pivotal, randomized, placebo-controlled, multinational phase Ⅲ trial of sunitinib in patients with unresectable, imatinib-resistant GISTs had to be unblinded early when interim data analysis showed a significantly longer median time to progression in patients who received sunitinib compared to those who received placebo (27.3 wk *vs* 6.4 wk; HR, 0.33, $P < 0.001$). Response rate was better in patients treated with sunitinib compared to those treated with placebo (6.8% *vs* 0%, $P = 0.006$). Despite the crossover after unblinding, overall survival was superior in the sunitinib arm (HR, 0.49; $P < 0.007$). This study established the role of sunitinib as a second-line therapy in patients with advanced imatinib-refractory and imatinib-intolerant GISTs[65].

Although a clinical benefit of sunitinib treatment was observed in all major mutant types, the primary response rate was significantly higher for KIT exon 9 mutants. The inhibitory effect of sunitinib was not substantially affected by KIT mutations in TK1 whereas GISTs with KIT-TK2 mutations were resistant to sunitinib treatment. Specifically, the imatinib-resistant KIT mutation V654A was highly sensitive to sunitinib[66,67].

Table 4 Novel agents being developed for GIST therapy

Agent	Molecular target	Clinical benefit in pilot studies
Kinase inhibitors		
Nilotinib	KIT, PDGFRs, bcr-abl	46%-77%[69,70]
Sorafenib	Raf, KIT, PDGFR-B, VEGFR, FLT3, RET	71%[71]
Dasatinib	Src, ABL, KIT, PDGFRs	Phase Ⅱ ongoing in advanced sarcomas and accepting patients
AZD2171	VEGFR, KIT, PDGFRs	Phase Ⅱ ongoing, not recruiting
OSI-930	VEGFR, KIT	Phase Ⅰ ongoing, not recruiting
PTK787	VEGFR, KIT, PDGFRs	67%[74]
XL820	KIT, PDGFR-B, VEGFR	Phase Ⅱ ongoing, not recruiting
AMG706	VEGFR, KIT, PDGFRs, RET	24%-27%[75,76]
mTOR and AKT inhibitors		
Perifosine	AKT	Phase II ongoing in combination with imatinib
Everolimus	mTOR	26%[73]
Temsirolimus	mTOR	Phase II ongoing, closed recruitment
Others		
IPI-504	Hsp90	78%[72], phase Ⅲ ended due to safety concerns
Flavopiridol	Transcription inhibitor	Phase Ⅰ ongoing in combination with doxorubicin

Clinical benefit is defined as complete or partial response or stable disease.

Sunitinib was generally well tolerated in patients with GISTs, with adverse events mild to moderate in severity. In the phase Ⅲ trial, the most frequent treatment-related adverse events were fatigue, diarrhea, hand-foot syndrome, rash, nausea, anorexia, and skin discoloration. Hypertension occurred in about 20% of treated patients, 5% being grade 3/4 in severity. Treatment discontinuation because of adverse events occurred in 9% and 8% of sunitinib and placebo recipients, respectively[65]. Hypothyroidism, possibly secondary to inhibition of the protein product of the RET proto-oncogene found in normal thyroid has been described in as high as 36% of sunitinib-treated GIST patients[68].

FUTURE DIRECTIONS

Currently, there is no established third-line treatment in patients with GISTs who failed to respond to both imatinib and sunitinib. Table 4 demonstrates the drugs in the pipeline for GIST therapy[69-76]. Nilotinib, a second-generation TK inhibitor engineered to inhibit KIT, PDGFR-A, and bcr-abl, is approved for the treatment of imatinib-resistant CML. In a phase I study of nilotinib in imatinib-resistant GISTs, 13 (72%) of the 18 patients who received nilotinib experienced stable disease lasting more than 6 wk. One patient achieved a partial response. Median progression-free survival was 25 wk. Nilotinib 400 mg twice daily was the dose recommended for future studies[69]. Recently, Montemurro *et al*[70] reported a retrospective analysis of 52 patients treated with nilotinib 400 mg twice daily as compassionate use in 12 European centers. All patients had failed both imatinib and sunitinib either due to resistance (96%) or intolerance (4%). One and 4 patients achieved complete and partial responses, respectively; whereas 19 had disease stabilization. The median progression-free survival was 12 wk (range 2 d-104 wk) and the median overall survival was 34 wk (range 2-135 wk). Most patients tolerated nilotinib well except 6 (12%) patients discontinued treatment due to grade 2-3 adverse effects[70].

The efficacy of sorafenib, a multi-kinase inhibitor of raf kinase, VEGFR, PDGFR, and KIT, in imatinib- and sunitinib-resistant GISTs was studied in a phase Ⅱ trial of 26 patients. Three (13%) patients achieved a partial response and 14 patients (58%) experienced stable disease. Median progression-free survival was 5.3 mo and median overall survival was 13.0 mo. The most common side effects were hand-foot syndrome (28%), hypertension (24%), and rash (20%)[71].

Heat shock proteins (Hsp) control the proper folding, function, and stabilization of various proteins. Laboratory studies have demonstrated that inhibition of Hsp90 results in selective destruction of the mutated KIT in human GIST cell lines. In a phase Ⅰ trial of IPI-504, an intravenous Hsp90 inhibitor, 78% of evaluable patients with imatinib-resistant (100%) and sunitinib-resistant (95%) GISTs experienced stable disease[72]. However, a phase Ⅲ trial of IPI-504 ended early because of safety concerns. Other strategies to inhibit growth of GISTs is to abrogate KIT mRNA expression with flavopiridol, a transcriptional inhibitor[77]; and inhibition of the AKT-mTOR pathway by mTOR inhibitors such as everolimus[73].

CONCLUSION

The discovery of near universal KIT protein expression, and activating KIT and PDGFR-A mutations advanced our understanding of GISTs significantly. Later, the finding of the high efficacy of imatinib in the treatment of GISTs changed the management and prognosis of this once very deadly malignancy. Imatinib is currently approved for the treatment of unresectable or metastatic GISTs, however, many centers around the world, including our own, use imatinib also in adjuvant and neoadjuvant settings. PET scans may be especially helpful in identifying imatinib-resistant tumors during neoadjuvant treatment. Further

studies are needed to tailor the imatinib treatment in these settings. On the other hand, imatinib should be continued until disease progression or intolerability in patients with metastatic or unresectable GISTs.

The standard therapy for metastatic GISTs resistant to imatinib is sunitinib. The efficacy of sunitinib in the first-line treatment of advanced GISTs and as adjuvant/neo-adjuvant treatment should be studied in randomized trials. Resistance to imatinib and sunitinib continues to be a challenging issue. Upcoming treatment options are second-generation kinase inhibitors and inhibition of the growth of GISTs via pathways other than KIT and PDGFR-A. We believe the combination of Hsp90 inhibitors and kinase inhibitors could yield superior results.

ACKNOWLEDGMENTS

We would like to thank Dr. Yusuf Bayraktar for providing the endoscopic image of a small bowel GIST.

Abstract

Acute pancreatitis is a common disease characterized by sudden upper abdominal pain and vomiting. Alcoholism and choledocholithiasis are the most common factors for this disease. The choice of treatment for acute pancreatitis might be affected by local complications, such as local hemorrhage in or around the pancreas, and peripancreatic infection or pseudoaneurysm. Diagnostic imaging modalities for acute pancreatitis have a significant role in confirming the diagnosis of the disease, helping detect the extent of pancreatic necrosis, and for diagnosing local complications. Magnetic resonance imaging (MRI) might be indicated in acute pancreatitis for detecting and characterizing local complications of acute pancreatitis that involve necrotic, hemorrhagic, infectious, vascular, and pseudocyst disorders. The general MRI sequences for pancreatitis require the combined use of T1-weighted, T2-weighted sequences, and magnetic resonance cholangiopancreatography. For imaging of pancreatic necrosis, the combination of T1-weighted and T2-weighted findings with dynamic contrast-enhanced imaging gives a comprehensive evaluation of the extent of necrosis and full range of inflammatory extension. For imaging of infectious complications, dynamic contrast-enhanced examinations might help differentiate pancreatic cellulitis or abscesses, from pancreatic fluid collection or simple pseudocysts. For vascular abnormalities, the combination of cross-sectional pancreatic parenchyma imaging with MRA represents a single diagnostic modality for the full evaluation of peripancreatic artery and vein involvement, such as arterial pseudoaneurysms and venous thromboses. The purpose of this pictorial review is to examine the MRI appearances of various local complications of acute pancreatitis and to discuss the practical setup of MRI in local complications of acute pancreatitis.

INTRODUCTION

Acute pancreatitis is a common and protean disease characterized by sudden upper abdominal pain and vomiting,

and is triggered by the leakage of activated pancreatic digestive enzymes. Alcoholism and choledocholithiasis are the most common physiological factors for acute pancreatitis[1,2]. Traditional management of acute pancreatitis tends to promote the use of conservative management. However, the choice of treatment can be influenced by local complications, such as local hemorrhage in or around the pancreas, and peripancreatic infection or pseudoaneurysm[2,3].

Increased levels of serum and/or urinary pancreatic amylase and lipase have been detected in most individuals with acute pancreatitis after the onset of symptoms. Therefore, acute pancreatitis is often diagnosed by clinical manifestations and laboratory examinations. However, diagnostic imaging modalities for acute pancreatitis have a significant role in confirming the diagnosis of the disease, helping detect the extent of pancreatic necrosis, and for diagnosing local complications[2,3].

Among a variety of imaging tools, computed tomography (CT) is considered the standard of reference for patients with acute pancreatitis; however, it has an increased radiation burden that can result from follow-up examinations[4] and displays different results for the potential aggravation of acute pancreatitis resulting from the use of iodinated contrast media[5-7]. The specific reasons for using magnetic resonance imaging (MRI) are as follows: (1) MRI is a diagnostic imaging method with no radiation hazard, which might be suitable for patients with multiple follow-up reviews; (2) MRI is a reliable method of staging the severity of acute pancreatitis, which has predictive value for the prognosis of the disease. It also has fewer contraindications than CT[8]; (3) MR cholangiopancreatography (MRCP) has the unique capability of providing noninvasive images of the pancreatic ducts and can demonstrate possible communication of a pancreatic pseudocyst with pancreatic ducts[9]; and (4) MRI in combination with MR angiography (MRA), a single diagnostic modality, is useful for assessing the signal consistency of fluid exudation or pseudocysts to identify local hemorrhage in or around the pancreas or pseudoaneurysm, which might help plan the surgery.

However, the possible drawbacks of MRI with respect to CT are cost and time consumption. Moreover, several MRI sequences require patients to hold their breath, which might be difficult for patients with severe acute pancreatitis.

MRI of pancreatitis and its complications has been reported[10]. However, to our knowledge, there is no report thoroughly assessing MRI for local complications of acute pancreatitis, including necrotic, hemorrhagic, infectious, vascular, and pseudocyst disorders.

In this pictorial essay, after briefly discussing the MRI technique, we review the MRI appearances of various local complications of acute pancreatitis, ranging from relatively common necrotic and hemorrhagic conditions to rare conditions, such as peripancreatic abscess and pseudoaneurysm. Knowledge of the classic MRI findings of these complications allows prompt recognition of the related pathologic condition, and might influence the choice of treatment.

MRI TECHNIQUE

For the appropriate evaluation of local complications of acute pancreatitis, it is necessary to assess all parts of the pancreas, including the peripancreatic parenchyma and the vasculature[1]. The general MRI sequences for pancreatitis require the combined use of T1-weighted sequences [e.g. fast spin-echo (FSE) imaging with multiple breath-hold acquisitions or single-breath-hold gradient echo (GRE) imaging], T2-weighted sequences [e.g. fast recovery fast spin-echo (FRFSE) or single-shot fast spin-echo (SSFSE) imaging], and MRCP (e.g. a thick-slab, SSFSE MRCP). The advantages or limitations of these sequences are as follows: (1) T1-weighted scan with fat suppression improves the delineation of pancreatic borders and the pancreas itself, and it has important value in MRI acquisition for evaluation of hemorrhagic complications of acute pancreatitis[3]. However, T1-weighted sequences with breath holding require patient cooperation, otherwise, respiratory artifacts will occur, which might affect the visualization of the whole pancreas and its adjacent structure[1-3]; (2) T2-weighted sequences have significant advantages in demonstrating fluid-filled lesions in or around the pancreas and the pancreatic duct, and SSFSE T2-weighted sequence can be used to guide acquisition of an MRCP series[2,3]. Using respiratory triggered or navigator-echo-based techniques allows the investigating of less cooperative patients; and (3) MRCP is obtained before gadolinium administration, allows noninvasive evaluation of pancreatic ducts and the whole extrahepatic biliary tract, and provides few respiratory artifacts or susceptibility effects[1-3]. However, the main weakness of MRCP for ductal visibility is the potential overlap of other fluid-containing organs (e.g. the stomach and duodenum)[3].

The methodology of contrast-enhanced MRI for patients with acute pancreatitis in our institute is detailed as follows. A 19-gauge needle was placed in the right antecubital vein. A dose of 0.2 mL/kg Gd-DTPA (469.01 mg/mL Bayer Schering Pharma AG; Berlin, Germany) was then administered. A bolus of 20 mL of physiological saline was given immediately following gadolinium administration. The contrast agent and physiological saline were injected at an infusion rate of 3 mL/s with a power injector (Spectris MR Injector System; Medrad, USA). After gadolinium chelate injection, the optimal dynamic contrast-enhanced method [e.g. T1-weighted acquisition performed with liver acquisition with volume acceleration (LAVA)] was used to assess the extent of pancreatic necrosis for the initial staging of acute pancreatitis, which has been shown to correlate with the course of the disease[1-3]. MRI LAVA scanning starts at 14-16 s after the intravenous administration of gadolinium. It costs a total of 65 s for three-phase dynamic contrast-enhanced scans (15 s for each phase and 10 s of the interval of phases for breathing). A total of (80-112) × 3 contrast-enhanced frames were obtained. Moreover, MRA, the post-processing technique after MRI LAVA, can be performed to supplement the information for visualization of pancreatic vascular network

Table 1 MRI parameters

Sequence	TR (ms)	TE (ms)	Slice thickness (mm)	Slice space (mm)	Matrix	Field of view (mm)	Number of excitation	Flip angle
FSE T1W	300	10	5	0.5-1	256 × 192	380 × 340	2	90°
GRE T1W	195	1.5	5-7	0.5-1	256 × 192	360 × 340	1	70°
FRFSE T2W	8000-13500	90-120	5	0.5-1	256 × 224	400 × 340	1	90°
SSFSE T2W	Not applicable	80-197	5	0.5	256 × 192	390 × 330	1	90°
SSFSE MRCP	Not applicable	830-1100	40-50	0	256 × 192	320 × 240	2	90°
LAVA T1W	3.8-6.1	1.8-2.1	5[1]	0	256 × 224	380 × 340	1	15°-20°

[1]A section thickness of 5 mm for LAVA is the section thickness of automatic reconstruction images from this sequence. MRI: Magnetic resonance imaging; FSE: Fast spin-echo; GRE: Gradient echo; FRFSE: Fast recovery fast spin-echo; SSFSE: Single-shot fast spin-echo; LAVA: Liver acquisition with volume acceleration; T1W: T1-weighted; T2W: T2-weighted.

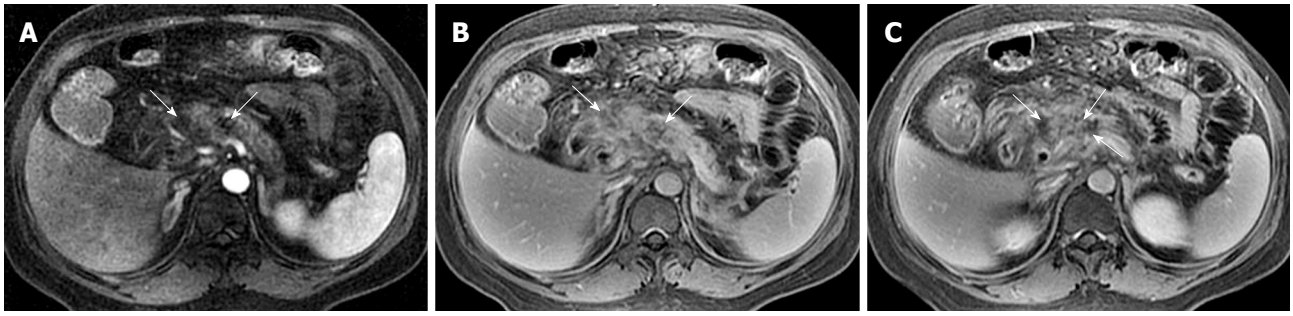

Figure 1 43-year-old woman with acute pancreatitis. Contrast-enhanced axial T1-weighted images during arterial phase (A) and late venous phase (B, C) show spotted, patchy non-enhanced areas in the pancreatic head and body (arrows).

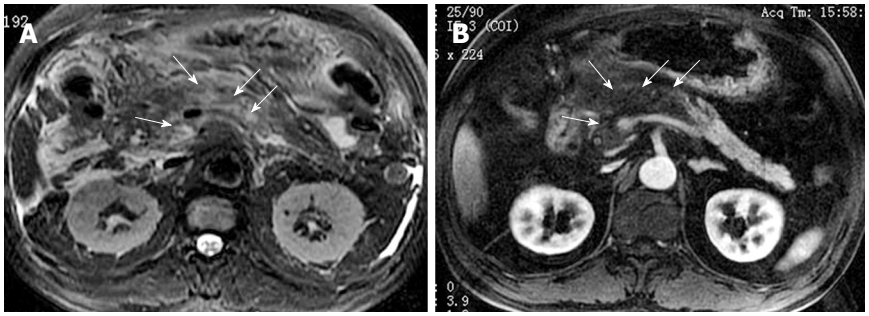

Figure 2 65-year-old man with acute pancreatitis. Axial T2-weighted image (A) shows the high-signal intensity in the pancreatic head and body (arrows). The arterial phase MR image (B) shows a large necrotic area ("black pancreas") in the pancreatic head and body (arrows).

and vascular complications of acute pancreatitis. The detailed protocols used with our 1.5-T MR imager for these sequences are listed in Table 1.

MRI FINDINGS

Necrosis

Pancreatic necrosis refers to a pathological collection of devitalized tissue in the pancreas, which is a relatively common local complication of acute pancreatitis[10].

Necrosis is diagnosed when focal or diffuse, conspicuous hypointense areas on T1WI corresponding to hyperintense areas on T2WI and well-marginated areas of non-enhancing pancreatic parenchyma in comparison to the signal intensity of the normal pancreatic parenchyma are present[1-3]. Dynamic contrast-enhanced MRI examination can identify surviving pancreatic tissue[10]. The focal pancreatic necrosis is characterized by multiple spotted, patchy non-enhancing areas (like "pepper") on contrast-enhanced MR images (Figure 1). The large diffuse non-enhanced area of the pancreas (the so-called "black pancreas") in acute pancreatitis on enhanced MR images represents diffuse pancreatic necrosis (Figure 2).

Necrosis of peripancreatic fatty tissue, which is a form of inflammatory extension, involves the spread of peripancreatic intra-abdominal fatty tissue and adipose tissue in the retroperitoneal space[2]. The covering of the pancreas is surrounded by the formation of the capsule, which is only a series of loose connective tissue. Therefore, the pancreatic capsule forms almost no block on the role of inflammatory extension. MRI might show the intra-abdominal inflammatory involvement located in omental or mesenteric fatty contents regions (Figure 3). The affected retroperitoneal space manifests the inflammation extension from the retroperitoneal space to anterior pararenal space of the left kidney, which is complicated by retroperitoneal steatonecrosis (Figure 4)[2,3]. It is important and helpful in evaluating the prognosis of acute pancre-

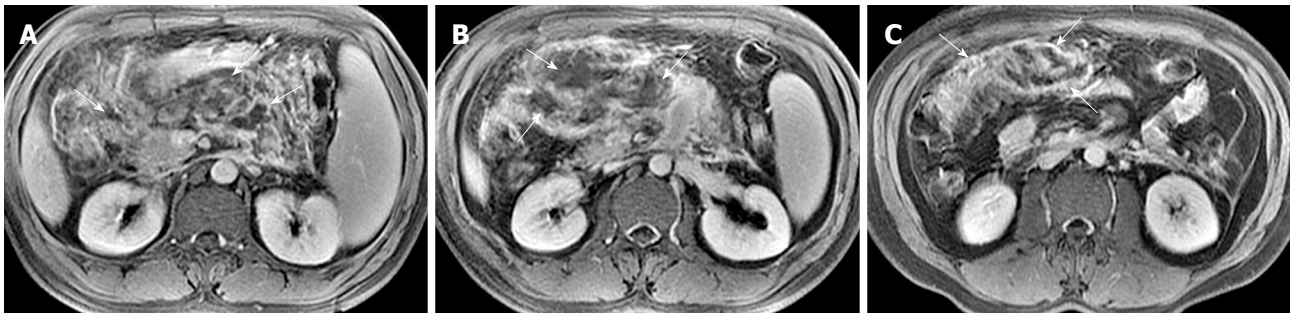

Figure 3 34-year-old man with acute pancreatitis. Contrast-enhanced axial T1-weighted images show peripancreatic inflammation extension (arrows) along the mesenteric adipose tissue region (A, B). There is addition irregular thickening and enhancement of the adjacent intestinal wall (arrows, C).

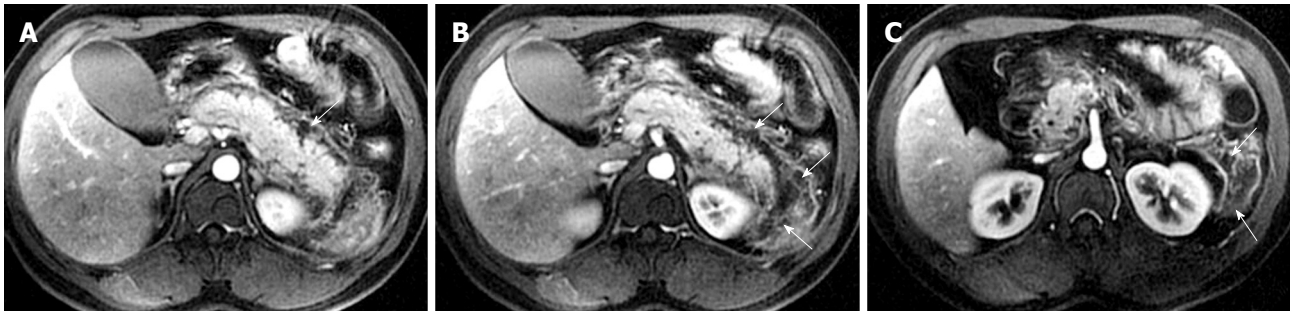

Figure 4 31-year-old man with acute pancreatitis. Contrast-enhanced axial T1-weighted images with fat suppression reveal thickening and enhancement of dorsal peritoneum (arrow, A). The peripancreatic inflammation extended from the retroperitoneal space to the anterior pararenal space of the left kidney (arrows, B and C).

Figure 5 30-year-old man with acute pancreatitis. Unenhanced axial T1-weighted image with fat suppression shows patchy hemorrhagic foci (arrows) in the pancreas and in the fatty tissue behind the pancreas.

atitis to differentiate between necrosis of peripancreatic tissue and central pancreas necrosis. Neoptolemos *et al*[11] reported that the evaluation of the integrity of the main pancreatic duct might be helpful in making a distinction between mild pancreatitis and severe pancreatitis, and for determining the necessity for surgery for local pancreatic complications in severe pancreatitis.

Hemorrhage

Hemorrhage of the pancreas is seen in 2%-5% of patients with acute pancreatitis and might occur in the setting of severe necrotizing pancreatitis[10]. With conversion from hemoglobin to methemoglobin in the hemorrhage regions, MRI findings of hemorrhagic lesions show spotted or patchy high signal intensity (like "salt") in T1-weighted images with fat suppression (Figure 5).

Peripancreatic hemorrhage might be secondary to the necrosis of peripancreatic tissue, which is visualized as patchy or large diffuse areas with hyperintensity on T1-weighted images with fat suppression[2] (Figure 6). Martin *et al*[12] reported that elevated peripancreatic signal on fat-suppressed T1-weighted spoiled gradient echo images is associated with poor outcome in acute pancreatitis. This might represent a simplified imaging method in regards to its relationship to clinical prognosis. Other local complications of acute pancreatitis, such as pancreatic pseudocysts and peripancreatic vascular invasion, can also show hemorrhage (mentioned below).

Infection

Pancreatic cellulitis is an infectious complication in patients with acute pancreatitis, whose incidence varies from 8.3% to 10.6%, and can be difficult to differentiate clinically from pancreatic abscess[13,14]. It is a clinical or radiological entity in the pancreas and peripancreatic region as a result of pathological pancreatic swelling, inflammatory cell infiltration, and tissue necrosis[15]. Contrast-enhanced MRI examination can show the range of the involvement of pancreatic cellulitis. MRI findings of pancreatic cellulitis include the formation of an ill-defined mass with ring-like and separated enhancement (like "Hornet's nest"), and non-enhanced regions within the central part of the mass (Figure 7). Pancreatic cellulitis can be absorbed completely and might also progress to a pancreatic abscess.

Pancreatic abscess is a typical infectious manifestation of acute necrotizing pancreatitis, whose incidence varies from 1% to 9%, and can result in high mortality in acute

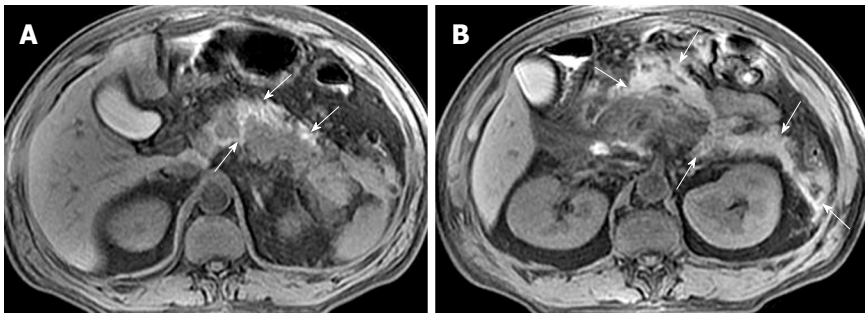

Figure 6 50-year-old man with acute pancreatitis. Unenhanced axial T1-weighted images with fat suppression reveal pancreatic and peripancreatic hemorrhage (arrows, A and B); Peripancreatic hemorrhage involvement include the retroperitoneal space and anterior pararenal space of the left kidney (arrows, B).

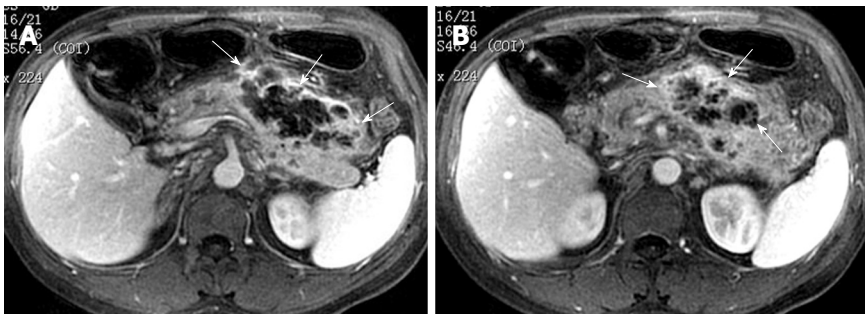

Figure 7 39-year-old man with acute necrotizing pancreatitis and peripancreatic cellulitis. Contrast-enhanced T1-weighted images show a ring-like and separated enhancing mass in pancreatic adjacent retroperitoneal space (arrows, A and B).

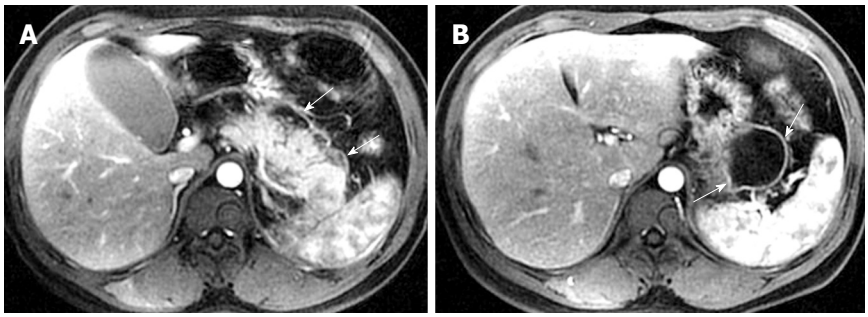

Figure 8 33-year-old man with acute necrotizing pancreatitis and peripancreatic abscess. Contrast-enhanced axial T1-weighted images reveal abnormal peripancreatic enhancement (arrows, A) and a liquid-like mass with a well-defined, thickened, and enhancing wall (arrows, B).

pancreatitis patients[16]. If pancreatic cellulitis was not well controlled, abscesses might occur 3-5 wk after the onset of acute pancreatitis and might be similar to pseudocysts[10]. Pancreatic abscesses with acute pancreatitis induce a systemic infection poisoning reaction resulting in symptoms of fever and local peritonitis. The performance of a pancreatic abscess on MRI might present as an encapsulated liquid-form mass with a significantly enhancing wall (Figure 8).

Pseudocyst

Pancreatic pseudocysts are local complications of acute or chronic pancreatitis, and they can be classified as acute pseudocysts in patients suffering from acute post-necrotic pancreatitis, and chronic pseudocysts that develop in patients already suffering from chronic pancreatitis[17]. The pathogenesis of pancreatic pseudocysts might be associated with an actively secreting pancreas in acute or chronic pancreatitis; an encapsulated cyst communicating with pancreatic ducts and/or partial pancreatic ductal obstruction. Patients with pancreatic pseudocysts are treated conservatively or percutaneously with aspiration under ultrasound guidance or surgically with external catheter drainage[17].

Pancreatic pseudocysts might be located within the pancreatic tissue or surrounding the pancreas. They often occur approximately four weeks after a first episode of acute pancreatitis[18-20]. MRI findings of a simple pseudocyst include a round or oval fluid collection surrounded by a thin or thick wall, with liquid signal performance of hypointensity on T1-weighted images and hyperintensity on T2-weighted images (Figure 9). Pancreatic pseudocysts can also present as complex pseudocysts associated with mucus, protein, and hemorrhage[2]. This often manifests as a heterogeneous lesion dominated by hyperintensity on T1-weighted images with fat suppression (Figure 10). Therefore, compared with CT, MRI might be more favorable when the a suspected pseudocyst with bleeding occurs.

Vascular disorders

Vascular complications of acute pancreatitis represent a spectrum of vascular abnormalities, such as peripancreatic artery involvement including pseudoaneurysm, and vein invasion including phlebothrombosis[1-4]. Dörffel *et al*[21] assessed vascular complications in acute pancreatitis by color duplex ultrasonography: the incidence of arterial pseudoaneurysms was 7% in acute pancreatitis, and the incidence of venous thromboses was 30% in acute non-necrotizing pancreatitis and 57% in necrotizing pancreatitis. MRI findings of artery invasion consist of the loss of normal vascular flowing void effect, the blurred edge of the local involving arterial wall and the

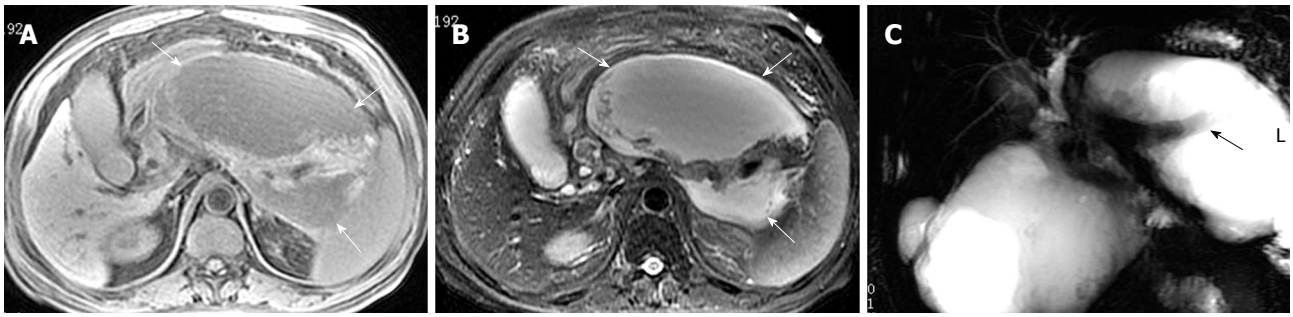

Figure 9 41-year-old man with a large peripancreatic pseudocyst who presented as abdominal distension for follow-up after acute pancreatitis. Unenhanced axial T1-weighted (A) and axial T2-weighted (B) images show a large lesion with typical liquid signal intensity around the pancreas (arrows). MRCP image (C) reveals the pancreas wrapped inside the large pseudocyst, just like the swimming fish (arrow).

Figure 10 35-year-old man with multiple pseudocysts complicated hemorrhage. Patient had previously suffered from acute pancreatitis. Unenhanced axial T1-weighted images (A and B) with fat suppression and axial T2-weighted image (C) with fat suppression reveal hemorrhagic pseudocysts with a mixed signal intensity dominated by hyperintensity (arrows).

Figure 11 30-year-old man with acute pancreatitis and splenomegaly. Axial T2-weighted images (A and B) show the involved segments (arrows) of splenic artery (A) and splenic vein (B). Enhanced arterial phase (C) and venous phase (D) images reveal clearly the involved segments (arrows) of the splenic artery (C) and vein (D).

poor enhancement at the involving segment on contrast-enhanced arterial phase images (Figure 11). The splenic artery, gastroduodenal artery, and pancreaticoduodenal artery are more frequently involved[10,22].

Pseudoaneurysm is an uncommon, usually delayed, complication of acute pancreatitis and might constitute a life-threatening emergency if rupture occurs[10]. MRI can directly show the pseudoaneurysm cavity that communicates with the adjoining arteries and the mural thrombosis in the pseudoaneurysm cavity. On enhanced MR images, the enhancement of pseudoaneurysm cavity corresponds with the arteries, whereas the non-enhanced region is illustrated as the mural thrombus (resembling a Chinese "Yin-Yang" diagram)[23] (Figure 12).

The splenic vein is the most common vein invaded by pancreatic inflammatory extensions due to its prox-

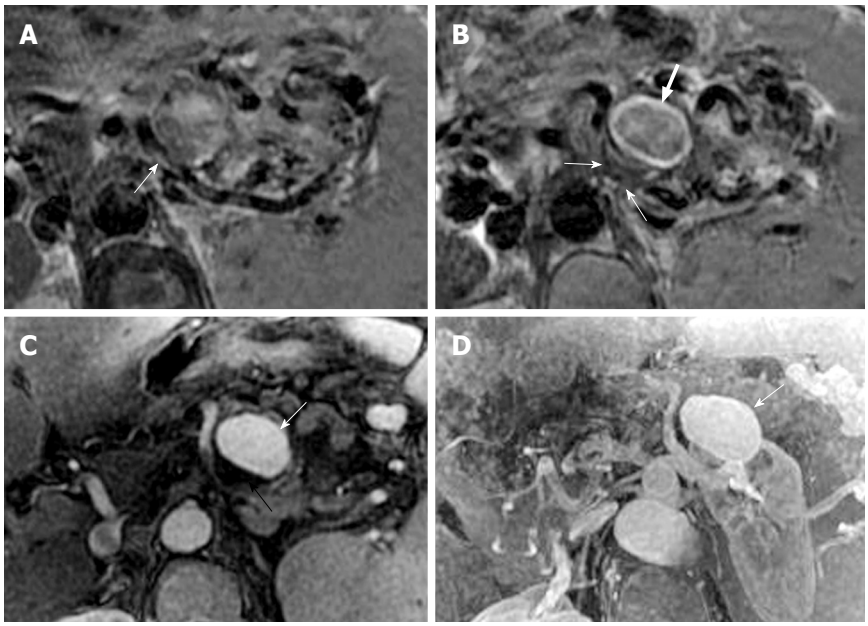

Figure 12 36-year-old man with a history of acute pancreatitis and a splenic artery pseudoaneurysm. The involved segment of the splenic artery (arrow, A) and an aneurysmal dilatation structure (large arrow, B) are seen on axial T2-weighted images. On enhanced arterial phase image (C), the enhancement of the pseudoaneurysm cavity (white arrow) and the crescent-form filling defect (black arrow) are similar to the Chinese "Yin-Yang" diagram. This pseudoaneurysm is also illustrated on contrast-enhanced MR angiography (arrow, D).

imity to the pancreas[10,22]. The involving vein segment might be complicated by local venous thrombosis. MRI shows the loss of normal vascular flowing void effect at this involving vein segment. After administration of a contrast agent, an intravenous filling defect can be seen on enhanced venous phase images (Figure 11).

Practical setup of MRI in local complications of acute pancreatitis

Cross-sectional T2-weighted imaging and contrast-enhanced fat-suppressed T1-weighted imaging combined with MRCP can be used to assess the severity of acute pancreatitis before therapeutic planning[1-3]. However, dynamic contrast-enhanced MRI in acute pancreatitis is not routinely performed, because, for the majority of patients, pancreatic change is easy to establish with various T1-weighted and T2-weighted sequences in transverse and coronal sections. Therefore, in our current pancreatic imaging practice, the decision process as to whether patients receive dynamic studies is as follows: (1) For imaging of pancreatic necrosis, the combination of T1-weighted and T2-weighted findings with dynamic contrast-enhanced appearances represents a comprehensive evaluation of the extent of necrosis and full range of inflammatory extension. We recommend that enhanced-MRI is essential; (2) For imaging of infectious complications, dynamic contrast-enhanced examinations might help differentiate pancreatic cellulitis or abscesses from pancreatic fluid collection or simple pseudocysts; and (3) For imaging of vascular abnormalities, the combination of cross-sectional pancreatic parenchyma imaging with MRA offers the possibility of a single diagnostic modality for the full evaluation of peripancreatic artery and vein involvement, such as arterial pseudoaneurysms and venous thromboses.

CONCLUSION

In summary, MRI might be indicated in acute pancreatitis for detecting and characterizing local complications of acute pancreatitis. Enhanced-MRI is essential for a comprehensive evaluation of the extent of pancreatic necrosis.

Abstract

AIM: To characterise differences between three widely used colorectal cancer cell lines using ultrastructural selective staining for glycogen to determine variation in metastatic properties.

METHODS: Transmission electron microscopy was used in this investigation to help identify intracellular structures and morphological features which are precursors of tumor invasion. In addition to morphological markers, we used selective staining of glycogen as a marker for neoplastic cellular proliferation and determined whether levels of glycogen change between the three different cell lines.

RESULTS: Ultrastructural analysis revealed morphological differences between the cell lines, as well as differentiation into two sub-populations within each cell line. Caco-2 cells contained large glycogen deposits as well as showing the most obvious morphological changes between the two sub-populations. SW480 cells also contained large glycogen stores as well as deep cellular protrusions when grown on porous filter membranes. HT-29 cells had trace amounts of glycogen stores with few cellular projections into the filter pores and no tight junction formation.

CONCLUSION: Morphology indicative of metastatic properties coincided with larger glycogen deposits, providing strong evidence for the use of selective staining to determine the neoplastic properties of cells.

INTRODUCTION

Cultured human colon carcinoma Caco-2, HT-29, and SW480 cell lines have been used as model cell lines by many researchers to investigate the cell biology and metastatic properties of colorectal cancer. The main tissue of origin of these cell lines, the colon, is a structure comprising a dynamic epithelium where there is continuous

renewal of normal colonic epithelial cells that originate in the crypts (secretory cells) and migrate to the tips of the villous folds (absorptive cells)[1]. This, therefore, results in cellular heterogeneity of all epithelial cells that are derived from any human adenocarcinoma cell line. The present study is designed to examine these heterogenous features ultrastructurally within the three chosen cells lines to determine whether varying malignant characteristics are expressed.

All epithelia form a barrier made of polarized cells in which the apical and basolateral domains of the cells can be separated into functional domains[2]. Cell adhesion is critical in the organisation of normal epithelia, in particular the establishment of the adherens junction, mediated by the presence of E-cadherin, which initiates a cascade of events leading to the formation of the tight junction, gap junction, and desmosomes, all key regulators of the junctional complex[3-5] and mediators of cellular polarisation. The loss of these structures results in the breakdown of the epithelium, leading to increased permeability and pathogenesis of disease[4]. An ultrastructural investigation into the various features of the junctional complex will provide evidence of cellular communication and adhesion to determine whether cellular polarisation is present.

Additionally, the invasive properties of cells are also reflected by cell shape, whereby epithelioid cells appear to be less invasive than spindle-shaped cells[6] due to cellular polarisation and establishment of a tight junction. Additional ultrastructural assays that might help determine the differences in the invasive properties of the aforementioned cells lines is their ability to leave the compartment to which they are normally restricted and to determine whether cells have the potential to carry out invasive growth. By culturing these cells on porous membrane filters, cellular anchorage and cellular sensing movement can be investigated by analysing the degree of cellular migration into the filter pores. By examining these characteristics at an ultrastructural level, comparative invasive properties can be evaluated in each of the cell lines.

In addition to using cellular morphology as a marker for invasive properties, storage of glycogen will also be analysed. Functionally, glycogen storage in the epithelium provides an energy store for cellular proliferation[7-9]. Large quantities of glycogen stores have also been reported in a variety of cultured cells, in particular cells undergoing neoplastic transformations[9-11]. Glycogen metabolism has been widely investigated in malignant cells originating from tissues which normally store glycogen, i.e. hepatomas[11,12] and cancers of the cervix[13]. Surprisingly, elevated stores of glycogen have been reported in all malignant cell lines (in a 58 cell line culture study) irrespective of tissue of origin[9], and in particular colon adenocarcinomas, originating from human colonocytes where glycogen is normally absent[9,10]. Furthermore, the variation in the amount of glycogen storage has been utilized as a marker for malignant processes in cells, whereby increasing levels of glycogen are indicative of more malignant cells due to abnormal cellular proliferation[9]. Glycogen storage has been reported in Caco-2, HT-29, and SW480 cells *via* a glycogen quantitative assay. The highest glycogen levels were found in Caco-2 cells, intermediate levels in HT-29 cells, and the lowest levels in SW480[10], suggesting that Caco-2 cells undergo extensive abnormal cellular proliferation compared to HT-29 and SW480 cells. These assays have not, however, yielded any information on the ultrastructural position of glycogen in the cells, as accumulation of glycogen particles are first observed in the apical cytoplasm followed by a basal distribution when glycogen particles continue to accumulate[7]. By incorporating a selective staining method to detect the presence of glycogen in the cell, this investigation will contribute to the ultrastructural localization of glycogen particles in these colorectal cancer cell lines for the evaluation of malignant properties.

Osmium tetroxide has been widely used by electron microscopists to routinely fix and stain intercellular membrane systems[14,15]; however, primary fixation in an osmium tetroxide-potassium ferrocyanide [$K_4Fe(CN)_6$] mixture combines selective fixation and staining of various cellular components, in particular glycogen[16,17] and intracellular membranes[14,18]. Osmium-ferrocyanide has been shown to bind selectively through the C_2 and C_3 dihydroxyl groups in glycogen. Chelation of the osmium-ferrocyanide complexes by donor atoms in the tissue helps reduce the osmium to a more stable oxidation state, allowing greater osmium deposition than that observed through post-fixation with osmium tetroxide alone. Therefore the osmium-ferrocyanide complex provides excellent preservation and contrast of glycogen complexes, which in many cases might otherwise remain unstained[17]. The osmium-ferrocyanide method will be incorporated into the present study to determine whether there is an ultrastructural variation of glycogen distribution between different colorectal cancer cell lines.

This study will use three cell lines: Caco-2, HT-29 and SW480 cells. The human colon adenocarcinoma cell line, Caco-2, undergoes spontaneous differentiation in cell culture resulting in structural and functional characteristics which resembles intestinal epithelium[19-23]. The Caco-2 cell line, although derived from a tumor of the human colon epithelium (colonocytes), surprisingly exhibits characteristics of foetal ileal epithelial cells from the small intestine (enterocytes)[23]. Many reports have identified the formation of a heterogenous population of Caco-2 cells in culture[7,20,24-26]. One population consists of dome-forming simple columnar polarized epithelium with a homogenous distribution of microvilli (brush border)[27] and established junctional complexes, in particular the tight junction[4,5]. The variant population comprises multilayered cuboidal cells[28], exhibiting large intercellular spaces (cysts) characteristic of motile cells[24,29]. Due to this functional differentiation, Caco-2 cells provide a model to investigate the intestinal barrier as well as drug transport across the intestinal mucosa[19,22] and provide our study with a model cell line that exhibits a heterogenous cell population.

HT-29 cells, although not homogenous in nature, when grown in control Dulbecco's modified Eagle's medium (DMEM) remain morphologically undifferentiated and comprise of a multilayer of unpolarized cells

that contain features of mucous secreting cells[30-32]. The junctional complex and, in particular, the tight junction is absent[33], resulting in disorderly development of cells. A unique feature of HT-29 cells is their ability to undergo polarisation and reversible differentiation into enterocytes after administration of galactose into the culture medium[31]. The undifferentiated form of HT-29 cells will be analysed in this investigation to avoid confounding effects attributable to cell culture medium to allow for a comparative framework between cells lines to investigate junctional properties, glycogen content, and other microanatomy of the HT-29 cell line.

The SW480 cell line also consists of a heterogenous population of cells, but these cells do not differentiate[34]. The predominant cell type in the SW480 cell line consist of flat polygonal cells which form typical epithelial colonies (E-type); the variant R-type cells consist of round, refractile cells with a disoriented morphology. The R-type cells display anchorage-independent growth, form multilayers and are regarded as more malignant[35]. Cellular morphology, glycogen content, and desmosome formation to determine cellular contact and organisation will be used to identify whether the predominant population of cells in the investigation consist of the E- or R-type.

The comparative ultrastructural and glycogen storage data will be examined in the Caco-2, HT-29 and SW480 cell lines at day 1 and day 12 post-confluency to help promote cellular differentiation. The data collected from this investigation will contribute to the utilisation of microanatomical cellular features to determine neoplastic transformations in human adenocarcinoma cell lines and to help identify sub-populations in the chosen cell lines.

MATERIALS AND METHODS

Cell culture

Caco-2, HT-29, and SW480 cell lines were obtained from the American Type Culture Collection. Caco-2 and HT-29 cells were cultured in advanced Dulbecco's modified eagle medium (DMEM) supplemented with 10% fetal calf serum, 0.5 mL Glutamax, and 0.5 mL antibiotics per 40 mL of medium. SW480 cells were cultured in L15 medium supplemented with 10% fetal calf serum, 0.5 mL Glutamax, and 0.5 mL antibiotics per 40 mL of medium. The cells were incubated at 37℃ in a humidified incubator with 5% CO_2 in air and medium was changed every day after the cells reached confluency.

Transmission electron microscopy

Cells were cultured on 0.4 μm pore size cell culture inserts (BD Falcon, NSW Australia) and collected on day 1 and day 12 post-confluency. Four culture inserts per treatment day were fixed in 2.5% gluteraldehyde (ProSci Tech, Queensland, Australia) in 0.1 mol/L sodium cacodylate buffer with 0.1 mol/L sucrose pH 7.4 for 1 h. Cells were next postfixed for 1 h in a 1% osmium tetroxide solution containing 0.8% potassium ferrocyanide in 0.1 sodium cacodylate buffer (to enhance plasma membranes and glycogen particles), dehydrated in graded alcohols, and infiltrated with 50% Spurr's resin/absolute ethanol for 1 h. The cells were then re-embedded in fresh Spurr's resin (Agar Scientific, Essex, UK) overnight under gentle agitation, re-embedded in fresh Spurr's resin, and left to polymerized at 60℃ for 24 h. Two areas of each cell culture insert (n = 8) were cut using a Leica ultracut UCT ultramicrotome (Leica, Heerbrugg, Switzerland) and silver-gold sections (80-90 nm) were mounted onto 200-mesh copper grids. Sections were stained with a 2% solution of aqueous uranyl acetate for 10 min, followed by Reynold's lead citrate stain for 10 min. Stained sections were then viewed using a JEOL 1400 (Tokyo, Japan) transmission electron microscope operating at 120 kV.

RESULTS

Overall, the application of the potassium-ferrocyanide methods results in selective staining of glycogen particles (approximate 20 nm in diameter), electron dense demarcation of plasma membranes, and demarcation of intranuclear indentations (intranuclear rods).

Ultrastructure of Caco-2

When grown on membrane filters, Caco-2 cells differentiated into two morphologically different populations, which will be described separately (Table 1).

Sub-population 1

On day 1 post-confluency, cells were simple squamous with irregular sparse microvilli (Figure 1A). Cells contained round euchromatic nuclei and showed evidence of all other cellular organelles, including mitochondria, rER, and Golgi (Figure 1B). Intercellular spaces between cells were evident, as well as tight junctions and desmosomes. When grown on porous membrane filters (Figure 1C), cellular processes marginally invaded into filter pores (Figure 1D). On day 12 post-confluency, cellular morphology and organisation changed to a stratified cuboidal formation and intercellular spaces increased, resulting in the loss of the tight junction, yet desmosomes were still evident (Figure 1E and F). Glycogen granules were distributed within the cytoplasm with a supranuclear predisposition (Figure 1E and G). Extensive intranuclear rods (indentations of the nuclear membrane) were evident (Figure 1F) and no invasive processes were observed projecting into the filter pores (Figure 1H).

Sub-population 2

On day 1 post-confluency, cells were simple cuboidal and contained regular microvilli (Figure 2A). No intercellular spaces were evident and a tight junction was present along the apical region of the lateral plasma membrane (Figure 2B). Small amounts of glycogen particles were evident and regularly distributed (Figure 2C). Several cellular processes projected into the filter pores (Figure 2D). On day 12 post-confluency, cells became simple columnar with a homogenous population of microvilli (Figure 1E). Glycogen accumulation increased in the cytoplasm of

these cells, exhibiting a supra- and sub-nuclear distribution (Figure 2F). Mucous storing vacuoles also occupied a large volume of these cells and were located in close proximity of the glycogen particles. Intercellular spaces were evident in the basal region of the lateral plasma membrane and the tight junction and plasma membrane interdigitation was also present (Figure 2F). No invasive projections into the filter pores were evident (Figure 2H).

Ultrastructure of HT-29 cells

No morphological heterogeneity was observed in the HT-29 cell line.

On day 1 post-confluency, the cells were stratified cuboidal with microvilli projecting into large intercellular spaces between cells (Figure 3A and B). Desmosomes were evident at meeting points along the lateral plasma membrane (Figure 3C and D). The nuclei were round and euchromatic. Mitochondria, rER and Golgi bodies were all present. The apical-most cells of the multilayer contained regular microvilli; no invasive processes were present and there were no obvious glycogen stores. On day 12 post-confluency, cells remained stratified cuboidal, expressing large intercellular spaces with microvilli projecting into them (Figure 3E). Golgi bodies were more evident, as well as large accumulations of mucous secreting vacuoles (Figure 3F and G). Desmosomes were present along contact sites of the lateral plasma membrane (Figure 3G) and no significant invasive processes or glycogen stores were evident (Figure 3H).

Ultrastructure of SW480 cells

On day 1 post-confluency, cells were simple squamous with irregular microvilli (Figure 4A). Mitochondria were densely distributed through the cell cytoplasm (Figure 4B) and tight junction formation was evident when upper leaflets of the plasma membrane were in close contact (Figure 4C). Long invasive cellular projections were present in the filter pores (Figure 4D). On day 12 post-confluency, cells were simple cuboidal with irregular sparse microvilli (Figure 4E). Large numbers of mitochondria with filamentous branching were evident, as well as the presence of glycogen accumulation (Figure 4F and G). Small intercellular spaces were present, but no desmosomes were evident (Figure 4F). Extremely long invasive processes projected into the filter pores and these projections contained cellular organelles, such as mitochondria (Figure 4H).

DISCUSSION

Utilising selective staining to examine differences in metastatic properties of Caco-2, HT-29, and SW480 cells advances our understanding of the commonly used colorectal cancer cell lines. Morphologically, after reaching confluency, many differences were apparent between the cell lines in this investigation. When grown in standard culture conditions, spontaneous differentiation predominantly occurred in the Caco-2 cell line; however, ultrastructural differences suggesting heterogenous populations also became evident in the HT-29 and SW480 cell lines when cells were examined 12 d post-confluency.

Evidence of a heterogenous population already existed in the Caco-2 cells one day after reaching confluency. Although both Caco-2 cell populations were simple squamous, one population exhibited regular microvilli and tight junction formation (sub-population 2), whereas the other population was void of these features (sub-population 1). By day 12 post-confluency, this heterogeneity was even more apparent, as population 2 cells exhibited a tight junction and became a simple layer of columnar polarized cells with regular microvilli indicative of regular epithelial cell assembly. No intercellular spaces were evident between adjoining cells and there was no evidence of invasive projections into membrane pores; glycogen accumulation, however, was abundant. These features were indicative of intestinal epithelial cells[19,20] and suggested that this sub-population of cells originated from the absorptive

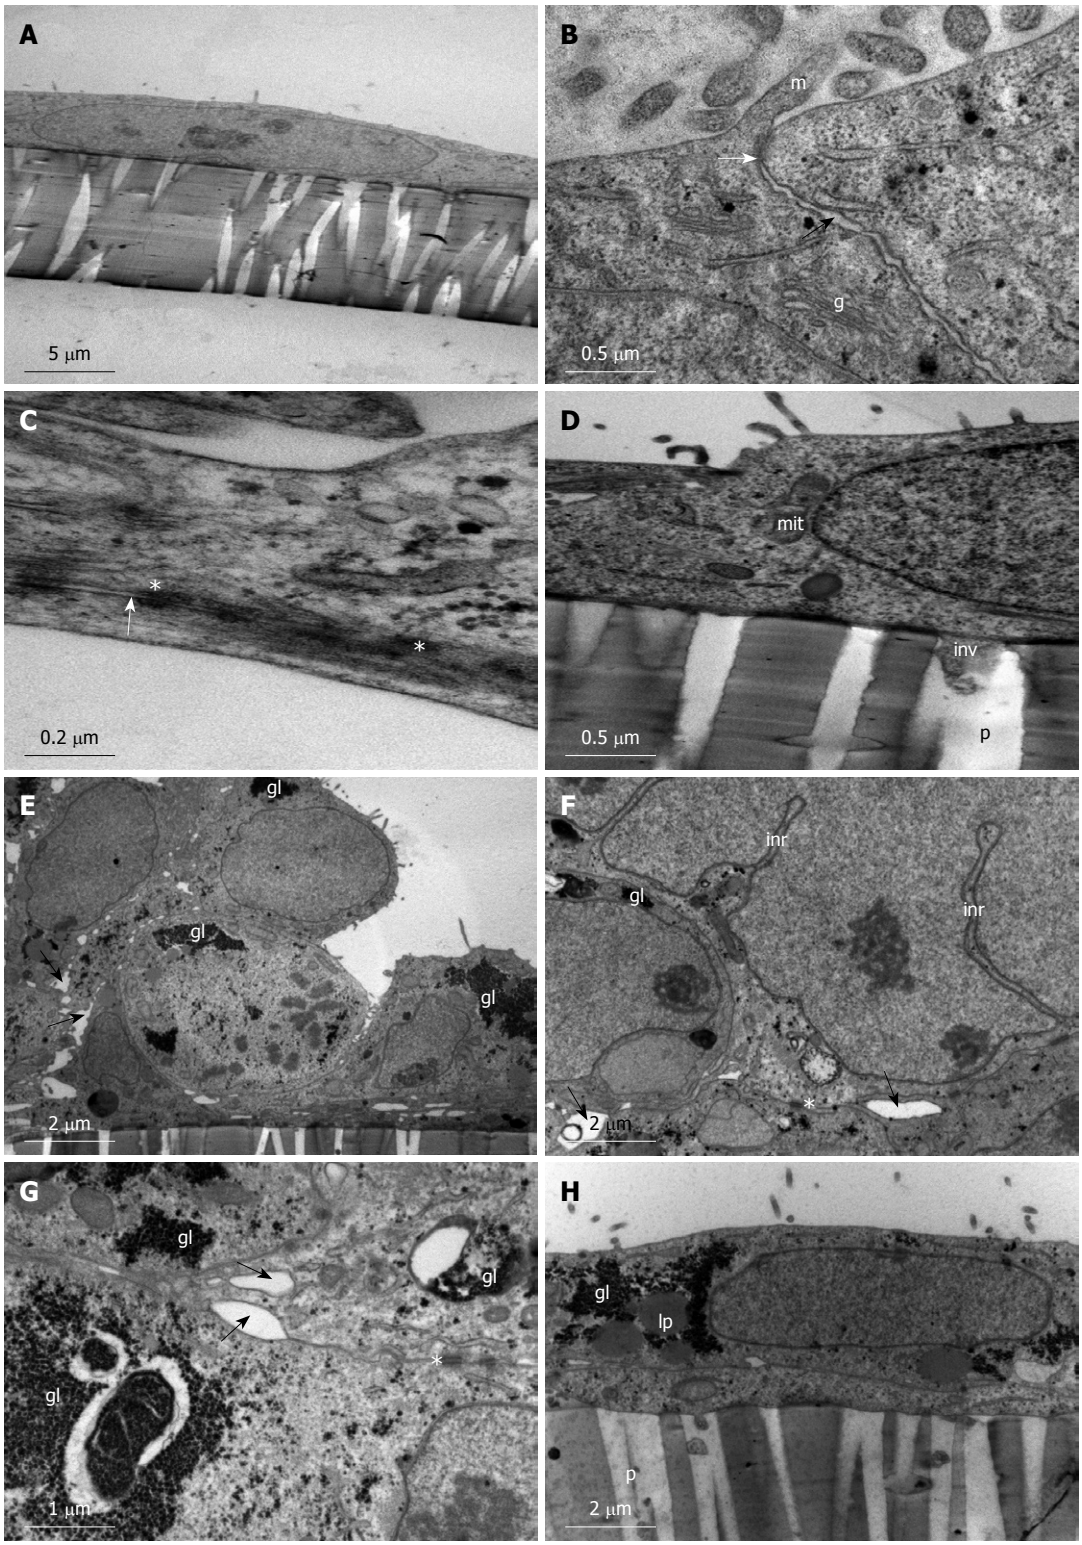

Figure 1 Spontaneous differentiation of Caco-2 into sub-population 1 of stratified cuboidal cells. A-D: Caco-2 cells grown on membrane filters examined on day 1 one post-confluency. A: Simple squamous cells with irregular sparse microvilli; B: Junction between two cells (black arrow) and establishment of a tight junction (white arrow) and the presence of microvilli (m) and golgi bodies (g); C: Desmosome (*) formation along the lateral plasma membrane between two cells (white arrow); D: Basolateral plasma membrane depicting attachment to membrane filter with evidence of small cell protrusions (inv) into the membrane pore (p). Mitochondria (mit); E-H: Caco-2 cells grown on membrane filters examined 12 d post-confluency. E: Cells appear stratified and cuboidal with large intercellular spaces (black arrows); large glycogen stores are evident (gl); F: Intercellular spaces (black arrows) and desmosomes (*) are evident between cells with glycogen deposits (gl) and indentations of the nucleus form large intranuclear rods (inr); G: High power image of intercellular spaces (black arrows) and desmosomes (*) present along the lateral plasma membrane with large glycogen deposits (gl) found in the cytoplasm; H: Basolateral plasma membrane showing attachment of the cell to the membrane filter. No invasive processes are evident projecting into the filter pores (p). Glycogen (gl) and some lipid (lp) droplets are present in the cell cytoplasm.

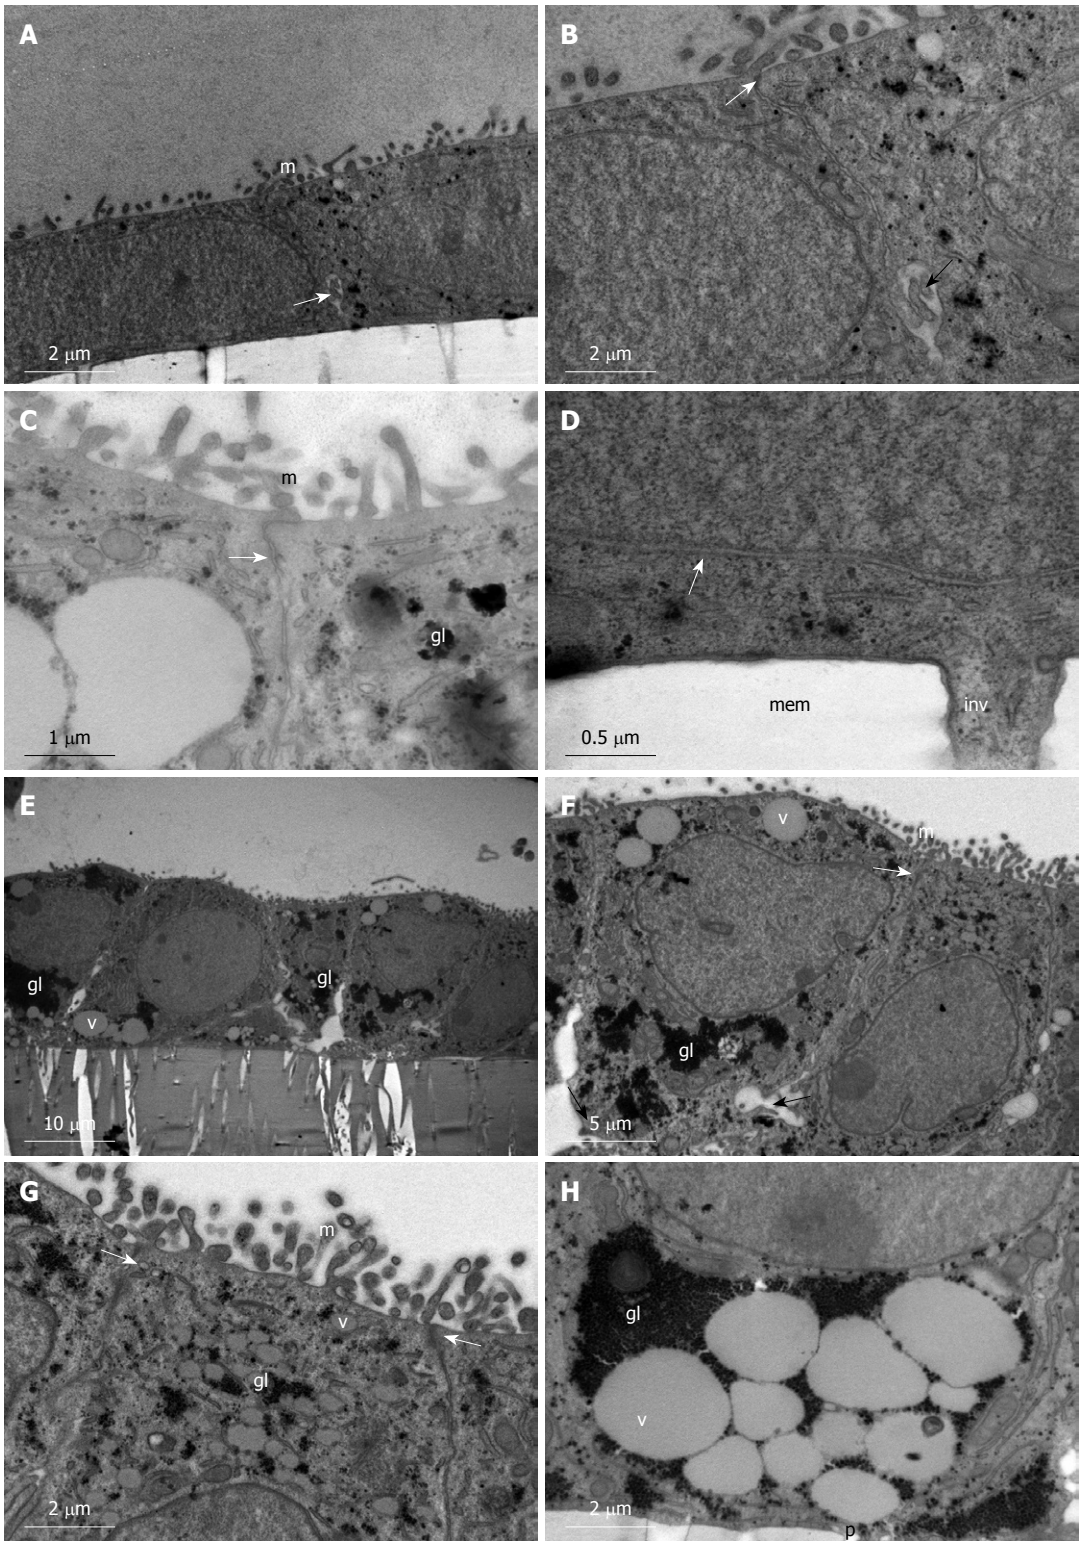

Figure 2 Spontaneous differentiation of Caco-2 into sub-population 2 of simple columnar monolayer of polarized epithelial cells. A-D: Caco-2 cells grown on membrane filters examined on day 1 post-confluency. A: Simple cuboidal epithelium with regular microvilli (m) and intercellular junctions (white arrow); B: Intercellular junction with a tight junction (white arrow) evident along the apical part of the lateral plasma membrane. A small intercellular space (black arrow) is evident near the basolateral region of the plasma membrane; C: High power image of a tight junction (white arrow) between cells showing glycogen particles (gl) and microvilli (m); D: Basolateral plasma membrane showing intercellular junction (white arrow) and small invasive projection (inv) into the filter pore. Membrane (mem); E-H: Caco-2 cells grown on membrane filters examined on day 12 post-confluency. E: Simple columnar polarized epithelium is present with large glycogen stores (gl), mucin filled vacuoles (v), and intercellular spaces along the basal part of the lateral plasma membrane; F: Junction between two columnar cells (white arrow); regular microvilli (m) are present as well as large glycogen stores (gl) and mucin filled vacuoles (v). Intercellular space (black arrow); G: High power micrograph showing the apical domain of cells with regular microvilli (m), glycogen stores (gl), mucin vacuoles (v), and tight junction formation (white arrows); H: High power image of the basal domain of cells with large mucin filled vacuoles (v) enclosed by large glycogen stores (gl). No invasive processes are evident projecting into filter pores (p).

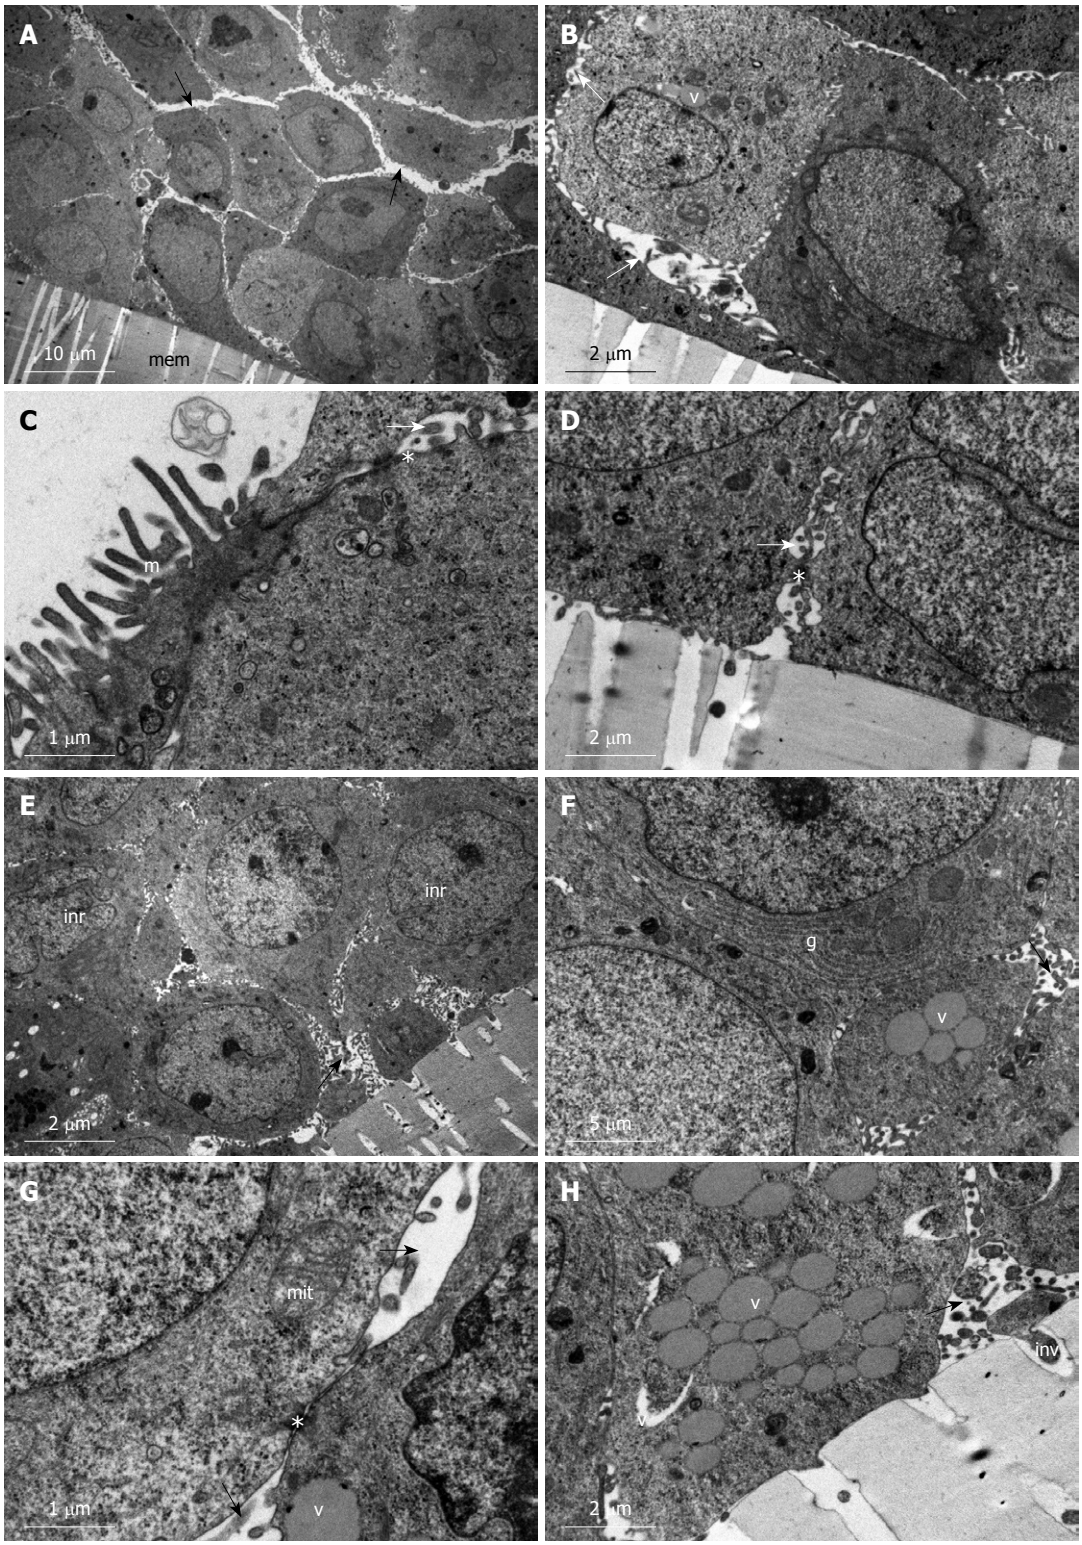

Figure 3 Undifferentiated heterogenous population of HT-29 cells. A-D: HT-29 cells grown on membrane filters (mem) and examined day 1 post-confluency. A: Stratified cuboidal cells arranged in clumps. Large intercellular spaces (black arrows) are evident with microvilli projecting into them; B: High power micrograph showing large intercellular spaces (approximate 2 μm) (white arrows) with microvillar projections and formation of small vacuoles (v); C: Microvillous (m) apical plasma membrane is present and desmosomes (*) are evident along contact sites of the lateral plasma membrane of adjoining cells and presence of intercellular spaces (white arrow); D: No invasive projections are evident along the basolateral plasma membrane. Desmosomes (*) are present at contact sites of the plasma membrane, which otherwise shows intercellular spaces (white arrow); E-H: HT-29 cells grown on membrane filters (mem) and examined day 12 post-confluency. E: Stratified cuboidal cells with microvillar projections entering the large intercellular space (black arrow). Intranuclear rods are evident (inr); F: High power micrograph of junction between two cells. Golgi bodies (g) as well as mucin filled vacuoles (v) are distributed throughout the cell cytoplasm and intercellular spaces are evident with microvilli projecting into their lumen; G: High power micrograph of a contact site between two opposing plasma membranes showing a desmosome (*). Large intercellular spaces (black arrows) are evident above and below the desmosomes contact site. Mitochondria (mit) and mucin filled vacuoles (v) are also evident; H: Basolateral attachment site showing minor invasive projections (inv) into the filter pore. Intercellular spaces (black arrow) and vacuoles (v) are evident.

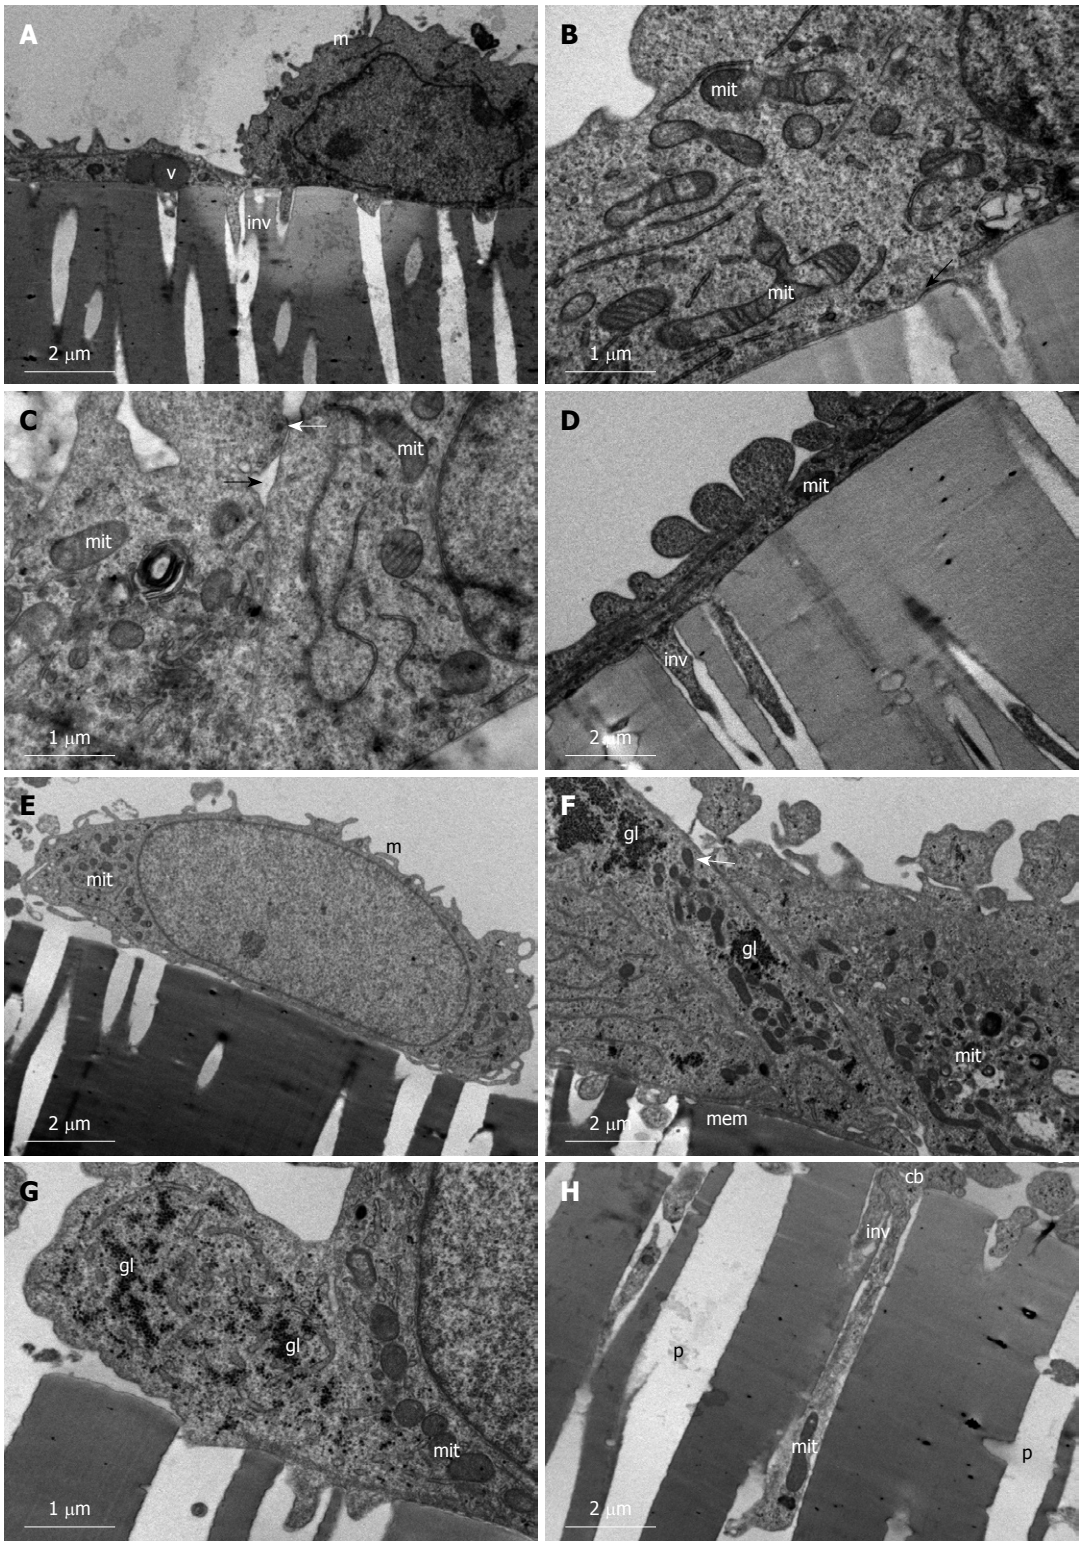

Figure 4 Undifferentiated heterogenous population of SW480 cells. A-D: SW480 cells grown on membrane filters and examined day 1 post-confluency. A: Simple squamous (left) and simple cuboidal (right) distinctions are already evident in cells on day 1 post-confluency. Cells exhibit vacuoles (v), microvilli (m), and invasive processes (inv) are evident projecting into filter pores; B: Large population of mitochondria (mit) are evident which exhibit branching characteristics; C: Intercellular junctions (black arrow) exhibit early formation of the tight junction (white arrow). Mitochondria (mit) with numerous cristae are present; D: Simple squamous cells exhibiting long invasive processes (inv) into the filter pores. Mitochondria (mit); E-H: SW480 cells grown on membrane filters and examined day 12 post-confluency. E: Cells remain a monolayer with microvillar (m) projections and abundant mitochondria (mit); F: Junction between two adjoining cells growing on membrane (mem) showing no intercellular spaces, tight junction formation (white arrow), abundant mitochondria (mit), and glycogen (gl) stores; G: High power micrograph depicting the glycogen (gl) granules in the cytoplasm in amongst mitochondria (mit); H: Basolateral region of cell body (cb) showing deep invasive processes (inv) projecting into filter pores (p). These processes extend to depths of approximately 10 μm and cellular organelles such as mitochondria (mit) are present in these processes, showing deep anchorage of cell.

enterocyte population when the original adenocarcinoma was excised. The polarisation of the Caco-2 epithelial layer indicated that epithelial organisation had been achieved[3] and the cells were contained in the epithelial monolayer without morphological indications of metastatic properties. The presence of glycogen however, suggested that neoplastic proliferation was still taking place in this population. This finding might be significant for tumor excision and treatment, as glycogen stores suggest a neoplastic cell; however, the morphological architecture indicates a contained tumor with possible clear margins and a better probability of complete surgical excision.

Sub-population 1 of Caco-2 cells did not form regular microvilli, and tight junctions did not polarise 12 d post-confluency. This cell population continued to grow in clumps of stratified cuboidal epithelium with large intercellular spaces between individual cells, suggesting high cellular motility (particularly in the apical population of cells)[24]. In the basal distribution of the cells, desmosomes were evident in areas of established cellular contact. Glycogen particles were abundant, with both an apical and basal distribution. Another additional feature that became apparent using a combined osmium tetroxide and potassium ferrocyanide selective staining, which would otherwise not have been adequately sampled, was the presence of intranuclear rods. These structures are indentations of the cytoplasm into the nucleus, whereby they increase the nucleocytoplasmic interactions[36] and carry out nucleocytoplasmic exchange, which is the most important transport phenomena in cells[37]. In the case of malignant colorectal cancer cells, intranuclear rods are suggested to carry out nucleocytoplasmic exchange of glycogen[37]. In a previous report in the Ehrlich-Lettré mouse ascites tumor, glycogen production that originated in the nucleus shifted from the nucleus to the cytoplasm *via* a transfer mechanism that allows the intranuclear glycogen to pour out into the cytoplasm *via* the intranuclear indentations (rods)[37]. Intranuclear rods are prevalent in the Caco-2 cell line (in particular sub-population 1); however, glycogen is predominantly expressed in the cytoplasm, which suggested that the nucleocytoplasmic exchange has occurred. Due to their disorganized arrangement, large intercellular spaces and lack of polarisation and tight junctional formation, sub-population 1 of Caco-2 cells did not form an impermeable monolayer or "classical epithelium". A lack of tight junction formation allows for dissociation of individual cells from the primary tumor due to a decrease in cell-cell adhesion, which consequently allows for the cancerous cells to invade the surrounding tissue, leading to metastasis[38]. Furthermore, for successive metastasis to occur, the tight junctions present in the surrounding tissue must be compromised to enable the tumor cells to penetrate[38]. In a previous investigation of colorectal cancer cells, using the tight junctional protein claudin-4 as a marker, a disruption of claudin-4 mediated tight junction formation enhanced cancer cell invasion and metastasis in colorectal cancer[3]. Finally, the morphology of the cells in sub-population 1 of the Caco-2 cell line did not provide strong evidence indicating the formation of enterocytes, and the high glycogen content signifies metastatic proliferation. Thus, data associated with future functional and transport studies carried out on sub-population 1 of Caco-2 cells might be restricted.

When grown under standard conditions, the HT-29 cells, although not homogenous, did not differentiate into a monolayer of polarized cells, as there is no evidence of any tight junction formation, which again suggests that cells can break away from the primary tumor and begin a metastatic process in surrounding tissue. These results are consistent with previous reports of a heterogenous HT-29 cell population[31,33,39]. At day 1 post-confluency, the cells were arranged into a large clump of microvillous stratified cuboidal epithelium up to seven layers thick. By day 12 post-confluency, large intercellular spaces were observed suggesting that cells remain relatively motile[24], even though some desmosomes were evident at points of plasma membrane contact of cells in the basal population. No invasive cellular projections were evident in the membrane filters, and trace amounts of glycogen particles were present in HT-29 cells when compared to the abundant glycogen stores found in both populations of Caco-2 cells. Reduced glycogen storage suggested that these cells were not undergoing comparable metastatic proliferation as the two sub-populations of the Caco-2 cell line. Previous glycogen assay studies have provided comparative data, where less glycogen content was present in HT-29 cells during both the exponential and stationary growth phase than in Caco-2 cells[10], indicating that the selective staining produced by the potassium-ferrocyanide fixation as a glycogen marker yields comparative results. An additional feature of the HT-29 cell line was the presence of mucin filled vacuoles, which provides evidence that these cells potentially originated from a mucous secreting population of the intestinal epithelium. Previous investigations of the HT-29 cell line have also isolated mucous-secreting sub-clones in the population, but this was achieved by inducing cellular differentiation by the administration of galactose to the culture medium[31]. This induced differentiation also resulted in polarisation and monolayer formation of the HT-29 cells[31]. The present study did not include differentiation of HT-29 cells by adding galactose; therefore, the presence of the mucin filled vacuoles might be indicative of a population of precursor cells that later form secretory intestinal epithelial cells.

When the SW480 cells were cultured under standard conditions, a non-homogenous population of undifferentiated cells was observed. One cell type was simple squamous with irregular microvilli, and the other population of cells were simple spindle-shaped with irregular microvilli. These results were similar to those reported by previous investigations, which also described a heterogenous undifferentiated population of SW480 cells with comparable morphological features[35]. By day one post-confluency, cell-to-cell contacts have been established, with no evidence of intercellular spaces; however, no desmosomes or tight junctions were evident. The glycogen content was equivalent in both populations of SW480 cells, indicating that comparable metastatic properties were present in both sub-populations of this cell line. By day one post-confluency, abundant mitochondria were

present throughout the cell cytoplasm when compared to the cytoplasm of the other two cell lines, and some mitochondria appeared to be branching. Large numbers of mitochondria indicated that these cells were highly active.

At 12 d post-confluency, glycogen particles were also evident, representing intermediate glycogen expression when compared to the large amounts found in Caco-2 cells and trace amounts found in the HT-29 cells. The glycogen stores were distributed amongst mitochondrial populations; however, no intranuclear rods were evident projecting into the nucleus. Another striking feature of the SW480 cell line, irrespective of cell type, was their ability to send deep invasive processes into the membrane filter pores (approximate 8 μm deep). These processes often contained cell organelles, such as mitochondria, which demonstrated deep cell anchorage. Previous reports have also reported that spindle-shaped SW480 cells exhibited vast migration through uncoated membrane filters, whereas cells with a more epithelioid shape (Caco-2 and HT-29) scarcely invaded membranes, even those coated with Matrigel[6]. These potentially invasive characteristics were not observed in Caco-2 or HT-29 cells in this investigation. Invasive processes have, however, been reported in Caco-2 cells in other literature when invasion was induced by adding a collagen matrix to the membrane filters[19]. The addition of the collagen promoted cell migration through the filter pores, which eventually led to the depolarisation of the model cells[19]. No invasion inducing agents were administered in this investigation and there is clear evidence that the SW480 cells presented the most invasive capabilities of the three cell lines. These results were comparable with a previous investigation where metastatic capacities were examined in the SW480 cell line using orthotopic tumor models[40]. When SW480 cancer cells were injected or implanted into the caecum of mice, SW480 cells had a 100% take rate, when compared to a take rate of 69% in HT-29 and 40% in Caco-2 cells. The SW480 cells also had the highest growth index, which was represented by the time it took between implantation and the appearance of disease symptoms[40]. The ultrastructural features observed in this study of the SW480 cancer cell line supported other literature that considered this cell line to be highly malignant[35].

In conclusion, this was the first study to incorporate selective staining for transmission electron microscopy to help identify glycogen storage and nucleocytoplasmic exchange of glycogen by identifying intranuclear rods. Ultrastructurally, the loss of the tight junction in sub-population 1 of Caco-2 cells, and in HT-29 and SW480 cells is indicative of highly disorganized epithelia, whereby individual tumor cells have the potential to dissociate from the primary tumor and begin a metastatic process in other tissue. Conversely, sub-population 2 of Caco-2 cells remained as a polarized monolayer of epithelia with extensive tight junction formation, suggesting organised epithelia with strong cell-cell adhesion with lower disassociation potential. Their glycogen storage, however, suggested that Caco-2 and SW480 cells were undergoing the largest amount of neoplastic transformation, and the abundant mitochondria present in both populations of SW480 cells was also indicative of that feature. The ultrastructural features examined in this study have contributed to our already vast knowledge of colorectal cancer cells. We propose the structural parameters detailed in this systemic study can be used as a quality control in the study of the ultrastructure of Caco-2, HT-29, and SW480 cells *in vitro*. The table herein presented might serve as a morphometric guide for others who wish to utilise these cells lines. Future 3D tomographical work will further capture the nucleocytoplasmic exchange and assist in identifying other key ultrastructural regulators of the invasive process of malignant cells. The identification of glycogen stores in these cells might result in drug therapy trials targeted against these abundant intracellular features.

COMMENTS

Background

The extensive variability that exists in the morphology, growth rate, and cell viability between different colorectal cancer cells in culture results in wide-ranging observations and the inability to standardise data. This investigation is designed to compile relevant ultrastructural data on three commonly used cancer cell lines to determine whether ultrastructural features and the presence of large glycogen stores can be used as indicators for the metastatic properties of cells.

Research frontiers

Large quantities of glycogen stores have been reported in a variety of cultured cells, particularly cells undergoing neoplastic transformations, even when the cells from the tissue of origin lack glycogen. By incorporating selective staining using an osmium tetroxide and a potassium ferrocyanide solution in routine transmission electron microscopy, these glycogen stores can be ultrastructurally identified and used as diagnostic markers for the metastatic properties of cells.

Innovations and breakthroughs

This is the first study to combined ultrastructural and functional features of colorectal cancer cells with selective staining for other neoplastic markers, such as glycogen.

Applications

The compilation of ultrastructural features and glycogen storage data from three commonly used colorectal cancer cell lines will assist future investigators in selecting appropriate cell models depending on their area of interest, particularly for drug therapy trials that might be directed against excessive intracellular glycogen stores.

Peer review

This investigation emphasizes the variability in morphology, behaviour, and metastatic properties of colorectal cancer cells and provides readers with a coherent guide on three commonly used colorectal cancer cell lines for use as a morphometric tool for future investigations.

Abstract

AIM: To identify differentially expressed hydrophobic proteins in colorectal cancer.

METHODS: Eighteen pairs of colorectal cancerous tissues in addition to tissues from normal mucosa were analysed. Hydrophobic proteins were extracted from the tissues, separated using 2-D gel electrophoresis and analysed using Liquid Chromatography Tandem Mass Spectrometry (LC/MS/MS). Statistical analysis of the proteins was carried out in order to determine the significance of each protein to colorectal cancer (CRC) and also their relation to CRC stages, grades and patients' gender.

RESULTS: Thirteen differentially expressed proteins which were expressed abundantly in either cancerous or normal tissues were identified. A number of these proteins were found to relate strongly with a particular stage or grade of CRC. In addition, the association of these proteins with patient gender also appeared to be significant.

CONCLUSION: Stomatin-like protein 2 was found to be a promising biomarker for CRC, especially in female patients. The differentially expressed proteins identified were associated with CRC and may act as drug target candidates.

INTRODUCTION

Cancer of the colon and rectum is termed colorectal cancer (CRC). CRC is ranked the third most common cancer worldwide. Statistical data from the World Cancer Report revealed that there are more than 940 000 cases of CRC each year with an annual mortality of around 500 000[1]. In Malaysia, CRC is the most common type of cancer amongst men and the 3rd most common cancer amongst women after breast and cervical cancer[2].

Proteomics in cancer is used to study the protein expression pattern of normal and cancerous tissues in order to elucidate the molecular mechanism associated with disease development and progression[3]. Membrane proteins which make up approximately 30% of the human proteome are important components of cells[4]. Membrane-associated proteins are involved in various

fundamental biological processes in cells including signal transduction, immune regulation and transportation[5]. Nevertheless, the hydrophobic nature of membrane proteins make the extraction of these proteins challenging as they are difficult to extract and analyse[6]. Solubilisation of membrane proteins requires the use of stringent reagents and the addition of urea and thiourea[7,8]. Moreover, these proteins are prone to precipitation at their isoelectric points which may lead to protein loss during 2D-Polyacrylamide Gel electrophoresis (2D-PAGE) separation[9,10]. Thus, the proteome of membrane proteins is normally under-represented. Many investigations have been carried out to improve extraction, enrichment and separation of membrane and membrane-associated proteins[11,12].

In this study, a mixture of reagents was added to the extraction buffer in order to increase the solubility of membrane proteins. Although it is impossible to extract all the membrane proteins from tissues, we obtained a consistent pattern of protein maps for cancerous and normal tissues, respectively. This enabled us to identify unique or differentially expressed membrane proteins in CRC tissues which may be useful for the diagnosis or treatment of CRC. The significance of these proteins in relation to cancer stages, grades and patient gender was also evaluated.

MATERIALS AND METHODS

Tissue samples

Surgically removed colorectal cancerous tissues and their respective normal mucosa were obtained from 18 patients who received treatment at Penang General Hospital, Malaysia. Written informed consent was obtained from all patients before surgery. The tissue specimens were kept in -80℃ until analysis. The tissues were grouped according to cancer stage, grade and patient gender (Table 1). The tumor type obtained was adenocarcinoma and normal mucosa was obtained from a site at least 10 cm away from the tumor. None of the patients received preoperative neo-adjuvant chemotherapy or radiotherapy. All the patients were > 40 years old at the time of surgery. The tissues were pathologically confirmed by the hospital's pathologist. Frozen sections of tissue were taken from cancerous tissues in the anterior and deep region to ensure adequacy of tumor and only cancerous tissue that contained > 90% malignant cells was used in this study.

Protein extraction

The membrane or membrane-associated proteins were extracted from the homogenised tissues using thiourea buffer (7 mol/L urea, 2 mol/L thiourea, 4% CHAPS and 0.2% carrier ampholytes). Briefly, 200 mg of tissue was homogenised in 1 mL of Tris buffer (40 mmol/L Tris) followed by sonication for 30 s and chilled on ice for 2 min. The lysate was then vortexed for 5 min before being centrifuged (12000 r/min, 15 min, 20℃). The supernatant was kept for a separate experiment while the pellet was rinsed twice with Tris buffer. The pellet was then suspended in 150 μL of thiourea buffer, sonicated, vortexed and centrifuged (12000 r/min, 15 min, 20℃) and the supernatant was collected for analysis.

Table 1 Clinical information of the patients studied

No.	Age (yr)	Sex	Duke's system	Localization	Degree of differentiation
1	57	F	C	Right colon	Well-differentiated
2	64	M	C	Caecum	Moderately-differentiated
3	45	M	B	Sigmoid colon	Well-differentiated
4	91	F	C	Sigmoid colon	Well-differentiated
7	75	F	B	Rectosigmoid	Well-differentiated
8	62	M	C	Rectum	Well-differentiated
9	71	F	C	Sigmoid colon	Moderately-differentiated

12	70	M	C	Sigmoid colon	Moderately-differentiated
13	63	M	B	Rectum	Moderately-differentiated
14	62	F	B	Rectosigmoid	Well-differentiated
15	54	F	B	Descending colon	Well-differentiated
17	74	M	B	Rectosigmoid	Moderately-differentiated
19	67	M	B	Rectum	Moderately-differentiated
20	53	F	C	Rectosigmoid	Moderately-differentiated
21	79	F	C	Rectosigmoid	Moderately-differentiated
23	67	M	C	Sigmoid colon	Moderately-differentiated
24	42	M	B	Descending colon	Well-differentiated

2-D gel electrophoresis

The protein concentration of the thiourea buffer extracts was determined using the RCDC protein assay kit (Bio-Rad, USA), and 500 μg of the extract in 185 μL of rehydration buffer (same composition as thiourea buffer) was used to rehydrate IPG strips (4-7 pH, 11 cm) for 15 h and focused using IEF Cell (Bio-Rad, USA) starting from 0 to 250 V within 15 min, followed by 250 to 8000 V within 2.5 h and maintained at 8000 V until 35000 V-h was achieved. Subsequently, the IPG strips were equilibrated for 15 min with gentle shaking in Sodium Dodecyl Sulfate-Polyacrylamide Gel electrophoresis (SDS-PAGE) Equilibration Buffer I (6 mol/L urea, 0.375 mol/L Tris pH 8.8, 2% SDS, 20% glycerol, 2% DTT and a trace amount of bromophenol blue), followed by another 15 min of gentle shaking in SDS-PAGE Equilibration Buffer Ⅱ (same composition as SDS-PAGE Equilibration Buffer 1, however, 2.5% iodoacetamide was used instead of 2% DTT). Second dimension separation was carried out under constant voltage of 200 V for approximately 3 h in 10% SDS-PAGE. The gel was stained overnight using Coomassie Blue (0.2% Coomassie Brilliant Blue R250, 50% MeOH and 2% acetic acid) and destained for 2 h.

Gel imaging and statistical analysis

The 2D-PAGE images were acquired by using the Versa-doc system (Bio-Rad, USA). The gel images were processed and analyzed using PDQuest version 7.3 (Bio-Rad, USA). The software was used to create a matchset to compare the images of cancerous and normal colorectal tissues. The matchset was used to analyze quantitative

and qualitative differences in protein spots between the images. The intensity of the protein spot was measured after normalization of the protein spot as a percentage of the total density of all proteins spots on each gel in order to minimise the variation which may be caused by the amount of sample loaded. β-actin protein spot was used as the landmark for gel image analysis. A protein was up-regulated if its expression level in cancerous tissues was 1.5-fold or more compared to normal colorectal tissue, and was down-regulated when the opposite occurred. A protein was uniquely expressed if it was found exclusively in either normal or cancerous colorectal tissue only. In addition, the statistical significance of the protein's change in expression was determined using the Wilcoxon signed-rank test (PDQuest version 7.3) at 95% level of confidence.

In-gel digestion

In-gel digestion was carried out according to Gam *et al*[13]. In brief, the protein spots of interest were excised from the gel. The Coomassie blue stain on the protein spot was removed by dehydrating the gel pieces in acetonitrile and rehydrating in 100 mmol/L NH_4HCO_3. This step was repeated three times. The gel pieces were then incubated in a volume of trypsin buffer (50 mmol/L NH_4HCO_3 and 5 mmol/L $CaCl_2$) containing 12.5 ng/μL trypsin and chilled at 4℃ for 45 min. The trypsin buffer with trypsin was then replaced by trypsin buffer without trypsin at a volume sufficient to wet the gel pieces and incubated overnight at 37℃. The peptides were then eluted from the gel pieces and dried using a sample dryer (Techne, UK) under a continuous flow of nitrogen gas and stored at -20℃ prior to analysis.

Liquid chromatography tandem mass spectrometry analysis

The dry peptides were suspended in 15 μL of ultrapure ddH_2O and were subjected to liquid chromatography tandem mass spectrometry (LC/MS/MS) analysis using an electrospray ionisation-ion trap mass spectrometer (Agilent). A 5 μL volume of the reconstituted sample was injected into a RPC-column (C18, 300 Å, 5 μm, 1 mm × 150 mm) connected to a HPLC (1100 Series, Agilent). A capillary pump was used to pump the mobile phase (A and B) at a flow rate of 15 μL/min. The linear gradient used was 5% B to 95% B in 65 min. Mobile phase A was 0.05% formic acid in deionized water and B was 0.05% formic acid in acetonitrile. The HPLC was interfaced to the mass spectrometer detector. An experimental method comprising 2 scan events was used for analysis. The first scan event was a full scan MS whilst the second scan was the data dependent MS/MS scan which is dependent on the results of the first scan event. Two of the most intense ions in the MS scan which surpassed the threshold set were automatically isolated and excited to the MS/MS scan. The MS parameters used were; dry gas flow rate of 15 μL/min, nebulizer pressure of 30.0 psi and dry gas temperature of 300℃. The parameters for the MS/MS scan were; default collision energy (voltage) of 1.15 V, charge state of 2, minimum threshold of 1000 counts, and isolation width of 2 m/z. The MS/MS data from the analysis were used to search for their corresponding protein identity in Swiss-Prot using MASCOT Search engine version 2.2 from Matrix Science (www.matrixscience.com). The search parameters used were *Homo sapiens* for taxonomy, trypsin for enzyme, carboxymethyl for fixed modifications, peptide tolerance of +/- 2 Da, MS/MS tolerance of +/- 0.8 Da and average experimental mass value. Further analysis of proteins was carried out using the ProtParam programme available at the EXPASY website (http://www.expasy.org/tools/protparam.html) for calculation of the proteins grand average of hydrophobicity (GRAVY). The Tmpred programme (http://www.ch.embnet.org/software/TMPRED_form.html) was used to determine the transmembrane domain of the proteins.

Western blotting

Western blotting was carried out using a semi-dry blotting method[14]. Protein extracts were separated by SDS-PAGE according to Laemmli[15]. A similar quantity of protein was loaded on to SDS-PAGE, after electrophoresis separation, the proteins in the gel were transferred using a TE 70 Semiphor semi-dry transfer unit (Hoefer Scientific, Germany) at 134 mA for 1.5 h to a nitrocellulose membrane. The membrane was incubated in 20 mL of mouse anti-SLP-2 antibody (Abnova, Taiwan) at 1:250 followed by incubation with 50 mL of HRP conjugated anti-mouse secondary antibody (Bio-Rad, USA). The reaction of HRP and its substrate 4-Chloro Naphthol (4CN) indicated the presence of stomatin-like protein 2 (SLP-2).

RESULTS

Two-dimensional gel electrophoresis for protein separation was carried out on a linear pH range of 4 to 7. A total of 13 differentially expressed proteins which were expressed abundantly in either cancerous or normal tissues were identified (Figure 1). Identification of differential protein expression in individual patients was accomplished by conducting a pair-wise comparison between the cancerous and normal tissues for each patient and is displayed in Figure 2. An average of 177.35 ± 26.60 protein spots was detected on 2D gel, with a coefficient variation of 15%. Eight proteins, namely tubulin α-1 chain (S4), tubulin β-2 chain (S5), chaperonin GroEL (S6), heat shock 70 kDa protein (S7), SLP-2 (S8), annexin A3 (S9), annexin A4 (S10) and ATP synthase D chain (S13) were up-regulated although only the up-regulation of tubulin β-2 chain, SLP-2, annexin A3 and annexin A4 were significant ($P < 0.05$) in CRC. Figure 3 shows the comparative analysis of spot intensity between normal and cancerous tissues for SLP-2, annexin A3 and annexin A4.

The identity of the proteins was determined by amino acid sequencing *via* tandem mass spectrometric analysis followed by protein database search. The representative

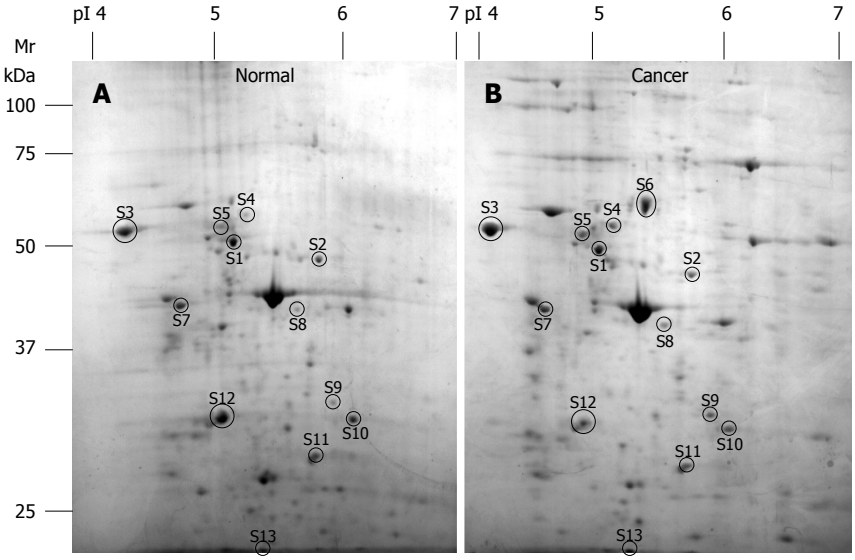

Figure 1 Protein expression profiles of normal mucosa (A) and CRC tissues (B). S1: F1-ATPase β subunit; S2: Ubiquinol-cytochrome C reductase; S3: Calreticulin; S4: Tubulin α-1 chain; S5: Tubulin β-2 chain; S6: Chaperonin GroEL; S7: Heat shock 70 kDa protein 5; S8: Stomatin-like protein 2; S9: Annexin A3; S10: Annexin A4; S11: Prohibitin; S12: Annexin V; S13: ATP synthase D chain.

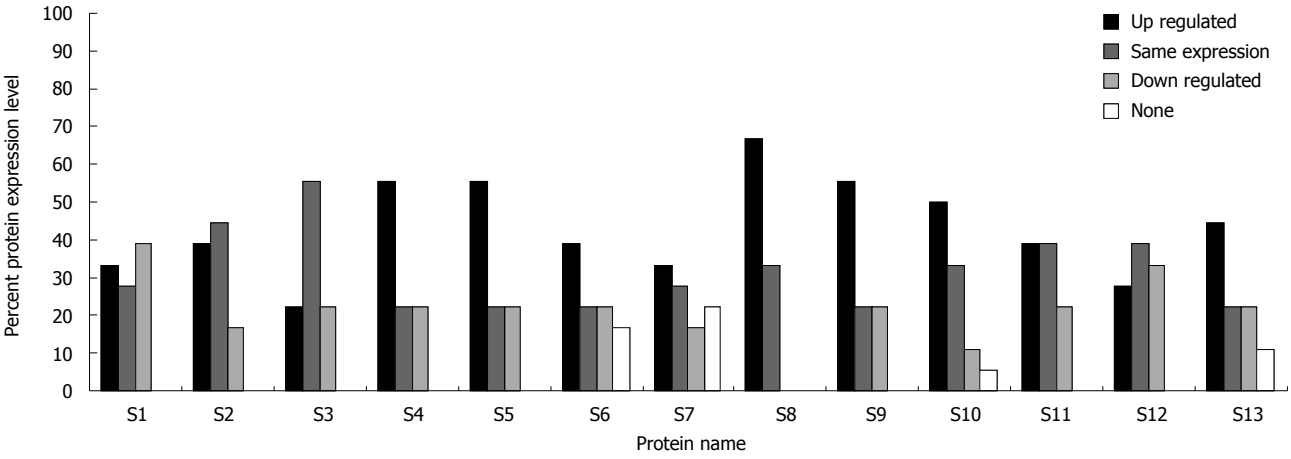

Figure 2 Distribution of proteins in cancerous tissues *vs* normal tissues in all 18 patients. An up-regulated protein is a protein with a higher expression level in cancerous tissues than in normal tissues, and *vice versa* for down-regulated proteins. Same expression is when the expression levels are the same between cancerous and normal tissues. None expression is when the protein was not found in either cancerous or normal tissues.

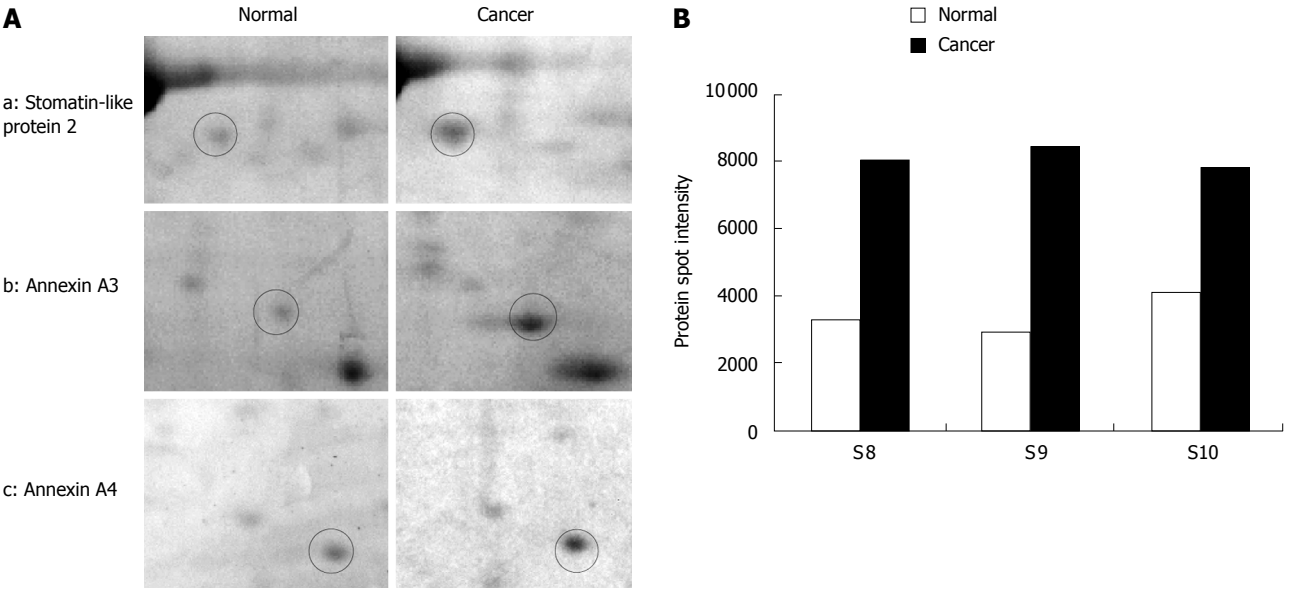

Figure 3 Protein spot analysis (A) and quantification of spot intensity (B) of (a) stomatin-like protein 2 (S8), (b) annexin A3 (S9) and (c) annexin A4 (S10) from normal and colorectal cancerous tissues in the same patient.

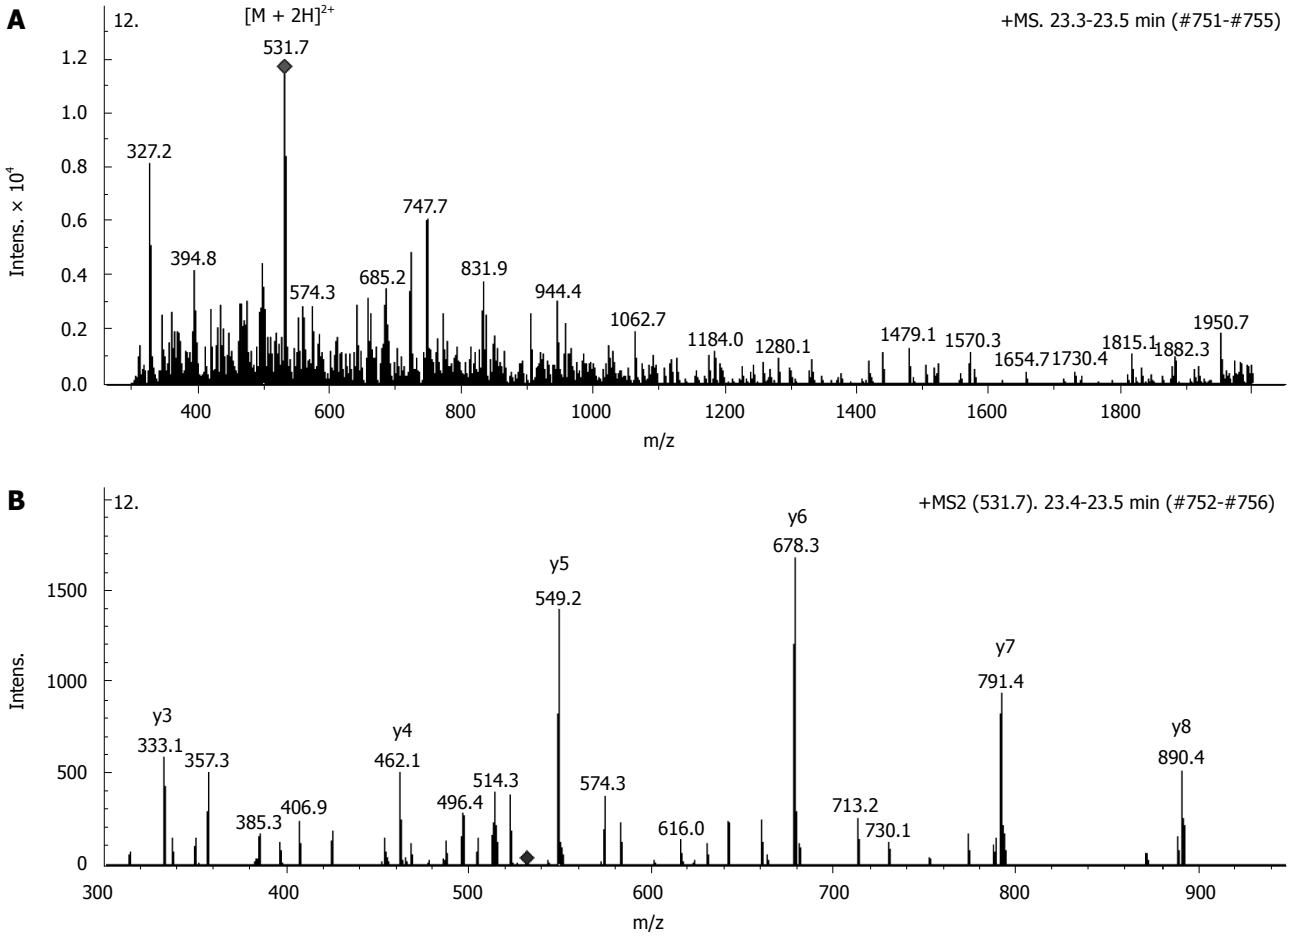

Figure 4 LC/MS/MS analysis of protein. A: Full scan MS spectra of 531.7 m/z peptide; B: MS/MS spectra of 531.7 m/z peptide ions of stomatin-like protein 2.

Figure 5 Western blotting for stomatin-like protein 2. Lane 1 and 2 are proteins extracted from normal and cancerous tissues, respectively, from the same patient.

MS and MS/MS spectra of SLP-2 are shown in Figure 4. Western blotting was used to confirm the results obtained from mass spectrometric analysis. Figure 5 shows a Western blot image of SLP-2 extracted from normal and cancerous tissue in the same patients, SLP-2 was only detected in cancerous tissue. Table 2 shows the 13 differentially expressed proteins identified in this study. The GRAVY score indicated the hydrophobic property of each protein, and the change in the protein expression levels is indicated as fold change (calculated as the ratio of total spot intensity of the protein in normal and cancerous tissues in all 18 patients). A positive value indicated that the protein expression level was higher in cancer compared to normal tissue or that it was up-regulated, while a negative value showed that the protein was down-regulated. Chaperonin GroEL was shown to have the greatest fold change (+265.0) although its up-regulation in all 18 patients was not statistically significant ($P < 0.05$).

Analysis of protein expression was carried out by comparing protein expression profiles of cancerous and normal tissues within and between cancer stage, pathological status (grade) and gender of the patients. The tissue specimens collected comprised 9 each of Duke's B and Duke's C, respectively. Figure 6A shows the level of up-regulation of the 13 proteins in Duke's B and C. The proteins which were up-regulated in > 50% of Duke's B cancer were SLP-2 (S8) and annexin A4 (S10), while F1-ATPase β subunit (S1), uniquinol-cytochrome c reductase (S2), tubulin α-1 chain (S4), tubulin β-2 chain (S5), SLP-2 (S8), annexin A3 (S9) and ATP synthase D chain (S13) were up-regulated in > 50% of Duke's C cancer. The up-regulation of both SLP-2 and annexin A4 was significant ($P < 0.05$) in Duke's B cancer, whilst only tubulin β-2 chain and SLP-2 were significantly ($P < 0.05$) up regulated in Duke's C cancer.

As for cancer grade, the tissues collected comprised 9 each of well-differentiated adenocarcinoma (WDC) and moderately-differentiated adenocarcinoma (MDC), respectively. Figure 6B shows the level of up-regulation of the 13 proteins in WDC and MDC. SLP-2 was expressed at > 50% in WDC and its up-regulation in WDC was

[1]Fold change is given as the ratio of the spot intensity in normal mucosa over tumour tissue (negative variation or decrease) or tumor tissue over normal tissue (positive variation or increase). [a]Differentially expressed proteins that are statistically significant ($P < 0.05$) among all 18 patients; [b]Differentially expressed proteins that are statistically significant ($P < 0.05$) in Duke's B stage; [c]Differentially expressed proteins that are statistically significant ($P < 0.05$) in Duke's C stage; [d]Differentially expressed proteins that are statistically significant ($P < 0.05$) in WDC; [e]Differentially expressed proteins that are statistically significant ($P < 0.05$) in MDC; [f]Differentially expressed proteins that are statistically significant ($P < 0.05$) in female patients; [g]Differentially expressed proteins that are statistically significant ($P < 0.05$) in male patients. pI: Isoelectric point; GRAVY: Grand average of hydrophobicity; TMR: Transmembrane region.

significant ($P < 0.05$). Tubulin α-1 chain (S4), tubulin β-2 chain (S5), SLP-2 (S8), annexin A3 (S9) and annexin A4 (S10) were up-regulated in > 50% MDC, however, only the expression levels of SLP-2, annexin A3 and annexin A4 were significant ($P < 0.05$).

There were 10 male patients and 8 female patients included in this study. All 13 proteins identified in the study were equal to or > 50% up-regulated in female patients except for calreticulin (S3) and heat shock 70 kDa protein (S7) (Figure 6C). In contrast, all 13 proteins were up-regulated in < 50% of male patients except SLP- 2 (S8) and annexin A3 (S9) which were up-regulated in 50% of male patients (Figure 6C). Only SLP-2 was significantly up-regulated ($P < 0.05$) in CRC male patients, while tubulin α-1 chain, tubulin β-2 chain, SLP- 2 and annexin A4 were significantly up-regulated in CRC female patients.

DISCUSSION

The potential use of membrane proteins in drug targeted therapy and diagnosis of diseases is enormous, where many of the biomarkers for indication of diseases are of membrane origin[16]. The membrane or membrane-associated proteins contain potential antibody recognition sites that may provide identification of cancer development[6]. Although the extraction of membrane proteins is difficult, a combination of reagents can be used to enhance the solubility of membrane proteins. In this study, tissues were homogenised and treated with Tris buffer prior to thiourea buffer extraction. This pre-treatment removed aqueous soluble proteins and minimised proteolysis. Thus, the remaining tissue pellet contained mainly hydrophobic proteins which were then extracted using thiourea buffer. Thiourea buffer is usually used as soluble buffer for hydrophobic proteins[17]. Dowling *et al*[18] and Alvarez-Chaver *et al*[9] reported proteomic data of membrane proteins isolated from colorectal cancer by using Triton X-114. Although some common differentially expressed proteins were identified in our study and in the study by Alvarez-Chaver *et al*[9], there were also different types of proteins reported by both studies which indicated the crucial roles of reagents in determining the type of protein extracted.

Separation of proteins was carried out using 2-D gel electrophoresis. A similar quantity of proteins from cancerous and normal tissues was used in the analysis to ensure that the change in protein intensity was a factor of tissue type and not tissue weight, this is because the density of cancerous tissues is generally higher than that of normal tissues. A total of 500 μg of protein was shown to be an ideal load for 2-D gel separation as it allows the visualisation of minute proteins with good spot quality, while abundant proteins were kept under the saturation level when stained with Coomassie Blue.

In this study, only those proteins that were consistently expressed in all the tissues were targeted, we believe that this approach will minimise the identification of false-positive proteins that result from tissue heterogeneity and sample handling. In addition, the normalisation of protein spots during gel image analysis also serves as a control for the determination of differential protein expression levels. We observed a consistent pattern of proteomes for normal and cancerous tissues, respectively (Figure 1). Nevertheless, the expression levels of the proteins varied between patients, where no single protein was solely up-regulated or down-regulated in either cancerous or normal tissues in all patients; i.e. an un-regulated protein in one patient can be expressed as a down-regulated protein in another patient. This observation may support the phe-

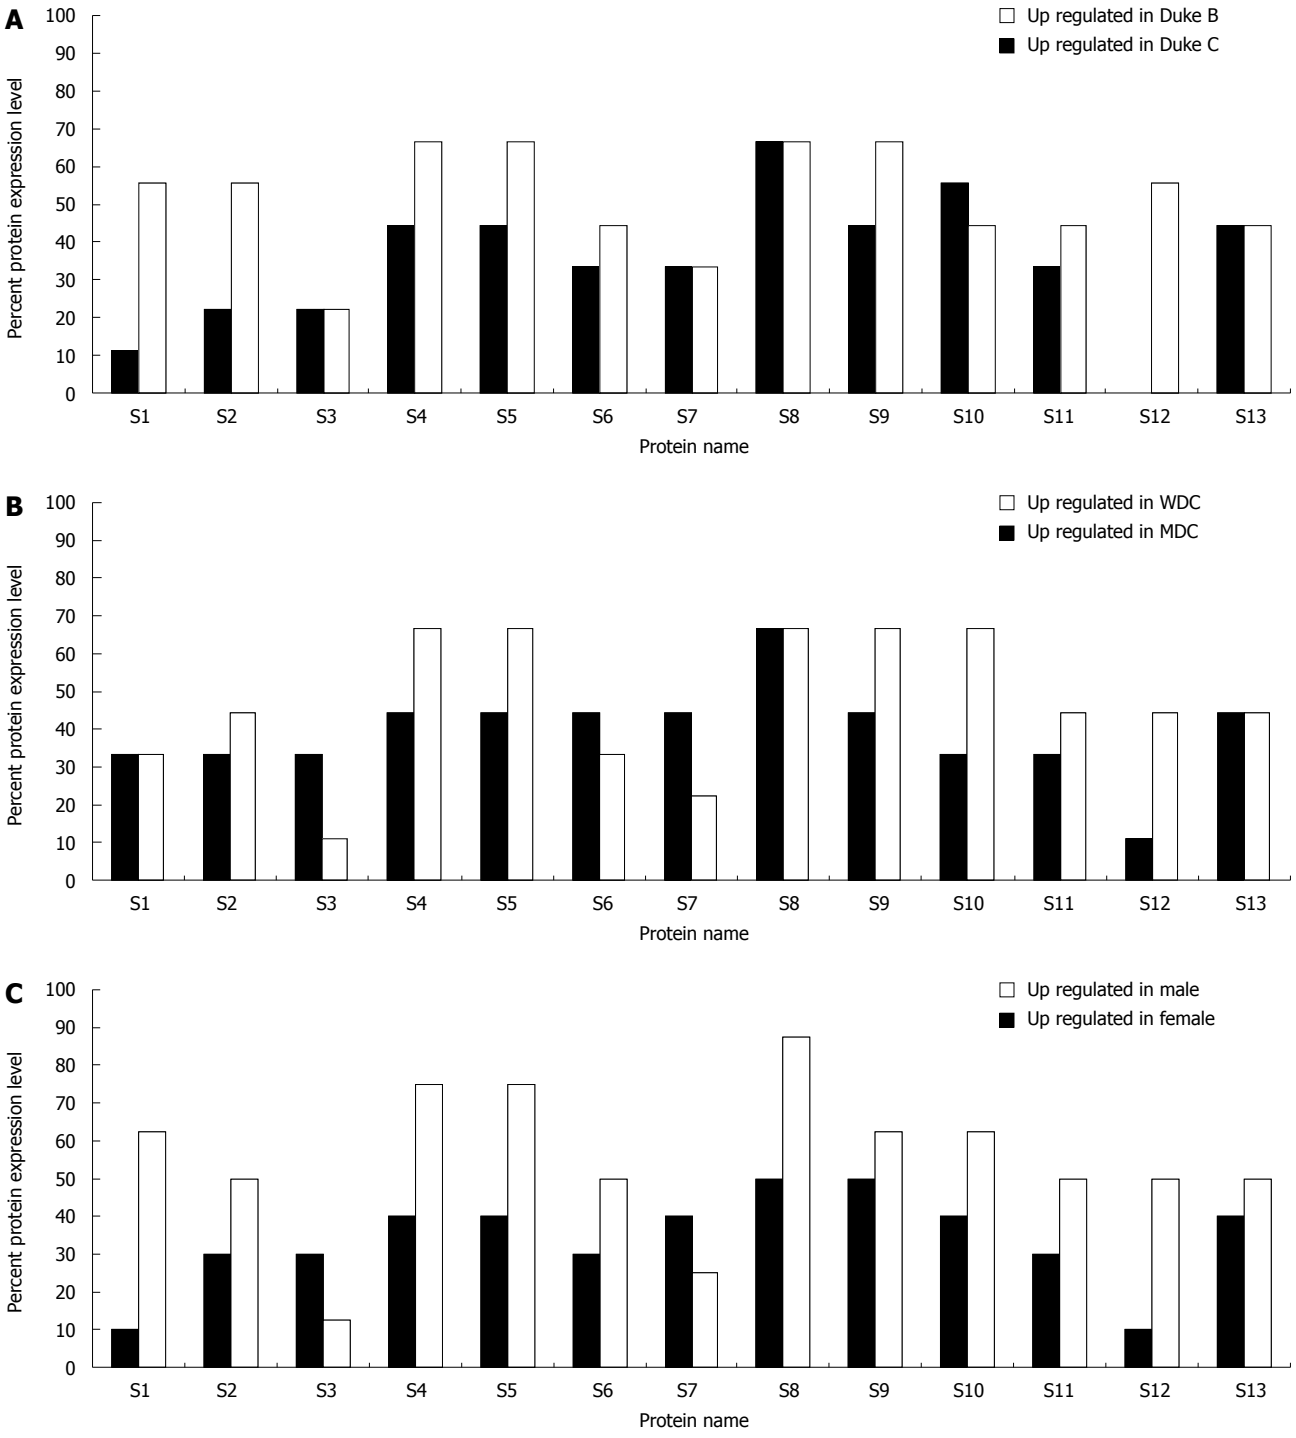

Figure 6 Distribution of proteins in cancerous tissues *vs* normal tissues in all patients in relation to cancer stage (A), grade (B) and gender (C). An up-regulated protein is a protein with a higher expression level in cancerous tissues than in normal tissues, and *vice versa* for down-regulated proteins.

nomenon that one drug does not fit all and therefore, customized drugs have become the current trend for the treatment of cancer. Nevertheless, protein expression level was found to be more consistent when the tissues were analysed according to cancer stage, grade and gender of the patients. The association of protein expression with stage and grade of CRC and gender of the patients showed the potential of developing stage, grade or gender specific treatment for CRC patients.

Duke's classification of tumor invasion has been proved to correlate with patient survival[19]. A greater number of proteins were found to be consistently up-regulated in Duke's C tissues compared to Duke's B tissues. In Duke's B cancer, the tumor has not yet metastasized and therefore may still undergo the process of differentiation, nevertheless, when it advances to Duke's C stage, where cancer has metastasized to the lymph nodes, the tumor may also reach a certain level of maturity and reveal

a greater consistency in the protein expression profile. In contrast, Kwong *et al*[20] reported that changes in the number of highly expressed proteins do not correlate with the progression of colorectal cancer from Duke's stage B to D.

Well-differentiated adenocarcinoma is less aggressive than moderately-differentiated adenocarcinoma, where the former has a greater resemblance to normal cells. We found that the pattern of protein expression in well-differentiated adenocarcinoma was closer to normal tissues, where only 1 protein was up-regulated in > 50% of well-differentiated tissues compared to 5 proteins in moderately-differentiated tissues.

With regard to the gender of patients, female patients showed a greater consistency in protein expression compared with male patients. In general, all 13 proteins identified had a much greater level of expression in female patients than in male patients except for heat shock 70 kDa protein and calreticulin. Calreticulin was identified as a down-regulated protein in this study. It has been reported that men have higher probabilities of developing polyps and tumors than women, although women are more likely to develop right-sided polyps and right-sided tumors than men[21], which may explain the different protein expression profiles in the two genders.

All 13 proteins identified in this study were among the highly expressed proteins in either cancerous or normal colorectal tissues. Of these proteins, SLP-2 has been shown to be a promising biomarker for CRC, particularly for female patients, where it was up-regulated in 87.5% of female patients, whereas in male patients, it was found to be up-regulated in 50% of patients. Moreover, in Duke's B, Duke's C, WDC and MDC, its up-regulation levels were 66.7%. Up-regulation of SLP-2 was statistically significant ($P < 0.05$) in both male and female patients and in the stages and grades of CRC tested. Its detection in CRC has not been reported, although it was reported to be up-regulated in other types of cancer. Over expression of SLP-2 was identified in human esophageal squamous cell carcinoma, lung cancer, laryngeal cancer, and endometrial adenocarcinoma which indicated that SLP-2 over expression is very common in cancer development. SLP-2 was associated with different stages of tumor progression from normal tissue to premalignant and malignant lesions of the esophagus[22]. High expression of SLP-2 was also attributed to advanced stages of breast cancer[23]. SLP-2 was reported to be involved in regulating cell growth and cell adhesion in human oesophageal squamous cell carcinoma[22]. SLP-2 plays an important role in sustaining T cell activation through the antigen receptor that is required for T cell differentiation during immunomodulation. It may also be involved in regulating ion channel conductance and/or the organisation of sphingolipid and cholesterol-rich lipid rafts[24].

The GRAVY score analysis of the thirteen proteins identified in this study showed that only prohibitin had a positive GRAVY score (0.024) indicating its hydrophobic nature. Nevertheless, Blonder *et al*[25] suggested that the GRAVY calculation does not reliably predict the hydrophobic nature of a protein. Therefore, the presence of the transmembrane domain of a protein is collectively used to predict the nature of a protein. Tmpred analysis of human SLP-2 (356 amino acids) has shown that it contains a single transmembrane domain, which putatively consists of 19 hydrophobic amino acids (amino acid 5-24). SLP-2 is a novel and unusual member of the stomatin gene superfamily. It is a peripheral membrane protein[24].

Besides SLP-2, other up-regulated proteins with significant expression were annexin A3, annexin A4 and tubulin β-2 chain. Annexin A3 and annexin A4 are members of the annexin family, a family of calcium-regulated phospholipid-binding proteins. Annexin A3 induces the migration and tube formation of vascular endothelial cells by inducing hypoxia-inducible factor-1 (HIF-1), which in turn causes the secretion of vascular endothelial growth factor (VEGF), an important factor in angiogenesis[26]. Annexin A4 forms complexes with protein kinase C, which has roles in cancer progression and was shown to be up-regulated in colorectal cancer[27]. Annexins have been reported to be involved in disease processes such as neoplasia. Furthermore, changes in the expression of annexins were linked with tumorigenesis[28]. Over expression of annexins in primary CRC increase significantly with advancing tumor stage, which suggests that annexins play a role in the progression and development of CRC[29]. Over expression of annexin A4 with advancing tumor stage was correlated with its role in promoting tumor cell migration. The distinct localization of annexin A4 in tumor cells was implicated to the loss of cell-to-cell adhesion and therefore increased tumor cell spread[30]. Our data showed that up-regulation of annexin A3 increased when the cancer stage advanced from Duke's B to Duke's C, while the opposite was observed for annexin A4. There have been no previous reports of annexin A3 participating in tumorigenesis or its association with different stages of CRC. Annexin A3 was reported to be up-regulated in colorectal tumor tissues and its cellular location was predominantly membrane-associated as revealed by immunohistochemistry assay[31]. Immunohistochemistry staining of annexin A3 in prostate cancer has shown its possible relationship with cancer grade[32]. In this study, we also observed that up-regulation of annexin A3 and annexin A4 in CRC increased when the cancer progressed from well-differentiated adenocarcinoma to moderately-differentiated adenocarcinoma.

The tubulin β-2 chain is one of the components of the cytoskeleton which plays a complex role in cells[33]. Significant differences in β-tubulin expression in polyps and invasive colon cancers indicates its possible roles in invasive cancer development[34]. A significant relationship between the expression of tubulins and stages of rectal cancer was suggested to be useful in identifying Dukes' B and Duke's C rectal cancer[34]. In this study, we found that the expression of tubulin β-2 chain increased significantly when the cancer advanced from Duke's B to Duke's C.

In conclusion, we have identified four hydrophobic proteins, namely SLP-2, tubulin β-2 chain, annexin A3

and annexin A4 which were abundantly expressed in cancerous tissues compared with normal tissues of the colon. Although a limited number of tissues were tested, the expression of these proteins in colorectal cancer was found to be significant suggesting that the possible use of these protein biomarkers in drug targeted therapy and in the diagnosis of colorectal cancer are worth further investigation.

ACKNOWLEDGMENTS

We would like to thank Universiti Sains Malaysia for providing RU grant to carry out this project. We also want to extent our gratitude to the National Institute of Nutraceutical and Pharmaceutical, Malaysia for their kindness in allowing us to use the LC/MS/MS.

COMMENTS

Background

Colorectal cancer (CRC) is the third most common cancer worldwide. In Malaysia, the incidence of CRC is increasing. An evaluation of the protein profile of CRC tissues may lead to an understanding of the changes in protein expression when cancer progresses. Proteomics is an emerging tool to study proteins and therefore can be used for the identification of potential biomarkers in the detection and treatment of CRC.

Research frontiers

Membrane proteins comprise approximately 30% of the total human proteome. They are important component of cells and perform vital cellular functions. Due to their hydrophobic nature, many membrane proteins are difficult to extract and remain under-represented in protein profiles.

Innovations and breakthroughs

The authors have successfully extracted hydrophobic proteins from CRC patients. This group of proteins are differentially expressed and significantly correlated with stage and grade of cancer and gender of the patients. In their study, stomatin-like protein 2 (SLP-2) was significantly up-regulated in cancerous tissues. SLP-2 has not been previously reported in CRC.

Applications

Hydrophobic proteins are mainly located on the cell membrane. Therefore, they have the potential to be cell surface markers that can be used in drug targeted therapies for CRC.

Terminology

A hydrophobic protein is a protein that contains a stretch of amino acids that have hydrophobic side chains. These amino acids are arranged so that the hydrophobic side chains are placed outside the protein in the three dimensional structure of the protein. This part of the protein will tend to embed itself in lipid structures such as cell membranes.

Peer review

This manuscript describes the identification of a number of protein biomarkers that are up regulated in colorectal cancer. Membrane proteins from both cancer and normal mucosa were isolated using 2-D gel electrophoresis and subjected to LC/MS/MS analysis.

Abstract

AIM: To investigate a relationship between the clinicopathological features and mucin phenotypes in advanced gastric adenocarcinoma (AGA).

METHODS: Immunohistochemical staining was performed to determine the mucin phenotypes in 38 patients with differentiated adenocarcinomas (DACs), 9 with signet-ring cell carcinomas (SIGs), and 48 with other diffuse-type adenocarcinomas (non-SIGs) of AGA. The mucin phenotypes were classified into 4 types: gastric (G), gastrointestinal (GI), intestinal, and unclassified.

RESULTS: The G-related mucin phenotypes were highly expressed in all the histological subtypes of AGA. The expression of the GI phenotype in SIG patients was lower than that in DAC patients (P = 0.02), and this phenotype was observed in 56% of the non-SIG patients in the intramucosal layer. Among non-SIG cases, the expression of the GI phenotype was significantly higher in patients with extended adenocarcinomas and those with positive rates of lymph node metastasis. There was no difference between the expressions of the G and other GI phenotypes factors. Among DAC and non-SIG patients, there were no differences between the survival rates of the corresponding patient groups.

CONCLUSION: The GI phenotype might possess more invasive characteristics than the G phenotype in non-SIG. Neither of the phenotypes indicated a poor prognosis of DAC and non-SIG.

INTRODUCTION

Recently, an immunohistochemical method for mucin staining has been developed, and the expression of the mucin phenotype in gastric adenocarcinoma has been reported[1-4]. Lauren[5] and Nakamura *et al*[6] histologically classified gastric adenocarcinomas into 2 main types: in-

testinal type of Lauren's histology or differentiated type, and diffuse type or poorly differentiated type. The diffuse type adenocarcinomas, as classified using Lauren's method[7] (non-solid type of poorly differentiated adenocarcinoma and the signet-ring cell carcinoma according to a Japanese classification[8]: PDC), which do not show clustering or glandular formation, can be further divided into 2 histological subtypes. In one of these subtypes, the adenocarcinomas are predominantly (> 50%) composed of isolated malignant cells containing intracellular mucin and the nucleus is located at the periphery of the cytoplasm (signet-ring cell carcinoma: SIG according to the Japanese classification). In the other subtype, the adenocarcinoma contains few (< 50%) signet-ring cancer cells (non-SIGs in PDC).

On the basis of the differences in immunohistochemical staining, the mucin phenotypes in gastric adenocarcinoma can generally be divided into 4 types: gastric (G), mixed or gastrointestinal (GI), intestinal (I), and unclassified (UC). Some studies on the intestinal or differentiated types of adenocarcinoma have described the relationship between the expression of mucin phenotypes and the occurrence, progression, and clinicopathological features of adenocarcinomas[9-14]. The expression of the mucin phenotype in diffuse or poorly differentiated adenocarcinomas has also been studied[15-22]. However, some of these studies have been restricted to SIG[15-22], and there have been few studies on advanced gastric adenocarcinoma (AGA)[23-27]. Therefore, there is little information on the effects of the mucin phenotypes on the clinicopathological and histological subtype-based features of AGA, particularly in the diffuse type as defined by Lauren's method[7]. To clarify the role of the mucin phenotype in the clinicopathological features and prognosis of AGA, further studies should take into account the histological subtypes of AGA.

To this end, we examined the expression of mucin phenotypes in the above-mentioned histological subtypes of AGA. The mucin phenotype-based analysis was performed according to the classification proposed by Watanabe *et al*[28,29]. We also determined the relationship between the expression of the mucin phenotypes and the clinicopathological features, including the prognosis of patients, who were grouped according to the different histological subtypes of gastric adenocarcinoma.

MATERIALS AND METHODS

We investigated 95 subjects with AGA who had undergone gastric resection at the Surgery I Department of Gunma University Hospital between 1994 and 2000. Among the 95 subjects, 38 had differentiated adenocarcinoma (DAC), 9 had SIG, and 48 had non-SIG of PDC. We defined AGA as an adenocarcinoma that invades deep into the muscularis propria. The definition of DAC includes papillary and tubular adenocarcinomas classified using the Japanese classification[8]. The definitions of SIG and PDC are described above. The definition of non-SIG is the adenocarcinoma of NSC excluding SIG.

We used a staining method which had been previously reported[25,26]. In brief, the samples obtained after gastric resection were fixed in 10% buffered neutral formalin, macroscopically examined, and photographed. Thereafter, the resected tumor, which included the tumor center, was cut into 3-4 mm wide slices. These slices were then embedded in paraffin and stained with hematoxylin-eosin (HE). The slices were then examined and color images were used for the histochemical mapping of the tissues and for measuring tumor size. For immunohistochemistry, we selected 1 or 2 HE-stained sections obtained from the tumor areas with the largest diameters and the deepest mucosal invasion. Paraffin blocks containing the selected HE-stained sections were cut into consecutive 3 μm sections for immunohistochemical staining.

The following protocol was employed for staining. Deparaffinized sections were treated with citrate buffer (pH 6.0), heated in a microwave oven for 20 min, and allowed to be cooled to room temperature. Endogenous peroxidase activity was blocked by incubating the sections for 20 min with 0.3% hydrogen peroxidase in absolute methanol, and the sections were then washed in tap water. Non-specific binding was blocked by using normal serum (Nichirei, Japan). The sections were incubated with a primary antibody overnight at 4℃ and then incubated with a biotinylated secondary antibody for 30 min at room temperature (Nichirei, Japan). Immunohistochemical staining was performed using a streptavidin-biotin-peroxidase kit (Nichirei, Japan) according to the manufacturer's instructions, with slight modifications. We used MUC5AC (diluted 1:100; antibody CLH2, Novocastra, UK) and human gastric mucin (HGM, diluted 1:50; antibody 45M1, Novocastra) antibodies as markers for the gastric foveolar phenotype; MUC6 (diluted 1:100; antibody CLH5, Novocastra) and M-GGMC-1 (diluted 1:50; antibody HIK1083, Kantou Chemicals, Japan) antibodies as markers for the pyloric gland phenotype; MUC2 (diluted 1:500; antibody Ccp58, Novocastra) as a marker for intestinal goblet cell mucin; and CD10 (diluted 1:200; antibody 56C6, Novocastra) as a marker for small intestinal enterocytes.

The markers HGM, M-GGMC-1, and CD10 exhibited both cytoplasmic and luminal membranous reactivity, whereas MUC5AC, MUC6, and MUC2 exhibited only cytoplasmic reactivity. The reactivity was estimated on the basis of the percentage of stained cells among the total number of tumor cells in each stained section. On the basis of the frequency of positive staining for the relevant marker, the adenocarcinoma phenotypes were classified into 4 groups: G, GI, I, and UC. The following criteria were used for the classification of the mucin phenotypes: (1) if more than 5% of the cells were positive for HGM, MUC5AC, MUC6, or M-GGMC-1, the phenotype was classified as G; (2) if more than 5% of the cells were positive for MUC2, the phenotype was classified as I; and (3) if even a single cell was positive for CD10, the phenotype was classified as I. If none of the above criteria were met, the phenotype was classified as UC. The mucin phenotype was determined by examining the intramucosal layer.

Table 1 Clinical profiles and tumor characteristics according to the histological subtypes

Histological subtype	Gender		Age at operation (yr)	Tumor site			Tumor size (cm)	
	Male	Female		U	M	L	< 5	> 5
DAC (n = 38)	28	10	58	9	12	17	17	21
SIG (n = 9)	3[a]	6[a]	62	2	1	6	3	6
Non-SIG (n = 48)	24	24	65	7	27	14	14	34

DAC: Differentiated-type adenocarcinoma; SIG: Signet-ring cell carcinoma; Non-SIG: Other diffuse-type adenocarcinomas; U: Upper segment of the stomach; M: Middle segment of the stomach; L: Lower segment of the stomach. [a]P = 0.05.

Table 2 Expression rates of the various mucin phenotypes at the intramucosal layer among patients classified according to the histological subtype

Antigen/histological subtype	HGM (%)	MUC5AC (%)	MUC6 (%)	M-GGMC-1 (%)	MUC2 (%)	CD10 (%)
DAC (n = 38)	97	95	84	90[a,b]	76[c]	0
SIG (n = 9)	100	100[d]	56	44[a,d]	33[c]	0
Non-SIG (n = 48)	96	98[e]	65	52[b,e]	56	0

HGM: Human gastric mucin. [a]P < 0.01, [b]P < 0.01, [c]P = 0.02, [d]P = 0.02, [e]P < 0.01.

In addition to determining the mucin phenotype, we reviewed the patients' profiles (age at operation and gender), the tumor site (upper segment of the stomach, U; middle segment of the stomach, M; and lower segment of the stomach, L), the tumor size, the histological findings (lymphatic and vessel invasion, metastasis to the lymph nodes and other sites), and patient survival. The relationships among these factors, particularly the comparison between the G and GI phenotypes, were determined.

The survival rates of the patients with G and GI phenotypes grouped according to the histological subtypes were examined by Kaplan-Meier analysis.

Statistical analysis was performed using the Pearson χ^2 test [Fisher's exact test (extended)] and the Student t-test. Two-tailed P-values < 0.05 were considered significant.

This work has been carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association and all the participants gave their written informed consent.

RESULTS

Clinical profiles and tumor characteristics of the patients with DAC, SIG, and non-SIG adenocarcinomas

The clinical profiles and tumor characteristics of the patients with DAC, SIG, and non-SIG are summarized in Table 1. Among women, the number with SIG was significantly higher than those with DAC (P = 0.05). There were no intergroup differences in the age at operation or size of tumor. For the site of tumor, the number in the lower segment in DAC was higher than that in SIG or DAC.

Typical photographs of a patient with SIG expressing the G phenotype and of a patient with non-SIG expressing the GI phenotype

Typical photographs of a patient with SIG expressing the G phenotype are shown in Figure 1. Immunohistochemical staining revealed a large number of HGM- or M-GGMC-1-positive cells in the mucosal portion of the tumor. No MUC2-positive cells were detected in the tumor area. The cancer cells, most of which were signet-ring cells, were scattered without clustering or glandular formation.

Figure 2 shows typical photographs of a patient with non-SIG expressing the GI phenotype. Immunohistochemical staining revealed a number of M-GGMC-1-positive cells in the mucosal portion of the tumor. We also observed sporadically distributed MUC2-positive cells. No HGM-positive cells were detected in the tumor area of the examined tissues. We observed scattered non-SIG cells similar to the SIG shown in Figure 1. No cluster and glandular formation of cancer cells was detected in any region of tumor.

Expression rates of the various mucin phenotypes at the mucosal layer among patients classified according to the histological subtypes

The expression rates of various mucin phenotypes at the mucosal layer among the patients classified according to the histological subtype are shown in Table 2. The expression rates of HGM and MUC5AC were higher than those of MUC6 and M-GGMC-1 in all the histological subtypes, particularly in the cases of SIG (P = 0.02) and non-SIG (P < 0.01). The expression rate of M-GGMC-1 in the cases of DAC was higher than that in the cases of SIG (P < 0.01) and non-SIG (P < 0.01).

The MUC2-expression rates in the cases of DAC, SIG, and non-SIG were 76%, 33%, and 56%, respectively. The MUC2-expression rate was lowest in the cases of SIG, and the expression rate in the cases of DAC was higher than that in the cases of SIG (P = 0.02) and non-SIG (P = 0.06). No CD10 expression was detected in any of the cases.

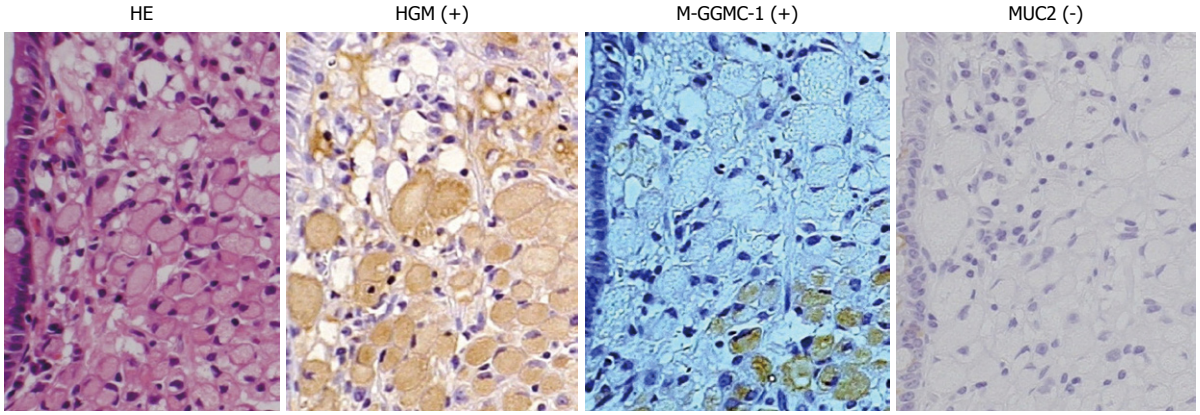

Figure 1 Typical photographs of a patient with signet-ring cell carcinoma (SIG) expressing the gastric (G) phenotype.

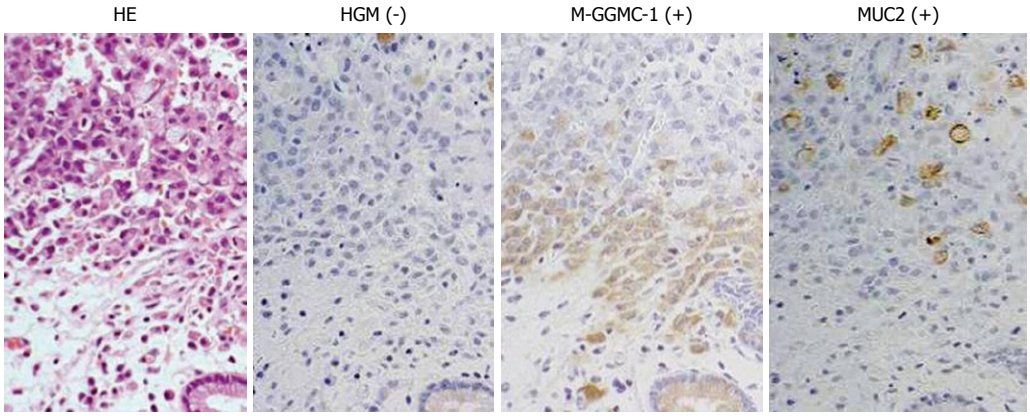

Figure 2 Typical photographs of a patient with non-SIG expressing the gastrointestinal (GI) phenotype.

Table 3 Expression rates of the various mucin phenotypes at the intramucosal layer of gastric adenocarcinomas according to the histological subtypes *n* (%)

Mucin phenotype/ histological subtype	G	GI	I	UC
DAC (n = 38)	9/38 (24)	29/38 (76)[a,b]	0/38 (0)	0/38 (0)
SIG (n = 9)	6/9 (67)	3/9 (33)[a]	0/9 (0)	0/9 (0)
Non-SIG (n = 48)	19/48 (40)	27/48 (56)[b]	0/48 (0)	2/48 (4)

G: Gastric phenotype; GI: Gastrointestinal phenotype; I: Intestinal phenotype; UC: Unclassified phenotype. [a]P = 0.02; [b]P = 0.06.

Expressions of G, GI, I, and UC phenotypes at the mucosal layer among patients classified according to the histological subtypes

The expressions of the G, GI, I, and UC phenotypes at the mucosal layer among the patients classified according to the different histological subtypes are shown in Table 3. The expressions of the G, GI, I, and UC phenotypes in patients with DAC were 24%, 76%, 0%, and 0%, respectively; the expressions in patients with SIG were 67%, 33%, 0%, and 0%, respectively; and the expressions in patients with non-SIG were 40%, 56%, 0%, and 4%, respectively. For all the histological subtypes, the expressions of the I and UC phenotypes were extremely low and those of the G and GI phenotypes were extremely high. The expression of the GI phenotype in the cases of DAC was higher than that in the cases of SIG (P = 0.02) and non-SIG (P = 0.06).

Comparison between the expressions of the G and GI phenotypes with respect to clinical and histological findings in patients classified according to the histological subtypes

Table 4 presents a comparison between the expressions of the G and GI phenotypes with respect to the clinical profiles, tumor site, tumor size, metastasis rate, and histological findings among the patients classified according to the histological subtypes. In SIG, all 6 female patients expressed the G phenotype and all 3 male patients expressed the GI phenotype (P = 0.01). Among the subjects with non-SIG, the number of GI phenotype cases with a tumor diameter greater than 5 cm was significantly higher than the corresponding number of G phenotype cases (P = 0.01). The positive rate of lymph node metastasis in the GI phenotype cases was also significantly higher than the corresponding value in the G phenotype cases (P = 0.01). There were no significant differences in other factors between the patients expressing the G and GI phenotype.

Table 4 Comparisons between the expression of G and GI phenotypes in clinical profiles, tumor site and tumor size, metastasis rate, and histological findings, according to the histological subtype

Histological subtype	DAC		SIG		Non-SIG	
Mucin phenotype	G (n = 9)	GI (n = 29)	G (n = 6)	GI (n = 3)	G (n = 19)	GI (n = 27)
Male:female	6:3	12:17	0:6[a]	3:0[a]	9:10	10:17
Mean age (yr)	57.2	60.3	63.2	55.3	68.2	60.9
Tumor site						
U	2	7	2	0	2	5

Lymph invasion	100	86	83	100	95	100

[a]P = 0.01, [b]P = 0.01, [c]P = 0.01.

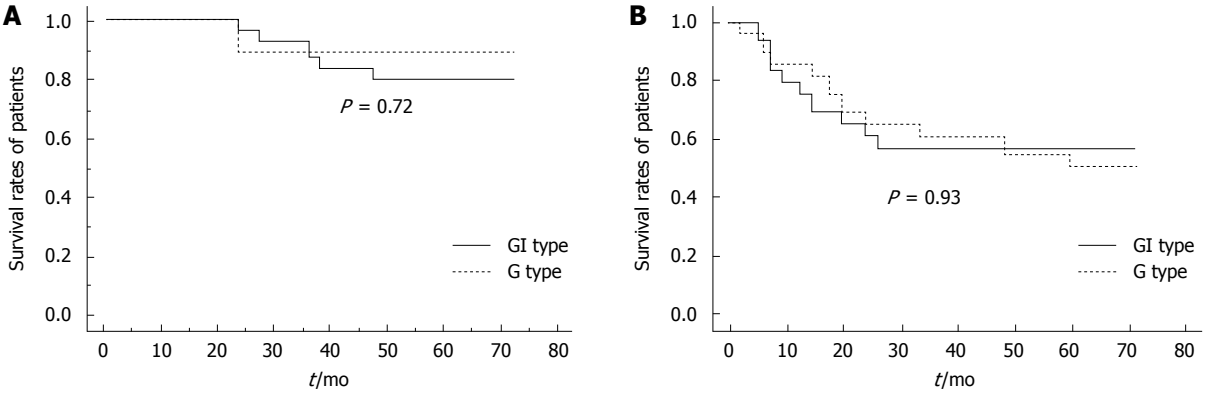

Figure 3 Survival rates of patients with the G and GI phenotypes in differentiated adenocarcinoma (DAC) (A) and non-SIG (B). The Kaplan-Meier method was used for the analysis.

Survival rates of the patients expressing the G and GI phenotype classified according to the histological subtypes

The survival rates of the G and GI phenotype cases classified according to the histological subtypes are shown in Figure 3. Among the patients with DAC, there was no significant difference between the survival rates of patients expressing the G phenotype and those expressing the GI phenotype (Figure 3A). The survival rates among the non-SIG patients expressing the G phenotype and those expressing the GI phenotype (Figure 3B) were also not significantly different (P = 0.93).

DISCUSSION

In the present study, HGM and MUC5AC were highly expressed in all histological subtypes. Among the SIG and non-SIG cases examined, the expression rates of MUC6 and M-GGMC-1 were lower than those of HGM and MUC5AC. The expression rates of MUC6 and M-GGMC-1 in the DAC were higher than those in the SIG and non-SIG cases. Pinto-de-Sousa *et al*[18] showed that the mucin phenotype is associated with the tumor site. In the SIG and non-SIG cases in the present study, the upper or middle segments of the stomach were the most common tumor sites. The differences between the rates of expression of the G-related phenotypes were believed to have been influenced by the tumor location. In addition, most cases of AGA showed the presence of gastric foveola phenotype. Further, we observed that the proportion of women in the SIG group was high and that none of the women with SIG expressed the GI phenotype. With regard to the clinical features of the mucin phenotype, the SIGs in women had specific clinical features.

On the basis of the examination of various mucin phenotype-expressing antigens, we classified almost all the AGAs (over 95%) as having either a G or GI phenotype. Furthermore, we failed to detect the expression of the pure I phenotype in any of the cases. The expression rate of the UC phenotype was also extremely low. Pinto-de-Sousa *et al* studied the mucin phenotypes of 23 diffuse-type adenocarcinomas classified according to Lauren's method[7] and showed that the MUC5AC-ex-

pression rate in these adenocarcinomas was significantly higher than that in the unclassified and expansive adenocarcinomas[18]. Further, Reis *et al*[4] studied the expression of MUC5AC in early gastric adenocarcinomas and suggested that all gastric adenocarcinomas retain at least some G phenotype cells in the initial stages of neoplasm development. Therefore, we postulate that almost all the cases of advanced DAC, SIG, and non-SIG exhibit or retain the features of G-related phenotypes in the intramucosal layer.

In the present study, the I phenotype (GI phenotype) was expressed in 56% of the non-SIG cases. Barresi *et al*[21] reported that 8 out of every 10 cases of diffuse-type adenocarcinomas were MUC2-positive. Tajima *et al*[23] studied the expression rates of the GI and I phenotypes in the cases of undifferentiated type AGA and reported that the I phenotype was expressed in half of the cases. Yamachika *et al*[15] and Bamba *et al*[16] reported that the progression of SIG was associated with a phenotypic shift from the G-type to the I-type expression. Other studies have described the invasive features of the I phenotype in gastric adenocarcinoma[19,22,26]. The results of our study and the abovementioned studies suggest that more than 50% of the cases with non-SIG AGA exhibit the features of the I phenotype and that this phenotypic feature is acquired or transformed during the initial progression stage of these adenocarcinomas. In addition, our results indicate that the GI phenotype is associated with invasive features.

The expression rate of the I phenotype (GI phenotype) among the SIG cases was 33% and the number of SIG cases was low (9 cases). We assume that SIG cells with the G phenotype cannot progress to the deep layer. It is also suggested that the morphological features of the SIG cells change and are subsequently classified as non-SIG during tumor progression.

In the present study, we also examined the relationships between the expression of mucin phenotypes and the clinicopathological features and prognosis of patients with DAC, SIG, and non-SIG. Among the non-SIG cases, the expression rate of the GI phenotype in both the patients with extended tumors and those with lymph node metastasis was significantly high. The survival rates of the DAC and non-SIG patients who expressed the G or GI phenotypes were not significantly different. These results indicate that the acquisition of the I phenotype in patients with non-SIG AGA is related to tumor extension and lymph node metastasis and that the existence or acquisition of this phenotype does not affect the survival rate of these patients. Our results indicate that the GI phenotype is associated with invasive features as described above. In SIG, the relationship between the survival rates of G and GI phenotype patients is unknown due to the small number of patients with these phenotypes.

The high rate of lymph node metastasis and the invasive tendency of the non-SIG cells with the GI phenotype may influence the 5-year survival rate, and the patients with the GI phenotype may thus show poor prognosis. However, in the present study, there was no difference between the survival rates of G and GI phenotype patients showing these features. With regard to the features of the mucin phenotype in differentiated-type gastric adenocarcinoma, the G phenotype has been reported to have malignant features[12,13]. In contrast to our study, Tajima *et al*[23] studied the expression of the mucin phenotype in patients with AGA and reported that patients with the G phenotype adenocarcinomas had a poorer outcome than those with the I phenotype adenocarcinomas. Mizoshita *et al*[24] reported that AGA patients expressing the GI phenotype had a relatively good prognosis. Although the reason for the difference is unclear, it could be attributed to the difference in the histological subtypes of the examined adenocarcinomas; this is because almost all the studies reporting the malignant potential of the G phenotype have considered differentiated adenocarcinomas[12,13]. Further, we mainly studied the diffuse type of AGA, which was classified into the SIG and non-SIG types, namely the restricted diffuse type of Lauren's classification. In addition, we assume that the prognosis of the patients with advanced non-SIG will also depend on postoperative treatments such as postoperative chemotherapy.

Therefore, we assume that the expression of the G or GI phenotypes in cases of the advanced non-SIG type of pure diffuse-type gastric adenocarcinoma does not indicate a poor prognosis during the 5-year postoperative period.

In conclusion, the GI phenotype showed a high expression rate (56%) in patients with advanced non-SIG, thereby indicating the acquisition of I phenotypic features during the progression of adenocarcinomas. In patients with advanced non-SIG, although the GI phenotype may be associated with greater invasiveness than the G phenotype, the survival rates of patients expressing either phenotype are similar, suggesting that neither the G nor the I phenotype indicates a poor prognosis in this type of adenocarcinoma. However, the presence of the I phenotype in patients with advanced SIG is unknown.

COMMENTS

Background

The relationship between the clinicopathological features and mucin phenotypes in advanced gastric adenocarcinoma (AGA) classified according to the histological subtype [differentiated adenocarcinoma (DAC), signet-ring cell carcinoma (SIG), and diffuse-type adenocarcinoma (non-SIG)] is unclear.

Research frontiers

Recently, the expression of the mucin phenotype in gastric adenocarcinoma was reported. Lauren and Nakamura histologically classified gastric adenocarcinomas into 2 main types: intestinal type of Lauren's histology or differentiated type, and diffuse type or poorly differentiated type. There is little information on the effects of the mucin phenotypes on the clinicopathological and histological subtype-based features of AGA, particularly in the diffuse type as defined by Lauren's method.

Innovations and breakthroughs

This study is the first report that investigated the mucin phenotype in advanced differentiated, SIG and non-SIG gastric adenocarcinomas. The GI phenotype might possess more invasive characteristics than the G phenotype in non-SIG patients. However, neither of the phenotypes indicates a poor prognosis of DAC and non-SIG.

Applications

Mucin phenotypes of gastric adenocarcinoma are related to the biological features in these cancers. The study of mucin phenotype is useful to clarify the biological features in gastric adenocarcinoma.

Terminology

Mucins of stomach are heavily glycosylated glycoproteins that are the major components of the mucous viscous gel covering gastric surface mucous cells, pyloric gland cells, intestinal goblet cells of the mature gastrointestinal tract, and the brush border of intestinal epithelial cells, *etc*.

Peer review

The data presented are interesting and helpful for further understanding the possible clinical value of mucin phenotypes of gastric carcinomas. The conclusions extracted are reasonable, although most of them are disproving.

Abstract

AIM: To evaluate the effects of positive regulation of recombinant human interleukin 1 receptor antagonist (rhIL-1Ra) on hepatic tissue recovery in acute liver injury in mice induced by carbon tetrachloride (CCl_4).

METHODS: Acute liver damage was induced by injecting 8-wk-old mice with CCl_4 1 mL/kg (1:3 dilution in corn oil) intraperitoneally (ip). Survival after liver failure was assessed by injecting 8-wk-old mice with a lethal dose of CCl_4 2.6 mL/kg (1:1 dilution in corn oil) ip. Mice were subcutaneously injected with 1 mg/kg recombinant human IL-1Ra twice a day after CCl_4 treatment for 5 d. Serum alanine amino transferase (ALT) and aspartate aminotransferase (AST) levels were determined with a commercial assay kit. Serum IL-1β, IL-1Ra levels were measured by enzyme-linked immunosorbent assay kit. Quantitative real-time polymerase chain reaction was used to determine liver IL-1β, IL-1Ra and IL-6 expression during CCl_4-induced acute liver injury. Liver sections were stained with hematoxylin-eosin. A histology-injury grading system was used to evaluate the degree of necrosis after acute liver injury. Proliferating cell nuclear antigen (PCNA) staining was used to evaluate the role of rhIL-1Ra in promoting hepatocyte proliferation.

RESULTS: Quantitative analysis showed a higher level of IL-6 mRNA expression and reduced serum AST and ALT levels in the livers of the rhIL-1Ra-treated group at the early phase of CCl_4-induced acute liver injury. Histological examination indicated a decrease in centrilobular necrotic areas in mice treated with rhIL-1Ra, and a novel role of rhIL-1Ra in promoting hepatocyte proliferation was also supported by an increase of PCNA staining. All these results, accompanied by a strong survival benefit in rhIL-1Ra-treated *vs* PBS-treated groups, demonstrated that rhIL-1Ra administration ameliorated the histological damage and accelerated the regeneration and recovery process of the liver.

CONCLUSION: rhIL-1Ra could be further developed as a novel therapeutic agent for the treatment of acute liver injury because of its ability to reduce hepatocellular damage and facilitate liver regeneration.

INTRODUCTION

The interleukin (IL)-1 family includes the structurally related proteins IL-1α, IL-1β, and interleukin 1 receptor antagonist (IL-1Ra) that bind to the same cell surface receptor. However, IL-1Ra functions as a competitive inhibitor of IL-1α and IL-1β[1]. IL-1α and IL-1β play a key role in inflammation[2]; in response to stimuli such as inflammatory agents, infections, or microbial endotoxins, a dramatic increase of IL-1 mediated by macrophages and various other cell types is seen[3,4]. IL-1Ra is a naturally occurring anti-inflammatory protein; it competitively blocks the binding of IL-1α and IL-1β to type I IL-1 receptor, but exerts no agonist activity[5,6]. IL-1Ra has been shown to inhibit the effects of IL-1 both *in vitro* and *in vivo*, and as an acute-phase protein, it can reduce the severity of several animal models of inflammatory disease[7]. Serum levels of IL-1Ra can rise dramatically during different inflammatory and noninflammatory conditions[8]. Human IL-1Ra is synthesized as a 177 amino acid precursor that contains a 25 amino acid signal sequence plus a 152 amino acid mature region[9,10].

Acute administration of carbon tetrachloride (CCl_4) is used to establish an experimental model of severe hepatocellular damage involving generation of oxidative stress and recruitment of inflammatory cells[11-13], which is reported to induce liver architectural and functional damage[14-16]. Liver regeneration involves a complex regulated response to CCl_4-induced acute liver injury[17,18].

In this study, we aimed to examine the effects of IL-1Ra as an acute phase protein in reducing hepatic injury and accelerating hepatocyte proliferation following CCl_4 administration. Although the anti-inflammatory effect of IL-1Ra has been described, the contribution of this cytokine to protect from the liver injury remains unclear. The present findings indicate that IL-1Ra is a critical factor that shows a potent antihepatotoxic activity in recovery of hepatocellular necrosis and in acceleration of liver regeneration during injury. IL-1Ra could provide a novel therapeutic approach by stimulating liver regeneration.

MATERIALS AND METHODS

Animals

Procedures were performed in male C57BL/6 mice (purchased from SLC Shanghai, China) 8 wk after birth, maintained in a conventional clean facility and in accordance with the National Animal Care and Use Committee.

Cytokine and reagents

Recombinant human IL-1Ra (rhIL-1Ra) was obtained from Dr Wei Han's Laboratory at the School of Pharmacy, Shanghai Jiao Tong University. Endotoxin level of the rhIL-1Ra was under 0.1 EU/μg. CCl_4 was purchased from Sigma, USA.

Acute liver injury and lethal dose performance

Acute liver injury was induced by injecting 8-wk-old mice with CCl_4 1 mL/kg (1:3 dilution in corn oil) intraperitoneally (ip). A lethal dose was administered by injecting 8-wk-old mice with CCl_4 2.6 mL/kg (1:1 dilution in corn oil) ip.

rhIL-1Ra and PBS injection

Mice were subcutaneously injected with 1 mg/kg rhIL-1Ra (diluted to 0.5 mg/mL with PBS) twice a day after CCl_4 administration for 5 d because human and murine IL-1Ra show an overall homology of 77% with no apparent species specificity[19]. The first rhIL-1Ra injection was performed at 1 h after CCl_4 treatment. The control group of mice was subcutaneously injected with the same volume of PBS.

Serum aspartate aminotransferase and alanine amino transferase

Serum aspartate aminotransferase (AST) and alanine amino transferase (ALT) levels were determined with a commercial assay kit (Nanjing Jiancheng Biological Technology, Inc., China). Enzyme activities were expressed as an international unit per liter (IU/L).

Enzyme-linked immunosorbent assay

Serum IL-1β and IL-1Ra level were measured by enzyme-linked immunosorbent assay (ELISA) kit (R&D system, Minneapolis, MN, USA) according to the manufacturer's instructions.

Histology-injury grading

Formalin-fixed, paraffin-embedded liver sections were stained with hematoxylin-eosin for the histological investigations. To evaluate the degree of necrosis after acute liver injury we created an injury grading score (Grade I - IV) based on severity of necrotic lesions in the liver parenchyma (Table 1).

Proliferating cell nuclear antigen staining

For proliferating cell nuclear antigen (PCNA) immunohistochemical staining, de-paraffinized sections of liver blocks were used. Liver tissues were fixed for 24 h in neutral buffered formalin, processed routinely and embedded in wax. Immunohistochemical staining was performed as previously described[16]. The sectioned liver tissues were stained using a mouse monoclonal antibody against PCNA and the SABC Staining Kit (Wuhan Boster Biological Technology, Wuhan, China) according to manufac-

Injury grading with respect to severity of necrosis in liver parenchyma: Grade 0: Normal histology; Grade Ⅰ: Presence of degenerated hepatocytes with only rare foci of necrosis; Grade Ⅱ: Mild centrilobular necrosis around the central vein, occupying only a part of Rappaport's zone Ⅲ; Grade Ⅲ: Established necrosis limited to zone Ⅲ; Grade Ⅳ: Extensive, confluent centrilobular necrosis involving Rappaport's zone Ⅲ and Ⅱ. rhIL-1Ra: Recombinant human interleukin 1 receptor antagonist.

turer's protocol, then subjected to photomicroscopic observation (NIS-Elements Basic Research, Nikon Eclipse 50i, Kanagawa, Japan).

Quantitative real-time polymerase chain reaction

Total RNA was obtained from the liver of mice and was prepared using TRIZOL reagent (Invitrogen, Carlsbad, CA, USA). The quantification and qualification of RNA were determined by UV absorbance and electrophoresis in 1.2% agarose. RNA quality was satisfied when the 28s rRNA banding was twice the intensity of the 18s rRNA without significant smearing of the rRNA bands. Quantitative real-time polymerase chain reaction (RT-PCR) reactions were performed with the MJ chromo 4 RT-PCR detection system (Bio-Rad Laboratories, Hercules, CA, USA). Specific primers were designed using Primer Premier 5.0 software (Premier Biosoft International, Palo Alto, CA, USA) and their sequences are listed as follows: IL-1β (sense) 5'TGAGCACCTTCTTTTCCTTC3', IL-1β (anti-sense) 5'GTTCATCTCGGAGCCTGTAG3'; IL-1Ra (sense) 5'AGACCTTGTGTCCTGTTTAGC3', IL-1Ra (anti-sense) 5'GGTCAATAGGCACCATGTCT3'; IL-6 (sense) 5'CCACTCCCAACAGACCTGTCTATAC3', IL-6 (anti-sense) 5'CACAACTCTTTTCTCATTTCCACGA3'; β-actin (sense) 5'AGCCTTCCTTCTTGGGTATG3', β-actin (anti-sense) 5'GTGTTGGCATAGAGGTCTTTAC3'. For the RT-PCR reaction, the following procedure was followed. Total RNA (5 μg) was used as a template for synthesizing the first-strand of cDNA with M-MuLV reverse transcriptase (MBI Fermentas, Vilnius, Lithuania) in a 20 mL reaction volume. PCR reactions were carried out by adding 100 × diluted cDNAs, 100 nmol/L of each primer, and SYB Premix Ex *Taq* (TaKaRa, Dalian, China) in 20 μL reactions. PCR conditions were optimized using Opticon monitor 3 software (Bio-Rad Laboratories) and involved the following steps: 95℃ for 5 min, 1 cycle; 95℃ for 5 s and 60℃ for 30 s, 40 cycles. Final data were analyzed with Opticon monitor 3 software (Bio-Rad Laboratories), presented as ratios to β-actin for each time point.

Statistical analysis

Results are expressed as mean ± SD. Statistically significant differences over time in the same treatment group, or among different treatment groups at a single time point, were determined by Student's *t* test. $P < 0.05$ was considered to be statistically significant. Results from survival experiments were analyzed using the log-rank test and expressed as Kaplan-Meier survival curves.

RESULTS

IL-1β, IL-1Ra and IL-6 expression during CCl_4-induced acute liver injury

Expression of IL-1β mRNA decreased in the first 12 h, and reached its lowest point at day 1.5 (Figure 1A). In contrast, expression of IL-1Ra mRNA was rapidly induced and reached a peak within 12 h following 1 mL/kg CCl_4 administration (Figure 1B). Serum level of IL-1β did not increase so rapidly (Figure 1C). We found that serum IL-1Ra enhanced markedly after CCl_4 administration (Figure 1D), induced by generation of oxidative stress and recruitment of inflammatory cells. We confirmed that an adequate ratio of serum IL-1Ra to IL-1 was crucial to the recovery of liver injury (Figure 1E), and we found that the ratio reached a peak at day 1.5 after CCl_4 administration. Furthermore, the expression of IL-6 mRNA was also stimulated by excessive treatment with rhIL-1Ra (Figure 1F).

rhIL-1Ra protects mice from acute hepatocellular damage

CCl_4-induced acute liver injury that results in a quantifiable liver damage recovers naturally within 7 d, as mice sacrificed 7 d after CCl_4 injection appear with normal liver histology. To confirm the role of rhIL-1Ra in protecting from hepatic damage, we investigated the effect of rhIL-1Ra on CCl_4-induced acute liver injury. Mice were subcutaneous injected with rhIL-1Ra and PBS after CCl_4 administration. Animals were sacrificed 1, 3, 5 and 7 d after CCl_4 administration for AST and ALT determination. The serum level of ALT or AST rapidly elevated to reach a peak at day 1 then decreased thereafter in PBS-treated control mice, while rhIL-1Ra treatment significantly inhibited the elevation of ALT and AST from day 1 to day 5 (Figure 2A and B). The reduction of serum AST and ALT indicated that rhIL-1Ra has a direct protective effect on hepatocytes. To evaluate the effect of rhIL-1Ra on hepatocellular necrosis and inflammation, histological changes in the liver after CCl_4 administration with or without rhIL-1Ra treatment were examined by histology-injury grading (Table 1). Liver sections from PBS-treated animals showed hepatocellular necrosis and inflammation at day 3 after CCl_4 administration; in contrast, liver sections from the rhIL-1Ra-treated group demonstrated only mild hepatocellular necrosis and in-

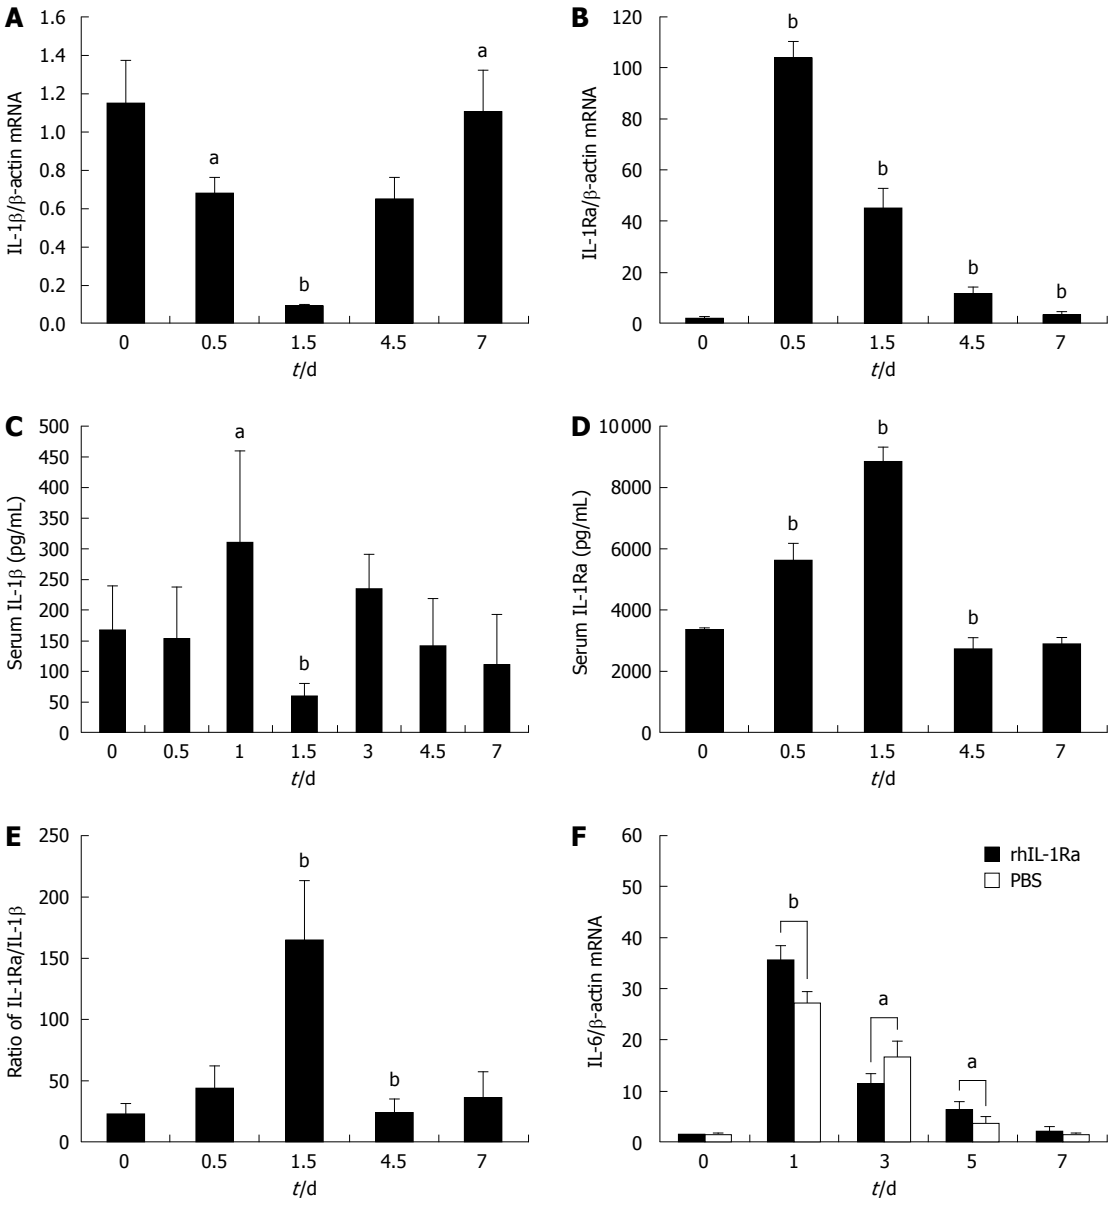

Figure 1 Interleukin (IL)-1β, interleukin 1 receptor antagonist (IL-1Ra) and IL-6 expression after carbon tetrachloride (CCl_4) (1 mL/kg) administration. A: Quantification of IL-1β mRNA levels; B: IL-1Ra mRNA levels; C: Serum IL-1β; D: Serum IL-1Ra; E: Ratio of serum level of IL-1Ra to IL-1β; F: Quantification of IL-6 mRNA levels of the livers treated with recombinant human IL-1Ra (rhIL-1Ra) or PBS. $^aP < 0.05$, $^bP < 0.01$.

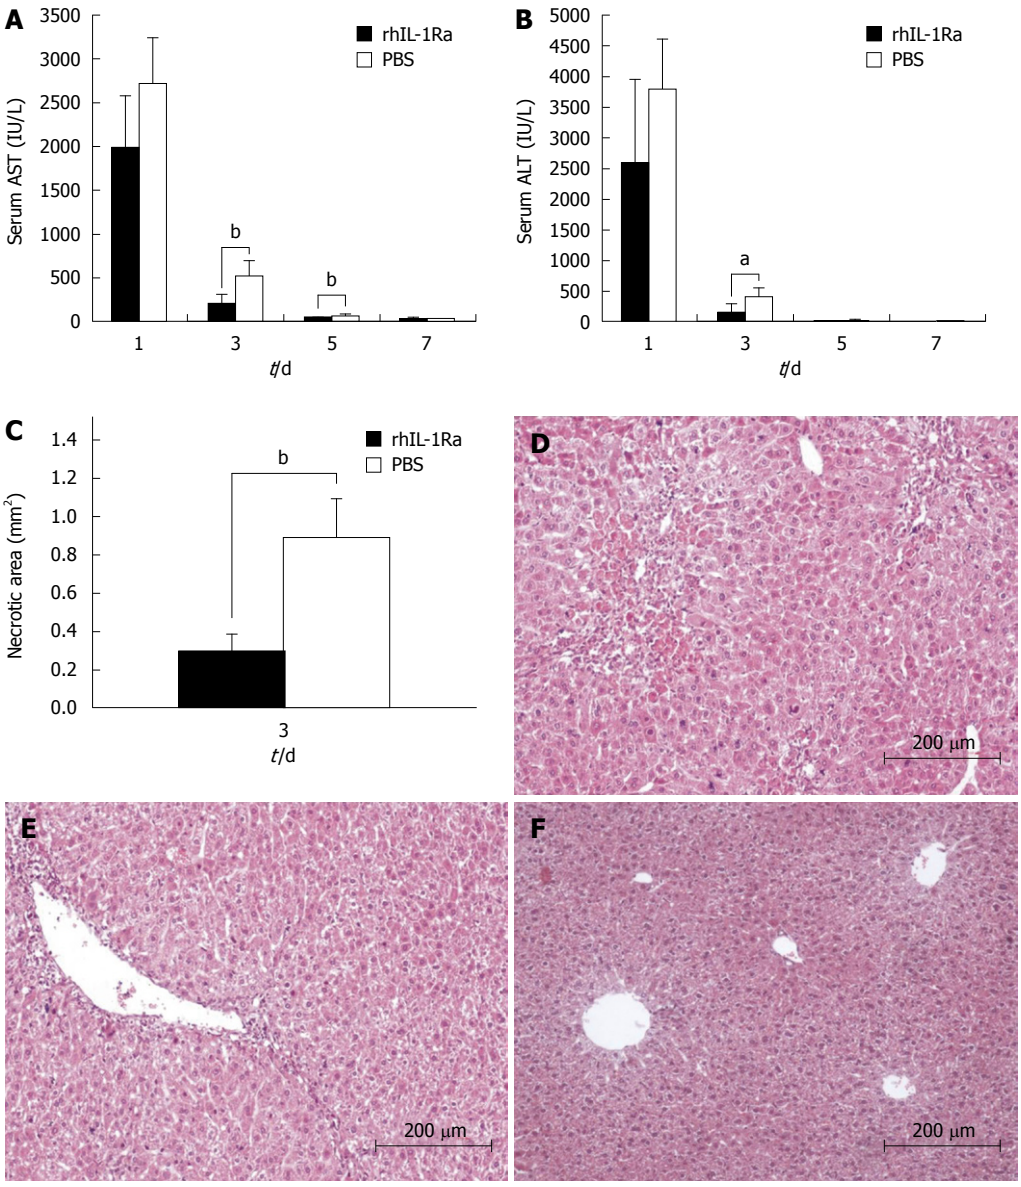
flammation was dramatically decreased. We found the necrotic areas were significantly diminished around the central vein (Figure 2D and E) and centrilobular regions (Figure 2C) in rhIL-1Ra-treated mice at day 3. However, rhIL-1Ra did not cause any liver injury to healthy mice (Figure 2F). These findings indicate that rhIL-1Ra has a potent anti-hepatotoxic activity in reducing hepatocellular necrosis around the central vein.

rhIL-1Ra promotes hepatocyte proliferation from an early phase

We also investigated the proliferation of hepatocytes by immunostaining of PCNA in sections of liver tissue at days 2 and 3. Our PCNA staining confirmed that the number of positive cells increased sharply at day 2 (Figure 3C). Great numbers of hepatocytes (Figure 3E) could be detected in the liver sections of rhIL-1Ra-treated mice at day 3, which demonstrated that rhIL-1Ra significantly increased the number of $PCNA^+$ cells. In contrast, PBS-treated mice showed a much fewer number of $PCNA^+$ cells (Figure 3D and F). In our study, we also confirmed rhIL-1Ra was unable to induce hepatocyte proliferation (Figure 3A and B) in normal mice. Numbers of $PCNA^+$ cells (Figure 3G) in at least 12 mm^2 tissue sections were counted for each mouse, which showed that mice receiving rhIL-1Ra after CCl_4 injection gained the potent advantage of accelerating hepatocyte proliferation from an early phase.

rhIL-1Ra increases probability of survival after a lethal dose performance

In dose-response experiments, we found that 2.6 mL/kg



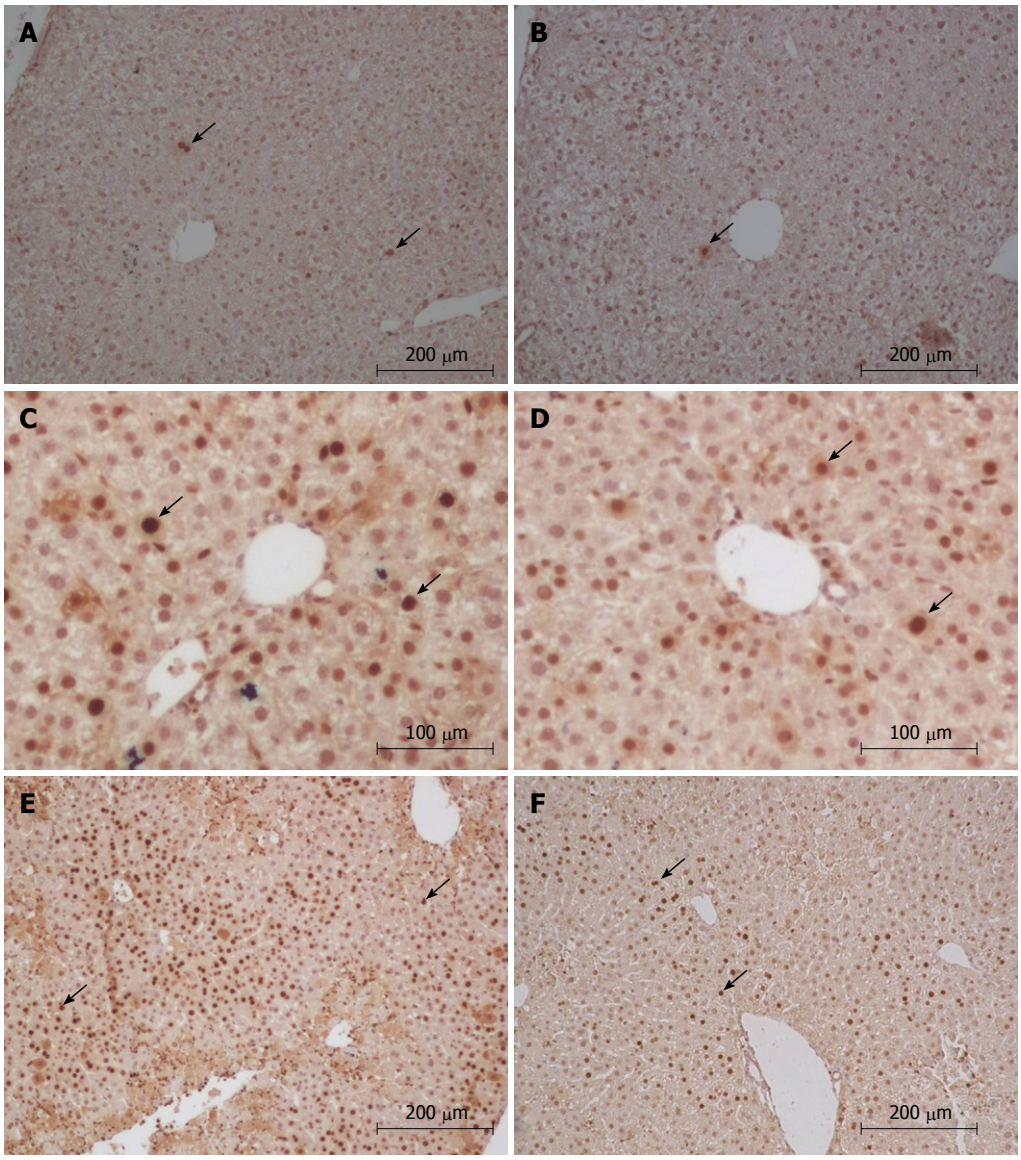


Figure 2 Acute liver injury (1 mL/kg CCl_4 administration) ± rhIL-1Ra. A: Serum aspartate aminotransferase (AST); B: Serum alanine amino transferase (ALT), with rhIL-1Ra or PBS; C: Necrotic areas. Representative findings from at least 12 mm^2 tissue sections were counted for each mouse; D-F: Hematoxylin and eosin (HE) stained liver sections; D: Group received PBS at day 3 after CCl_4 administration, shows necrosis with clusters of inflammatory cells around central vein (original magnification, × 100); E: Group received rhIL-1Ra at day 3 after CCl_4 administration, demonstrates mostly histological recovery with only inconspicuous necrosis still remaining around central vein and very few inflammatory cells are present (original magnification, × 100); F: Normal liver histology with rhIL-1Ra treatment, which shows no difference from normal liver tissue histology. $^aP < 0.05$, $^bP < 0.01$.

CCl_4 is a median lethal dose (mortality 50%, data not shown) within 24 h. rhIL-1Ra treatment in the CCl_4-induced acute liver failure model offers a survival benefit in treated mice, increasing the probability of survival significantly from 10.0% to 55.0% at day 3 after CCl_4 injection ($P = 0.006$, Figure 4).

DISCUSSION

The model of acute intoxication with CCl_4 has been used for decades to investigate the response of acute and chronic liver injury, because the elementary lesions caused by this hepatotoxin replicate those seen in most cases of human liver diseases. Pro-inflammatory cytokines such as IL-6 and IL-1β are believed to play a key role in the pathogenesis of CCl_4-induced liver injury[8,18,20,21], which make it a good model for us to study signal transduction and cell cycle events in a synchronized manner *in vivo*. The CCl_4-induced acute liver injury model is generated with 1 mL/kg dose for a typical hepatic injury, which would function as a strong regenerative stimulus. Regarding liver damage, IL-1Ra plays a critical role in the prevention of fatty liver and hypercholesterolemia under inflammatory conditions[22-24]. In this study, we investigated the severity of CCl_4-induced acute liver injury in mice after rhIL-1Ra treatment; the results demonstrate that rhIL-1Ra hypodermal injection affords protection from liver injury.

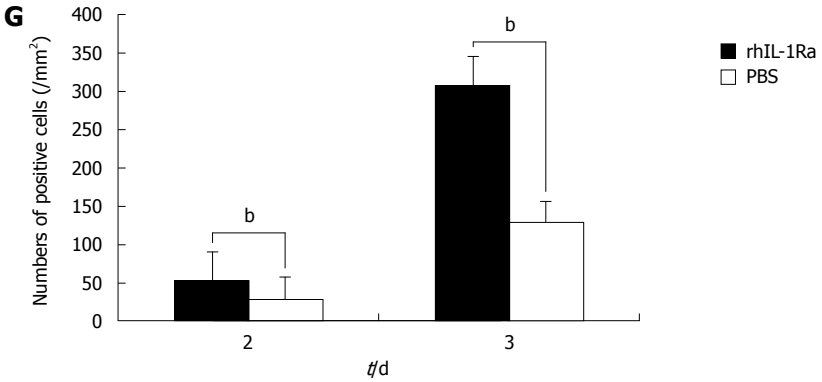

Figure 3 Immunostaining of proliferating cell nuclear antigen (PCNA) shows rhIL-1Ra promotes hepatocyte proliferation. A: Normal liver (original magnification, × 100); B: Normal liver in rhIL-1Ra treated mice (original magnification, × 100); C: Group received rhIL-1Ra at day 2 after CCl_4 administration, numerous $PCNA^+$ hepatocytes in centrilobular areas and scattered $PCNA^+$ hepatocytes at the edge of hepatocellular necrosis (original magnification, × 200); D: Group received PBS at day 2 after CCl_4 administration, few $PCNA^+$ hepatocytes in centrilobular areas at day 2 (original magnification, × 200); E: Group received rhIL-1Ra at day 3 after CCl_4 administration, numerous positive cells in centrilobular areas around central vein (original magnification, × 100); F: Group received PBS at day 3 after CCl_4 administration shows fewer numbers of positive cells (original magnification, × 100); G: Numbers of $PCNA^+$ cells after CCl_4 administration with rhIL-1Ra or PBS, at least 12 mm^2 tissue sections were counted for each mouse. Arrows point to PCNA+ hepatocytes. $^bP < 0.01$.

The balance between IL-1β and IL-1Ra has been extensively studied in a variety of experimental animal models of disease; either local overproduction of IL-1β or underproduction of IL-1Ra predisposes to the devel-

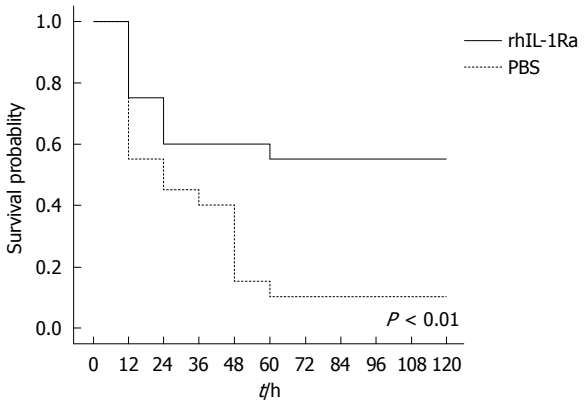

Figure 4 rhIL-IRa treatment increased probability of survival after a lethal dose administration of CCl_4 (2.6 mL/kg). Mice were administered with either PBS as a control (n = 20) or rhIL-1Ra (n = 20) twice a day for 5 d. Survivals were scored twice a day for 5 d, and the results were analyzed using the log-rank test and expressed as the Kaplan-Meier survival curves. P = 0.006.

opment of disease and the therapeutic administration of IL-1Ra is efficacious in preventing tissue damage[25]. Serum IL-1β and IL-1Ra are mediators of inflammation. Down-regulation in the release of the pro-inflammatory cytokine IL-1β and the up-regulation of its antagonist (IL-1Ra) may be a part of the inflammatory response to infection[8]. It is necessary to functionally inhibit the biologic effects of IL-1β on hepatocytes. We confirmed that liver IL-1β mRNA originally decreased in the first 12 h after CCl_4 treatment, and reached its lowest level at day 1.5. On the other hand, liver IL-1Ra mRNA increased to its highest level at day 1.5. These results show that the liver has a strong power to trigger compensatory growth mechanisms, which suppress the liver IL-1β expression. Several observations have emphasized that an adequate ratio of IL-1Ra to IL-1β is protective in inflammatory or immune liver disease[26-28]. Both serum IL-β and serum IL-1Ra were elevated after CCl_4 treatment, but serum IL-1Ra increased 100-fold greater than IL-1β at day 1.5. Serum IL-1Ra to IL-1β ratio was much higher in contrast to normal mice, which suggests a beneficial effect of IL-1Ra on CCl_4-induced acute liver injury. By analyzing the ELISA data of IL-1Ra and IL-1β, we found that serum IL-1β increased after CCl_4 treatment, which simultaneously stimulated the production of IL-1Ra as a compensatory reflection. The effects of IL-1Ra on blocking receptor binding of IL-1β during the acute-phase response may serve to suppress the inflammatory consequences of early IL-1β release after CCl_4-induced acute liver injury; with subsequent recovery, serum IL-1Ra decreased.

The level of serum aminotransferases is a very important marker to judge the severity of acute hepatic injury. After CCl_4 treatment the level of serum AST and ALT was significantly elevated, and attenuated by rhIL-1Ra in our experiment. The histological studies also showed that rhIL-1Ra inhibited inflammation and necrosis, which are the most common characteristics of CCl_4-induced liver damage. These findings suggest that rhIL-1Ra protects hepatocytes from the oxidative damage caused by CCl_4, which is likely due to inhibition of the pro-inflammatory mediators.

Serum IL-1Ra can rise dramatically during different inflammatory and non-inflammatory conditions such as sepsis[29] and chronic rheumatic diseases[30-32]. In addition, it plays a crucial role in regulating IL-1 signaling in various inflammatory states. IL-1Ra deficiency has been associated with major metabolic dysfunctions[33,34]. Serum levels of IL-1Ra were found to correlate with serum IL-6 concentrations[35], and administration of either IL-1 or IL-6 to patients increased the circulating levels of IL-1Ra[36,37]. Liver is a recognized target organ for pro-inflammatory cytokines such as TNFα, IL-1 and IL-6[38,39]. Regarding liver regeneration, IL-6 is thought to result in enhanced transcription, triggering hepatocytes to leave their quiescent state (G0) and enter a prereplicative phase (G1). Expression of IL-6 appears to be essential for the priming of hepatocytes[40,41]. Previous studies showed that IL-1Ra production was enhanced by IL-1β, and increasing IL-1β and IL-6 exhibits a strong stimulatory effect on the acceleration of IL-1Ra expression[8]. IL-6 is a marked signal to trigger liver regeneration, as demonstrated in a previous study[42], and in this current study, we found that the production of IL-6 could also be enhanced by excessive rhIL-1Ra treatment. *In vitro,* IL-1β inhibits hepatocyte proliferation[43]. Isoda *et al*[33] found that mRNA levels of IL-1β were significantly elevated in livers of IL-1Ra-/- mice, and liver growth is also inhibited by hepatocyte proliferation inhibitor and IL-1β[44,45]. It is of particular interest that excessive rhIL-1Ra inhibits the activity of IL-1β, which rapidly and significantly increased the number of $PCNA^+$ hepatocytes.

IL-1Ra is well tolerated clinically and has a short half-life, making it an ideal protective agent for acute hepatocellular damage and for accelerating liver regeneration. Healthy humans are the most sensitive indicators of IL-1 agonist activity: 1 ng/kg of intravenous IL-1β produces symptoms[46]. In contrast, the intravenous infusion of 10 mg/kg of IL-IRa in healthy humans, a 10 million-fold molar excess, gives no effect[47]. Histopathological studies showed that rhIL-1Ra-treated healthy mice show no changes in contrast with normal liver, and excessive rhIL-1Ra treatment could not induce hepatocellular proliferation in healthy mice. We used very classical methods to judge whether rhIL-1Ra has an effect on repairing the damage of mice CCl_4-induced acute liver injury and accelerating liver regeneration. The work indicates that rhIL-1Ra administration accelerates recovery from acute CCl_4-induced liver injury. To confirm that rhIL-1Ra dramatically prevented CCl_4-induced liver injury, a lethal dose of CCl_4 was used, and rhIL-1Ra treatment resulted in survival benefits in mice with acute hepatic failure. This work indicates that rhIL-1Ra accelerates recovery from acute CCl_4-induced liver injury and offers a strong survival advantage in injured mice.

Although additional studies are necessary to confirm this effect in humans, our findings provide a rationale

to develop new pharmacological strategies in the clinical management of patients with acute liver injury. This approach might also provide a novel therapeutic tool for regenerative liver cell therapy.

COMMENTS

Background

Interleukin 1 receptor antagonist (IL-1Ra) is a member of the interleukin 1 cytokine family and is a major anti-inflammatory cytokine. It acts as a natural inhibitor of the pro-inflammatory cytokines IL-1α and IL-1β through its action of blocking the binding of interleukin-1 to cell-surface receptors, and modulates a variety of IL-1-related immune and inflammatory responses. Although the anti-inflammatory effect of IL-1Ra has been described, the contribution of this cytokine in protecting from liver injury remains unclear.

Research frontiers

IL-1Ra is well tolerated clinically and has a short half-life, making it an ideal protective agent for acute hepatocellular damage and for accelerating liver regeneration. The authors used very classical methods to judge whether recombinant human IL-1Ra has effects on repairing the damage of carbon tetrachloride (CCl_4)-induced acute liver injury in mice and on accelerating liver regeneration.

Innovations and breakthroughs

The authors aimed to examine the effects of IL-1Ra as an acute phase protein in accelerating hepatocyte proliferation following CCl_4-induced liver injury. The results indicate that IL-1Ra is a critical factor that shows a potent antihepatotoxic activity in recovery of hepatocellular necrosis and accelerates liver regeneration during injury. IL-1Ra could provide a novel therapeutic approach by stimulating liver regeneration.

Applications

Although additional studies are necessary to confirm this effect in humans, the authors' findings provide a rationale to develop new pharmacological strategies in the clinical management of patients with acute liver injury. This approach might also provide a novel therapeutic tool for regenerative liver cell therapy.

Peer review

It is interesting and well-written. I suggest the authors perform electron microscopic examination in order to investigate the ultrastructural features of the hepatocytes of normal compared to recombinant human IL-1Ra-treated mice, and CCL_4-compared to recombinant human interleukin 1 receptor antagonist-treated mice.

Abstract

AIM: To compare anxiety and depression levels in adult patients with celiac disease (CD) on a gluten-free diet (GFD) with controls.

METHODS: The levels of anxiety, depression and of a probable anxiety or depressive disorder were assessed by the Hospital Anxiety and Depression Scale in 441 adult patients with CD recruited by the German Celiac Society, in 235 age- and sex-matched patients with inflammatory bowel disease (IBD) in remission or with slight disease activity, and in 441 adult persons of a representative German general population sample (GP). Potential demographic (age, sex, social class, family status) and disease-related (latency to diagnosis, duration of GFD, compliance with GFD, thyroid disease) predictors of anxiety and depression in CD were tested for by regression analyses.

RESULTS: The level of anxiety in CD patients was predicted (R^2 = 0.07) by female gender (P = 0.01). Female sex (OR = 3.6, 95% CI: 1.3-9.4, P = 0.01) was associated with a probable anxiety disorder. Living alone (OR = 0.5, 95% CI: 0.2-0.9, P = 0.05) was associated with a reduced risk of an anxiety disorder. The level of depression and a probable depressive disorder were not predicted by any of the demographic and medical variables tested for. The levels of anxiety in patients with CD (6.6 ± 3.4) and with IBD (6.9 ± 3.7) were higher than those of persons in the GP (4.6 ± 3.3) (both P < 0.001). The levels of depression in persons with CD (4.2 ± 3.4), IBD (4.6 ± 3.4) and of the GP (4.2 ± 3.8) did not differ (P = 0.3). The prevalence of a probable anxiety disorder in persons with CD (16.8%) and IBD (14.0%) was higher than that of the GP (5.7%) (P < 0.001). The prevalence of a probable depressive disorder did not differ significantly between the three groups (P = 0.1).

CONCLUSION: Anxiety in adult German female celiacs on a GFD is higher than in persons of the GP. Female celiacs on a GFD should be screened for anxiety.

INTRODUCTION

Celiac disease (CD) is an autoimmune disorder which is precipitated, in genetically predisposed persons, by the ingestion of gluten, the major storage protein of wheat and similar grains. Originally considered a rare malabsorption syndrome of childhood, CD is now recognized as a common condition that may be diagnosed at any age and that affects many organ systems. In most affected people, CD remains undiagnosed, although the rate of diagnosis is increasing. CD occurs in adults and children at rates approaching 1% of the population. The disease is recognized not only throughout Europe and in countries populated by persons of European ancestry but also in the Middle East, Asia, South America and North Africa[1]. The highest CD prevalence in the world is found in a North African population originally living in the Western Sahara with a figure of 5.6%[2]. Among adults, two to three times as many women have the disease as men, for unknown reasons. The therapy for the disease is a gluten-free diet (GFD); however, the response to therapy is poor in up to 30% of patients mainly because of non-adherence to the GFD[1].

Along with the many gastrointestinal, nutritional and metabolic consequences of CD, there have been significant concerns about increased rates of psychological symptoms and mental disorders in celiacs (CDs)[3]. Most studies have been on depression[4-17]. Case series in Gastroenterological departments[4] and case control studies in primary care demonstrated that depression can be a symptom of undiagnosed CD[5]. Whether the levels of depression in CDs under a GFD are comparable to those of controls [general population (GP), other chronic somatic diseases] is under debate. Some studies found more depression in CDs compared to controls of the GP[6-11,13,15,17], others did not[12,14,16]. A few studies also explored anxiety. Some studies reported more anxiety in CDs compared to controls[8,13], some did not[7,16]. The majority of studies were performed in Italy[6-11,13,17] and Scandinavia[12,15,16]. No study has been performed in Germany until now. Only two studies included more than 200 CDs[14,15].

The data regarding potential disease-related determinants of anxiety and depression in CDs on a GFD are also contradictory: one Italian study found no correlation between duration of, and compliance with, GFD and depressed mood[10], whereas another reported increasingly depressed mood with the duration of GFD[13]. An elevated risk of depression in CD patients with type 1 diabetes mellitus and autoimmune thyroiditis has been reported by one study for each of these diseases[14,9]. The influence of demographic factors which are associated with depression in the GP, such as marital status or social class index[18], were only controlled for in a minority of studies[7,8,13]. Moreover, gender aspects in anxiety/depression in CD have been considered only by a few studies, although Scandinavian studies found that female CDs reported more anxiety and depression than male patients[16]. These open questions on anxiety and depression in CDs on a GFD provided us with the aims of our study which were: (1) to explore the potential impact of disease-related, demographic and gender variables on anxiety/depression in CDs; and (2) to compare the levels of anxiety/depression and the frequency of anxiety and depressive disorder in CDs with a sample of the GP and with patients having another chronic somatic disease, with adequate large sample sizes, in a central European country (Germany).

MATERIALS AND METHODS

Ethics

The surveys were approved by the ethics committees of the University of Tübingen and Leipzig and of the board of physicians of the Saarland.

Patients

CD: Within the German Celiac Health Survey of the German Celiac Society DZG, a set of questionnaires was sent out in May 2005 by the DZG to 1000/18 355 of their members ≥ 18 years old, self-reporting a diagnosis of CD according to the membership directory of the DZG, following consecutive postal codes 0-9. To ensure a geographically representative sample every 18th member of the list was contacted by a letter signed by the board of directors of the DZG in which the aims of the study were explained. The letter included a set of questionnaires with a stamped self-addressed envelope enclosed. The patients were asked to give their written informed consent and to fill out and send back the questionnaires within four weeks. Patients < 18 years were not included in the study. There were no other primary exclusion criteria. All patients gave their voluntary informed consent after full written explanation of the aims of the study, including considerations regarding ethics and data protection and the anonymous deposition of the questionnaires[19].

Inflammatory bowel diseases: We selected inflammatory bowel diseases (IBDs) (patients with IBD) for comparison because both diseases have similar gastrointestinal (abdominal pain, diarrhea) and general (fatigue) symptoms and disease-associated disorders (e.g. bone, skin, liver).

Consecutive adult patients (≥ 18 years) with diagnosis of Crohn's disease or ulcerative colitis confirmed

by endoscopy and histology, attending three tertiary care centers for evaluation and/or therapy and members of the German's Crohn's Disease/Ulcerative Colitis Foundation (DCCV), were invited to participate in a study on health-related quality of life (HRQOL)[20]. Patients unable to speak German or with suspicious diagnosis and indeterminate colitis were excluded. Based on the hospital registry and medical documentation, a total of 730 adults were identified who had been attending the specialized outpatient clinic of the Tübingen University Hospital at least once in the last three years with confirmed diagnosis of either Crohn's disease or ulcerative colitis. Every one of these patients received a set of questionnaires by mail and was asked to return it once completed. One reminder was sent out three weeks after initial postal contact. Forty-five consecutive IBD patients of the coloproctological outpatient department of the Department of General and Abdominal Surgery of the University of the Saarland and 23 consecutive IBD inpatients of the Department of Internal Medicine I of the Klinikum Saarbrücken were asked to participate in the study during regular outpatient visits or during a hospital stay after admission for any acute complications of their disease. Physicians were trained to offer instruction and help if persons did not understand the meaning of questions when needed, to collect the questionnaires and to record clinical data using standardized forms. The study took place between January and June, 2000. In edition 4 (2000) of the journal of the German Crohn's disease/Ulcerative Colitis Foundation (DCCV) "Bauchredner", the main topic was "Health-related quality of life and life satisfaction in IBD" and all readers suffering from IBD were invited to participate in our study. The DCCV is the largest patient association for IBD in Germany with around 15 000 members (patients, relatives, physicians). Seventy-six patients indicated their interest to the DCCV and received the set of questionnaires by mail and were asked to return the completed set to the study center in Saarbrücken.

Disease activity was measured by the German Inflammatory Bowel Disease activity Index (GIBDI$_{\text{Crohn's disease}}$ resp. GIBDI$_{\text{Ulcerative colitis}}$). The GIBDI had been validated for the assessment of disease activity in surveys within the German Competence Network Inflammatory Bowel Diseases[21].

General German population: A representative sample of the German GP was selected with the assistance of a demographic consulting company (USUMA, Berlin, Germany). The random selection was based on multistage sampling with three stages (according to the typical random selection procedure in national surveys in Germany). First, 258 sample point regions were randomly drawn from the last political election register, covering rural and urban areas from all regions in Germany. The second stage was a random selection of households using the random route procedure (based on a starting address). The third stage was a random selection of household respondents with the Kish selection grid. The sample aimed to be representative in terms of age, gender, and education for the general German population. The inclusion criteria for the study were age at or above 14 and the ability to read and understand the German language. All subjects were visited by a study assistant informed about the investigation. Self-rating questionnaires were presented. The assistant waited until participants answered all questionnaires, and offered help if persons did not understand the meaning of questions. Data collection took place in 1998[22].

Questionnaires

Medical questionnaires: In both patient surveys a self-developed medical questionnaire assessing the history of the disease and therapy, current symptoms necessary to calculate activity scores, disease-related comorbidities and current medication was included. CDs were asked about comorbid dermatitis herpetiformis, diabetes mellitus type 1, autoimmune thyroiditis, autoimmune liver-biliary tract disease, recurrent aphtae, anemia, Addison's disease, osteoporosis and duodenal carcinoma or lymphoma. Latency of diagnosis was calculated by the reported difference of the time between first medical assessment because of CD-associated symptoms and final diagnosis.

The demographic questionnaire of the German Competence Network "Inflammatory Bowel Diseases"[21] was included in both patient surveys. By questions on education, the occupational status and the available income were used to calculate a social index. Data of this social index can be compared to a representative sample of the general German population[23].

The Hospital Anxiety and Depression Scale (HADS) was specifically designed for the assessment of anxiety and depression in patients with physical illness. With 7 items each on a 4-point Likert scale ranging from 0 to 3, subscale scores for anxiety and depression can be calculated. Scores $\geqslant$ 11 on the anxiety scale are indicative of a probable anxiety disorder (mainly general anxiety disorder). Scores $\geqslant$ 11 on the depression scale are indicative for a probable depressive disorder[24,25]. The HADS is a reliable and valid psychological screening tool for anxiety and depressive disorder in physically ill persons[25] with a validated German version available[26].

Statistical analysis

All statistical analyses were performed with the Statistical Package for the Social Sciences (SPSS, Release 17.0, Chicago 2008). One missing item of each subscale of the HADS was substituted by the individual median. If more items were missing the patient was excluded from analysis.

Data derived from descriptive statistical analysis are presented in the form of percentages for categorical variables and of the mean and the standard deviation (SD) for continuous data. Categorical data were compared using the χ^2-test and continuous data by *t*-tests or analysis of variance with post-hoc Bonferroni adjusted pairwise comparisons. In addition, anxiety and depres-

sion scores were compared between CDs and IBDs using analysis of covariance adjusting social class index.

Because we were interested in assessing the possible impact of demographic and medical factors on anxiety and depression, the anxiety and depression scores of the HADS served as dependent variables for a multiple regression analysis. Present age, family status, gender, social class index, latency of diagnosis, duration of and compliance with GFD and CD-associated thyroid disease were included as independent variables in a direct multiple regression analysis.

In order to estimate the risk for a possible anxiety and depressive disorder (coded 1 = no, 2 = yes), a logistic regression (all independent variables were included within a single step; no automated stepwise selection procedures were used) was performed with the same variables. The variables were coded as follows for the regression analyses: (1) Demographic variables: sex (1 = male, 2 = female), present age (continuous), living in a family or partnership (1 = yes; 2 = no) and social class index (1 = low, 2 = middle, 3 = high); and (2) CD-associated variables: reported latency between first medical assessments because of CD-associated symptoms and final CD diagnosis (continuous), reported duration of GFD (continuous), reported adherence to GFD (1 = rarely; 2 = sometimes; 3 = most of the time; 4 = all of the time), thyroid disease (1 = no, 2 = yes), DM type 1 (1 = no, 2 = yes).

The internal validity of the model of the logistic regression analysis was tested by the omnibus test of the model coefficient and the Hosmer-Lemeshow-test.

A prevalence of mental disorders of 10% estimated by the HADS in the general German population[23] given a sample size of 219 for each group was calculated to provide 80% power to assess a 10% difference between CD and controls.

Due to multiple comparisons the level of significance was set to $P = 0.01$ for group comparisons.

RESULTS

Return rates

CD: Almost half of the total questionnaires (52.2%, 522 of 1000) were returned. Since six questionnaires were excluded due to missing data, a total of 516 questionnaires were usable for further analyses. Of these, 213 (41.3%) of the respondents indicated that the CD diagnosis was made by duodenal biopsy, 37 (7.2%) by serological tests (CD-specific antibodies), 34 (6.6%) by stool tests (transglutaminase antibodies), and 232 (45.0%) by duodenal biopsy plus serological tests. The 445 patients reporting a biopsy-proven CD were included for further analysis. HADS data were available from 441 patients. Patients who took part in the survey did not differ from those who did not send back the questionnaires in terms of age, sex and geographical region of Germany.

IBD: The total response rate was 63.4% (550/868). Of the 550 returned questionnaires, 128 were excluded from analysis due to colo- or ileostoma ($n = 59$), uncertain diagnosis ($n = 16$), impossibility of calculation of GIBDI because of missing data ($n = 51$), missing HADS data ($n = 6$) or missing declaration of consent ($n = 2$). Patients with moderate ($n = 40$) and severe ($n = 10$) disease activity were excluded from comparison. The IBD group thus consisted of 366 patients; 50% were females. To ensure a sex-matched comparison with CDs, 131 randomly selected male patients were excluded from analysis. Of the 235 included for comparison, 138 (56.3%) patients were in remission, 107 (43.7%) patients had a slight disease activity.

To check for a possible selection bias, the data of responders were compared to the known structural data on all outpatients of the Tübingen outpatient clinic (place of residence, diagnosis, gender, age, duration of disease, age at disease onset, number of consultations in 2000). No indication of systematic selection effect was found in respondents *vs* non-respondents. Likewise, there was no difference in terms of gender and age in patients from the departments of the Saarland University Clinics who did and did not participate. There were no significant differences in the demographic variables and HADS scores of the patients included in and excluded from comparison.

GP: The initial sample consisted of 2952 subjects of whom 2037 (69.0%, $n = 1142$ women) fully participated. Forty-five subjects < 18 years were excluded. Thus the GP sample consisted of 1992 adult persons. Of these, 441 GPs (persons of GP) (346 women, 95 men) were randomly selected for comparison. There were no significant differences in the demographic variables and HADS scores of the persons included in and excluded from comparison.

Medical and demographic data of the celiac sample

The sample consisted of 78.5% women. The most frequently self-reported CD-associated diseases were dermatitis herpetiformis Duhring ($n = 45$, 9.3%) and autoimmune thyroiditis ($n = 25$, 5.6%). Type 1 diabetes mellitus was reported by 2 patients (0.5%). There were no gender differences in the demographic and medical variables assessed. The level of anxiety ($P = 0.0002$) and the frequency of a probable anxiety disorder ($P = 0.01$) were higher in female than in male CDs (Table 1).

Predictors of anxiety and depression in CD

Anxiety was significantly predicted only by female gender ($R^2 = 0.07$, $P = 0.01$). Depression was not significantly predicted by any of the medical and sociodemographic variables tested.

Predictors of a probable anxiety and depressive disorder

Because only in 2/8 patients with CD and diabetes mellitus type 1 an anxiety or depressive disorder was diagnosed, this variable was not entered into the regression analysis.

Anxiety disorder: The model correctly classified 84.8%

Table 1 Demographic data of the celiac disease sample with gender comparison

Variable	Total sample	Females	Males	Test-value *P*-value
Sex (*n*, %)	441 (100)	346 (78.5)	95 (21.5)	
Age, mean (SD)	46.3 (15.1)	45.7 (15.0)	48.5 (15.0)	Not significant
Living in partnership (*n*, %)	334 (76.1)	253 (73.8)	80 (84.2)	Not significant
Social class index (*n*, %)				Not significant
Lower class	26 (6.3)	18 (5.6)	7 (7.5)	
Middle class	271 (65.3)	220 (68.8)	50 (53.8)	
Upper class	118 (28.4)	82 (25.6)	36 (38.7)	
Number of CD-associated diseases (*n*, %)				Not significant
None	240 (55.2)	175 (51.3)	65 (69.9)	
One	118 (27.1)	100 (29.3)	17 (18.3)	
Two	48 (11.0)	40 (11.7)	8 (8.6)	
> Two	29 (6.7)	26 (7.7)	3 (3.2)	
Latency to diagnosis, yr, mean (SD)	5.6 (10.0)	5.9 (9.8)	4.9 (10.7)	Not significant
Years since start of GFD, mean (SD)	8.5 (7.7)	8.5 (7.7)	8.7 (7.7)	Not significant
Compliance with GFD				Not significant
Rarely		20 (5.8)	2 (2.1)	
Sometimes		9 (2.9)	0	
Most of the time		86 (25.0)	30 (32.3)	
All of the time		229 (66.6)	61 (65.6)	
Anxiety, mean (SD)	6.7 (4.09)	7.1 (4.1)	5.3 (3.5)	t = -3.7, P < 0.001
Depression, mean (SD)	4.1 (3.6)	4.3 (3.8)	3.2 (3.9)	t = -2.5, P = 0.01
Probable anxiety disorder (*n*, %)	68 (15.4)	63 (18.2)	5 (5.2)	χ^2 = 9.6, P = 0.001
Probable depressive disorder (*n*, %)	25 (5.7)	24 (6.9)	1 (1.0)	Not significant

Some discrepancies between total number of patients and absolute numbers of some variables are due to missing data. CD: Celiac disease; GFD: Gluten-free diet.

of the patients. Only female sex (OR = 3.6, 95% CI: 1.3-9.4, P = 0.001) was associated with a probable anxiety disorder. Living alone (OR = 0.45, 95% CI: 0.20-0.99, P = 0.05) was associated with a reduced risk of a probable anxiety disorder. The omnibus test of the model coefficient was significant (χ^2 = 20.2, P = 0.009). The level of significance in the Hosmer Lemeshow test was P = 0.5 (χ^2 = 6.9) above the predefined P-value of 0.05, thus confirming the adequacy of the model.

Depressive disorder: None of the variables tested was significantly associated with a probable depressive disorder. The omnibus test of the model coefficient was not significant (χ^2 = 13.5, P = 0.10).

Comparison with GP and patients with chronic IBD

In the CD sample, there were more patients of a higher social class than in the IBD sample (χ^2 = 14.0, P = 0.006). There were no differences between the samples in the other variables tested (Table 2).

The level of anxiety in CDs (6.7 ± 4.0) and IBDs (6.9 ± 3.7) was higher than that seen in GPs (4.6 ± 3.6) (all P < 0.001). After adjusting for social class there was no significant difference in the anxiety level between CDs and IBDs (F = 1.3, P = 0.3).

The level of depression in CDs (4.1 ± 3.6), IBDs (4.6 ± 3.4) and GPs (4.2 ± 3.8) did not differ (P = 0.3). After adjusting social class index, IBDs reported higher depression than CDs (F = 3.9, P = 0.02).

The frequency of a probable anxiety disorder was higher in CDs (15.4%) and IBDs (14.0%) than in GPs (5.7%) (all P < 0.001). There was no difference in the frequency of a probable depressive disorder between the three groups (P = 0.1).

DISCUSSION

We assessed medical and demographic predictors of anxiety and depression in adult patients with CD and compared their levels of anxiety and depression and the frequency of an anxiety or depressive disorder with age- and sex-matched patients with IBD in remission or slight disease activity, and with a representative German population sample. Only female sex, but not medical variables such as duration of and compliance with GFD, predicted anxiety. Depression was not predicted by any of the medical and demographic variables. Anxiety, but not depression, was higher in CDs and IBDs than in GPs.

Comparisons of the results with other studies

Factors associated with anxiety and depression in CD: Two Italian studies found no gender differences in anxiety and depression[10,27] whereas two Scandinavian studies reported lower levels of psychological well-being in female CD patients[16,28]. The higher levels of anxiety in German and Scandinavian women might be explained by general gender differences and/or CD-specific factors. Higher levels of anxiety and frequency of anxiety disorder in women have also been found in the general German population[22]. A higher psychosocial burden on female CDs because of buying and preparing food for the family can be presumed[28,29].

Table 2 Comparisons of patients with celiac disease with patients with inflammatory bowel disease in remission or having slight disease activity and with subjects of the general population

Variable	Celiac disease *n* = 441 (1)	Inflammatory bowel disease *n* = 235 (2)	General population *n* = 441 (3)	Overall comparison	Comparison subgroups
Sex (female) (*n*, %)	346 (78.5)	183 (77.9)	346 (78.5)	Not significant	
Age (mean, SD)	46.3 (15.1)	44.9 (12.4)	49.9 (16.8)	Not significant	
Social class index (*n*, %)			No comparable data available	Not possible	$\chi^2 = 14.5$
Lower	26 (6.3)	28 (11.9)			$P < 0.01$
Middle	271 (65.3)	167 (71.1)			
Upper	118 (28.4)	40 (17.0)			
Living in partnership or with family (*n*, %)	334 (76.1)	187 (80.3)	No comparable data available	Not significant	
Anxiety				$F = 45.9$	1, 2 > 3
Total, mean (SD)	6.7 (4.0)	6.9 (3.7)	4.6 (3.3)	$P < 0.001$	
Depression				Not significant	
Total, mean (SD)	4.1 (3.6)	4.6 (3.4)	4.2 (3.8)		
Probable anxiety disorder				$\chi^2 = 23.2$	1, 2 > 3
Total (*n*, %)	68 (15.4)	33 (14.0)	25 (5.7)	$P < 0.001$	
Probable depressive disorder				Not significant	
Total (*n*, %)	25 (5.7)	12 (5.1)	38 (8.6)		

In contrast to findings in the GP[18,30], low social class index was not associated with anxiety and depression in CDs. In contrast to the GP[18,30], living in a family was associated in CDs with the risk of an anxiety disorder. We speculate that the problems of buying and preparing food in a family with CDs and non-CDs might lead to financial and interpersonal problems which can contribute to an anxiety disorder.

In line with one Italian longitudinal study[7] and one Italian cross-sectional study[10], we found no association between depressed mood and the duration of GFD. We also found no association between anxiety and the duration of GFD. This finding is not contradictory to the results of longitudinal studies which reported a decrease of anxiety (state) after starting a GFD[7,12]: a GFD may reduce psychological symptoms due to malabsorption of tryptophan, but may also increase psychological distress associated with the financial and social restrictions of GFD and disease-related worries[6,31].

We confirm the results of two Italian studies which found no association between non-compliance with GFD and anxiety/depression[10,13].

The limited number of CDs with diabetes mellitus type 1 prohibited a comparison with an American study which reported a higher prevalence of depression in CD patients with type 1 diabetes mellitus (5.8% of the sample) compared to celiacs without type 1 diabetes mellitus[14]. We could not confirm a higher prevalence of depressive disorders in CDs with autoimmune thyroiditis[9].

Anxiety/depression in CDs compared to controls: The different instruments used to assess anxiety and depression do not allow a comparison of prevalence rates in studies on anxiety/depression in CD. Moreover, the studies differed in the ways of recruiting patients and in the type of controls used. Some studies used healthy subjects[6-10,13,14,17], GP[15,16] or patients with diabetes[13], IBD[6], irritable bowel syndrome[14] and chronic hepatitis[10] for controls. Despite these limitations, we can state that our finding that CDs are not more depressed than controls is in line with the results of one American[14] and two Scandinavian[11,16] studies and in contrast to the findings of the Italian studies[6-11,13,17]. Our finding of more anxiety in CDs compared to GP controls is in line with that of Italian studies[7-9] and in contrast to Scandinavian studies[11,16].

Limitations of the study

Some limitations of the study have to be considered. First, the study population consisted of adult CDs recruited among members of the German Celiac Society which may have induced a selection bias. A large hospital-based register of CD patients is not available in Germany. Furthermore, to our knowledge, most CDs attending tertiary care outpatient departments in Germany are associated with the German Celiac Society. Additionally, we cannot exclude a response bias of CDs sending back the questionnaires. Nevertheless, the CD sample of our study is the best available one in Germany. Second, we cannot exclude a response bias of CD and IBD patients sending back the questionnaires. Third, another potential bias of the study is the different approach to completing and returning the questionnaires. In the subsamples of the GP and the IBD patients of the departments of Homburg/Saar and Saarbrücken, help was offered if persons did not understand the meaning of questions and the questionnaires were recollected by research assistants or physicians. The questionnaires of the celiac and IBD sample of the department of Tübingen were completed without potential external support and returned by mail. Fourth, all data on the history and type of diagnosis, CD-associated diseases and on adherence to regimen relied solely on the participants' self report. Due to data protection in this type of survey, information from clinical records, interviews or serological/radiological tests was not available. Fifth, due to the type of study (postal survey) we were unable to use standardized psychiatric interviews for the confirmation of a probable

mental disorder when the critical cut-off scores of the HADS were surpassed. Furthermore, the items on anxiety of the HADS cover general anxiety but not phobic symptoms. Therefore, our data cannot comment on the high frequency of social phobia seen in Italian patients[8]. However, the HADS is one of the best screening tools available for anxiety and depressive disorders in patients with somatic diseases[25]. Finally, because of the cross-sectional nature of the study the results show only associations between factors and do not allow for conclusions for causality.

In conclusion, German patients with CD on a GFD do not differ from the GP in levels of depression, but there is a subgroup of mainly female CDs with a probable anxiety disorder. Mental disorders increase the risk of a reduced health-related quality of life[31] and of irritable bowel-like symptoms in CDs[32]. A screening for comorbid anxiety disorders in female patients with CD on a GFD by general practitioners and gastroenterologists is therefore recommended, and screening is possible by using the ultra-brief screening scale for anxiety and depression, PHQ-4[33]. The two questions on anxiety in the PHQ-4 can be directly asked: "Over the last two weeks, have you often been bothered by feeling nervous, anxious, or on edge? Over the last two weeks, have you often not been able to stop or control worrying?"

COMMENTS

Background

Previous studies have yielded conflicting results regarding the presence of an association of celiac disease (CD) in patients on a gluten-free diet (GFD) and anxiety/depression.

Research frontiers

Anxiety and depression are common symptoms in the general population (GP) as well as in other chronic somatic diseases and are associated with demographic factors such as age, gender and social class. Most studies on anxiety/depression in CD were not adequately powered to detect differences in anxiety and depression between CD and controls. In this study with adequately powered sample sizes, the authors demonstrate that anxiety in CD patients on a GFD is higher than in the GP and comparable to that of patients with inflammatory bowel disease who are in remission and have slight disease activity.

Innovation and breakthroughs

Recent reports have highlighted the importance of female gender and other autoimmune disorders associated with CD as predictors of depression in CD. This is the first study to report an association between anxiety disorder and female gender in CD. The study did not confirm findings that autoimmune thyroid disorder is a risk factor for depressive disorder in CD.

Applications

The study substantiated the necessity of exploring not only somatic but also anxiety symptoms in female CD patients on a GFD.

Peer review

This paper is worthy of publication as the first comprehensive study of anxiety and depression in German adult CD. It needs to be substantially revised, reduced in size, particularly in the Discussion and number of tables, and be less speculative.

Abstract

AIM: To evaluate the results of segmental duodenectomy (SD) and pancreaticoduodenectomy (PD) for duodenal gastrointestinal stromal tumor (GIST) and help clinicians with surgical management.

METHODS: All patients who underwent surgery for non-metastatic GIST of the duodenum in a single institution since 2000 were prospectively followed up. Seven patients (median age 51 years, range: 41-73 years) were enrolled: five underwent SD and two underwent PD.

RESULTS: All the patients had a complete resection (R0), with no postoperative morbidity and mortality. Among the SD group, GIST was classified as low risk in two patients, intermediate risk in two, and high risk in one, according to the Fletcher scale, (*vs* two high risk patients in the PD group). With a median follow-up of 41 (18-85) mo, disease-free survival (DFS) rates were 100% after SD and 0% after PD ($P < 0.05$). The median DFS was 13 mo in the PD group.

CONCLUSION: Whenever associated with clear surgical margins, SD is a reliable and curative option for most duodenal GISTs, and is compatible with long-term DFS.

Segmental duodenectomy for gastrointestinal stromal tumor of the duodenum. *World J Gastroenterol* 2010; 16(22): 2788-2792 Available from: URL: http://www.wjgnet.com/1007-9327/full/v16/i22/2788.htm DOI: http://dx.doi.org/10.3748/wjg.v16.i22.2788

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors of the digestive tract, with an estimated annual incidence between 10 and 20/10^6 people[1,2]. Although GISTs are encountered all along the digestive tract, the most frequent sites of occurrence are the stomach (50%) and small bowel (30%). Duodenal GISTs are less frequent and account for < 5% of cases, but still represent approximately 30% of primary duodenal tumors[3].

Surgery is still the only curative approach for GIST[4-6], but the optimal surgical procedure for duodenal GIST remains to be established. A number of authors have reported various procedures including pancreaticoduo-

denectomy (PD), pancreas-sparing duodenectomy, segmental duodenectomy (SD), or wedge local resection, but few have correlated the different options with oncological results[7-16].

Two major tumor characteristics have to be considered for surgical resection of duodenal GIST, which differs from duodenal adenocarcinoma[17]. First, GIST spreads specifically hematogenously and is rarely, if ever, associated with lymphatic invasion, as in other sarcomas[18]. Secondly, GISTs are well encapsulated tumors that rarely have a tendency to local invasion[4]. For these reasons, radical lymphadenectomy or extended resection of adjacent organs should not confer a survival advantage in non-metastatic duodenal GIST[6,19,20].

Therefore, this study was undertaken to audit the oncological results of segmental duodenal resection in comparison with more extensive procedure such as PD for primary non-metastatic duodenal GIST.

MATERIALS AND METHODS

This was a prospective cohort study of all surgical patients treated in our department for primary non-metastatic duodenal GIST from 2000 to 2008. Inclusion criteria were patients presenting with suspicion of non-metastatic duodenal GIST in a single hospital (Figures 1 and 2). Exclusion criteria were a clearly metastatic disease, poor health condition that precluded laparotomy (severe pulmonary disease, non-treatable coagulation abnormality), and patient's refusal to participate in this study. All patients had complete surgical resection (R0). Seven cases were included. Median age was 51 years (range: 41-73 years).

Five patients had an SD and two a cephalic PD. PD was the operation chosen for relatively large and difficult-to-reach tumors (first and second part of the duodenum). Among the SD group, one patient had a duodenal patch resection of a small D1 GIST with direct closure (case 3, Table 1), the others had a complete SD with latero-lateral duodeno-jejunal reconstruction (Figure 3).

Pathological diagnosis of GIST was confirmed for all according to histological and immunohistochemical work-up. All tumors were c-kit positive. GIST was classified according to the Fletcher scale[21] and our scale[4].

The primary endpoint for this analysis was disease-free survival (DFS), which was defined as time from surgery to GIST recurrence. Follow-up was available for all patients at the date set for collecting data, November 2008. Follow-up was carried out through routine visits at our Outpatient Oncological Clinic. Clinical assessment was made every 3 mo during the first 2 years after surgery and every 6 mo thereafter, with detection of recurrence as soon as possible to allow adjuvant therapy with imatinib. Yearly chest X-rays and abdominal computed tomography (CT) were routinely performed in all patients and additional imaging was requested when clinical suspicion of GIST recurrence occurred. The median follow-up was 41 (18-85) mo.

Statistical analysis

Statistical analysis was performed using GraphPad InStat (GraphPad Software, San Diego, CA, USA). When appropriate, data were analyzed using two-sided Fischer's test or two-sided t test. $P < 0.05$ was considered statistically significant.

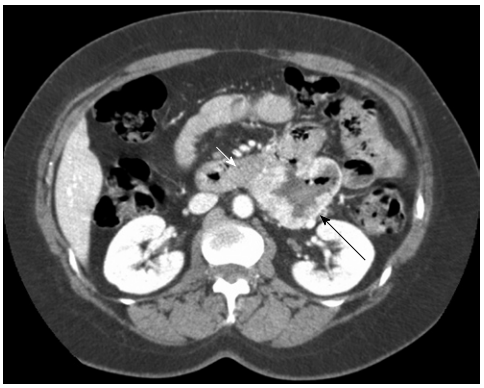

Figure 1 Gastrointestinal stromal tumor (GIST) located in the third part of the duodenum with typical computed tomography (CT) appearance. Note the typical CT appearance of GIST with an area of necrosis (central cavitations with surrounding highly vascular tissue) (white arrow: pancreas; black arrow: GIST).

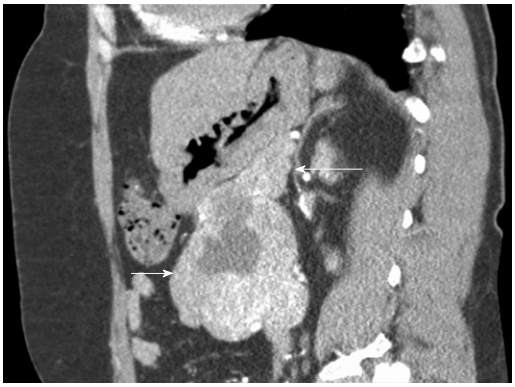

Figure 2 GIST located ion the horizontal duodenum (patient 5, Table 1). Note the close relation between the GIST (short arrow) and the pancreas (long arrow), which was easily dissected during surgery.

Figure 3 Duodeno-jejunal anastomosis. Latero-lateral duodeno-jejunal anastomosis between the second part of the duodenum and the first jejunal loop was easily performed after distal duodenectomy and Kocher maneuver.

RESULTS

Study population and pathological data

Seven patients were included in the analysis. Four patients presented with upper digestive tract hemorrhage,

Table 1 Patients characteristics and follow-up

Cases	Localization	Size (cm)	Mitosis/50 HPF	Fletcher grade	Surgery	Follow-up	DFS	Second-line therapy
1	D2	6.5	34	HR	PD	60	13	Imatinib and hepatectomy
2	D1	7	19	HR	PD	56	12	Imatinib
3	D1	2.5	3	LR	SD	85	85	-
4	D2	2	2	LR	Atypical duodenectomy	40	40	-
5	D2-3	10	10	HR	SD	37	37	-
6	D3	7	2	IR	SD	29	29	-
7	D4	5.5	5	IR	SD	18	18	-

D1: First part of the duodenum; D2: Second part of the duodenum; D3: Third part of the duodenum; D4: Forth part of the duodenum; HR: High risk; IR: Intermediate risk; LR: Low risk GIST according to Fletcher scale; HPF: High-power field; DFS: Disease free survival.

the others with abdominal discomfort. In all patients, the diagnosis of duodenal GIST was made through CT after it was suspected by endoscopy in those with digestive bleeding. No preoperative biopsies were performed.

All GISTs were localized without metastases or peritoneal dissemination. According to the Fletcher classification, the GISTs were considered as high risk in the two patients in the PD group, and in the SD group as high risk in one, intermediate risk in two, and low risk in two patients ($P > 0.05$). According to our classification, the two GISTs in the PD were classified as malignant, as was one of the five GISTs in the SD group ($P < 0.05$).

Postoperative outcomes

No postoperative morbidity and mortality were recorded. All patients had complete surgical (R0) resection of their duodenal GIST. Five patients underwent SD and two PD (Table 1). GIST-free surgical margins along the duodenum ranged from 0.5 cm to 3 cm.

Follow-up results

The median follow-up was 41 mo (range: 18-85 mo). Median follow-up was 58 mo (range: 56-60 mo) and 37 mo (range: 18-85 mo) for the PD and SD group, respectively. Two patients in the PD group demonstrated recurrence with a median disease-free interval of 13 mo, whereas no recurrence was observed in the SD group ($P < 0.05$). All patients are alive and disease free in the SD group with a median DFS of 37 mo. The two patients with recurrence after PD presented with liver metastases, which were treated with imatinib mesylate, and one was also treated with partial hepatectomy. A statistically significant difference was detected between the PD and SD group for DFS ($P = 0.048$), however, this should be balanced by a higher rate of malignant GIST and longer median follow-up in the PD group.

DISCUSSION

The optimal surgical procedure for GISTs of the duodenum remains poorly defined in terms of oncological results. This study was undertaken to compare oncological results of SD and the more radical PD. According to our data, duodenal GIST prognosis is dependent on tumor malignant potential when clear surgical margins can be achieved and not on size of surgical margins or lymphatic dissection. The data presented herein demonstrate that SD is associated with prolonged DFS.

Surgical resection is still the only curative therapy for GIST[1,6,19]. GISTs are known to be resistant to chemotherapy and radiotherapy, and the recently developed molecular targeted therapies (imatinib mesylate and sunitinib), while being highly effective in disease control, are not curative[1,5,6]. The optimal surgical procedure for duodenal GIST remains poorly defined in terms of oncologic results. The reports in the literature addressing surgical procedures for duodenal GIST demonstrate the feasibility of various surgical procedures: PD, pancreas-sparing duodenectomy, SD, or wedge local resection[8,9,11-17,22-25]. These papers can help us a little to determine which surgical procedure is optimal in terms of short- and long-term oncological results. The largest series of duodenal GISTs ($n = 156$) evaluated prognosis according to tumor grade[3]. In this pathological review, around 60% of patients underwent pancreas-preserving duodenectomy and 11% had PD, but due to the retrospective nature of this analysis, no correlation between type of operation and oncological results were reported. Very recently, Tien *et al*[26] have reported their experience, in which they compared nine PD with 16 limited operations (11 wedge resections, and five SDs) for duodenal GIST. They have shown that the type of operation is not correlated to operative risk or disease recurrence. They have concluded that limited procedures, like SD, should be attempted for duodenal GIST without involvement of the papilla of Vater. Others have reported similar results[10].

The choice of surgical procedure for duodenal GIST can be guided by the size and exact location of the tumor[6,11,17,25]. However, some principles of GIST surgical treatment have to be considered by a visceral surgeon when approaching duodenal GIST[1,4,6,10,17]. First, GISTs are mesenchymal tumors that behave as other sarcomas and not like adenocarcinomas[4,18]. GIST spreads specifically hematogenously and is rarely, if ever, associated with lymphatic invasion, as in other sarcomas[4,6,18]. Therefore, lymphadenectomy is not recommended[4,11,19]. This seems true for duodenal GIST as local lymph node invasion has never been described, even after PD[3,11-13,17]. Secondly,

GISTs are well encapsulated tumors that rarely show a tendency to local invasion even for high risk tumors[4,6,20]. They should be approached with the intention of performing complete *en bloc* removal (R0 resection) of the tumor and surrounding digestive tract tissue[1,4,6,7,10,19]. The size of surgical margins along the segment of digestive tract involved are not formally defined, however there is little submucosal spread in GIST and clear margins of 1 or 2 cm are recommended[4,6,19,20]. When extracapsular GIST mobilization is possible, there is no need for extensive surgical margins on adjacent organs and peri-tumoral resection with an intact capsule is sufficient[4,6,19,20].

Segmental or atypical duodenectomy for duodenal GIST is in accordance with these principles and could be beneficial for patients because it does not involve the excessive resection and morbidity associated with PD. After complete surgical resection, duodenal GIST prognosis seems not to be influenced by the pancreatic margins, according to the present study and the sparse literature on the subject. Prognosis is mainly dependent on malignant status, which is determined by size and mitotic rate (Fletcher scale). This has been clearly shown for duodenal GIST in the study by Miettinen *et al*[3] and was true in our small series. However, some authors have advocated the need for PD as pancreatic invasion cannot be ruled out on preoperative studies[17,27]. Although close contact between the GIST capsule and pancreas is usually the rule for large duodenal GISTs on CT (Figures 1 and 2), this is rarely correlated with pancreatic tumoral invasion, which allows treatment with pancreas-sparing duodenectomy[12,28,29]. As a result of these considerations, we think that segmental or atypical duodenectomy is the optimal procedure for duodenal GIST, as previously proposed by others[10-13,15,22-25,30]. The exact type of duodenectomy to perform might be influenced by GIST size and location, ranging from wedge resection with primary closure for small proximal duodenal GIST to SD with duodeno-jejunal anastomosis for large distal duodenal GIST[11,15,30-32]. One exception to this might be periampullary or ampullary GIST, which can present with jaundice, for which pancreas-preserving duodenectomy can be challenging compared to cephalic PD, when the ampulla needs to be resected to obtain clear surgical margins[8,27].

The present study has several limitations. First, it could be argued that a higher rate of malignant GIST is present in the PD group, because in part, PD was chosen for larger and more difficult-to-reach lesions. Furthermore, a longer median follow-up was available for the PD group. These two points could counter-balance the results. Finally, the sample was small, but duodenal GIST remains a rare tumor. Previous studies published in the literature have not reported large numbers of patients, and most of the time, only case reports[8-17,19,22-27,30].

In conclusion, pancreas-preserving segmental or atypical duodenectomy seems to be a reliable and curative option in duodenal GIST. Despite being limited in their extent, these methods of resection, when performed with negative margins, are compatible with long-term DFS, and should be preferred, whenever possible, to PD. This is related to the tumoral characteristics of GIST, which is generally well encapsulated, even when highly malignant and with extremely rare lymphatic spread. When clear surgical margins are achieved, prognosis depends on tumoral malignant potential and not on the extent of the surgical margins, especially the pancreatic margin, for duodenal GIST. However, PD remains a good alternative for tumors in the vicinity of the ampulla of Vater.

COMMENTS

Background

Duodenal gastrointestinal stromal tumors (GISTs) are rare primary duodenal tumors, and there are few guidelines to help the clinician in their surgical management. Surgery is still the only curative approach for GIST, but the optimal procedure remains to be established. Although, numerous authors have reported various surgical procedures, few have correlated their results with oncological outcomes.
