Abstract

Rectal cancers extending through the rectal wall, or involving locoregional lymph nodes (T3/4 or N1/2), have been more difficult to cure. The confines of the bony pelvis and the necessity of preserving the autonomic nerves makes surgical extirpation challenging, which accounts for the high rates of local and distant relapse in this setting. Combined multimodality treatment for rectal cancer stage Ⅱ and Ⅲ was recommended from National Institute of Health consensus. Neoadjuvant chemoradiation using fluoropyrimidine-based regimen prior to surgical resection has emerged as the standard of care in the United States. Optimal time of surgery after neoadjuvant treatment remained unclear and prospective randomized controlled trial is ongoing. Traditionally, 6-8 wk waiting period was commonly used. The accuracy of studies attempting to determine tumor complete response remains problematic. Currently, surgery remains the standard of care for rectal cancer patients following neoadjuvant chemoradiation, whereas observational management is still investigational. In this article, we outline trends and controversies associated with optimal pre-treatment staging, neoadjuvant therapies, surgery, and adjuvant therapy.

INTRODUCTION

The mainstay of treatment for colorectal cancer is surgery. Complete, margin-negative resection confers the greatest chance for cure. However, chemotherapy and radiation have important roles in assuring long-term, recurrence-free survival. Colon cancer and extraperitoneal rectal cancers (lesions above the anterior peritoneal reflection, or 12-15 cm from the anal verge) are generally treated with surgery followed by adjuvant chemotherapy; these patients are believed to be at high risk for harboring micrometastasis and, therefore, of developing of recurrent disease. Mid to low rectal cancers lying below

the anterior peritoneal reflection and extending through the rectal wall, or involving locoregional lymph nodes (T3/4 or N1/2), have historically been more difficult to cure. The confines of the bony pelvis and the necessity of preserving the autonomic nerves makes surgical extirpation challenging, which accounts for the high rates of local and distant relapse in this setting. The Gastrointestinal tumor study group and National surgical adjuvant breast and bowel project trials demonstrated that chemoradiotherapy following surgical resection could reduce local recurrence from 55% to 33%, with significantly prolonged disease-free survival (DFS)[1,2]. This was the basis for the National Institute of Health consensus statement in 1990 recommending combined modality therapy for Stage Ⅱ and Ⅲ rectal cancer[3]. In the 20 years since, there have been considerable advances in treatment.

We will outline current trends and controversies in the treatment of locally advanced rectal cancer. The topics to be covered include staging, neoadjuvant therapies, surgery, and adjuvant therapy.

OPTIMAL CLINICAL STAGING

Pre-treatment evaluation, including accurate staging, is critical when planning treatment for rectal cancer patients. The mainstay of treatment is surgery, which runs the gamut from local excision to radical resection with or without chemoradiation. Accurate staging is the first crucial, necessary step in optimizing therapy, maintaining quality of life, and limiting over- and under-treatment.

Most rectal cancers are diagnosed at colonoscopy, usually after patients present with asymptomatic anemia or change in bowel habits. Histologic confirmation is important, as benign stricture and inflammatory conditions may mimic malignancy. Full colonoscopy is necessary in order to identify synchronous polyps and malignancies, which occur in about 30% and 3%-5% of cases, respectively[4,5]. If the colon cannot be fully evaluated preoperatively due to colonic obstruction, it is recommended at 3-6 mo postresection[6].

Once a patient is diagnosed with rectal cancer, the most commonly ordered imaging study is computed tomography (CT). When properly performed with oral and intravenous contrast, CT provides important information regarding extent of disease. Although it is not a very accurate imaging modality for determining the degree of primary tumor penetration into the rectal wall or involvement of locoregional lymph nodes, CT scanning of the chest, abdomen and pelvis accurately identifies distant metastatic disease in the lung, liver, pelvic and periaortic lymph nodes.

Staging of the primary rectal lesion begins with a detailed digital rectal examination (DRE). This confers important information about the primary lesion, including its location with respect to the top of the anorectal ring (external sphincter complex) as well as its mobility. The degree of tumor fixity in the pelvis corresponds to depth of penetration through the rectal wall. Mobile lesions are often limited to the mucosa, submucosa or muscularis propria, whereas tethered lesions are likely to extend into the perirectal fat (mesorectum). A fixed lesion may signify extension of tumor into surrounding anatomic structures such as the seminal vesicles, prostate or vagina (T4 lesions). Rigid proctosigmoidoscopy provides the best estimate of tumor distance from the anal verge.

Endorectal ultrasonography (ERUS) and magnetic resonance imaging (MRI) are the most accurate tools for assessing T and N stage. ERUS is advantageous in imaging small, superficial tumors, whereas MRI is useful in evaluating bulky tumors that extend to the circumferential margin (CRM)[7]. Based on the results of large meta-analyses, the accuracy of ERUS in determining T and N stage is 87% and 74%, respectively[8]. The accuracy of MRI in determining T and N stage is 71%-91% and 45%-79%, respectively[9], similar to that of ERUS. Introduction of endoluminal coil MRI improves imaging resolution of the rectal wall. However, the true strength of MRI lies in phased-array MRI, which facilitates accurate assessment of tumor encroachment of the CRM, or invasion into surrounding anatomic structures[10]. Both MRI and ERUS are less accurate in assessing locoregional lymph node metastasis. Morphology, such as irregular border or heterogeneous intensity, is often more predictive than lymph node size[11]. It is important to remember that 18% of nodal metastases occur in lymph nodes measuring less than 5 mm[12]. Rather than being competing modalities, however, ERUS and MRI are often complimentary in the process of rectal cancer staging. ERUS is particularly useful in the staging of early rectal cancers; it also has the advantage of low cost, and can be performed quickly in the outpatient office. Phased-array MRI is much more expensive and not as readily available; however, it affords a comparatively greater field of vision, enhancing the ability to identify at-risk CRM and invasion of adjacent organs.

CHEMORADIATION: POSTOPERATIVE *VS* PREOPERATIVE

A paradigm shift in preoperative radiotherapy (RT) was introduced by the Swedish Rectal Cancer Trial in 1997. This study randomized 1168 patients to receive either one week of RT followed by surgery, or surgery alone. Compared with surgery alone, patients who received preoperative RT had reduced local recurrence (11% *vs* 27%, $P < 0.001$) and prolonged survival [5-year overall survival (OS) of 58% *vs* 48%, $P = 0.004$][13]. At a median follow-up of 13 years, the benefits in terms of local recurrence (9% *vs* 26%, $P < 0.001$) and OS (38% *vs* 30%, $P = 0.008$) remained significant in patients who received preoperative RT[14]; however, these patients did experience more gastrointestinal complications and had a higher rate of hospitalization over the 6-mo period following surgery[15].

Total mesorectal excision (TME) involves sharp dis-

section along the embryonic planes between the visceral and parietal layers of the endopelvic fascia. This ensures complete removal of locoregional lymph nodes contained within the mesorectum, while preserving the autonomic nerves and limiting blood loss. Multiple retrospective and cohort studies have shown that TME is associated with lower rates of local recurrence compared to the less optimal blunt surgical technique. The Dutch TME trial (published in 2003) was the first to compare the results of TME with and without preoperative short-course RT. Of 1861 accrued patients, 924 and 937 were randomized to receive either preoperative radiation followed by TME, or TME alone. Local recurrence was significantly lower in patients, who received preoperative RT plus TME (2.4% *vs* 8.2%, $P < 0.001$), but there was no difference in OS[16]. Long-term follow-up showed lower recurrence rates in the preoperative RT arm, especially in the subgroups of patients with nodal involvement, patients with tumor located between 5-10 cm from the anal verge, and patients with free CRMs[17].

While preoperative short-course radiotherapy consisting of 25 Gy in 5 fractions has been the favored treatment in Northern Europe and Scandinavia, in North America and in some European countries long-course chemotherapy has been the treatment of choice, based in part on the results of the Gastrointestinal Tumor Study Group and National Surgical Adjuvant Breast and Bowel Project (NSABP) trials. With theoretical advantages of better tolerance and increased efficacy, many centers moved toward preoperative neoadjuvant chemoradiation: 50.4 Gy delivered in 28 fractions, and concurrent fluoropyrimidine-based chemotherapy. The majority of patients receiving chemoradiotherapy obtain tumor downstaging (in which the final pathologic stage at time of surgery is lower than the initial clinical stage at time of presentation)[18]. Indeed, as many as 15%-20% of patients will have a complete pathologic response to treatment, with no viable tumor cells noted in the resected rectum. Tumor downsizing may facilitate complete tumor resection and, in the setting of low-lying tumors, may alter the surgical plan by making a sphincter-saving procedure possible[19,20].

Although two prospective, randomized controlled trials comparing preoperative and postoperative chemoradiation failed to accrue; NSABP R03[21] and the Intergroup 1047 trial[22] in the United States, the German Rectal Cancer Study Group successfully completed such a trial. The German CAO/ARO/AIO 94 trial[19] compared preoperative and postoperative long-course chemoradiation for T3 or T4 and/or node-positive rectal cancer. Chemoradiotherapy consisted of 50.4 Gy in 28 fractions with concurrent infusional fluorouracil (1000 mg/m^2 per day for 5 d in the first and fifth week of radiation). Four hundred twenty-one and 402 patients were randomly allocated to receive preoperative and postoperative chemoradiotherapy, respectively. There was 6% local recurrence in the preoperative group and 13% in the postoperative group ($P = 0.006$). Grade 3 or higher acute and long-term toxicity occurred significantly less frequently in patients who received neoadjuvant chemoradiation ($P = 0.001$ and $P = 0.01$, respectively). However, the rates of sphincter preservation, DFS and OS did not differ between the two groups.

Comparison of long- and short-course radiotherapy was the aim of a Polish randomized study[23,24] of patients with T3/4 mid to low rectal cancer. The results demonstrated higher rates of complete pathologic response in the group of patients receiving long-course chemoradiotherapy: 16% and 1% had complete pathologic response in the long-course and short-course chemoradiotherapy groups, respectively. Although rates of sphincter preservation were similar in both study groups, patients receiving long-course chemoradiotherapy had a 4% rate of positive CRM at time of surgery, compared with 13% in the short-course group ($P = 0.017$). However, there was no significant difference in local recurrence, DFS or OS.

The recently reported MRC CR07 and NCIC-CTG C016 multi-center randomized study[25] of 1350 patients compared the outcomes of preoperative short-course RT *vs* initial surgery followed by selective postoperative chemoradiation in patients with positive CRM. The primary outcome was local recurrence. This study demonstrated a significant decrease in local recurrence in patients receiving preoperative short-course RT (hazard ratio 0.39, $P < 0.0001$), which was associated with a 6% absolute improvement in DFS at 3 years ($P = 0.03$). Again, these data demonstrate the superiority of preoperative chemoradiotherapy.

The above data indicate that both preoperative long-course and short-course radiotherapy followed by proper TME provide excellent local control. The advantages of long-course chemoradiotherapy include tumor downsizing and downstaging, which may alter the surgical treatment plan in favor of a sphincter-preserving procedure. Long-course chemoradiation is associated with higher acute toxicity than short-course (18.2% *vs* 3.2%, respectively)[23]. On the other hand, short-course RT may lead to more long-term complications secondary to higher dose per fraction. In the United States, long-course chemoradiotherapy consisting of 5040 cGy, delivered concurrently with 5-fluorouracil (5FU) chemotherapy, is the most common regimen[6].

With improvements in surgical technique, including TME, the utility of chemoradiation in early T3 lesions without at-risk CRM has been called into question. A study of 95 T3N0 rectal cancer patients undergoing TME demonstrated less than 10% local recurrence rate without adjuvant therapy[26]. A pooled analysis of 3791 patients from several randomized studies showed no difference, in terms of OS, in T3N0 rectal cancer patients who received surgery plus chemotherapy with, or without, radiation (85% *vs* 74%-80%, respectively). Moreover, local relapse was similar among stage Ⅱ patients undergoing surgery alone (14%) or surgery plus radiotherapy (12%)[27]. It has been suggested that patients at lower

risk of local recurrence, e.g., those with proximal T3N0 lesions with clear margin, may be adequately treated by surgery and only adjuvant chemotherapy. However, correctly assessing T and N stage remains problematic. Two studies have reported the limitations of ERUS or MRI in determining accurate nodal stage, with false negative rates of up to 22%-28%[28,29]. Therefore, preoperative chemoradiation for clinical T3N0 rectal cancer patients should be considered by weighing the risk of unnecessary treatment against the possibility that the patient may ultimately require postoperative chemoradiation, which is associated with lower local control and higher toxicity than preoperative chemoradiation. Currently, preoperative chemotherapy remains the standard of treatment for T3N0 patients based on the principle that overtreatment is less harmful than undertreatment.

MAXIMIZING RESPONSE TO NEOADJUVANT CHEMORADIATION

Fluoropyrimidine-based chemotherapy synergizes with long-course radiotherapy. A 2 × 2 study of the European Organization for Research and Treatment of Cancer (EORTC) 22921 trial[30] assessed the efficacy of adding chemotherapy to RT, with or without adjuvant (postoperative) chemotherapy. The addition of chemotherapy at some point in the treatment regimen, either preoperatively or postoperatively, conferred a significant benefit in terms of local control. RT is fundamental to neoadjuvant treatment of rectal cancer, resulting in increased pathological response rate and better local control. However, it has no effect on distant metastasis. These findings imply that fluorouracil acts as a potent radiation sensitizer but has no significant eradicating impact on micrometastatic disease. In an attempt to improve response rates and reduce distant metastasis, new preoperative strategies are being investigated; these include combinations of new chemotherapeutic agents used concurrently with RT as well as induction chemotherapy. Currently efforts are being made to integrate novel agents in combination with RT, using the pathologic complete response (pCR) rate as a surrogate endpoint. Pathological CR has demonstrated correlation with clinical outcomes, i.e., relapse-free survival, DFS and OS[31,32].

Capecitabine, an oral pro-drug of fluoropyrimidine designed to enable selective 5FU activation in tumor tissue, has been studied as an agent used concurrently with RT. Several phase Ⅰ / Ⅱ studies have revealed a pCR rate of 7%-31% with acceptable toxicities[33-36]. Two randomized controlled trials showed capecitabine to be non-inferior to 5FU in the perioperative treatment of stage Ⅱ-Ⅲ rectal cancer. The NSABP R-04[37] compared the efficacy of continuous infusion 5FU to capecitabine delivered concurrently with preoperative RT, with or without oxaliplatin, in 1608 patients. The rates of pCR were 19% and 22% in patients who received 5FU and capecitabine, respectively (P = 0.12). Long-term outcomes of DFS and OS are awaited. Another phase Ⅲ trial from Germany[38] demonstrated that capecitabine, used in the neoadjuvant or adjuvant setting, is not inferior to 5FU in terms of 5-year OS (capecitabine 76%; 5FU 67%, P = 0.053). The use of oral capecitabine (825 mg/m^2 taken twice daily) throughout the course of radiation has been an alternative option; it is not inferior to infusional fluoropyrimidine in terms of efficacy or toxicity, and has the potential advantage of convenience for the patient.

The results of two phase Ⅲ studies studying combined oxaliplatin and fluoropyrimidine used concurrently with radiotherapy have also been reported. The ACCORD12 trial compared CRT using capecitabine + 45 Gy RT to capecitabine + oxaliplatin (CAPEOX) + 50 Gy RT[39]. This study showed pCR rates of 13.8% and 18.8% in the capecitabine/RT and CAPEOX/RT groups, respectively (P = 0.11). Another phase Ⅲ study from Italy investigated the efficacy of adding weekly oxaliplatin to protracted infusion of 5FU, concurrently with radiation, in locally advanced rectal cancer patients[40]. There was no difference in the pCR rate (16% in the 5FU group *vs* 15% in the 5FU + oxaliplatin group, P = 0.98). Interestingly, fewer patients in the 5FU + oxaliplatin arm were found to have metastatic disease after neoadjuvant chemoradiation (0.5% *vs* 3%, P = 0.014); this data may imply that oxaliplatin is potentially efficacious in controlling micrometastasis. Another trial of NSABP R-04[37], reported at the 2011 American Society of Clinical Oncology Annual Meeting, demonstrated that oxaliplatin does not improve pCR rates (19.1% *vs* 20.9%, P = 0.46), but significantly increases toxicity. However, neither randomized controlled trial showed any improvement in acute endpoints, i.e., pCR. At this time, single agent fluoropyrimidine, either infusional 5FU or capecitabine used concurrently with pelvic radiation, remains the standard of care in stage Ⅱ and Ⅲ rectal cancer.

Attempts have been made to integrate molecularly targeted therapy with preoperative combined modalities, in order to improve the efficacy of standard neoadjuvant chemoradiation. The addition of cetuximab to capecitabine was evaluated in a phase Ⅰ / Ⅱ trial in which only 5% of patients reached pCR; however, there was no unexpected toxicity[41]. Another study from Germany also reported a suboptimal pCR rate (9%) after preoperative cetuximab + capecitabine, oxaliplatin and radiotherapy[42]. Data on preoperative bevacizumab are limited to a few phase Ⅰ studies. However, in contemplating treatment with bevacizumab, the known adverse effects of this monoclonal antibody (such as bowel perforation, bleeding, and impaired surgical wound healing) must be considered.

Induction chemotherapy followed by neoadjuvant chemoradiation was considered a potential approach to controlling micrometastasis. A phase Ⅱ United Kingdom trial, using this new strategy of neoadjuvant chemotherapy with CAPEOX prior to CRT and surgery, has been reported[43]. One hundred five individuals, identified by high-resolution MRI as poor-risk rectal cancer patients, were enrolled. The definition of "poor-risk"

entailed one of the following features: CRM threatened or involved by tumor, low-lying tumor at or below the levators, T3 tumor with radial margin > 5 mm, T4 lesion, or N2 disease. The results showed the feasibility of this approach, with overall rates of 5-year and DFS 75% and 68%, respectively. In the setting of locally advanced rectal tumors, these are very impressive statistics.

A Spanish trial[44] was conducted to compare this new strategy with the more conventional approach of neoadjuvant chemoradiation followed by surgery and adjuvant chemotherapy. One hundred eight patients were randomized to receive 4 cycles of CAPEOX for the induction period, followed by neoadjuvant chemoradiation and then surgery; or else to receive neoadjuvant chemoradiation followed by surgery, and subsequently 4 cycles of adjuvant CAPEOX. There was no difference in pCR rate (13% *vs* 14%). Significantly less toxicity and a greater ability to tolerate chemotherapy throughout the schedule were found in patients who received induction chemotherapy. Another phase Ⅱ study from Memorial Sloan-Kettering Cancer Center[45] was conducted to determine the efficacy of induction chemotherapy, followed by chemoradiotherapy and then surgery, for stage Ⅲ or potentially resectable stage Ⅳ rectal cancer patients. Thirty-four patients were enrolled. Seventeen of 27 patients who ultimately underwent TME had > 90% pathological tumor response. At a median follow-up of 25 mo, no local recurrence was identified. Three-year DFS and OS were 63% and 100%, respectively, in patients with resected stage Ⅲ rectal cancer. This study showed a promising clinical outcome with tolerable toxicity. We believe that this approach will become one of the mainstays of treatment for patients with locally advanced rectal cancer in the future, but the data must be borne out in larger phase Ⅲ studies.

PREDICTORS OF RESPONSE TO NEOADJUVANT THERAPY

Several parameters associated with tumor response to neoadjuvant chemoradiation have been identified. Some studies have concluded that lower pre-treatment carcinoembryonic antigen (CEA) level is associated with better response to treatment[46-50]. The cut-off CEA levels associated with response rate were 2.5[46], 3[47], and 5 ng/mL[48-50]. However, because the pre-treatment CEA level in a majority of patients is normal and the cut-off level inconclusive, the applicability of CEA in predicting treatment response remains unclear.

Location of tumor, including tumor distance from the anal verge and the extent of luminal involvement by tumor, has also been examined. Bulky T3 lesions are less likely to show significant downstaging[51]. In a study of 247 patients, T3 tumors with > 2.5 mm extension into the mesorectum demonstrated a lesser response to therapy, with a low degree of downstaging[51]. It cannot be determined if this is merely attributable to tumor volume or to actual tumor biology. Predictably, this study also noted that poorly differentiated histology and metastatic disease were associated with limited response to treatment. Similarly, other reports have found that there is comparatively less downsizing in lesions with > 60% circumferential involvement. Interestingly, in this study lesions located higher than 5 cm from the anal verge were more likely to show a significant response to neoadjuvant chemoradiation[46].

In the past decade, many studies have attempted to identify correlations between immunohistochemical biomarkers such as Ki-67, p53, p21, bax/bcl2, epidermal growth factor receptor, thymidylate synthase, and tumor response after neoadjuvant chemoradiation. Currently, however, these studies remain inconclusive[52-54].

RESTAGING AFTER NEOADJUVANT CHEMORADIATION

Identifying the 15%-20% of patients who achieve a complete response to neoadjuvant therapy remains a challenge. Because of their fundamental roles in the neoadjuvant chemoradiation setting, DRE, endoscopy, ERUS, CT, MRI and positron emission tomography (PET) have been proposed as investigational tools to determine tumor response to treatment. The problem is that none of these modalities are capable of accurately predicting pCR[55], the reason being that fibrosis and inflammation caused by radiation have a deleterious affect on accuracy. A study from our institution[56] demonstrated that DRE is an inaccurate method for determining response to treatment after neoadjuvant chemoradiation; the overall concordance between DRE and pathologic response following neoadjuvant chemoradiotherapy was only 22%. A study from Italy showed that only half of patients who were defined as having complete response on endoscopic biopsy had true pCR according to pathology from surgical resection[55].

The accuracy of ERUS and MRI in the setting of post-neoadjuvant chemoradiation is also limited. A prospective study compared the accuracy of CT, MRI and ERUS *vs* pathologic assessment in determining clinical T and N stage in 90 patients receiving long-course neoadjuvant chemoradiation. The accuracy of these imaging modalities in determining T stage was low (37% by CT, 34% by MRI, and 27% by ERUS); most of this was due to over-staging. The rate of accuracy in nodal staging was 62% by CT, 68% by MRI and 65% by ERUS[57].

Because of the limited accuracy of all existing imaging modalities in staging rectal cancer post-neoadjuvant chemoradiation, several groups have investigated novel imaging methods. Diffusion-weighted MRI is a functional MRI imaging technique with better accuracy than that of conventional MRI[58-60]. However, the role of this emerging method is still investigational, and more studies with larger numbers of patients are awaited. In the meantime, repeat CT of the chest, abdomen and pelvis is useful in identifying development of interval metastatic disease, the presence of which could alter the surgical plan.

PET is a functional imaging study. Theoretically, the change of activity in the tumor should relate to the treatment response. Support to this idea, there are some studies demonstrated the relative change of maximum standardized uptake value relate to tumor response[61-63]. On the contrary, the data from another study demonstrated 63% sensitivity and 74.4% specificity of PET to predict patients with complete response[64]. While, PET is sometimes utilized in the process of restaging, the current data on the efficacy of this modality is inconsistent and limited; thus we do not routinely use PET as a restaging tool.

OPTIMAL TIMING OF SURGERY AFTER NEOADJUVANT THERAPY

In an attempt to increase response to chemoradiation, some groups have investigated lengthening the interval between chemoradiotherapy and surgery. Traditionally, surgery has been recommended 6-8 wk after neoadjuvant chemoradiation[65-69] to allow for tumor regression without extensive fibrosis. Indeed, several studies have shown that extending the period between chemoradiation and surgery may increase rates of complete pathologic response without increasing perioperative complications[63-65]. However, the effect of a longer interval on long-term outcome has yet to be defined. A well-designed multicenter prospective trial of increasing the interval between neoadjuvant chemoradiation and surgery is ongoing[70]. It is unclear if this will impact outcome; nevertheless, it may be of significance in the development of nonoperative strategies (see below). Some have also proposed adding chemotherapy to the waiting period, in an attempt to treat potential micrometastatic disease[71,72]. Habr-Gama *et al*[71] have reported the preliminary results of a study adding chemotherapy in the interval between neoadjuvant chemoradiation and surgery, which demonstrate an increased rate of complete clinical response.

MINIMALLY INVASIVE SURGERY FOR LOCALLY ADVANCED RECTAL CANCER

Laparoscopic surgery for rectal cancer has been proven feasible, but it is not yet a standard treatment in the United States. The United Kingdom Medical Research Council Trial of Conventional *vs* Laparoscopic-Assisted Surgery in Colorectal Cancer trial[73] demonstrated equivalent long-term recurrence and survival results in rectal cancer patients who did not receive neoadjuvant treatment. The Comparison of Open *vs* Laparoscopic surgery for Mid and Low Rectal Cancer after Neoadjuvant Chemoradiotherapy trial[74] is a prospective randomized trial that includes 340 patients with locally advanced rectal cancer receiving neoadjuvant chemoradiotherapy, randomized to laparoscopic and open groups in a ratio of 1:1. The conversion rate is only 1.2% (2 in 170 patients). From the short-term results, operative time is significantly longer in the laparoscopic group, but estimated blood loss was significantly less. The rate of positive circumferential resection margin did not differ significantly between the two groups; nor did distal resection margin. The long-term oncological outcomes are awaited.

PREDICTORS OF RECURRENCE AND SURVIVAL

Several factors are reportedly predictive of recurrence and survival. Some of these features are the same in patients who receive or do not receive neoadjuvant chemoradiation. Some differ.

Post neoadjuvant chemoradiation CEA level

It has been proposed that post-neoadjuvant chemoradiation CEA levels < 2.5 ng/mL[75] and 5 ng/mL[76] are associated with significantly better DFS and OS. Another study, however, discerned no correlation[77]. Moreover, most studies focusing on correlations between predictors and long-term outcomes do not focus on CEA levels[77-79]. Thus, application of this parameter in attempting to predict recurrence and survival remains inconclusive.

Tumor response and nodal status after neoadjuvant chemoradiation

The pathologic response of tumor to treatment is one of the most significant prognostic factors in rectal cancer[18,80]. In terms of recurrence and survival, pCR is most strongly correlated with excellent outcome[80-85]. Several tumor regression grading systems classify tumor response following neoadjuvant chemoradiation in patients with pathologic partial response. All of these grading systems are consistent and demonstrate a strong association between pathologic response and outcome[18,32,79,83]. In the setting of neoadjuvant chemoradiation, preoperative treatment reduces lymph node yield at the time of surgery. However, the ratio of positive lymph nodes to total lymph nodes is prognostic, and may in fact be a more useful prognostic factor than total number of lymph nodes culled following neoadjuvant chemoradiation[83]. Several studies have associated positive pathological lymph node (ypN) status with poor prognosis[30,77-83].

Distal resection margin

Historically, the standard guidelines have recommended a distal resection margin (DRM) of 4-5 cm from the distal edge of tumor[6,86]. However, several reports have found that a DRM < 2 cm does not increase recurrence rates[87,88] or negatively impact survival[88]. In the setting of low rectal cancer located < 5 cm from the anal verge, 1-2 cm may be acceptable[6]. Especially following preoperative treatment with neoadjuvant chemoradiation, the 1-2 cm DRM rule seems to be less important than obtaining a clear resection margin[89,90].

CRM

The standard cut-off point of the CRM is still a matter of controversy. Most published studies have used < or = 1 mm[91-93], 2 mm[94-96], or 5 mm[7,97] as acceptable cut-off points in chemoradiotherapy-naïve patients. All reported significantly higher recurrence rates and shorter survival in patients with CRM < or = 1 mm[91-93], 2 mm[94-96], or 5 mm, respectively[7,98]. Therefore, in patients who have not received neoadjuvant chemoradiation and whose pathology indicates a close CRM (less than 1-5 mm), adjuvant chemoradiation should be strongly considered regardless of other pathological results[90,98]. In patients who have already received neoadjuvant chemoradiation, adjuvant chemotherapy should be considered[95-97].

Perineural invasion and lymphovascular invasion

These are poor prognostic factors in colon and rectal cancer in general. Even with neoadjuvant chemoradiotherapy, Perineural invasion and lymphovascular invasion remain predictors of poor outcome[20,97].

Acellular mucin pools

Acellular mucin pools (AMP) has been found in 11%-27% of surgical cases after neoadjuvant chemoradiation[99,100]. The question is whether AMP after neoadjuvant chemoradiation should be considered residual disease or not. Several reports have concluded that AMP does not have a significant impact on outcome[99-101]. The College of American Pathologists has recommended that AMP not be interpreted as residual disease[102].

POSTOPERATIVE ADJUVANT CHEMOTHERAPY: IS IT NECESSARY?

There is a high risk of local recurrence and distant metastasis in stage Ⅱ and Ⅲ rectal cancer patients treated by surgery alone. The role of adjuvant chemotherapy is to eradicate micrometastatic disease. Patients with T3 or node-positive disease who are initially treated by transabdominal resection should receive six months of adjuvant therapy, consisting of a "sandwich regimen" of two-month fluoropyrimidine-based chemotherapy followed by concurrent chemotherapy and radiation, followed by another 2 mo of chemotherapy.

Previously, the standard adjuvant chemotherapy regimen for rectal cancer was 5FU with or without leucovorin. The use of combination oxaliplatin, 5FU and leucovorin (FOLFOX4) or capecitabine in adjuvant treatment has been extrapolated from data available for colon cancer. According to the MOSAIC trial[103], FOLFOX4 compared to 5FU + leucovorin improved DFS and OS in stage Ⅲ colon cancer patients. The X-ACT study[104] showed that, in terms of DFS and OS, the efficacy of capecitabine in adjuvant treatment of stage Ⅲ colon cancer was comparable to that of 5FU + leucovorin.

There has been much consideration of the need for adjuvant chemotherapy in patients who have already received preoperative chemoradiation. The EORTC 22921 study[28,105] assessed the value of adjuvant chemotherapy in patients undergoing preoperative CRT followed by surgery. Patients were allocated into four arms: preoperative RT; preoperative CRT; preoperative RT + adjuvant chemotherapy; and preoperative CRT + adjuvant chemotherapy. No difference in OS was found between the groups receiving preoperative and postoperative chemotherapy (P = 0.12). The addition of chemotherapy after preoperative CRT did not impact rates of local recurrence or survival. Of concern, however, is the fact that only 42.9% of assigned patients adhered to their postoperative chemotherapy regimens. DFS and OS benefits were shown in the subgroup of patients with pathological T (ypT) 0-2 cancers[106]. These results indicate that patients who do obtain downstaging after CRT may be more likely to derive a survival benefit from adjuvant chemotherapy as well.

Given that most of the patients in EORTC 22921 did not receive adequate doses of adjuvant chemotherapy, we cannot assume from this study that adjuvant chemotherapy is definitely not beneficial to patients receiving neoadjuvant chemoradiation. To date, preoperative chemoradiation followed by surgery and adjuvant chemotherapy remains the standard of practice in the United States for treating stage Ⅱ and Ⅲ rectal cancers[6] regardless of final pathological results. Options for adjuvant chemotherapy include four months of FOLFOX, capecitabine, or 5FU + leucovorin.

CLINICAL COMPLETE RESPONSE: CAN SURGERY BE AVOIDED?

Habr-Gama *et al*[107] have proposed a definition of clinical complete response (cCR), based on the findings of clinical and endoscopic examination, as follows: (1) whitening of the mucosa in an area of the rectal wall; (2) any associated telangiectasia; (3) scarring of the rectal wall (which manifests as a slight stiffness of the wall during insufflation); and (4) if tumor cannot be felt or seen. These parameters are subjective, however, and require more clinical substantiation. Moreover, cCR may not be equivalent to pCR. Surgery is still the standard of management following neoadjuvant chemoradiation[6,86].

There have been studies of local excision as an option for patients with cCR after neoadjuvant chemoradiation[108,109]. However, complete response of the primary tumor cannot predict response in regional lymph nodes, which are involved in 7%-17% of patients who have cCR of the primary tumor[110-112]. For this reason local excision may not be adequate treatment of these patients. In the setting of low-lying rectal cancer, sphincter-preserving procedures (intersphincteric dissection with coloanal anastomosis) may be performed in patients who obtain a tremendous response from neoadjuvant chemoradiation[20].

Habr-Gama *et al*[113] have also reported very interesting long-term outcomes of observational management in patients with cCR following neoadjuvant chemoradiation. They selected the 122 of 361 patients who received

neoadjuvant chemoradiation and were considered to have cCR. These patients had very low rates of both local recurrence and distant metastasis (5% and 7%, respectively). Isolated local recurrences confined to the rectum developed in 5% of patients over a median follow-up period of 59.9 mo[114]. Significantly more data from larger studies will be required to evaluate this approach. Nevertheless, observational management may be an alternative choice for some carefully selected patients.

CONCLUSION

Concurrent chemoradiotherapy is widely accepted as an effective way to achieve local control and survival in patients with locally advanced rectal cancer. The accuracy of preoperative staging is crucial in preventing under- or over-treatment. ERUS and MRI are suitable imaging tools for local preoperative staging, while CT and PET are helpful in evaluation of metastasis. Fluoropyrimidine-based chemotherapy (either 5FU or capecitabine) used concurrently with radiotherapy is the standard treatment. The addition of oxaliplatin increases toxicity without having any significant impact on tumor sterilization.

Optimal timing of surgery remains unclear. Previous recommendations to resect at 6-8 wk after neoadjuvant chemoradiation appear reasonable; but a longer interval may increase tumor downsizing. However, the effect of a longer waiting time on long-term outcome is yet to be defined.

The accuracy of studies attempting to determine tumor response remains problematic. Clinical complete response, as determined by existing methods, may not be equivalent to pCR. At this time, surgery remains the standard of care for rectal cancer patients following neoadjuvant chemoradiation. Observational management is still investigational but may be used in carefully selected high-risk patients, ideally in the setting of a clinical trial. Pathologic features such as ypT, ypN, tumor response, and CRM are accurate prognostic factors associated with long-term outcome.

Extrapolating from colon cancer trials, adjuvant chemotherapy (5FU/leucovorin, capecitabine or FOLFOX) remains the standard of care following rectal cancer resection, irrespective of pathologic response. Future directions will require a rethinking of management strategies, and may include different optimal drug combinations, treatment sequences, and approaches to neoadjuvant radiation, chemotherapy and/or targeted therapy. The goal is to achieve improvement in response and patient survival. The challenges include individualizing care to improve long-term oncologic outcome, while minimizing toxicity and maintaining quality of life.

Abstract

Oxidative stress has been shown to play an important role in the pathogenesis of acute pancreatitis (AP). Antioxidants, alone or in combination with conventional therapy, should improve oxidative-stress-induced organ damage and therefore accelerate the rate of recovery. In recent years, substantial amounts of data about the efficiency of antioxidants against oxidative damage have been obtained from experiments with rodents. Some of these antioxidants have been found beneficial in the treatment of AP in humans; however, at present there is insufficient clinical data to support the benefits of antioxidants, alone or in combination with conventional therapy, in the management of AP in humans. Conflicting results obtained from experimental animals and humans may represent distinct pathophysiological mechanisms mediating tissue injury in different species. Further detailed studies should be done to clarify the exact mechanisms of tissue injury in human AP. Herein I tried to review the existing experimental and clinical studies on AP in order to determine the efficiency of antioxidants. The use of antioxidant enriched nutrition is a potential direction of clinical research in AP given the lack of clues about the efficiency and safety of antioxidant usage in patients with AP.

INTRODUCTION

Acute pancreatitis (AP) can present as a wide clinical spectrum ranging from a mild, self-limiting localized disease to fatal widespread multi-organ failure with high mortality rates. Mild pancreatitis is the inflammation and edema of the pancreas, with additional features of necrosis and secondary injury to extrapancreatic organs in severe pancreatitis[1-3]. AP is characterized by acute inflammation and necrosis of pancreatic parenchyma, necrosis of pancreatic fat, hemorrhage, and inflammatory infiltration[4]. Since pancreatic cell death occurs according to either necrosis or apoptosis mechanisms, many necrotic and apoptotic cells can be seen within pancreas parenchyma. The study of Booth *et al*[5] found that oxygen free radical (OFR) induction in acinar cells promoted apoptosis whereas inhibition of OFR generation led to an increase in necrosis accompanied by reduced ATP. These findings suggest that OFR generation within acinar cells may be a protective response during pancreatitis. The main reason for necrotic or apoptotic cell death is the early activation of pancreas zymogens, especially cathepsin and trypsinogen inside the pancreas. Scott *et al*[6] showed that excessive OFR in

a pathologic state can cause tissue and cell damage. The OFR participates in the pancreas edema process in AP, and may participate in the pancreas necrosis process. Furthermore, OFR are involved in the generation of pain as another important clinical feature of patients suffering from AP[7]. The OFR, as highly reactive species, directly attacks lipids and proteins in the biological membranes and thus disrupts their functions. The action of OFR includes oxidation of lipids in the pancreatic cell membrane and oxidatively modified proteins, depolarization of the mitochondrial membrane, and induction of DNA fragmentation[8].

Aerobic organisms require ground state oxygen to live; however, the use of oxygen during normal metabolism produces OFR[9,10]. OFR are required for the maintenance of tissue homeostasis. Physiologic levels of OFR can regulate transcription, serve as signal molecules and defend against pathogen infections[11]. The mitochondria, endoplasmic reticulum, cytosol, and nuclear membranes have all been shown to be sources of OFR[12]. The primary function of the electron transport chain located in the inner mitochondrial membrane is ATP synthesis via oxidative phosporylation[13]. The superoxide radical formed during cellular metabolism is mainly produced during electron transport in the mitochondria and is released to both the mitochondrial matrix and intermembrane space[9,10,14,15]. Superoxide, depending on its location, causes potential oxidative damage to different proteins and lipids, as well as DNA[16]. The end product of the respiratory chain is water generated in a four-electron reduction of molecular oxygen. However, a small portion of oxygen is involved in the generation of OFR, including superoxide anion radicals, hydrogen peroxide, hypochlorous acid, and the extremely reactive hydroxyl radical[10,17]. These free radicals, each containing an unpaired electron, are energetically unstable and highly reactive. OFR can attack the double bonds of unsaturated phospholipids in cell membranes, which eventually degrade the structural integrity of cell membranes. Lipid oxidation can lead to the loss of the integrity of both plasma membrane and intracellular membranes, such as that of lysozomes and the endoplasmic reticulum, which then leads to an intracellular leak of proteases or an influx of Ca2+ resulting in necrosis[18]. OFR also impairs the functions of enzymes by causing fragmentation of polypeptide chains or cross-linking sulfhydryl groups in proteins. In addition, they cause strand breaks or abnormal cross-linking in DNA[19-21]. Damage to DNA may lead to a DNA-damage response, including activation of p53 and poly-ADP ribose polymerase (PARP) (a nuclear enzyme). While activation of p53 causes apoptosis and cell cycle arrest, hyperactivation of PARP leads to necrosis[22]. The hydroxyl radical is the most reactive species and can attack and damage almost all molecules found in the living cell. Being so reactive, it attacks DNA, a free radical chain reaction cascades through the DNA and causes chemical alterations of the bases as well as strand breakage. The best characterized biological damage caused by hydroxyl radicals may be their ability to stimulate the free radical chain reaction known as lipid peroxidation[12,23]. One hydroxyl radical can result in conversion of many hundred fatty acid chains into lipid hydroperoxides. Accumulation of lipid hydroperoxides in a membrane disrupts its functioning. Some of the products of lipid peroxidation, malonaldehyde (MDA) and 4-hydroxynonenal, increase the permeability and deformability of the membranes in which they are found. Mitochondrial membranes are particularly susceptible to this sort of damage, perhaps because they combine a high risk of OFR-mediated peroxidation[12]. We have shown mitochondrial degeneration within pancreatic acinar cells in experimental pancreatitis[1,24].

OFR indirectly act on the arachidonic acid cascade by increasing the production of thromboxane, which lowers tissue circulation by its potent platelet-aggregating and vasoconstricting effects[25]. Additionally, OFR enhance the production of leukotriene B4 which promotes activation of leukocytes and discharge of lysosomal enzymes[26]. As a secondary effect, polymorphonuclear leukocytes are responsible for the respiratory burst that leads to an enhanced production of radical species and activated enzymes and further cell damage[27]. The results of Rau *et al*[28] indicate that OFR play an important mediator function in early and later courses of AP. Their findings suggest that OFR species are important mediators but not necessarily triggers of tissue damage in AP. The degree of oxidant-antioxidant balance changes in the early phase of human AP, correlating with the clinical severity of pancreatitis[29]. Park *et al*[30] reported higher plasma levels of lipid peroxides and myeloperoxides and lower superoxide dismutase (SOD) activity in patients with severe AP than in those with mild AP. OFR may thus be closely associated with the inflammatory process and the severity of AP. Thareja *et al*[31] reported that high oxidative stress was observed during the early phase of AP and that gradually improving antioxidant status was associated with a better clinical outcome in patients with AP. The concentration of plasma lipid peroxides is a particularly meaningful index for determining the severity of the disease in humans[30,32].

During the later stages of AP, the major pathophysiological role seems to be the attraction and activation of leukocytes, which in turn contribute to enhanced radical generation and acinar cell damage[33,34]. Oxidative stress in the neutrophils (activated during the inflammatory response to acinar injury) may be responsible for further propagation of local and systemic inflammation[5]. Synergy between pro-inflammatory cytokines and oxidative stress occurs in the development of the inflammatory response in AP[35]. Proinflammatory cytokines such as interleukin (IL)-1, 6 and tumor necrosis factor (TNF) and microvascular ischemia are also important factors in the pathophysiology of AP[33,34]. Serum levels of proinflammatory cytokines, such as TNF-alpha and IL-1beta, increase during the course of AP and appear to be the driving force for the initiation and propagation of

the systemic response. Accordingly, pretreatment with either an antibody against TNF-alpha or a blockade of TNF-alpha production with pentoxifylline ameliorates experimental AP[36]. A cross-talk between oxidative stress and proinflammatory cytokines, particularly TNF-alpha amplifies the inflammatory cascade through different mechanisms, such as the activation of mitogen activated protein kinases and nuclear factor-kappa B (NF-κB) and/or the inactivation of protein phosphatases[35,37-39].

In addition to increased levels of plasma and tissue lipid peroxides, decreased levels of plasma antioxidants such as vitamin A, vitamin C[40], vitamin E[41], selenium[42], β carotene, whole-blood glutathione, and the activity of plasma glutathione peroxidase[21] have been found in patients with AP. Moreover, lower levels of selenium in toenails of AP patients and lower selenium concentrations in red blood cells of patients with severe AP have been detected[40].

Since experimental[42,43] and clinical studies[31,44] have provided some support for the concept that oxidative stress is the common pathway for the pathogenesis of AP, one reasonable idea is to use antioxidant regimens in the management of AP to complement its traditional therapy. In fact elucidation of all of the mechanisms above mentioned and their interactions is critical in developing a treatment based on the pathophysiology of AP. However, clinical evidence showed that antioxidant administration to patients with AP was not as beneficial as the antioxidant administration to experimental animals. Perhaps the key steps in the pathogenesis of AP are not yet fully understood. It is not possible to clearly determine whether oxidative stress is a cause or an effect of AP. This review highlights the experimental and clinical evidence of the benefit of various antioxidants in AP.

ANTIOXIDANT THERAPY IN AP

Antioxidants may function to prevent the formation of, or to detoxify, free radicals or to scavenge OFR. Halliwell[45] has proposed this useful definition, "an antioxidant is any substance that, when present at low concentrations compared to those of an oxidizable substrate, significantly delays or prevents oxidation of that substrate". In experimental pancreatitis, the beneficial effects of antioxidants may be associated with the inhibition of NF-κB activity[46]. Types of antioxidants include antioxidant vitamins (e.g., ascorbic acid, α tocopherol, β-carotene), inorganic antioxidants (e.g., selenium), synthetic antioxidants (e.g., butylated hydroxyanisole), and a range of plant-derived polyphenols[47]. Organisms widely use glutathione peroxidase, glutathione transferase, SOD, catalase (CAT), and a variety of other antioxidants to protect themselves against generation of OFR[48-50]. Some authors have studied the effects of various antioxidants in experimental animals and patients with AP. They used both natural and synthetic antioxidants in order to protect the pancreas from deleterious effects of OFR. The following sections summarize data obtained from experimental and clinical studies about the efficacy of some oxidants in AP.

Alpha tocopherol

Tocopherols belong to a class of phenolic antioxidants which can inhibit lipid auto-oxidation by scavenging free radicals and by reacting with singlet oxygen. The vitamin E activity of alpha-tocopherol may be attributed to its efficient inhibition of *in vivo* lipid oxidation[51]. Fat-soluble antioxidants act directly in the lipid bilayer of plasma and cell membranes by interacting with membrane lipophilic components. A natural antioxidant, alpha-tocopherol has been found to be beneficial in inhibiting intermolecular connections of lipid peroxides in liver of dogs with AP[52]. Vitamin E, including tocopherols and tocotrienols, is a fat-soluble antioxidant. To my knowledge the effect of vitamin E on AP has not been studied. Since they accumulate within tissues, fat-soluble substances have high toxic risk thereby limiting their clinicical application and widespread utilization. The results of combined therapies, including vitamin E, will be discussed below.

Ascorbic acid

Ascorbic acid functions in multiple, complex ways, acting as a hydrogen donor, a metal inactivator, and a peroxide destroyer[31]. The study of Bonham *et al*[53] demonstrated that plasma ascorbic acid concentration was significantly below normal in patients with early phase AP; however, Sajewicz *et al*[32] reported that patients with AP had double the plasma ascorbic acid values than healthy volunteers. Few studies have investigated the therapeutic efficacy of ascorbic acid in experimental animals with AP whereas many have examined its effects singly or within an antioxidant mixture in patients with AP. Two decades ago, Nonaka *et al*[54] reported that CV3611, a synthetic free radical scavenger prepared from ascorbic acid, had an important therapeutic effect on the development of AP in mice. However since then, another experimental or clinical study evaluating the benefit of this agent in AP has not been performed. Du *et al*[55] have reported that high dose vitamin C has a therapeutic effect in humans with AP. Their results indicate that vitamin C decreases hospitalization and duration of disease, and increases the cure rate by blocking lipid peroxidation, diminishing proinflammatory cytokines, and improving cellular immune function. The results of combination therapies will be discussed below.

Beta-carotene

Beta-carotene protects lipids by interfering with photosensitized oxidation, and behaves as a reducing agent by trapping radicals. In addition to its singlet oxygen-quenching properties, beta-carotene has good radical-trapping properties at low partial pressures of oxygen, a condition which prevails in healthy tissues. In biological systems, alpha-tocopherol and beta-carotene exhibit synergism by mutually reinforcing their respective activities.

Synergism also takes place in a cascade where ascorbic acid can be regenerated at the expense of more oxidizable substrates[51]. In patients with mild AP, the concentrations of beta-carotene at final review has been found significantly higher than those in patients with severe AP[56]. The correlation between low antioxidant level and high severity of disease suggests the utility of antioxidant supplementation therapies. Lavy *et al*[57] have reported some possible protective effects of treatment with beta carotene in regards to the severity of post-endoscopic retrograde cholangiopancreatography pancreatitis (ERCP). In a double-blind trial, 321 patients were given a single dose of natural beta carotene. The rate of severe pancreatitis was found to be lower in the beta carotene-treated group. Adverse events were not reported.

Caffeic acid phenethyl ester

Caffeic acid phenethyl ester (CAPE) is a phenolic compound and an active substrate of propolis. Several investigators have shown that CAPE acts as an anti-inflammatory by inhibiting the release of arachidonic acid from cell membranes, and suppressing cyclooxygenase (COX)-1 and COX-2 enzyme activities[58], and reducing antioxidant activity by lipoxygenase inhibition[59,60]. Buyukberber *et al*[46] have found CAPE to be benefical in improving the biochemical and histopathological findings in cerulein-induced AP in rats. Turkyilmaz *et al*[61] have also reported the beneficial effect of CAPE on acute necrotizing pancreatitis in rats. To my knowledge, no clinical data has been reported about the effect of CAPE on AP in humans. The data obtained from experimental animals are promising. CAPE has been shown to inhibit the production of proinflammatory cytokines by inhibiting nuclear transcription factor activity[62].

Carnitine

As an antioxidant, acetyl l-carnitine culminate most probably protects tissues from oxidative stress by stabilizing cell membranes, rendering them more resistant to free radicals, perhaps by facilitating the repair of the phospholipid bilayer damaged by oxidant stress, rather than acting as a direct scavenger of free radicals or decreasing their generation[63]. Data so far obtained would suggest that prior administration of acetyl l-carnitine ahead of caerulein challenge has proven protective efficacy that could possibly be ascribed, in part, to its regulation of the oxidant/antioxidant balance and modulation of nitric oxide (NO) release and myeloperoxidase activity that may ultimately lead to regulation of the inflammatory events associated with AP[64].

Green tea

Another naturally occurring antioxidant comes from the caffeine-free extract from leaves of green tea (Camellia sinensis), shown to reduce the degree of AP and attenuate the activation of the transcription factor NF-κB, as well as the formation of proinflammatory cytokines[65]. It also significantly decreases lipid peroxidation[65,66] and the formation of nitrogen-derived radicals in rodents[65].

Melatonin

Melatonin, the hormone produced mainly by the pineal gland, has been studied widely. Both *in vitro* and *in vivo* studies have identified melatonin as a potent scavenger of highly toxic hydroxyl radical and other oxygen-based radicals. Potent anti-inflammatory effects of melatonin may be related to a reduction of the inflammatory mediators produced during the inflammatory process[67]. Several experimental studies showed that melatonin is effective in reducing oxidative stress-mediated AP in rodents[68,69]. Recently, we reported a potent therapeutic effect of melatonin on caerulein-induced AP and associated liver injury[1]. We also demonstrated its potent effect on the protection of cell ultrastructure[43]. Melatonin decreases tissue MDA levels and increases antioxidant enzyme levels or activities[1,3,43]. Melatonin treatment was found to promote the spontaneous regeneration process of pancreatic tissue in rats[69]. Jaworek *et al*[70] have reported that pinealcetomy aggravates AP in the rat. Interestingly, Belyaev *et al*[71] presented the dynamic changes of endogenous melatonin in the early phase of human AP. Melatonin concentrations during the first 24 h after the onset of pain in younger patients (< 35 years) were significantly higher than levels in older patients (> 35 years). They concluded that high endogenous serum melatonin levels in the first 24 h after the onset of AP played a protective role and favoured a mild disease course in humans, especially in young patients. Another clinical study performed by Chen *et al*[72] indicates that delayed neutrophil apoptosis is associated with mild and severe AP in humans. Neutrophil apoptosis plays a critical role in minimizing the autodestructive potential of neutrophils. The data from the study show that melatonin promotes neutrophil apoptosis in human AP. Melatonin administration is promising for the treatment of AP in humans. However, further studies are still needed.

N-acetyl-cysteine

N-acetyl-cysteine (NAC) is a thiol compound which, by providing sulphydryl groups, can act both as a precursor of reduced glutathione and as a direct free scavenger, hence regulating the redox status in the cells. In this way, it can interfere with several signaling pathways that play a role in regulating apoptosis, angiogenesis, cell growth and arrest, and inflammatory response[73]. NAC has been found to be hugely effective in reducing oxidative stress-induced pancreatic injury in rats[74,75] by enhancing the ability of acinar cells to produce IL-10[74], preventing the impairment of Ca^{2+}[75], and downregulating the expression of chemokines, monocyte chemotactic protein-1, and macrophage inflammatory protein-2[76]. Moreover extrapancreatic complications (liver and lung injury) during AP induced by bile-pancreatic duct obstruction were palliated by NAC treatment[77]. Onur *et al*[78] have reported that NAC, especially combined with hyperbaric oxygen, decreases oxidative stress parameters, serum amylase, cal-

cium, and lactate dehydrogenase levels, as well as the histopathological score. To our knowledge, only one study shows the effects of NAC in patients with AP. Recently, Milewski *et al*[79] investigated the effects of NAC (administered by intravenous or oral route) on post-ERCP. Regretfully, NAC failed to demonstrate any significant preventive effect on post-ERCP pancreatitis or on serum and urine amylase activity. The results of combination therapies, including NAC, will be discussed below.

Resveratrol

Alcoholic AP predominates in countries where other forms of alcoholic drinks rather than wine are preferred. Presumably, wine contains factors that protect the pancreas against alcohol-induced AP. One of these factors may be resveratrol. Resveratrol, a naturally occurring antioxidant, acts as a free radical scavenger[80], but to date, no clinical study has been performed on antioxidant and free radical scavenger potentials of resveratrol on AP. Resveratrol has been found beneficial in AP in rats[81-83]. Lawinski *et al*[84] found stilbene derivatives (resveratrol and diethylstilbestrol) effective in preventing pancreatic cells from structural changes to OOH-induced AP in Wistar albino rats. Resveratrol and diethylstilbestrol protect the pancreas against prooxidative activity of hydroperoxide; stilbene derivatives significantly inhibit the free radical generating reactions. Leonard *et al*[85] have demonstrated that resveratrol can clear hydroxyl, superoxide, and metal inductive radicals. Kimura *et al*[86] have found that resveratrol inhibits lipoxygenase, an enzyme that is converted into powerful inflammatory and white cell stimulating agents known as leukotrienes, hepoxillins, and lipoxins through arachidonic acid. Resveratrol may exert its therapeutic effect on severe AP by lowering pancreatic OFR and reducing pancreatic tissue infiltration of neutrophils[87]. Due to its strong effect of inhibiting activation of NF-κB and reducing secondary activation of cytokines, resveratrol is regarded as a promising drug for blocking the initiation and progress of AP. Though no document as yet illustrates the function of resveratrol in AP in humans, primary trials have found that resveratrol could inhibit the production of TNF and IL-6 in pancreatitis. More research is required[87]. An increasing amount of data has confirmed that resveratrol could relieve the pathologic injury of the pancreas and extra-pancreatic organs (intestines, brain, lungs, *etc*.) induced by severe AP[88-90]. Further clinical studies are needed.

Quercetin

Quercetin is a naturally occurring plant flavonoid abundantly present in onions, fruits, and Chinese herbs. Several studies pointed out the beneficial biological activities of quercetin which include antioxidant, antiinflammatory, antiatherosclerotic, and anti-tumor properties[91-93]. The study of Carvalho *et al*[94] has demonstrated that the flavonoid quercetin attenuates the severity of cerulein-induced AP in mice. In particular, they reported that quercetin treatment reduces pancreatic inflammation and associated tissue injury through suppression of neutrophil infiltration, TNF-alpha, IL-1β and IL-6 cytokine production, and TNF-alpha expression, and increased IL-10 cytokine production. Since high oral and subcutaneous doses of quercetin did not manifest any clinical signs of toxicity, it may be safe and nontoxic in the treatment of AP; however, further experimental and clinical investigations are needed.

Selenium

Selenium, a trace element necessary for cellular function in many organisms, is a co-factor for the antioxidant enzyme glutathione peroxidase[95]. Glutathione peroxidase catalyses the reduction of both hydrogen peroxide and lipid hydroperoxides[96] and as such acts as an intracellular defence against free radical injury[97]. Nowadays, the role of micronutrients, in particular selenium, is receiving increased attention. Lower levels of selenium in toenails of AP patients and lower selenium concentrations in red blood cells of patients with severe AP have been found[40]. Selenium administration 24 h after induction of experimental AP has been demonstrated to be associated with amelioration of pancreatic injury and lung injury although it has not reversed the diminished serum selenium level[98]. Kuklinski *at al*[99] reported their clinical results of 4 years of selenium therapy. They concluded that an improvement in the prognosis of AP could be achieved if antioxidative selenium therapy with sodium selenite was introduced in time. In rare cases, total necroses and complications in organs only occurred in those patients who were admitted to this therapy too late. Wollschläger *et al*[100] reported that selenium therapy caused a significant increase in selenium, a moderate increase in glutathione peroxidase activity, and a significant decrease in MDA activity, while SOD remained unchanged in patients with AP. Lindner *et al*[101] did report, however, that substitution of sodium selenite had no beneficial effect of the clinical outcome of patients with AP (32 selenium administered, 35 placebo administered). On the other hand, Kocan *et al*[102] found selenium to be beneficial in decreasing inflammation in one patient with AP. The results of combination therapies including selenium will be discussed below.

RESULTS OF COMBINED ANTIOXIDANT THERAPIES

Recently we reported the beneficial effect of an antioxidant mixture of NAC and ascorbic acid on experimental AP in rats. The antioxidant mixture reduced tissue MDA levels and increased tissue CAT and glutathione peroxidase activities[1,42] in L-arginine-induced experimental AP. Hardman *et al*[103] have demonstrated that early exogenous anti-oxidant intravenous supplementation using a combination of NAC, selenium, and vitamin C reduces pancreatic injury in rats. However, a case-control study demonstrated no benefit from intravenous administration of these multicompound anti-oxidants in clinical

AP although critically, many patients in the clinical study received antioxidants relatively late in the course of the disease[104]. A randomized trial by Siriwardena *et al*[105] also failed to show any benefit to AP patients given selenium intravenously as part of a cocktail of antioxidants including NAC and vitamin C. On the other hand, Sateesh *et al*[106] demonstrated the beneficial effects of vitamin C and NAC on decreasing oxidative stress and improving antioxidant status in 23 patients with AP. They concluded that antioxidant supplementation associated with standard medical treatment may decrease the length of hospital stay and rates of complications in patients with AP, but a larger clinical trial is needed to support this hypothesis. The study of Bansal *et al*[107] showed that vitamin-based antioxidant therapy had no significant beneficial effect on organ dysfunction or on clinical outcomes in severe AP during the hospital stay. They administered vitamin A (intramuscularly), E (orally) and C (intravenously) together for a period of 14 d. Kuklinski *et al*[108] showed the beneficial effect of an adjuvant antioxidant therapy with selenium and D-alpha-tocopherol in 90 patients with necrotizing or mild AP. They reported that the average lethality rate of 34% fell to 1.1%. This study represents the vital benefits of antioxidant therapy. Uden *et al*[109] administered organic selenium, beta carotene, vitamin C, vitamin E and methionine to patients with recurrent pancreatitis (idiopathic chronic 8, alcoholic chronic 7, and idiopathic acute 5) and they reported the beneficial role of antioxidants in pain reduction. Recently, Zhao *et al*[110] reported the significant beneficial effects of the combination of ebselen and ethylhydroxyethyl cellulose (EHEC) on severe AP in Sprague Dawley rats. The mixture prevented pancreatitis- induced multiple organ injury. Ebselen (2-phenyl-1,2-benzisoselenazol-3(2H-one) is a non-toxic selenoorganic drug with anti-inflammatory, antiatherosclerotic, and cytoprotective properties that downregulates the production of OFRs[111,112]. Ebselen is a mimic of glutathione peroxidase that also reacts with peroxynitrite and can inhibit enzymes such as lipoxygenases, NO synthases, nicotinamide adenine dinucleotide phosphate oxidase, protein kinase C and H(+)/K(+)-ATPase[113,114]. The combination of ebselen and EHEC may be a new potential for treatment of severe AP[110].

While the trial clearly showed that the given combination of antioxidants was not effective in patients with AP when administered intravenously, antioxidants administered through another route may be beneficial, given that the benefits of enteral versus parenteral nutrition in patients with AP are well proven[115,116]. In particular, a growing body of clinical evidence from other disease settings suggests that supplementation of enteral nutrition with antioxidants can be beneficial[117,118].

In conclusion, based on the reported experimental studies, using antioxidant regimens in the management of AP as a supplement and combined with traditional therapy is rational and reasonable. If this hypothesis is correct, antioxidant therapy should reduce the inflammatory process involved in pancreatitis and thereby accelerate the recovery rate. Some of the antioxidants have been shown to be beneficial in the treatment of human AP. However, the present studies indicate that insufficient clinical data support using antioxidants alone or in combination with conventional therapy in the management of AP. Further double blind, randomized, placebo-controlled clinical trials with a larger sample size need to be conducted.

Abstract

AIM: To investigate the impact of dietary copper given at different time points on the onset of fulminant hepatitis.

METHODS: The Long-Evans cinnamon (LEC) rat model of Wilson's disease (WD) was used to study the impact of high dietary copper (hCu) on the induction of fulminant hepatitis at early or late time points of life. High Cu diet was started in rat pups or in adults (month 5) for three months. Animals that received reduced dietary copper (rCu) throughout their lifetime served as a control. Hepatitis-associated serum markers (alanine aminotransferase, aspartate transaminase, bilirubin) were analyzed in animal groups receiving hCu or rCu. Liver copper content and liver histology were revealed at sacrifice. A set of 5 marker genes previously found to be affected in injured liver and which are related to angiogenesis (*Vegfa*), fat metabolism (*Srebf1*), extracellular matrix (*Timp1*), oxidative stress (*Hmox1*), and the cell cycle (*Cdkn1a*) were analyzed by real-time polymerase chain reaction.

RESULTS: Regardless of the time point when hCu was started, LEC rats (35/36) developed fulminant hepatitis and died. Animals receiving rCu (36/36) remained healthy, did not develop hepatitis, and survived long term without symptoms of overt disease, although liver copper accumulated in adult animals (477 ± 75 μg/g). With regard to start of hCu, onset of fulminant hepatitis was significantly ($P < 0.001$) earlier in adults (35 ± 9 d) that showed pre-accumulation of liver copper as compared to the pup group (77 ± 15 d). Hepatitis-associated serum markers, liver copper and liver histology, as well as gene expression, were affected in LEC rats receiving hCu. However, except for early and rapid onset of hepatitis, biochemical and molecular markers were similar at the early and late time points of disease.

CONCLUSION: Rapid onset of fulminant hepatitis in asymptomatic LEC rats with elevated liver copper suggests that there is a critical threshold of liver copper which is important to trigger the course of WD.

INTRODUCTION

Wilson's disease (WD) is a genetic disorder transmitted by a recessive gene located on chromosome 13[1,2]. Diagnosis of WD is mostly established on the basis of combined biochemical and clinical parameters, and lately by specific genetic analysis[3-6]. Presentation of WD includes hepatic insufficiency, acute and chronic active hepatitis, fulminant hepatitis and/or extra hepatic manifestations. Although it is a rare disease, fulminant hepatitis is frequently observed in WD patients and is followed by high mortality that accounts for approximately 5% of acute liver failure (ALF) observed worldwide. The disease is linked to an imbalance of copper homeostasis that is due to mutation of the *ATP7B* copper transporter gene expressed primarily in the liver[7,8]. More than 600 mutations have been reported in human *ATP7B*. Effective drug treatment of WD has been established which aims at chelation or reduction of copper[1]. However, compliance to take lifelong treatment or to reduce dietary copper intake is low in patients[9]. Liver transplantation remains the only treatment option of WD patients encountering ALF.

In healthy individuals copper is absorbed *via* the intestine and delivered to the liver, where it is either transferred by *ATP7B* into ceruloplasmin that is secreted into blood or exported *via* bile[2]. Malfunction of the *ATP7B* gene in WD patients leads to large quantities of toxic copper in the liver and other organs. However, manifestation and onset of the disease induced by toxic copper can vary to a great extent between WD patients[10-12]. Individual mutations of the *ATP7B* gene as well as mutations outside of this locus have been implicated to be important for the course of the disease as suggested, e.g., by rare studies of twins having the same mutation of the *ATP7B* gene but presenting different courses of WD[13,14]. Besides genetic factors, environmental factors, such as the amount of dietary copper intake, may also have an impact on WD[15,16]. However, studies of such factors are difficult in humans.

Much has been learned from animal models of WD. The Long-Evans cinnamon (LEC) rat has a large deletion of the *ATP7B* gene[17] and has many characteristics that are also observed in patients, e.g., low ceruloplasmin, high liver copper levels, and sensitivity to anti-copper therapy. The LEC rat strain can be housed on a commercial diet containing standard copper concentrations (about 7-15 mg/kg). Using this standard chow, 40%-60% of LEC rats spontaneously encounter fulminant hepatitis at the age of 80-120 d[18]. The LEC rat is therefore a highly attractive model to analyze pathogenesis of the liver, and is also used to study the effect of novel therapeutic approaches for liver disease, e.g., hepatocyte transplantation or gene transfer[19,20].

In the present study, the role of low and high dietary copper given at different time points was investigated in male and female LEC rats. We hypothesized that preloading of copper may affect the course and onset of disease. A high copper (hCu) diet was given to juvenile and adult rats that could pre-accumulate liver copper. The impact on hepatitis, liver copper, histology, gene expression, and survival was examined.

MATERIALS AND METHODS

Animals

LEC rats that lack functional *ATP7B*[17] and Long-Evans agouti (LEA) rats expressing wild-type *ATP7B* were a kind gift of S. Gupta (Albert Einstein College of Medicine, New York, United States). Rats were genotyped for *ATP7B* by polymerase chain reaction (PCR) analysis using primers essentially as described previously[21]. For the hCu regimen, animals received a solid diet that contains a standard concentration (13 mg/kg) of copper (1324, Altromin, Germany). Animals of the hCu groups additionally received tap water containing 20 mg copper/L [copper (Ⅱ) chloride, Sigma-Aldrich]. For the reduced copper (rCu) regimen, rats received a specialized solid diet (C1041, Altromin) with a copper content of 0.3 mg/kg and distilled tap water. Female rats (n = 12) which were reported to have higher sensitivity to copper[18,22] and male rats (n = 6) were analyzed for each group. LEA rats, heterozygotes and LEC rats housed on standard diet were used as controls. The incidence of severe jaundice with strong disturbance of common as well as spontaneous behaviour, and weight loss (> 20%) which was accompanied by coma, led to sacrifice of the animals. The protocol for animal use was approved by local authorities.

Analysis of serum samples

Blood was taken under retrobulbar anesthesia with isoflurane (1-chloro-2,2,2-trifluoroethyl difluoromethyl ether, Abbott). Activities of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) and total concentration of bilirubin in serum were analyzed photometrically using a Cobas Modular System (Roche Diagnostics, Germany). Ceruloplasmin oxidase activity was determined using the modified protocol of Schosinsky *et al*[23] adapted to a 96-well plate.

Liver histology

For histological evaluation, liver specimens were fixed by immersion for at least 24 h in 4% formaldehyde solution, and were subsequently dehydrated and embedded in paraffin wax in order to cut serial sections at a thickness of 5 μm. Morphologic parameters were determined after hematoxylin and eosin staining using standard protocols, and scored by a blinded observer, e.g., for polyploidy, steatosis, apoptosis, and proliferation.

Table 1 Genes analyzed by real-time polymerase chain reaction in liver

Gene symbol	Synonym	Accession number	Primer (forward/reverse)

Srebf1	Sterol regulatory element binding protein-1	AF286470	AGAAGGCCAGTGGGTACCTG TGCGGGCCACAAGAAGTAG

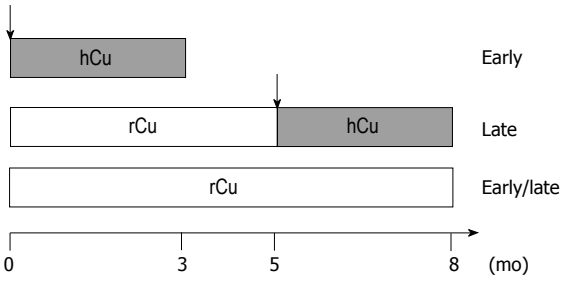

Figure 1 Schematic representation of study design. For the early copper regimen, Long-Evans cinnamon (LEC) rat pups received a high copper (hCu) diet up to month 3. For the late copper regimen, LEC pups were first housed on a reduced copper (rCu) diet until adult (month 5). Thereafter, rats received hCu for 3 mo up to the end of observation time (month 8). LEC rats received rCu diet throughout the observation period (early/late). *ATP7B* heterozygotes as well as Long-Evans agouti rats were also studied using an early hCu regimen. Arrow indicates start of hCu regimen.

Copper determination

For determination of copper content, liver samples were dried for 72 h at 70 ℃. Dry weight was determined using the analytical balance ME235S (Sartorius, Germany). Liver was redissolved in 65% nitric acid (Merck, Germany) and copper concentration was determined by flame atomic absorption spectroscopy (Shimadzu AA6300, Japan).

Real-time PCR analysis

Randomly chosen liver samples were immediately frozen after resection. Total RNA was extracted after disruption of tissue using a homogenizer and RNeasy kit (Qiagen, Hilden, Germany). Reverse transcription-PCR was carried out as described[24]. Briefly, RNA was reverse transcribed using SuperScript Ⅱ according to the instructions of the manufacturer (Invitrogen). Primers for PCR (Table 1) were synthesized by MWG Biotech (Germany). For quantitative real-time PCR, a SYBR® Green kit (Eurogentec, Belgium) was used. PCR was performed on the ABI PRISM™ 7900HT sequence detector (PE Applied Biosystems, United States). Each sample was tested in three independent experiments. The ct value was normalized to the expression of the house-keeping gene *HPRT* (Δct method). Relative expression level of gene normalized to house-keeping gene was determined by the equation $2^{\Delta ct}$ and fold-change was calculated thereafter.

Statistical analysis

Statistical analysis was performed using SPSS 17.0 software. Data are given as mean ± SE and median. Data were analyzed by the Student's two tailed *t* test using Bonferroni correction for post-hoc pairwise comparisons or Kruskal-Wallis test. Kaplan-Meier survival test and logrank test were performed for time to event data.

RESULTS

Onset of fulminant hepatitis

The role of low and high dietary copper in the induction of severe liver disease was studied with respect to the start of a copper diet in LEC rats of different age (Figure 1). A hCu was started early in pups or late in adults at month 5. The latter animals received a rCu up to month 5. The time point of hCu in adults was chosen to encompass the phase of fulminant hepatitis that occurs in LEC rats at the age of 80-120 d when using commercial chow[18]. LEC rats subjected to hCu displayed significantly elevated hepatitis-associated markers (Figure 2A), and developed severe jaundice (bilirubin > 2.0 mg/dL). With regard to start of hCu, levels of serum markers increased significantly earlier ($P < 0.001$) after the late regimen as compared with the early regimen (Figure 2B). Both genders displayed similar onset of significantly elevated serum markers (Table 2). LEC rats receiving a rCu diet or animals of the control groups did not develop hepatitis.

LEC rats (36/36) receiving rCu survived the observation period (8 mo), and no signs of overt morbidity were recorded in individual rats (18/18) as compared to controls, even when monitored beyond the observation period (up to month 20). In contrast, survival was significantly impaired ($P < 0.001$) in LEC rats (35/36) that received hCu (Figure 2C). LEC rats subjected to an early hCu regimen showed a mean survival of 77 ± 15 d that was only moderately shorter when compared to control LEC rats that were housed on a commonly used standard diet (84 ± 5 d). In contrast, LEC rats that received a late hCu regimen had a significantly reduced survival (35 ± 9 d) with regard to start of hCu. Survival of male and female LEC rats did not differ (Table 2).

Impact of dietary copper on liver histology

Nuclei of hepatocytes were found to be highly enlarged in LEC rats receiving early and late hCu regimens (Figure 3). Pronounced fatty acid changes, inflammation and, to a lesser extent, necrosis were observed in LEC rats receiving hCu. No marked changes in liver histology, including enlargements, fatty metamorphosis and inflammation, or cholangiofibrosis, that are routinely found in adults[18] were observed in LEC rats that received a rCu diet. The liver histology in the control groups was found to be

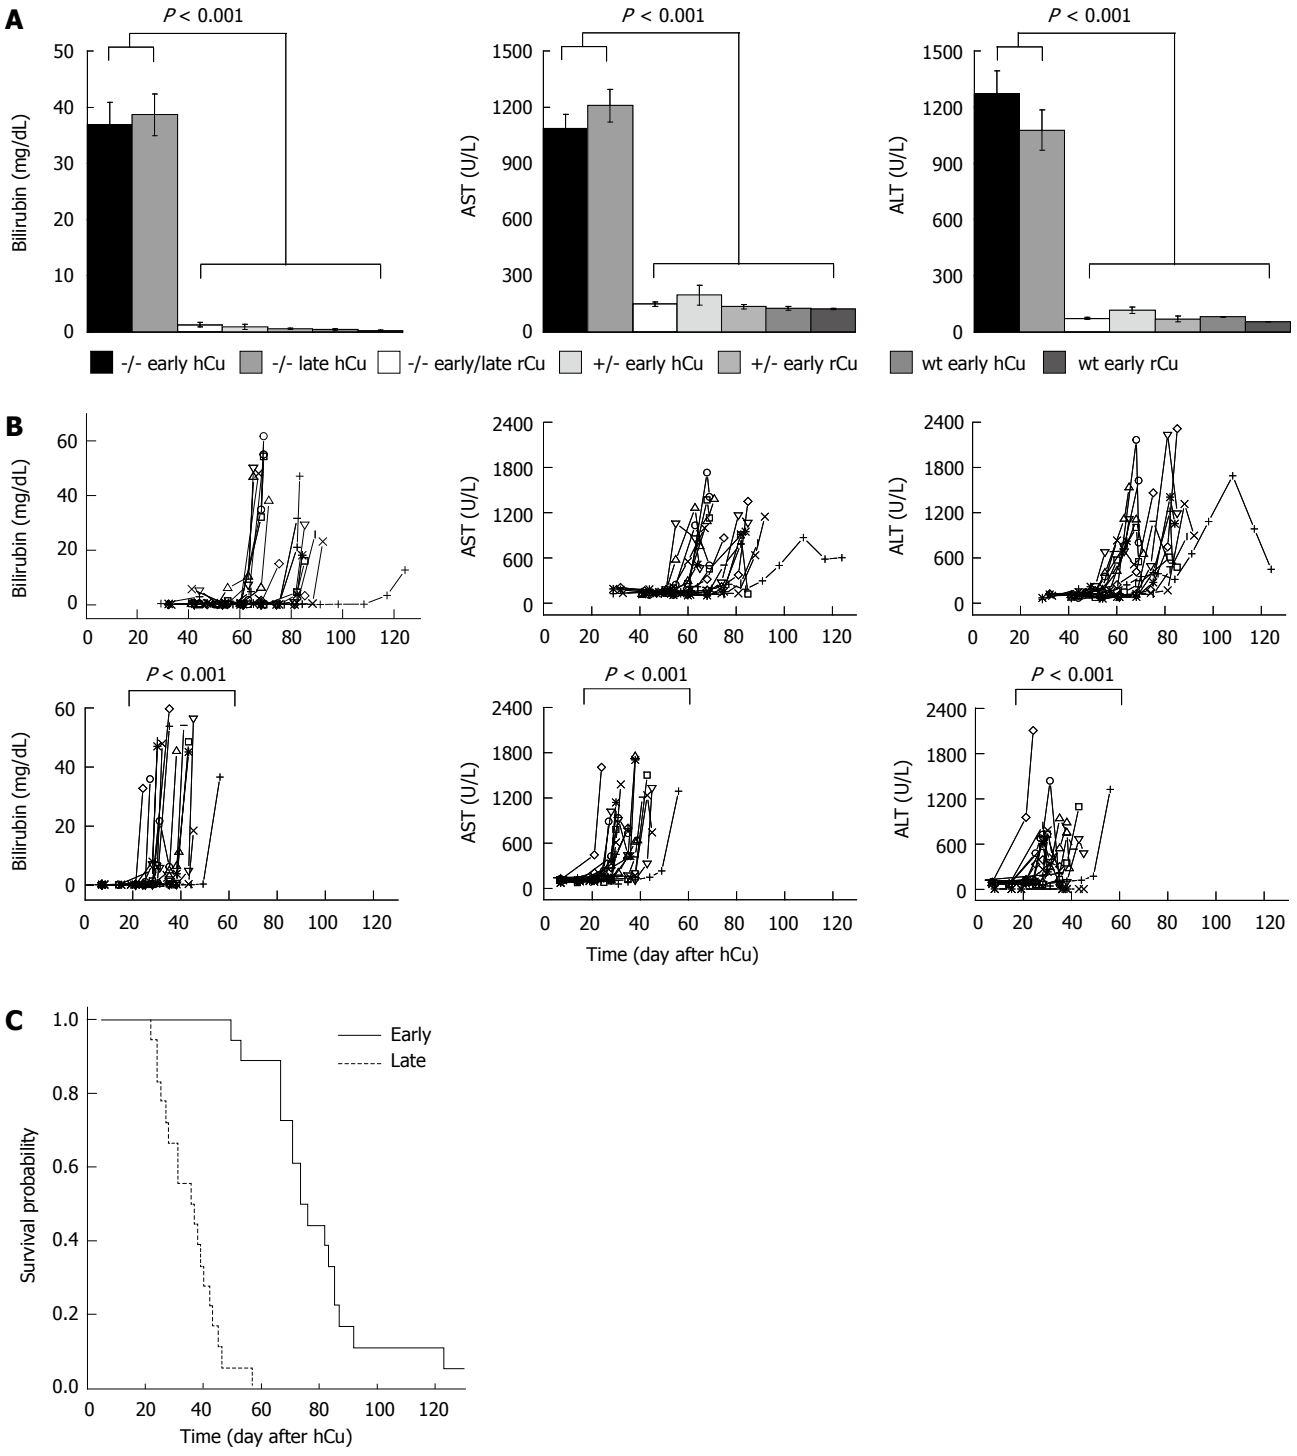

Figure 2 High copper regimen induces fulminant hepatitis. A: Bilirubin, aspartate transaminase (AST) and alanine aminotransferase (ALT) were determined in Long-Evans cinnamon (LEC) rats (-/-), heterozygotes (+/-) or Long-Evans agouti (LEA) rats (wt). Animals received a high copper (hCu) or reduced copper (rCu) diet as an early or late regimen. Median ± SE of maximal values obtained from animals are shown; B: Time course of serum markers in LEC rats that received early (top) or late (bottom) hCu. X-axis represents day after start of hCu. Animals of other groups showed normal levels. Of note, the onset of increased values following late hCu was at day 189 ± 42 after birth. Each line represents one animal. Logrank test using threshold (mean ± SE of LEA rats ×2) was used; C: Kaplan-Meier survival curve of LEC rats receiving an early and late hCu regimen are shown. Survival is represented as day after start of hCu. Of note, age of animals at death in late group was 190 ± 9 d.

normal regardless of the copper regimen used.

Accumulation of liver copper

High concentrations of copper were determined in the livers of LEC rats (Figure 4) following hCu, resembling WD[25]. LEC rats receiving rCu exhibited significant liver copper after the early (422 ± 62 μg/g) and late regimen (477 ± 75 μg/g) as compared to heterozygotes or wild type rats. Male and female LEC rats did not significantly differ with respect to liver copper (Table 2). Ceruloplasmin activity, which is absent in the LEC rat strain[20], was not affected by a copper diet (Figure 5).

Table 2 Male and female Long-Evans cinnamon rats after copper diet

		Early hCu		Late hCu		rCu		Long-Evans agouti
		Male	Female	Male	Female	Male	Female	Female
Bilirubin	> 0.4 mg/dL[1] (d)	55 (67 ± 5)	63 (60 ± 1)	28 (30 ± 1)	28 (32 ± 1)	0.3[2] (0.3 ± 0)	0.2[2] (0.2 ± 0)	0.2[2] (0.2 ± 0)
AST	> 240 U/L[1] (d)	74 (75 ± 3)	68 (68 ± 1)	28 (34 ± 3)	30 (33 ± 1)	115[2] (117 ± 4)	103[2] (103 ± 3)	114[2] (114 ± 5)
ALT	> 110 U/L[1] (d)	44 (50 ± 2)	54 (54 ± 1)	28 (30 ± 2)	28 (31 ± 1)	69[2] (69 ± 6)	75[2] (75 ± 6)	54[2] (54 ± 1)
Liver Cu	(μg/g)	868 (880 ± 93)	1036 (1058 ± 59)	1494 (1452 ± 161)	1235 (1178 ± 59)	503 (495 ± 75)	309 (326 ± 29)	46 (44 ± 9)
Survival	(day after hCu)	85 (81 ± 4)	81 (75 ± 9)	37 (37 ± 6)	35 (35 ± 2)	NA	NA	NA

NA: Not available; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; hCu: High copper; rCu: Reduced copper. [1]Sera up to sacrifice were analyzed by logrank test using thresholds calculated from Long-Evans agouti rat (mean ± SE) × 2; [2]Max values up to sacrifice are given. Data of male and females did not differ (logrank, *t* test, Kruskal-Wallis, Kaplan-Meier).

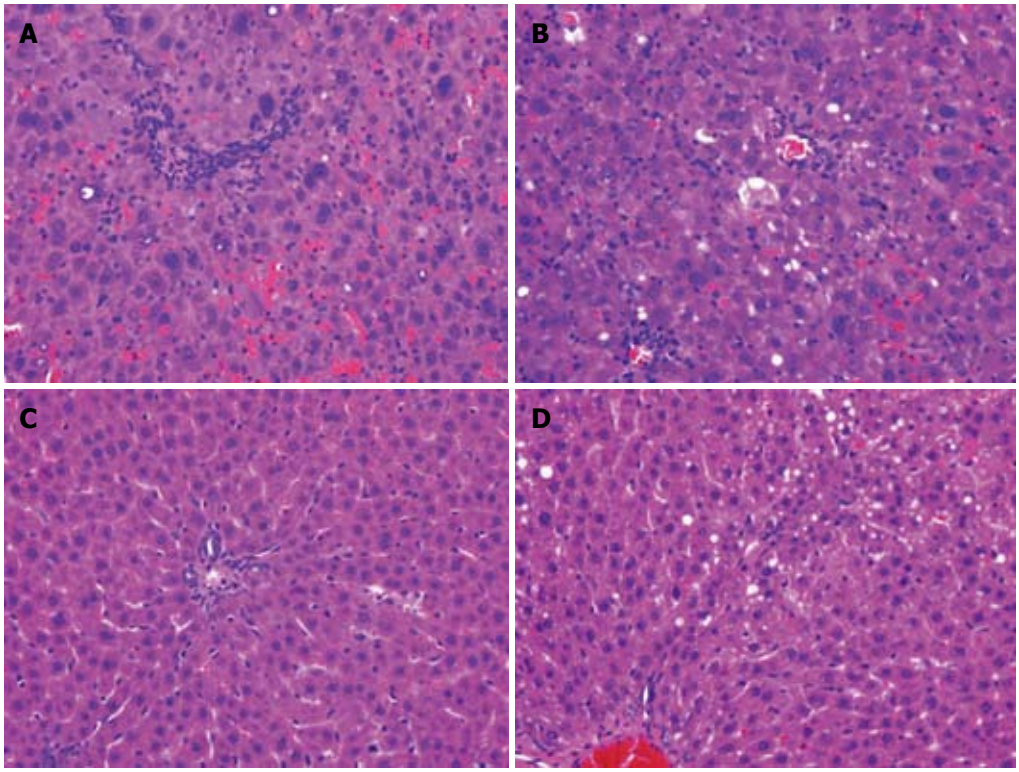

Figure 3 Liver of Long-Evans cinnamon rats is significantly affected by high copper regimen. Hematoxylin and eosin staining of liver. Livers were obtained from Long-Evans cinnamon rats that received high copper at an early or late time point (A, B) or after a reduced copper diet (C: late regimen). As a control, liver of Long-Evans agouti rat is depicted (D). Note highly irregular architecture of liver parenchyma, polyploidy, enlarged nuclei and inflammation (A, B) as compared to C and D. Liver histology of other groups was normal. One representative staining (40× magnification) of female rats is shown.

Gene expression in liver

In order to investigate whether the different copper diet regimens also have an impact on major biochemical pathways, gene expression in the liver was determined in animals at sacrifice. A small set of five marker genes was analyzed that relate to different areas of metabolism previously found to be affected in injured liver, including angiogenesis (*Vegfa*), fat metabolism (*Srebf1*), extracellular matrix (*Timp1*), oxidative stress (*Hmox1*), and the cell cycle (*Cdkn1a*). A highly different (fold-change > 8.5) expression of marker genes was observed when LEC rats receiving an early hCu regimen were compared to LEC rats receiving rCu (Figure 6). mRNA levels of Vegfa (8.5) and Srebf1 (13.9) were downregulated at the time points of fulminant hepatitis in LEC rats receiving hCu, whereas Timp1 (9.8), Cdkn1 (10.1) and Hmox1 (10.6) were upregulated at this time point. Marker gene expression was not affected in LEC rats receiving rCu, in LEA rats or in *ATP7B* heterozygotes (data not shown). Of note, none of the five genes displayed a significantly different (fold-change > 2) level of expression when LEC rats receiving early and late hCu regimen were compared.

DISCUSSION

The early hCu regimen used here for juvenile LEC rats closely resembles previous protocols. Onset of fulminant hepatitis was observed by us at about day 80, which is of a similar range as compared to others[18,25,26]. The high dietary copper regimen was achieved by copper

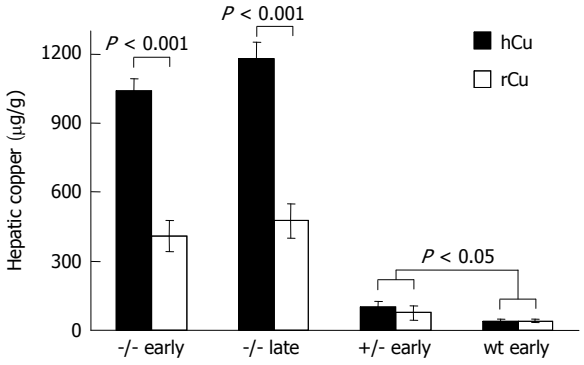

Figure 4 Increased liver copper is found in Long-Evans cinnamon rats irrespective of copper diet. Copper was determined in the liver of Long-Evans cinnamon rats (-/-; *n* = 9), heterozygotes (+/-; *n* = 5) and Long-Evans agouti rats (wt; *n* = 3) after receiving high copper (hCu) or reduced copper (rCu) diet according to an early or late regimen, respectively. Copper concentration is given as mean ± SE of liver dry weight.

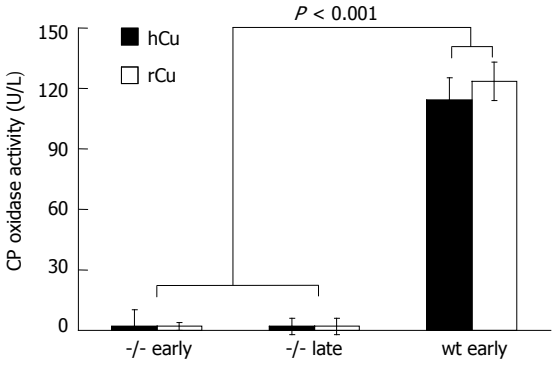

Figure 5 Ceruloplasmin oxidase is independent of high copper treatment. Ceruloplasmin (CP) oxidase was determined in Long-Evans cinnamon rats (-/-) that received high copper (hCu) or reduced copper (rCu). Sera (*n* = 6) were obtained from animals after an early or late hCu regimen. As control, values obtained from Long-Evans agouti rats (wt) (*n* = 3) are shown. Data are expressed as mean ± SE.

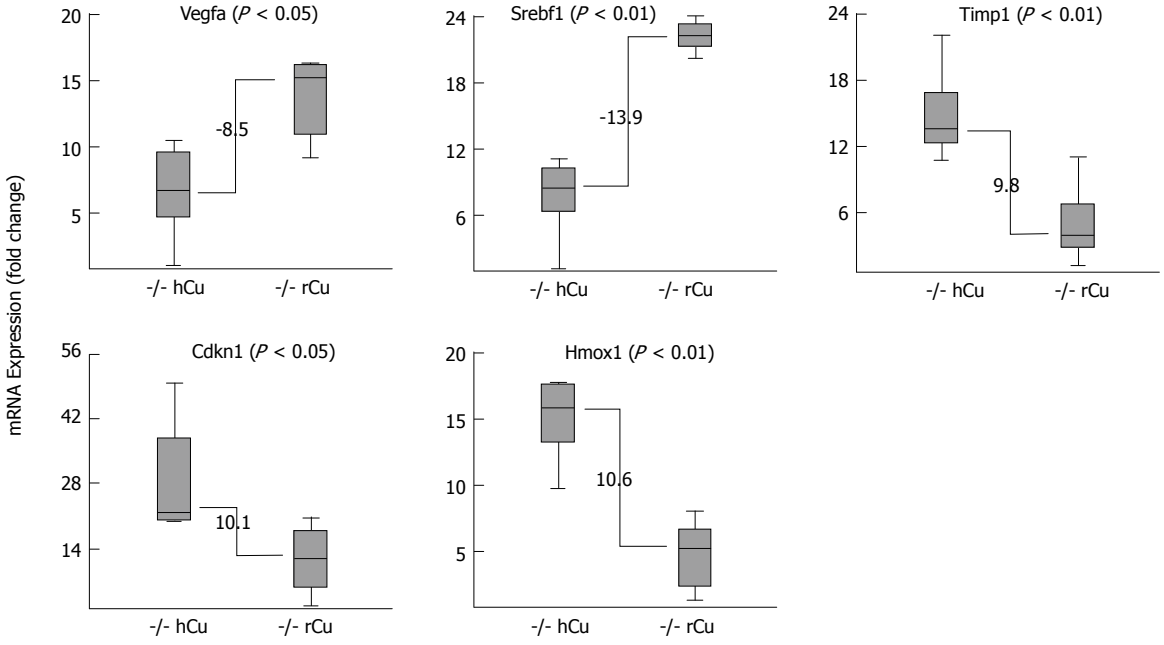

Figure 6 Liver gene expression of Long-Evans cinnamon rat is significantly altered after high copper regimen. Relative expression of individual mRNA in Long-Evans cinnamon (LEC) rats (*n* = 7) that were subjected to early high copper (hCu) regimen (left boxes) and in age-matched LEC rats (*n* = 5) receiving reduced copper (rCu) (right boxes). Animals were analyzed at fulminant hepatitis. Fold-change was calculated within groups by the Δct method using the *HPRT* gene for normalization. Data are shown as a box plot representation as calculated from three independent experiments. Numbers refer to difference of fold-change with regard to the median of each group.

enriched tap water (20 mg copper/L) and a standard solid diet (13 mg copper/kg). As compared to previous studies that employed a standard solid diet, only the overall dietary copper burden given to the LEC rats was moderately increased[18,25,26]. Much higher dietary copper concentrations have been reported in LEC rats[26-28], and intraperitoneal injection of 3 mg/kg copper for 3 d was shown to result in jaundice and fulminant hepatitis within 2 d after the last injection, suggesting that besides the absolute amount of copper the route of administration is also important[29]. As one result of our high dietary copper regimen, all LEC rats (with the exception of one animal used for the early regimen) encountered fulminant hepatitis and death. This is in contrast to previous studies using a standard solid diet only, where 40%-60% of LEC rats survived[18,25,26]. Since the high dietary copper regimen can induce fulminant hepatitis in nearly all LEC rats, such protocols may now allow a more quantitative analysis of therapy, e.g., by cell-based approaches[30].

Prevention of hepatitis and almost disease-free long term survival were observed in LEC rats that received a low copper diet throughout their lifetime. Hepatitis in LEC rats is closely associated with copper intake[18,31], and it was therefore noted early that a copper deficient diet can reduce serum levels of AST and ALT in addition to

diminution of copper concentration in the liver[27]. In the latter study of male LEC rats, animals at the age of 30 d were monitored for 35 d or 15 wk[18,32]. A rCu diet that was enriched for L-proline could also improve survival (up to month 5) in male LEC rats[26]. We could confirm previous results regarding the impact of reduced dietary copper intake in a long-term study (up to 20 mo). Since male LEC rats seem to be more resistant to copper[33,34], we also investigated female LEC rats; however, a significant difference between genders was not observed for onset of hepatitis, liver copper, and survival.

Onset of hepatitis as determined by serum markers ALT, AST, and bilirubin was significant earlier (about 2 wk) in LEC rats that received a late hCu regimen. The finding of a significantly earlier onset of hepatitis and death in animals having elevated liver copper at start of hCu suggests that copper preloading of the liver above a critical threshold may accelerate the onset of disease. In contrast, LEC rats remained apparently asymptomatic showing liver copper levels that were about 10-fold higher as compared to LEA rats, suggesting that a high liver copper level can be tolerated for an extended time but induces a rapid onset of disease when dietary copper intake is increased. It should be stated that the effect of copper preloading could not be demonstrated by inspection of liver tissue since the stains obtained at early and late time points after hCu treatment did not significantly differ. Inflammation and necrosis were almost absent in stains of liver tissue at early and late time points when a rCu diet was used, suggesting that preloading with significant but subcritical levels of copper does not result in gross histological alterations of liver tissue and adverse immune responses.

The liver of LEC rats was characterized by determination of mRNA levels after a hCu regimen to assess the impact of dietary copper on gene expression. Notably, an almost identical gene expression was observed in juvenile and adult LEC rats after the hCu regimen, indicating that pre-accumulated copper levels do not affect gene expression at least at the time point of fulminant hepatitis. Marked differences were however observed between LEC rats at fulminant hepatitis and age-matched asymptomatic LEC rats that received a rCu diet. Inhibitory molecule Cdkn1a (p21) was found to be markedly upregulated suggesting that the cell cycle is blocked at G0 in the phase of fulminant hepatitis, confirming previous results obtained in LEC rats as well as in rats after hepatectomy[35,36]. It is conceivable that arrest of the cell cycle within the liver is a common molecular determinant of fulminant hepatitis. Timp1, an important mediator of extracellular matrix remodeling during toxic liver injury[37], was highly upregulated in LEC rats after hCu corroborating our observations of significant changes in liver architecture. The role (if any) of Timp-1 mRNA regulation by a copper diet with regard to the activity of metalloproteinase (MMP), e.g., MMP-9, which was shown to be highly induced in fulminant hepatic failure[38], remains to be studied. Expression of *Srebf1* was down-regulated in LEC rats after the hCu regimen, suggesting that copper overload may be followed by reduction of lipid biosynthesis. Of note, Srebf1 activity was found to be increased in copper-deficient rats[39]. *Hmox1*, which is related to oxidative stress induced by iron deposition that is also commonly observed in LEC rats, was found to be highly upregulated after the hCu regimen, as reported before[36]. In contrast, *Vegfa*, a strong mediator of angiogenesis that was recently observed to be induced in hepatoma cells by hCu *via* a ceruloplasmin promotor, was down-regulated after hCu regimen. LEC rats which have a low ceruloplasmin expression may differ in this respect from wild type[40]. Although our analysis of gene expression in the liver of LEC rats after hCu regimen showed a significant modulation of important markers of copper metabolism, the study is limited since only one time point was examined. Clearly, further studies are needed that are beyond the scope of this article to explore the molecular events following toxic copper exposure of the liver.

Accumulation of dietary copper in the liver over a lifetime may play a role in the course of WD even when the genetic constitution of patients is similar[13-16]. While WD is frequently observed in the 2nd and 3rd decade of life, presentation of typical WD symptoms at the preschool age is relative rare and onset of disease above the age of 40 has been noted[12]. The finding that LEC rats have moderate liver copper but no overt disease may possibly resemble the observation of rare asymptomatic WD patients[41,42]. Conversion from a state of low to high dietary copper is followed by rapid development of severe disease in LEC rats, a situation that may also apply to WD patients after discontinuation of therapy[9,43]. Our findings indicate the importance of a stringent maintenance of anti-copper therapy for management of WD patients in order to balance liver copper level below a critical threshold, and reinforce the lifetime risk of WD patients of developing liver failure when dietary copper intake is increased or anti-copper therapy has failed.

Taken together our results demonstrate that asymptomatic LEC rats having significantly elevated liver copper either rapidly develop fulminant hepatitis when dietary copper is increased or survive long term on a rCu diet, suggesting that there may exist a critical threshold of liver copper important to trigger onset of WD. A stringent diet of low copper throughout the lifetime is followed in LEC rats by escape from hepatitis, moderately low liver copper, and long term survival without overt disease. The data underline the importance of environmental factors, such as dietary copper, with respect to the phenotype and course of WD, and suggest that similar molecular and physiologic mechanisms are initiated when tolerable copper thresholds are exceeded during the lifetime.

COMMENTS

Background

Fulminant hepatitis is a life-threatening disorder that is also observed in Wilson's disease (WD), an inherited disease that is caused by mutation of the *ATP7B* gene encoding a crucial copper transport protein in the liver. The dietary intake of copper during a lifetime can affect the course of WD. Analysis of dietary copper intake was assessed in a rat model of WD. The study is related to the understanding of copper toxicity and the molecular events of pathogenesis.

Research frontiers

High copper is toxic to cells. In humans, the liver has the role of excreting excessive copper and preventing toxicity. The molecular events following copper toxicity are not understood. The relationship between liver copper levels and onset of disease is important to understand for improving current therapy approaches.

Innovations and breakthroughs

Accumulation of liver copper in individuals carrying two allelic mutations of *ATP7B* is ultimately followed by development of WD; however, rate, onset, course of disease, including acute liver failure (ALF), varies greatly between patients. Studies of monozygotic twins having identical mutations of *ATP7B* are most informative to decipher the role of genetic and environmental factors for the course of WD. However, these studies are casual and rare. The Long-Evans cinnamon rat carrying a natural mutation of *ATP7B* has been established as a model to study the pathophysiology of WD. This study illustrates for the first time that a stringent copper-restricted diet can completely prevent development of fulminant hepatitis in the long-term (up to 20 mo). Reduced dietary copper intake is associated with no overt disease symptoms, although elevated levels of liver copper were observed. This state of disease rapidly shifts to severe disease, liver failure, and death if dietary copper intake is increased. The molecular events following induction of ALF seem to be identical in WD regardless of the time point of disease onset.

Applications

The observation of different degrees of disease progression with regard to liver copper levels underlines the importance of a stringent maintenance of drugs during anti-copper therapy of WD and provides a novel basis for efforts to achieve compliance. Counselling and monitoring of dietary aspects in WD could be reinforced for effective management of patients.

Terminology

Fulminant hepatitis is the appearance of severe, life-threatening complications that occur rapidly after the first signs of liver disease (such as jaundice). The damage to the liver is broad, leading to the death of most (80%-90%) of the liver cells.

Peer review

This article is about the correlation between dietary copper level and the onset of fulminant hepatitis in the rat model of WD, especially at different time points. The article presents an interesting topic of WD to simulate the liver injury and onset of fulminant hepatitis. Although the model has been previously described the current study provides additional new value to the field.

Abstract

AIM: To clarify differences in mucin phenotype, proliferative activity and oncogenetic alteration among subtypes of colorectal laterally spreading tumor (LST).

METHODS: LSTs, defined as superficial elevated lesions greater than 10 mm in diameter with a low vertical axis, were macroscopically classified into two subtypes: (1) a granular type (Gr-LST) composed of superficially spreading aggregates of nodules forming a flat-based lesion with a granulonodular and uneven surface; and (2) a non-granular type (NGr-LST) with a flat smooth surface and an absence of granulonodular formation. A total of 69 LSTs, comprising 36 Gr-LSTs and 33 NGr-LSTs, were immunohistochemically stained with MUC2, MUC5AC, MUC6, CD10 (markers of gastrointestinal cell lineage), p53, β-catenin and Ki-67 antibodies, and examined for alteration in exon 1 of v-Ki-ras2 Kirsten rat sarcoma viral oncogene homolog (KRAS) and exon 15 of v-raf murine sarcoma viral oncogene homologue B1 (BRAF) by polymerase chain reaction followed by direct sequencing.

RESULTS: Histologically, 15 Gr-LST samples were adenomas with low-grade dysplasia (LGD), 12 were high-grade dysplasia (HGD) and 9 were adenocarcinomas invading the submucosa (INV), while 12 NGr-LSTs demonstrated LGD, 14 HGD and 7 INV. In the proximal colon, MUC5AC expression was significantly higher in the Gr-type than the NGr-type. MUC6 was expressed only in NGr-LST. MUC2 or CD10 did not differ. P53 expression demonstrated a significant stepwise increment in progression through LGD-HGD-INV with both types of LST. Nuclear β-catenin expression was significantly higher in the NGr-type. Ki-67 expression was significantly higher in the Gr-type in the lower one third zone of the tumor. In proximal, but not distal colon tumors, the incidence of KRAS provided mutation was significantly higher in the Gr-type harboring a specific mutational pattern (G12V). BRAF mutations (V600E) were detected only in two Gr-LSTs.

CONCLUSION: The two subtypes of LST, especially in the proximal colon, have differing phenotypes of gastrointestinal cell lineage, proliferation and activation of Wnt/β-catenin or RAS/RAF/extracellular signal-regulated kinase signaling.

INTRODUCTION

Colorectal cancer (CRC) is considered to arise from an adenoma precursor, and a model for genetic alterations in the adenoma-carcinoma sequence has been proposed [1,2]. In this model, an adenomatous polyposis coli (*APC*) gene mutation occurs at the earliest stage, followed by a v-Ki-ras2 Kirsten rat sarcoma viral oncogene homolog (KRAS) mutation, as well as a change in p53. Along this sequence, the Wnt/APC/β-catenin and RAS/RAF/extracellular signal-regulated kinase (ERK) signaling pathways also play important roles[3-7]. Previous studies have primarily considered protruded adenomatous polyps as the most likely precursor of CRC[1,2]. However, recent advances have led to changes in the diagnosis of early colorectal tumors, which can now be morphologically divided into three groups: classical protruded tumors, depressed tumors, and laterally spreading tumors (LSTs)[8,9]. The latter two are possible candidates for alternative pathways of colorectal tumorigenesis. LSTs are considered to be less invasive, as neoplastic cells tend to spread along the surface of the lumen, and are usually categorized into two subtypes: granular type (Gr-LST) and flat- or non-granular type (NGr-LST); NGr-LSTs were more often associated with submucosal invasion compared to Gr-LSTs[9,10]. An earlier report demonstrated unique cell kinetics in LSTs[11]. Subsequent studies also evaluated alteration of APC[12] or β-catenin[12-15] for Wnt/APC/β-catenin, mutation of KRAS[11,12,14,16-19] or v-raf murine sarcoma viral oncogene homologue B1 (BRAF)[12,14,19] for RAS/RAF/ERK and mutation of phosphoinositide-3-kinase (PI3K) catalytic-α polypeptide[12,19] for the PI3K/AKT signaling pathway in LSTs. In addition, promoter methylation of CpG islands including its methylator phenotype (CIMP) in association with other genetic alterations has been shown to make important contributions to LST development[14,18].

In an earlier study, *de novo* appearance of gastric mucin genes MUC5AC and MUC6, which are present in surface foveolar cells and mucous neck cells of the oxyntic mucosa and antral-type glands in the stomach[20], was shown in colonic adenomas[21]. Altered expression of MUC2 as an intestinal apomucin known to be expressed in goblet cells[22], and CD10 expressed on the brush borders of intestinal epithelial cells[23], occurred during progression of adenoma to early adenocarcinoma state[24-26]. While considerable effort has been made to identify gene mutations and alteration of gastrointestinal phenotypes in conventional colorectal tumors, less attention has been paid to LSTs. Therefore, in the present study, we focused on differences in expression of MUC2, MUC5AC, MUC6 and CD10, p53 alteration, nuclear translocation of β-catenin, cell proliferation, and KRAS/BRAF mutations in morphologically different LST subtypes.

MATERIALS AND METHODS

Patients and materials

LSTs are defined as superficial elevated lesions greater than 10 mm in diameter with a low vertical axis[8-10] and are macroscopically classified into two subtypes: (1) Gr-LSTs composed of superficially spreading aggregates of nodules forming flat based lesions with a granulonodular and uneven surface (Figure 1A and C); and (2) NGr-LSTs with flat smooth surfaces and an absence of granulonodular formation (Figure 1B and D).

The material for our study was a series of 69 LSTs (from 69 patients) resected endoscopically or surgically at Jundendo University Hospital (Tokyo, Japan) between May 2008 and July 2011. Patients with familial polyposis coli, hereditary non-polyposis colorectal carcinoma, multiple colorectal carcinomas, or inflammatory bowel disease were not included in the analysis. Proximal LSTs were classified as tumors proximal to the splenic flexure and the remaining tumors were defined as distal. Resected specimens were fixed in 15% formalin and processed for embedding in paraffin wax according to routine procedures and then sections were cut and stained with hematoxylin and eosin (H and E). This study was approved by the Institutional Review Board and the ethical committee of our hospital.

Pathological review

All slides stained with H and E were reviewed by two experienced gastrointestinal pathologists (Mitomi H, Yao T) independently. According to the World Health Organization classification[27], adenoma was classified as tubular, tubulovillous or villous type with low grade dysplasia (LGD) or high grade dysplasia (HGD). Intramucosal carcinoma and carcinoma *in situ* were included in adenoma with HGD. Adenocarcinoma invading submucosa (INV) was classified as well, moderately or poorly differentiated. The subjects were classified according to the most advanced lesion identified. Interobserver variation was resolved by reevaluation and discussion to reach consensus.

Immunohistochemistry

Briefly, 4 μm thick tissue serial sections were dewaxed in xylene and rehydrated, then endogenous peroxidase activity was blocked by incubation in 3% hydrogen peroxidase. For heat-induced antigen retrieval, sections were transferred to citrate buffer (10 mmol/L, pH 6.0) and heated at 100 ℃ in a water bath. The primary antibodies employed were MUC2 (Ccp58, 1:100 dilution; Leica Biosystems/Novocastra Laboratories, Newcastle Upon Tyne, UK), MUC5AC (CLH2, 1:100 dilution; Novocastra Laboratories), MUC6 (CLH5, 1:100 dilution; Novocastra Laboratories), CD10 (56C6, 1:100 dilution; Novocastra Laboratories), p53 (PAb 1801, 1:100; Leica Biosystems/Novocastra Laboratories), β-catenin (14/Beta-Catenin,

LSTs: Laterally spreading tumors.

dilution 1:100, BD Biosciences, San Diego, CA), and Ki-67 (MIB-1, 1:100; DAKO, Glostrup, Denmark), with incubation for 120 min at room temperature. Immunostaining was performed using the streptavidin-biotin-peroxidase complex method using a Histofine SAB-PO Kit (Nichirei Corp., Tokyo, Japan). The chromogen was 3,3' -diaminobenzidine and the sections were counterstained lightly with Mayer's hematoxylin to facilitate recognition of structures.

Assessment of immunostaining

Distinct cytoplasmic staining for MUC2, MUC5AC, MUC6 and apical staining for CD10 were considered positive, as was nuclear staining for p53 and Ki-67, regardless of the staining intensity. Expression of β-catenin, which generally showed an inverse relationship between membranous and nuclear (with cytoplasmic) reactivity, was evaluated only with respect to nuclear localization in this study. Immunostaining for all markers was evaluated by two of the authors (Mitomi H, Nakae K) independently, without prior knowledge of clinicopathological data. Discrepancies were resolved by re-evaluation to reach consensus.

Immunoreactive scores (IRSs) for MUC2, MUC5AC, MUC6 and CD10 were classified into five grades: 0 points, positive cells < 5% of tumor area; 1 point, 5%-24%; 2 points, 25%-49%; 3 points, 50%-74%; 4 points, ≥ 75%. IRSs for p53 and nuclear β-catenin were also classified into five grades: 0 points, positive nuclei < 5% of tumor cells; 1 point, 5%-24%; 2 points, 25%-49%; 3 points, 50%-74%; 4 points, ≥ 75%. For topological evaluation of the Ki-67 labeling index (LI; %), tumor glands in the lamina propria were separated into three equal zones (upper, middle and lower thirds), and the number of immunoreactive nuclei per approximately 300 tumor cells were counted in each zone (for a total of approximately 1000 cells in whole glands).

Mutation analysis of KRAS and BRAF

Mutation analysis for KRAS and BRAF were performed using genomic DNA derived from formalin-fixed paraffin-embedded tissue of 29 Gr-LSTs (10 LGD, 10 HGD and 9 INV) and 27 NGr-LSTs (10 LGD, 10 HGD and 7 INV). Mutations were examined in exon 1 of KRAS and exon 15 of BRAF by polymerase chain reaction followed by direct sequencing. The primer sequences in this study were as previously described[28].

Statistical analysis

All statistical analysis were carried out using StatView for Windows Version 5.0 (SAS Institute Inc., Cary, NC, United States). IRSs and LI are presented as mean ± SD. Continuous data were compared with the Mann-Whitney *U* test. Categorical analysis of variables was performed using either the χ^2 test (with Yates' correction) or the Fisher's exact test, as appropriate. Correlations among expression levels of the encoded proteins were assessed with the Spearman's rank correlation coefficient. A P value < 0.05 was considered statistically significant, with classification into two grades: $P < 0.05$ and $P < 0.01$.

RESULTS

Clinicopathological characteristics of LST

The clinicopathological characteristics of the Gr-LSTs (15 LGD, 12 HGD, 9 INV) and NGr-LSTs (12 LGD, 14 HGD, 7 INV) are shown in Table 1. Gr-LSTs were located equally in proximal and distal colons, whereas NGr-LSTs were more frequently found in the distal colon, but without reaching statistical significance. Gr-LSTs were

Tubular type[d]	0	13
Tubulovillous type[d]	12	1
INV	9	7
Well differentiated type	7	7
Others	2	0

Age and size of tumor are represented as mean ± SD (range); Gr-type: Granular type of laterally spreading tumor; NGr-type: Flat- or non-granular type of laterally spreading tumor; LGD: Adenoma with low grade dysplasia; HGD: Adenoma with high grade dysplasia; INV: Adenocarcinoma invading submucosa; INV-others: Mixed well and moderately differentiated type (n = 1) and mixed well and poorly differentiated adenocarcinoma (n = 1); [b,d]$P < 0.01$, Gr-type *vs* NGr-type, tubular type *vs* tubulovillous type.

significantly larger than NGr-LSTs. Histologically, 12 out of 13 (92%) tubulovillous adenomas with HGD were Gr-LSTs, whereas all of the 13 tubular adenomas with HGD were NGr-LSTs. All NGr-INVs and 7 out of 9 (78%) Gr-INVs were well differentiated adenocarcinomas. The two other Gr-INVs were an adenocarcinoma coexisting with well and moderately differentiated histology, and a mixed well and poorly differentiated type adenocarcinoma.

IRSs of MUC2, MUC5AC, MUC6, CD10, p53 and nuclear β-catenin in LSTs

For the MUC2 IRS (Figure 2A-C), significant stepwise decrement was evident in progression through LGD - HGD-INV in Gr- and NGr-LSTs. For the MUC5AC IRS (Figure 2D-F), the Gr-type value was significantly higher than that of the NGr-type, in the proximal colon. MUC6 was expressed only in NGr-LSTs (Figure 2G-I). A low extent of CD10 expression was detected in HGD and INV, but not LGD of both Gr- and NGr-LSTs (Figure 2J-L).

For the p53 IRS (Figure 3A), a stepwise increment in progression was noted through LGD to INV in Gr- and NGr-LSTs, which was statistically significant. For the nuclear β-catenin IRS (Figure 3B), the NGr-type value was significantly higher than the Gr-type. A similar trend for p53 and nuclear β-catenin IRSs was observed in proximal and distal LSTs (data not shown). For the Ki-67 LI (%) in the lower zone (Figure 3C), the Gr-type value was significantly higher than that of the NGr-type. A similar trend without statistical significance was found in the upper and middle zones (data not shown).

Representative H and E features and expression of MUC2, MUC5AC, MUC6, CD10, p53 and β-catenin are illustrated in Figure 4.

Correlations among IRSs for the encoded proteins

Data for correlations among IRS are given in Table 2. Significant inverse relationships were found between p53 and MUC2 or MUC5AC. In addition, inverse associations were shown between nuclear β-catenin and MUC2 in NGr-LSTs, or MUC5AC in Gr-LSTs. Reciprocally, inverse associations were noted between Ki-67 and MUC2 in Gr-LSTs, or MUC5AC in NGr-LSTs.

KRAS and BRAF mutations

The results for KRAS and BRAF mutations analyzed are shown in Table 3. In proximal colon lesions, the incidence of KRAS mutations was significantly higher in Gr-LSTs (69%) than in NGr-LSTs (6%; $P < 0.001$). BRAF mutations were only detected in distal Gr-LSTs. In Gr-LSTs, 7 out of 29 (24%) tumors showed mutations from wild-type GGC (glycine) to GAC (aspartic acid) in codon 13 of the *KRAS* gene, and 5 (17%) tumors harbored mutations from GGT (glycine) to GTT (valine) in codon 12. In NGr-LSTs, 2 out of 27 (7%) tumors had mutations from GGC (glycine) to GAC (aspartic acid) in codon 13 of the *KRAS* gene. BRAF mutations were GTG (valine) to GAG (glutamic acid) in codon 600. A schematic representation of KRAS and BRAF mutational patterns is shown in Figure 5.

Association of KRAS or BRAF mutations with clinicopathological parameters and IRSs of the encoded proteins

Since there were only two cases of NGr-LST harbored mutations of KRAS, and neither had BRAF mutations, we analyzed only Gr-LSTs with respect to the relationship of KRAS or BRAF mutations with clinicopathological parameters (age, sex, location, size of tumor, and dysplastic grade) and IRSs of the encoded proteins. No significant link was observed with clinicopathological parameters. The MUC5AC IRS was significantly higher in mutated Gr-LSTs compared to non-mutated tumors (1.2 ± 1.3 *vs* 0.2 ± 0.6, $P < 0.05$). No significant differences were found in other IRSs (data not shown).

DISCUSSION

Only a few reports are available on the phenotypic expression of gastrointestinal cell lineage with immunohistochemistry of MUC2, MUC5AC, MUC6 and CD10 in relation to colorectal adenoma-carcinoma sequence[24-26]. In proximal colon lesions, MUC5AC expression was significantly higher in Gr-LSTs than NGr-LSTs. Expression of MUC5AC or HGM was increased in adenoma with villous histology or polypoid growth[21,24,25]. Enhanced MUC6 immunoreactivity was reported to be exhibited in large adenomas[21]. In the current study, MUC6 was expressed only in NGr-LSTs, suggesting it as a marker of a morphologically distinct tumor. The molecular mechanisms responsible for the aberrant expression of gastric mucin,

MUC5AC and MUC6 in colorectal tumors are still unclear and may be due to changes in transcriptional regulation.

It was previously reported that none of the four NGr-LSTs harbored p53 mutations, whereas 7 out of 24 (29%) Gr-LSTs were positive[16]. We have shown that no significant differences in p53 expression, along with an inverse relation of p53 to MUC2 or MUC5AC expression in two types of LSTs. An experimental study identified MUC2 expression as increased along with induction of wild-type p53 in carcinoma cell lines *in vitro*, and potential p53-binding sites in the MUC2 promoter, which contributes to stimulation of promoter activity[29]. P53 overexpression as an indirect sign of loss of functional p53 by its mutation is possibly related to the down-regulation of MUC2 expression in colorectal LST. A detailed study on the relation of p53 to the altered mucin expression appears warranted.

We have documented high nuclear β-catenin expression in NGr-LSTs in line with a previous study[15]. In an analysis of LSTs, no mutation of β-catenin exon 3 was found, while LOH at 5q (APC locus) was more frequently detected in NGr-LSTs than in Gr-LSTs[12]. To date, there is only one case report of NGr-LST harboring interstitial deletion of β-catenin exon 3[13]. Nuclear accumulation of β-catenin has been observed in tumors with mutations in the β-catenin or APC gene[3]. Taken together, the available data suggest that activation of Wnt/APC/β-catenin signaling in NGr-LSTs is due primarily to alterations in the *APC* gene. Furthermore, in-

verse associations were shown between nuclear β-catenin and MUC2 or MUC5AC in LSTs. Experimental studies have demonstrated that abrogation of MUC2 in tumors of the rat colon is related to nuclear β-catenin localization and its mutation[30,31]. Interaction of mucin core protein with Wnt/APC/β-catenin signaling may have some role in the progression of LSTs.

Ki-67, considered to be a reliable indicator for accurately assessing growth fraction, is increased with a shift in the proliferative zone toward the upper compartment in LSTs[11]. In the current study of Ki-67, a similar upward shift was detected in Gr- and NGr-LSTs. Furthermore, higher proliferation in the lower compartment was more apparent in Gr-LSTs, which may explain the morphologic variation in LSTs. We also found an inverse association between tumor cell proliferation (Ki-67) and MUC2 in LST. This is in line with the fact that decreased *in vivo* expression of MUC2 is related to colon carcinogenesis, accompanied by increased cell proliferation[32].

We have shown that, in proximal colon, the incidence of KRAS mutation was significantly higher in Gr-LST (69%) than NGr-LST (6%), with a relatively frequent and specific pattern in Gr-type for G12V, as it was for G12C in another report[16]. Previously reported incidences of KRAS mutation were 21%-83% in Gr-LST and 17%-26% in NGr-LST[12,16,17-19]. In the current study, BRAF mutations (V600E) were only detected in two Gr-LSTs. Gr-LSTs, particularly those located in the proximal colon, exhibited frequent KRAS mutations and high CIMP[18]. BRAF mutations are often characteristic of CIMP-high/microsatellite instability-high colorectal cancer[6], and are infrequent in LST[12,14,19]. These facts suggest that proximal Gr-LST is a possible candidate for early lesions of CIMP-high/microsatellite stable cancer. Furthermore, MUC5AC expression was significantly higher in KRAS mutated Gr-LSTs than in non-mutated tumors. Aberrant MUC5AC expression is thought to be related to KRAS mutations in experimental colon carcinogenesis[31]. *In vitro*, upregulation of MUC5AC may occur through concomitant activation of the EGFR/RAS/RAF/ERK signaling pathway and Sp1 binding to the gene promoter[33]. We therefore hypothesize that ERK signal activation induced by mutated RAS in relation to aberrant gastric mucin expression may play in a role in the development and progression of Gr-LSTs in the proximal colon.

In conclusion, as summarized schematically in Figure 6, the two subtypes of LST have differing mucin pheno-

COMMENTS

Background

Laterally spreading tumors (LSTs) in the colorectum are usually categorized into two subtypes: granular (Gr-LST) and flat- or non-granular types (NGr-LST). While considerable effort has been made to identify gene mutations and alteration of gastrointestinal phenotypes in conventional colorectal tumors, less attention has been paid to LSTs.

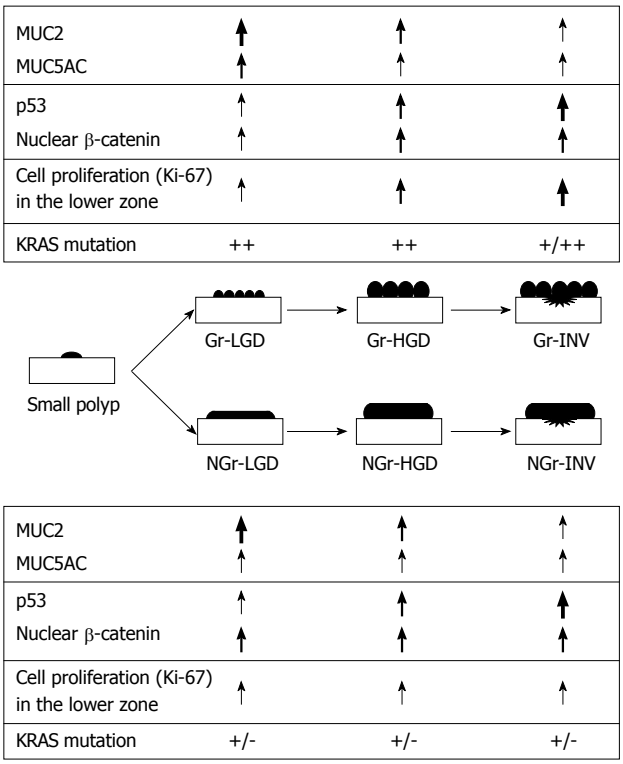

Figure 6 Alterations of expression of mucin core protein, p53 and β-catenin, cell proliferation and v-Ki-ras2 Kirsten rat sarcoma viral oncogene homolog mutations in malignant transformation of laterally spreading tumors. Large arrow: Marked upregulation; Medium arrow: Moderate upregulation; Small arrow: Mild upregulation; ++: Frequently mutated; +: Infrequently mutated; -: Not mutated; LGD: Adenoma with low grade dysplasia; HGD: Adenoma with high grade dysplasia; INV: Adenocarcinoma invading into submucosa; KRAS: v-Ki-ras2 Kirsten rat sarcoma viral oncogene homolog; Gr: Granular; NGr: Non-granular.

Research frontiers

The authors focused on differences in expression of MUC2, MUC5AC, MUC6 and CD10, p53 alteration, nuclear translocation of β-catenin, cell proliferation, and v-Ki-ras2 Kirsten rat sarcoma viral oncogene homolog (KRAS)/v-raf murine sarcoma viral oncogene homologue B1 mutations in morphologically different LST subtypes.

Innovations and breakthroughs

The authors showed that the two types of LSTs have different phenotypes, particularly with respect to MUC5AC (expression greater in Gr- *vs* NGr- types) and MUC6 (only expressed in NGr-type). They showed a higher nuclear β-catenin expression in NGr-type, and Ki-67 was much more prevalent in the Gr-type. Finally, the incidence of KRAS mutations was much more frequent in Gr-LST.

Applications

The subtypes of LSTs may be different candidates for alternative pathways of colorectal tumorigenesis. The results of the study represent a further impact on research in colorectal carcinogenesis.

Peer review

This is a good descriptive study in which the authors clarify differences in mucin phenotype, proliferative activity and oncogenetic alteration among subtypes of LST. The results are interesting and suggest that they are different candidates for alternative pathways of colorectal carcinogenesis.

Abstract

AIM: To support probe-based confocal laser endomicroscopy (pCLE) diagnosis by designing software for the automated classification of colonic polyps.

METHODS: Intravenous fluorescein pCLE imaging of colorectal lesions was performed on patients undergoing screening and surveillance colonoscopies, followed by polypectomies. All resected specimens were reviewed by a reference gastrointestinal pathologist blinded to pCLE information. Histopathology was used as the criterion standard for the differentiation between neoplastic and non-neoplastic lesions. The pCLE video sequences, recorded for each polyp, were analyzed off-line by 2 expert endoscopists who were blinded to the endoscopic characteristics and histopathology. These pCLE videos, along with their histopathology diagnosis, were used to train the automated classification software which is a content-based image retrieval technique followed by *k*-nearest neighbor classification. The performance of the off-line diagnosis of pCLE videos established by the 2 expert endoscopists was compared with that of automated pCLE software classification. All evaluations were performed using leave-one-patient-out cross-validation to avoid bias.

RESULTS: Colorectal lesions (135) were imaged in 71 patients. Based on histopathology, 93 of these 135 lesions were neoplastic and 42 were non-neoplastic. The study found no statistical significance for the difference between the performance of automated pCLE software classification (accuracy 89.6%, sensitivity 92.5%, specificity 83.3%, using leave-one-patient-out cross-validation) and the performance of the off-line diagnosis of pCLE videos established by the 2 expert endoscopists (accuracy 89.6%, sensitivity 91.4%, specificity 85.7%). There was very low power (< 6%) to detect the observed differences. The 95% confidence intervals for equivalence testing were: -0.073 to 0.073 for accuracy, -0.068 to 0.089 for sensitivity and -0.18 to 0.13 for specificity. The classification software proposed in this study is not a "black box" but an informative tool based on the query by example model that produces, as intermediate results, visually similar annotated videos that are directly interpretable by the endoscopist.

CONCLUSION: The proposed software for automated classification of pCLE videos of colonic polyps achieves high performance, comparable to that of off-line diagnosis of pCLE videos established by expert endoscopists.

INTRODUCTION

Colorectal cancer is the second leading cause of cancer-related death in the United States[1]. Its development includes several morphological stages, from benign to adenomatous polyps with low grade dysplasia to adenocarcinoma. Suspicious lesions are usually detected with standard colonoscopy by endoscopists who either perform confirmatory biopsy, or if high certainty exists, perform immediate therapy such as resection or ablation of diseased tissue. Because standard endoscopic imaging can only diagnose disease states with moderate levels of certainty[2,3], histopathology remains the criterion standard for final diagnosis[4]. However, the requirement for *ex vivo* histology implies a large proportion of unnecessary polypectomies and often requires a separate endoscopic procedure to be performed for treatment. It also increases the cost of colorectal cancer screening.

Probe-based confocal laser endomicroscopy (pCLE, Mauna Kea Technologies, France) enables the endoscopist to image the epithelial tissue *in vivo*, at the microscopic level with a confocal miniprobe, and in real-time during ongoing endoscopy. Preliminary findings by Meining *et al*[5] demonstrated the applicability of pCLE in diagnosing colorectal neoplasia *in vivo* with high sensitivity and specificity (93% and 92%, respectively) in 13 patients with colorectal lesions. Venkatesh *et al*[6] and De Palma[7] pointed out that confocal endomicroscopy offers the ability to target biopsies much more precisely and thus to reduce the number of random biopsies. In a recent study including a large pool of 75 patients, Buchner *et al*[8] compared off-line diagnosis of pCLE videos to virtual chromoendoscopy (Narrow-Band Imaging and Fujinon Intelligent Color Enhancement) and showed that off-line diagnosis of pCLE videos had higher sensitivity (91% *vs* 77%) with similar specificity (76%). As noted by Wallace *et al*[9], endoscopists now have the challenging task of performing "optical biopsies" and diagnosing pCLE video sequences *in vivo*.

In order to provide an objective support for pCLE diagnosis, we aimed to design a computer-based system for the automated classification of colonic polyps into neoplastic and non-neoplastic lesions. As physicians typically rely on similarity-based reasoning to establish a diagnosis from image queries, we propose a content-based image retrieval (CBIR) approach to automatically estimate the pathology of a new pCLE video. Indeed, contrary to "black box" classification systems, a CBIR-based classification system extracts, from a training database, annotated pCLE videos that are visually similar to the video of interest and directly interpretable by the endoscopist. The pathology of the video query is then estimated from the histopathological votes of these already diagnosed videos. Another advantage of CBIR-based classification is that the extracted similar videos can be presented to the endoscopist in a second reader paradigm to better support pCLE diagnosis.

The main goal of this study was to compare, using the same database of colonic polyps, the clinical performance of our automated pCLE classification software with that of off-line diagnosis of pCLE videos established by endoscopists expert in pCLE, with histopathology remaining the criterion standard reference.

MATERIALS AND METHODS

Patients

The patients included in the study were enrolled between November 2007 and March 2009 for previous studies approved by the Mayo Clinic Institutional Review Board, and from which we collected all available data to ensure as large a sample size as possible. These patients were enrolled into the study of Buchner *et al*[8] and for further studies by the same Mayo Clinic group. Only the patients with complete diagnostic data were considered in our study. All study participants gave full written consent. Patients were enrolled if they were due for surveillance or screening colonoscopies, evaluation of known or suspected polyps on other imaging modalities, and endoscopic mucosal resection of larger flat colorectal neoplasia. Exclusion criteria were patients with non-corrected coagulopathy, women who were pregnant or breast feeding, those with documented allergy to fluorescein, and patients with no colorectal lesions found during a study colonoscopy. Twenty-four hours before the procedure, patients were prepped with 2-4 L polyethylene glycol solution. Conscious sedation was performed with intravenous administration of midazolam and meperidine.

Endoscopy equipment and procedure

All procedures were performed by the authors (either Wallace MB or Buchner AM) using a high-definition colonoscope (Fujinon EC450HL5 or 490 ZW, Fujinon, Ft Wayne, NJ, United States; Olympus CFH180, Olympus, Center Valley, NY, United States). The system was equipped with the EPX 4400 processor (Fujinon Inc.) or CV 180 Exera (Olympus, Co.). The primary screening method was white-light high-definition colonoscopy. Then, either Fujinon Intelligent Color Enhancement

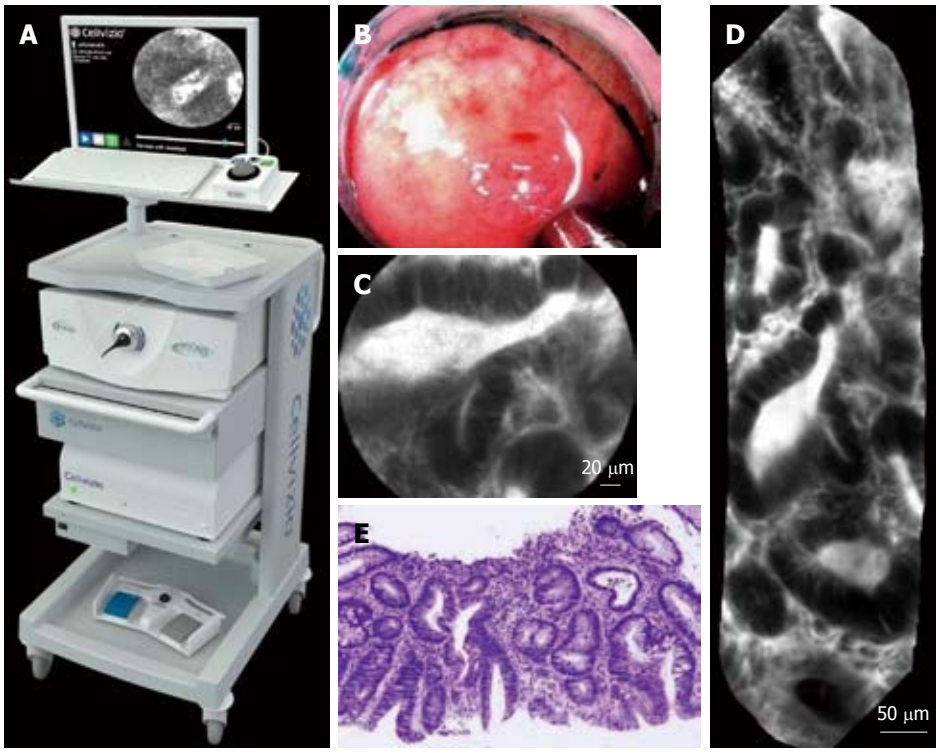

Figure 1 Imaging modalities of colonic polyps. mode 4 with a Fujinon colonoscope or Narrow-Band Imaging with an Olympus 180 series scope was used to characterize lesions in all patients.

The surface pit pattern of the lesion was classified according to Kudo criteria. Anatomical site and morphological class of lesions were recorded in accordance with the Paris classification[10]. Fluorescein sodium 2.5-5.0 mL 10% (AK Fluor, Akorn Pharmaceutical, Lake Forest, IL, United States) solution was administered intravenously after the first polyp was identified. Immediately after fluorescein injection, pCLE video sequences of the lesions were acquired and recorded. According to the visual examination of both endoscopic and pCLE images, real biopsies were targeted to the most suspicious parts of the polyp. Appropriate treatment procedures, ranging from simple polypectomies to complex endoscopic mucosal resection of lesions, were then performed.

Probe-based confocal laser endomicroscopy acquisition protocol

During a pCLE acquisition protocol, the endoscopist typically inserts, through the working channel of a standard endoscope, a confocal miniprobe (Coloflex UHD, Cellvizio GI) of external diameter 2.5 mm, which is made of 30 000 optical fibers bundled together. The pCLE imaging setup, shown in Figure 1, allows the acquisition of pCLE images of field-of-view 240 μm at a rate of 9 to 12 frames per second. In stable pCLE video sequences, the probe is in constant contact with the tissue. Representative endoscopic, pCLE, and histopathology images of tubular adenoma are shown in Figure 1.

Prior to pCLE evaluation of the study polyps, the 2 expert endoscopists (Wallace MB, Buchner AM) viewed extensive published material on pCLE and performed a self-calibration on training pCLE videos of 20 polyps of known pathology (10 neoplastic and 10 non-neoplastic). These "training" polyps were evaluated by a gastrointestinal pathologist (Krishna M) and came from 9 patients not included in the study. Once acquired, the pCLE videos of the study lesions were evaluated off-line and in random order by the 2 expert endoscopists, who were blinded to histology diagnosis and endoscopic appearance of the lesion. The off-line diagnosis of pCLE videos was made based on the established modified Mainz criteria[11] for diagnosis of colorectal neoplasia, and according to pit pattern and overall crypt and vessel architecture. Of the whole pCLE video imaging of a polyp, the sequence of the video containing the most malignant pCLE features was considered to represent the polyp.

Histopathology as criterion standard diagnosis

All resected specimens were reviewed by a reference gastrointestinal pathologist (Krishna M) blinded to the pCLE information. Only the size and anatomic location were provided, which is the routine clinical practice at the Mayo Clinic institution. Intraepithelial neoplasia were defined using modified Vienna criteria[12,13]: benign polyps and hyperplastic polyps were classified as non-neoplastic lesions, while tubular adenoma, villous adenoma, tubulovillous adenoma and adenocarcinoma were classified as neoplastic lesions.

Standard bag-of-visual-words technique for content-based image retrieval

As endoscopists use perceptual similarities between pCLE videos of known diagnosis to establish a diagnosis on a new pCLE video, we propose a content-based retrieval approach to design the automated pCLE

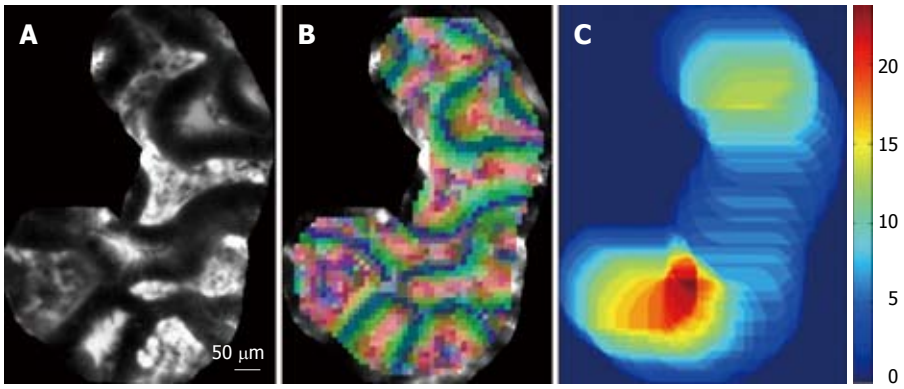

Figure 2 Adjusting bag-of-visual-words technique for probe-based confocal laser endomicroscopy video retrieval. A: Neoplastic probe-based confocal laser endomicroscopy mosaic obtained with non-rigid registration; B: Colored visual words mapped to the disk regions of radius 60 pixels in the mosaic image; C: Overlap scores of the local regions in the mosaic space, computed from the translation results of mosaicing.

video classification software. We revisited the standard bag-of-visual-words (BoW) technique which has been successfully used in many content-based image retrieval applications in computer vision[14]. A thorough technical presentation of our methodology has been disclosed previously[15], but without detailed clinical evaluation.

The standard BoW technique for image retrieval can be divided into four steps: region detection on the image, description of the regions, discretization of the feature space and similarity measuring between images. The detection step extracts salient regions in the image using sparse detectors. During the description step, a descriptor computes for each salient region its description vector. Then, the discretization step uses the result of a clustering method that builds K clusters, i.e., K visual words, from the union of the description vector sets gathered across all the images of the training database. Each description vector counts for one visual word, so an image can be represented by a signature of size K which is the histogram of its visual words. By construction, image signatures are invariant by viewpoint changes (image translation, rotation and scaling) and affine illumination changes. Finally, the similarity measuring step defines the similarity distance between two images as an adequate distance between their signatures: the most similar training images to the image of interest are defined as being the closest ones in terms of this distance.

Adjusting bag-of-visual-words technique for probe-based confocal laser endomicroscopy video retrieval

First, we observed that discriminative information is densely distributed in pCLE images. Second, we noticed that several pCLE image patterns have the same shape but represent different objects characterized by their different size (e.g., mesoscopic crypts and microscopic goblet cells both have a rounded shape). Therefore, pCLE image description must not be invariant by scaling. To avoid scale invariance and to extract all the image information, we decided to apply, instead of standard sparse detectors, a dense detector that was made of overlapping disks having a fixed radius and localized on a dense regular grid. We maintained the invariance by in-plane translation and rotation, because the pCLE miniprobe translates and rotates along the tissue surface. Besides, as the diffusion rate of fluorescein administered before imaging procedure decreases through time, invariance by affine illumination changes is also preserved.

Expert endoscopists pointed out that the field-of-view of single still images may not be large enough to make a robust diagnosis. Thus, we decided to retrieve not single images but complete videos, using the video mosaicing technique[16,17] (available in the Cellvizio software) to include spatial overlap between time-related images. Examples of mosaics built with the video mosaicing tool are shown in Figure 1. To ensure on-line retrieval, we use the translation results of the real-time version of the video-mosaicing technique to weight the contribution of each local image region to its visual word, as illustrated in Figure 2. Then, we computed the video signatures with a histogram summation technique. The whole pipeline of our retrieval-based software classification framework can be run on-line during ongoing colonoscopy (Figure 3).

Classification of probe-based confocal laser endomicroscopy videos using similarity distance

Once the visual signature of the video query is computed, the k-Nearest Neighbor search step identifies the k closest training videos to the video query, by relying on the similarity distance between the video signatures. We then used the known histopathology diagnosis of these training videos to classify the query video, either as neoplastic or as non-neoplastic. Each of the k most similar training videos delivers a "histopathological" vote which is weighted by the inverse of its similarity distance to the video query.

Due to the relatively small size of our pCLE database, we needed to learn from as much data as possible. To avoid any bias while having a large training set, we employed cross-validation. As several videos were acquired for the same patient, we performed a leave-one-patient-out cross-validation[18]: all videos from a given patient were excluded from the training set before being tested as queries of our retrieval and classification software. Cross-validation also allowed us to find the optimal number of nearest neighbors, $k = 9$, which is the one that maximizes the accuracy of the retrieval-based software classification results.

fication were obtained using leave-one-patient-out cross-validation. Statistical analysis was performed by André B.

To test for statistical difference between the two methods of interest, namely automated software classification and off-line classification by expert endoscopists, we used McNemar's tests[19] and showed the corresponding power calculations with a type I error alpha = 0.05. Two-sided P values < 0.05 were assumed to indicate statistical significance.

In order to assess statistical equivalence between the two methods, we used the two-sided Z-test between proportions[19,20] and computed 95% CI. Because the 135 pCLE videos constituted a small sample size, we used a correction for continuity for McNemar's test.

The statistics on overall accuracy are dependent on the relative fraction of non-neoplastic and neoplastic lesions examined, which in this study were 31.1% and 68.9%, respectively. Even though observations were made for more than one polyp in some patients, for the purposes of statistical analysis, individual polyps (and their corresponding videos) were assumed to constitute independent observations. It is recognized that there was multiple testing of outcome data arising from individual polyps. Since the statistical tests were meant to highlight differences, and since the correction by Bonferroni's method did not affect statistical significance in any of the comparisons, all P values are presented uncorrected for multiple testing.

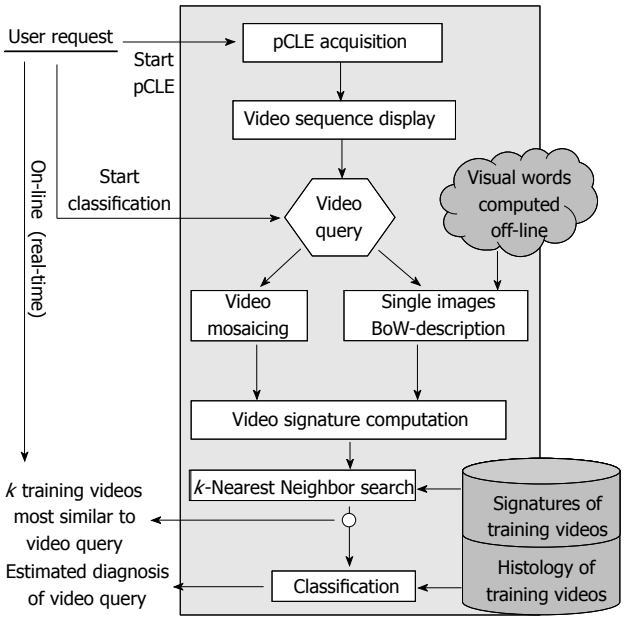

Figure 3 Pipeline of the probe-based confocal laser endomicroscopy retrieval-based software classification framework. From the acquisition of the probe-based confocal laser endomicroscopy (pCLE) video query by the Cellvizio system to the on-line automated diagnosis estimation.

RESULTS

Study population and colorectal lesion characteristics

Table 1 summarizes the demographic and general characteristics of the study population. None of the 71 patients experienced any endoscopic complications or adverse reactions to sodium fluorescein, with the exception of transient yellow discoloration of the skin and urine, which resolved by the time of discharge from the recovery room (skin) or within 24 h (urine). Histopathology and morphological classification of the 135 analyzed colorectal lesions are shown in Table 2.

Qualitative results of visual similarities between probe-based confocal laser endomicroscopy videos

The pCLE database contained 135 pCLE videos representing each of the 135 polyps. The pCLE appearance of neoplastic lesions, compared to that of non-neoplastic lesions, included dilated irregular vessels, fluorescein leakage, cellular features of epithelial mucin depletion, and histological features of villiform crypts with increased optical density along the epithelial border.

As the automated pCLE classification software is a similarity-based system that classified pCLE videos based on the votes of visually similar videos, its clinical relevance can be qualitatively evaluated by examining the intermediate results of video retrieval. Examples of mosaics built with the video mosaicing tool are shown in

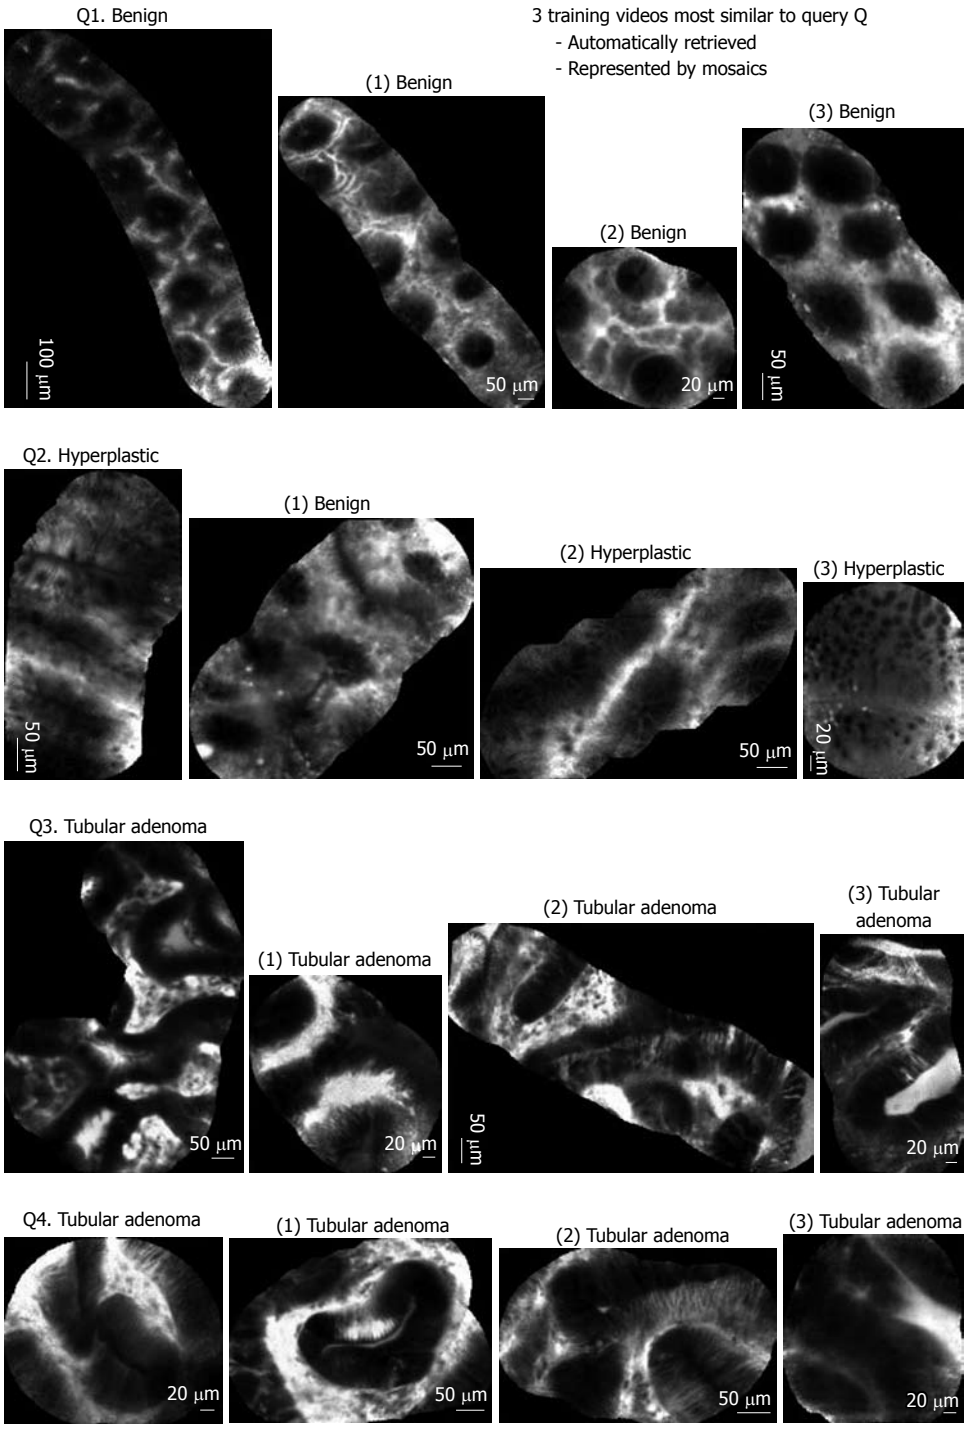

Figure 4 Typical results of automated probe-based confocal laser endomicroscopy video retrieval. The probe-based confocal laser endomicroscopy (pCLE) videos are represented by mosaic images; they are annotated with their histopathology diagnosis. Video queries are highlighted in gray and followed by their 3 most similar videos. Automated software classification (hyperplastic vs neoplastic) of query videos is based on the votes of the similar videos. With respect to histopathology, both the automated software classification and the pCLE diagnosis established by expert endoscopists are correct for these queries.

Figures 4 and 5. Figure 4 shows 5 typical results of the automated pCLE retrieval software. We observed that, despite the high variability in appearance of a given histopathological class (neoplastic or non-neoplastic), the automatically retrieved videos called "neighbors" looked quite similar to the video queries (Q1, Q2, Q3 and Q4, respectively). In addition, we noticed that the closer the neighbor was to the query, the more similar it was to it.

In terms of classification, the pathological class was estimated by the weighted votes of the 3 retrieved neighbors. In Figure 4, video queries Q1, Q2, Q3 and Q4 have been correctly classified with respect to histopathology, both by automated software classification and by expert endoscopists.

Figure 5 shows 3 other results that revealed some limitations of the automated pCLE retrieval software. Video query Q5 corresponds to a rare variety of hyperplastic polyp correctly classified as non-neoplastic by the expert endoscopists, but misclassified by the automated software classification because it was not represented in the training database for retrieval. Video query Q6 corresponds to the ambiguous serrated adenoma case, correctly classified as non-neoplastic by the automated software classification, but misclassified by the expert endoscopists who considered serrated adenomas as malignant. Video query Q7 corresponds to a tubulovillous

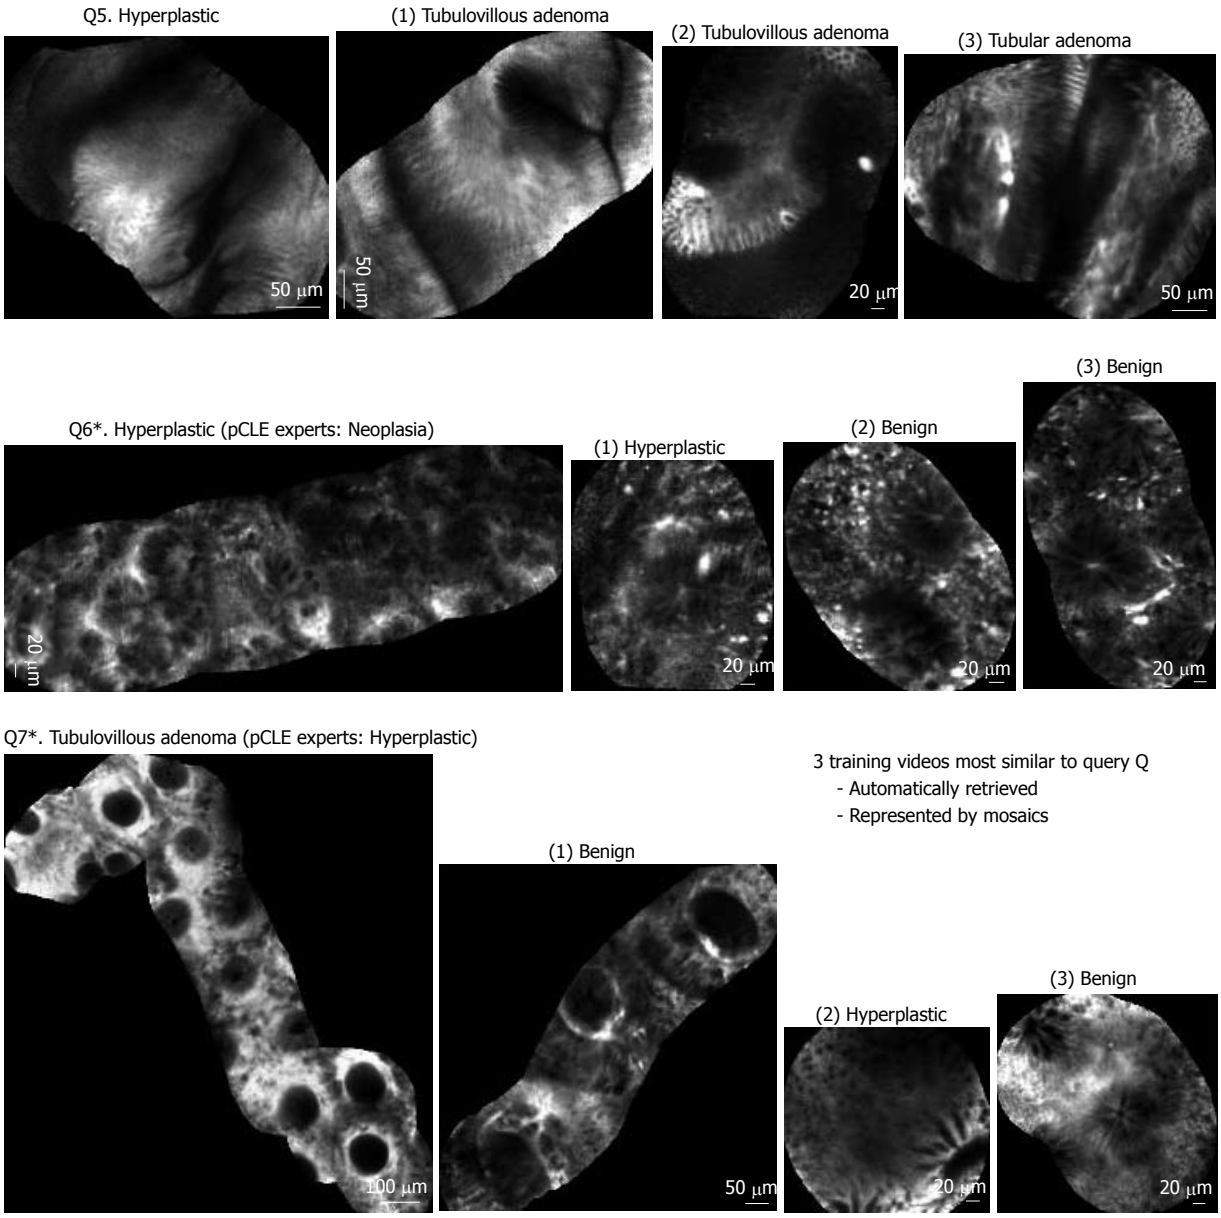

Figure 5 Results of automated probe-based confocal laser endomicroscopy video retrieval represented as mosaics. With respect to histology: the automated software classification is correct for video query Q6 but incorrect for video queries Q5 and Q7, whereas the off-line diagnosis of probe-based confocal laser endomicroscopy videos established by the expert endoscopists is correct for video queries Q5 but incorrect for video queries Q6 and Q7 (for which this disagreement is marked by *).

adenoma misclassified as non-neoplastic both by the expert endoscopists and by the automated software classification (this may be explained if a sampling error occurred and the corresponding biopsy was not performed exactly on the imaging spot).

Quantitative results of automated pCLE classification compared to off-line diagnosis of pCLE videos established by experts

Classification accuracy, sensitivity and specificity of the two methods, automated pCLE software classification (first method) and off-line diagnosis of pCLE videos established by the 2 expert endoscopists (second method), are listed in Table 3. Automated software classification reached a sensitivity of 92.5%, a specificity of 83.3% for a resulting accuracy of 89.6%. Expert review reached a sensitivity of 91.4%, a specificity of 85.7% and the same accuracy of 89.6%.

When testing for statistical difference, the *P* values provided by McNemar's tests showed that the differences between the 2 methods were not statistically significant and that there was very low power (< 6%) to detect the observed differences.

When testing for statistical equivalence, the 95% confidence intervals provided by two-sided *Z*-tests between proportions were: -0.073 to 0.073 for accuracy, -0.068 to 0.089 for sensitivity and -0.18 to 0.13 for specificity. These intervals included zero and were sufficiently small to suggest that the methods were equivalent. In particular, the -0.18 lower bound for specificity was acceptable

if the automated pCLE classification software was only taken as a second-reader tool to support pCLE diagnosis.

DISCUSSION

The present study demonstrates that, using a fairly representative database of colonic polyps, our automated software for the pCLE video classification has overall high accuracy, sensitivity and specificity, that are comparable to those of the off-line diagnosis of pCLE videos established by two endoscopists expert in pCLE. As the automated classification software can be run on-line during ongoing colonoscopy, it could be used as a second-reader tool to support and improve not only off-line but also on-line diagnosis of pCLE established by endoscopists with various levels of expertise. In the majority of cases, the second reader would agree with a moderately experienced endoscopist, who would thus be comforted in his/her diagnosis. For cases when they disagree, the endoscopist would have the opportunity to rethink his/her diagnosis and have more accurate *in vivo* interpretation. Besides, especially for small polyps, this second-reader tool could assist the endoscopist in adopting the "Diagnose, Resect and Discard Strategy" that dispenses with histopathological examination.

Gomez *et al*[21] analyzed *in vivo* pCLE interpretation in distinguishing between neoplastic and non-neoplastic lesions among 3 expert endoscopists and estimated an average accuracy of 75% (sensitivity 76%, specificity 72%) with good to moderate interobserver agreement. Buchner *et al*[22] demonstrated that accurate interpretation of pCLE images by 11 endoscopists, considered as non-expert in pCLE, can be learned rapidly with a short 2-h training session. The learning curve pattern of pCLE in predicting neoplastic lesions was demonstrated with improved accuracies in time from 63% to 86% as observers' experience increased. Thus, prospectively, the automated classification software could be valuable not only for *in vivo* diagnosis support, but also for training support to improve the learning curve of new endoscopists. Indeed, we have shown in a preliminary study[23] how interpretation difficulty can be automatically estimated by the software, in order to develop a self-training simulator for pCLE diagnosis with adjustable level of difficulty. For surgical skills, evidence of the learning effect from the use of training tools have been provided in the thesis by Brydges[24], however, further investigation is needed for the extension of learning effect analysis to diagnostic skills.

One of the advantages of our classification software is that it is not a "black box" but an informative tool based on the query by example model: it produces, as intermediate results, visually similar annotated videos that are directly interpretable by the endoscopist. From the qualitative observations of visual similarities between pCLE videos, we suggest that the visually convincing results of the intermediate video retrieval step account for the relevance of the whole pCLE classification software. As few similar videos (less than 10) are necessary to classify a video query with high accuracy, this visual information should be clinically useful for the endoscopist.

Further limitations of the classification software may include three main issues. First, a large training database is needed to be sufficiently representative of non-typical pCLE cases. This is even more challenging since the practice of pCLE is evolving and that new cases with atypical pCLE features may still be encountered. Second, the definition of "criterion standard" for colorectal cancer screening is debatable because expert endoscopists and pathologists do not always agree. This can be illustrated by many examples of hyperplastic polyps redefined later as sessile serrated lesions by gastrointestinal pathologists, as in the study by Khalid *et al*[25]. The third limitation is that an obtained biopsy may be acquired unintentionally from the area that does not correspond with the obtained pCLE imaging.

The task of the automated pCLE classification software is not to replace the endoscopist or the pathologist but to assist the endoscopist in making an informed decision. Before using the computer-based classification tool during an ongoing endoscopy procedure, more work is needed to improve its accuracy and to develop underlying tools that are both ergonomic and complementary. In particular, the on-line display of the retrieval outputs, for instance of the 3 most similar videos to the video query, together with their histopathology and possible multimodal clinical data, may be a precious underlying indicator for diagnosis decision. Such a sophisticated "Smart Atlas" for pCLE would allow endoscopists in different centers to share and enrich their pCLE knowl-

edge during ongoing endoscopy. Further studies are warranted to evaluate the impact of using automated pCLE retrieval and classification software on the pCLE learning curve and on the diagnostic performance of the endoscopists.

ACKNOWLEDGMENTS

The authors thank Dr. Muhammad Waseem Shahid for his contribution to data collection and analysis. A preliminary report of this study was presented at the AGA Late Breaking Abstract Forum (Imaging and Advanced Technology-Confocal Endoscopy), Digestive Disease Week, 2010. The present study uses data from the following clinical trial: NCT 00874263.

COMMENTS

Background

Histopathology is the criterion standard for the diagnosis of colorectal cancers, but it implies a large proportion of unnecessary polypectomies and an inherent delay in diagnosis. Probe-based confocal laser endomicroscopy (pCLE) is a recent technology that enables, during ongoing endoscopy, *in vivo* imaging of the epithelium at the microscopic level.

Research frontiers

Several studies have already demonstrated the applicability of pCLE in diagnosing colorectal neoplasia *in vivo* with high sensitivity and specificity. Because pCLE is a relatively recent imaging technology, the interpretation of pCLE videos of colonic polyps for diagnostic purposes is still challenging for many non-expert endoscopists.

Innovations and breakthroughs

This is believed to be the first study to propose, with the aim of supporting *in vivo* diagnosis of colorectal cancers, content-based image retrieval-based classification software that automatically extracts visually similar annotated videos directly interpretable by the endoscopist. The extracted annotated videos can be presented to the endoscopist in a second reader paradigm to better support pCLE diagnosis. Furthermore, this study demonstrates that this novel software achieves a high diagnostic performance, which is statistically comparable to that of off-line diagnosis of pCLE videos established by expert endoscopists.

Applications

The classification software proposed in this study is an objective tool which has the potential to support the interpretation of pCLE videos of colonic polyps for diagnostic purposes. Further studies are warranted to evaluate the impact of using the automated classification software on the pCLE learning curve and on the diagnostic performance of endoscopists.

Terminology

pCLE: An imaging system that allows the endoscopist to visualize the epithelium *in vivo*, at the microscopic level and in real-time during ongoing endoscopy; Content-based image retrieval: A computer vision technique that automatically extracts, given a query image, several training images with the most similar appearance to the query.

Peer review

This is a good descriptive study in which authors support probe-based confocal laser endomicroscopy diagnosis by designing a software for automated classification of colonic polyps. The results are interesting and suggest that the proposed software for automated classification of pCLE videos of colonic polyps achieves high performance, comparable to that of off-line diagnosis of pCLE videos established by expert endoscopists.

Abstract

AIM: To analysis the factors that predict the response to entecavir therapy in chronic hepatitis patients with hepatitis B virus (HBV) genotype C.

METHODS: Fifty patients [hepatitis B e antigen (HBeAg)-negative:HBeAg-positive = 26:24] with HBV genotype C, who received naïve entecavir therapy for > 2 years, were analyzed. Patients who showed HBV DNA levels ⩾ 3.0 log viral copies/mL after 2 years of entecavir therapy were designated as slow-responders, while those that showed < 3.0 log copies/mL were termed rapid-responders. Quantitative hepatitis B surface antigen (HBsAg) levels (qHBsAg) were determined by the Architect HBsAg QT immunoassay. Hepatitis B core-related antigen was detected by enzyme immunoassay. Pre-C and Core promoter mutations were determined using by polymerase chain reaction (PCR). Drug-resistance mutations were detected by the PCR-Invader method.

RESULTS: At year 2, HBV DNA levels in all patients in the HBeAg-negative group were < 3.0 log copies/mL. In contrast, in the HBeAg-positive group, 41.7% were slow-responders, while 58.3% were rapid-responders. No entecavir-resistant mutants were detected in the slow-responders. When the pretreatment factors were compared between the slow- and rapid-responders; the median qHBsAg in the slow-responders was 4.57 log IU/mL, compared with 3.63 log IU/mL in the rapid-responders (P < 0.01). When the pretreatment factors predictive of HBV DNA-negative status at year 2 in all 50 patients were analyzed, HBeAg-negative status, low HBV DNA levels, and low qHBsAg levels were significant (P < 0.01). Multivariate analysis revealed that the low qHBsAg level was the most significant predictive factor (P = 0.03).

CONCLUSION: Quantitation of HBsAg could be a useful indicator to predict response to entecavir therapy.

INTRODUCTION

Hepatitis B virus (HBV) is a major causative agent of chronic liver diseases[1]. Various strains of HBV have been isolated all over the world, and have been classified as HBV genotypes from A to J[2]. In Japan, about 85% of patients have HBV genotype C, and about 12% have HBV genotype B[3]. Worldwide, HBV genotypes show specific geographical distributions. HBV genotypes A and D are prevalent in the United States and Europe, while HBV genotypes B and C are prevalent in Asia[4]. Disease progression and prevalence of hepatitis B e antigen (HBeAg)-positive status are often associated with HBV genotypes[5]. Therefore, we analyzed the clinical and virological features of patients with HBV genotype C and homogenous backgrounds, because HBV genotype C is the predominant type in Japan.

Entecavir is widely used as a first-choice nucleot(s)ide analog (NA) for chronic hepatitis B patients, because less than 1% of entecavir-naive patients developed resistant mutants after 5 years of therapy[6-8]. However, in HBeAg-positive patients, the response rate to entecavir therapy is less favorable compared with HBeAg-negative patients[6,7]. In addition, some patients show a slow-response, which indicates that serum HBV DNA levels remain high after long-term entecavir therapy. However, it is unclear which patients become slow-responders. Therefore, the aim of this study is to clarify the virological and clinical characteristics of the slow-responders before and during long-term entecavir therapy for HBV genotype C.

MATERIALS AND METHODS

Patient population

From July 2007, 102 consecutive hepatitis B surface antigen (HBsAg)-positive patients with chronic liver disease were enrolled in a naïve entecavir therapy in our hospital. Ten patients dropped out, 15 patients discontinued therapy, 10 patients received immunosuppressive therapy during entecavir therapy, and 10 patients received entecavir for less than 2 years. Thus, 57 patients were analyzed in this prospective, single center study. The institutional review board of the hospital approved the study. Serum samples were drawn from the patients after obtaining written informed consent.

All the patients received 0.5 mg of entecavir daily. Patients with poor adherence were excluded from the study.

All patients were positive for HBsAg for more than 6 mo, had serum HBV DNA of ≥ 3 log viral copies/mL, were negative for anti-HCV, and were negative for anti-human immunodeficiency virus before entecavir therapy. Patients with decompensated cirrhosis, acute hepatitis, or acute exacerbation were excluded. Liver biopsy was not performed in some patients; therefore, the liver disease status was diagnosed by the clinical, laboratory, and imaging tests.

HBeAg-positive patients whose serum HBV DNA levels remained ≥ 3.0 log copies/mL after 2 years of entecavir therapy were considered to be slow-responders, while patients with < 3.0 log copies/mL were designated as rapid-responders.

Table 1 Baseline characteristics of the patients with hepatitis B virus genotype C

	HBeAg-negative group	HBeAg-positive group	*P* value
No.	26	24	NS
Age (yr)	57.2 (35-80)	44.2 (35-71)	< 0.01
Gender, M:F	15:16	16:11	NS
Diseases, CH:LC/HCC	21:5	23:1	NS
ALT (IU/mL)	38 (13-950)	102 (812-602)	< 0.01
Platelet counts ($\times 10^4$/mL)	18.6 (3.4-4.9)	18.0 (8.4-26.8)	NS
Albumin (mg/dL)	4.3 (3.4-4.9)	4.2 (2.3-5.0)	NS
Serum HBV DNA level (log copies/mL)	5.1 (3.9-8.8)	7.6 (5.6-8.8)	< 0.01

All data are shown by median (range). HBeAg: Hepatitis B e antigen; HBV: Hepatitis B virus; ALT: Alanine aminotransferase; CH: Chronic hepatitis; LC: Liver cirrhosis; HCC: Hepatocellular carcinoma; NS: Not significant.

Laboratory tests

Quantitation of HBsAg (qHBsAg) was performed using the Architect HBsAg QT immunoassay (Abott Japan, Tokyo, Japan), in accordance with the manufacturer's instructions[9]. The detection range was 0.05 to 250 IU/mL. If HBsAg levels were found to be higher than 250 IU/mL, samples were diluted to 1:500 to 1:20 000. In this study, the results of the quantitative HBsAg levels are shown as the logarithmic value. HBV genotypes were detected by enzyme immunoassay (EIA) (Institute of Immunology, Tokyo, Japan)[10]. The HBV core-related antigen (HBcrAg) was detected by a chemilimunescent EIA method (Fujirebio Inc., Tokyo, Japan)[11]. Pre-C mutation and Core promoter mutations were detected by polymerase chain reaction (PCR) (HBV DNA precore/core promoter mutation decision kit; Roche Diagnostics Japan, Tokyo, Japan). Drug-resistant mutations in HBV against nucleotide analogs (NAs; lamivudine, adefovir and entecavir) were detected by the PCR-Invader method (BML Inc., Tokyo, Japan)[12].

RESULTS

Of the 57 patients, 50 patients were genotype C, three patients were HBV genotype A, one was genotype D, and three were of indeterminate genotype on EIA. Thus, the 50 patients with HBV genotype C were analyzed. Baseline characteristics of the 50 patients are shown in Table 1. The median age of the HBeAg-negative group age was significantly higher, the median alanine aminotransferase (ALT) level was significantly lower, and the median HBV DNA level was significantly lower than those in the HBeAg-positive group.

After 2 years of entecavir therapy, the rates of normalization (< 40 IU/L) of ALT levels were 87.0% in the HBeAg-negative group and 92.5% in the HBeAg-positive group (*P* = Not significant).

In contrast, at year 2, the rates of reduction in HBV

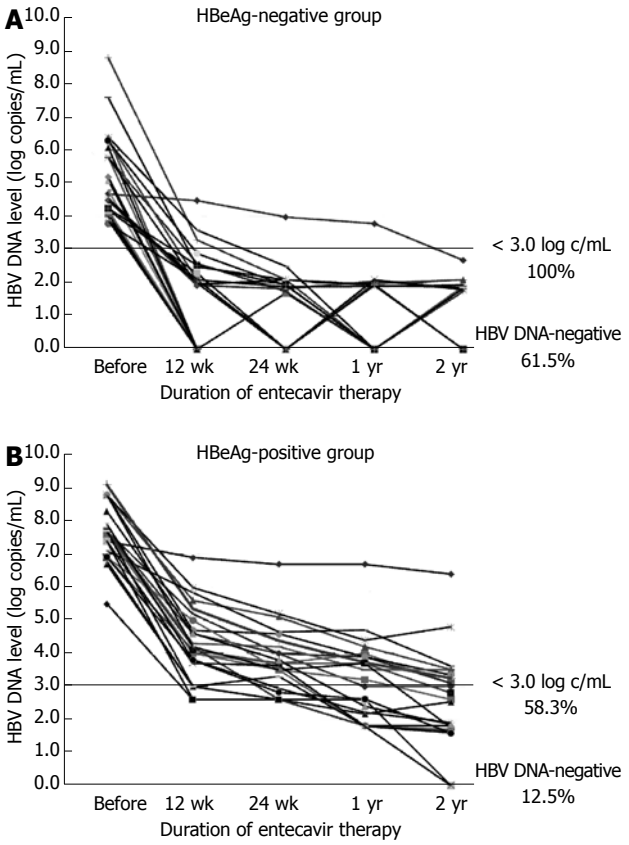

Figure 1 Hepatitis B virus DNA levels before and during entecavir therapy. A: In the hepatitis B e antigen (HBeAg)-negative group, hepatitis B virus (HBV) DNA levels in all patients decreased to < 3.0 log copies/mL at year 2. Of these patients, 61.5% shown to be negative for HBV DNA by the real-time polymerase chain reaction method; B: In the HBeAg-positive group, 58.3% of patients (rapid-responders) showed < 3.0 log copies/mL at year 2, while 41.7% of patients (slow-responders) showed ≥ 3.0 log copies/mL. In addition, at year 2, only 12.5% of the patients were negative for HBV DNA.

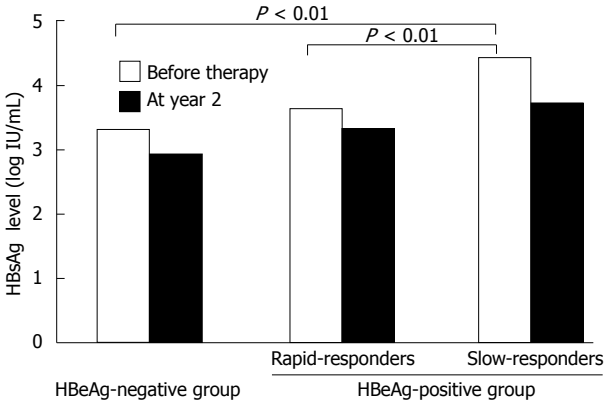

Figure 2 Median quantitative hepatitis B surface antigen levels among patients receiving entecavir therapy. Quantitative hepatitis B surface antigen (HBsAg) levels (qHBsAg) levels in slow-responders in the HBeAg-positive group were significantly higher than those in rapid-responders and the hepatitis B e antigen (HBeAg)-negative group. The median qHBsAg level at year 2 in the slow-responders remained higher than in other groups.

DNA to < 3.0 log copies/mL were 100% in the HBeAg-negative group and 58.3% in the HBeAg-positive group ($P < 0.01$). Thus, in the HBeAg-positive group, 58.3% of patients were designated as rapid-responders, and 41.7% were designated as slow-responders (HBV DNA levels ≥ 3.0 log copies/mL at year 2) (Figure 1). In addition, in the HBeAg-negative group, real-time PCR indicated that 61.5% of the patients were negative for HBV DNA, compared to 12.5% of the HBeAg-positive patients ($P < 0.01$).

Baseline data

When pre-treatment factors were compared between the rapid- and slow-responders (Table 2), age, gender, disease, platelet counts, and albumin were not significantly different. The median ALT level in the rapid-responders group was 131 IU/L compared with 31 IU/L in the slow-responders ($P = 0.02$). The pre-treatment median HBV DNA levels were 7.4 log copies/mL in the rapid-responders, and 8.3 in the slow-responders ($P = 0.06$). The was no difference in the rate of Pre-C and Core promoter mutations between the responder groups. In contrast, the rate of Pre-C mutations in the HBeAg-negative group was 83.3%, compared with 0% in the HBeAg-positive group. Pre-treatment HBcrAg levels did not differ among the three groups. In contrast, the pre-treatment median qHBsAg level was 3.63 log IU/mL in the rapid-responders, compared with 4.57 log IU/mL in the slow-responders ($P < 0.01$).

Data at year 2

At year 2 of therapy, the median qHBsAg level in the rapid-responders was 3.25 log IU/mL, compared with 4.12 log IU/mL in the slow-responders ($P = 0.01$). The median HBcrAg level in the rapid-responders was 5.85 log U/mL, compared with > 6.8 (the upper limit of the detection range) in the slow-responders ($P < 0.01$). In Figure 2, qHBsAg levels before treatment and at year 2 are shown for the HBeAg-negative group, and the rapid-responder and slow-responders in the HBeAg-positive group.

Among all the slow-responders, no entecavir-resistant mutations were found, although three patients showed M204I lamivudine-resistant mutations (Table 3).

Comparison between HBV DNA-negative and -positive patients at year 2 during entecavir therapy in all the patients

At year 2 of entecavir therapy, among 50 patients, real-time PCR showed that 19 (38.0%) were negative for HBV DNA, compared with 31 (62.0%) who were still positive for HBV DNA (Table 4). The pretreatment clinical and virological characteristics between the HBV DNA-negative and -positive groups were compared by univariate analysis. In the HBV DNA-negative group, the median ALT level was significantly lower, the rate of HBeAg-negative status was significantly higher, the median HBV DNA level was lower, and the median qHBsAg level was lower, than those in the HBV DNA-positive group.

However, when multivariate analysis using logistic regression analysis was performed, the median qHBsAg level was the only significant factor that predicted the negative HBV DNA status at year 2 of entecavir therapy

DISCUSSION

In this study, the clinical and virological features of patients with HBV genotype C who received naïve-entecavir therapy were analyzed. After 2 years of entecavir therapy, about 42% of the HBeAg-positive patients showed HBV DNA levels ≥ 3 log copies/mL, while all of the HBeAg-negative patients showed < 3 log copies/mL. Therefore, the factors associated with the slow response to entecavir therapy among the HBeAg-positive group were studied initially. In addition, among the 50 patients, 38% showed HBV DNA-negative status at year 2. Thus, the pretreatment factors that predict the loss of HBV DNA were analyzed in all 50 patients. According to the multivariate analysis, qHBsAg levels are the most important factor for predicting the response to entecavir therapy in patients with HBV genotype C.

In Japan, HBV genotype C is the most prevalent[3]. The response rates to interferon or NA therapy in patients with HBV genotype C, as well as D, are poor when compared to those with HBV genotype B or A[13]. Thus, in this study, only subjects with HBV genotype C were studied.

Recently, a decline in HBsAg levels during PEG-interferon therapy was reported to be significant in the evaluation of the response to therapy[14-17]. In these reports, HBsAg levels were found to be one of the best viral markers for predicting response to anti-viral therapy and viral

activity levels in hepatocytes, correlating with cccDNA levels[14,18]. Although qHBsAg is a predictor of response to entecavir therapy[19], there have been no reports in a homogeneous HBV genotype setting. In this study, qHBsAg was demonstrated to be the most significant predictor of entecavir therapy in patients with HBV genotype C.

HBV DNA levels are also considered an important factor associated with response to anti-viral therapy[17]. In this study, there was a tendency for higher HBV DNA levels in the slow-responders as compared to rapid-responders. The association between HBV DNA levels and response to therapy may be clarified further in a larger number of patients.

HBcrAg levels indicate the serum HB core antigen levels plus HBeAg levels[11]. HBcrAg levels are reported to be associated with cccDNA levels in hepatocytes[20]. However, this study showed no association between HBcrAg levels and slow response. This may be explained by the narrow quantitation range of HBcrAg levels, because HBcrAg levels in most patients in the HBeAg-positive group were greater than the upper level of the detection range of the assay.

The association between Core promoter mutation and response rate to NAs is also interesting, because the replication level of HBV is thought to be high in patients with Core promoter mutations. We reported previously that, in patients with HBV genotype C, the rates of HBeAg-positive status and Core promoter mutations are higher than those in patients with HBV genotype B[5]. In this study, a higher rate of Core promoter mutations was observed in the HBeAg-positive patients with HBV genotype C. In addition, a higher rate of Pre-C mutations was observed in the HBeAg-negative group. However, no association between the mutation rate and response rate to therapy was demonstrated in this study.

Higher ALT levels are considered an important factor in predicting good response to PEG-interferon therapy[21]. However, low ALT levels were observed in the HBV DNA-negative group at year 2 of therapy, because a high proportion of the HBeAg-negative patients had low ALT levels, compared to the HBeAg-positive patients. Thus, we consider that, during entecavir therapy, ALT levels are not associated with treatment response.

In this study, no resistant mutations against entecavir were found during 2 years therapy. As reported previously, resistant mutations against entecavir are rarely developed during 5 years of entecavir therapy[8]. Therefore, slow response was not caused by entecavir-resistant mutants.

In conclusion, we suggest that qHBsAg is a significant and convenient indicator for predicting response to entecavir therapy.

ACKNOWLEDGMENTS

COMMENTS

Background

Entecavir is a nucleot(s)ide analog that is widely used for the treatment of chronic hepatitis B patients. The efficacy of entecavir is very good for hepatitis B e antigen (HBeAg)-negative patients, but not so good for HBeAg-positive patients. The prognosis and response to anti-viral therapies depend on hepatitis B virus (HBV) genotype. The factors that affect the efficacy of entecavir therapy are still unclear, especially in patients with HBV genotype C.

Research frontiers

As quantitation assay of serum hepatitis B surface antigen (HBsAg) has been recently developed, allowing the serum level of HBsAg to be determined over a very wide range. The upper range of HBsAg levels could be detected to 6.7 log IU/mL by the Architect HBsAg QT immunoassay when samples were diluted to 1:20 000. Thus, the authors could analyze the relationship between the efficacy of entecavir therapy and various HBV markers.

Innovations and breakthroughs

This study showed that the quantitative HBsAg level is a significant factor for predicting the efficacy of entecavir therapy in patients with HBV genotype C. Patients with low levels of HBsAg before entecavir therapy often show HBV DNA levels < 3.0 log copies/mL or are negative for HBV DNA at year 2 during therapy.

Applications

Using the quantitation of HBsAg, the efficacy of various anti-viral therapies can be predicted before treatment. The quantitation of HBsAg could be a useful tool for determining the treatment schedule for chronic hepatitis B patients.

Peer review

Although small in patient numbers, the subject matter is interesting and original. This study adds to the emerging data suggesting HBsAg decline is a predictor of response.

Abstract

AIM: To evaluate the effects of omeprazole on gastric mechanosensitivity in humans.

METHODS: A double lumen polyvinyl tube with a plastic bag was introduced into the stomach of healthy volunteers under fluorography and connected to a barostat device. Subjects were then positioned so they were sitting comfortably, and the minimal distending pressure (MDP) was determined after a 30-min adaptation period. Isobaric distensions were performed in stepwise increments of 2 mmHg (2 min each) starting from the MDP. Subjects were instructed to score feelings at the end of every step using a graphic rating scale: 0, no perception; 1, weak/vague; 2, weak but significant; 3, moderate/vague; 4, moderate but significant; 5, severe discomfort; and 6, unbearable pain. After this first test, subjects received omeprazole (20 mg, after dinner) once daily for 1 wk. A second test was performed on the last day of treatment.

RESULTS: No adverse effects were observed. Mean MDP before and after treatment was 6.3 ± 0.3 mmHg and 6.2 ± 0.5 mmHg, respectively. One subject before and 2 after treatment did not reach a score of 6 at the maximum bag volume of 750 mL. After omeprazole, there was a significant increase in the distension pressure required to reach scores of 1 (P = 0.019) and 2 (P = 0.017) as compared to baseline. There were no changes in pressure required to reach the other scores after treatment. Two subjects before and one after omeprazole rated their abdominal feeling < 1 at MDP, and mean (± SE) abdominal discomfort scores at MDP were 0.13 ± 0.09 and 0.04 ± 0.04, respectively. Mean scores induced by each MDP + 2, 4, 6, 8, 10, 12, 14, 16, 18 and 20 (mmHg) were 1.1 ± 0.3, 2.0 ± 0.4, 2.9 ± 0.5, 3.3 ± 0.4, 4.6 ± 0.3, 5.2 ± 0.3, 5.5 ± 0.2, 5.5 ± 0.3, 5.7 ± 0.3, and 5.4, respectively. After omeprazole, abdominal feeling scores for the same incremental pressures over MDP were 0.3 ± 0.1, 0.8 ± 0.1, 2.0 ± 0.4, 2.8 ± 0.4, 3.8 ± 0.4, 4.6 ± 0.4, 4.9 ± 0.3, 5.4 ± 0.4, 5.2 ± 0.6, and 5.0 ± 1.0, respectively. A significant decrease in feeling score was observed at intrabag pressures of MDP + 2 mmHg (P = 0.028) and + 4 mmHg (P = 0.013), respectively, after omeprazole. No significant score changes were observed at pressures ⩾ MDP + 6 mmHg.

CONCLUSION: Although the precise mechanisms are undetermined, the present study demonstrated that omeprazole decreases mechanosensitivity to mild gastric distension.

Inhibition of gastric perception of mild distention by omeprazole in volunteers. *World J Gastroenterol* 2012; 18(39): 5576-5580 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i39/5576.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i39.5576

INTRODUCTION

According to Rome Ⅲ, the classification for functional gastrointestinal disorders published in 2006, functional dyspepsia (FD) is defined as the presence of one or more dyspepsia symptoms (postprandial fullness, early satiation, epigastric pain, or epigastric burning) that originate from the gastroduodenal region in the absence of any organic, systemic, or metabolic disease that is likely to explain the symptoms[1]. Alteration of gastric motility, visceral hypersensitivity, impaired accommodation of meals, gastritis induced by *Helicobacter pylori* (*H. pylori*) infection, and dysfunction of the central nervous system have all been implicated in the pathophysiology of FD[2-4]. Duodenal acidification increases proximal gastric mechanosensitivity, induces proximal gastric relaxation, and seems to inhibit the proximal gastric accommodation to a meal[5]. Hypersensitivity not only to acid in the duodenum but also gastric distension has been proposed among the possible mechanisms of FD. Thus, the mechanism by which decreased duodenal acid exposure affects symptoms of dyspepsia warrants investigation.

Omeprazole, a proton pump inhibitor that strongly decreases acid secretion, has been prescribed in the treatment of FD worldwide. This is the best first-line treatment when compared with ranitidine, cisapride, and placebo for primary care of *H. pylori*-negative dyspepsia patients[6,7]. However, changes in patients' perceptions of gastric distention after omeprazole administration have yet to be clarified. The gastric barostat test has been reported to be the gold standard method for evaluating gastric perception[8-11]. In the present study, we examined the effects of omeprazole on mechanosensitivity in humans using the barostat test.

MATERIALS AND METHODS

Study subjects

Ten healthy volunteers were recruited (8 men, 2 women; mean age, 31.6 ± 2.1 years; range, 23 to 41 years). None of the subjects had any history of gastrointestinal disease, nor were they taking any medications. Per individual interviews, no subjects had any dyspepsia symptoms (postprandial fullness, early satiation, epigastric pain, or epigastric burning). A check for *H. pylori* infection was not requested. Written informed consent was obtained from each participant. The ethics committee of Aichi Medical University approved all the study protocols (No. 369-3).

Gastric barostat

The barostat system was set up as reported previously[12]. After the patient had fasted for 12 h, a double lumen polyvinyl tube with an adherent finely folded plastic bag (Mui Scientific, Mississauga, Ontario, Canada) was introduced through the mouth into the stomach under fluorography. The polyvinyl tube was then connected to a barostat device (Distender series Ⅱ TM; G and J Electronics, North York, Ontario, Canada). The bag was unfolded by inflation with 300 mL of air and was positioned in the proximal stomach with the subject in a recumbent position, after which the bag was deflated. Subjects were then positioned so they were sitting comfortably with their knees bent (80°) and trunk upright.

Gastric sensitivity to intragastric bag distension

After a 30-min adaptation period, minimal distending pressure (MDP) was determined by increasing the intrabag pressure by 1 mmHg every 3 min until a volume of 30 mL was reached. Gastric perception of distention by a barostat device was examined[12]. Isobaric distensions were performed in stepwise increments of 2 mmHg (2 min each) starting from the MDP while the corresponding intragastric volume was recorded continuously. Subjects were instructed to score feelings in the upper abdomen at the end of every distending step using a graphic rating scale that included verbal descriptors, as follows: 0, no perception; 1, weak/vague; 2, weak but significant; 3, moderate/vague; 4, moderate but significant; 5, severe discomfort; and 6, unbearable pain. The endpoint of each sequence of distensions was established at an intrabag volume of 750 mL or when the subject reported unbearable pain (score 6).

Effects of omeprazole on the barostat test

This study was investigated the effects of omeprazole (Omepral®; AstraZenca, Osaka, Japan) on the barostat test. After the first barostat test, 10 volunteers received omeprazole (20 mg, once after dinner) as the medication for 1 wk. The second barostat study was performed on the morning after the last medication.

Statistical analysis

Data are expressed as mean ± SE. Statistical evaluation was performed using one way-analysis of variance. Values of $P < 0.05$ were considered statistically significant. Analyses were performed using a personal computer with Office Excel 2003 software (Microsoft, Redmond, WA, United States), and Analyse-it Software (Analyse-it Software, Ltd., Road Leeds, United Kingdom).

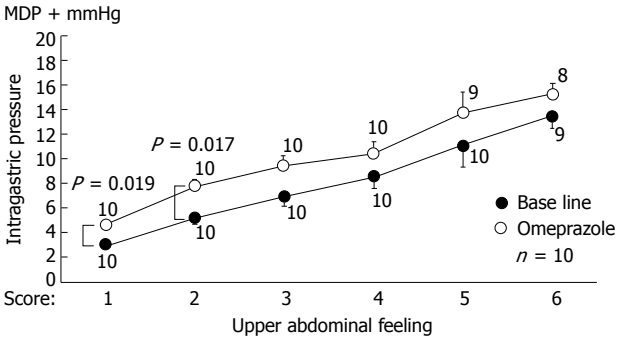

Figure 1 Intragastric pressure by a barostat device at each score of upper abdominal feeling. The distention pressure required to induce a weak/vague feeling (score 1) in the upper abdomen increased from 3.0 ± 0.5 mmHg over the minimal distending pressure (MDP) at baseline to 4.6 ± 0.4 mmHg over the MDP after omeprazole, $P = 0.019$. The distention pressure to induce a weak but significant feeling (score 2) increased from 5.2 ± 0.7 mmHg to 7.8 ± 0.6 mmHg, $P = 0.017$. The *n* sizes for each data point are indicated on the graph.

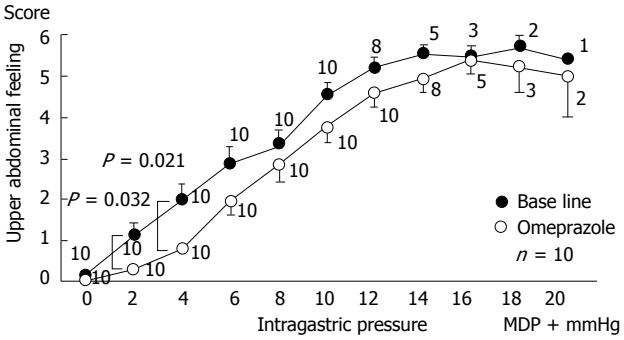

Figure 2 Score of upper abdominal feeling during gastric distension by a barostat device. The mean scores at the intrabag pressures of minimal distending pressure (MDP) + 2 mmHg and + 4 mmHg were decreased from baseline after omeprazole: 1.1 ± 0.3 *vs* 0.3 ± 0.1, $P = 0.028$; and 2.0 ± 0.4 *vs* 0.8 ± 0.1, $P = 0.0132$, respectively. No significant changes were observed at pressures > MDP + 4 mmHg. The *n* sizes for each data point are indicated on the graph.

RESULTS

No adverse effects were observed with omeprazole. Oral intubation with subsequent positioning of the barostat bag was well-tolerated by all subjects. The mean MDP before and after omeprazole was 6.3 ± 0.3 mmHg and 6.2 ± 0.5 mmHg, respectively. One subject at baseline and 2 after omeprazole did not reach discomfort scores of 6 at the maximum bag volume of 750 mL.

The distention pressures (mmHg) required to induce scores of weak/vague (score 1, $n = 10$), weak but significant (score 2, $n = 10$), moderate/vague (score 3, $n = 10$), moderate but significant (score 4, $n = 10$), severe discomfort (score 5, $n = 10$), and unbearable pain (score 6, $n = 9$) were 3.0 ± 0.5, 5.2 ± 0.7, 7.0 ± 1.0, 8.6 ± 0.9, 11.1 ± 0.8, and 13.5 ± 0.9, respectively, at baseline. After 1 week of daily omeprazole, the distension pressure required to induce the same scores ($n = 10$ for scores 1 to 4; $n = 9$, score 5; $n = 8$, score 6) were 4.6 ± 0.4, 7.8 ± 0.6, 9.4 ± 0.9, 10.4 ± 1.0, 13.8 ± 1.8, and 15.3 ± 1.0, respectively. The distended pressure needed to reach scores of 1 ($P = 0.019$) and 2 ($P = 0.017$) (Figure 1) increased significantly after omeprazole. No changes in pressure were demonstrated for other scores after treatment.

Eight subjects scored 0 for the MDP at baseline and 9 scored 0 for the MDP after omeprazole. The mean discomfort scores (± SE) at MDP before and after omeprazole were 0.13 ± 0.09 and 0.04 ± 0.04, respectively.

The mean scores induced by each MDP + 2, 4, 6, 8, 10, 12, 14, 16, 18 and 20 mmHg were 1.1 ± 0.3 ($n = 10$), 2.0 ± 0.4 ($n = 10$), 2.9 ± 0.5 ($n = 10$), 3.3 ± 0.4 ($n = 10$), 4.6 ± 0.3 ($n = 10$), 5.2 ± 0.3 ($n = 8$), 5.5 ± 0.2 ($n = 5$), 5.5 ± 0.3 ($n = 3$), 5.7 ± 0.3 ($n = 2$), and 5.4 ($n = 1$), respectively. After omeprazole, the abdominal feeling scores for the same incremental pressures over MDP were 0.3 ± 0.1 ($n = 10$), 0.8 ± 0.1 ($n = 10$), 2.0 ± 0.4 ($n = 10$), 2.8 ± 0.4 ($n = 10$), 3.8 ± 0.4 ($n = 10$), 4.6 ± 0.4 ($n = 10$), 4.9 ± 0.3 ($n = 8$), 5.4 ± 0.4 ($n = 5$), 5.2 ± 0.6 ($n = 3$), and 5.0 ± 1.0 ($n = 2$), respectively. A significant decrease in the feeling score was observed at intrabag pressures of MDP + 2 mmHg ($P = 0.028$) and + 4 mmHg ($P = 0.013$), respectively, after omeprazole (Figure 2). No significant score changes were seen at pressures ⩾ MDP + 6 mmHg.

DISCUSSION

In this study, we have shown for the first time the inhibitory effect of 1 wk of treatment with omeprazole on perception of mechanical distension by a barostat device. Namely, a significant increase was observed in the pressure required to induce a weak/vague feeling (score 1) and a weak but significant feeling (score 2). In other words, the perceived intensity of MDP + 2 and + 4 mmHg were significantly decreased after omeprazole treatment.

We recruited normal volunteers who were paid for their participation, and not all participants scored a weak/vague abdominal feeling (score 1) at intrabag pressure of MDP, indicating that the results obtained in the present study are limited to dyspepsia-free normal subjects.

The mechanisms by which omeprazole decreases perceptions of discomfort associated with gastric distension remain unknown. Omeprazole is a proton pump inhibitor that strongly decreases acid secretion. In a previous report of 5-d treatment with omeprazole at a similar dose (20 mg) to the present study, the number of hours with intragastric pH greater than 4 during a 24-h period was found to be 10.5 h[13]. Omeprazole has been reported to be most effective in patients who rated epigastric pain or heartburn as their most bothersome symptom[6,7]. Visceral hypersensitivity as well as gastric dysmotility, impaired accommodation to the meals, *H. pylori*-induced gastritis, and dysfunction of the central nervous system have all been implicated in the pathophysiology of FD[2-4]. Hypersensitivity to gastric distension and acid has especially been demonstrated in patients with FD. After the first report that gastric distension-induced perception was significantly increased in subjects with FD compared with controls in 1991[14], it has been reported that the hypersensitivity against distension might present in 34% to 66% of patients with FD[15]. In addition, duodenal acidification-

induced dyspeptic symptoms occur more significantly in patients with FD than in healthy volunteers[16].

A growing set of evidence has clarified the role of acid on dyspeptic symptoms and mechanosensitivity. First, acid infusion into the stomach induced dysmotility-like predominant dyspeptic symptoms in healthy Japanese control subjects[17]. Second, intraluminal infusion of hydrochloric acid affected sensitization of stomach mucosal mechanoreceptors[18]. Next, distal esophageal infusion also increased gastric sensitivity to distension[19]. Finally, intraduodenal acid infusion increased fundic compliance, decreased the tone and phasic contractile activities of the fundus, and increased proximal gastric mechanosensitivity[5,20,21]. These data suggest that the presence of acid in the upper gut might enhance mechanosensitivity. This putative mechanism has been supported by animal studies. Protons evoke multiple currents in primary afferent neurons that are carried by several acid-sensitive ion channels. Among these, acid-sensing ion channels (ASICs) and transient receptor potential vanilloid-1 (TRPV1) ion channels have been most thoroughly studied[22-24]. Taken together, it is speculated that an omeprazole-induced decrease in acid secretion followed by the downregulation of chemoreceptors might suppress distension-induced mechanosensitivity, resulting in the reduced perception of gastric distension demonstrated in the present study.

In this study, the inhibitory effect of omeprazole on perception induced by intragastric bag distension was demonstrated only with mild distension stimulus and weak feeling in the abdomen in normal volunteers. The precise reasons for these limited effects are unclear. Jones *et al*[22] demonstrated that both TRPV1 and ASIC3 knock-out mice were significantly less sensitive to colon distension, with an average response magnitude only 58% and 50% of controls, respectively. The data may suggest that afferent nociceptive signal transfer occurs mainly *via* a mechanoreceptor, rather than a chemoreceptor at moderate and severe distension.

It is well-known that gut infection is one of the risk factors for functional gastrointestinal disorders such as irritable bowel syndrome and FD[25]. Visceral hypersensitivity after infection has been reported in both animals[26] and humans[27]. Proton pump inhibitors have been reported to have potential anti-inflammatory effects apart from acid suppression[28]. Therefore, it is possible that the omeprazole-induced decreased perception of gastric distension might be mediated by the anti-inflammatory action of omeprazole.

In conclusion, although the precise mechanisms are undetermined, the present study demonstrated that omeprazole decreases mechanosensitivity to mild gastric distension, suggesting that the drug might be effective in the treatment of FD.

COMMENTS

Background

Hypersensitivity to gastric distension has been proposed among the possible mechanisms of functional dyspepsia (FD). Omeprazole has been prescribed in the treatment of FD. They examined the effects of omeprazole on mechanosensitivity in humans.

Research frontiers

The gastric barostat test is the gold standard method for evaluating gastric perception. They examined the effects of omeprazole on mechanosensitivity in humans using the barostat test.

Innovations and breakthroughs

Omeprazole is a proton pump inhibitor that strongly decreases acid secretion. The data suggest that suppression of acid secretion may decrease mechanosensitivity of the proximal stomach as well as dyspeptic symptoms.

Applications

Although the precise mechanisms are undetermined, the present study demonstrated that omeprazole decreases mechanosensitivity to mild gastric distension.

Terminology

These studies used the gastric barostat test in which a plastic bag with a double lumen polyvinyl tube was introduced into the stomach under fluorography. The tube was connected to a barostat device, which is a computer-controlled pump. Isobaric distensions were performed in stepwise increments. This method is the gold standard for evaluating gastric perception.

Peer review

This is a good descriptive study in which authors evaluate the effects of omeprazole on gastric mechanosensitivity in humans. The results are interesting and suggest that omeprazole decreases mechanosensitivity to mild gastric distension.

Abstract

AIM: To evaluate the potential of thioredoxin (TXN) and thioredoxin-interacting protein (TXNIP) expression as biomarkers for predicting gastric cancer recurrence.

METHODS: TXN and TXNIP expression levels were acquired from gene expression microarray data for 65 human gastric cancer tissues. We determined whether each gene expression level was associated with cancer recurrence and investigated the relationship between the two genes. For validation, the expression levels of TXN and TXNIP were measured by quantitative real-time reverse transcription polymerase chain reaction in 68 independent stage Ⅲ gastric cancer patients. The correlation between gene expression and cancer prognosis was evaluated. Immunohistochemical staining was performed to investigate the protein expression levels of TXN and TXNIP and to characterize the expression patterns of each protein.

RESULTS: TXN was a prognosis-related gene (P = 0.009), whereas TXNIP, a TXN inhibitor, demonstrated a negative correlation with TXN in the gene expression microarray data. In the 68 stage Ⅲ patients, the expression levels of both TXN and TXNIP had a statistically significant effect on recurrence-free survival (RFS, P = 0.008 and P = 0.036, respectively). The low TXN and high TXNIP expression group exhibited a better prognosis than the other groups, and the high TXN and low TXNIP expression group exhibited a poorer prognosis (P < 0.001 for RFS and P = 0.001 for overall survival). More than half of the patients in the simultaneously high TXN and low TXNIP expression group experienced a recurrence within 1 year after curative surgery, and the 5-year survival rate of the patients in this group was 29%, compared with 89% in the low TXN and high TXNIP expression group. The TXN protein was overexpressed in 65% of the gastric cancer tissues, whereas the TXNIP protein was underexpressed in 85% of the cancer cells. In a correlation analysis, TXN and TXNIP were highly correlated with many oncogenes and tumor suppressors as well as with genes related to energy, protein synthesis and autophagy.

CONCLUSION: TXN and TXNIP are promising prognostic markers for gastric cancer, and performing personalized adjuvant treatment based on TXN and TXNIP expression levels would be an effective practice in the treatment of gastric cancer.

INTRODUCTION

Gastric cancer is the second leading cause of global cancer mortality, and it has the highest mortality rates in East Asia, including South Korea, Japan and China[1]. The standard treatment for gastric cancer is surgery. However, relapses occur in many patients who undergo curative resection, even after adjuvant therapy[2,3]. Even among individuals with the same stage of cancer, gastric cancer patients present with diverse clinical manifestations and prognoses. The clinical diversity of gastric cancer arises from its molecular biological diversity, which is caused by changes in different genes. Molecular markers are important in predicting patient outcome and in personalizing treatments according to the individual biology of the patient. Importantly, in the adjuvant treatment setting, uniform adjuvant treatment after curative resection of gastric cancer has been performed regardless of the individual molecular prognostic markers of the cancer. However, cancer researchers have identified biomarkers that can predict recurrence and survival[4-8], and doctors should consider using biomarker-driven personalized adjuvant treatment.

Thioredoxin (TXN) is a low-molecular-weight redox protein and a putative oncoprotein that provides growth and survival advantages to tumor cells through the activation of redox-sensitive transcription factors, such as nuclear factor kappa B (NF-κB), p53, and activator protein-1 (AP-1)[9,10]. TXN inhibits apoptosis via apoptosis signaling kinase-1 (ASK-1) and phosphatase and tensin homolog (PTEN)[11]. TXN also induces hypoxia-inducible factor-1α (HIF-1α), which increases the production of vascular endothelial growth factor and leads to tumor angiogenesis and drug resistance[12]. The overexpression of TXN has been found in several cancers, including lung[13], pancreatic[14], cervical[15], and colorectal cancers[16] as well as hepatomas[17]. The increased expression of TXN in tumors has been associated with decreased patient survival in several cancers and with resistance to anticancer drugs[18,19]. The TXN-interacting protein (TXNIP), also known as vitamin D3 up-regulated protein-1 (VDUP1) and TXN-binding protein-2 (TBP-2), inhibits the interaction between TXN and other factors. TXNIP overexpression inhibits TXN activity, which in turn inhibits tumor cell proliferation and cell cycle progression[20,21]. Recently, it was reported that knockout of the *TXNIP* gene in a mouse model induced *Helicobacter pylori* (*H. pylori*)-related gastric cancer[22]. However, there is little information regarding the prognostic value of the expression level of TXN and TXNIP in gastric cancer.

In this study, we evaluated the use of TXN expression combined with TXNIP expression as prognostic markers to individualize the postoperative treatment strategy following gastric cancer removal.

MATERIALS AND METHODS

Gene expression microarray data analysis

The previously generated gene expression data from gastric cancer patients are available in the NCBI's GEO public database (microarray data accession number, GSE13861)[23]. Sixty-five gastric cancer patients underwent curative surgery as a primary treatment, with clinical data obtained from the Yonsei University Severance Hospital (Table 1). Sixty-five surgically removed frozen gastric adenocarcinoma tissues and 19 normal surrounding tissue samples were used for the microarray experiments. The total RNA was extracted from the fresh-frozen tissues using a mirVana RNA Isolation Labeling Kit (Ambion, Austin, TX, United States). For the labeling and hybridization, 500 ng of total RNA was used, according to the manufacturer's protocols (Human-HT12 v.3 Expression BeadChip, Illumina, San Diego, CA, United States). The microarray data were normalized using the quantile normalization method in the Linear Models for Microarray Data package in the R language environment. The expression level of each gene was transformed into a log2 base prior to further analysis. The random variance *t* test was applied to identify the differentially expressed genes between the two tissue types. The gene expression differences were considered significant if the *P* value was less than 0.001. Cluster analysis was performed with Cluster 3.0 and TreeView[24]. Univariate analysis was performed by dividing the patients into two groups based on the median value of each gene expression level to search for prognostic genes.

Quantitative reverse transcription-polymerase chain reaction and analysis

Paraffin-embedded cancer tissues were collected from gastric adenocarcinoma patients who underwent curative surgery between 1999 and 2007 as a primary treatment at Gangnam Severance Hospital. The clinical data of the patients were reviewed to obtain age, sex, tumor location, tumor differentiation, and stage based upon the American Joint Committee on Cancer 2002 criteria. The patients were followed up for more than 36 mo after surgery or until recurrence or death within 36 mo after surgery.

Sixty-eight stage Ⅲ gastric cancer tissues were chosen to validate the microarray data (Table 1). The total RNA was extracted according to the manufacturer's instructions (RecoverAll™ Total Nucleic Acid Isolation; Applied Biosystems, Foster City, CA, United States). The

qRT-PCR: Quantitative reverse transcription-polymerase chain reaction; TMA: Tissue microarray; TNM: Tumor node metastasis.

TXN and *TXNIP* genes were assayed using quantitative reverse transcription-polymerase chain reaction (qRT-PCR) with TaqMan gene-specific primers (Applied Biosystems, Foster City, CA, United States). Real-time RT-PCR amplification was performed using the 7900HT Fast Real-Time PCR System with a 384-well block module (Applied Biosystems, Foster City, CA, United States). The cycling conditions were as follows: 48 ℃ for 30 min and 95 ℃ for 10 min, followed by 40 cycles at 95 ℃ for 15 s and at 60 ℃ for 60 s. The relative amounts of mRNA were calculated from the threshold cycle (C_T) number using the expression of β-2 microglobulin as an endogenous control. All of the experiments were performed in triplicate, and the values were averaged.

Tissue microarray construction and immunohistochemical staining

Paraffin-embedded tissue microarray blocks of gastric cancer tissue specimens were created from tissues from 328 patients. Each block had 3-mm cores of gastric cancer tissue. The 4-μm thick sections were deparaffinized and processed to block endogenous peroxidase activity. Next, an antigen retrieval step was performed. Subsequently, primary anti-TXN (Polyclonal, 1:500, Abcam, Cambridge, MA, United States) and anti-TXNIP antibodies (Polyclonal, 1:100 Sigma, St. Louis, MO, United States) were applied to the sections. The sections were then incubated with a secondary antibody (HRP-rabbit/mouse), and the stains were developed using a Nova-RED substrate kit (VECTOR Laboratory, Burlingame, CA, United States). The samples were then counterstained with Harris hematoxylin.

The TXN and TXNIP protein expression levels were evaluated by two pathologists. Over-expression was defined as staining higher in more than 50% of cancer cells compared to the matching normal cells, regardless of cytoplasmic or nuclear location. Underexpression was defined as no staining or staining positivity lower than that of the matching normal tissue, and normal expression was defined as a level of staining positivity similar to that of the matching normal tissue. For slides that were heterogeneously stained within a tumor, we graded the highest intensity within the tumor.

Statistical analysis

The BRB-Array Tools system was used for the analysis of the microarray data. Statistical analysis were primarily performed with PASW Statistics 17.0 (SPSS Inc., Chicago, IL, United States). A χ^2 test was used to compare the difference between the groups. Kaplan-Meier plots and a log-rank test were used to estimate patient survival. Associations between the expression levels of the two targets and in-trans correlation were analyzed using the Pearson correlation coefficient. A *P* value of less than 0.05 was considered statistically significant, and all tests were two tailed.

RESULTS

Expression of TXN mRNA in microarray data for gastric cancer

First, a hierarchical clustering analysis was applied to the gene expression data from the 65 human primary tumor tissue samples. Unsupervised clustering revealed 2 distinctive subtypes with clear differences in overall gene expression patterns[23]. Recurrence-free survival (RFS) was found to differ significantly between the 2 clusters ($P = 0.001$ by the log rank test), indicating that the molecular features of these tumors reflected in gene expression patterns might be strong independent predictors of clinical outcomes.

We next sought to identify genes whose expression was unique to the poor prognostic subgroup by cross-comparing gene lists. Between the two groups, 1258 genes were differentially expressed ($P < 0.001$) and presented more than a 1.5-fold difference between the two groups. Next, a univariate analysis identified 84 prognostic genes ($P < 0.01$). Of the 84 genes, TXN was a prognosis-related gene ($P = 0.009$ by univariate analysis) and was up-regulated in the poor prognostic group. From the correlation analysis between the expression levels of TXN and associated genes, we determined the relative correlations. TXNIP, a TXN inhibitor, demonstrated a negative correlation with TXN ($r = -0.295$, $P = 0.024$). The survival analysis based on the hierarchical clustering of TXN- or TXNIP-related genes demonstrated that each cluster influenced patient survival ($P = 0.025$ and $P = 0.036$, respectively) (Figure 1).

qRT-PCR validation of TXN and TXNIP expression

To determine if *TXN* and *TXNIP* gene expression was associated with prognosis among patients with the same

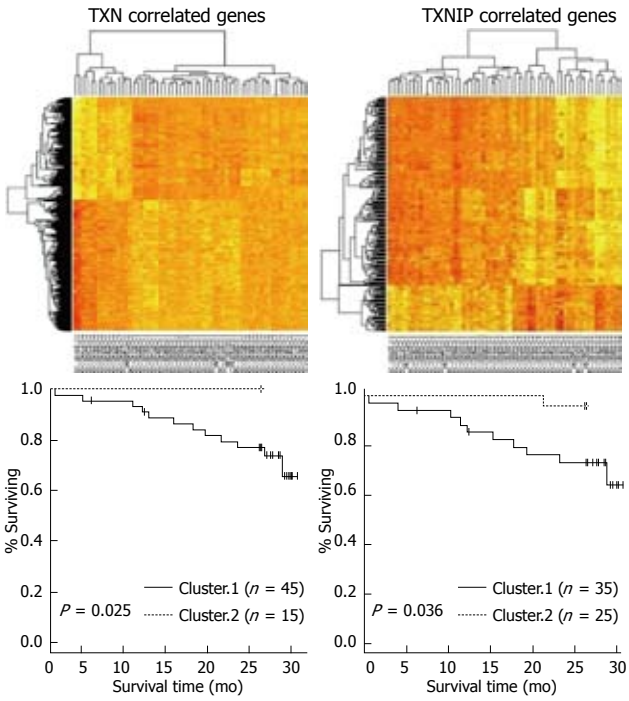

Figure 1 Survival analysis based on hierarchical clustering of thioredoxin or thioredoxin-interacting protein correlated genes.

stage of cancer, 68 stage Ⅲ patients were randomly selected for qRT-PCR analysis (Table 1). The median follow-up duration after curative resection was 89.5 mo. By the last follow-up visit, 44 patients had experienced a recurrence, and 16 patients had died of gastric cancer. The patients were divided into high or low expression groups according to the TXN and TXNIP expression levels. RFS and overall survival (OS) were analyzed between the two groups (Figure 2A-D). Both TXN and TXNIP expression influenced RFS, and these associations were significant (P = 0.008 and P = 0.036, respectively). The patients in the high TXN expression or low TXNIP expression groups presented a poor prognosis. TXN expression also influenced OS (P = 0.015), but TXNIP expression did not have a significant relationship with OS (P = 0.053).

Stage Ⅲ patients were classified into the following three combination groups based on the TXN and TXNIP expression levels: Group 1, simultaneously low TXN and high TXNIP levels (n = 20); Group 2, neither Group 1 nor Group 3 (n = 35); and Group 3, simultaneously high TXN and low TXNIP levels (n = 13). As expected, Group 1 exhibited a better prognosis than the other groups, and Group 3 presented with a poor prognosis (Figure 2E and F; P < 0.001 for RFS and P = 0.001 for OS). More than half of the Group 3 patients experienced a recurrence within 1 year after curative surgery, and their 5-year survival rate was one-third (29%) that of Group 1 (89%) (Table 2). There was no relationship between the TXN/TXNIP expression levels and either tumor stage or histological cell type.

Immunohistochemical assay of TXN and TXNIP expression

The gastric glands were relatively well stained with the anti-TXN antibody regardless of the presence of cancerous and non-cancerous lesions based on the immunohistochemical assay results. Thioredoxin was overexpressed in approximately 65% of cancer tissues regardless of the histological type and TNM stage (Table 3). Thioredoxin staining was observed in the cytoplasm or nucleus or in both areas of the cancer cells. The histological location of thioredoxin in the cytoplasm or the nucleus in cancer tissues varied among patients, and there was heterogeneity in the staining intensity within the individual samples. In contrast to the staining with the anti-thioredoxin antibody, the staining of the gastric cancer tissue with the anti-TXNIP antibody was weak. TXNIP was underexpressed in almost 85% of the cancer cells and was found in the cytoplasm or nucleus of the cancer cells. There was a tendency for TXNIP to be underexpressed in two poor prognosis groups: diffuse histology type (P = 0.009) and high-stage gastric cancer (P = 0.011) (Table 3). Representative immunohistochemical staining results are shown in Figure 3.

Table 2 Prognoses of stage Ⅲ gastric cancer patients according to the thioredoxin and thioredoxin-interacting protein gene expression levels

Group	Mean RFS, (95% CI), mo	3-yr recurrence-free rate (%)	5-yr survival rate (%)
1: Low TXN and high TXNIP	Non applicable	70	89
2: Neither group 1 nor group 3	36.7 (15.5-57.9)	51	73

Bioinformatic in-trans correlation analysis of TXN and TXNIP expression

Approximately 7000 genes were significantly correlated with TXN according to the bioinformatic in-trans correlation analysis of TXN expression with whole mRNA-expressing genes (P < 0.001). These findings suggest that TXN plays an important role in gastric cancer. Glutaredoxin 2 (GLRX2) and peroxiredoxin 4 (PRDX4) were highly correlated with TXN (r = 0.76, P < 0.001 and r = 0.72, P < 0.001, respectively; Table 4), and this correlation explains the function of TXN as a reactive

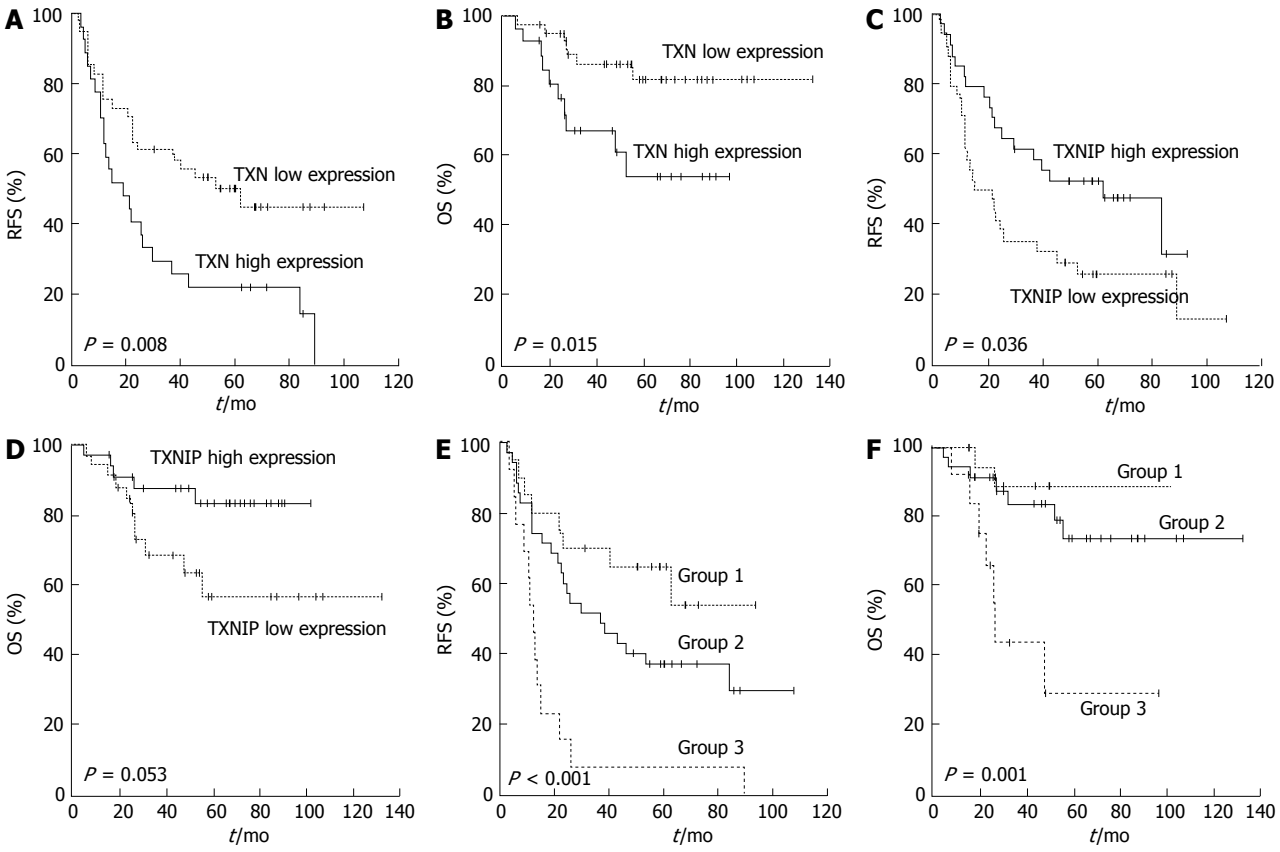

Figure 2 Kaplan-Meier plot of recurrence-free survival and overall survival according to gene expression. Gene expression was measured using quantitative reverse transcription-polymerase chain reaction. Stage III gastric cancer patients were divided into two or three groups according to their gene expression levels. A, B: Survival curves according to thioredoxin (TXN) expression level; C, D: Survival curves according to thioredoxin-interacting protein (TXNIP) expression levels; E, F: Survival curves according to the combination of the TXN and TXNIP expression levels (Group 1: Simultaneous low TXN and high TXNIP expression; Group 2: Neither group 1 nor group 3; Group 3: Simultaneous high TXN and low TXNIP expression). The prognosis was compared across the groups using the log-rank test.

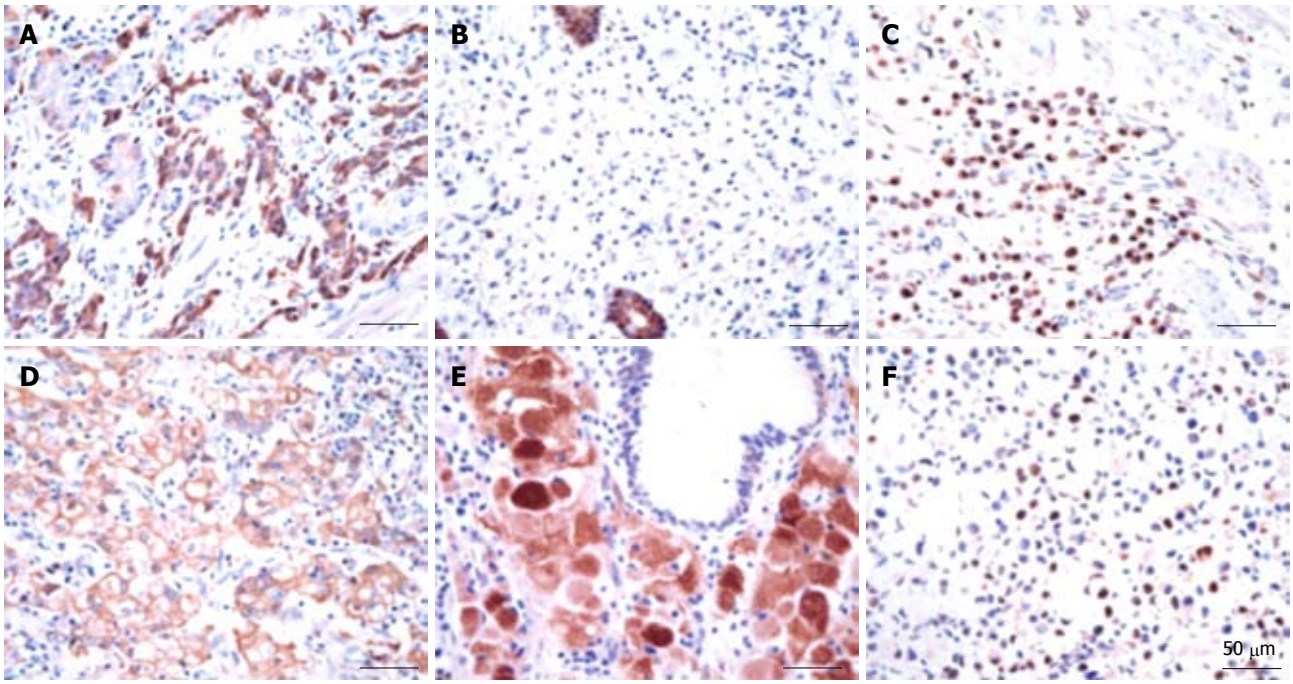

Figure 3 Representative images of immunohistochemical assay (×400). A: The cytoplasm of gastric cancer cells was strongly stained with the anti-thioredoxin (TXN) Ab; B: The cytoplasm of gastric cancer cells was not stained with the anti-TXN Ab; C: The nuclei of gastric cancer cells were strongly stained with the anti-TXN Ab; D; The nuclei of gastric cancer cells were not stained with the anti-TXN Ab; E: The cytoplasm of gastric cancer cells was strongly stained with the anti-thioredoxin-interacting protein (TXNIP) Ab, but the nuclei were not stained; F: The nuclei of gastric cancer cells were strongly stained with the anti-TXNIP Ab, but the cytoplasm was not stained.

TXN: Thioredoxin; TXNIP: Thioredoxin-interacting protein.

oxygen species (ROS) scavenger with these known redox molecules. Ribosomal proteins and mitochondrial ribosomal proteins (i.e., RPL6, RPL29, MRPL22, MRPL42, MRPS17 and ATP5S) were highly correlated with TXN ($P < 0.001$; Table 4), which suggests the active involvement of TXN in protein synthesis and mitochondrial ATP synthesis for energy production. TXNIP was negatively correlated with TXN and known poor prognostic markers, such as AURKA, ERBB3, CCNB1, and many genes that are significantly correlated with TXN (Table 4). These results indirectly support the functional role of the TXNIP in the inhibition of TXN.

DISCUSSION

We demonstrated that TXN and TXNIP are poor and good prognostic gastric cancer markers, respectively. In stage Ⅲ patients who underwent curative gastrectomy, the 3-year recurrence-free rate ($P < 0.001$) and the 5-year survival rate ($P = 0.001$) were significantly different between patients with different TXN and TXNIP expression levels (Table 2). High TXN and low TXNIP patients had a definitively poor prognosis. Most of these patients experienced a recurrence within 2 years and died within 4 years. Thus, it is necessary to perform intensive treatment and plan post-adjuvant treatment for these patients.

The gene expression microarray data imply that TXN plays an important role in gastric cancer. TXN functions as a ROS scavenger with known redox molecules, such as GLRX2 and PRDX4, and TXN is actively involved in protein synthesis and mitochondrial ATP synthesis for energy production. Hypoxia-induced genes [i.e., ERO1L and hypoxia inducible gene 2 (*HIG2*)] were significantly correlated with TXN. Tumors with high TXN expression also exhibited elevated *ERO1L* and *HIG2* levels; therefore, these tumors are in a relatively high hypoxic state compared with tumors with low TXN expression. Additionally, autophagy-related genes (i.e., *ATG10*, *ATG16L2*, and *ATG12*) were negatively correlated with TXN expression, which indirectly suggests that TXN is involved in autophagic inhibition in a hypoxic cancer state. Autophagy is associated with cancer pathogenesis and chemotherapy resistance; therefore, the function of TXN in autophagy should be elucidated through additional studies.

Grogan *et al*[25] demonstrated that TXN was localized to tumor cells and was overexpressed in gastric cancer tissues compared with the levels in normal gastric mucosa. TXN overexpression was typically found in both the nucleus and the cytoplasm of neoplastic cells. These findings are consistent with our immunohistochemical staining results. Furthermore, high TXN expression was observed regardless of the gastric cancer stage or cell type.

Our study confirmed that TXNIP was significantly underexpressed in gastric cancer tissues compared with normal tissues; furthermore, it was expressed at the lowest levels in cancer patients with poor prognoses. TXNIP is a known potent tumor suppressor whose expression is markedly decreased in various human cancers, including gastric cancer. Knockout of the TXNIP gene in a mouse model was associated with *H. pylori*-related gastric cancer[22]. In an *in vitro* experiment, TXNIP overexpression in pancreatic cells resulted in a higher basal level of apoptosis and an increased sensitivity to cisplatin and oxaliplatin[26]. In microarray data analysis, TXNIP expression was negatively correlated with the expression of TXN expression, known as poor prognostic cancer biomarkers[27-29], and many genes that are significantly correlated with TXN. These results indirectly confirm the functional role of the TXNIP in TXN inhibition. Additionally, autophagy-related genes were correlated with TXNIP, and these data support that TXNIP induces cancer cell autophagy.

In this study, we analyzed the gene expression profile

of human gastric cancer to identify potential biomarkers that could be used to classify patients according to prognosis after curative resection. We found that TXN and TXNIP were significantly associated with prognosis. TXN up-regulation and the simultaneous down-regulation of TXNIP were associated with a poor prognosis in gastric cancer patients. Bioinformatic analysis revealed that TXN and TXNIP were highly correlated with many oncogenes and tumor suppressor genes and demonstrated that TXN and TXNIP were associated with genes related to energy, protein synthesis and the modulation of autophagy under hypoxic or other stressful conditions. One of the limitations of this study is that we did not elucidate how TXN and TXNIP affect the recurrence of gastric cancer after curative resection. Further investigation of TXN and TXNIP in gastric cancer would likely identify unknown pathogenic mechanisms. In addition, because our results were derived from retrospective assessment, it is necessary to utilize *TXN* and *TXNIP* gene expression-based prediction in a prospective randomized trial(s) to validate the true clinical relevance of TXN and TXNIP. It will be beneficial to identify effective anti-tumor treatments other than the current standard adjuvant chemotherapy for gastric cancer patients with potent recurrence factor, high TXN and low TXNIP expression. Furthermore, TXN-targeted agents or those that up-modulate TXNIP could be used in targeted therapy in the treatment of gastric cancer patients who are selected based on biomarker gene signatures.

In conclusion, TXN and TXNIP are promising prognostic markers for gastric cancer, and performing personalized adjuvant treatment based on TXN and TXNIP expression levels would be an effective practice in the treatment of gastric cancer.

COMMENTS

Background

The standard of treatment for gastric cancer is surgery. After curative resection, even among individuals with the same stage of cancer, diverse recurrence patterns are present. However, uniform adjuvant treatment after curative resection has been performed. Authors evaluated the use of thioredoxin (TXN) expression combined with thioredoxin-interacting protein (TXNIP) expression as prognostic markers to individualize the postoperative treatment strategy following gastric cancer removal.

Research frontiers

TXN is putative oncoprotein that provides growth and survival advantages to tumor cells through the activation of redox-sensitive transcription factors. TXNIP is a potent tumor suppressor and inhibits the interaction between TXN and other factors. They have been recognized as cancer-related markers in diverse malignancies.

Innovations and breakthroughs

High TXN and low TXNIP expression in human gastric cancer tissue definitively related with poor prognosis of gastric cancer patients who had undergone curative resection.

Applications

The establishment of adjuvant treatment strategy based on our discovery would be useful to accomplish better outcomes after surgical treatment. The patients with high TXN and low TXNIP expressions in cancer tissue require novel treatment and should be more carefully monitored after surgery.

Terminology

Redox (reduction-oxidation) reactions: Many important biological processes involve redox reactions. Free radicals are a part of redox molecules and can become harmful to the human body if they do not reattach to the redox molecule or an antioxidant. Unsatisfied free radicals can trigger the mutation of cells they encounter and are thus cancer causing.

Peer review

This study investigated the potential of TXN and TXNIP genes as a prognostic marker after curative resection of gastric cancer. Patients with high TXN and low TXNIP expression in cancer tissue manifested significantly more recurrence and shorter survival. However, it is necessary to validate through the prospective trial and to elucidate the functional mechanism of TXN and TXNIP.

Abstract

AIM: To evaluate the effect of photodynamic therapy (PDT) on metal stent patency in patients with unresectable hilar cholangiocarcinoma (CC).

METHODS: This was a retrospective analysis of patients with hilar CC referred to our institution from December, 1999 to January, 2011. Out of 232 patients, thirty-three patients with unresectable hilar CC were treated. Eighteen patients in the PDT group were treated with uncovered metal stents after one session of PDT. Fifteen patients in the control group were treated with metal stents alone. Porfimer sodium (2 mg/kg) was administered intravenously to PDT patients. Forty-eight hours later, PDT was administered using a diffusing fiber that was advanced across the tumor by either endoscopic retrograde cholangiopancreatography or percutaneous cholangiography. After performance of PDT, uncovered metal stents were inserted to ensure adequate decompression and bile drainage. Patient survival rates and cumulative stent patency were calculated using Kaplan-Meier analysis with the log-rank test.

RESULTS: The PDT and control patients were comparable with respect to age, gender, health status, pretreatment bilirubin, and hilar CC stage. When compared to control, the PDT group was associated with significantly prolonged stent patency (median 244 ± 66 and 177 ± 45 d, respectively, $P = 0.002$) and longer patient survival (median 356 ± 213 and 230 ± 73 d, respectively, $P = 0.006$). Early complication rates were similar between the groups (PDT group 17%, control group 13%) and all patients were treated conservatively. Stent malfunctions occurred in 14 PDT patients (78%) and 12 control patients (80%). Of these 26 patients, twenty-two were treated endoscopically and four were treated with external drainage.

CONCLUSION: Metal stenting after one session of PDT may be safe with acceptable complication rates. The PDT group was associated with a significantly longer stent patency than the control group in patients with unresectable hilar CC.

INTRODUCTION

Hilar cholangiocarcinoma (CC) is a rare tumor that is asymptomatic early on, making it difficult to diagnose, and is associated with a high mortality[1]. Surgical resection with negative histologic margins is the most robust predictor of long-term survival. However, due to the lack of characteristic early symptoms, a definitive diagnosis is often not reached until the tumor is at an advanced stage. As a result, a large proportion of patients are beyond the scope of curative treatment by the time of diagnosis, and only palliative management is possible[2]. Palliative therapies for unresectable CC such as stent, radiotherapy and chemotherapy, have generally been disappointing in prolonging life[3]. Endoscopic or percutaneous biliary drainage alleviates jaundice, but there is no evidence that it prolongs survival.

Although endoscopic biliary metal stenting is the mainstay of palliative treatment in patients with unresectable hilar CC[4], tumor ingrowth or overgrowth is a significant problem in uncovered stents. In particular, the duration of metal stent patency for hilar CCs was shorter than that for distal bile duct cancer because the malignant hilar stricture provides an acute angle that hinders full expansion of the metal stent and promotes biliary sludge formation within. Several clinical trials have reported the therapeutic effect of photodynamic therapy (PDT) for unresectable hilar CC[5,6]. The ability of PDT to destroy cancer and neovascular cells may prolong biliary stent patency. However, the effect of PDT on stent patency has not yet been determined. Therefore, the primary aim of this study was to explore the effect of PDT on stent patency in unresectable hilar CC. We also evaluated overall survival and procedure-related complications after PDT compared with endoscopic biliary drainage alone for unresectable hilar CCs.

MATERIALS AND METHODS

Patients

This was a non-randomized, retrospective study. From December, 1999 to January, 2011, 232 patients with hilar cholangiocarcinoma were referred to our institution. This study included patients with unresectable hilar CC without chemoradiation who were palliated with only metal stents (control group) or with one session of PDT followed by metal stents (PDT group). Patients were deemed inoperable if they met the following criteria: the presence of type Bismuth-Corlette Ⅳ lesions, advanced type Ⅲ lesions containing T3 tumors, or other types Ⅱ-Ⅲ tumors if surgery was contraindicated due to lymph nodes or liver metastases; and age > 80 years or the presence of other co-morbid conditions. Among these patients, metal stents were placed when they met the following conditions: the patient did not want an additional PDT due to the high cost, the patient was referred from a distant location; and there was a change to poor performance status during follow-up. We included patients with lymph node and liver metastasis but excluded those with extrahepatic distant metastasis whose prognoses are expected to be extremely poor.

Using these criteria, 199 patients were excluded because of surgery (n = 38), a plastic stent (n = 72), palliative chemotherapy or radiotherapy (n = 30), more than two sessions of PDT (n = 21), a Karnofsky performance status of less than 60 (n = 10), percutaneous biliary drainage only (n = 11), unavailability for follow-up (n = 4), refusal of endoscopic treatment (n = 12) and sudden death during diagnostic workup (n = 1). After these exclusions, 33 patients with unresectable hilar CC were included in this study. Eighteen patients were treated using uncovered metal stents after one session of PDT (PDT group) and 15 patients were treated by endoscopic metal stenting alone (control group). All patients underwent a standard pretreatment evaluation that included thin-section, contrast-enhanced, multiphase spiral computed tomography and/or magnetic resonance imaging of the abdomen. Tissue diagnosis was obtained by endoscopic retrograde cholangiopancreatography (ERCP) or percutaneous transhepatic cholangioscopy (PTCS) or direct peroral cholangioscopy with biopsy and/or cytology. Patients with no histological confirmation were diagnosed as having malignant disease on the basis of clinical outcome during follow-up for at least 12 mo. All tumors were staged using the American Joint Committee (7th edition) on Cancer Staging criteria for perihilar bile duct cancer[7]. Clinical, laboratory, radiological, endoscopic, and histopathologic data were collected prospectively and analyzed retrospectively. The local institutional review board approved this study.

Photodynamic therapy

PDT was administered by methods described previously[8,9]. Briefly, patients received porfimer sodium (Photofrin Ⅱ, Axcan Pharma, Quebec, Canada) intravenously at a dose of 2 mg/kg 48-h before ERCP or PTCS. For light distribution, we used flexible cylindrical diffuser probes (BioLitec, Stirling, Scotland) mounted on a 400-μm quartz fiber with an active distal tip length of 2 cm. The light source was a diode laser system (Ceralas PDT 633; CeramOptec, Bonn, Germany) with a maximum power output of 2 W and a wavelength of 633 ± 3 nm. The power emitted by the diffuser tip was calibrated to 400 mW/cm before PDT was conducted using an integrating sphere power meter. The mean irradiation time was 452 s (range: 400-600 s), using a power density of 300-400 mW/cm and energy dose of 180-200 J/cm (of diffuser length). The PDT with PTCS was usually applicable for more advanced Bismuth type-Ⅲ lesions. To perform the percutaneous PDT procedure, a guide wire was first inserted through the stricture into the common bile duct. A 6-F guiding catheter was then inserted along the guide wire, after which the guide wire was removed. A diffuser fiber was then inserted into the guiding catheter and the stricture site was irradiated from the distal to the proximal region under cholangioscopy and fluoroscopy.

Peroral PDT with ERCP was performed in patients who had coagulopathy or refused percutaneous mo-

dality or bismuth Ⅱ and some of Ⅲ. To perform the peroral PDT, the preloaded catheter (catheter and PDT fiber) was advanced across the bile duct tumor using a 0.035-inch guide wire. The tip of the catheter was cut just below its metal marker, allowing the fiber to pass. Tumor segments were treated sequentially proximal to distal. In both percutaneous or peroral PDT, PDT was performed in both sides of the intrahepatic duct in Bismuth Ⅲ and Ⅳ strictures. In the case of multiple strictures, as many second branches as possible were treated. After PDT was performed, uncovered metal stents (MI tech, Seoul, South Korea) with diameters of 10 mm and stent lengths of 6 and 8 cm were inserted to ensure adequate decompression and bile drainage. In patients with percutaneous PDT, metal stent was inserted using the Rendezvous technique.

Definition of events and follow-up

The clinical outcome was evaluated according to the following parameters: (1) functional success, as measured by a decrease in the bilirubin level to less than 50% of the pretreatment value within 7 d; (2) early complications (occurring within 30 d); (3) late complications including stent malfunction; and (4) revision methods such as endoscopic retrograde biliary drainage or percutaneous transhepatic biliary drainage (PTBD). Stent patency was calculated as the interval between stent insertion and stent occlusion. Stent occlusion was defined as signs of jaundice or cholangitis (e.g., fever, tenderness in the right upper quadrant, and/or > 2-fold elevation of the total serum bilirubin above baseline after stent insertion).

Follow-up of symptoms and biochemical parameters was done at 1 mo intervals. Tumor markers for carbohydrate antigen (CA) 19-9 and abdominal computed tomography scans were done every 3 mo. ERCP was performed to confirm obstruction and to perform biliary decompression if a new episode of cholangitis occurred. Enrolled patients were followed until death. If the patient died with a patent stent, the time interval was recorded as censored data.

Statistical analysis

Statistical analysis were performed using SPSS software (ver. 18.0; SPSS Inc., Chicago, IL). Numerical data are presented as the median with range. Intergroup comparisons were performed using the Mann-Whitney *U* test. Estimates of probabilities of survival for the follow-up study and cumulative stent patency were calculated using the Kaplan-Meier method with the log-rank test. Data are presented as medians and 95% CI. For survival rates, all deaths related to CC and procedures were included, but deaths unrelated to CC were treated as censored patients. All of the data were analyzed using an intention-to-treat analysis. Intention-to-treat survival was calculated from the day of treatment until death or the last follow-up. *P* values ≤ 0.05 were deemed to indicate statistical significance.

[1]American Joint Committee Cancer (AJCC) staging 7th edition; [2]Decrease of bilirubin to less than 50% of the pretreatment value within 7 d. Data are expressed as medians (range). PDT: Photodynamic therapy; CA: Carbohydrate antigen.

RESULTS

Thirty-three patients (24 male), mean age 67.9 years (range: 44-89 years) were treated. A total of 18 (55%) patients received PDT (percutaneous PDT = 11, peroral PDT = 7) and metal stenting, whereas 15 (45%) underwent metal stenting alone. Baseline clinical and demographic profiles in the two treatment groups were similar, except for bismuth type Ⅳ (Table 1). There were more patients with bismuth type Ⅳ in the PDT group than in the control group (10/18 *vs* 4/15; *P* = 0.025). There were no significant differences between the groups with regard to age, gender, pre-procedure bilirubin, CA 19-9, stent length, or tumor stage. The diagnosis was confirmed histologically in 14 PDT patients (78%) and 10 control patients (67%). Histological confirmation of malignancy in PDT group was obtained by brush cytology in three ERCP patients and by intraductal biopsy examination in 11 PTCS patients. In the control group, histological confirmation was obtained by brush cytology in nine ERCP patients, and by intraductal biopsy in one direct cholangioscopy (using the mother-baby scope technique). Successful drainage was achieved in 83% and 86% of patients in PDT and control patients, respectively. No significant difference was observed in the degree of decrease of total bilirubin between the two groups (*P* = 0.2).

Stent patency and survival

The metal stent patency duration was longer in the PDT

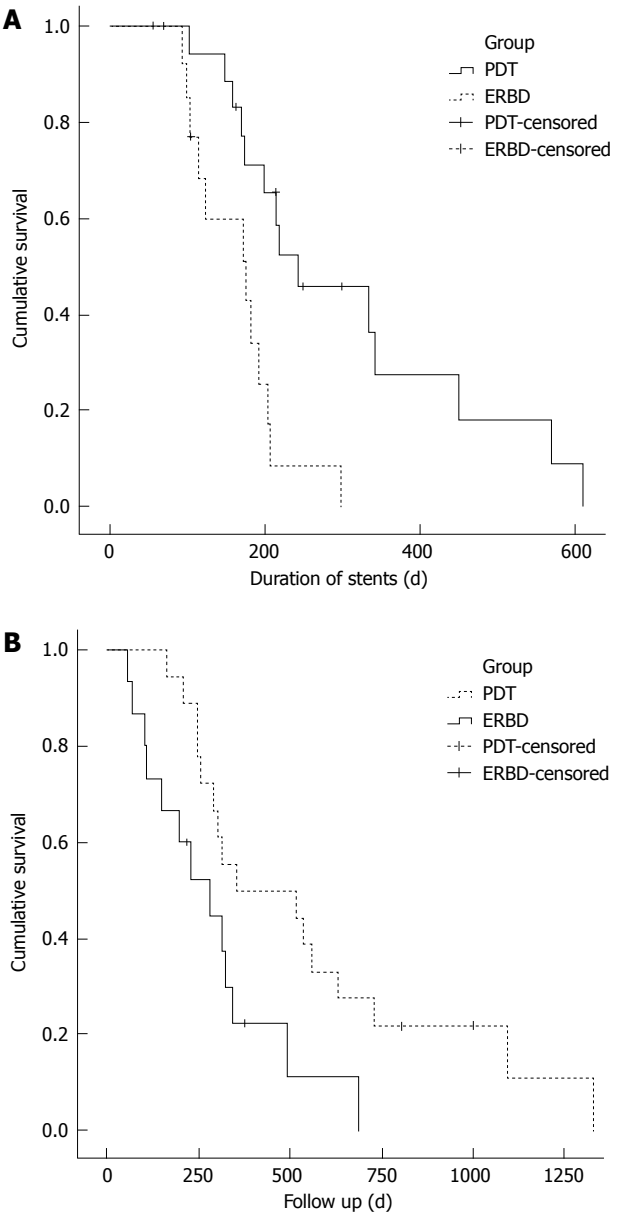

Figure 1 Kaplan-Meier analysis of metal stent patency rates and overall survival in the photodynamic therapy and control groups. A: Kaplan-Meier analysis of metal stent patency rates. The median stent patency was longer in the photodynamic therapy (PDT) group than in the control group (244 d *vs* 177 d; $P = 0.002$); B: Kaplan-Meier analysis of overall survival. The median survival in the PDT group was 356 d, *vs* 230 d in the stent-only group ($P = 0.006$). ERBD: Endoscopic retrograde biliary drainage.

group than in controls (Figure 1A). The median stent patency (range) was 244 ± 66 d (72-570 d) in the PDT group and 177 ± 45 d (70-309 d) in the controls ($P = 0.002$). Table 2 shows the results of univariate analysis of all variables associated with stent patency in all patients. PDT treatment ($P = 0.002$) was a significant predictive factor of longer stent patency on univariate analysis (Table 2). Factors including age, gender, bismuth type, pretreatment CA 19-9 and total bilirubin, T stage, number of endoprostheses (unilateral *vs* bilateral), and PDT method (PTCS *vs* ERCP) did not significantly affect stent patency according to univariate analysis.

Table 2 Univariate analysis of all prognostic factors associated with stent patency and patient survival in all patients

Variables	Cases	Univariate (Kaplan-Meier and log-rank test)			
		Median stent patency (d)	*P* value	Median patient survival (d)	*P* value

[1]American Joint Committee Cancer (AJCC) staging, 7th edition. PDT: Photodynamic therapy; PTCS: Percutaneous cholangioscopy; ERBD: Endoscopic retrograde biliary drainage; CA: Carbohydrate antigen; ERCP: Endoscopic retrograde cholangiopancreatography.

Compared with the controls, the PDT group was associated with longer patient survival (Figure 1B). The median survival time (range) was 356 ± 213 d (163-1330 d) in the PDT group and 230 ± 73 d (56-687 d) in the controls ($P = 0.006$). Table 2 shows the results of the univariate analysis of all variables considered. Statistically significant predictors of longer survival were PDT treatment and a lower total bilirubin level before the procedure.

Complications

Early complications were experienced by two control patients (13%) and three (17%) in the PDT group. In the control group, cholangitis occurred in 2 patients (13%), while in the PDT group, cholangitis and cholecystitis were each observed in one patient (6%). PDT-specific adverse events occurred in one patient in the PDT group, who experienced dermal phototoxicity. No stent migration occurred in either group.

Stent malfunctions occurred in 14 (78%) and 12 (80%) of the control and PDT patients, respectively. Among these 26 patients, 22 (85%) with tumor ingrowth were treated endoscopically with insertion of one or two plastic stents (10F) into unilateral or bilateral ducts through metal stents. In four patients with tumor recurrence, tumor ingrowth and overgrowth occurred in the hilar portion and more proximal intrahepatic duct, resulting in revisionary treatment with PTBD.

DISCUSSION

Hilar CC has an extremely poor prognosis, with an average five-year survival rate of 5%-10%. Surgery provides

the only possibility for a cure, but due to its anatomical location and natural history, the disease is locally advanced in most patients at the time of diagnosis. Therefore, effective palliation to alleviate symptoms associated with jaundice and the prevention of biliary sepsis are the fundamental goals for most patients with hilar CC[5]. Although relief of biliary obstruction by endoscopic placement of metal stents is regarded as an optimal palliative measure in hilar CC, the clinical course after even successful stent insertion is one of disease progression and death from liver failure or cholangitis within 4-9 mo[10]. This clinical course[1] is related to the ability to decompress affected proximal segments[2] and recurrent stent occlusion, because these stents are unable to remodel malignant tissues[11].

PDT is an evolving therapy for treatment of cancers that are resistant to standard oncologic treatment. PDT involves the injection of an intravenous photosensitizing drug followed by endoscopic application of light to the tumor bed. The interaction between light and the photoagent causes death of cancer cells and tumor thrombosis by generating oxygen free radicals. PDT is currently being used for cases of hilar cholangiocarcinoma[12,13]. Even in patients with advanced hilar CC, PDT has been shown to improve survival, quality of life, and to have a performance superior to that of biliary stenting in uncontrolled and randomized controlled trials[6,14-16]. In our study, Kaplan-Meier analysis demonstrated improved survival in the PDT group compared with the stent-only group (356 d *vs* 230 d, $P = 0.006$), in accordance with previous reports[11,14,17].

Effective palliation is essential, because biliary drainage and prevention of cholestasis are crucial for prevention of pruritus, cholangitis, and death in patients with hilar CC. The approach to palliative decompression has evolved from surgery and percutaneous to endoscopic management in order to prevent cholestasis and improve mortality. Endoscopy of hilar CCs is generally challenging and complex due to the involvement of multiple bile ducts requiring two or more stents; indeed, patency rates of endobiliary stents are lower than those of distal tumors[16,18,19]. Moreover, the efficacy of endoscopic stenting in a hilar CC is often limited by stent patency, which is related to proximal tumor obstruction, because the stent does not affect tissue remodeling, unlike benign conditions[11,20,21]. To address this issue, multiple studies have investigated the positive effects of the combination of bile duct stenting with PDT on patient survival[6,14,15]. However, a paucity of information exists regarding the effect of PDT on stent patency.

In our study, metal stent patency was longer in the PDT group than in the stent-only group. The median stent patency was 244 d in the PDT group and 177 d in the control group ($P = 0.002$). The main causes of obstruction of metal stents in bile ducts is tumor ingrowth or overgrowth[22]. PDT offers the possibility of tumor "remodeling", which can enhance or prolong the decompression effect[23]. Accepting this hypothesis, the ability of PDT to destroy cancer cells and lessen cholestasis may prolong stent patency. In this context, this study is meaningful because the longer stent patency that is achieved by PDT may diminish the need for further procedures, such as stent revision or percutaneous biliary drainage, improving the quality of life of hilar CC patients whose prognosis is poor.

This study was limited because of its retrospective nature and small sample size. Thus it may be not possible to reach statistical significance in terms of differences in overall survival between the groups. Because hilar CC is a rare malignancy and PDT is offered at few tertiary centers in South Korea, inclusion of sufficient patients to complete a well-designed palliative study is problematic. However, the study population was derived from a larger cohort of patients with CC, who were followed until death. Median survival of this cohort was comparable to that of other cohorts reported in the literature, which may decrease the possibility of significant selection bias.

In summary, metal stenting after one session of PDT may be safe with acceptable complication rates. The PDT group was associated with a significantly longer stent patency period and patient survival compared with the control group in patients with unresectable hilar CC. A prospective randomized multicenter study is required to confirm these data.

COMMENTS

Background

Although endoscopic biliary metal stenting is the mainstay of palliative treatment in patients with unresectable hilar cholangiocarcinoma (CC), tumor ingrowth or overgrowth in uncovered stents is a significant problem. The duration of metal stent patency for hilar CCs was shorter than that for the distal bile duct. Photodynamic therapy (PDT) is an evolving therapy for treatment of hilar CCs that are resistant to standard oncologic treatment.

Research frontiers

The authors observed that the one session of PDT with metal stenting was associated with a significantly longer stent patency period and patient survival compared with the metal stent only group in patients with unresectable hilar CC.

Innovations and breakthroughs

Metal stent patency was longer in the PDT group than in the stent-only group. The median stent patency was 244 d in the PDT group and 177 d in the control group ($P = 0.002$). The ability of PDT to destroy cancer cells and lessen cholestasis may prolong stent patency.

Applications

Just one session of PDT with endoscopic retrograde cholangiopancreatography (ERCP) or percutaneous transhepatic cholangioscopy (PTCS) before metal stent placement is promising because it prolongs stent patency in unresectable hilar CC. A prospective randomized multicenter study is required to assess this technique.

Terminology

PDT is an emerging palliative strategy for unresectable hilar CC based on the intravenous administration of photosensitizing agents that preferentially accumulate in malignant cells. PDT is performed to the targeted area of bile ducts using ERCP or PTCS.

Peer review

PDT in patients with CC has been reported as effective palliative treatment providing improvement in cholestasis and quality of life, and prolonging survival. The authors conclude that metallic stenting after PDT may be a safe, acceptable modality associated with longer stent patency in patients with unresectable hilar CC.

Abstract

AIM: To evaluate the surgical outcomes following radical antegrade modular pancreatosplenectomy (RAMPS) for pancreatic cancer.

METHODS: Twenty-four patients underwent RAMPS with curative intent between January 2005 and June 2009 at the National Cancer Center, South Korea. Clinicopathologic data, including age, sex, operative findings, pathologic results, adjuvant therapy, postoperative clinical course and follow-up data were retrospectively collected and analyzed for this study.

RESULTS: Twenty-one patients (87.5%) underwent distal pancreatectomy and 3 patients (12.5%) underwent total pancreatectomy using RAMPS. Nine patients (37.5%) underwent combined vessel resection, including 8 superior mesenteric-portal vein resections and 1 celiac axis resection. Two patients (8.3%) underwent combined resection of other organs, including the colon, stomach or duodenum. Negative tangential margins were achieved in 22 patients (91.7%). The mean tumor diameter for all patients was 4.09 ± 2.15 cm. The 2 patients with positive margins had a mean diameter of 7.25 cm. The mean number of retrieved lymph nodes was 20.92 ± 11.24 and the node positivity rate was 70.8%. The median survival of the 24 patients was 18.23 ± 6.02 mo. Patients with negative margins had a median survival of 21.80 ± 5.30 mo and those with positive margins had a median survival of 6.47 mo (P = 0.021). Nine patients (37.5%) had postoperative complications, but there were no postoperative mortalities. Pancreatic fistula occurred in 4 patients (16.7%): 2 patients had a grade A fistula and 2 had a grade B fistula. On univariate analysis, histologic grade, positive tangential margin, pancreatic fistula and adjuvant therapy were significant prognostic factors for survival.

CONCLUSION: RAMPS is a feasible procedure for achieving negative tangential margins in patients with carcinoma of the body and tail of the pancreas.

INTRODUCTION

Distal pancreatectomy, originally described at the Mayo Clinic in 1913, has been the standard procedure for carcinoma of the body or tail of the pancreas[1]. This traditional approach is, however, associated with a high tangential margin positive rate and is not based on the physiologic lymphatic drainage of the pancreas[2]. So far, there has been little progress in overcoming these shortcomings. Radical antegrade modular pancreatosplenectomy (RAMPS), which was first introduced by Strasberg *et al*[3] in 2003 as a surgical treatment for carcinomas of the body and tail of the pancreas, is known as a feasible procedure for achieving a higher rate of negative tangential margins than the traditional approach. RAMPS is performed in a right-to-left fashion after early ligation of blood vessels, whereas pancreatosplenectomy is performed in a left-to-right fashion. In fact, RAMPS improves the tangential margin negative rate and provides better surgical exposure, especially in obese patients[3].

Strasberg *et al*[2] reported that negative tangential margins were obtained in 91% of all patients and that the 5-year overall survival rate was 26%. However, there have been few studies on the clinical outcomes following RAMPS[4]. The purpose of this study is to evaluate the surgical outcomes following RAMPS for carcinoma of the body and tail of the pancreas.

MATERIALS AND METHODS

Patients

Twenty-four patients underwent RAMPS with curative intent between January 2005 and June 2009 at the National Cancer Center in South Korea. History-taking, physical examination, liver function tests, tumor marker (carbohydrate antigen 19-9) levels, and abdominal computed tomography (CT) scans were used for diagnostic and staging workup. A whole-body positron emission tomography scan was added when necessary. Clinicopathologic data, including age, sex, operative findings, pathologic results, adjuvant therapy, postoperative clinical course and follow-up data were collected and analyzed retrospectively. A pancreatic fistula after surgery was defined based on the International Study Group of Pancreatic Fistula definition[5]: a drain output of any measurable volume on or after postoperative day 3 with an amylase concentration greater than 3 times the serum amylase concentration. Postoperative complications were reviewed and graded using the Clavien-Dindo classification[6].

Operative procedures

The operation was performed according to the procedure introduced by Strasberg *et al*[2]. After dissection of the gastro-colic ligament, we entered the lesser omentum and dissected the celiac axis, hepatic artery, and trunk of the splenic artery to divide the splenic artery. The neck of the pancreas was divided using electrocautery, and the pancreatic duct stump was ligated. After we divided the neck of the pancreas, the vertical plane of dissection reached the level of the aorta where the left renal vein was exposed. The left adrenal vein was ligated and divided when a posterior RAMPS was performed. During lymph node dissection, we removed regional nodes along the common hepatic and celiac artery. The soft tissue to the left of the hepatoduodenal ligament and superior mesenteric artery was also dissected. Lymph nodes along the splenic artery and splenic hilum were removed en-bloc with the specimen. Removal of the nerve plexus and lymph nodes was performed in the same manner (Figure 1).

GA: Left gastric artery; CHA: Common hepatic artery; SMA: Superior mesenteric artery; SMV: Superior mesenteric vein; Lt. RV: Left renal vein; LK: Left kidney; gl: Gland.

Adjuvant therapy

We performed adjuvant concurrent chemoradiation therapy (CCRT) on all patients without severe medical comorbidities or poor physical status. Several studies have demonstrated the positive effects of CCRT[7-17]. Twenty patients (83.3%) underwent adjuvant CCRT using multiple-field techniques. The initial irradiated field, which was defined as the tumor bed plus regional nodes, received 45 Gy in 25 fractions using a 4-field technique (anteroposterior, posteroanterior and paired laterals) with 15-MV X-rays. The tumor bed boost field received an additional 5.4-10.8 Gy in 3 to 6 fractions of 1.8 Gy. Concomitant 5-fluorouracil-based chemotherapy during radiotherapy was given to all patients. Patients were followed every 3 mo with CT scans and tumor marker levels to detect recurrent disease.

Table 1 Pathological results

Parameters	*n* (%)
Mean tumor diameter	4.09 ± 2.15 cm
Tumor diameter in negative margin (*n* = 22)	3.80 ± 1.73 cm

Statistical analysis

The χ^2 test, the independent *t* test, the Kaplan-Meier method with the log-rank test and a Cox regression model were used for statistical analysis. A *P* value of less than 0.05 was considered significant. SPSS® version 19.0 (Chicago, IL, United States) was used for all statistical analyses. This study was approved by the Institutional Review Board of the National Cancer Center in South Korea.

RESULTS

Operative findings and histopathologic results

The mean age of the total 24 patients was 60.00 ± 7.79 years with a male:female ratio of 1.18:1. The mean operative time was 305.42 ± 155.68 min. One patient required a blood transfusion during surgery. Three patients (12.5%) who had cancer in the body of the pancreas with diffuse infiltration into the head and tail were converted to a total pancreatectomy. Nine patients (37.5%) underwent combined vessel resection, including 8 superior mesenteric-portal vein (SMV-PV) resections and 1 celiac axis resection. Two patients (8.3%) underwent combined resection of other organs, including the colon, stomach or jejunum. Posterior RAMPS, including resection of the adrenal gland, was performed in 5 patients (20.8%).

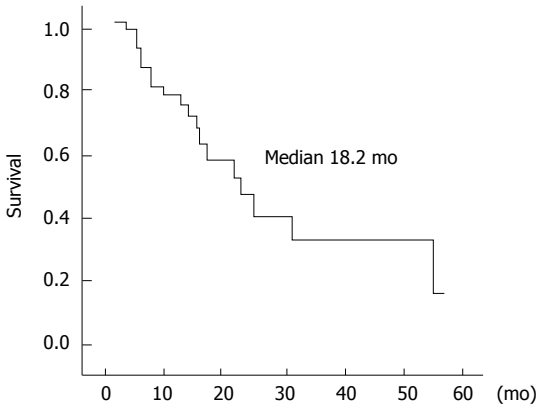

Figure 2 Overall survival curve of the 26 patients.

Histopathologic examination showed that 21 cases (87.5%) were T3. As for histologic grade, moderately differentiated adenocarcinoma was found in 17 patients (70.8%). The mean number of retrieved lymph nodes was 20.92 ± 11.24 and node positivity was observed in 17 patients (70.8%). The pancreatic parenchymal resection margin was negative for all patients with a mean distance of 16.52 ± 13.8 mm. Negative tangential margins were obtained in 22 patients (91.7%). The mean tumor diameter of all patients was 4.09 ± 2.15 cm. Two patients with positive tangential margins had a mean tumor diameter of 7.3 cm (Table 1). Among 9 patients with combined vessel resection, 1 patient had no evidence of vascular invasion on pathology.

Nine patients (37.5%) had postoperative complications (Table 2). Pancreatic fistula occurred in 4 patients (16.7%): 2 patients had a grade A fistula and 2 had a grade B fistula. Intra-abdominal fluid collections and grade B pancreatic fistulae were treated with percutaneous drainage and intravenous antibiotics. Patients with PV-SMV thrombosis were treated with percutaneous thrombectomy and stenting. There were no postoperative mortalities.

Survival and prognostic factors

In this study, the median survival was 18.23 ± 6.02 mo with a median follow-up period of 20.06 ± 14.46 mo (Figure 2). Twenty-one patients (87.5%) had recurrence at follow-up. Two patients (8.3%) had local recurrence, 14 patients (58.3%) had distant metastasis, and 5 patients (20.8%) had both.

Celiac axis resection (Appleby operation) was performed in 1 patient who died of recurrent disease 12.5 mo after surgery. Three patients who underwent total pancreatectomy had a median survival of 21.23 ± 4.25 mo which was similar to the median survival of all patients in this study. One patient was free of cancer at his last

Table 3 Prognostic factors by univariate analysis

Factors		*n*	Median survival (mo)	*P* value
Age	≤ 60 yr	11	21.84 ± 12.90	0.249

RAMPS: radical antegrade modular pancreatosplenectomy; WD: Well differentiated; MD: Moderately differentiated; PD: Poorly differentiated.

visit, while the other 2 patients had local or systemic recurrence.

Twenty patients (83.3%) underwent adjuvant CCRT. CCRT was also performed in patients with pancreatic fistula with the exception of 1 patient with grade A pancreatic fistula who was not a candidate because of age.

On univariate analysis, histologic grade, positive tangential margin, pancreatic fistula and adjuvant therapy were significant prognostic factors for survival (Table 3). Unfortunately, this study was not powered to show significant factors on multivariate analysis.

DISCUSSION

Because carcinomas of the body and tail of the pancreas are often found in a larger size than those of the head, unresectable cases are more common and the recurrence rate after resection is also higher[18-22]. The goals of pancreatic cancer surgery are to obtain tumor-free margins and perform a sufficient regional lymphadenectomy. However, conventional distal pancreatectomy, which is performed in the left-to-right direction along the anterior border of Gerota's facia, is inappropriate for achieving this goal because the tumor easily infiltrates the retroperitoneum and spreads to lymph nodes at an early stage. There have been few surgical methods to overcome these limitations. Yang *et al*[23] introduced retrograde distal pancreatectomy, which cuts the neck of the pancreas first and proceeds with dissection in the right-to-left direction. This procedure is a useful method for exposing the portal-superior mesenteric vein junction, which helps to avoid operative injuries. RAMPS was introduced with the theoretical advantages of obtaining a higher rate of negative tangential margins and a higher lymph node count. Therefore, we applied RAMPS to all distal pancreatectomy cases.

The margin-negative rate of RAMPS reported by Strasberg *et al*[2] and our institute was 91% and 91.7%, respectively, which is higher than the margin-negative rate of conventional distal pancreatectomy (70% to 80%)[5,7,8]. In our study, only 2 patients showed positive resection margins. These 2 patients had a lower median survival than patients with negative margins (6.47 mo *vs* 21.80 ± 5.30 mo, $P = 0.03$). The first patient with a positive tangential margin underwent posterior RAMPS and was stage T3N1 with a tumor size of 10.5 cm. He received adjuvant CCRT after recovering from grade B pancreatic fistula, but had multiple liver metastases at follow-up and survived 6.5 mo. The second patient underwent anterior RAMPS with combined jejunal resection due to gross invasion. He had stage T3N0 disease with a tumor size of 4.0 cm. He had both local recurrence and distant metastasis after adjuvant CCRT and survived 19.0 mo.

RAMPS has also been applied to laparoscopic distal pancreatectomy because it provides good surgical exposure for performing a right-to-left distal pancreatectomy. Kang *et al*[24] and Choi *et al*[25] reported outcomes of laparoscopic distal pancreatectomy performed on well-selected patients with left-sided pancreatic ductal adenocarcinomas.

In a previous study performed by Strasberg *et al*[2], the mean number of retrieved lymph nodes and lymph node positivity rate were 14.3 and 48%, respectively. In our study, the mean number of retrieved lymph nodes was 20.92 ± 11.24 and the lymph node positivity rate was 70.8%. Lymph node status is known to be a very important prognostic factor in pancreatic cancer. Some previous reports emphasized the lymph node ratio (the number of positive lymph nodes/the total number of retrieved lymph nodes) in pancreatic cancer[26]. However, few studies have mentioned the number of retrieved lymph nodes, which makes it difficult to compare the surgical efficacy of RAMPS with conventional distal pancreatectomy.

Strasberg *et al*[2] reported that the median survival time and the 5-year survival rate after RAMPS were 21 mo and 26%, respectively, which were better than those of previous reports[18]. It is known that patients with left-sided pancreatic cancer have poorer survival rates than patients with right-sided pancreatic cancer. However, surgical outcomes for patients with left-sided cancer were better than those with right-sided pancreatic cancer. Our patients had a median survival of 18.23 ± 6.02 mo, which was a little better than the survival following distal pancreatectomy reported by previous studies of conven-

tional distal pancreatectomy. However, our patients were mostly T3 or higher (87.5%), and lymph node positivity was 70.8%, which means that most of our patients were advanced stage. When viewed in this light, our results are better than those reported by previous studies and are comparable with those of right-sided pancreatic cancer.

We had 19 patients (79.2%) with systemic recurrence. Therefore, even though RAMPS has surgical advantages in terms of local control, there are limitations in preventing cancer progression, especially through systemic recurrence.

We performed distal pancreatectomy for carcinomas of the body and tail of the pancreas using RAMPS, with a negative tangential margin of 91.7%, no mortality and acceptable morbidity. It is suggested that RAMPS is a safe and feasible procedure for carcinomas of the body and tail of the pancreas. Further studies with larger sample sizes are needed to confirm our results.

COMMENTS

Background

Radical antegrade modular pancreatosplenectomy (RAMPS) is known as a feasible procedure for achieving a higher rate of negative tangential margins than the traditional approach. Although RAMPS is widely performed, there have been few studies on its clinical outcomes.

Applications

This study provides reference data for future larger studies.

Terminology

RAMPS was first introduced in 2003 as a surgical treatment for carcinomas of the body and tail of the pancreas.

Peer review

RAMPS seems to be a feasible procedure for achieving negative tangential margins for patients with carcinoma of the body and tail of the pancreas.

Abstract

AIM: To explore differences in biochemical indices between neonatal intrahepatic cholestasis caused by citrin deficiency (NICCD) and that with other etiologies.

METHODS: Patients under 6 mo of age who were referred for investigation of conjugated hyperbilirubinaemia from June 2003 to December 2010 were eligible for this study. After excluding diseases affecting the extrahepatic biliary system, all patients were screened for the two most common *SLC25A13* mutations; the coding exons of the entire *SLC25A13* gene was sequenced and Western blotting of citrin protein performed in selected cases. Patients in whom homozygous or compound heterozygous *SLC25A13* mutation and/or absence of normal citrin protein was detected were defined as having NICCD. Cases in which no specific etiological factor could be ascertained after a comprehensive conjugated hyperbilirubinaemia work-up were defined as idiopathic neonatal cholestasis (INC). Thirty-two NICCD patients, 250 INC patients, and 39 infants with cholangiography-confirmed biliary atresia (BA) were enrolled. Laboratory values at their first visit were abstracted from medical files and compared.

RESULTS: Compared with BA and INC patients, the NICCD patients had significantly higher levels of total bile acid (TBA) [all measures are expressed as median (inter-quartile range): 178.0 (111.2-236.4) μmol/L in NICCD *vs* 112.0 (84.9-153.9) μmol/L in BA and 103.0 (70.9-135.3) μmol/L in INC, $P = 0.0001$]. The NICCD patients had significantly lower direct bilirubin [D-Bil 59.6 (43.1-90.9) μmol/L in NICCD *vs* 134.0 (115.9-151.2) μmol/L in BA and 87.3 (63.0-123.6) μmol/L in INC, $P = 0.0001$]; alanine aminotransferase [ALT 34.0 (23.0-55.0) U/L in NICCD *vs* 108.0 (62.0-199.0) U/L in BA and 84.5 (46.0-166.0) U/L in INC, $P = 0.0001$]; aspartate aminotransferase [AST 74.0 (53.5-150.0) U/L in NICCD *vs* 153.0 (115.0-239.0) U/L in BA and 130.5 (81.0-223.0) U/L in INC, $P = 0.0006$]; albumin [34.9 (30.7-38.2) g/L in NICCD *vs* 38.4 (36.3-42.2) g/L in BA and 39.9 (37.0-42.3) g/L in INC, $P = 0.0001$]; glucose [3.2 (2.0-4.4) mmol/L in NICCD *vs* 4.1 (3.4-5.1) mmol/L in BA and 4.0 (3.4-4.6) mmol/L in INC, $P = 0.0014$] and total cholesterol [TCH 3.33 (2.97-4.00) mmol/L in NICCD *vs* 4.57 (3.81-5.26) mmol/L in BA and 4.00 (3.24-4.74) mmol/L in INC, $P = 0.0155$] levels. The D-Bil to total bilirubin (T-Bil) ratio was significantly lower in NICCD patients [all measures

are expressed as median (inter-quartile range): 0.54 (0.40-0.74)] than that in BA patients [0.77 (0.72-0.81), P = 0.001] and that in INC patients [0.74 (0.59-0.80), P = 0.0045]. A much higher AST/ALT ratio was found in NICCD patients [2.46 (1.95-3.63)] compared to BA patients [1.38 (0.94-1.97), P = 0.0001] and INC patients [1.48 (1.10-2.26), P = 0.0001]. NICCD patients had significantly higher TBA/D-Bil ratio [3.36 (1.98-4.43) *vs* 0.85 (0.72-1.09) in BA patients and 1.04 (0.92-1.14) in INC patients, P = 0.0001], and TBA/TCH ratio [60.7 (32.4-70.9) *vs* 24.7 (19.8-30.2) in BA patients and 24.2 (21.4-26.9) in INC patients, P = 0.0001] compared to the BA and INC groups.

CONCLUSION: NICCD has significantly different biochemical indices from BA or INC. TBA excretion in NICCD appeared to be more severely disturbed than that of bilirubin and cholesterol.

INTRODUCTION

Citrin deficiency, caused by mutations in the *SLC25A13* gene on chromosome 7q21.3, is an autosomal recessive disease that was first discovered in Japan and thereafter identified worldwide[1-8]. At least two main phenotypes of citrin deficiency have been established: neonatal intrahepatic cholestasis caused by citrin deficiency (NICCD, OMIM #605814)[9-11] and adult-onset type Ⅱ citrullinemia (CTLN2, OMIM #603471)[1,12]. The clinical features and diagnostic criteria of CTLN2 have been well established, but those of NICCD have not yet been established.

Children with NICCD usually have transient intrahepatic cholestasis that disappears by the age of 1 year with appropriate management[13]. However, some patients need liver transplantation or may die from the disease during infancy[14-17]. Others may develop severe CTLN2 symptoms unexpectedly one to several decades later[13]. Prompt detection and specific lactose-free and/or medium-chain triglyceride formula may contribute to the avoidance of a complicated course in the NICCD phase. However, the prompt diagnosis of NICCD is still a challenge because the clinical features of cholestasis induced by citrin deficiency are presently not fully understood[18].

Some biochemical indices, including total bilirubin (T-Bil), direct bilirubin (D-Bil), aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), γ-glutamyltranspeptidase (GGT), and α-fetoprotein (AFP) have been analyzed or compared between patients with NICCD, biliary atresia (BA) or idiopathic neonatal cholestasis (INC), with significant differences found between them[4]. However, comparisons of serum total bile acid (TBA) and total cholesterol (TCH) levels between different causes of neonatal cholestasis has rarely been reported before[19].

Bilirubin, bile acids and cholesterol are all mainly physiologically excreted by the hepatobiliary system. Usually, the blood levels of all these compounds increase in the event of blockage of the extrahepatic biliary system. However, they may be affected to different extents in intrahepatic cholestasis with different etiology. For instance, blood TCH and TBA levels are usually elevated significantly in Alagille syndrome, even in cases in which the bilirubin level is only mildly elevated; however, the blood TCH level is usually normal in cases of progressive familial intrahepatic cholestasis type 1 or 2 despite significant elevation of blood TBA and bilirubin levels. Therefore, comparison of these biochemical indices in neonatal cholestasis cases with different etiologies will enable better characterization of the biochemical changes of the disease and may help elucidate the mechanism of cholestasis caused by citrin deficiency.

Therefore, the aims of this study were to explore the differences in biochemical indices, including D-Bil, TBA, TCH and their ratios between cholestasis with different etiologies, and to explore the mechanism of cholestasis caused by citrin deficiency.

MATERIALS AND METHODS

Subjects

Patients under 6 mo of age who were referred to the Children's Hospital of Fudan University, a tertiary referral hospital and primary specialized paediatric hospital in Eastern China, from June 2003 to December 2010, for investigation of conjugated hyperbilirubinaemia were eligible for this study. Conjugated hyperbilirubinemia was defined as serum T-Bil levels > 75 μmol/L, with a conjugated fraction accounting for > 20% of the total, or having conjugated bilirubin levels > 17 μmol/L with serum T-Bil levels < 75 μmol/L[20]. Patients who had obvious extrahepatic abnormalities or prolonged prothrombin time that could not be corrected by parenteral administration of vitamin K1 were excluded. Subjects who satisfied the above criteria as well as the following specific criteria for each of the three groups were included.

BA group: Patients with neonatal cholestasis in whom no isotope excretion was demonstrated by hepatobiliary iminodiacetic acid (HIDA) scintigraphy, and in whom diagnosis of BA was confirmed by laparoscopic or laparotomic cholangiography were eligible for this group.

INC group: Intrahepatic cholestasis was defined as con-

Table 1 Differential diagnosis have been excluded

Affecting bile duct	Infectious	Metabolic	Others
Biliary atresia	Herpes viruses	α-1 antitrypsin deficiency	Endocrinological
Choledochal cyst	Rubella virus	Neonatal iron storage disease	Hypothyroidism
Cholelithiasis	Enteroviruses	Amino acid disorders	Panhypopituitarism/septo-optic dysplasia
Inspissated bile	Hepatitis viruses	Tyrosinemia	Genetic
Tumor	Human immunodeficiency virus	Hypermethioninemia	ATP8B1 deficiency
Hemangioma	Syphilis	Mevalonate kinase dificiency	ABCB11 deficiency
Bile duct stenosis/stricture/perforation	Toxoplasmosis	Glucogen storage diseases	ABCB4 deficiency
Neonatal sclerosing cholangitis	Bacterial sepsis	Gaucher disease	Bile acid synthetic defects
Caroli disease	Urinary tract infections	Niemann–Pick disease	Neonatal Dubin–Johnson syndrome
Alagille syndrome		Wolman disease	Various trisomies
		Zellweger syndrome	Arghrogryposis
		Infantile Refsum disease	Hematological
		Mitochondrial disorders	Hemophagocytic lymphohistiocytosis
		Urea cycle disorders	Langerhans cell histiocytosis
			Miscellaneous drug effects
			Total parenteral nutrition

jugated hyperbilirubinemia following the exclusion of diseases affecting the extrahepatic biliary system (Table 1) by imaging of the hepatobiliary system. The imaging procedures included an ultrasound scan and HIDA scintigraphy in each case and laparotomic/laparoscopic cholangiography in selected cases. Idiopathic neonatal cholestasis (INC) was defined when no specific etiological factor (Table 1) could be ascertained after a comprehensive conjugated hyperbilirubinemia test[21]. Patients with at least single-allele mutation of *SLC25A13* gene were excluded from this group as well.

NICCD group: The strategy of testing for *SLC25A13* gene mutations in intrahepatic cholestatic infants had been reported previously[22,23]. All intrahepatic cholestasis infants with unknown causes were screened for the two most common mutations of the *SLC25A13* gene in Chinese, 851del4 and 1638ins23. For patients with various aminoacidemia or patients with only single-allele mutation who were found by the above screening method, the entire 18 coding exons together with the flanking sequence of the *SLC25A13* gene were amplified by polymerase chain reaction and directly sequenced. Western blotting analysis of citrin protein was performed on patients with biopsied liver specimens available. Only patients in whom homozygous or compound heterozygous *SLC25A13* gene mutation and/or absence of normal citrin protein were demonstrated, for whom a definite diagnosis of citrin deficiency could be made, were regarded as NICCD patients in this study. Patients with a probable diagnosis of citrin deficiency, that is, in whom there was only a heterozygous *SLC25A13* gene mutation and in whom absence of normal citrin protein could not be demonstrated by Western blotting were excluded.

Retrospective analyses of biochemical indices

The medical files of the patients who satisfied the above inclusion and exclusion criteria were reviewed following the approval of the Institute's Ethics Review Committee. Sex, birth weight, gestation age or term/preterm, age at which conjugated jaundice was first noticed, and the biochemical indices at presentation, were abstracted. Liver function tests and other routine laboratory data were obtained using standard methods.

Statistical analysis

Statistical analysis was performed using Stata/SE 10.0 for Windows (StataCorp LP, College Station, TX, United States of America). The descriptive data of the quantitative variables were reported in box-whisker plots and compared using Kruskal-Wallis rank tests among the three groups. For results with overall statistical significance, a Mann-Whitney test with a Bonferroni correction was further performed to test the medians between a series of pairwise groups. All *P* values were two-sided. Results were considered statistically significant at the 0.05 level.

RESULTS

Basic information

In total, 32 patients (19 male and 13 female) with a definite diagnosis of citrin deficiency were included in the NICCD group. Thirty-nine patients (24 male and 15 female) were included in the BA group. Two hundred and fifty patients (174 male and 76 female) were included in the INC group. The birth weight and the days at which conjugated jaundice was first noticed in the three groups are illustrated in Figure 1 or Table 2. The median birth weight was lowest in the NICCD group, but the difference did not reach statistical significance (Table 2). Conjugated jaundice was noticed earlier in the BA group compared with the INC group ($P < 0.05$, Figure 1A).

Comparison of biochemical indices among three groups

The biochemical data of the three groups were compared (Figure 1B-E, Table 2). The NICCD group had significantly lower ALT, AST, total protein, albumin, and glucose levels compared with the BA and INC groups, suggesting that the synthetic function and glucose metabolism were more severely damaged in the NICCD

Table 2 Comparison of birth weight, biochemical indices and their ratios among the three groups

[a]P < 0.05 between BA and INC; [c]P < 0.05 between BA and NICCD; [e]P < 0.05 between INC and NICCD. NICCD: Neonatal intrahepatic cholestasis caused by citrin deficiency; BA: Biliary atresia; INC: Idiopathic neonatal cholestasis; TBA: Total bile acid; T-Bil: Total bilirubin; D-Bil: Direct bilirubin; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; GGT: γ-glutamyltranspeptidase; TCH: Total cholesterol.

group than in the other two groups. The NICCD group also had significantly higher TBA and lower D-Bil and cholesterol levels compared with the BA and INC groups, indicating that the excretion of bile acids, D-Bil and cholesterol might be affected differently in NICCD patients. Significantly lower T-Bil and GGT levels were noticed in the NICCD group only when compared with the BA group.

Comparison of ratios of biochemical indices

To compare further the different biochemical indices, a series of ratios was calculated. The highest ratio of D-Bil to T-Bil was found in the BA group and the lowest in the NICCD group (Table 2, Figure 1F). A much higher AST/ALT ratio was found in the NICCD group compared to the INC and BA groups (Table 2).

The ratios between D-Bil, bile acids and cholesterol were also compared (Table 2). The ratio of serum TBA to D-Bil was significantly higher in the NICCD group than the ratios in the BA and INC groups (Figure 1G, P < 0.05). Significant differences were also found for the ratio of TBA to TCH between the NICCD and BA groups and between the NICCD and INC groups (Figure 1H, P < 0.05).

DISCUSSION

Citrin deficiency is one of the most common classical inborn errors of metabolism of amino acids, organic acids and fatty acid oxidation in Eastern Asia, including China[24]. The biochemical characteristics and mechanism of cholestasis caused by citrin deficiency are still not fully understood. Although differences in some indices among patients with BA, INC and NICCD have been reported previously, the very small sample sizes of the studies precluded a definite conclusion[4,19,23]. In the present study, the cohorts of NICCD, INC and BA had numbers large enough to test previous findings. Additionally, by comparing the elevation of D-Bil, TBA and cholesterol levels and the ratios of these compounds, it was found that the excretion of bile acids appeared to be more severely affected in NICCD than in BA and INC.

A previous study with a small number of subjects demonstrated that patients with cholestasis caused by citrin deficiency had lower ALT and AST levels and higher AST to ALT ratios compared to those with BA or idiopathic neonatal hepatitis[25]. Low albumin and glucose levels were also associated with NICCD in a previous case series[26,27]. In the present study, those findings were confirmed. Previous studies also showed that patients with NICCD had lower birth weight compared to normal controls or to the national standard. In our study, although a lower median birth weight in the NICCD group was noticed, the differences did not reach statistical significance compared to patients with BA or INC. This could be explained by the different control groups (normal control or national standard used in previous studies *vs* patients with cholestasis of other causes) and the large difference observed within the NICCD group in this study.

The serum TBA level in NICCD has previously been compared with that in BA and INC in a study that had very few subjects[19]. In the present study, the serum level of TBA as well as the ratio of serum TBA to D-Bil and cholesterol levels was compared. In BA, we can suppose that excretion of D-Bil, bile acids and cholesterol is affected to the same extent in consideration of complete blockage of the biliary system. If the ratio of TBA to D-Bil in the BA group was taken as the reference value, the median for INC was found to be 1.22 (1.04/0.85) times higher

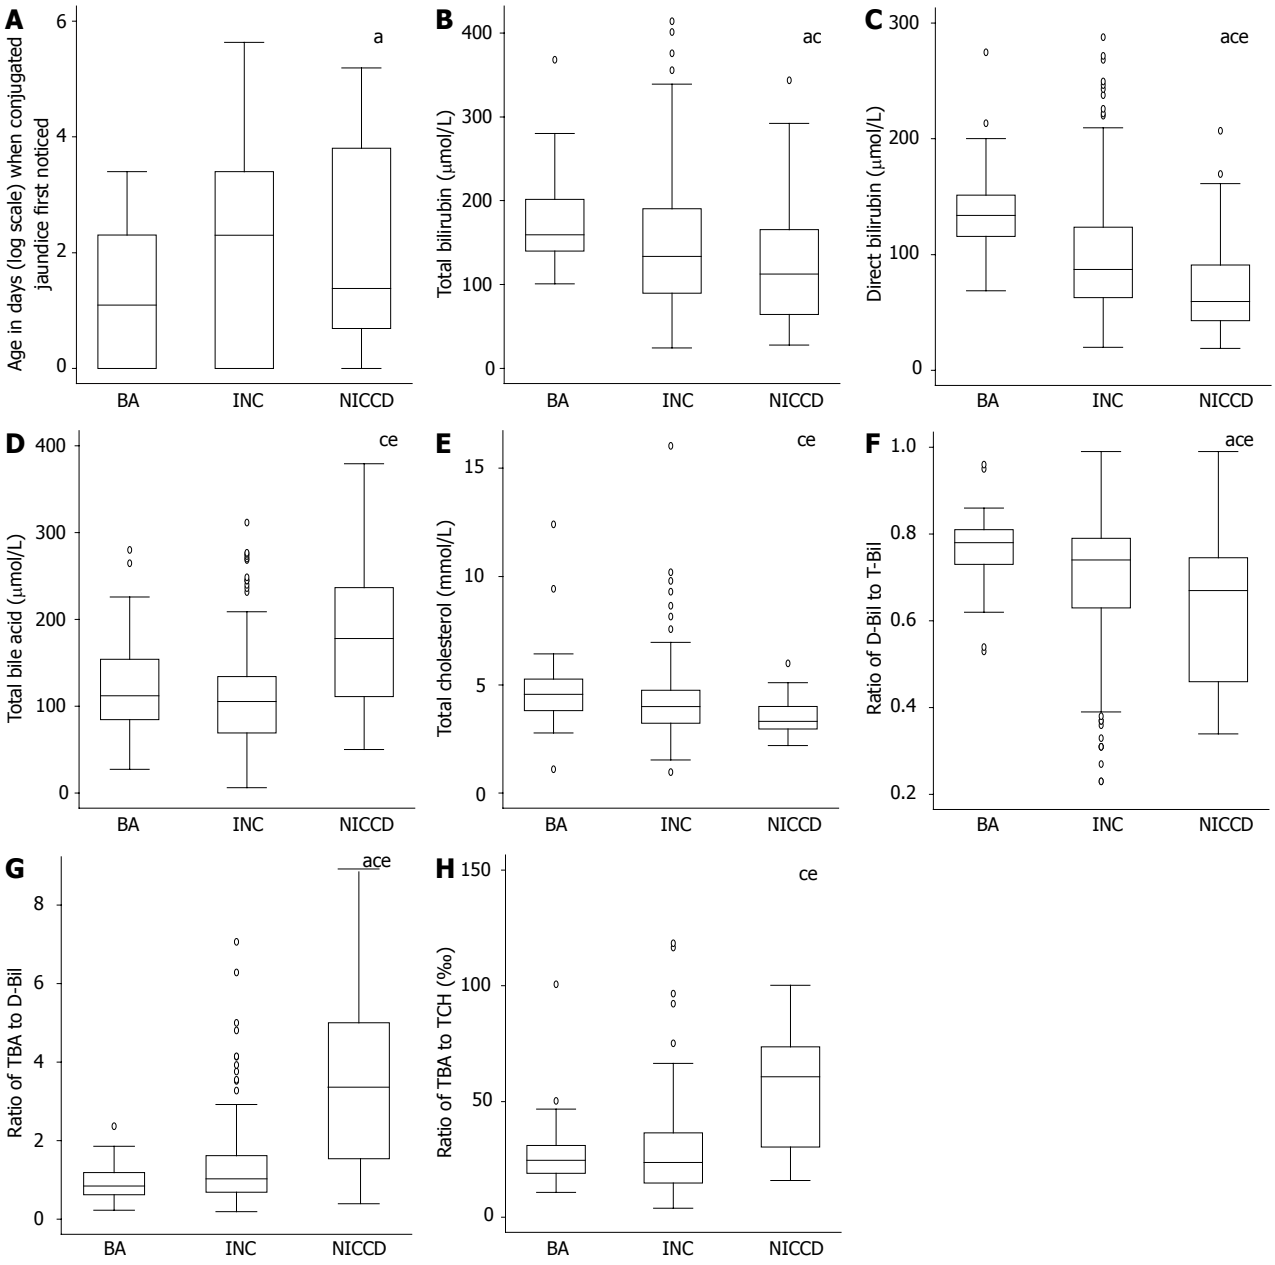

Figure 1 Comparison of the age when conjugated jaundice was first noticed (A), biochemistry indices (B-E), and ratios of some biochemical indices (F-H) in patients with neonatal intrahepatic cholestasis caused by citrin deficiency, idiopathic neonatal cholestasis and biliary atresia. $^{a}P < 0.05$ between BA and INC; $^{c}P < 0.05$ between BA and NICCD; $^{e}P < 0.05$ between INC and NICCD. Normal range: T-Bil (2-20 μmol/L), D-Bil (0-6 μmol/L), total bile acids (< 40 μmol/L), and TCH (3.12-5.20 mmol/L). NICCD: Neonatal intrahepatic cholestasis caused by citrin deficiency; BA: Biliary atresia; INC: Idiopathic neonatal cholestasis; TBA: Total bile acid; T-Bil: Total bilirubin; D-Bil: Direct bilirubin; TCH: Total cholesterol.

and that of NICCD 3.95 (3.36/0.85) times higher. For the ratio of TBA to cholesterol, if the median value of the BA group was taken as a standard, the median in the INC group was nearly the same as the standard but that in the NICCD group was 2.46 (60.7/24.7) times higher. These results indicate that the excretion of bile acids is much more severely affected than the excretion of bilirubin and cholesterol in NICCD patients. As a consequence, we may speculate that the failure to excrete bile acids from hepatocytes to the canalicula is the main mechanism of cholestasis caused by citrin deficiency.

The main limitation of this study was its retrospective nature. It could be argued that some biochemical indices were affected by the drugs that patients were taking. However, prior to the determination of a clear diagnosis, the management of patients had been similar in the three groups; therefore, the patients in the different groups would have been affected by these variables in the same way. Another measure that was used to avoid sample bias was using the first available laboratory data obtained when patients were referred to us. Although significant differences in TBA and TBA ratios were found between the NICCD and other two groups, no cut-off levels can be presented at this time.

COMMENTS

Background

Citrin deficiency is one of the most common metabolic disorders in Eastern Asia. It has at least two main phenotypes: neonatal intrahepatic cholestasis caused by citrin deficiency (NICCD) and adult-onset type Ⅱ citrullinemia. The clinical features of and the mechanism of cholestasis in NICCD have yet to be established.

Research frontiers

Some biochemical indices of patients with NICCD have been compared to those of patients with biliary atresia (BA) and of patients with idiopathic neonatal cholestasis (INC). Comparison of these biochemical indices in neonatal cholestasis cases with different etiologies will better characterize the biochemical changes of the disease and may further the understanding of the mechanism of cholestasis caused by citrin deficiency.

Innovations and breakthroughs

Apart from confirming previous findings that NICCD patients had significantly lower alanine aminotransferase (ALT) level, lower direct bilirubin (D-Bil) to total bilirubin ratio, and significantly higher aspartate aminotransferase to ALT ratio compared to the BA and INC patients, this study specifically compared the serum level of total bile acid (TBA) and its ratio to D-Bil and cholesterol, and found that NICCD patients had significantly higher TBA levels as well as higher TBA to D-Bil and TBA to cholesterol ratios than patients with BA and INC.

Applications

The excretion of TBA appears to be much more severely disturbed than that of D-Bil and cholesterol in cholestasis caused by citrin deficiency. Further study of this condition will help elucidate the mechanism of cholestasis in NICCD, and the ratios could be further developed as indices for the differential diagnosis of neonatal cholestasis.

Peer review

The authors present an interesting retrospective study comparing liver specific biochemical parameters in different groups of infants with cholestasis.

Abstract

AIM: To investigate the effects of emergent preoperative self-expandable metallic stent (SEMS) *vs* emergent surgery for acute left-sided malignant colonic obstruction.

METHODS: Two investigators independently searched the MEDLINE, EMBASE and Cochrane Central Register of Controlled Trials, as well as references of included studies to identify randomized controlled trials (RCTs) that compared two or more surgical approaches for acute colonic obstruction. Summary risk ratios (RR) and 95% CI for colonic stenting and emergent surgery were calculated.

RESULTS: Eight studies met the selection criteria, involving 444 patients, of whom 219 underwent SEMS and 225 underwent emergent surgery. Seven studies reported difference of the one-stage stoma rates between the two groups (RR, 0.60; 95% CI: 0.48-0.76; $P < 0.0001$). Only three RCTs described the follow-up stoma rates, which showed no significant difference between the two groups (RR, 0.80; 95% CI: 0.59-1.08; $P = 0.14$). Difference was not significant in the mortality between the two groups (RR, 0.91; 95% CI: 0.50-1.66; $P = 0.77$), but there was significant difference (RR, 0.57; 95% CI: 0.44-0.74; $P < 0.0001$) in the overall morbidity. There were no significant differences between the two groups in the anastomotic leak rate (RR, 0.60; 95% CI: 0.28-1.28; $P = 0.19$), occurrence of abscesses, including peristomal abscess, intraperitoneal abscess and parietal abscess (RR, 0.83; 95% CI: 0.36-1.95; $P = 0.68$), and other abdominal complications (RR: 0.67; 95% CI: 0.40-1.12; $P = 0.13$).

CONCLUSION: SEMS is not obviously more advantageous than emergent surgery for patients with acute left-sided malignant colonic obstruction.

INTRODUCTION

Colorectal cancer is the fourth most common malignancy worldwide, with an estimated number of 1 023 000 new cases and 529 000 deaths each year[1]. The incidence of colorectal cancer has been increasing rapidly in Asia over the past few decades[2]. About 7%-29% of the patients with colorectal cancer present with bowel obstruction[3,4]. And benefit of surgical management of malignant large bowel obstruction remains controversial, especially for left-sided colonic obstruction. Emergent colorectal surgery for acute obstruction is associated with a mortality rate of 15%-20% and a morbidity rate of 15%-20%, both significantly higher than that in the elective situation[5-7]. Emergent surgery is an independent factor of mortality and morbidity, and about two-thirds of patients end up with a permanent stoma[3,6,8,9].

In 1991, colonic stenting was introduced to restore luminal patency in patients with malignant obstruction of the left side colon[10]. Tejero *et al*[11] used self-expandable metallic stent (SEMS) as a bridge to surgery in two patients with colonic obstruction in 1994. Stent placement before elective surgery, also known as a bridge to surgery, improved the clinical condition of the patient and seemed to decrease the mortality, morbidity, and number of colostomies in uncontrolled studies[12-15]. Although preoperative SEMS insertion has such advantages, it may result in the related complications such as perforation, stent migration, and reobstruction. As shown in the recent randomized controlled trials (RCTs), whether preoperative SEMS can reduce mortality, complication rate and stoma rate is still a big controversy[16-18]. Thus, this meta-analysis was performed to evaluate the effects of preoperative SEMS *vs* emergent surgery for acute left-sided malignant colonic obstruction.

MATERIALS AND METHODS

Search strategy

SEMS was first used in 1991. We therefore, searched the databases, including the Cochrane Central Register of Controlled Trials (1991-April 2011), MEDLINE (1991-September 2011), EMBASE (1991-September 2008), Elsevier ScienceDirect (1998-September 2008), SpringLink (up to September 2011), Ovid LWW (1991-September 2011) and BMJ Journals Online (up to September 2008). The following keywords were used: "intestinal obstruction", "colon", "rectum", "left-sided colon", "surgery", "resection", "stents", "randomized" and "controlled study". The detailed search strategy is available from the authors. All included studies also had access to the PubMed "related articles" function and the Science Citation Index. In addition, the reference lists of included studies were scrutinized. No language restrictions were applied.

Data extraction

Data were independently abstracted from each study by two researchers, and disagreement was resolved by consensus. Data were extracted from each study using a pre-designed review form. Data to be extracted were as follows: (1) treatment details: primary anastomosis rate, and the incidence of stoma creation; (2) short-term adverse events: mortality and morbidity such as anastomotic leak rate, abscess and extra abdominal complications; and (3) long-term outcomes: follow-up stoma rate.

Inclusion and exclusion criteria

Studies fulfilling the following criteria were included in the meta-analysis: (1) RCTs or other comparative studies comparing SEMS as a bridge to surgery and emergent surgery; (2) reports on at least one of the outcome measures mentioned below; and (3) studies reporting patients with malignant acute left-sided colonic obstruction.

Quality of methodology

The quality of nonrandomized studies was assessed using the Newcastle-Ottawa Scale with some modifications to meet the needs for this meta-analysis[19], and the quality of randomized studies was evaluated by means of the modified Jadad score[20]. The quality of the studies was evaluated based on three items: patient selection, comparability of study groups, and assessment of outcome. Studies achieving five or more stars were considered high quality. The quality of randomized studies was evaluated by means of the modified Jadad score including the following four areas: (1) randomization method; (2) hidden subgroups; (3) blinding; and (4) the description of the loss to follow-up and drop-out and the intention-to-treat. The total score of 1 to 3 points were ascribed to low-quality studies, whereas a total score of 4 to 7 points to high-quality researches.

Statistical analysis

Using the Cochrane Collaboration's RevMan 5.1 software provided by meta-analysis, the results of included measurement of indicators were all count data, and 95% CI was used for the efficacy analysis. The heterogeneity between studies was tested. When there was homogeneity among studies ($P > 0.1$, $I^2 < 50\%$), a fixed effects model was used for meta-analysis; if there is significant heterogeneity among studies ($P < 0.1$, $I^2 > 50\%$), the random effects model was used. We also analyzed the different quality of the possible causes, and conducted subgroup analysis. If the heterogeneity among the studies was too large, descriptive analysis was performed.

RESULTS

Selection of trials

The initial search strategy retrieved 88 articles after screening all titles, abstracts and full texts. Twenty-two articles were excluded due to lack of comparison with other surgical strategies in most of the cohort studies, 45 articles were excluded because of comparison stenting *vs* surgery without a bridge to the surgery, and 13 studies were excluded because there was no control. Finally, 8 trials with 444 patients were included, of whom 219

Table 2 Basic characteristics of included nonrandomized controlled studies in the meta-analysis

Year	Author	Design	Total	SEMS	Surgery	Match	Study quality (rate, max 11)
2008	Dastur	R	43	19	23	1,2,3,4,5,6	8
2002	Martin	R	52	26	26	1,2,3,4,5,8	7
2006	Ng	R	60	20	40	1,2,3,5,6,8	8
2007	Pessione	R	16	9	7	1,2,3,4,5,8	7

Matching: 1 = age, 2 = sex, 3 = diagnosis, 4 = tumor site, 5 = tumor stage, 6 = American Society of Anesthesiologists score, 7 = body mass index, 8 = comorbidity. SEMS: Self-expandable metallic stent. "R" represents that the study was a randomized clinical trail.

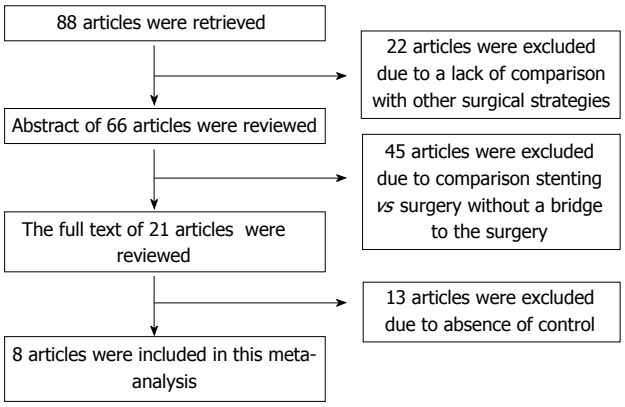

Figure 1 Flow chart of selection of studies and reasons for exclusion from the meta-analysis.

(49.3%) successfully underwent stent insertion and 225 (50.7%) underwent emergent surgery. There were 17 (7.8%) deaths in the SEMS as a bridge to surgery group and 21 (9.3%) deaths in the emergent surgery group. There were only three RCTs[16-18] and five nonrandomized controlled studies (NRCTs)[12-14,21,22]. The flow chart of selection of studies and reasons for exclusion is presented in Figure 1. Characteristics of studies included in the meta-analysis are presented in Tables 1 and 2.

Quality of studies

Three RCTs were of moderate to good methodological quality evaluated by the modified Jadad score[20]. Because of the special strategies under assessment, no blind method was used in all the RCTs. All five NRCTs contained groups matched for age, sex, and diagnosis; five articles contained information on tumor site, tumor stage, American Society of Anesthesiologists score, or body mass index, respectively. All studies were scored more than five stars using the modified Newcastle-Ottawa scale[19].

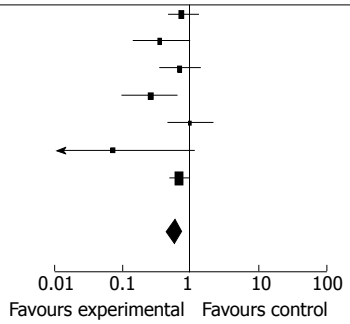
Meta-analysis of treatment details and long-term outcomes

Our meta-analysis showed statistically significant difference between the SEMS group (175 patients) and the emergent surgery group (201 patients) in seven studies with regard to the one-stage stoma rate [risk ratios (RR): 0.60, 95% CI: 0.48-0.76; $P < 0.0001$]. There was no significant heterogeneity between the studies ($P = 0.14$, $I^2 = 37\%$) (Figure 2A). Only three RCTs compared the two groups (101 patients in the SEMS group and 105 in the emergent surgery group) and described the follow-up stoma rates. There was neither significant difference in follow-up stoma rates (RR: 0.80; 95% CI: 0.59-1.08; $P = 0.14$), nor heterogeneity ($P = 0.17$, $I^2 = 44\%$) between the two groups (Figure 2B).

Anastomosis rates were reported by all eight trials involving 219 patients in the SEMS group and 225 in the emergent surgery group. There was a significant difference between the two groups, with a pooled RR of 1.64 (95% CI: 1.39-1.94; $P < 0.00001$) (Figure 2C).

Meta-analysis of short-term adverse events: Mortality and morbidity such as anastomotic leak rate, abscess and extra abdominal complications

Six trials reported mortality in 149 patients in the SEMS group and 175 patients in the emergent surgery group. There was no significant difference (RR: 0.91; 95% CI: 0.50-1.66; $P = 0.77$) and heterogeneity ($P = 0.65$, $I^2 = 0\%$) between the two groups (Figure 2D).



Seven trials with 200 patients in the SEMS group and 218 patients in the emergent surgery group reported the overall morbidity. There was no significant difference between the two groups with a pooled RR of 0.57(95% CI; 0.44-0.74; $P < 0.0001$). However, significant heterogeneity was observed ($P = 0.0001$, $I^2 = 78\%$) (Figure 2E).

Further complication analysis was also performed, such as anastomotic leak, abscess and extra abdominal complications. The incidence of anastomotic leakage in

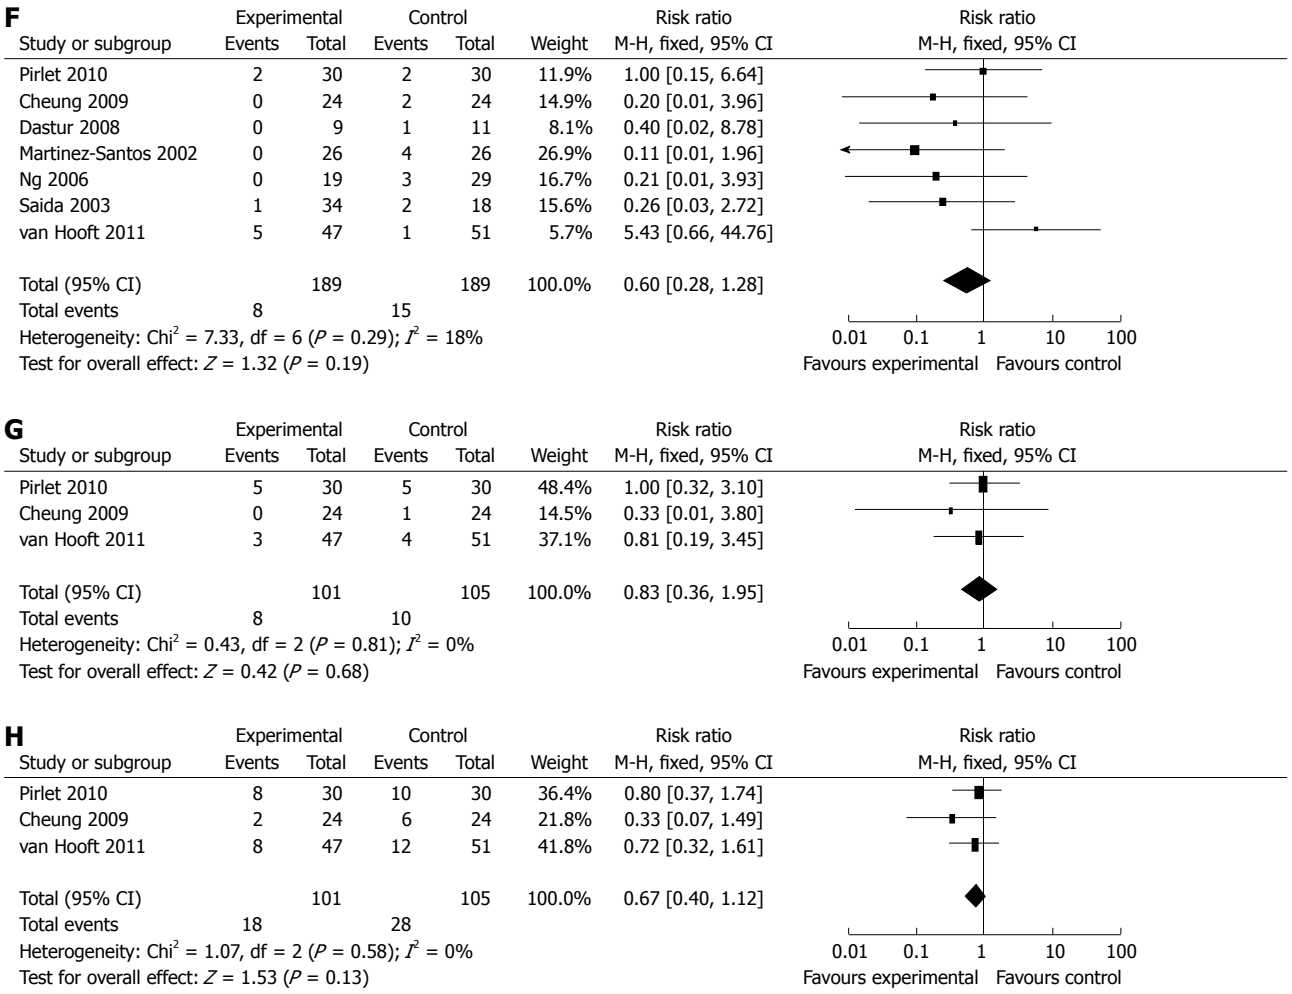

Figure 2 Colonic stenting *vs* emergent surgery. A: One-stage stoma rates; B: Follow-up stoma rates; C: Anastomosis rates; D: Mortality; E: Morbidity; F: Anastomotic leak; G: Abscesses; H: Extra abdominal complication. M-H: Mantel Haenszel.

the two groups was reported in seven studies. SEMS did not reduce the incidence of anastomotic leakage in patients treated with emergent surgery (RR: 0.60; 95% CI: 0.28-1.28; $P = 0.19$). No significant heterogeneity was observed between the two groups ($P = 0.29$, $I^2 = 18\%$) (Figure 2F).

Three studies compared the rates of abscesses, including peristomal abscess, intraperitoneal abscess and parietal abscess and extra abdominal complication. The analyses showed no significant difference in occurrence of abscess (RR: 0.83, 95% CI: 0.36-1.95; $P = 0.68$) and extra abdominal complications (RR: 0.67, 95% CI: 0.40-1.12; $P = 0.13$). No significant heterogeneity was found in abscess ($P = 0.81$, $I^2 = 0\%$) (Figure 2G) and extra abdominal complications ($P = 0.58$, $I^2 = 0\%$) (Figure 2H).

RCTs vs NRCTs

We also compared three RCTs with other NRCTs. There were significant differences in the morbidity (RCT group, RR 1.18; 95% CI: 0.79-1.77; $P = 0.08$ *vs* NRCTs group, RR 0.34; 95% CI: 0.21-0.56; $P < 0.0001$), anastomotic leak rate (RCT group, RR 5.43; 95% CI: 0.66-44.76; $P = 0.53$, *vs* NRCT group, RR 0.21; 95% CI: 0.05-0.82; $P = 0.02$), and anastomosis rates (RCT group, RR 1.57; 95% CI: 1.10-2.08; $P = 0.002$, *vs* NRCT group, RR 1.69; 95% CI: 1.38-2.08; $P < 0.00001$). There were no differences in the stoma rates (RCT group, RR 0.65; 95% CI: 0.50-0.85; $P = 0.002$, *vs* NRCT group, RR 0.52; 95% CI: 0.34-0.08; $P = 0.003$) and mortality (RCT group, RR 1.09; 95% CI: 0.47-2.50; P=0.53, *vs* NRCT group, RR 0.54; 95% CI: 0.2-1.45; $P = 0.22$).

DISCUSSION

Meta-analysis can be used to evaluate the existing literature both qualitatively and quantitatively by comparing and integrating the results of different studies and taking into account the variations in characteristics that could influence the overall estimate of the outcome of interest[23]. Although meta-analysis is traditionally applied and best confined to RCTs, meta-analytical techniques using NRCTs might be a good method in some clinical settings in which either the number or the sample size of RCTs was insufficient[24].

The concept of colonic stenting as a bridge to elective surgery in patients with acute left-sided malignant

colonic obstruction has been established to reduce the morbidity, mortality and number of colostomies. The nonrandomized or retrospective studies showed a significant reduction of morbidity and mortality, and need for stoma placement when SEMS was inserted before surgery with palliative intent. In contrast to these studies, two RCTs failed to confirm the findings.

Our meta-analysis illustrated that SEMS placement significantly decreased the one-stage stoma rates (RR: 0.60; 95% CI: 0.48-0.76; $P < 0.0001$) and increased anastomosis rates (RR: 1.64; 95% CI: 1.39-1.94; $P < 0.00001$), but no difference was found by the end of follow-up. The results of 206 patients in three RCTs which reported follow-up stoma rates demonstrated no difference. The difference of the stoma rate in the follow-up was partly caused by the high leakage rate of primary anastomosis in one stent group[16], probably because bowel decompression and improvement of the patients' clinical condition were insignificant at the time of elective operation. Another reason might be that more patients with complete obstruction had been selected in a Holland study[16]. In a retrospective study from a renowned tertiary referral centre, complete obstruction has been identified as a risk factor for complications[25]. Additionally, the elective nature of the operation and the surgeons' faith in the idea of bridge to surgery might have made the surgeons less conservative than the emergent surgery group.

The perioperative mortality is frequently used to evaluate the outcome of SEMS. Our study failed to reveal the difference between the two groups. Six studies including 324 patients came to a conclusion that there was no difference (RR: 0.91; 95% CI: 0.50-1.66; $P = 0.77$) between SEMS group and emergent surgery group. These outcomes might imply the potential benefits for preoperative SEMS as a bridge to surgery. It is hard to evaluate this outcome as the patients picked up did not match with the clinical stages. Clinical stage is considered as one of independent factors for prognosis. When SEMS is used as a bridge to surgery, there is concern about the oncologic outcome of those patients whose disease is potentially curable, because theoretically SEMS placement could induce tumor dissemination and worsen long-term survival[26]. More subgroup analyses should be performed to obtain a more accurate assessment.

In acute colonic obstruction, doctors and patients both want to remove the tumor with primary anastomosis with a shorter hospital stay. But the major concern is how to avoid complications. In right-sided bowel obstruction, a resection with primary anastomosis has been generally accepted by surgeons, but it is controversial in left-sided bowel obstruction. It is believed that the left colon obstruction has a high risk of radical resection and anastomosis with a high incidence of complications. Even with modern enema techniques and nutritional support, the rates of postoperative complications are still as high as 40%-50% (both significantly higher than in the elective situation with a < 14.0% anastomotic leakage rate and 10.0% operative mortality)[5,6,15,17,21-23,27,28] because of the long procedure time, peritoneal contamination, thin proximal wall of obstruction bowel, inflammatory edema, and poor blood supply. Although preoperative SEMS can potentially ameliorate bowel edema, there was no improvement in the overall situation. There was a significant difference between the two groups in the overall complications in seven studies with 418 patients, (RR: 0.57; 95% CI: 0.44-0.74; $P < 0.0001$). We found that SEMS, as a bridge to elective surgery, could decrease the incidence of anastomotic leakage. Leakage occurred in eight patients in the stenting group as compared with 15 patients in the control group. Anastomotic leakage could increase local recurrence and postoperative mortality. SEMS as a bridge to surgery can provide abundant bowel preparation to decrease tissue edema. But, there was no difference in the operation-related complications as shown in three studies involving 206 patients with abscess (RR: 0.83; 95% CI: 0.36-1.95; $P = 0.68$) and extra abdominal complications (RR: 0.67; 95% CI: 0.4-1.12; $P = 0.13$). Abscess was found as the main complication and pneumonia as the most common adverse event.

The major adverse events occurring in the SEMS group was bowel perforation during the stent placement procedure. Procedure- and stent-related complications were found in 5%-23.1% of patients, with an average rate of stent-related perforations of 5%[29,30]. The oncological consequences of potential tumor dissemination caused by perforations are unclear[15]. The data from NRCTs are inconsistent, ranging from no difference between colonic stenting and emergent surgery to a significantly reduced 5-year survival rate for patients treated with colonic stenting before elective surgery[27]. But the possibility of dissemination should be taken into account and the silent perforations should not be disregarded.

A cost-effectiveness analysis, including cost per quality-adjusted life-year as an outcome measure, was also performed in the meta-analysis. As a result, mortality, morbidity, quality-of-life dimensions, and stoma rates between treatment groups suggest that the probability of colonic stenting which could become more effective than emergent surgery is negligible. As only two authors have evaluated the cost-effectiveness, the results may have limitations, and a large sample would be gathered and assessed.

As this meta-analysis has a few limitations, there might be bias in the results. First, only three studies were RCTs, and confounding factors such as age and gender inevitably existed. Second, there was difference in the selection criteria, such as different protocols, method of procedures and so on. Finally, publication bias might exist when the meta-analysis was based on published studies, because positive results are more likely to be published than negative results.

In summary, the current meta-analysis demonstrated that SEMS as a bridge to surgery for obstructed left-sided colon cancer decreased the incidence of primary stoma rates and anastomotic leakage. But the consequence

failed to show the effect on mortality and complications related to surgery. Therefore, preoperative SEMS can be used as an alternative approach for emergent surgery, but should be used with caution, mainly because of concerns of overt and silent perforations. Future studies are needed to further investigate the oncological outcomes and establish whether specific groups of patients could benefit more from either colonic stenting or emergent surgery.

COMMENTS

Background

Colorectal cancer is one of the most commonly diagnosed malignancies worldwide. And many patients with colorectal cancer present with an acute left-sided colonic obstruction. The benefit of surgical management of malignant large bowel obstruction remains controversial. Stent placement before elective surgery as a bridge to surgery is an alternative for emergent surgery in patients with acute left-sided malignant colonic obstruction. Its benefits are uncertain.

Research frontiers

The authors performed a systematic review of the literature and meta-analysis of the one-stage stoma rates, follow-up stoma rates, anastomotic leakage rates, abscess, extra abdominal complications, morbidity and mortality of SEMS compared with emergent surgery.

Innovations and breakthroughs

The current meta-analysis demonstrated the advantage of SEMS as a bridge to surgery for obstructed left-sided colon cancer in term of decreasing the incidence of primary stoma rates and anastomotic leakage. But the consequence failed to show the effect on mortality and complications related to surgery.

Applications

The analysis has shown that preoperative SEMS can be used as an alternative approach for emergent surgery, but should be used with caution, mainly because of the concerns of overt and silent perforations. Future studies are needed to further investigate oncological outcomes and establish whether specific groups of patients could benefit more from either colonic stenting or emergent surgery.

Terminology

SEMS: SEMS is a metallic tube or stent, used to hold a structure in the gastrointestinal tract in order to allow the passage of food, stool, or other secretions required for digestion; Systematic review: A literature review focused on a research question that tries to identify, appraise, select and synthesize all high quality research evidence relevant to that question; Meta-analysis: A combination of the results of several studies that address a set of related research hypotheses.

Peer review

Overall, this is a nice review with good metrics and appropriate analysis.

Abstract

AIM: To compare postoperative complications and prognosis of esophageal squamous cell carcinoma patients treated with different routes of reconstruction.

METHODS: After obtaining approval from the Medical Ethics Committee of the Sun Yat-Sen University Cancer Center, we retrospectively reviewed data from 306 consecutive patients with histologically diagnosed esophageal squamous cell carcinoma who were treated between 2001 and 2011. All patients underwent radical McKeown-type esophagectomy with at least two-field lymphadenectomy. Regular follow-up was performed in our outpatient department. Postoperative complications and long-term survival were analyzed by treatment modality, baseline patient characteristics, and operative procedure. Data from patients treated *via* the retrosternal and posterior mediastinal routes were compared.

RESULTS: The posterior mediastinal and retrosternal reconstruction routes were employed in 120 and 186 patients, respectively. Pulmonary complications were the most common complications experienced during the postoperative period (46.1% of all patients; 141/306). Compared to the retrosternal route, the posterior mediastinal reconstruction route was associated with a lower incidence of anastomotic stricture (15.8% *vs* 27.4%, $P = 0.018$) and less surgical bleeding (242.8 ± 114.2 mL *vs* 308.2 ± 168.4 mL, $P < 0.001$). The median survival time was 26.8 mo (range: 1.6-116.1 mo). Upon uni/multivariate analysis, a lower preoperative albumin level ($P = 0.009$) and a more advanced pathological stage (pT; $P = 0.006$; pN; $P < 0.001$) were identified as independent factors predicting poor prognosis. The reconstruction route did not influence prognosis ($P = 0.477$).

CONCLUSION: The posterior mediastinal route of reconstruction reduces incidence of postoperative complications but does not affect survival. This route is recommended for resectable esophageal squamous cell carcinoma.

INTRODUCTION

The therapeutic treatment of esophageal cancer has undergone important changes over the past several decades. For patients with localized esophageal cancer, subtotal esophagectomy with a thoracic-abdominal-cervical incision (McKeown-type esophagectomy), combined with extensive lymphadenectomy, is now generally recognized as the optimal treatment in terms of long-term survival[1-5].

After subtotal esophagectomy, a gastric tube formed by resection of the lesser curvature is generally considered to be the most suitable esophageal substitute available[6-10]. Reconstruction under such circumstances commonly uses either the posterior mediastinal (PM) or retrosternal (RS) route[6,10,11]. However, the optimal route remains controversial, principally because most previous studies focused exclusively on postoperative complications and quality of life, rather than prognosis[6-9,12].

Thus, for the first time, we conducted a retrospective study to compare not only the incidence of postoperative complications but also prognosis in patients with esophageal squamous cell carcinoma (ESCC) treated *via* the PM and RS routes.

MATERIALS AND METHODS

Patient selection

After approval was obtained from the Medical Ethics Committee of Sun Yat-Sen University Cancer Center, 306 patients diagnosed with ESCC were consecutively recruited between January 2001 and March 2011. Careful preoperative evaluations were conducted to ensure that there were no contraindications to surgical treatment. All patients included in the present evaluation underwent radical esophagectomy. Exclusion criteria included any history of malignant disease, the presence of a second primary tumor, prior non-curative resection (R1/R2), prior use of an esophageal substitute that was not a gastric tube, and any prior neoadjuvant treatment. Disease was staged based on the recommendations of the American Joint Committee on Cancer (AJCC 2010). The baseline characteristics of the 306 patients enrolled in the present study are shown in Table 1.

Surgery and complications

All patients underwent McKeown-type esophagectomy with at least two-field lymphadenectomy, as described in previous studies[1,4,5]. Three-field lymphadenectomy was performed only if the cervical lymph nodes were thought to be abnormal upon preoperative evaluation. No definitive criteria have been established, therefore, each reconstructive option was determined by the individual surgeon. Pyloroplasty was performed if a patient showed abnormal gastric motility preoperatively. Neither a manubrium nor a partial clavicle was reconstructed.

Complications that occurred during hospital stay and during long-term follow-up were recorded. These included anastomotic leakage, chylothorax, pulmonary complications, cardiac complications, and recurrent laryngeal nerve (RLN) palsy. Drainage, conservative management, symptomatic and function-supportive treatment, and observation, respectively, were used as initial treatments. The treatment of choice for anastomotic stricture (the options included bougienage and stent placement) depended on the extent and history of the stricture. Surgical details, and complications, are summarized in Table 2.

Follow-up

After completion of primary treatment, patients were followed up in our outpatient department every 4-6 mo for the first 3 years and every 12 mo thereafter. Radio-

therapy and/or chemotherapy and/or surgical resection were adopted if and when local recurrence and/or metastasis occurred. The chosen treatment modality was determined by consideration of symptoms, the physical condition of the patient, and the clinical stage of disease. Patient-specific therapeutic schedules used the best available remedies at any time. Survival status was explored *via* direct telecommunication with patients or family members in October 2011.

Statistical analysis

We used SPSS 19.0 (SPSS, Inc., Chicago, IL) for statistical analysis. Overall survival (OS) was defined as the interval from the date of surgery to the date of death or final clinical follow-up. Correlations between the reconstructive route and clinicopathological characteristics and postoperative complications were assessed using the *t* and χ^2 tests. To detect factors associated with an increased risk of chylothorax, crude and adjusted analyses were performed using both univariate and multivariate logistic regression. Survival was analyzed *via* the Kaplan-Meier method and the differences between curves were assessed with the aid of the log-rank test. Multivariate Cox's regression analysis was performed with inclusion of parameters that prior univariate analysis had identified as significant. $P < 0.05$ was considered to be significant.

RESULTS

Of the 306 patients, 120 and 186 were treated *via* PM and RS reconstruction, respectively. Baseline patient characteristics are summarized in Table 1.

Table 3 Association between recurrent laryngeal nerve palsy, lymphadenectomy, and development of an anastomotic fistula

Variable	Recurrent laryngeal nerve palsy (%)	*P* value
Lymphadenectomy		
Three-field	15 (24.6)	
Two-field	38 (12.4)	0.094
Anastomotic fistula		
No	42 (15.6)	
Yes	11 (28.9)	0.043

Pulmonary complications were the most common during the perioperative period (46.1% of all patients; 141/306). Patients in the RS group were more likely to preserve the thoracic duct ($P < 0.001$). The mean blood loss was 282.6 mL for the entire cohort and was 65.4 mL greater in the RS group than in the PM group ($P < 0.001$). A positive association between development of chylothorax and use of the RS route was observed ($P = 0.008$). Anastomotic stricture, the combined incidence of which was 12.4% (38/306), was more common in the RS than in the PM group ($P = 0.018$). Details of the operations and complications are listed in Table 2. Upon subgroup analysis, RLN palsy was found to be highly associated with three-field lymphadenectomy ($P = 0.094$) and anastomotic fistula ($P = 0.043$) (Table 3).

The median follow-up interval was 32.1 mo for surviving patients. A total of 201 patients were alive at last follow-up. The predicted 1-, 3- and 5-year overall survival rates after primary surgery were 75%, 60% and 50% respectively. The median survival time was 26.8 mo (range: 1.6-116.1 mo).

Preoperative albumin level ($P = 0.009$), pT status ($P = 0.006$), and pN status ($P < 0.001$) were independent factors prognostic for survival upon uni/multivariate analysis (Table 4). However, reconstruction route was not a significant prognostic factor ($P = 0.477$; Figure 1).

DISCUSSION

In the present study of patients with histologically diagnosed esophageal squamous cell carcinoma who underwent radical McKeown-type esophagectomy with at least two-field lymphadenectomy, we compared survival and complications in patients according to whether the RS or PM route was used. Our work had the advantages that it was performed in patients with the same disease etiology treated with a uniform therapeutic modality, and who underwent long-term follow-up focusing not only on postoperative complications but also on prognosis.

We confirmed that the reconstruction route was not associated with any significant variance in the extent of cardiac ($P = 0.494$) or pulmonary ($P = 0.214$) complications, as has been shown in previous studies[6,7,10].

The incidence of RLN palsy was 17.3% in our entire cohort, and did not differ between the PM and RS groups ($P = 0.707$). In esophagectomy patients, the

prime etiology of RLN palsy is direct mechanical injury inflicted on the RLN during dissection[5,13]. Fang *et al*[14] reported that development of RLN palsy was closely linked to cervical dissection (22.9% *vs* 9.6%, $P = 0.089$) and anastomotic leakage (53.8% *vs* 13.5%, $P = 0.001$). These data lend support to our conclusion that surgical trauma and fistula-induced secondary corrosion play important roles in the development of RLN palsy (Table 3). Thus, RLN injury would be reduced if trauma during cervical lymphadenectomy were minimized and new anastomotic fistulae were managed in a timely manner.

The conduit is longer when the posterior route of reconstruction is used, therefore, a higher frequency of anastomotic leakage would be expected because a segment of stomach that is more remote from the blood supply is used (compared to the RS route)[8,9]. However, a recent meta-analysis by Urschel *et al*[10] showed that the reconstruction route chosen did not affect the frequency of anastomotic fistula (95% CI: 0.35-2.94; $P = 0.98$), in agreement with our data. Additionally, we found a significant association between anastomotic stricture and use of the RS route ($P = 0.018$). After review of the literature, we suggest that patients undergoing RS reconstruction are more at risk of anatomic stricture because of the narrow entrance to the thoracic inlet and the severe foregut angulation that are created when the RS route is used[7,11,15]. In this context, some authors recommend removal of the manubrium and the sternoclavicular joints[16,17]. We did not take these options; rather we prioritized thoracic stability and better patient appearance. Also, application of cervical anastomosis, which permits better intraoperative exposure at the cost of more severe postoperative pressure, has been reported to decrease fistula but increases stricture development[18]. This was not observed in our present work (anastomotic fistula, $P = 0.182$; anastomotic stricture, $P = 0.110$) (data not shown).

Chylothorax, the overall incidence of which was 6.2%, was significantly associated with use of the RS route ($P = 0.008$). However, prophylactic thoracic duct ligation or resection, which is known to mitigate against chylothorax[19,20], was more likely to be performed in patients of the PM group ($P < 0.001$). Additionally, each reconstructive option was determined by the preference of the individual surgeon. Therefore, surgeon characteristics and decisions regarding whether to perform thoracic duct ligation or resection seemed to be the major factors contributing to the higher incidence of chylothorax observed in the RS group. The route of reconstruction may not be important, in agreement with the data of previous studies[11,12].

Turning to surgical bleeding, Turnbull *et al*[21] considered that such bleeding was reduced when the PM technique was used because the extent of tunneling associated with this approach is less than that required when RS reconstruction is used. This is in line with the findings of the present study ($P < 0.001$). Although bleeding

often requires blood transfusion, the clinical significance of a 64.5-mL loss of blood is marginal.

In the present study, the 5-year OS rate was 50% (median: 26.8 mo), which was better than in previous studies[1,3]. This can be attributed to the strict enrolment criteria. Specifically, to facilitate objective comparisons, we excluded patients with pT4-stage disease, those with preoperative metastasis, and those who underwent non-radical (R1/R2) resections.

To date, the most commonly cited argument as to why the RS route of reconstruction should be favored is that it affords a radiotherapeutic advantage if local recurrence occurs[6,7], thus contributing to a favorable prognosis. However, to the best of our knowledge, no prior study has evaluated long-term survival in patients treated *via* the RS and PM reconstructive routes. Only the biological behavior of a tumor and the chosen treatment modality could influence survival. Thus, the objective of the present study was not to verify the independently prognostic significance of a given reconstructive route but to ascertain whether the route of reconstruction influenced the efficacy of a uniform treatment modality, thereby inducing a difference in survival. To explore this question, we performed prognostic analysis but failed to demonstrate any significant survival difference according to whether the RS or PM route was used (median OS, 25.4 mo *vs* 27.4 mo; $P = 0.477$) (Figure 1). Several possible explanations may be advanced. First, improvements in patient selection and surgical techniques, especially in the context of McKeown-type esophagectomy combined with extended lymphadenectomy, have decreased the rates of local recurrence[4,7,22]. Second, various treatment modalities (chemotherapy and/or radiotherapy and/or surgical resection) have been shown to be satisfactory in terms of efficacy and to allow acceptable levels of post-recurrence survival[23-26]. Thus, recurrence is no longer an intractable problem for which no effective treatment is available.

Several prognostic factors were identified upon uni/multivariate survival analysis; these included preoperative albumin level and pathological stage (pT and pN status). Lower preoperative albumin levels have long been regarded as indicative of poor nutritional status, abnormal liver function, and a metabolic response to acute phase disease[27,28]. A lower albumin level was significantly associated with a shorter survival time ($P = 0.009$). A similar result was reported by Lien *et al*[29] in patients with adenocarcinoma of the gastric cardia. The importance of pathological stage, the best-established prognostic factor for malignant disease, was emphasized once again in our present work.

The present study has both strengths and weaknesses. The work was retrospective in nature. All work was performed in a single institution, with patients who had disease of uniform etiology and who were identically treated. However, the data may be biased to some extent, because we could not control for surgical experience or guarantee that all documentation was completely accurate. However, we attempted to minimize the latter possible source of error by using consistent definitions when performing our review of records, and all data were independently checked.

In conclusion, this is believed to be the first retrospective study to investigate systematically the influence of reconstructive route on both clinical complications and prognosis. Use of the PM route of reconstruction reduces the incidence of postoperative complications, without compromising survival, and must be recommended for use in patients with resectable ESCC.

COMMENTS

Background

For patients with localized esophageal cancer, subtotal esophagectomy with a thoracic-abdominal-cervical incision (McKeown-type esophagectomy), combined with extensive lymphadenectomy, is now generally recognized as the optimal treatment in terms of long-term survival. Reconstruction under such circumstances commonly uses either the posterior mediastinal (PM) or retrosternal (RS) route. Despite studied and debated for decades, there remains no consensus as to the optimal route of reconstruction after subtotal esophagectomy.

Research frontiers

Postoperative complications and quality of life are hot topics and have been analyzed in previous studies. A recent meta-analysis showed that PM and anterior mediastinal routes of reconstruction are associated with similar outcomes.

Innovations and breakthroughs

To date, the most commonly cited argument as to why the RS route of reconstruction should be favored is that it affords a radiotherapeutic advantage if local recurrence occurs, thus contributing to a favorable prognosis. However, no prior study has evaluated long-term survival and, their results may be biased based on their small sample size. The authors' work had the advantages that it was performed in a large cohort with the same disease etiology treated with a uniform therapeutic modality, and who underwent long-term follow-up focusing not only on postoperative complications but also on prognosis.

Applications

Use of the PM route of reconstruction reduces the incidence of postoperative complications but does not affect survival. This route is recommended for treatment of patients with resectable esophageal squamous cell carcinoma.

Peer review

This paper is well written. The authors retrospectively reviewed 306 consecutive patients. They described that choice of reconstruction method was determined by surgeon preference, because there are still no criteria. Therefore, the surgeon factor should be included in all analyses. Especially in the analysis of risk for postesophagectomy chylothorax, the major factor seemed to be the surgeon and not route of reconstruction.

Abstract

AIM: To assess the safety and efficacy of carbon dioxide (CO_2) insufflation during endoscopic retrograde cholangiopancreatography (ERCP).

METHODS: The Cochrane Library, Medical Literature Analysis and Retrieval System Online, Excerpta Medica Database, Science Citation Index Expanded, Chinese Biomedical Literature Database, and references in relevant publications were searched up to December 2011 to identify randomized controlled trials (RCTs) comparing CO_2 insufflation with air insufflation during ERCP. The trials were included in the review irrespective of sample size, publication status, or language. Study selection and data extraction were performed by two independent authors. The meta-analysis was performed using Review Manager 5.1.6. A random-effects model was used to analyze various outcomes. Sensitivity and subgroup analyses were performed if necessary.

RESULTS: Seven double-blind RCTs involving a total of 818 patients were identified that compared CO_2 insufflation (n = 404) with air insufflation (n = 401) during ERCP. There were a total of 13 post-randomization dropouts in four RCTs. Six RCTs had a high risk of bias and one had a low risk of bias. None of the RCTs reported any severe gas-related adverse events in either group. A meta-analysis of 5 RCTs (n = 459) indicated that patients in the CO_2 insufflation group had less post-ERCP abdominal pain and distension for at least 1 h compared with patients in the air insufflation group. There were no significant differences in mild cardiopulmonary complications [risk ratio (RR) = 0.43, 95% CI: 0.07-2.66, P = 0.36], cardiopulmonary (e.g., blood CO_2 level) changes [standardized mean difference (SMD) = -0.97, 95% CI: -2.58-0.63, P = 0.23], cost analysis (mean difference = 3.14, 95% CI: -14.57-20.85, P = 0.73), and total procedure time (SMD = -0.05, 95% CI: -0.26-0.17, P = 0.67) between the two groups.

CONCLUSION: CO_2 insufflation during ERCP appears to be safe and reduces post-ERCP abdominal pain and discomfort.

Carbon dioxide insufflation for endoscopic retrograde cholangiopancreatography: A meta-analysis and systematic review. *World J Gastroenterol* 2012; 18(39): 5622-5631 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i39/5622.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i39.5622

INTRODUCTION

Endoscopic retrograde cholangiopancreatography (ERCP) refers to radiographic visualization of the pancreatobiliary system by retrograde injection of contrast media through the ampulla of Vater[1]. ERCP, which was first introduced in the late 1960s[2], is now widely performed by endoscopists to diagnose various pancreatic and biliary diseases[1,3]. Although the exact number of patients undergoing ERCP worldwide each year is unknown, it has been reported that approximately 54 000 and 500 000 patients undergo ERCP annually in the United Kingdom and United States, respectively[4-6]. ERCP has become an invaluable tool in the diagnosis of numerous pancreatic and biliary diseases and is considered to be the gold standard study for the pancreatobiliary system[1,3-5].

Gas is deliberately insufflated into the bowel lumen during ERCP to provide operating space to ensure adequate visualization by the camera and manipulation of instruments in the duodenum[1-4]. Currently, air is the most commonly used gas for insufflation during ERCP worldwide[6]. However, air has some potential disadvantages. Air is not absorbed by the bowel and must be passed from the gastrointestinal tract in the form of flatus, which may lead to post-ERCP abdominal pain and discomfort (e.g., abdominal distension) because of gas retention in the gastrointestinal tract[7]. Recently, carbon dioxide (CO_2) has been introduced as an alternative to air for insufflation during ERCP[8-14].

CO_2 is rapidly absorbed from the bowel and is delivered directly to the lungs by the circulation[15,16]. Ultimately, it is excreted by the lungs during respiratory exchange[15,16]. Theoretically, CO_2 has the potential to reduce post-ERCP abdominal pain and discomfort due to lower gas retention[15,16]. However, the absorption of CO_2 may cause hypercapnia and acidosis, which must be prevented through hyperventilation[17]. The absorption of CO_2 may be associated with various cardiopulmonary side effects such as tachycardia, cardiac arrhythmias, hypoxemia, and pulmonary edema[17]. Elderly patients with cardiopulmonary diseases are more likely to suffer from these adverse events[9,17].

The use of CO_2 insufflation during ERCP is controversial. Some authors suggest that the application of CO_2 insufflation reduces post-ERCP abdominal pain and discomfort[8,11,12,14], thus they recommend the use of CO_2 in ERCP, whereas others do not think so[9,10,13]. To date, we have been unable to identify any meta-analysis that assesses the role of carbon dioxide insufflation during ERCP. We conducted a meta-analysis and systematic review to assess the safety and efficacy of CO_2 insufflation during ERCP for reduction of post-ERCP abdominal pain and discomfort.

MATERIALS AND METHODS

Identification of trials and data extraction

We searched the following databases up to December 2011 to identify randomized controlled trials (RCTs): The Cochrane Library, Medical Literature Analysis and Retrieval System Online (MEDLINE), Excerpta Medica Database (EMBASE), Science Citation Index Expanded, and Chinese Biomedical Literature Database (CBM). Search strategies for these databases are shown in Table 1. We also hand searched the references in relevant publications to explore additional relevant clinical trials. After completing all searches, we merged the search results using the software package Endnote X4 (reference management software) and removed duplicated records. Two independent authors (Lin YX and Xiong XZ) scanned the title and abstract of every record identified by the searches for inclusion. If compliance with inclusion criteria was not clear from the abstract, we retrieved full texts for further assessment. Only RCTs comparing CO_2 insufflation with air insufflation during ERCP were considered for the review, irrespective of sample size, publication status, or language. Two independent authors (Wu SJ and Lu J) independently extracted and confirmed the data and entered them into an electronic data collection form. We resolved all differences between authors by discussion.

Outcomes

Data for the following outcomes were extracted: abdominal pain (pain scores *via* visual analogue scale and number of pain-free patients at various time points after ERCP), abdominal distention, gas-related complications (severe gas-related adverse events and mild cardiopulmonary complications), cardiopulmonary changes (heart rate, blood pressure, blood pH, *etc.*), cost analysis, and total procedure time.

Assessment of methodological quality

Two authors (Cheng Y and Cheng NS) independently assessed the methodological quality of the included trials using the quality checklist recommended by the Cochrane Handbook[18]. We assessed the risk of bias of the trials based on the following domains: random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data, selective reporting and other sources of bias[18]. Following the evaluation of the above domains, an included trial was judged as a trial with a low risk of bias if it was evaluated as "low" in all of the above domains. If the risk of bias was judged as "unclear" or "high", then the trial was listed under the group of trials with "high risk of bias". We resolved all disagreements by discussion and referral to a third author (Wu TX) for adjudication.

Statistical analysis

We performed the meta-analysis using the software pack-

age Review Manager 5.1.6. Two authors (Wu SJ, Lu J) confirmed and entered all data into Review Manager independently. For dichotomous outcomes, we calculated the risk ratio (RR) with 95% CI[19]. For continuous outcomes, we calculated the mean difference (MD) with 95% CI[19]. For continuous outcomes with different measurement scales in different RCTs, we calculated the standardized mean difference (SMD) with 95% CI[19]. We described the heterogeneity with the Chi-squared test[19]. A *P* value less than 0.10 was considered to be significant heterogeneity[19]. We also used the I^2 statistic to measure the quantity of heterogeneity[19]. For all analysis, we employed the random-effects model. We intended to perform funnel plots and assessed their visual asymmetry to determine reporting biases[20]. In case of missing data, we contacted the original investigators to request further information. If there was no reply, we performed the analysis on an "intention-to-treat" (ITT) principle, if applicable[21]. Otherwise, we adopted the available-case analysis (also known as per-protocol analysis and PP analysis). We conducted the meta-analysis and systematic review according to the Cochrane Handbook for Systematic Reviews of Interventions[22] and Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA)[23].

RESULTS

Search results

We identified a total of 88 records through electronic searches of The Cochrane Library (n = 4), MEDLINE (n = 16), EMBASE (n = 47), Science Citation Index Expanded (n = 20), Chinese Biomedical Literature Database (n = 1), and hand search of the references of the included RCTs (n = 3). We excluded 15 duplicates and 64 clearly irrelevant records by reading titles and abstracts. Twelve full-text articles were retrieved for further assessment. We excluded five articles for the reasons listed in Figure 1.

Description of included trials

Seven RCTs (5 articles[8-12] and 2 conference abstracts[13,14]), which were published between 2007 and 2011, were identified that fulfilled the inclusion criteria. A total of

Table 2 Study characteristics

Author	Year	Country	Study design	Participants	Participants (CO_2/Air)	Mean age (CO_2/Air)
Bretthauer *et al*[8]	2007	Norway	Multi-centers	Low risk	118 (58/58)	57/54
Maple *et al*[12]	2009	United States	Single-center	Low risk	105 (50/50)	57/51.7
Dellon *et al*[9]	2010	United States	Single-center	High risk and low risk	78 (36/38)	60.1/59.7
Kuwatani *et al*[10]	2011	Japan	Multi-centers	Low risk	80 (40/40)	66.1/68.7
Luigiano *et al*[11]	2011	Italy	Single-center	Low risk	78 (39/37)	66.1/67.1
Mei *et al*[13]	2011	Australia	Single-center	Not mentioned	61 (34/27)	Not mentioned
Arjunan *et al*[14]	2011	India	Single-center	Low risk	298 (147/151)	Not mentioned

Low risk refers to patients without chronic obstructive pulmonary diseases; high risk refers to patients with chronic obstructive pulmonary diseases.

Table 3 Risk of bias in included trials

Arjunan *et al*[14]	Unclear risk	Unclear risk	Low risk	Low risk	Unclear risk	Unclear risk

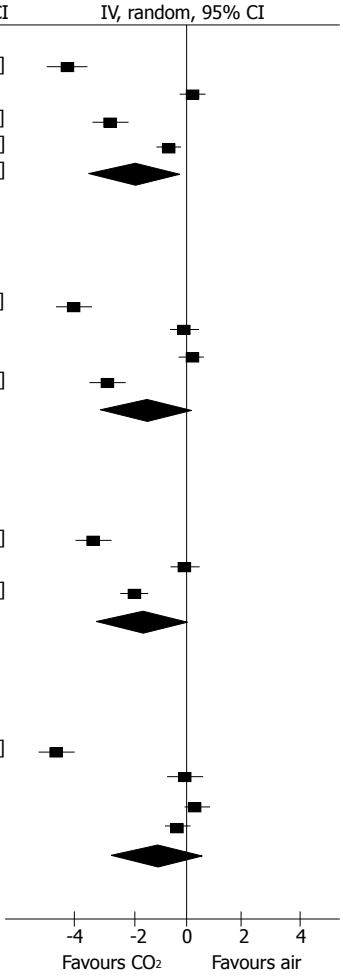
818 patients were included: 404 were assigned to the CO_2 group and 401 were allocated to the air group (13 post-randomization dropouts). Details on the included studies are shown in Table 2.

Risk of bias of included studies

The risk of bias is summarized in Table 3. Six RCTs[8,10-14] had a high risk of bias and one RCT[9] had a low risk of bias. All trials were double-blind RCTs with a parallel group study design. There were a total of 13 post-randomization dropouts in four RCTs[8,9,11,12] which were not included in the analysis. Only one RCT[9] reported costs.

Effects of interventions

Abdominal pain scores (intensity of pain): Seven RCTs reported the abdominal pain scores. Pain was measured with a 10-point visual analogue scale (VAS)[10,12-14] or a 100-mm VAS[8-9,11] at various time points, including before the procedure, during the procedure, 30 min, 1 h, 90 min, 3 h, 6 h and 24 h after ERCP. Four RCTs[8,11,12,14] showed decreased post-ERCP abdominal pain scores in the CO_2 group compared with the air group, while the other three RCTs[9-10,13] did not. The meta-analysis of 5 RCTs[8-12] showed that the abdominal pain scores 1 h after ERCP was significantly lower in the CO_2 group than the air group (I^2 = 98%; SMD = -1.81, 95% CI: -3.58--0.04, P = 0.04). The pain scores 3 h, 6 h and 24 h after ERCP were also lower in the CO_2 group than in the air group, but the differences were not significant (Figure 2A).



Pain-free patients (incidence of pain): Only two RCTs[8,12] reported the number of pain-free patients at various time points, including 1, 3, 6 and 24 h after ERCP. The meta-analysis showed that the rate of pain-free patients 1 h and 6 h after ERCP was significantly higher in the CO_2 group than in the air group: (I^2 = 74%; RR = 1.79, 95% CI: 1.01-3.20, P = 0.05) and (RR = 2.22, 95% CI: 1.37-3.62, P = 0.001), respectively. The rate of pain-free patients 3 h and 24 h after ERCP were also higher in the CO_2 group than in the air group, but the differences were not significant (Figure 2B).

Abdominal distention: Abdominal distension was measured with a 100-mm VAS in two RCTs[10,11]. The meta-analysis showed that abdominal distension 1 h after ERCP was significantly lower in the CO_2 group than in the air group (SMD = -1.43, 95% CI: -1.93--0.92, P < 0.00001). There was no significant difference in abdominal distension between the two groups at 3 h, 6 h and 24 h after ERCP (Figure 2C). Three RCTs[9,12,14] reported the increase in abdominal girth. Maple *et al*[12] and Arjunan *et al*[14] stated that CO_2 insufflation was associated with less increase in abdominal girth than air insufflation. However, Dellon *et al*[9] indicated that there was no significant difference between groups with regard to increase in abdominal girth. One RCT[8] reported the number of patients with bowel distention as assessed by X-ray photographs. There were fewer patients with bowel distention in the CO_2 group than in the air group (RR = 0.76, 95% CI: 0.60-0.98, P = 0.03).

Complications: None of the RCTs reported any severe gas-related adverse events in either group (e.g., death, embolism, cardiac arrhythmias, and significant respiratory events). Mild cardiopulmonary complications (e.g., respiratory depression, hypotension, and bradycardia) were reported in five RCTs[8-12]. There was no significant difference in the number of patients with any mild car-

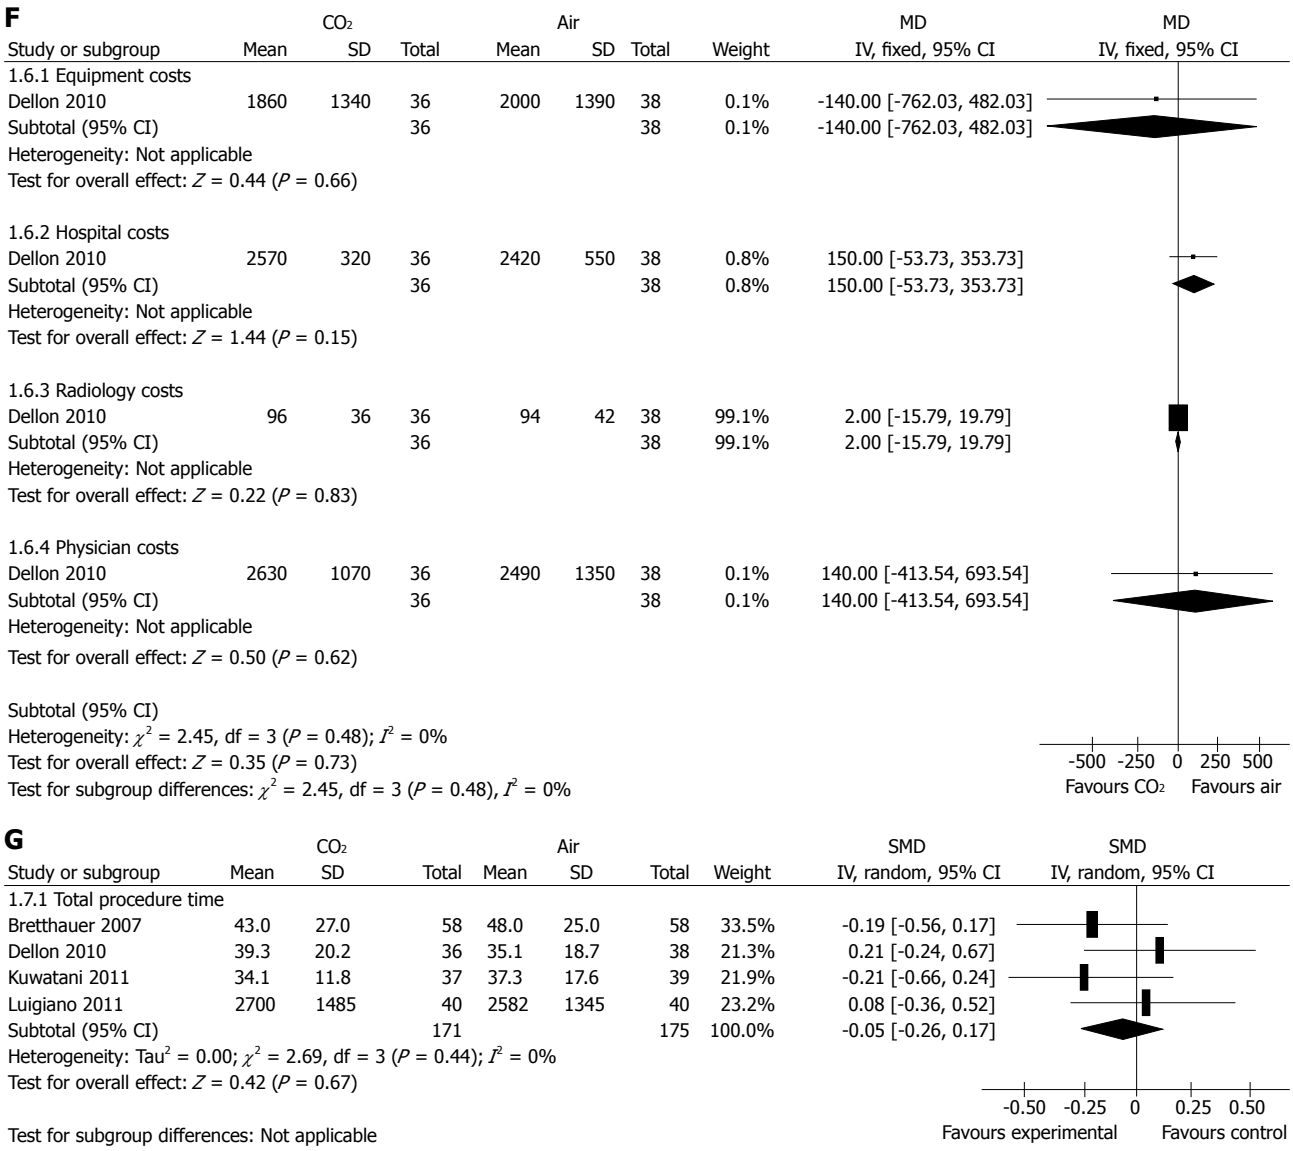

Figure 2 Forest plots of meta-analysis. A: Carbon dioxide *vs* air in abdominal pain scores; B: Carbon dioxide *vs* air in pain-free patients; C: Carbon dioxide *vs* air in abdominal distension; D: Carbon dioxide *vs* air in mild cardiopulmonary complications; E: Carbon dioxide *vs* air in change in blood carbon dioxide level; F: Carbon dioxide *vs* air in total costs; G: Carbon dioxide *vs* air in total procedure time. IV: Inverse-variance; M-H: Mantel Haenszel; ERCP: Endoscopic retrograde cholangiopancreatography; VAS: Visual analogue scale; MD: Mean difference; SMD: Standardized mean difference.

diopulmonary complications between groups (I^2 = 39%; RR = 0.43, 95% CI: 0.07-2.66, P = 0.36) (Figure 2D).

Cardiopulmonary changes: Changes in blood CO_2 levels were reported in three RCTs[8,9,11]. There was no significant difference in the change in blood CO_2 level between the two groups (I^2 = 96%; SMD = -0.97, 95% CI: -2.58-0.63, P = 0.23). Only one RCT[10] reported blood oxygen saturation (SpO_2); Kuwatani *et al*[10] stated that there was no significant difference between the two groups at any time point (Figure 2E).

Cost analysis: Only one RCT[9] reported the cost analysis. There were no significant differences in the total costs for ERCP (I^2 = 0%; MD = 3.14, 95% CI: -14.57-20.85, P = 0.73), including equipment costs, hospital costs, radiology costs, and physician costs (Figure 2F).

Total procedure time: Four RCTs were included in the meta-analysis[8-11]. There was no significant difference in the total procedure time between the two groups (I^2 = 0%; SMD = -0.05, 95% CI: -0.26-0.17, P = 0.67). Maple *et al*[12] stated that there was no difference in total procedure time between the two groups (Figure 2G).

DISCUSSION

This systematic review with meta-analysis of RCTs assessed the safety and efficacy of CO_2 insufflation *vs* air insufflation during ERCP for reduction of abdominal pain and discomfort. The meta-analysis of 5 RCTs indicated that CO_2 insufflation during ERCP was associated with less post-ERCP abdominal pain and distension for at least 1 h. There were no significant differences in mild cardiopulmonary complications, cardiopulmonary

changes, cost analysis, and total procedure time between the two groups.

Post-ERCP abdominal pain and discomfort are common in clinical practice[24]. Abdominal pain related to insufflation is nonspecific and may mimic the symptoms of severe post-ERCP complications, including pancreatitis and perforation, which can be a source of stress to both patients and endoscopists[9]. Some patients need hospitalization for further evaluation and observation of post-ERCP abdominal pain and discomfort[7,15]. Post-ERCP abdominal pain and discomfort may result from air insufflation, as air is difficult to dissolve in blood and stays in the bowel for several hours after ERCP[7,16]. CO_2 has unique characteristics in that it is cheap, colorless, nonflammable, non-explosive, easily excreted, and nontoxic to patients[16]. CO_2 insufflation during ERCP was first introduced by Bretthauer *et al*[8] in 2007. Bretthauer *et al*[8] found that CO_2 insufflation effectively reduced post-ERCP abdominal pain and discomfort and recommended its routine use in ERCP. Then the benefits of CO_2 insufflation were further demonstrated by three later RCTs[11,12,14]. On the contrary, three additional RCTs[9,10,13] showed no differences in post-ERCP abdominal pain or discomfort between CO_2 insufflation and air insufflation. Although this meta-analysis suggested that CO_2 insufflation was associated with less abdominal pain and discomfort for at least 1 h, it included only 5 RCTs and all had small sample sizes. Consequently, the data from three ongoing RCTs performed by Mei *et al*[13], Arjunan *et al*[14] and Janssens *et al*[15] (Trial number: UMIN000005755) are anticipated to resolve the controversy.

The safety of CO_2 insufflation during ERCP is another major concern for patients and endoscopists. Air insufflation is associated with rare but severe adverse events such as combustion when using electrocautery and gas embolisms[16,25]. CO_2 is non-flammable and more soluble than air. In theory, CO_2 insufflation is safer than air insufflation with regard to combustion and embolisms. CO_2 is the most commonly used gas for insufflation in laparoscopy. The safety of CO_2 insufflation for endoscopy has been well established in colonoscopy[16]. None of the included RCTs reported any severe CO_2-related adverse events (e.g., death, embolism, cardiac arrhythmias, or significant respiratory events). With regard to other adverse effects from CO_2 insufflation, the meta-analysis showed there were no differences in mild cardiopulmonary complications and cardiopulmonary changes between the two groups. However, all RCTs except one[9] excluded patients with chronic obstructive pulmonary diseases (COPD). The safety of CO_2 insufflation during ERCP for high-risk patients (e.g., patients with cardiopulmonary diseases or American Society of Anesthesiologists (ASA) Physical Status classification Ⅲ or Ⅳ) needs further evaluation.

There are other potential benefits of CO_2 insufflation for ERCP, such as the possibility of immediate computed tomography cholangiopancreatography after ERCP, which has recently been introduced to obtain clear images, and the possibility of intraoperative ERCP during laparoscopy[16,26].

The feasibility of CO_2 insufflation during ERCP is as follows. First, to date there have been three types of commercial CO_2 insufflators available: Olympus KeyMed ECR, Olympus UCR, and CO_2-EFFICIENT[15]. In addition, the cost of a CO_2 insufflator is not very high, at approximately 7000 euros[15]. CO_2 gas is inexpensive and convenient to obtain[15]. Dellon *et al*[9] found that the total costs for ERCP (including equipment costs, hospital costs, radiology costs, and physician costs), is similar between groups ($7170 in the CO_2 group *vs* $7000 in the air group). Moreover, the safety of CO_2 insufflation during ERCP has been well documented in the RCTs (see above). Thus, it appears that widespread implementation of CO_2 insufflation during ERCP is anticipated.

This review included a total of seven RCTs. Most excluded patients with COPD, whereas only one study[9] included patients with COPD. Thus, the results of this review may only be relevant to low-risk patients without cardiopulmonary diseases.

The overall quality of the current best evidence was low. Only one RCT had a low risk of bias. There were a total of 13 post-randomization dropouts in four RCTs. All four RCTs adopted the available-case analysis (also known as per-protocol analysis and PP analysis) without performing an intension-to-treat (ITT) analysis. Only one RCT reported the cost analysis. Further RCTs are anticipated to perform both PP analysis and ITT analysis in case of post-randomization dropouts (missing data) and report the costs of ERCP.

Dellon *et al*[7] conducted a systematic review published in 2009 which assessed the role of CO_2 insufflation for flexible sigmoidoscopy, colonoscopy, ERCP, and double-balloon enteroscopy. This review included nine RCTs, but only one used CO_2 insufflation for ERCP. In addition, the authors did not perform a meta-analysis because of obvious heterogeneity. Our findings are similar to the previous systematic review in terms of the safety of CO_2 insufflation. In contrast to our study, the previous systematic review showed a reduction in abdominal pain for at least 6 h in the CO_2 insufflation group when compared with the air group.

The limitations of our review are as follows. The first concerns the small number of included RCTs and the small sample size of each RCT. We included only seven RCTs with 404 patients undergoing ERCP with CO_2 insufflation; thus, there is a lack of available data on this issue to date. In addition, we did not perform funnel plots to assess the publication bias due to the small number of included RCTs.

This review currently provides the best available evidence for comparison of CO_2 insufflation versus air insufflation during ERCP. On the basis of this evidence, CO_2 insufflation during ERCP appears to be safe for the majority of patients and results in less post-ERCP abdominal pain and discomfort than air insufflation. Further RCTs with a low risk of bias and a greater number of patients are necessary to assess the role of CO_2

insufflation in high-risk patients. Future RCTs need to be conducted and reported according to the Consolidated Standards of Reporting Trials (CONSORT) statement[27].

COMMENTS

Background

Endoscopic retrograde cholangiopancreatography (ERCP) is now widely performed by endoscopists to diagnose various pancreatic and biliary diseases. Currently, air is the most commonly used gas for insufflation during ERCP worldwide. However, air has some potential disadvantages.

Research frontiers

Recently, carbon dioxide (CO_2) has been introduced as an alternative to air for insufflation during ERCP. Many studies, including randomized controlled trials (RCTs), have been conducted to assess the safety and efficacy of CO_2 insufflation during ERCP for reduction of post-ERCP abdominal pain and discomfort. However, the use of CO_2 insufflation during ERCP is controversial.

Innovations and breakthroughs

The authors identified all RCTs comparing CO_2 insufflation with air insufflation during ERCP. They conducted a meta-analysis and systematic review according to the Cochrane Handbook for Systematic Reviews of Interventions and Preferred Reporting Items for Systematic reviews and Meta-Analysis. They found that CO_2 insufflation during ERCP appears to be safe and reduces post-ERCP abdominal pain and discomfort.

Applications

Due to reduced post-procedure abdominal pain and discomfort, CO_2 insufflation may be preferable to air insufflation during ERCP and should be recommended in clinical practice.

Terminology

ERCP refers to radiographic visualization of the bile duct and pancreatic duct by retrograde injection of contrast media into the pancreatobiliary system; RCTs refer to trials in which people are allocated at random to receive one of several clinical interventions.

Peer review

This is the first well-designed meta-analysis on the role of CO_2 insufflation in ERCP. The results are interesting and suggest that CO2 insufflation may be preferable to air insufflation during ERCP. However, this article has several limitations, such as a small number of RCTs.

Abstract

A 67-years-old male presented with periumbilical abdominal pain, fever and jaundice. His anaerobic blood culture was positive for *clostridium perfringens*. Computed tomogram scan of the abdomen and abdominal ultrasound showed normal gallbladder and common bile duct (CBD). Subsequently magnetic resonance cholangiopancreaticogram showed choledocholithiasis. Endoscopic retrograde cholangiopancreaticogram-with sphincterotomy and CBD stone extraction was performed. The patient progressively improved with antibiotic therapy Choledocholithiasis should be considered as a source of *clostridium perfringens* bacteremia especially in the setting of elevated liver enzymes with cholestatic pattern.

INTRODUCTION

Clostridium species are the second most common causes of anaerobic bacteremia, with *Clostridium perfringens* the most frequently isolated. Malignancies, gastrointestinal disorders and other chronic illnesses have been associated with *clostridium perfringens* bacteremia. *Clostridium perfringens* can cause food poisoning, gas gangrene, necrotizing enterocolitis, tuboovarian abscess, emphysematous cholecystitis, discitis, and liver abscess. Choledocholithiasis has rarely been reported as a source of *Clostridium perfringens* bacteremia. We describe a case of *clostridium perfringens* bacteremia caused by choledocholithiasis in the absence of gallbladder stones and with normal common bile duct (CBD) diameter and discuss management and review of the literature of this interesting but rare entity.

CASE REPORT

A 67-year-old male with medical history of coronary artery disease, diabetes mellitus, hypertension, hypothyroidism, chronic obstructive pulmonary disease (COPD) and diverticulosis presented with abdominal pain and fever. Fever with chills started four days prior to admission. Abdominal pain was sharp, periumbilical, non-radiating, lasted for 4 h, unrelated to food and resolved on its own. He denied nausea, vomiting, blood in stools but had chronic constipation. His last colonoscopy was

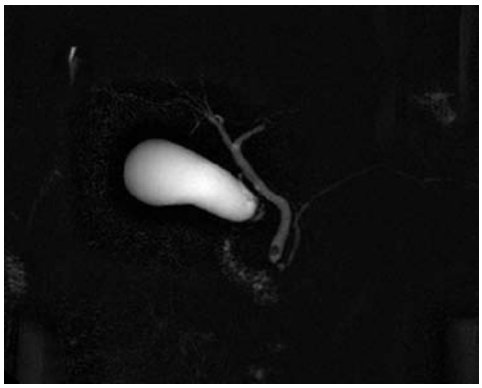

Figure 1 Magnetic resonance cholangiopancreatography shows filling defects within the distal common bile duct.

two years prior and showed sigmoid diverticulosis and colon polyps. On physical examination his heart rate was 103 and he had scleral icterus. The remainder of physical examination including abdominal examination was normal. Initial laboratory data showed white cell count of 8.2 (4.8-10.5), total bilirubin: 3 (0.2-1.0 mg/dL), direct bilirubin: 0.4 (0.0-0.2 mg/dL), aspartate transaminase: 131 (15-46 U/L), alanine transaminase: 86 (7-56 U/L) and alkaline phosphatase: 254 (38-126 U/L). His liver enzymes were normal one year earlier. Computed tomography (CT) scan of the abdomen and pelvis showed normal gallbladder, normal CBD diameter and colonic diverticulosis without diverticulitis. Ultrasound (US) of the abdomen revealed no stone in the gallbladder and the CBD diameter was 4.5 mm. Anaerobic blood culture was positive for clostridium perfringens. Patient was treated with vancomycin, aztreonam and metronidazole. He was allergic to penicillin. Urine culture was negative. Magnetic resonance cholangiopancreatography (MRCP) showed revealed a 6 mm ovoid filling defect and additional smaller filling defects within the distal common bile duct (Figure 1). Subsequently, endoscopic retrograde cholangiopancreatography confirmed the diagnosis of choledocholithiasis for which sphincterotomy and stone extraction was performed (Figure 2). Following the procedure, liver enzymes improved. He was discharged home on ertapenem and he had colonoscopy on outpatient basis that showed sigmoid diverticulosis.

DISCUSSION

Clostridium bacteremia is a rare occurrence that can lead to a devastating outcome. Early recognition and treatment of *clostridium* bacteremia can be life saving. The aim of this report is to present a rare case of *Clostridium perfringens* bacteremia caused by choledocholithiasis. There are few epidemiological studies documenting the incidence of *clostridium* bacteremia. A retrospective population-based surveillance for clostridial bacteremia among all residents of the Calgary Health Region (population 1.2 million) during 2000-2006 showed that the incidence of clostridium bacteremia was 1.8/100 000 per year. *Clostridium perfringens* was the most common isolate accounting for 42% of cases followed by *Clostridium Septicum, Clostridium ramosum, Clostridium clostridiiforme,* and *Clostridium difficile*[1]. Another review of blood cultures drawn in a rural hospital in Wisconsin, United States from 1990-1997 yielded clostridium infection in 0.12% of drawn cultures with *Clostridium perfringens* being the most common (21.7%)[2]. A review of blood cultures in a Japanese tertiary center during 2001-2009 showed that only 18 patients had *clostridium perfringens* bacteremia[3]. *Clostridium perfringens* is an anaerobic gram positive rod that can produce a wide spectrum of diseases related to toxin production. *Clostridium perfringens* produce four principal toxins including alpha, beta, epsilon, and iota toxins[4]. Alpha toxin can produce gas gangrene[5] while beta toxin can produce necrotic enteritis[6]. *Clostridium perfringens* has also been reported to cause tuboovarian abscess[7], necrotizing enterocolitis[8], emphysematous cholecystitis[9], discitis[10], and liver abscess[11]. *Clostridium perfringens* bacteremia has been reported to occur following colonoscopy and gynecological procedures[12,13]. Advanced age and co-morbidities such as hemodialysis, cancer, heart disease, diabetes, Crohn's disease, COPD, stroke and asthma increase the risk for clostridial infections. Advanced age increases the risk independent of co-morbidities which could be explained by age-related increase of clostridial species in the normal intestinal flora[1]. *Clostridium perfringens* bacteremia has been associated with intravascular hemolysis and death. Alpha toxin

produced by *clostridium perfringens* can cause hemolysis, platelet destruction and widespread capillary damage. Intravascular hemolysis can be fatal unless treatment is instituted early. Sudden severe hemolytic anaemia, very low MCV, hemolyzed blood samples and negative Coombs test in a patient with fever should prompt the clinician to consider *clostridium perfringens* infection. The morphological findings seen on blood cell examination are spherocytes, microspherocytes, and neutrophils with vacuoles or Dohle bodies[14-16]. Fortunately, our patient did not manifest these abnormalities. In our patient it is difficult to determine if the predominance of indirect hyperbilirubinemia is caused by intravascular hemolysis that was limited by early antibiotics use or by choledocholithiasis. Therefore we would encourage clinicians to obtain peripheral blood smear in patients with *clostridium perfringens* bacteremia with any evidence suggestive of intravascular hemolysis.

When the clinician encounters *clostridium perfringens* bacteremia, discovery of the source is very important. Sources of *Clostridium perfringens* bacteremia include colon, biliary tree, lungs, tuboovarian, endometrium and decubitus ulcer. Unlikely sources include urinary tract, pancreas, small bowel, esophagus and brain abscess or unknown source[2]. Choledocholithiasis has been rarely reported as a cause of *Clostridium perfringens* bacteremia[17]. We report an unusual case of *Clostridium perfringens* bacteremia caused by choledocholithiasis in the absence of gallbladder stones and with normal CBD diameter. This case demonstrates the importance of pursuing an extensive differential diagnosis because the identification of the underlying source may be necessary to prevent a fatal outcome. Our patient presented with *clostridium perfringens* bacteremia along with newly elevated liver function tests leading to consideration of biliary source for his bacteremia. This led to further imaging for evaluation of the biliary tract despite normal gallbladder and common bile duct seen on abdominal US and CT scan of the abdomen.

Clostridium perfringens bacteremia is a rare occurrence. We would like to emphasis the importance of discovery of the source of bacteremia and the early administration of antibiotics. It is important to recognize the occurrence of intravascular hemolysis with *Clostridium perfringens* bacteremia. Imaging of the biliary system by MRCP or endoscopic US is needed despite normal ultrasound and CT scan of the abdomen when biliary source of *Clostridium perfringens* bacteremia is suspected.

Abstract

We describe a patient with a *Homo sapiens* mutL homolog 1 (*MLH1*)-associated Lynch syndrome with previous diagnoses of two distinct primary cancers: a sigmoid colon cancer at the age of 39 years, and a right colon cancer at the age of 50 years. The mutation identified in his blood and buccal cells, c.1771delG, p.Asp591Ilefs*25, appears to be a *de novo* event, as it was not transmitted by either of his parents. This type of *de novo* event is rare in *MLH1* as only three cases have been reported in the literature so far. Furthermore, the discordant results observed between replication error phenotyping and immunohistochemistry highlight the importance of the systematic use of both pre-screening tests in the molecular diagnosis of Lynch syndrome.

INTRODUCTION

Lynch syndrome or hereditary non-polyposis colorectal cancer syndrome (MIM#120435)[1] is a familial form of cancer mainly involving the colon, rectum or endometrium and, more rarely, the small bowel, urinary tract, ovaries, stomach, brain or skin. The pathology is transmitted in an autosomal dominant mode of inheritance with an incomplete penetrance. It is linked to mutations in the genes of the DNA mismatch repair system (MMR), including *Homo sapiens* mutL homolog 1 (*MLH1*), *Homo sapiens* mutS homolog 2 (*MSH2*), and to a lesser extent,

Homo sapiens mutS homolog 6 (*MSH6*) and PostMeiotic Segregation increased 2 (*PMS2*). International scientific community defined the clinical and familial criteria which had to be fulfilled to consider a likely diagnosis of Lynch syndrome, and thereby the value of a mutation screening of *MMR* genes in a patient. The initial recommendations following the Amsterdam (1991)[2] and Amsterdam Ⅱ (1999) criteria[3] were too restrictive. New criteria were therefore proposed at the Bethesda conference in 2004[4], in order to increase the sensitivity of mutation carrier detection. These recommendations include an age at diagnosis younger than 50 years, or younger than 60 years when the tumor has a microsatellite instability-high phenotype (MSI-high), which is the hallmark of tumors linked to a defective *MMR* gene system[5,6].

Here we report on the unique case of a *de novo* mutation encountered by our Oncogenetic Laboratory through its diagnostic activity in Lynch syndrome. In our molecular diagnostic strategy, replication error (RER) phenotyping is performed systematically before sequencing of the *MMR* genes whenever tumor tissue is available, and this is done concomitantly with immunohistochemistry in order to direct the sequencing as far as possible. Sequencing of either *MLH1*, *MLH2* or both genes is initiated each time a tumor is found to be MSI-high or -low (low microsatellite instability: one system with replication error), even when the immunohistochemistry results are ambiguous or show no extinction of a MMR protein. The sequencing step is also initiated under three specific circumstances: (1) the finding of an microsatellite stable (MSS) phenotype with validated Amsterdam criteria; (2) when no tumor material is available; and (3) in the case of a discrepancy between the immunohistochemistry results and the RER phenotype.

Whenever necessary, DNA samples are sent to another laboratory within the French MMR network (Groupe Génétique et Cancer MMR) for further testing of *MSH6*.

CASE REPORT

The patient is a 54 year-old man who had previously presented two distinct primary cancers, a sigmoid colon cancer at the age of 39 years, and a right colon cancer at the age of 50 years. He is the sixth of a family of 10 siblings, three of whom have had polyps removed: two brothers and one sister, at the ages of 38, 42 and 38 years respectively. A fourth sibling, another of his sisters, was diagnosed with cervical cancer at 45 years of age, but it is not in the tumor spectrum for Lynch syndrome. Among the older generations of the patient's family, the maternal grandfather died of colon cancer at the age of 84 years and the mother's medical records report an ovarian cyst and ovariectomy (Figure 1).

The right colon tumor had been removed by a colectomy covering 30 cm of the right colon and 5 cm of the ileum. The tumor measured 7 cm × 5 cm × 1.5 cm and was located in the caecum, invading the terminal ileum. The pathology examination revealed a grade 3 stage for the poorly differentiated, burgeoning and stenosing adenocarcinoma, and cancer staging was classified as pT-3N0Mx. Immunochemistry and molecular biology analyses were performed on formalin-fixed paraffin-embedded material from this tumor.

The immunohistochemistry analysis for the MMR proteins MLH1, MSH2 and MSH6[7] was performed but did not demonstrate a loss of expression, albeit a very weak expression was detected for MLH1 and MSH2.

RER phenotyping was then performed and showed an instable phenotype for four of the five markers routinely tested in our laboratory (BAT25, BAT26, NR21, NR22 and NR24)[8,9], with stability noted only for the NR24 system. The tumor was thus classified MSI-high, and the patient was considered for mutational analysis of *MMR* genes, according to the Bethesda criteria.

In keeping with routine practice at our laboratory, we started with the search for large rearrangements using a commercial Multiplex Ligation-dependent Probe Amplification (MLPA®) kit for *MLH1* and *MSH2* (P003-B1 kit, MRC-HOLLAND, Amsterdam, The Netherlands)[10]. This revealed the isolated loss of *MLH1* exon 16. In such cases of single exon deletion or duplication, we systematically verify the hybridizing sequence of the MLPA probes to exclude a false result caused by a single nucleotide polymorphism (SNP). However, in the present case, the sequence analysis showed a single nucleotide deletion of a G in position 1771 (NM_000249.3: c.1771delG, p.Asp591Ilefs*25). This mutation had previously been described in a Taiwanese Lynch family[11]. It had been classified as deleterious because of the occurrence of a premature stop codon at position 615, which disrupts the interacting protein domains to *Pms*2 and exonuclease 1[12].

From this point on, we set out to investigate the status of the mutation within the tumor. Finding the mutation in a homozygous or hemizygous state would have meant that the second hit in the carcinogenetic process was a loss of heterozygosity, and that the mutation was the first hit. Unfortunately, the poor quality of the DNA extracted from the Formaldehyde-fixed Paraffin-embedded material did not enable us to get readable sequences. We confirmed the presence of mutation c.1771delG (p.Asp591Ilefs*25) in a second independent sample (DNA extracted from a buccal swab spotted onto a FTA paper). Once the mutation had been confirmed, a presymptomatic test was offered to the patient's family. In this context, we tested both parents but did not identify any parental origin for the mutation as both parents tested negative for the mutation, in both blood and buccal cell samples. We then performed the complete sequencing of *MLH1* to exclude any other mutational event that could have been the true cause of the patient's personal and familial history of cancer, but we did not identify anything else.

These results led us to question the patient's paternity, given that a meta-analysis performed in 2005 reported false paternity in a median of 3.7% of births[13]. Nevertheless, a genetic fingerprinting kit (AmpFℓSTR® SGM

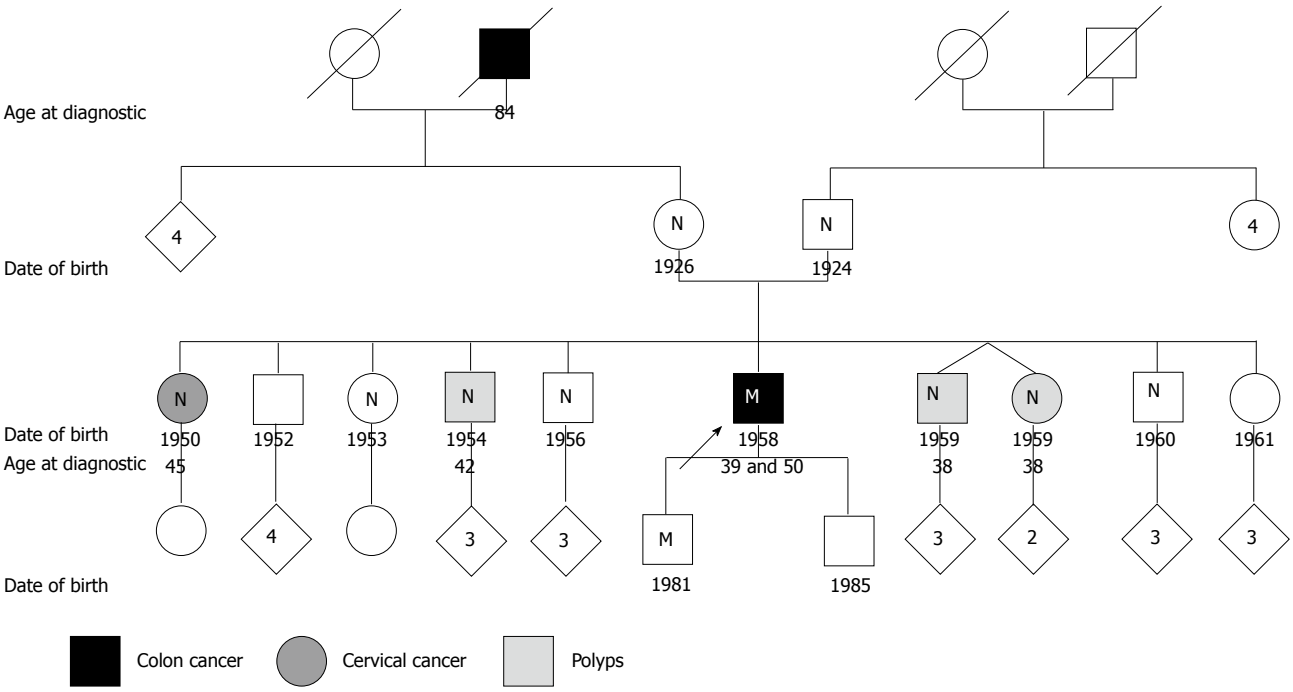

Figure 1 Pedigree. Family tree shows the segregation and clinical manifestations in the family with *de novo Homo sapiens* mutL homolog 1 mutation. N: Normal carrier status; M: Mutated carrier status.

Plus®; Applied) confirmed the paternal and maternal status of the supposed parents without ambiguity.

In order to further investigate the possibility of a mosaicism, we performed a haplotyping study using two frequent SNP within the *MLH1* gene (rs1800734 and rs2241031) chosen for their high heterozygosity frequencies and their belonging to different ancestral haplotypes. However, the lack of proband informativity meant that this analysis did not enable us to identify the maternal or paternal origin of the chromosome harboring the mutation. However, because we had tested two different types of tissues of different origins, i.e., mesodermic for blood cells and ectodermic for buccal cells, we were able to exclude mosaicism with quite a high level of confidence. We were finally able to conclude that the Lynch syndrome-causing mutation observed in our patient was a *de novo* event.

Up to now, we have been able to test seven of the patient's nine siblings and have not identified any of them as a carrier of the mutation, even those who have had polyps or cervical cancer. This could be considered as a further argument for a *de novo* mutation, since it does not follow the Mendelian transmission ratio of 1:2 and it is not concordant with polyp antecedents.

Finally, a presymptomatic test in our patient's 30 year-old son revealed the presence of mutation c.1771delG (p.Asp591Ilefs*25) in a heterozygous state, thereby highlighting the transmission (and conservation) of this *de novo* mutation by the proband.

DISCUSSION

Here we report on a French Lynch family in whom we have identified a frame-shift mutation that induces a premature stop codon in a crucial part of the *MLH1* gene. This mutation has never been reported in the open access *MMR* mutation database (INSIGHT, Newfoundland *etc.*), or in the French MMR network database (unpublished data). Moreover, we have never found this mutation in 592 chromosomes of patients of similar geographic origin who have been tested in our laboratory as part of routine Lynch syndrome screening.

In contrast with certain other genes, such as *NF1,* which exhibit a *de novo* mutation rate of about 50%, this event in *MLH1* is relatively rare (1% to 5%) according to the study recently published by Win *et al*[14]. To our knowledge, a *de novo* point mutation in *MLH1* has only been described three times until now. The first occurrence was a c.2101C>T (p.Gln701X) mutation in exon 18, which was detected in a 35 year-old man[15]. The second was a c.666dupA (p.Asn222Lysfs*4) mutation in exon 8 found in a 31 year-old man[16]. The third mutation was a nonsense mutation in exon 13, c.1459C>T (p.Arg487X) identified in a 36 year-old patient[14]. In all three cases the patients had no family history of colorectal cancer and seemed to develop cancer younger than inherited mutation carriers. In addition to these three single nucleotide mutations, two large deletions have already been published, one of the entire *MLH1* gene and one of exon 15, once again in a young man without any family history of cancer[14,17]. *De novo* mutations seem to be more frequent in *MSH2*, for which four different mutations have already been described[14,18,19], including the recurrent mutation c.942+3A>T. The latter can even be considered as a kind of mutation hotspot, as it has been proved to occur *de novo* with a relatively high frequen-

cy[20]. The nucleotide implicated in this mutation is part of the BAT26 homopolymer containing 26 adenines. This particular context is hypothesized to be responsible for misalignment during replication or recombination. Even though the *de novo MLH1* mutation described here arose in two families of different ethnic origin, a similar explanation cannot be considered.

This case report confirms the relevance of preceding *MMR* gene sequencing by the combination of the two prescreening tests (RER phenotyping and immunohistochmistry) in the molecular diagnostic strategy in Lynch syndrome, especially for young patients without familial antecedents. Indeed, it is worth noting that most of these patients would not have been considered as candidates for mutation analysis according to the Amsterdam I and II criteria; this might be the reason why *de novo* events in *MLH1* were not described prior to the implementation of the Bethesda criteria. It is also interesting to point out the discordance between immunohistochemistry and RER phenotyping results for our patient's tumor, which confirms the benefit of a dual approach for the screening of Lynch syndrome patients. Indeed, MSI-high phenotypes with conservation of protein expression have already been described and can easily be explained when they concern a missense mutation that does not occur in the epitope of the antibody used. Inversely, extinction of a protein associated with an MSS or MSI-low phenotype can also be encountered, especially when the *MSH6* gene is affected[21]. In glioblastoma, in the context of Turcot syndrome, changes in microsatellite profiles have also been described as more subtle than those in colorectal tumors[22] and thus have to be considered very carefully.

In conclusion, the frequency of *de novo* mutations in *MMR* genes may be higher than actually observed in diagnostic laboratories because once a mutation is identified, the parents of the proband are not systematically analyzed in routine practice. This may be because they are deceased, as the average age at molecular diagnosis of our index cases is 53 years, or because they do not wish to be tested

Moreover, we show here that the combined use of molecular biology and immunohistochemistry should be recommended when screening patients with suspected Lynch syndrome. This combined strategy should help to avoid missing a tumor linked to a deficiency in a *MMR* gene, and also to orientate the subsequent sequencing to one of these genes in a more precise and therefore cost-effective manner.

Abstract

Ischemic bowel disease results from an acute or chronic drop in the blood supply to the bowel and may have various clinical presentations, such as intestinal angina, ischemic colitis or intestinal infarction. Elderly patients with systemic atherosclerosis who are symptomatic for the disease in two or more vascular beds have multiple comorbidities and are particularly at risk. The clinical evolution and outcome of this disease are difficult to predict because of its pleomorphic aspects and the general lack of statistical data. In this paper, we present the case of a patient who was monitored in our unit for six years. For this patient, we encountered iterative changes in the clinical pattern, beginning with chronic "intestinal angina" and finishing with signs of acute mesenteric ischemia after an episode of ischemic colitis. This evolution is particularly rare in clinical practice, and the case is instructive because it raises discussions about the natural history of the condition and the therapeutic decisions that should be made at every stage of the disease. An important lesson is that ischemic bowel disease should always be considered in patients who have multiple risk factors for atherosclerosis and have experienced recurrent "indistinct" abdominal symptoms. In these cases, aggressive investigation and therapeutic decisions must be taken whenever possible. Despite an absence of standardized protocols, angiographic evaluation and revascularization procedures have beneficial outcomes. Current advances in endovascular therapy, such as percutaneous transluminal angioplasty with stenting, should be increasingly used in patients with chronic mesenteric ischemia. Such therapy can avoid the risks that are associated with open repair. However, technical difficulties, especially in severe stenotic lesions, frequently occur.

INTRODUCTION

Ischemic colitis (IC) was first described by Boley *et al*[1]. The condition is a common form of ischemic injury to the gastrointestinal tract and represents approximately one half of all cases involving gastrointestinal ischemia[2]. On average, this disease is found in association with approximately 1-3/1000 acute hospital admissions, but occasionally a mild and transient clinical course may lead to misdiagnoses. Elderly patients are typically affected, and the most common admission signs are hematochezia, abdominal pain and diarrhea[3]. The rapid onset of abdominal pain, tenderness over the affected

bowel area (typically the left side of the colon) and mild to moderate hematochezia are the classic signs, although confusion can appear in cases that are considered to be inflammatory bowel disease or various forms of common bacterial colitis[4]. There is a lack of data regarding the natural history and outcomes of IC. A recent study[5] found that IC is clinically presumed in only 24.2% of cases, and unfavorable outcomes (as defined by mortality and/or the need for surgery) occur at a rate of 12.9%, including an overall mortality rate of 7.7%.

The taxonomy of the disease is somewhat unclear, especially when "puzzling" terms, such as ischemic colitis and colonic ischemia, are employed. According to the American Gastroenterological Association (AGA) technical review on intestinal ischemia[6], ischemic bowel disease can be either acute or chronic. Whereas the acute condition includes various forms of acute mesenteric ischemia (AMI) up to intestinal infarction, the milder chronic variant includes chronic mesenteric ischemia (CMI) (also known as "intestinal angina") and colonic ischemia (CI). CI can appear under various clinical-endoscopic aspects, including (1) reversible colopathy (submucosal or intramural hemorrhage); (2) transient colitis; (3) chronic colitis; (4) stricture; (5) gangrene; and (6) fulminant universal colitis. Most of these aspects have a mixed, ischemic-inflammatory pattern in which ischemic colitis results from an inadequate perfusion that leads to potentially life-threatening colonic inflammation[7]. In its chronic forms, healing is associated with a degree of fibrosis that determines colonic stenosis.

Beyond this almost scholastic classification, it is important to bear in mind that in current practice, these three major categories (AMI, CMI and CI) may be quite intricate. Moving from one to another occurs in a mix of clinical presentations that can appear in the same patient at various moments, depending on factors such as localization, extent of vascular disease, severity of ischemia, or bowel distension, among others. Our case reflects such a patient, in whom the clinical pattern changed several times in a couple of years. The case began as chronic "intestinal angina" and finished with signs of acute mesenteric ischemia after an episode of ischemic colitis.

CASE REPORT

We present the case of a male Caucasian patient who was monitored in our unit between 2006 and 2012. The hallmark of his long medical background was a severe vascular pathology that was facilitated by the combination of several risk factors: heavy smoking since the age of 18 (more than 20 cigarettes/d), type 2 diabetes that was poorly controlled by diet and medication for more than 15 years, obesity, dyslipidemia and moderate to severe hypertension since 1993. An episode of acute thrombosis of the left femoral artery occurred in 1999, which resulted in the amputation of his left thigh. The patient continued to smoke and neglect the recommended therapy, and four years later, he suffered another acute thrombotic episode, this time of the right lower limb with the occlusion of the popliteal artery. His right foot was amputated just below the knee. A complete hemostasis investigation was performed at that time, and there was no sign of coagulation abnormality (including less common genetic defects, such as deficiencies of protein C/S, antithrombin Ⅲ, or factor V Leiden mutation). Aspirin and oral anticoagulation by coumadin were strongly recommended, but the patient appeared to disregard the advice by taking his treatment erratically. Finally, in 2005, a coronarography was performed to investigate an episode of unstable angina. The procedure showed a narrow stenosis (75%) of the circumflex artery; a stent (3.5 × 30 mm) was placed after the dilatation with a balloon catheter.

The patient was first hospitalized in the gastroenterology unit in September 2006, when he was 61 years old. The patient complained of postprandial pain that occurred especially after taking his medication, which consisted of beta blockers, thiazides, angiotensin enzyme inhibitors, aspirin, statins and coumadin. Gastroduodenal, biliary, pancreatic and colonic pathologies were eliminated by upper and lower digestive endoscopy, echography and computed tomography (CT) scans. The initial diagnosis was irritable bowel disease, but a lack of response to specific medication, the suggestive medical history and an improvement in the abdominal pain with sublingual nitroglycerin led to the suspicion of intestinal angina. A mesenteric arteriography was performed in January 2007, which showed a severe (> 75%) incomplete thrombotic occlusion of the upper mesenteric artery and a weak perfusion of the affected bowel loop (Figure 1). The case was concluded to be chronic mesenteric ischemia, but endovascular mesenteric revascularization or surgical bypass were not performed because of the patient's lack of compliance. The patient was discharged with a prescription of long-acting nitrates, and pentoxyfillin was added to his antihypertensive, antiagregant and coumadin treatments.

The evolution was more or less stable until March 2011, when the patient was re-admitted to the unit with episodes of persistent diarrhea and hematochezia, which were spaced by sub-occlusive events of colicky left-lower-quadrant abdominal pain and distension, vomiting and vasovagal symptoms. The examination showed mild pyrexia, tachycardia and a distended abdomen, and there was pain and tenderness in the left lower quadrant upon palpation. A digital rectal examination confirmed hematochezia but did not detect any other lesions. Laboratory investigations showed mild anemia (hemoglobin = 11.1 g/dL), neutrophil leukocytosis (14.800 leukocytes/mm^3 with 78% neutrophils), increased values of ESR (130 mm/h), hyperfibrinogenemia (780 mg/dL) and elevated C-reactive protein titers (27 mg/L). Other biochemical tests were within normal ranges. A plain abdominal radiography did not detect pneumoperitoneum or air-fluid levels. The recent use of antibiotics was denied by the patient, and stool cultures for aerobic/anaerobic pathogens (*Clostridium difficile* included) were negative. Amoebiasis serology,

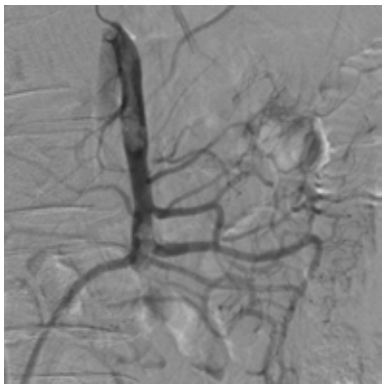

Figure 1 Selective upper mesenteric artery angiogram showing severe incomplete thrombosis with more than a 75% reduction of the arterial lumen and poor perfusion of the bowel loop.

a parasitological investigation and tuberculin intradermoreaction were also negative.

A contrast-enhanced CT scan (Figure 2) revealed segmental colitis involving the splenic flexure and the descending colon. The wall of the colon was markedly thickened with homogeneous enhancement and sharp definition, and it had a "dry" appearance. Concentric layers of low and high attenuation of the colonic wall ("double halo" sign) could be observed on sagittal sections, which suggested colonic edema. A long and narrow area of axial stenosis was present just below the splenic flexure. The stenosis extended to the distal third of the descending colon. Cecal and right colic distension were also observed, but there were no pericolic streakiness or fluid collections.

A colonoscopy found segmental edematous and hemorrhagic areas of the colonic mucosa surrounding large and deep ulcerations that were covered by pseudomembranes. When the pseudomembrane was washed off, the ulcerations revealed an erythematous and congestive granulation tissue. "Geographic"-like areas of mucosal denudation and "cobble stoning" were also observed (Figure 3A). The rectum was spared by an abrupt transition between normal and affected mucosa, and the ulcerative lesions extended to the sigmoid and descending colon. A narrow, long axial inflammatory stenosis was observed just below the splenic flexure. Biopsies showed edema, submucosal hemorrhage and necrotic areas, and an inflammatory infiltration with intravascular thrombi. The crypts had an atrophic appearance, but no cryptitis/cryptic abscesses or granulomas were observed (Figure 3B). Hemosiderin-laden macrophages were present in the mucosa and submucosa, and hyalinization and hemorrhages were observed in the lamina propria, which histologically confirmed ischemic colitis.

The therapeutic decision was to pursue a conservative treatment. After one week of bowel rest, fluid replacement, broad spectrum antibiotics and parenteral nutrition, the patient recovered well and was discharged. Six months later, in November 2011, the patient returned to the emergency room with acute abdominal pain, sudden evacuation of his bowel contents, abdominal distention,

A: Coronal sections with zones of mural thickening of the colon just below the splenic flexure and a long and narrow axial stenosis of the descending colon; B: Sagittal sections showing (arrow) the "double halo" sign, a tomographic equivalent of the classic "thumbprinting" that is observed in barium enemas.

fever, vomiting and gross hematochezia. Abdominal tenderness, rebound and guarding occurred rapidly with tachycardia, polypnea and hypotension. A CT scan showed a huge thrombus in the abdominal aorta, which extended below the first lumbar vertebra and occluded more than 95% of the aortic lumen (Figure 4). The thrombosis spared the emergence of the celiac trunk and the upper mesenteric artery and appeared to completely occlude the origin of the inferior mesenteric; in the clinical context, this outcome suggested an intestinal infarction. An emergency laparotomy was performed in the following hours. The laparotomy showed a segmental infarction of the descending and sigmoid colon with a transmural hemorrhage and necrosis. Similar lesions were identified at the hepatic flexure. The attached mesentery was also hemorrhagic, and marked colic distention was observed. A total colectomy with ileostomy was successfully performed *per primam*, but unfortunately, the patient was lost in the following days after sepsis and cardiovascular complications.

DISCUSSION

This instructive case presented several clinical aspects of atherothrombotic disease of the mesenteric territory. Most surveys do not include mesenteric ischemia among the major clinical consequences of atherosclerosis, especially considering that coronary and cerebrovascular

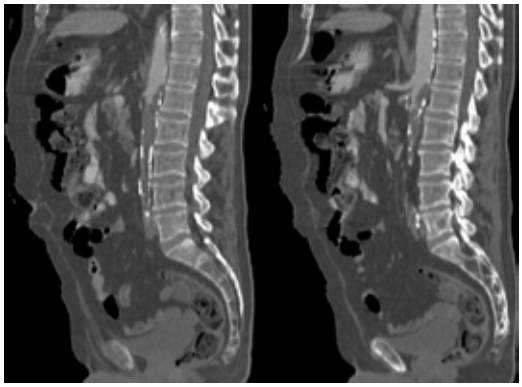

Figure 4 Calcification of the abdominal aorta with extensive thrombosis inside, which completely obstructed the lumen below the 2nd lumbar vertebra. Note that the celiac trunk and upper mesenteric artery are spared, whereas the lower mesenteric is completely occluded.

events with peripheral arterial disease may be credited with 60%-75% of the clinical manifestations of the disease[8-10]. However, even if mesenteric ischemia is not listed in those studies, there is a significant degree of overlap, as 41% of patients present symptoms of the disease in two or more vascular beds[11]. Moreover, recent research[12] found a higher incidence than was preliminarily reported[13,14], increasing the estimate of hospitalizations to 16.4/100 000. Multi-vascular disease is encountered in 24% of cases, and comorbidities, such as hypertension (72%), diabetes (21%) and coronary artery disease (21%), frequently occur[12]. This observation is consistent with our case. In addition to mesenteric arterial thrombosis and embolization, other medical conditions can cause bowel ischemia, such as mesenteric venous thrombosis, trauma, small vessel disease (i.e., diabetes mellitus, vasculitis, amyloidosis, rheumatoid arthritis, radiation), hematologic disorders (i.e., protein C/S or antithrombin Ⅲ deficiency, sickle cell disease), shock, medications (i.e., digitalis, diuretics, nonsteroidal antiinflammatory drugs (NSAIDs), catecholamines, estrogens, danazol, neuroleptics), colonic obstruction, cocaine abuse or long-distance running[15]. In our case, iterative mesentero-aortic thrombosis was the primary cause of the clinical manifestations of the ischemic bowel disease that was encountered in our patient; however, other secondary factors, such as diabetic vasculopathy and even chronic obstructive pulmonary disease[16], should not be overlooked.

Clinical patterns of mesenteric ischemia may be either acute ("gangrenous") or chronic ("nongangrenous") forms[15,17]. Nongangrenous forms (80%-85%) are typically transient and reversible but can progress to chronic and irreversible strictures (10%-15%) or chronic segmental colitis (20%-25%). Acute forms[18] have four major causes: sudden complete arterial occlusion by emboli (50%), thrombosis of atherosclerotic stenosis (20%), small vessel occlusion (20%) and venous thrombosis (10%). Whereas embolic occlusion of the mesenteric arteries is typically brutal and dramatic, often presenting the hallmark "pain out of proportion with physical findings", acute thrombosis of a stenotic atherosclerotic lesion may have a more insidious onset, and there may be a history of intestinal angina, which was the case in our patient. It is important not to miss the clinical signs of chronic mesenteric ischemia in a vascular patient, and it is also important to use angiography to aggressively evaluate the arterial damage in the mesenteric territory. Following the individual patient's anatomic and comorbidity considerations, early revascularization with percutaneous angioplasty/stenting or open repair may prevent a worse outcome, although protocols are not yet fully standardized, and symptomatic recurrences that require reinterventions occur as frequently as 20% of the time[19].

Chronic nongangrenous colonic ischemia, which is frequently expressed by ischemic colitis, indicates a higher degree of impairment of the intestinal blood flow and, as a consequence, more severe vascular damage. The colon is particularly susceptible to hypoperfusion, and low-flow states often precipitate to preexisting mesenteric microvascular atherosclerosis. "Watershed areas", such as the splenic flexure (Griffith's point), ileocecal junction and rectosigmoid, are specific localizations of ischemic lesions, but diffuse and extended ischemic injury of the entire bowel can also be encountered[20]. Ischemia is segmental and superficial, and it only extends to the mucosa and submucosa ("partial mural ischemia")[20,21]. The subsequent inflammation and fibrosis that follow this decrease in the blood supply lead to a "true" colitis that includes edema, neutrophil afflux and hyalinization. Ghost cells and hemosiderin-laden macrophages are highly specific findings that can facilitate

diagnosis; these findings should be differentiated from other entities, such as infectious colitis (i.e., *Salmonella*, *Shigella*, *Campylobacter*, *E. coli* O157:H7, *Clostridium difficile*), inflammatory bowel disease, medication-induced colitis (i.e., NSAIDs, hormones, anticoagulants, diuretics, antibiotics), malignancy, fecal impaction with stercoral ulcer, systemic disorders and amyloidosis[22]. Although therapy classically relies on conservative treatment and anticoagulation, the recurrence of disease, especially in high-risk vascular patients, can impose angiographic evaluation and revascularization procedures that may have beneficial outcomes despite an absence of standardized protocols[22,23].

In conclusion, ischemic bowel disease may be an expression of systemic atherosclerosis, especially in patients who have cumulative risk factors, such as dyslipidemia, diabetes or smoking, and a multi-vascular atherothrombotic pathology. These patients occasionally present all of the clinical forms of mesenteric ischemia, including intestinal angina, ischemic colitis and intestinal infarction. The symptoms may develop over several years and may be intricate, so their recognition is important. Simple anticoagulation does not always prevent major incidents, and revascularization procedures, such as percutaneous angioplasty or stenting, may ensure a better prognosis. In patients with ischemic bowel disease, the important lesson is to always consider aggressive investigations and therapeutic decisions while taking into account the associated benefits and risks. Angiographic evaluation and revascularization procedures are associated with beneficial outcomes despite an absence of standardized protocols. Current advances in endovascular therapy, such as percutaneous transluminal angioplasty with stenting, should be increasingly used in patients with chronic mesenteric ischemia. These procedures will limit the risks that are associated with open repair. However, technical difficulties, such as undistensible stenotic lesions, frequently occur.

Abstract

We present a rare case of a gastrointestinal stromal tumor (GIST) in the stomach with prominent calcification at presentation. A 61-year-old woman visited our hospital because of epigastric discomfort. A spherical calcified lesion with a diameter of about 30 mm was incidentally shown in the left upper quadrant on an abdominal X-ray. Computed tomography demonstrated that the tumor was growing from the upper gastric body, with calcification in the peripheral ring area. A laparoscopic partial gastrectomy was performed, and the resected specimen revealed a well-circumscribed tumor with exophytic growth from the gastric muscularis propria. Microscopic examination revealed spindle-shaped tumor cells with calcification and hemorrhage. Additionally, positive immunoreactivity of the tumor to KIT and CD34 and a low mitotic index resulted in the diagnosis of very low risk GIST. There are a few case reports of heavily calcified GIST, although solitary or punctate calcification of primary GIST has been reported in several case series. Dystrophic calcification of necrotic or degenerative tissue is the supposed cause of primary calcified GISTs. In contrast, appearance of calcification after administration of imatinib mesylate, which may be one indicator of disease response, is possibly caused by a different mechanism.

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are the most common primary mesenchymal neoplasms of the gastrointestinal tract[1,2]. In the past decade, histological and clinical features of GISTs have become increasingly clear[1,2], however, calcified tumor mass is an unusual feature of GISTs at initial presentation, and the mechanism is not clear. We describe here an uncommon case of gastric GIST with prominent calcification.

CASE REPORT

A 61-year-old woman without a significant medical history visited our hospital due to epigastric discomfort. There were no positive findings on physical examination. Initial laboratory tests demonstrated low hemoglobin level (9.6 g/dL), which was probably due to iron deficiency anemia.

An abdominal X-ray showed a spherical calcified lesion measuring approximately 30 mm in the left upper quadrant (Figure 1A). An upper gastrointestinal barium study revealed an exogastric mass (Figure 1B). A plain computed tomography (CT) demonstrated calcification in the peripheral ring area of the tumor growing from the upper gastric body. With an abdominal enhanced CT, the tumor was enhanced heterogeneously, except for the calcified section (Figure 2A and B). There was no evidence of liver metastasis or diffuse peritoneal spread. Magnetic resonance imaging of the central portion of the tumor showed low signal intensity on T1-weighted images (Figure 2C) and high signal intensity on T2-weighted images (Figure 2D). Indicative of calcification, peripheral portions showed low intensity on both T1 and T2-weighted images. Endoscopic examination revealed a round submucosal tumor with the upper part depressed (Figure 3A). Endoscopic ultrasonography (EUS) indicated the tumor originated from the fourth layer of the gastric wall (Figure 3B). Although EUS-guided fine needle aspiration was considered for the diagnosis of the submucosal lesion, it was impossible to perform due to calcification of the tumor wall with a sonic shadow (Figure 3B). After informed consent was obtained, laparoscopic partial gastric resection was performed.

The resected specimen revealed a well-circumscribed tumor measuring 32 mm × 23 mm × 23 mm originating from the gastric muscularis propria. The sliced surface of the tumor showed a firm, solid, whitish-gray parenchyma with circular calcification and internal bleeding (Figure 4A). Microscopic investigation revealed spindle-shaped tumor cells (Figure 4B) with calcification and hemorrhage. The cells exhibited low mitotic activity of fewer than 5 mitoses per 50 high power field (HPF) and no prominent signs of nuclear atypia. Immunohistochemical staining demonstrated positive reactivity to KIT (Figure 4C) and CD34 (Figure 4D). On the other hand, there was negative reactivity to S-100 protein, smooth muscle actin, and desmin (not shown). Since the mitotic index of this tumor was less than 5/50 HPF, its diagnosis was established as very low risk GIST according to risk stratification guidelines[1]. The patient had an uneventful postoperative course and was discharged on the 7th postoperative day. The patient has been followed up for 10 mo without any signs of recurrence.

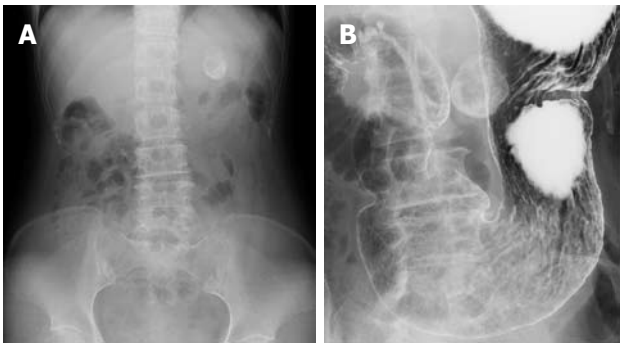

Figure 1 Radiological findings. A: Abdominal X-ray indicated a spherical calcified lesion in the left upper quadrant; B: Barium study showed a round calcification bordering the gastric wall.

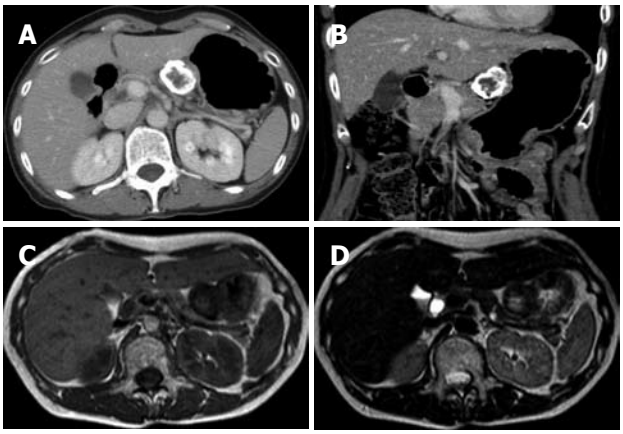

Figure 2 Computed tomography and magnetic resonance imaging findings. Contrast-enhanced axial (A) and coronal (B) computed tomography examination demonstrated that the marginal zone of the tumor was calcified, and that the internal portion of the tumor was enhanced heterogeneously. Magnetic resonance imaging T1-weighted image (C) and T2-weighted image (D) revealed a low intensity marginal zone of tumor reflecting calcification.

DISCUSSION

GISTs are defined as mesenchymal tumors in the gastrointestinal tract that express KIT, a tyrosine kinase growth factor receptor[1]. Clinical, histological and molecular features of GISTs have become increasingly clear in the past decade[1,2], and radiologic appearances of these tumors have also been well described[2-7]. Small GISTs (< 5 cm) are often seen as well-defined with a homogeneous appearance on contrast-enhanced scans, whereas larger lesions (> 10 cm) are more likely to have irregular and lobulated margins with heterogeneous enhancement[2-4].

Although several cases of primary GIST with calcification have been reported[3-6], solitary or punctate calcification was shown in most cases[4,5]. In contrast, there are only six case reports describing heavily calcified

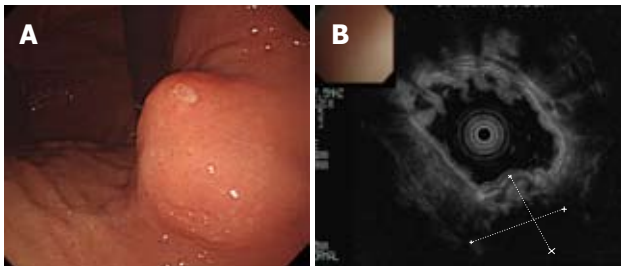

Figure 3 Endoscopy and endoscopic ultrasound of stomach. A: Endoscopic examination revealed a round submucosal tumor; B: The tumor originated from the fourth layer of the gastric wall as indicated by endoscopic ultrasound. The deeper section could not be visualized because of calcification.

GISTs[8-13]; three cases located in the stomach, one in the colon, and two in the rectum. Although Ghanem *et al*[4] referred to a solitary calcification as an aggressive finding, the evidence was not clearly shown. Regarding primary lesion, Tateishi *et al*[5] suggested that the frequency of calcification was not a reliable finding for the distinction of low- and high-grade GISTs. Particularly, with respect to malignant GIST of the stomach, no CT feature (including calcification) other than size was found to have predictive value[6].

The mechanism of calcification at presentation is unclear. Yoshida *et al*[8] suggested that the calcification of GIST may be developed mostly from necrotic tissue. In the earlier literature, a true GIST would be included in the imaging studies of leiomyoma, leiomyoblastoma, or leiomyosarcoma arising in the gastrointestinal tract. Prior to the appearance of the definition of GIST, the major mechanism of calcified gastric submucosal tumors was also supposed to be dystrophic calcification of necrotic or degenerative tissue[14].

In addition, several cases have demonstrated increasing calcification in mesenteric metastasis after therapy with imatinib mesylate[7,15]. Histological examination of liver metastasis after therapy showed myxomatous degeneration, leaving small pyknotic nuclei in an eosinophilic myxoid background, with no signs of an inflammatory reaction or necrosis[16,17]. Imatinib mesylate alters the balance from cellular proliferation to apoptosis by inhibiting the tyrosine kinase activity of KIT[16]. Because cellular death of GISTs following imatinib therapy is by apoptosis and not by necrosis, which is the principal mechanism of cell death following conventional cytotoxic chemotherapy[7], the mechanism of calcification following administration of imatinib is probably different from that of primary calcification.

[^{18}F]-fluorodeoxyglucose-positron emission tomography has been reported as useful for the evaluation of early response to imatinib mesylate treatment[16,18,19]. Furthermore, a decrease in tumor size or a tumor density on post-treatment CT has been reported as a good predictor for tumor response[19,20]. Sandrasegaran *et al*[7] also reported that four of twenty-two mesenteric masses showed calcification as well as cystic changes following at least 6 mo of therapy. It is suggested that calcification, in addition to a reduction in tumor size and extensive cystic changes, may indicate disease response[15].

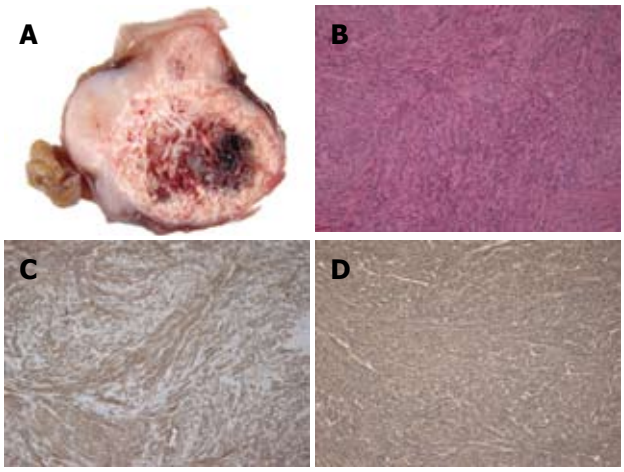

Figure 4 Pathological findings. A: Sliced sections of the resected mass demonstrated a firm, solid, whitish-gray parenchyma with circular calcification and internal bleeding; B: Microscopically, the tumor was characterized by spindle-shaped tumor cells (hematoxylin and eosin, original magnification ×100); Immunohistochemically, the tumor cells were positive for KIT (C) and CD34 (D).

In conclusion, we present here a rare case of gastric GIST with prominent calcification. To assess the mechanism and clinical relevance of calcification of GIST at presentation and following administration of imatinib, further accumulation of patients with pathological investigation would be required.

Abstract

Here, we present the case of a 53-year-old man with a hepatothorax due to a right diaphragmatic rupture related to duodenal ulcer perforation. On admission, the patient complained of severe acute abdominal pain, with physical examination findings suspicious for a perforated peptic ulcer. Of note, the patient had no history of other medical conditions or recent trauma, and the initial chest radiography and laboratory findings were not specific. A subsequent abdominal computed tomography revealed intrathoracic displacement of the liver, gallbladder, transverse colon and omentum through a right diaphragmatic defect. The patient then underwent an explorative laparotomy that confirmed duodenal ulcer perforation. A primary repair of the duodenal perforation was performed, and the diaphragmatic defect was repaired using a polytetrafluoroethylene patch after the organs were reduced and the cavity irrigated. This particular case proves interesting as right-sided spontaneous diaphragmatic ruptures are very rare and difficult to diagnose. Additionally, the best treatment for such large diaphragmatic defects is still controversial, especially in cases of intrathoracic or intra-abdominal contamination.

INTRODUCTION

Non-traumatic, spontaneous diaphragmatic ruptures are extremely rare, accounting for approximately 1% of all diaphragmatic ruptures. Here, we present the case of an acute right diaphragmatic rupture related to duodenal ulcer perforation which resulted in displacement of the liver, gallbladder, transverse colon and omentum into the intrathoracic cavity.

CASE REPORT

A 53-year-old male patient presented to the emergency room complaining of acute abdominal pain, which reportedly started 30 min previously. Of note, he denied any relevant past medical history, any recent trauma, and any medication use. At the time of admission, the patient continued to complain of severe epigastric pain, and a physical exam revealed a rigid abdomen, with both tenderness and rebound tenderness observed throughout the abdomen. His vital signs were relatively stable, with a blood pressure of 120/80 mmHg, a heart rate of 95 beats

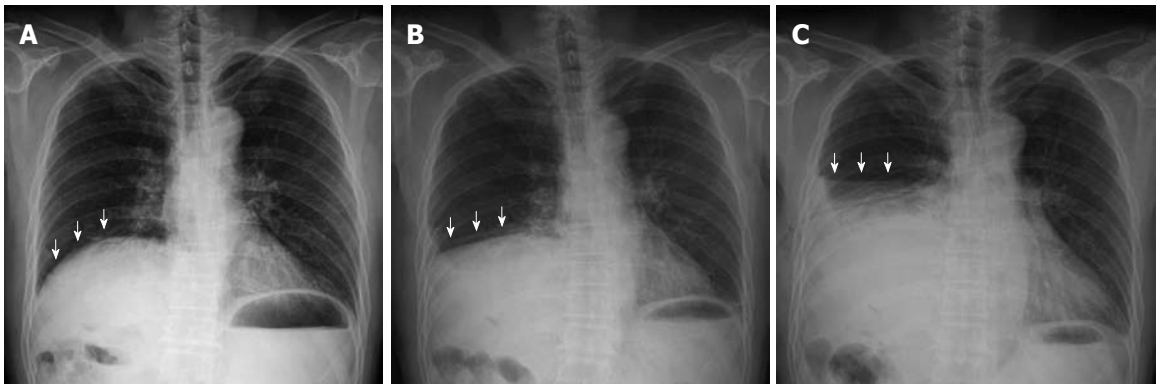

Figure 1 Gradual elevation of the right diaphragmatic border can be seen (arrows). A: Chest radiography on admission; B: Two hours after admission; C: After thoracostomy.

Figure 2 Chest computed tomography coronal reformatted images revealing intrathoracic displacement of the liver, bowel, and omentum through the defect (arrowheads) of the diaphragm (arrows).

per minute, oxygen saturation of 98%, and a body temperature of 37 ℃. The initial chest radiograph revealed a slight elevation of the right diaphragmatic border, though at the time this was not deemed to be significant (Figure 1A). Further laboratory findings showed no other abnormalities, such as anemia or leukocytosis (Figure 1). Due to the generalized peritonitis on the physical exam, a perforated peptic ulcer was suspected, and thus an abdominal computed tomography (CT) was performed. Unexpectedly, no free air or fluid collections were observed in the abdominal cavity. Instead, the CT showed significant displacement of the right lobe of the liver, the bowel and the omentum into the right hemithorax, with the reformatted coronal images providing better views of

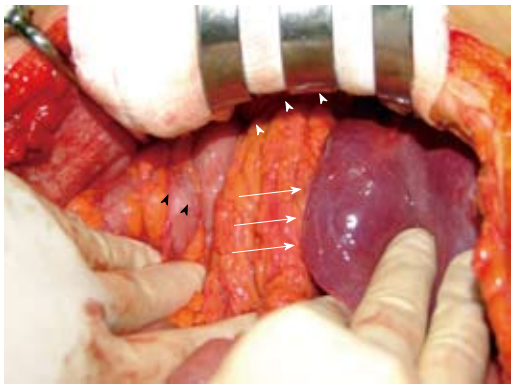

Figure 3 Herniation of the right hepatic lobe, gallbladder, transverse colon, and omentum through the diaphragmatic defect (white arrowheads), showing only the left hepatic lobe (white arrows) and residual transverse colon (black arrowheads) in the right upper abdomen.

the right diaphragmatic border and showing a loss of a part of the diaphragm (Figure 2). Notably, pneumothorax and hydrothorax were also observed, and an injury to the lung parenchyma could not be ruled out.

Initially, a tube thoracostomy was performed, with significant care taken to avoid any injury to the liver and/or bowel. As foul-smelling fluid and bowel contents were noted in the drainage from the chest tube, bowel perforation was also suspected along with diaphragmatic rupture. Accordingly, an exploratory upper midline laparotomy was performed 4 h after admission. At first no evidence of bowel perforation - such as fluid collection or fecal material - was observed in the abdomen. Instead, only the left lobe of the liver was found to have protruded into the right upper abdomen, with the right lobe rotated and herniated into the right hemithorax through the right diaphragmatic defect, along with the gallbladder, transverse colon, and omentum (Figure 3). Exploration of the entire abdomen revealed the site of perforation (approximately 0.5 cm in size) at the first portion of the duodenum immediately distal to the pylorus. Before reducing the herniated organs, a primary repair of the duodenal perforation was performed.

The medial portion of the right side of the diaphragm

Figure 4 Chest radiograph 12 d after surgery showing normal positioning of the right diaphragmatic border compared to the preoperative chest radiograph.

was nearly lost, with only the lateral portion remaining. As this lateral segment blocked reduction, the herniated organs were returned to their respective appropriate locations after the lateral diaphragm was incised, leaving a 12 cm × 10 cm defect. Because of the large size of this defect, primary repair was not possible. Accordingly, another chest tube was inserted just above the diaphragm after the thoracic cavity was thoroughly irrigated. Repair of the diaphragmatic rupture was then performed using a polytetrafluoroethylene patch (GoreTex; W.L. Gore, Flagstaff, AZ, United States) with 1-0 prolene sutures. No other evidence of perforation was noted in the herniated bowel. The abdominal cavity was then irrigated, and an omental patch was applied to the site of the duodenal perforation repair. After surgery, the patient was immediately sent to the intensive care unit for mechanical ventilation, whereby the thoracostomy tubes and abdominal drains were removed in sequence. A post-operative chest radiograph revealed that the right diaphragmatic border had returned to a normal position (Figure 4). After marked improvement in duodenal edema, the patient was discharged on post-operative day 20 with no further complications. Although the patient took oral antibiotics for only one week after discharge, no postoperative complications, including infections, occurred during the following year.

DISCUSSION

Diaphragmatic rupture is a rare complication of abdominal or thoracic trauma, reported in 1%-7% of major blunt trauma patients and 10%-15% of penetrating trauma patients[1,2]. However, approximately 1% of all diaphragmatic ruptures occur spontaneously, often resulting from a sudden increase in abdominal pressure secondary to heavy physical effort, sudden twisting movements, childbirth, and/or severe coughing[3-5]. Other cases have been reported to be caused by static sport activities (e.g., Pilates) or associated with endometriosis[6]. As the patient described here had no recent history of trauma, the exact reason for his diaphragmatic rupture remains unclear. However, given the clinical context, we conjecture that leaked digestive juice may have corroded the diaphragm, as occurs in cases of empyema. Another possibility is that portions of the diaphragm, such as the septum, may have been weakened or altered by previously unrecognized trauma. If this occurred, the pain resulting from the subsequent duodenal ulcer perforation and the associated abdominal muscle tension may have increased the intra-abdominal pressure, thus prompting the weakened diaphragm to rupture. We cannot determine the exact order of these incidents with any certainty. However, for whatever reason, the perforation of the duodenal ulcer seems to have acted as the precipitating event for the diaphragmatic rupture. Roughly 90% of diaphragmatic ruptures occur on the left side[1,2]. Right-sided diaphragmatic ruptures are comparatively rare and difficult to diagnose, as chest radiography often does not reveal any specific signs other than elevation of the right diaphragmatic border. Accordingly, delayed diagnosis is common in right-sided ruptures, often resulting in severe complications, such as strangulation ileus and intrathoracic herniation of the hollow organs (stomach, colon, and small bowel)[2,3].

The initial diagnostic tool is conventional chest radiography, though this modality has limited sensitivity and specificity (17%-40%). Currently, CT is most helpful for emergency diagnosis, as the coronal and sagittal reformatted images offer superior diagnostic value for right diaphragmatic rupture, with a specificity of nearly 100% and a sensitivity of 50%[7,8].

Cases of right diaphragmatic rupture with hepatothorax may result in severe atelectasis of the right lung or tension mediastinum, thereby severely impeding respiration and circulation. As such, if concern exists for right diaphragmatic rupture, an abdominal CT should be performed quickly, and surgical repair via a trans-thoracic or trans-abdominal approach should be considered immediately following radiographic confirmation. Because the size of the defect is often too large for a primary repair to be performed, prosthetic mesh may prove necessary[9,10]. Mesh infection was a significant concern in the case described here, given the intra-abdominal and intra-thoracic contamination from the bowel perforation. Fortunately, such complications did not occur and were likely prevented by the extensive irrigation and intensive antibiotic therapy.

Abstract

Crohn's disease is a granulomatous systemic disorder of unknown etiology. Obvious pulmonary involvement is exceptional. Tracheal involvement in Crohn's disease is even more unusual, only a few cases have been reported to date. We herein report a rare case of tracheobronchial nodules and pulmonary infiltrates in both lungs as a complication of Crohn's disease. A 42-year-old man underwent pancolectomy for multiple broken colon caused by Crohn's disease. Forty days later pulmonary symptoms and radiologic abnormalities were noted. A search for bacterial (including mycobacteria) and fungal in the repeated sputum proved negative. The treatment consisted of intravenous antimicrobials for one month, but there was no improvement in pyrexia or cough and radiologic abnormalities. Fibreoptic bronchoscopy (FOB) was performed and revealed nodes in the trachea and the right upper lobe opening. Histopathology of tracheobronchial nodules and bronchial mucosa biopsy specimen both showed granulomatous inflammation with proliferation of capillaries and inflammatory cells. Oral steroid and salicylazosulfapyridine were commenced and led to marked improvement in symptoms and an almost complete resolution of his chest radiograph. Repeated FOB showed that nodes in the trachea disappeared and the ones in the right upper lobe opening diminished obviously. Crohn's disease can be associated with several respiratory manifestations. The form of tracheal and bronchopulmonary involvement in Crohn's disease is rare and responded well to steroids.

INTRODUCTION

Crohn's disease has long been recognized to cause both intestinal and extraintestinal complications. Extra-intestinal manifestations occur in at least 25% of Crohn's disease patients[1]. Although some papers have reported respiratory tract involvement in Crohn's disease, such as tracheobronchitis[2], tracheobronchial stenosis[3], upper bronchial pseudotumors and stenosis[4], granulomatous bronchiolitis[5], reports of involvement in both respiratory tract and lung parenchyma in Crohn's disease are very rare. We describe a patient with Crohn's disease who presented with tracheobronchial nodules and pulmonary infiltrates.

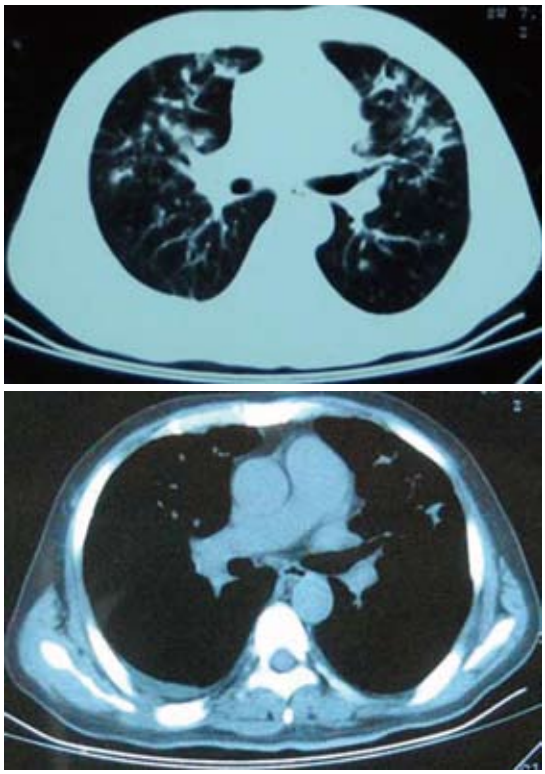

Figure 1 Computed tomography scan of the thorax (January 19, 2009), showing multiple patchy shadows in both lung fields with a little right pleural effusion.

Figure 2 Fibreoptic bronchoscopy (March 9, 2009), showing nodes in the right upper lobe opening.

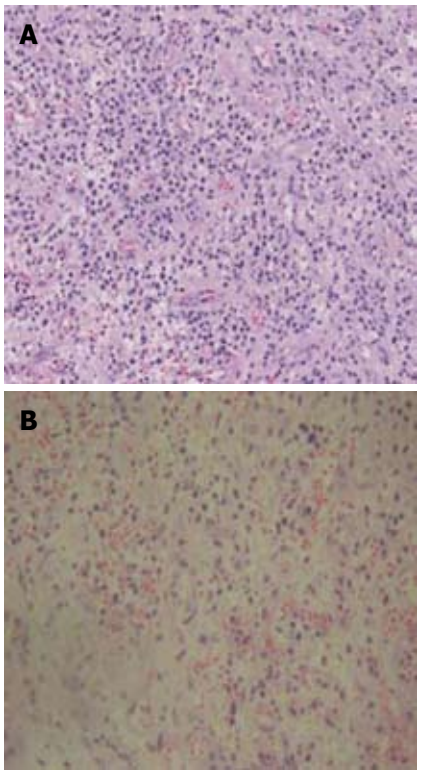

Figure 3 Transfiberoptic bronchoscopy mucosal biopsy, showing polypoid hyperplasia of granulation tissue and hyperplasia of capillary with inflammatory cells (hematoxylin and eosin stain, ×200). A: Tracheobronchial nodules; B: Left lingular lobe.

CASE REPORT

A 42-year-old man was admitted to our department because of a slow onset of cough and pyrexia in January 19, 2009. Forty days prior to this presentation, severe abdominal pain and diarrhea led to his referral to abdominal computed tomography (CT) that revealed free gas under the diaphragm. The patient underwent celiotomy. During operation, multiple broken colon was identified and pancolectomy was performed. The pathology of resected specimen revealed Crohn's disease of colon. His symptoms were resolved after the operation. On admission, he was expectorating about 20 mL of grossly frothy sputum per day and he had a pyrexia of 37.7 ℃. Laboratory data on admission were: white cell counts 8.5 × 10^9/L, 63% segmented neutrophils, a moderate increase of erythrocyte sedimentation rate (30 mm in the first hour). A CT scan of the chest revealed bilateral lung patchy shadows (Figure 1). Initial treatment consisted of intravenous azithromycin (0.5 g, once a day) with aztreonam (2.0 g, twice a day) for 2 wk. A search for bacterial (including mycobacteria) and fungal in the repeated sputum proved negative. The purified protein derivative skin test and cytoplasmic-antineutrophil cytoplasmic antibodies (c-ANCA) were also negative. Intravenous cefoperazone/sulbactam (3.0 g, twice a day) was substituted for 2 wk, but there was no improvement in pyrexia or cough, and his chest CT revealed no dissipation. On day 36 after admission, the patient underwent fibreoptic bronchoscopy (FOB) which showed nodes in the trachea and the right upper lobe opening (Figure 2). Transbronchial lung biopsy was performed in tracheobronchial nodules and left lingular lobe. Histopathology of tracheobronchial nodules and bronchial mucosa biopsy specimen both showed granulomatous inflammation with proliferation of capillaries and inflammatory cells (Figure 3). Fibercoloscope was performed in the following day, which showed cobblestones in the residual sigmoid colon. On day 55, antibiotic treatment was discontinued and the patient was started on prednisone 50 mg daily and salicylazosulfapyridine (SASP) (1.0 g, four times a day) for a presumptive

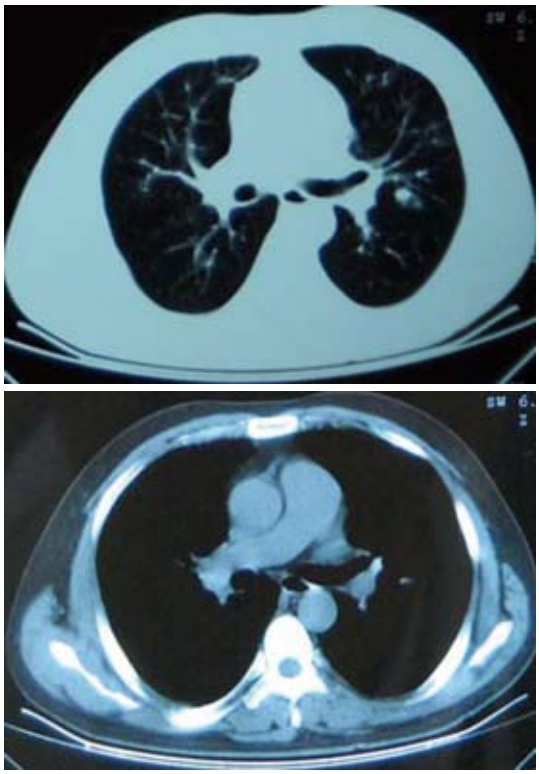

Figure 4 Computed tomography scan of the thorax (April 5, 2009), showing multiple patchy shadows in both lung fields almost disappeared.

diagnosis of Crohn's disease related tracheobronchial nodules and tracheobronchitis associated with pulmonary infiltrates. Within 48 h, the patient's temperature turned normal. There was improvement in cough and the volume of sputum being expectorated a week later. A follow-up CT 3 wk later showed disappearance of the bilateral patchy shadows (Figure 4). He underwent repeated FOB in the following day which showed that nodes in the trachea disappeared and the ones in the right upper lobe opening diminished obviously (Figure 5).

DISCUSSION

Crohn's disease is a granulomatous inflammation of unknown etiology that mainly affects the small bowel, although extracolonic manifestations are common. Extraintestinal manifestations occur in at least 25% of Crohn's disease patients, most commonly in the skin and genitourinary system[6]. It has been rarely reported in the lung. The overall prevalence of concomitant bronchopulmonary manifestations is as low as 0.4%[7]. Several forms of involvement of the lung parenchyma are recognized[8-11]. Diffuse, nongranulomatous interstitial inflammatory lymphoid infiltration has also been described in Crohn's disease[12].

The clinical features of extraintestinal involvement in our patient seem to be interesting for several reasons. Both tracheal-bronchus and lung parenchyma are involved. Transfiberoptic bronchoscopy biopsy of the tracheobronchial nodules and bronchial mucosa in the

Figure 5 Fibreoptic bronchoscopy (April 6, 2009), showing nodes in the right upper lobe opening diminished obviously.

left lingular lobe revealed a benign, nongranulomatous inflammation with proliferation of capillaries and inflammatory cells. Although tracheobronchial involvement in Crohn's disease has been described in literature, the extent of involvement seen in the current patient with nodules in trachea and right upper lobe bronchus, seems quite unusual. There are few previous reports of tracheobronchial nodules. Crohn's disease can involve the lung parenchyma, the tracheobronchial tree, and the pleura[13]. The patient underwent colectomy prior to admission. The pulmonary manifestations of Crohn's disease in some patients may only become clinically remarkable after surgery[14]. Colectomy may aggravate respiratory symptoms[15]. However, the pathogenesis of Crohn's disease-related airway disease remains unknown. It may involve an inflammatory component because a large proportion of these patients are responsive to steroid therapy. The lung and the gastrointestinal tract have a similar embryological origin (a potential source of common antigenicity), and some authors considered a breakdown in the intestinal barrier and entry of dietary antigens as the cause of extracolonic involvement in Crohn's disease[16]. One proposed mechanism is that many of the extraintestinal manifestations of Crohn's disease, including lung disease, are secondary to circulating inflammatory mediators released by the inflamed bowel mucosa[17]. These inflammatory mediators may survive in the pulmonary system for a long time, causing smoldering injuries. This explains the development of pulmonary disease after colectomy in some of the patients with Crohn's disease.

Clinically, when assessing the relationship between respiratory disease and Crohn's disease, one should always keep in mind that the two conditions may have occurred together simply by chance, and therefore other differential diagnoses should be made, such as sarcoidosis, a systemic vasculitis (Wegener's granulomatosis or Churg-Strauss disease), or a prior pulmonary process. In the current patient, the diagnosis of Crohn's disease was initially clearly established on histological grounds of the resected bowel specimen. Although sarcoidosis and Crohn's disease may coexist in the same patient[18], the absence of typical sarcoid granulomata in tracheobron-

chial biopsies, and the lack of evidence for extrapulmonary sarcoid involvement led the authors to rule out sarcoidosis. In view of the absence of histological findings suggestive of Wegener's granulomatosis, the lack of c-ANCA and no extrapulmonary involvement, the diagnosis of Wegener's granulomatosis was unlikely. Post-obstructive pneumonia results from airway obstruction, commonly due to lung cancer. A mismatch in scope of bilateral and diffuse lung infiltrates with tracheobronchial nodules excluded a diagnosis of post-obstructive pneumonia.

The initial lesion of tracheobronchial Crohn's disease seems to be mucosal inflammation, with symptoms of cough and pyrexia[19]. Mucosal inflammation may be accompanied by bronchial suppuration. Biopsy shows either severe nonspecific chronic inflammation or non-caseating tuberculoid granulomas. These appearances have been associated with those in the bowel, and it is possible that the gut and the lung are both affected because they share common antigens. The lung and gastrointestinal tract contain submucosal lymphoid tissues and play crucial roles in host mucosal defense. The similarity in the mucosal immune system causes the same pathogenetic changes. The clinical courses between upper airway and gastrointestinal tract disease are not entirely parallel[20]. It was thought that the tracheobronchial nodules and pulmonary infiltrates were both caused by Crohn's disease, because the pathological finding resembled that of the colon. In addition, they almost vanished as good response to steroids while multiple antibiotic regimens failed to produce clinical improvement.

Drug-induced disease must be kept in mind in patients taking sulfasalazine, mesalamine, methotrexate, and anti-tumor necrosis factor-alpha. Sulfasalazine and 5-aminosalicylic acid derivatives have been reported to cause interstitial pneumonitis, eosinophilic pneumonia, or bronchiolitis obliterans organizing pneumonia in rare cases[21,22]. Other commonly used medications in inflammatory bowel disease patients include 6-mercaptopurine, azathioprine, and methotrexate. These drugs may also cause pneumonia *via* opportunistic infections, or acute pneumonitis or pulmonary fibrosis[23]. Lung abnormalities observed in our patient were unrelated to pharmacological treatment.

Patients with pulmonary involvement of Crohn's disease can be cured with glucocorticoid and SASP, for they are strikingly steroid-responsive frequently. Pulmonary manifestations almost vanished after receiving oral prednisone and SASP in the present case. In all patients with airway disease, marked and long-lasting responses were seen following systemic or inhaled administration of steroids. These findings were not commonly observed for patients with chronic bronchitis without Crohn's disease. Intravenous steroids were required in the initial management of life-threatening complications such as asphyxiating subglottic stenosis or extensive interstitial lung disease. Bronchial lavages with methylprednisolone were effective in some patients with severe airway inflammation. Bronchoscopic dilatation or stent placement should be considered in cases of tracheal stenosis due to Crohn's disease refractory to steroid treatment[24]. Other interventional pulmonology techniques, such as bronchoscopic resection or ablation, could not be generally indicated for treatment modalities potentially contraindicated because of the risk of stenosis or fistula.

In summary, this case illustrates a rare form of tracheal and bronchopulmonary involvement in Crohn's disease with nodes and multiple patchy shadows in both lung fields. As is the case with other forms of pulmonary involvement in Crohn's disease, this manifestation responded well to steroids. It is believed that early investigation and vigorous treatment of bronchopulmonary involvement of Crohn's disease is essential.

Abstract

Endoscopic sphincterotomy (EST) is considered as a possible etiological factor for severe cholangitis. We herein report a case of severe cholangitis after endoscopic sphincterotomy induced by barium examination. An adult male patient presented with epigastric pain was diagnosed as having choledocholithiasis by ultrasonography. EST was performed and the stone was completely cleaned. Barium examination was done 3 d after EST and severe cholangitis appeared 4 h later. The patient was recovered after treated with tienam for 4 d. Barium examination may induce severe cholangitis in patients after EST, although rare, barium examination should be chosen cautiously. Cautions should be also used when EST is performed in patients younger than 50 years to avoid the damage to the sphincter of Oddi.

INTRODUCTION

Endoscopic retrograde cholangiopancreatography (ERCP) is an important diagnostic technique for biliary and pancreatic diseases. Endoscopic sphincterotomy has become a well established modality for common bile duct (CBD) stones[1,2]. However, endoscopic sphincterotomy is considered as a possible etiological factor for recurrent ascending cholangitis[3,4]. Here we report a case of severe cholangitis after endoscopic sphincterotomy induced by barium examination, and the patient was recovered after treatment with tienam.

CASE REPORT

A 40-year-old man presented with dull aching epigastric pain for 2 wk. He had a history of CBD stones for 2 years. The patient was averagely built and nourished. No jaundice was present. Biochemical parameters were all

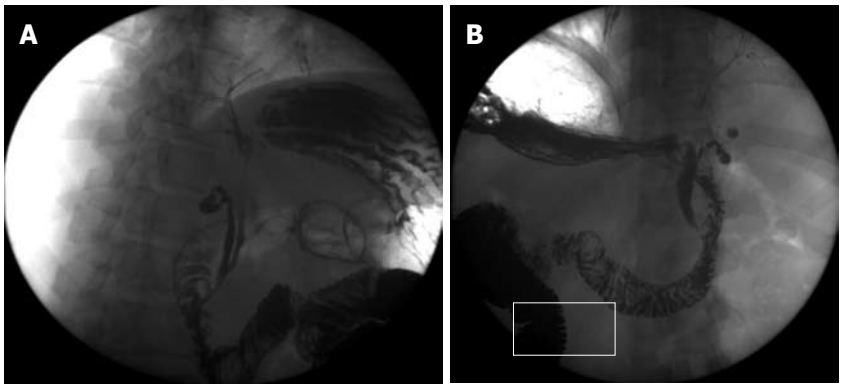

Figure 1 Barium refluxed into the biliary tree of the patient after endoscopic sphincterotomy.

within normal limits. Total white blood cell (WBC) count and hemoglobin measurement were normal. Liver function tests showed that serum bilirubin was 13.5 μmol/L, alkaline phosphatase 55 U/L, aspartate aminotransferase (AST) 40 U/L and alanine aminotransferase (ALT) 35 U/L. Ultrasonography revealed CBD stones in the ampulla of vater and a dilated CBD of 12 mm in diameter. ERCP displayed a dilated CBD. Endoscopic sphincterotomy (EST) was performed in the Second Affiliated Hospital of China Medical University and stones were removed from the biliary tract. The general condition of the patient was good except for slight dull epigastric pain.

To rule out the disease of stomach, barium examination was made 3 d after EST. In the process of barium examination, barium could be seen refluxed into the biliary tree (Figure 1). Four hours later, the patient had a high fever and chills, and the body temperature was climaxed to 39.8 ℃. On investigation, total WBC count was increased to 22.45 × 10^9/L, and hemoglobin was normal. Liver function tests showed serum bilirubin 33.5 μmol/L, alkaline phosphatase 155 U/L, AST 143 U/L and ALT 235 U/L, urine amylase 85 U/L and blood amylase 110 U/L. Ultrasonography showed a dilated CBD and no specific manifestation of the pancreas. Severe cholangitis after endoscopic sphincterotomy induced by barium examination was then diagnosed. The patient was recovered after treated with tienam for 4 d. He is still alive 5 years after the treatment, but suffered from 1-3 recurrent episodes of reflux cholangitis each year.

DISCUSSION

Endoscopic papillotomy with stone extraction continues to be a therapeutic choice and the reference standard in the treatment of symptomatic choledocholithiasis, especially for the solitary bile duct stones up to 12 mm in diameter. The overall success rate with EST was 95.7% in the present report. The most frequent complication encountered was bleeding, followed by acute pancreatitis, acute cholangitis, and perforation[5,6]. It has been found recently that the incidence of acute biliary pancreatitis may be lowered by pancreatic duct stenting[7].

After endoscopic sphincterotomy, the biliary sphincter is rendered permanently insufficient. The loss of this physiologic barrier between duodenum and biliary tract results in duodenocholedochol reflux and bacterial colonization of the biliary tract. Our previous study showed that about 35.9% of the patients with a T-tube after cholecystectomy and choledochotomy had duodenal-biliary reflux. Most of them had hypomotility of the sphincter of Oddi[8]. After EST, biliary reflux of duodenal chyme occurs in most patients, aerobilia is seen in about half, and bacterobilia in all the patients[9,10]. Most patients with bacterobillia did not inevitably develop symptomatic recurrent cholangitis, but 20% patients had upper abdominal pain during the follow-up of about 36 mo[11]. Another study showed that 65% patients after EST had duodenobiliary refux, detected by barium studies, although no clinical symptoms were observed [12]. The presence of bacteria in the biliary system, which is sterile under physiologic conditions, might lead to complications after EST. Misra *et al*[13] studied the incidence of duodenobiliary reflux and acute cholangitis after placement of self-expanding metal stent across the main duodenal papilla, and found that severe reflux of barium was evident in all the patients. However, none of them developed acute cholangitis because of reflux.

To avoid the damage to the biliary sphincter, endoscopic papillary balloon dilation (EPBD) was introduced as a less traumatic alternative to EST in the management of biliary tract stones[14]. However, a high incidence rate of procedure-induced pancreatitis was reported[15]. But, more recently, May *et al*[16] and Mathuna *et al*[17] found that the complication rates of pancreatitis by EPBD were similar to those by EST. Toda *et al*[18] studied the early results of EST and EPBD and found no difference in the early complications between EST and EPBD. The incidence rates of cholangitis by EST and EPBD were 4.0% and 4.2%, respectively. Yasuda *et al*[19] showed that preservation of papillary function after EPBD was not complete, but remained somewhat reduced. Preservation was more successful with EPBD than with EST. The incidence of pneumobilia was significantly higher in post-EST than in post-EPBD patients. Yasuda *et al*[20] also found that during long-term follow-up, patients who underwent endoscopic sphincterotomy (ES) had significantly more biliary complications than those who underwent EPBD. The biliary sphincter dysfunction after ES results in additional late complications.

Reflux of duodenal contents into the biliary tract af-

ter EST was the consequence of reduction or abolition of sphincter activity, as documented by manometry even 15 years following the sphincterotomy[21]. One study found that sphincterotomy was associated with a 5-fold higher incidence of recurrent brown CBD stones compared with choledocholithotomy[22]. One study reported the potentials of endoscopic papillary large balloon dilatation (EPLBD) with minor EST for the complete removal of CBD stones and found that the recurrence of CBD stones was especially low in cases of periampullary diverticulum treated with EPLBD by minor EST[23].

In our patient after EST, severe cholangitis occurred 4 h after gastrointestinal barium X-ray examination was done. In the process of barium examination, barium refluxed to the CBD, gallbladder and intrabiliary bile duct. Barium examination may induce severe cholangitis in patients after EST. Although the incidence is low, we should avoid early barium examination in patients after EST. The patient was younger than 50 years, if choledochotomy was performed and the sphincter of Oddi was preserved, reflux cholangitis might not occur.

In conclusion, EST, as a standard treatment of choledocholithiasis, destroyed the integrity of sphincter of Oddi which may induce reflux cholangitis. As a motivation factor, barium examination may induce severe cholangitis in patients after EST, although rare, it should be performed cautiously. Cautions should also be used when EST was performed in patients younger than 50 years to avoid the damage to the sphincter of Oddi.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/esps/. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/…"), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$), and CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

15 Morse SS. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: http://www.cdc.gov/ncidod/eid/index.htm

Patent (list all authors)

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to esps@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted original articles are suggested to write science news to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for science news should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Enhanced recovery after surgery (ERAS) employs a multimodal perioperative care pathway with the aim of attenuating the stress response to surgery and accelerating recovery. It has been difficult to determine the relative importance of some of the individual components of these pathways such as epidural analgesia and laparoscopic colorectal surgery. Some argue that only a rigid adherence to the published ERAS protocol can achieve the proposed benefits of fast-track surgery. In this article, we explore some of the areas where the evidence base may be changing and ask whether a more flexible and individualised approach should be considered.

INTRODUCTION

Enhanced recovery after surgery (ERAS) or "fast track surgery" is a concept first described by Kehlet[1] in the early 1990's. The approach employs a multimodal perioperative care pathway with the aim of attenuating the stress response to surgery and accelerating recovery[2]. Implementation of enhanced recovery protocols has led to improved outcomes across a range of different specialties including reductions in postoperative morbidity and hospital stay[3-5].

The fundamental premise of ERAS is the incorporation of evidence-based practice. It would seem to follow therefore that the evolution of enhanced recovery guidelines should be dynamic, allowing modifications of certain aspects of the program as new data becomes available. Some authors have advocated a rigid adherence to the ERAS protocol, citing study data that demonstrates a proportional relationship between deviation from the protocol and increased morbidity[6]. However, as evidence for components of the ERAS protocol change, it may be that a more flexible and individualised approach should be considered.

PERIOPERATIVE FLUID ADMINISTRATION

Traditionally, patients undergoing major colorectal surgery have received liberal volumes of intravenous fluids[7]. Excess intravenous fluid during and after surgery has been associated with delayed gut function and increased complication rates[8-10]. Fluid restriction has been proposed as a possible method of improving recovery and reducing postoperative complications. Brandstrup *et al*[10] found that randomising patients undergoing elective colorectal

resection to a restricted fluid protocol reduced cardiopulmonary and wound morbidity. MacKay *et al*[11] found no difference in recovery of gastrointestinal function or time to discharge with postoperative fluid restriction while using a conservative intra-operative protocol.

Goal directed fluid therapy *via* oesophageal Doppler (OD) monitoring offers an opportunity to individualise peri-operative fluid administration. OD provides a real time representation of haemodynamic function, and has been shown to be comparable with other methods for estimating cardiac output such as LIDCO. A number of studies have shown that goal-directed fluids reduce morbidity, critical care admissions,and hospital stay[12]. It is not clear however whether these benefits are still significant within an enhanced recovery protocol.

Other goal-directed techniques employ central venous oxygen saturation ($ScvO_2$) as a surrogate for mixed venous oxygen saturation. $ScvO_2$ is related to tissue oxygenation and so can be used to titrate oxygen and fluid therapy, particularly in the immediate postoperative period. This approach requires central venous access which is not always available as some groups have developed a less invasive approach to monitoring. While a number of different fluid protocols have been proposed, the optimal approach is still unclear.

EVOLVING POSTOPERATIVE ANALGESIA

Epidural analgesia was considered central to early ERAS protocols, since it reduces the endocrine-mediated stress response[13,14], and improves postoperative intestinal function[15]. Epidural analgesia also provides superior pain control to systemic opiates, particularly in the first 24-36 h after surgery[16]. Data on the effect of epidural analgesia come predominantly from studies in open surgery while the benefits in laparoscopic surgery are less clear. Levy *et al*[17,18] performed a meta-analysis to address this question but concluded that there was a paucity of quality data. The authors subsequently performed a study in which patients were randomised to receive epidural, spinal or patient-controlled opiate analgesia following elective laparoscopic colorectal resection. They demonstrated a significantly longer hospital stay, time to return of bowel function and duration of nausea in the epidural group. Intra-thecal morphine has been proposed as an alternative[19]. A meta-analysis provides encouraging results in patients undergoing abdominal surgery; reduced post-operative pain in the first 48 h and significantly reduced opiate consumption compared with systemic opiates[20]. Transversus abdominus plane blocks have also been gaining in popularity although comparative data is still lacking[21].

Epidurals can cause vasodilatation and hypotension[22], resulting in excess fluid challenges, third space shift and fluid overload. As studies emerge demonstrating benefits of alternative analgesic techniques, it does raise the question: Should epidural analgesia be the standard technique for all colorectal resections? Perhaps a more individualised approach dependent on the procedure, use of laparoscopy and placement of incisions should be considered. In this way more patients may be able to avoid potential complications while maintaining adequate analgesia and facilitating early mobilisation.

LAPAROSCOPIC AND OPEN SURGERY IN ENHANCED RECOVERY

The adoption of laparoscopic techniques within colorectal surgery came at a similar time to the introduction of "fast-track" surgery. Early studies examining the effect of laparoscopic surgery showed clear superiority in short term outcomes when compared with open surgery using traditional recovery technique[23,24]. Patients undergoing laparoscopic surgery have reduced in-patient stays, less morbidity and improved postoperative pain[25,26]. What is less clear is how much of the benefit is attributable to laparoscopy and how much is an effect of differing peri-operative care pathways.

Since these early trials there have been a number of small trials comparing laparoscopic and open colorectal surgery within an enhanced recovery setting with conflicting results[11,26-28]. Most recently, Vlug *et al*[29] performed a four-armed randomised study of patients undergoing either open or laparoscopic surgery, in an enhanced recovery or standard recovery programme. They demonstrated a significantly faster recovery time following colonic surgery in those patients undergoing laparoscopic procedures within an ERAS programme.

What is clear is that there are still a number of areas within the enhanced recovery protocol where the evidence-base continues to change. The relative contributions of different facets of the protocol also remain to be determined. While this is the case we should accept a flexible approach to facilitate the adoption of techniques supported by randomised data. There may also be scope for a degree of individualisation to reflect the wide range of patients and procedures to which enhanced recovery is now being applied.

Abstract

Crohn's disease and ulcerative colitis, the major forms of inflammatory bowel diseases (IBD) in man, are complex diseases in which genetic and environmental factors interact to promote an excessive mucosal immune response directed against normal components of the bacterial microflora. There is also evidence that the pathologic process is due to defects in counter-regulatory mechanisms, such as those involving the immunosuppressive cytokine transforming growth factor (TGF)-β1. Indeed, studies in human IBD tissues and murine models of colitis have documented a disruption of TGF-β1 signalling marked by a block in the phosphorylation of Smad3, a signalling molecule associated with the activated TGF-β receptor, due to up-regulation of Smad7, an intracellular inhibitor of Smad3 phosphorylation. Knock-down of Smad7 with a specific antisense oligonucleotide restores TGF-β1/Smad3 signalling, thus resulting in a marked suppression of inflammatory cytokine production and attenuation of murine colitis. These findings together with the demonstration that Smad7 antisense oligonucleotide is not toxic when administered in mice have paved the way for the development of a Smad7 antisense oligonucleotide-based pharmaceutical compound that is now ready to enter the clinics. In this article we review the available data supporting the pathogenic role of Smad7 in IBD and discuss whether and how Smad7 antisense therapy could help dampen the ongoing inflammation in IBD.

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC), the major forms of inflammatory bowel diseases (IBD) in humans, are chronic inflammatory disorders of the gastrointestinal tract. In CD, the inflammation is typically transmural and can affect the gastrointestinal tract anywhere from the mouth to the anus. In contrast, the inflammatory lesion in UC is restricted to the mucosa and extends proximally from the rectum to involve all or part of the colon[1]. The cause of both IBD remains unknown even though there is evidence that the pathologic process results from the interaction of genetic, environmental and immunological factors[2-5]. Studies conducted in experimental models of colitis also suggest that IBD-associated tissue damage is due to an excessive immune response directed against to normal constituents of the bacterial microflora, which is inappropriately controlled

by counter-regulatory mechanisms[6,7]. An example of such mechanisms is that involving transforming growth factor (TGF)-β1, a pleiotropic cytokine with potent immune-suppressive activity. Indeed mice deficient in TGF-β1 or unable to respond to the cytokine develop intestinal inflammation[8-11], while induction of TGF-β1 protects or attenuates colitis in some murine models of IBD[12-14]. TGF-β1 activity is mediated by binding of the cytokine to a heterodimeric transmembrane serine/threonine kinases receptor, consisting of type Ⅰ (TGF-βRⅠ) and type Ⅱ (TGF-βRⅡ) subunits[15,16]. In particular, binding of TGF-β1 to TGF-βRⅡ promotes phosphorylation and activation of TGF-βRⅠ, which in turn phosphorylates/activates Smad2 and Smad3. These two Smad proteins form then a heterocomplex with Smad4, which translocates to the nucleus and regulates the functional activities of many target genes[15-17]. Smad3-deficient mice exhibit a diminished cell responsiveness to TGF-β1 and spontaneously develop a chronic inflammation in the stomach and colon, supporting the anti-inflammatory role of TGF-β1-associated Smad3 in the gastrointestinal tract[18]. In this article we review the current information on the activity of TGF-β1 in IBD and murine models of colitis and discuss data showing that restoring TGF-β1 signaling is sufficient to dampen intestinal inflammation.

DEFECTIVE TGF-β1 ACTIVITY ASSOCIATES WITH HIGH SMAD7 IN IBD

Active TGF-β1 is highly produced in the human gastrointestinal tract of healthy individuals and supposed to play a decisive role in negatively controlling inflammatory pathways[19]. Lamina propria mononuclear cells (LPMC) isolated from the normal human colon express high levels of phosphorylated (p)-Smad3, and respond to exogenous TGF-β1 with a marked inhibition of inflammatory cytokines[19]. On the other hand, neutralization of endogenous TGF-β1 in cultures of normal mucosal explants and LPMC results in enhanced synthesis of inflammatory cytokines[19]. A different scenario emerges when p-Smad3 is analyzed in LPMC and tissue samples of patients with IBD. Indeed, in both CD and UC, phosphorylation of Smad3 is markedly reduced as compared to normal controls, despite TGF-β1 is produced at high level in these patients[20,21]. Moreover, IBD LPMC do not phosphorylate Smad3 and produce huge amounts of inflammatory cytokines when stimulated with exogenous TGF-β1[20-22].

The Smad family also includes two Smad inhibitors, namely Smad6 and Smad7. Smad7 associates stably with the ligand-activated TGF-β1R I complex and blocks phosphorylation of Smad2/Smad3[15,23]. Attenuation of TGF-β1 signaling by Smad7 is also dependent on the ability of Smad7 to induce degradation of TGF-β1RI after recruitment of E3 ubiquitin ligases and to recruit protein phosphatase 1 to the receptor complex *via* interaction with growth arrest and DNA damage protein 34[24]. Since up-regulation of Smad7 associates with inhibition of TGF-β1-induced Smad2/3 activation, we explored the possibility that the diminished activation of TGF-β1-associated Smad signaling in IBD could be related to high Smad7. To this end, we examined Smad7 in the same intestinal samples analyzed for Smad3 phoshorylation. Smad7 was over-expressed in whole mucosal and LPMC samples of CD patients and UC patients as compared to controls[20]. Interestingly, silencing of Smad7 with an anti-sense oligonucleotide restored the responsiveness of IBD LPMC to exogenous TGF-β1, as indicated by the enhanced phosphorylation of Smad3 and diminished synthesis of inflammatory cytokines[20]. Similar results were seen in *ex-vivo* organ cultures of CD mucosal explants, in which inhibition of Smad7 with antisense oligonucleotide associated with high Smad3 phosphorylation and decreased inflammatory cytokine production. These effects were blocked by a neutralizing TGF-β1 antibody, clearly indicating that Smad7 knockdown allows endogenous TGF-β1 to act and suppress inflammatory signals[20].

High Smad7 expression and defective TGFβ-associated Smad3 activation are not however specific hallmarks of IBD, because similar alterations were documented in the stomach of patients with *Helicobacter pylori*-related gastritis[25]. By contrast, Smad7 expression is not up-regulated in the duodenum of patients with active celiac disease[26], raising the possibility that induction of Smad7 in the gut is not an epiphenomenon of the ongoing inflammation but rather can reflect changes in the local inflammatory milieu.

SMAD7 EXPRESSION IS POST-TRANSCRIPTIONALLY REGULATED IN IBD

Further experimentation was performed to understand how Smad7 expression is regulated in IBD. Since experiments with cell lines have shown that Smad7 can be induced by activators of nuclear factor-κB [e.g., tumor necrosis factor (TNF)-α and interleukin (IL)-1β] and STAT-1 [e.g., interferon (IFN)-γ and IL-7] and these transcription factors are hyper-activated in IBD[20,27], we initially hypothesized that Smad7 in CD and UC tissue was regulated by these signaling pathways. However, functional studies showed that Smad7 protein expression remained unchanged in IBD LPMC following treatment with IFN-γ/Stat1 or TNF-α/NF-kB inhibitors[20,27]. Smad7 is also rapidly induced by TGF-β1-driven Smad3 signaling, thus representing an important effector in the feedback loop that restrains TGF-β1 activity[23]. We feel however it is unlikely that high Smad7 is induced by TGF-β1 in IBD, because p-Smad3 was reduced in samples exhibiting enhanced Smad7 expression[20]. Analysis of Smad7 RNA expression revealed that IBD and control samples contained similar levels of transcripts, raising the possibility that, in IBD, Smad7 is post-transcriptionally regulated[28]. Indeed, Smad7 was found to be ubiquitinated and targeted for proteasome

degradation in control but not IBD samples. Difference in the level of ubiquitination of Smad7 between IBD and controls seems to be secondary to the different status of acetylation of the protein, because acetylation and ubiquitination compete for the same lysine residues of Smad7[29,30]. Thus, acetylation prevents ubiquitination and protects Smad7 protein against proteasomal degradation[27]. Smad7 was highly acetylated *in vivo* in IBD but not control samples[28]. We have also shown that in IBD, the transcriptional coactivator p300 interacted with and promoted Smad7 acetylation, and that silencing of p300 diminished acetylation and expression of Smad7[28].

INHIBITION OF SMAD7 ATTENUATES GUT INFLAMMATION IN MICE

The mouse models of Th1 or Th2-mediated colitis induced by intra-rectal administration of trinitrobenezene sulfonic acid (TNBS) or oxazolone and showing immunological similarities with CD or UC, respectively[13,31,32], were used to confirm the inflammatory role of Smad7. In both these models, colitis was marked by enhanced production of TGF-β1, reduced phosphorylation of Smad3 and high expression of Smad7[33]. Oral Smad7 antisense oligonucleotide was taken-up by epithelial cells and LPMC in the small intestine and colon and induced no toxicity. This treatment reduced Smad7 and restored TGF-β1-associated p-Smad3 expression and ameliorated both forms of colitis[33]. Analysis of inflammatory cytokines in the colon of treated mice revealed that restoration of TGF-β1 signaling by inhibition of Smad7 resulted in a significant down-regulation of IL-12 and IFN-γ and reduced expression of Th1-associated transcription factors (i.e., T-bet and Stat1) in TNBS-colitis, and reduced production of IL-4 in mice with oxazolone-induced colitis[33]. These studies suggest that resolution of gut inflammation may be accomplished by down-regulating Smad7 and allowing endogenous TGF-β1 to inhibit inflammatory pathways which promote tissue injury.

SMAD7 ANTISENSE IS SAFE AND TOLERATED IN PATIENTS WITH CD

Altogether the above data indicate that Smad7 is a molecular target for direct therapeutic interventions in IBD. To this end, we have recently developed a pharmaceutical compound containing the Smad7 antisense oligonucleotide and formulated it as a solid oral dosage form. The formulation is protected by an external coating, which allows the antisense oligonucleotide to transit through the stomach and proximal small intestine and reach the terminal ileum and right colon where the active compound is released[34]. To examine whether this drug was safe and tolerated, we conducted a phase 1, open-label study in patients with active, steroid-dependent/resistant CD. Fifteen patients were allocated to three treatment groups receiving oral Smad7 antisense oligonucleotide, once daily for 7 d at doses of 40, 80 or 160 mg. The drug was well-tolerated and no patient experienced serious adverse event (AE). Twenty-five AEs were registered in 11 patients, but the majority of AEs was mild and considered unrelated to treatment. Interestingly, treatment associated with a significant reduction in the fraction of circulating CCR9-positive T cells secreting IFN-γ and IL-17A[34]. This finding could be therapeutically relevant as CCR9-positive T cells represent a subset of inflammatory T cells with gut homing properties, which are increased in the active phases of CD[35]. Moreover, administration of Smad7 antisense oligonucleotide to patients resulted in a significant clinical benefit[34].

CONCLUSION

TGF-β1 plays a critical role in the control of gut immune homeostasis and therefore defects in the production and/or activity of the cytokine inevitably associate with pathological responses[8,9,36]. This is for example seen in the inflamed gut of IBD patients and mice with experimental colitis, where TGF-β1 is unable to signal and dampen inflammatory signals due to high Smad7, a protein which binds to TGF-βR and prevents TGF-β1/Smad3 signaling[20,21,33]. Such an alteration is not however irreversible, as knockdown of Smad7 with a specific antisense oligonucleotide restores TGF-β1 activity, inhibits inflammatory cytokine production and attenuates colitis in mice[20,33]. In line with this, results of an exploratory phase 1 trial, testing the Smad7 antisense oligonucleotide in active CD patients, have recently shown that the compound is safe and tolerable and that such treatment attenuates signs and symptoms of CD, supporting the pathogenic role of Smad7 in CD[34]. Appropriately designed placebo-controlled clinical trials will however be necessary to confirm the safety profile of this approach, show if Smad7 is a valid therapeutic target in CD, and examine the long-term risks of Smad7 knockdown. In particular, it would be relevant to exclude the possibility that restoring TGF-β1 activity favors the development of strictures[37], given that TGF-β1 is a powerful inducer of fibrogenesis in many organs[38-40]. TGF-β1 can also exert various effects on the cellular and molecular mechanisms involved in tumor development. In particular TGF-β1 can act as a tumor suppressor in early stages of tumorigenesis and promote advanced tumor cell invasiveness and metastasis[41-43]. Similarly, Smad7 may regulate differently tumorigenesis depending on the cell context analyzed. For example, over-expression of Smad7 promotes initiation of pancreatic cancer, skin cancer, scleroderma and lung cancer, associates with a worse prognosis in sporadic colorectal cancer (CRC)[44] and enhances liver metastasis in a murine model of CRC[45]. Moreover, genome-wide association studies have shown that common alleles of Smad7 can influence the risk of CRC[46] and that patients carrying on the rs12953717 single nucleotide polymorphism in the *SMAD7* gene

have increased risk of CRC. In contrast, Smad7 inhibits metastasis of human melanoma cells to bone and metastasis of human breast cancers to the lung or liver[47-50]. We have recently shown that over-expression of Smad7 in T cells and natural killer cells makes worse the course of experimental colitis yet protects from the development of colitis-associated colon-cancer[51]. Therefore, further experimentation will be also needed to ascertain if inhibition of Smad7 in the inflamed gut can enhance the risk of colitis-associated CRC.

Abstract

Worldwide prevalence of *Helicobacter pylori* (*H. pylori*) infection is approximately 50%, with the highest being in developing countries. We compared cure rates and tolerability (SE) of second-line anti-*H. pylori* levofloxacin/amoxicillin (LA)-based triple regimens *vs* standard quadruple therapy (QT). An English language literature search was performed up to October 2010. A meta-analysis was performed including randomized clinical trials comparing 7- or 10-d LA with 7-d QT. In total, 10 articles and four abstracts were identified. Overall eradication rate in LA was 76.5% (95% CI: 64.4%-97.6%). When only 7-d regimens were included, cure rate was 70.6% (95% CI: 40.2%-99.1%), whereas for 10-d combinations, cure rate was significantly higher (88.7%; 95% CI: 56.1%-109.9%; $P < 0.05$). Main eradication rate for QT was 67.4% (95% CI: 49.7%-67.9%). The 7-d LA and QT showed comparable efficacy [odds ratio (OR): 1.09; 95% CI: 0.63-1.87], whereas the 10-d LA regimen was significantly more effective than QT (OR: 5.05; 95% CI: 2.74-9.31; $P < 0.001$; $I^2 = 75\%$). No differences were reported in QT eradication rates among Asian and European studies, whereas LA regimens were more effective in European populations (78.3% *vs* 67.7%; $P = 0.05$). Incidence of SE was lower in LA therapy than QT (OR: 0.39; 95% CI: 0.18-0.85; $P = 0.02$). A higher rate of side effects was reported in Asian patients who received QT. Our findings support the use of 10-d LA as a simple second-line treatment for *H. pylori* eradication with an excellent eradication rate and tolerability. The optimal second-line alternative scheme might differ among countries depending on quinolone resistance.

Levofloxacin/amoxicillin-based schemes *vs* quadruple therapy for *Helicobacter pylori* eradication in second-line. *World J Gastroenterol* 2012; 18(40): 5669-5678 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i40/5669.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i40.5669

INTRODUCTION

Since 1982, when Warren and Marshall first discovered *Helicobacter pylori* (*H. pylori*) in the stomach, eradication of the infection has being recognized as crucial for prevention and treatment of gastroduodenal and more recently even extraintestinal diseases[1-4]. The worldwide prevalence of *H. pylori* infection is approximately 50%, with the highest being in developing countries[5]. Standard first-line therapy consists of a proton pump inhibitor (PPI) plus clarithromycin and amoxicillin or metronidazole[6] and achieves successful eradication in up to 80% of patients. During the past decade, an alarming decrease in eradication rates has been observed[7], mostly due to antibiotic resistance to clarithromycin and metronidazole[3,8]. Conversely, resistance to amoxicillin and tetracycline remains a rare occurrence worldwide[9-11]. Choice of a second or even third course of therapy is more controversial[6,9,12-14]. Recently, the concept of cumulative eradication rate has been introduced in treatment of *H. pylori* infection focusing on final cure rate after one or more courses of treatment. In this perspective, if the overall eradication rate is considered even after four consecutive empirical treatments, 99.5% of patients can be cured[15]. Currently, the recommended second-line regimen is a 7-14-d complex scheme consisting of PPI, bismuth, tetracycline and metronidazole[16,17]. However, bismuth salts, applied to decrease bacterial load, are no longer available in many countries[18]. Eradication rate of the quadruple regimen ranges from 65% to 80% and a high incidence of side effects are noted (up to 50% of patients), with consequently poor compliance[19-22]. For this reason, a triple therapy consisting of PPI, metronidazole and amoxicillin or tetracycline for a minimum of 7 d has been recommended as an alternative[6]. Meanwhile, new drugs, such as levofloxacin, rifabutin, furazolidone and azithromycin have been tested in various combinations and doses to overcome falling eradication rates[13,14,23-31].

Among those, levofloxacin-based second-line schemes represent the most promising alternative[32,33]. In particular, association with amoxicillin has been extensively studied, due to rare *H. pylori* resistance. Currently, a 10-d triple levofloxacin (250 mg BD)/amoxicillin (LA)-based therapy has been recommended as second-line therapy in Italy, and as third-line empirical treatment by European guidelines[6,16]. However, heterogeneity in terms of dosage, combination and duration of treatment do not allow a definitive conclusion.

Moreover, in consideration of differences in quinolone resistance among countries, the ideal second-line treatment for *H. pylori* infection may differ between areas, countries and races[10,20,34].

Here we compare eradication rates and tolerability exclusively of second-line anti-*H. pylori* LA-based triple schemes and standard quadruple therapy (QT) in European and Asian studies, in order to guide clinical decision making.

Studies providing information on use of anti-*H. pylori* LA-based triple therapy and standard quadruple scheme in second-line were identified through a systematic search in the MEDLINE and EMBASE databases by using various combinations of the terms "*H. pylori*", "levofloxacin", "amoxicillin", "quadruple", "bismuth", "second-line" and "rescue". Additionally, references of retrieved articles were screened for further studies (cross-referencing). We also performed a full manual search of all review articles, recently published editorials and all retrieved original studies presented at Digestive Disease Week, United European Gastroenterology Week, and European Helicobacter Study Group conferences. In addition, reference lists from relevant identified papers were manually searched. All original research articles and abstracts published until the 31 October 2010 were included. The search was limited to randomized controlled trials (RCTs) and studies comparing the two regimens (LA *vs* QT). Two investigators (Di Caro S and Fini L) independently extracted data by using a structured form. Only data from patients undergoing second-line eradication treatments were included in the analysis. There was a > 95% agreement in data extraction between the two investigators.

The following data were extracted from the articles: first author, year of publication, characteristics of study population (sample size, race, sex, age range and mean of study participants), therapy scheme (drugs, duration of treatment, dosage), intention-to-treat (ITT) and per-protocol eradication rates, incidence of side effects, discontinuation due to side effects.

Study outcomes for the meta-analysis were *H. pylori* eradication and incidence of adverse effects. Sub-analyses were performed comparing 7-d *vs* 10-d levofloxacin-based regimens in terms of efficacy and adverse events between European and Asian populations. Eradication rate analysis was based on ITT data. In the tolerability analysis, patients who discontinued treatment due to severe side effects were included.

The meta-analysis was performed using the Preferred Reporting Items for Systematic reviews and Meta-Analyses 2009 guidelines. Odds ratio (OR) was used as a measure of association, and summary ORs along with 95% CI were calculated based on a random-effects model using the DerSimonian and Laird methods. Heterogeneity was evaluated to establish if any clinical, methodological, or statistical variability existed among studies included. If significant heterogeneity existed, the random-effects model was used. Also, inconsistency statistic (I^2) was calculated to evaluate level of heterogeneity (0%-30%: homogeneity; 30%-50%: moderate heterogeneity; 50%-80%: substantial heterogeneity; > 80%: considerable heterogeneity). A pooled analysis was used to assess differences between levofloxacin regimens (7 d *vs* 10 d) and study populations. All statistical tests were two-sided and conducted at a significance level of 0.05. Independent academic biostatisticians from Baylor University Medical Center (Daoud Y) performed the statistical analysis. Data were analyzed with Review Manager (RevMan) 5.1 developed by the Cochrane collaboration.

[1]Demographic data were reported together for both arms. In studies including patients after failure of more than one therapy, extrapolated data on patients pre-treated in second-line are reported in parenthesis; in those cases demographic data are referred to the entire study population. Pts: Patients (total number); L + A: Levofloxacin/amoxicillin-based therapy; Days of therapy (tp): Duration of L + A scheme; UBT: Urea breath test; Q: Quadruple standard therapy; UD: Ulcer-like dyspepsia; DD: Dysmotility-like dyspepsia; RD: Reflux-like dyspepsia; N: Normal; OE: Esophagitis; G: Gastritis; GU: Gastric ulcer; D: Duodenitis; O: Other; FD: Functional dyspepsia; DU: Duodenal ulcer; A: Adenoma; E: Erosion; GA: Gastric atrophy; F: Family history; NA: Not available.

TEN-DAY LEVOFLOXACIN SECOND-LINE SCHEMES DISPLAY SIGNIFICANTLY HIGHER ERADICATION RATE AND LOWER INCIDENCE OF SIDE EFFECTS

Out of 79 titles initially generated by literature searches, 14 studies (10 articles and four abstracts) fulfilling the inclusion criteria were eligible for our analysis. All studies were published from September 2003 to May 2009 and included 677 patients in the LA-based triple therapy group and 608 subjects in the QT group. First-line therapy was a standard triple anti-*H. pylori* scheme. Tolerability data were available in seven articles. Demographic and clinical data of patients available are reported in Table 1. Studies were divided into two categories based on ethnicity of the study population (Asian and Caucasian population). In all studies, *H. pylori* infection was determined by ^{13}C urea breath test (UBT), rapid urea test, histology or culture before treatment, and histology and/or ^{13}C-UBT after administration of eradication therapy. Heterogeneity of data available on levofloxacin dose, ranging from 300 mg/d to 1 g/d (Table 1), does not allow a definitive conclusion.

Data on comparison of second-line levofloxacin-based triple regimens to bismuth-based QT after failure of one cycle of eradication therapy are listed in Table 2.

In our analysis, we extrapolated exclusively the data matching our strict inclusion criteria. We also re-calculated all the eradication percentages from the included studies. In all cases, the results matched the reported data, except one.

In an Italian population study, 10-d levofloxacin-based triple scheme in association with either amoxicillin or tinidazole, was superior to both 7-d and 14-d QT. Specifically, triple therapy eradication rates were 94% with amoxicillin *vs* 63% and 68% at 7 d and 14 d, respectively for QT. A high incidence of adverse events

Table 2 Levofloxacin-based second-line therapies *vs* quadruple bismuth-based regimens for *Helicobacter pylori* treatment

[1]Data arisen from abstract publication; [2]side effects calculated on the entire study population (not stratified for number of failed previous therapy). L: Levofloxacin; OD: Once daily; BD: Twice daily; LA/La: Levofloxacin/Lansoprazole; ITT: Intention-to-treat eradication rates; PP: Per-protocol; NA: Not available; LAR: Levofloxacin/amoxicillin/rabeprazole; LAO: Levofloxacin/amoxicillin/omeprazole; LAE: Levofloxacin/amoxicillin/esomeprazole; LAP: Levofloxacin/amoxicillin/pantoprazole.

(33%) was observed in the 14-d QT group, although the same scheme administered for 7 d was well tolerated. Dropouts and severe adverse events were observed exclusively in the quadruple regimen[21]. The same authors compared two 10-d levofloxacin-based (500 mg OD) triple schemes in combination with either amoxicillin or azithromycin with the standard QT regimen. Eradication rates of levofloxacin-based groups were higher, even if not significantly, compared with standard QT (86.6% and 71.4%, respectively), but incidence of side effects was significantly lower (26.6% *vs* 60%). Dropouts occurred only in the QT group[35,36].

In terms of duration of treatment, the same researchers compared efficacy and tolerability of 7 d and 10 d levofloxacin/amoxicillin-based treatment to 7 d QT, demonstrating a higher cure rate for the triple 10-d levofloxacin regimen (91.3%) compared to both the 7-d levofloxacin-based or QT regimen (74% and 68%, respectively), with optimal tolerability[35,36]. Zhang *et al*[37] also confirmed similar results.

Orsi *et al*[38] have studied efficacy of a 12-d treatment course by comparing the levofloxacin/amoxicillin-based regimen with QT. Both regimens were equally effective (86% *vs* 88%) but the triple regimen was better tolerated (incidence of side effects: 8.6% *vs* 24%).

A drastic difference in eradication rates were observed in another Italian study in which the levofloxacin-based triple and quadruple regimens achieved an eradication rate of 70% *vs* 35%, respectively, in second-line, even if patients were given a full-dose course of PPI for 1 wk prior to bismuth therapy. Interestingly, levofloxacin-based triple regimen was successful in most patients with both metronidazole- and clarithromycin-resistant strains, whereas QT was less effective, particularly when metronidazole resistance occurred[39].

Bilardi *et al*[39] used LA-based triple therapy both in first- and second-line compared to standard first-line triple and quadruple second-line regimens, respectively. In first-line, eradication rate of levofloxacin-based and standard triple regimen was 69.8% and 74%, respectively, while as rescue regimen, levofloxacin-based therapy achieved an eradication rate of 62.5% compared to 40% for the standard QT regimen.

Gisbert e*t al*[40] compared 7-d levofloxacin-based therapy with a quadruple ranitidine bismuth citrate-based regimen and reported an identical eradication rate of

68% for both regimens, with similar incidence of side effects (38% *vs* 36%, respectively). Nevertheless, the antisecretory activity of ranitidine might have contributed to the eradication rate in the QT regimen. Conversely, dose of levofloxacin (500 mg BD) and duration (7 d) of treatment might have affected efficacy (shorter treatment) and tolerance (high dosage) in the triple regimen[40].

In the study by Kuo *et al*[41], levofloxacin triple regimen and QT eradication rates were 69.9% *vs* 63.9%, respectively, and although compliance was similar, incidence of side effects was 12.6% in the LA *vs* 35.2% in the QT groups. In this study, levofloxacin resistance was analyzed and was a crucial predictor for eradication failure (21.2% of patients).

In a Korean trial, 7 d levofloxacin-based therapy and standard QT achieved comparable but low cure rates (51.6% *vs* 48.9%), even if the triple regimen was better tolerated (adverse events incidence: 10% *vs* 31.4%)[42]. Another Asian trial confirmed the high cure rate of levofloxacin-based therapy for 7 d (85.7%)[43].

Finally, few studies have demonstrated superiority of the recommended QT regimen compared with the levofloxacin triple regimen. QT was superior to levofloxacin-based regimen for persistent *H. pylori* infection in the study conducted by Perri *et al*[29] (eradication rate: 63% in the levofloxacin group). In this trial bismuth- and ranitidine/bismuth citrate-based QT regimens achieved a cure rate of 83% and 85%, respectively, although a higher incidence of side effects was observed in the bismuth-treated group (30.9% *vs* 5.1%). Conversely, adverse events occurred in 3.3% of patients treated with levofloxacin.

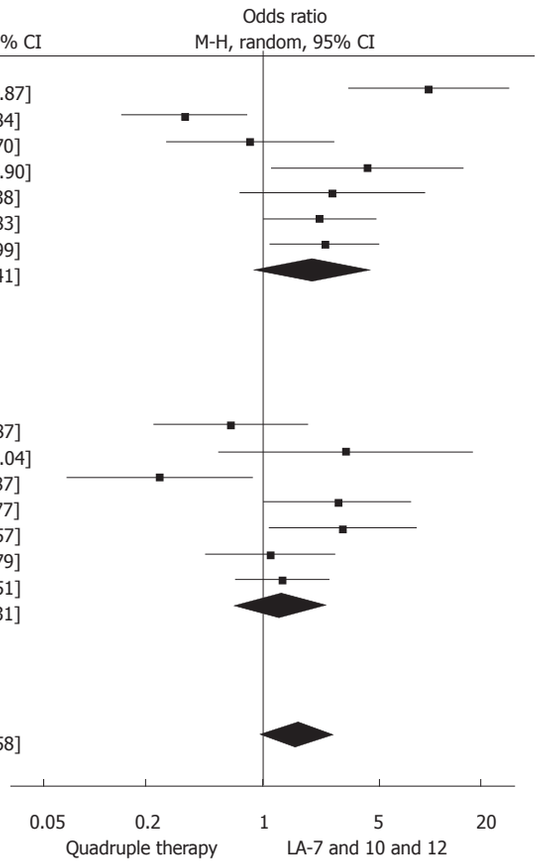
Wong *et al*[44] reported an eradication rate of 73% and 64% in second-line for QT and levofloxacin-based regimens, respectively. Similarly, in a study conducted in Hong Kong, second-line 7-d triple levofloxacin-based therapy achieved an eradication rate of 61% *vs* 87% with QT, due to resistance to levofloxacin (18% of patients)[19]. However, the study included a small sample of refractory patients and eradication rate was superior in subjects in the LA group with dual resistance to metronidazole and clarithromycin respect to antibiotics resistant patients in Q group (79% *vs* 65%, respectively). However, treatment choice was based on antibiotic susceptibility testing and might not reflect common clinical practice[19].

Results of our meta-analysis are summarized in Figure 1. Overall eradication rate (pooled data) with levofloxacin was 76.5% (95% CI: 54.4%-97.6%). When exclusively 7-d regimens were included, cure rate was 70.6% (95% CI: 40.2%-99.1%), whereas for the 10-d regimen, eradication rate was significantly higher (88.7%; 95% CI: 56.1%-109.9%; $P < 0.05$). Mean eradication rate for QT was 67.4% (95% CI: 42.4%-91.6%).

The meta-analysis showed a trend indicating superiority of any LA regimens (7, 10 or 12 d) to QT (OR: 1.59; 95% CI: 0.98-2.58; $P = 0.06$; Figure 1A). Both 7-d LA and QT regimens showed comparable efficacy (OR: 1.09; 95% CI: 0.63-1.87; $P = 0.40$; Figure 1B), whereas the 10-d LA regimen was significantly more effective (OR: 5.05; 95% CI: 2.74-9.31; $P < 0.00\,001$; Figure 1C).

No differences were reported in QT eradication rates between Asian and European studies, whereas LA regimens were more effective in Caucasians (78.3% *vs* 67.7%; $P = 0.05$). Of note, if data on comparison between LA and QT regimens were stratified by ethnicity (Figure 1A), any levofloxacin regimen was more effective in the Caucasian population ($P = 0.09$). Those findings were not confirmed when only 7-d levofloxacin regimens were included (Figure 1B). No data were available on 10-d levofloxacin regimens in Asian populations (Figure 1C).

Mean incidence of side effects (pooled data) was lower in LA regimens (13.7%, 95% CI: 12%-24%) compared with standard QT (27.2%, 95% CI: 24%-34%). The OR for this comparison was 0.39 (95% CI: 0.18-0.85; $P = 0.02$) at meta-analysis (Figure 2). When incidence of side effects (pooled data) was stratified by ethnicity, no differences were registered between the two geographical areas for the levofloxacin regimens (14.8% *vs* 12.1%, respectively in Europe and Asia), whereas a slightly higher rate was reported in the Asian population treated with QT (32.5% *vs* 23.3%, $P = 0.09$). Moreover, the lower risk of occurrence of side effects in the levofloxacin arms overall was mainly due to the Asian studies contribution.



DISCUSSION

Antibiotic resistance is the main cause of failure in curing *H. pylori* infection[45-49]. Other factors determining eradication rate are: *H. pylori* strain, patient compliance, and properties of drugs administered[2].

Levofloxacin, a second-generation fluoroquinolone, with a broad spectrum of activity against Gram-positive and Gram-negative bacteria[50-52], is a recognized antimicrobial alternative to the standard antibiotics used to treat *H. pylori* infection. Levofloxacin is mainly indicated to treat infections of respiratory and genitourinary tract, skin and skin structures[33,51,53-55]. In recent years, its role has been successfully extended to treatment of *H. pylori* infection and has been included as treatment of choice in guidelines[15,33,56]. Its optimal tolerance spectrum, with the most frequent adverse events being nausea and diarrhea, makes it a safe alternative[57]. Only a few cases of QTc prolongation, seizures, glucose disturbances and tendonitis have been reported[33,51,56]. Although primary resistance is infrequent, resistance to quinolones is easily acquired in areas of high consumption[58]. In Asian countries, levofloxacin resistance has recently increased[59,60]. In particular, in Hong Kong, Korea and Japan, estimated *H. pylori* resistance rates for levofloxacin are 11.5%, 21.5% and 15% respectively[61,62]. In the Chinese adolescent population, all *H. pylori* strains were found to be resistant to levofloxacin[63,64]. In Europe, such as Spain, France, Netherlands, Austria and Portugal, fluoroquinolone resistance is less than 10%[65-69]. However, despite a reported levofloxacin resistance rate of 18%, Italian guidelines recommend levofloxacin regimens for second-line therapy, with optimal results[16]. Moreover, antibiotic

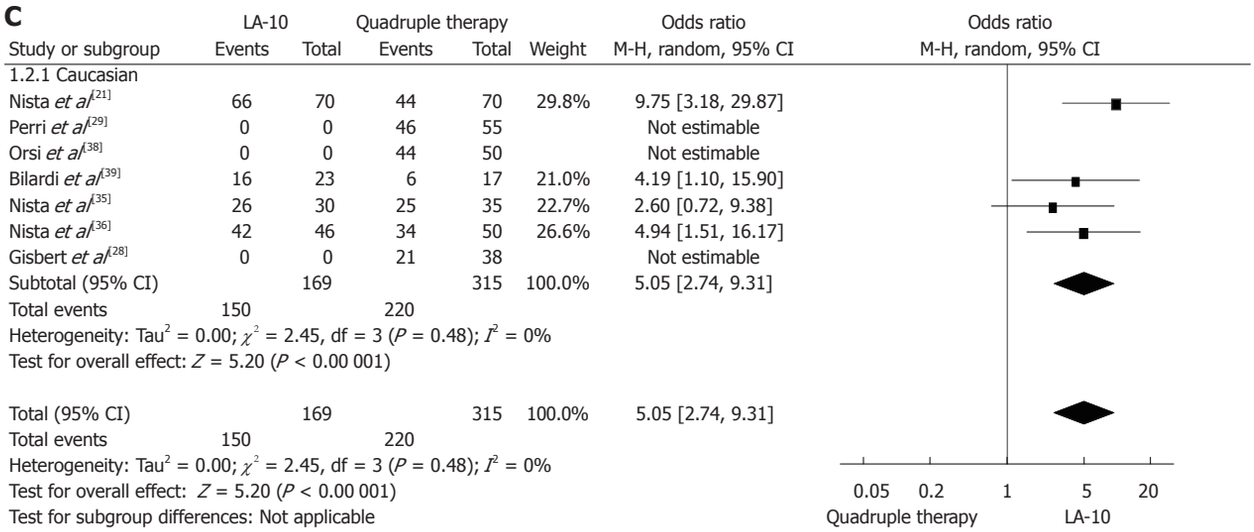

Figure 1 Meta-analysis comparing the efficacy of anti-*Helicobacter pylori* levofloxacin/amoxicillin-based triple therapy *vs* quadruple therapy 7-10 or 12 d (A), 7 d (B), 10 d (C) levofloxacin/amoxicillin regimens were considered. CI: Confidence interval; LA: Levofloxacin/amoxicillin.

resistance testing is not routinely performed to guide prescription. Therefore, even if widely used, published data on levofloxacin-based regimens for *H. pylori* eradication are extremely heterogeneous. Differences in dosages, length of treatment, drug combination, patients' demographic characteristics, and previous courses of therapy, preclude a definitive conclusion.

The present study included only studies comparing cure rate and tolerability of standard QT regimen to 7 or 10 d combination of LA-based triple therapy in second-line, to provide guidance in clinical practice. In accordance with previous reports[70-72], our data showed that 7 d LA-based triple regimen and QT achieved similar efficacy results, whereas LA-based regimen administered for 10 d was more effective than QT. Thus, tolerability was optimal in LA-based triple therapy and patients experienced a lower rate of adverse events compared to patients treated with standard QT, with the exception of a single discordant study[28]. However, in a multicenter study, the same author reported remarkably superior tolerability using a 10-d levofloxacin-based regimen[38,40].

In previous studies, dose of quinolone appeared the crucial factor influencing the incidence of side effects[70,71,73]. In most studies included in the analysis, levofloxacin has been administered at a dosage of 500 mg daily. Interestingly, a higher incidence of side effects was registered in one of the trials using 1 g in two divided doses[28].

Statistical comparison of side effects experienced in 7-d *vs* 10-d groups was not consistent due to the structure of the selected studies. With the exception of the study by Gisbert *et al*[28], tolerability was excellent in all other trials using levofloxacin-based regimens for 10 d or longer. Probably, acceptance of LA therapy depends on the simplicity of the therapeutic regimen itself. Although a new preparation of single three-in-one capsules containing bismuth subcitrate potassium, metronidazole, and tetracycline has been recently proposed in first-line[74], QT still consists of a complex scheme (12 pills/d), and bismuth salts are no longer available in many countries. On the contrary, levofloxacin-based therapy appears simple (5 pills/d), effective (10-d regimen eradication rate: 88.7%) and safe (overall side effects incidence: 13.7%). Duration of treatment appeared the unique factor influencing the efficacy[75].

Nevertheless, considering that the ideal for *H. pylori* infection might differ between areas, countries and races[76-78], we performed an additional analysis on efficacy in different parts of the world.

In a sub-analysis comparing Asian and European trials, QT was equally effective, while LA-based regimens were more effective in the European population. Differences in efficacy rates between Asian and European populations using LA-based schemes might be explained with primary antibiotic resistance and/or genetic background. The meta-analysis showed that the LA-based regimen was more effective in Caucasians only when any regimen was included. However, 10-d levofloxacin-based treatment has never been tested in Asian countries and efficacy increases with duration of treatment, therefore, it is difficult to establish whether differences reported depended on ethnicity or duration of therapy.

Regarding incidence of side effects, ethnicity appeared to affect tolerability of QT compared with LA-based therapy in Asian populations. However, the single outlier among European trials might bias this finding.

Apart from levofloxacin, other regimens containing fluoroquinolones have been proposed both in first- and second-line *H. pylori* treatment. Among these, moxifloxacin-based regimens appear interesting (eradication rate up to 90% and 70%, respectively in first and second-line[72,75,79]. With respect to levofloxacin, moxifloxacin has been relatively more recently introduced on the market, with a consequent possibly lower rate of antibiotic resistance. However, it is more expensive. Nevertheless, no conclusive recommendations can be issued on which

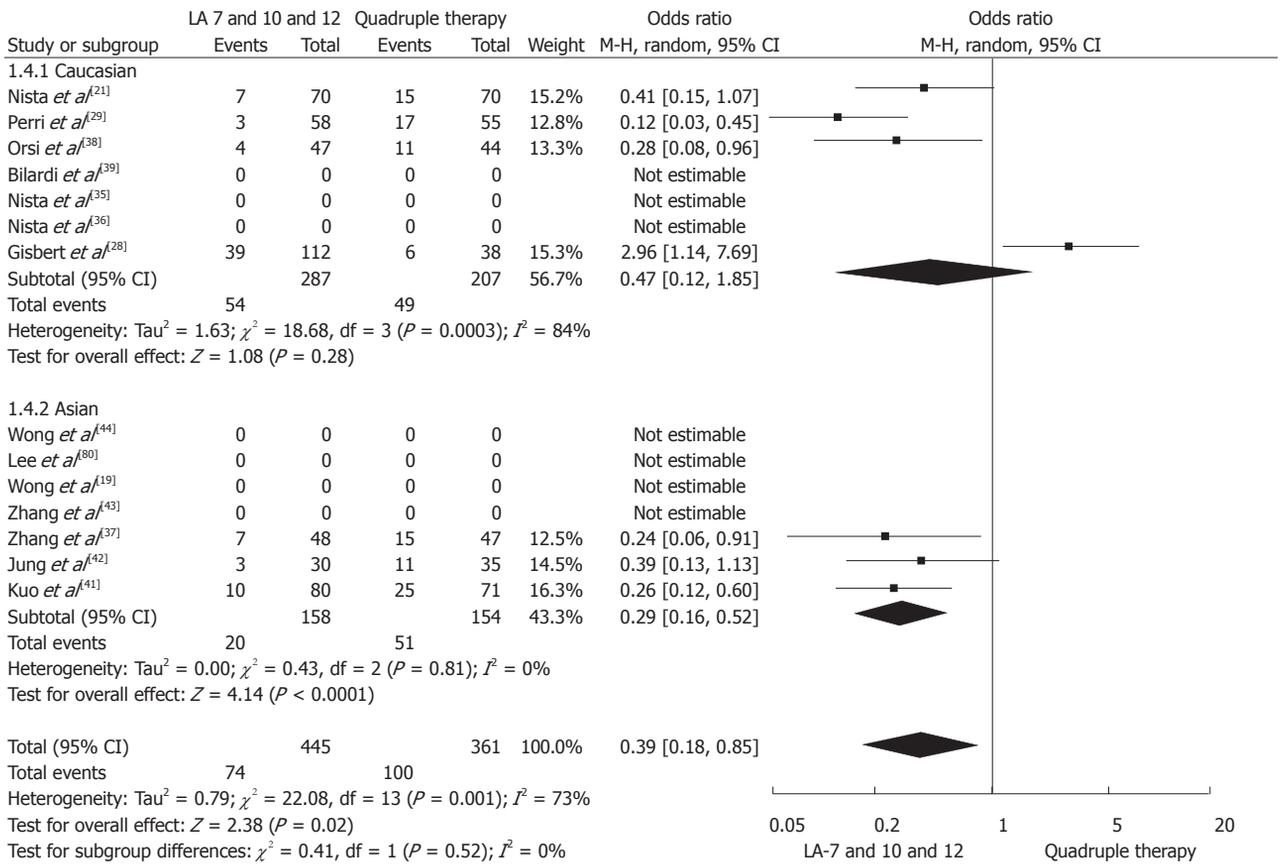

Figure 2 Meta-analysis comparing the incidence of side effects with levofloxacin/amoxicillin-based triple therapy *vs* quadruple therapy for *Helicobacter pylori* eradication. CI: Confidence interval; LA: Levofloxacin/amoxicillin.

fluoroquinolone should be used because there are no trials comparing the two drugs.

Our results are in accordance with previous meta-analyses assessing efficacy and safety of second-generation fluoroquinolones, including levofloxacin and moxifloxacin[13,71,72,79], for *H. pylori* eradication. However, compared to previous studies, our study included the most up to date collection of RCTs and most importantly, compared exclusively second-line treatments and analyzed geographical stratification.

Our meta-analysis had several limitations, mainly due to heterogeneity among trials (different dosing schedules and duration of treatment). Sub-analyses were mainly affected by the small sample size for each category. Finally, the lack of data available on use of 10 d LA-based therapy in Asian populations did not allow a definitive conclusion about the influence of ethnicity on treatment success. Moreover, considering the suboptimal tolerance of QT in Asian populations, alternative strategies, such as 10 d LA-based therapy, and randomized trials in this geographic setting would be desirable.

In our analysis, we selected exclusively RCTs comparing LA-based triple regimens to standard QT to provide practical useful data on a specific treatment to use as rescue regimen of choice due to the rare *H. pylori* resistance to amoxicillin.

In conclusion, this meta-analysis strongly supports the use of 10 d LA-based triple regimen as a simple (5 pills/d) second-line treatment for *H. pylori* eradication, with an excellent eradication rate and tolerability profile in comparison to standard recommended QT in Asian and European countries. Nevertheless, quinolone resistance monitoring in different geographical areas is required.

Abstract

Carcinoma of the esophagus is an aggressive and lethal malignancy with an increasing incidence worldwide. Incidence rates vary internationally, with the highest rates found in Southern and Eastern Africa and Eastern Asia, and the lowest in Western and Middle Africa and Central America. Patients with locally advanced disease face a poor prognosis, with 5-year survival rates ranging from 15%-34%. Recent clinical trials have evaluated different strategies for management of locoregional cancer; however, because of stage migration and changes in disease epidemiology, applying these trials to clinical practice has become a daunting task. We searched Medline and conference abstracts for randomized studies published in the last 3 decades. We restricted our search to articles published in English. Neoadjuvant chemoradiotherapy followed by surgical resection is an accepted standard of care in the United States. Esophagectomy remains an essential component of treatment and can lead to improved overall survival, especially when performed at high volume institutions. The role of adjuvant chemotherapy following curative resection is still unclear. External beam radiation therapy alone is considered palliative and is typically reserved for patients with a poor performance status.

INTRODUCTION

Carcinoma of the esophagus is an aggressive disease associated with a poor overall survival (OS). In 2011, 16 980 patients will be diagnosed in the United States, and 14 710 will die from their disease[1]. The incidence of adenocarcinoma of the esophagus is rising dramatically worldwide, while the incidence of squamous cell carcinoma (SCC) is decreasing[2]. While survival rates in metastatic esophageal cancer remain low, outcomes among patients with resectable locoregional disease have improved with the incorporation of multimodality treatment including chemotherapy, radiation and surgical resection. Multiple clinical trials have addressed the preferred treatment sequence in managing locally advanced esophageal cancer (LAEC); however, no standard therapy has been established.

Esophagectomy remains the cornerstone treatment for early-stage esophageal carcinoma; however surgery alone is rarely curative for tumors invading beyond the muscularis propria or involving locoregional lymph nodes. As a result, many clinical trials have addressed the role of chemotherapy and radiation in the neoadjuvant or adjuvant setting, with conflicting results.

The majority of the studies published in the last three decades included mostly patients with SCCs, and a distinction between the two subtypes was not always made. However, it remains unclear as to whether histology should dictate treatment approach. Extrapolation from old literature is acceptable until further data in adenocarcinoma is available. Enrollment in clinical trials should be encouraged.

In this article we will review the literature on the treatment of locally advanced mid-distal esophageal cancer. Treatment recommendations for cervical esophageal cancer will not be included in this review.

TREATMENT WITH SURGERY ALONE *VS* RADIOTHERAPY ALONE

Surgical resection remains the standard treatment for early-stage disease. Endoscopic mucosal resection (EMR) is recommended for T1a tumors if negative margins can be achieved. Esophagectomy upfront is recommended in patients with positive margins following EMR, or in patients with T1b disease.

Surgery alone as a treatment option for esophageal cancer was found to be superior when compared to radiation therapy. In a randomized trial of patients with LAEC, 39 patients were randomized to surgery and 35 patients to 45 Gy to 53 Gy radiation over four to five weeks[3]. The median survival for surgery was 21.6 mo compared with 8.2 mo for the radiation only group. In another trial comparing 47 surgical patients to 52 patients undergoing radiation[4], OS was improved with surgery [odds ratio (OR) 2.74].

Despite innovations in surgical techniques and declines in perioperative mortality, 5-year survival rates rarely exceed 50% among patients with stage Ⅱ or higher disease[5-7]. Median overall and disease-free survival does not appear to differ significantly based on the surgical approach (transthoracic *vs* transhiatal resection)[5]. In recent years, mortality rates after esophagectomy have decreased significantly. High-volume institutions have superior operative mortality rates (more than 12% absolute reduction in mortality when compared to low volume centers)[8].

PREOPERATIVE RADIOTHERAPY *VS* SURGERY ALONE

Radiotherapy as a single modality has been evaluated as a treatment option for esophageal cancer. In a small trial of 17 patients with clinical stage I esophageal SCC treated with radiation alone, the five-year survival rate was 59%[9]. In another single-institution series of 101 patients with LAEC treated with radiotherapy alone, the five-year survival rate was 21%. Survival was superior for adenocarcinoma compared to SCC, however the difference was not statistically significant[10].

Several randomized trials comparing neoadjuvant radiotherapy and surgery *vs* surgery alone in patients with LAEC have been reported[3,11-15]. Investigators used different radiation doses and techniques. There was no statistically significant difference in OS with preoperative radiotherapy compared with surgery alone.

In a trial by Launois *et al*[11], 124 patients with SCC of the esophagus were randomized to receive preoperative radiation for eight days *vs* surgery alone. No significant differences in outcome were noted between the two groups. Of the 62 irradiated patients, 14 died during operation, compared with 11 of the 47 non-irradiated patients, which was not statistically significant. 5-year survival rates were similarly poor (9.5% *vs* 11.5%).

In 1987, Gignoux *et al*[12] from the European Organization for Research on Treatment of Cancer (EORTC) compared surgery alone to 33 Gy of preoperative radiation therapy followed by surgery. Although local disease control was improved, there was no difference in survival or resectability of tumors.

Another prospective randomized clinical trial (RCT) randomized patients to preoperative radiation followed by surgery (104 patients) *vs* surgery along (102 patients)[13]. No significant differences were reported between the two groups in resection rates, operative mortality, anastomotic leaks, positive margins or lymph nodes metastases. The 5-year survival rates in the combined modality treatment group and the surgery alone group were 35% and 30% respectively.

In a four-arm Scandinavian study of patients with non-metastatic squamous cell esophageal carcinoma[14], patients were randomized to surgery alone, preoperative radiation, preoperative chemotherapy, or preoperative chemoradiation. Although the three-year survival was significantly higher in the pooled groups receiving radiotherapy as compared with the pooled groups not receiving radiotherapy, patients who received preoperative radiation alone *vs* surgery alone had a median survival of 10 mo *vs* 7 mo respectively which was not statistically significant.

In a different study, 176 patients with potentially operable SCC or adenocarcinoma of the esophagus were randomly assigned to preoperative radiotherapy or surgery alone[15]. Preoperative radiotherapy was not associated with any significant operative complications. The median OS for the entire cohort was 8 mo, and the 5-year survival was 13%. There was no significant difference in survival between the two groups. Trials of preoperative radiation are summarized in Table 1.

A meta-analysis of 1147 cases, predominantly SCC, from five RCTs examining preoperative radiotherapy and surgery compared to surgery alone[16] failed to demonstrate a conclusive survival benefit in LAEC. The hazard ratio (HR) associated with neoadjuvant radiotherapy was 0.89 (95% CI: 0.78-1.01; $P = 0.06$).

POSTOPERATIVE RADIOTHERAPY *VS* SURGERY ALONE

In order to reduce the risk of local recurrence, several randomized trials have compared surgery alone to sur-

gery followed by adjuvant radiation therapy. Studies enrolled a heterogonous population including patients with positive celiac nodes[17,18] and R1 resections[19]. Investigators used varying doses of radiation with different fractionations. Radiation was delivered from 6-12 wk following surgery.

These trials had conflicting results: three failed to demonstrate any survival benefits with adjuvant radiation[17,18,20], while one trial showed inferior survival among patients who received adjuvant radiation therapy[19]. One trial showed improvement in quality of life in the surgery-only arm[18] compared to the adjuvant radiation arm. A pooled analysis of the five adjuvant radiation trials[21] showed no significant difference in survival following adjuvant radiotherapy when compared to surgery alone. A reduction in local recurrence was reported in some of these trials at the expense of toxicity. Preoperative radiotherapy was compared to postoperative radiotherapy in a small randomized trial; no difference in survival was detected between the two arms but patients receiving preoperative radiotherapy experienced higher morbidity[3].

PREOPERATIVE CHEMOTHERAPY *VS* SURGERY ALONE

Multiple randomized trials compared preoperative chemotherapy to surgery alone for the treatment of resectable esophageal cancer. Of the seven trials summarized in Table 2, four showed no survival benefit while three were positive demonstrating improved survival with neoadjuvant chemotherapy. Roth *et al*[22] randomized 39 patients with potentially resectable cancer of the middle or lower esophagus to receive either surgery along, or preoperative and postoperative therapy with cisplatin, vindesine, and bleomycin. The overall resectability rates were similar for the two groups. Patients responding to chemotherapy preoperatively had a significantly prolonged survival (greater than 20 mo) when compared with either nonresponders (median 6.2 mo) or patients in the surgical monotherapy arm (median 8.6 mo).

In a phase Ⅲ study[23], forty six patients with potentially resectable SCC of the esophagus were randomized to undergo either immediate surgery (n = 24) or surgery plus preoperative chemotherapy (n = 22). Chemotherapy consisted of three cycles with cisplatin and 5-fluorouracil (5-FU). The response rate to chemotherapy was 50% (17 of 34 patients). Side effects of therapy were higher than expected based on results of previous phase Ⅱ studies. Two drug-related deaths were observed. The resectability rate for patients in the surgery only group was 79% compared with 70% for patients receiving preoperative chemotherapy. Patients who responded to preoperative chemotherapy had a prolonged median survival (13 mo) compared with nonresponders (5 mo), but the median survival for the chemotherapy group and the surgery only group was identical (10 mo).

In a later study, Law *et al*[24] randomized 147 patients to receive surgery alone or preoperative cisplatin and 5-FU. Of the 60 patients in the preoperative chemotherapy arm, 58% had a significant response. Curative resections were possible in 67% of these patients compared with 35% in the control group. Median survivals were 16.8 and 13 mo, respectively (P = 0.17).

In a randomized phase Ⅲ trial[25], 42 patients were randomized to receive either two cycles of chemotherapy (cisplatin, bleomycin, 5-FU and vinblastine) followed by surgery or surgery alone. Median survival time was 17 mo in both groups. However, early survival appeared to be better in the control group.

Larger, more recent studies have shown improved benefits for patient receiving neoadjuvant therapy. In the medical research council study[26], 802 patients with resectable esophageal cancer were randomly allocated either two cycles of cisplatin and 5-FU followed by surgical resection or resection alone.

Postoperative complications were similar in both groups. OS was prolonged in the chemotherapy group with a median survival of 16.8 mo compared with 13.3 mo in the surgery only group. In the Medical Research Council adjuvant gastric infusional chemotherapy trial[27], 503 patients with resectable adenocarcinoma of the stomach, esophagogastric junction, or lower esophagus were randomly assigned to either perioperative chemotherapy or surgery alone. Chemotherapy consisted of three preoperative and three postoperative cycles of intravenous epirubicin, cisplatin and continuous intravenous infusion of 5-FU. With a median follow-up of four years, OS was significantly improved in the perioperative chemotherapy arm (36% *vs* 23%).

Several pooled and meta-analyses addressed the role of neoadjuvant chemotherapy followed by surgery compared to surgery alone. Malthaner *et al*[21] included five studies in a meta-analysis[14,23-26,28]. No significant difference in outcome was detected (relative risk ratio, 1.00; 95% CI: 0.83-1.19; P = 0.98).

Another meta-analysis was published in 2002 and included eleven RTCs comparing surgery alone to preoperative chemotherapy[29]. Again, there was no statistically significant difference in 3-year survival rates among patients who received preoperative chemotherapy com-

pared to those who did not.

Two other meta-analyses showed survival benefits with preoperative chemotherapy; the first was a Cochrane Review which pooled 11 RTCs. A statistically significant difference in survival favouring preoperative chemotherapy was detected at five years[30]. A more updated meta-analysis[31] comparing survival with or without neoadjuvant chemotherapy in 9 RTCs (total of 1981 patients) found that chemotherapy was associated with a significant survival benefit (pooled HR of 0.87; $P = 0.005$) corresponding to an absolute survival difference at 2 years of 5.1%.

POSTOPERATIVE CHEMOTHERAPY *VS* SURGERY ALONE

A small number of randomized trials have evaluated postoperative chemotherapy compared with surgery alone. Pouliquen *et al*[32] found no improvement in survival rates with postoperative chemotherapy consisting of cisplatin and 5-FU in patients with SCC. Duration of dysphagia was similar for both groups as well. Another randomized trial compared surgery alone *vs* surgery followed by adjuvant cisplatin and 5-FU in 242 Japanese patients with SCC[33]. Disease free survival at 5 years favoured the adjuvant therapy arm (55% *vs* 45%), however, improvement in OS did not reach statistical significance (61% *vs* 52%). Despite the short duration of adjuvant chemotherapy, 25% of patients in the chemotherapy arm failed to receive the full course of adjuvant therapy.

PREOPERATIVE *VS* POSTOPERATIVE CHEMOTHERAPY

A small number of randomized trials have evaluated postoperative chemotherapy compared to preoperative chemotherapy. A recent Japanese study[34] randomized 330 patients with SCC of the esophagus to surgery followed or preceded by two courses of cisplatin plus 5-FU. The primary end point was progression-free survival. Progression-free survival did not reach the stopping boundary, but OS in the preoperative group was superior to that of postoperative group. The study was published early and concluded that preoperative chemotherapy with cisplatin plus 5-FU can be regarded as standard treatment. In a prior trial[33], PFS was better in patients who received postoperative *vs* preoperative chemotherapy, but the OS was not different for the two groups. Patients with node-negative cancer did not benefit from postoperative chemotherapy.

Concurrent chemotherapy and radiation

Concurrent chemoradiation has been tested in LAEC as neoadjuvant, adjuvant or definitive therapy in order to optimize local and systemic disease control.

Definitive chemoradiation: Definitive chemoradiation has been studied in primarily in locally advanced, squamous cell unresectable esophageal cancer. RTOG 85-01[35] was a pivotal trial which compared radiation alone *vs* concurrent chemoradiation (cisplatin and 5-FU) in patients with LAEC, ninety percent of whom had SCC. The chemoradiotherapy group received two additional chemotherapy cycles following radiation.

An interim analysis showed a significant benefit with chemoradiation with a five-year survival of 27% compared to 0 %[36]. However, 46% of patients in the chemoradiation arm had locally recurrent or persistent disease in the esophagus which lead to the intergroup 0123[37] trial where patients with LAEC were randomized to two different radiation doses concurrent with chemotherapy (50.4 gray *vs* 64.8 gray). A higher dose was not associated with improved locoregional control.

Preoperative chemoradiation: The poor outcome associated with surgery alone and the high locoregional recurrence with definitive chemoradiation provided the rational for evaluating neoadjuvant chemoradiation followed by surgery in patients with resectable esophageal cancer.

More than ten randomized trials compared neoadjuvant chemoradiation followed by surgery to other treatment modalities. These trials are summarized in Table 3.

Table 3 Randomized trials of preoperative chemotherapy and radiation *vs* surgery alone

van Hagen[41]1	386	Carbo/paclitaxel	49	24	58	44

[1]The difference in survival was statistically significant. CDDP: Cisplatin; 5-FU: 5-flurouracil; CRT: Chemotherapy and radiation.

Four trials were conducted with preoperative sequential chemotherapy and radiation and 8 trials were performed with chemoradio-therapy. The sequential trials were restricted to SCC and all but three of the concurrent trials included patients with adenocarcinoma. None of the four trials of sequential therapy showed a survival benefit[14,38-40]. However, the combined radiation arms in the second Scandinavian trial showed a survival benefit compared to the non-radiation arms[14]. Additionally, chemotherapy was not associated with a survival benefit. In the EORTC trial, while preoperative therapy was associated with longer disease-free survival, longer interval of local control, and lower rates of cancer-related deaths, postoperative deaths were higher and were attributed to the hypofractionated radiation regimen used[38]. Of the 8 randomized trials of neoadjuvant chemoradiation[41-49], 4 showed a survival benefit from[41,45,47,49]. In the Irish study, 113 patients were randomized to 40 Gy in 3 wk concurrent with cisplatin and 5-FU followed by surgery *vs* surgery alone[47]. The trial resulted in a significant survival benefit with a median and 3 year survival of 16 mo and 32% for the chemoradiation group *vs* 11 mo and 6% for the surgery only group ($P = 0.01$). This trial was highly criticized for the low survival in the surgery only arm compared to other studies and for short follow up. Tepper *et al*[45] intended to randomize 475 patients to neoadjuvant chemoradiotherapy with 50.4 Gy over 5.5 wk concurrent with cisplatin and 5-FU and surgery *vs* surgery alone in a Cancer and Leukemia Group B study, however the trial was closed due to poor accrual. Only 56 patients were enrolled. Median and 5 year survival was 4.5 years and 39% for chemoradiation patients *vs* 1.8 years and 16% for surgery only patients ($P = 0.02$). The study was criticized for being underpowered. While the Michigan study showed a near doubling of 3-year survival in chemoradiation patients, the study was also underpowered to detect a significant difference. The study was powered to detect an increase in median OS from 1 year to 2.2 years[46]. A recently published phase Ⅲ study (the study "Effect of preoperative concurrent chemoradiotherapy on survival of patients with resectable esophageal or esophagogastric junction cancer")[41] randomized patients with resectable esophageal cancer to receive surgery alone or weekly administration of carboplatin and paclitaxel for 5 wk and concurrent radiotherapy followed by surgery. Seventy-five percent of patients had adenocarcinoma. R0 resection was achieved in 92% of patients in the chemoradiotherapy-surgery group *vs* 69% in the surgery group ($P < 0.001$). A pathological CR was achieved in 29% of patients who underwent resection after chemoradiotherapy. Postoperative complications were similar in both groups as was in-hospital mortality. Median OS was 49.4 mo in the chemoradiotherapy-surgery group *vs* 24.0 mo in the surgery group (HR 0.657; 95% CI: 0.495-0.871; $P = 0.003$).

A three arm study from China, where patients with SCC were randomized to preoperative chemoradiation, postoperative chemoradiation, or surgery alone, showed a survival benefit for both preoperative and postoperative chemoradiation. A recent French trial (FFCD9901) determined the effect of preoperative chemoradiation in stage I and II esophageal cancers (71% SCC)[44]. There was no difference in survival and postoperative 30 d mortality rates were trending higher in chemoradiation patients (7.3% *vs* 1.1%; $P = 0.054$).

The majority of patients included in these studies had SCC. Clinical staging was suboptimal by modern standards. An Irish[47] and Dutch[41] trial each showed statistically significant improvement in OS with combined preoperative chemoradiation but the Irish study was criticized for the lack of appropriate staging, premature closure, and an unusually poor survival rate in the surgery-alone arm.

Several meta-analyses have addressed the benefit of trimodality therapy over surgery alone for esophageal cancer. The first, by Fiorica *et al*[49] pooled six RCTs comparing preoperative chemoradiation and surgery *vs* surgery alone. Chemotherapy and radiation followed by surgery significantly decreased mortality (OR 0.53; 95% CI: 0.31-0.92; $P = 0.03$). However, the risk of postoperative mortality was higher in the multimodality arm.

A second meta-analysis, by Urschel *et al*[50], pooled nine RCTs including 1116 patients. A statistically significant survival difference was found at three years in

favor of preoperative chemoradiation (OR 0.66; 95% CI: 0.47-0.92; $P = 0.016$). Neoadjuvant chemoradiation was associated with a lower rate of resection, but a higher rate of complete (R0) resection. There was a non-significant trend toward increased treatment mortality with neoadjuvant chemoradiation.

A third meta-analysis by Gebski *et al*[51] pooled 10 RTCs comparing neoadjuvant chemoradiotherapy *vs* surgery alone with a total of 1209 patients. A significant survival benefit was evident for preoperative chemoradiotherapy with a HR of 0.81 (0.70-0.93; $P = 0.002$), corresponding to a 13% absolute difference in survival at 2 years. The HR was 0.84 (0.71-0.99; $P = 0.04$) for SCC and 0.75 (0.59-0.95; $P = 0.02$) for adenocarcinoma.

A fourth meta-analysis by Jin *et al*[52] pooled 11 RTCs comparing neoadjuvant chemoradiotherapy *vs* surgery alone with a total of 1308 patients. A significant survival benefit was evident for preoperative chemoradiotherapy at 3 years with an OR of 1.78 (1.20-2.66; $P = 0.004$). In a sub-group analysis, SCC patients did not benefit from neoadjuvant chemoradiotherapy.

The most recent meta-analysis by Sjoquist *et al*[31] included 12 RTCs of neoadjuvant chemoradiotherapy *vs* surgery alone. The HR for all-cause mortality with neoadjuvant chemoradiotherapy was 0.78 (95% CI: 0.70-0.88; $P < 0.0001$); the HR for SCC was 0.80 (95% CI: 0.68-0.93; $P = 0.004$) and for adenocarcinoma was 0.75 (95% CI: 0.59-0.95; $P = 0.02$). This analysis also compared neoadjuvant chemoradiation *vs* chemotherapy and demonstrated a non-statistically-significant survival benefit for neoadjuvant chemoradiation (HR 0.88, 95% CI: 0.76-1.01; $P = 0.07$).

Postoperative chemoradiation: There are no randomized trials demonstrating that chemoradiation benefits patients who did not receive neoadjuvant therapy for LAEC. The role of adjuvant therapy is particularly uncertain in patients who have positive margins or node positive disease. Based on the intergroup 0116 trial[53] of patients with gastric cancer [20% of whom had gastro-esophageal junction (GEJ) adenocarcinoma], patients often receive adjuvant chemoradiation following resection; however toxicities associated with administration of chemoradiation after esophagectomy (e.g., pneumonitis) can be significant.

One randomized trial evaluated postoperative chemoradiation *vs* postoperative radiotherapy following esophagectomy. No difference in survival was detected (38 mo for both groups)[3]. Toxicity was higher in the combined treatment arm.

NEOADJUVANT CHEMOTHERAPY *VS* NEOADJUVANT CHEMO-RADIATION

Two randomized trials compared neoadjuvant chemotherapy to neoadjuvant chemoradiation. Both trials included patients with adenocarcinoma, were closed early, and were underpowered to show a survival advantage.

In an Australian trial[54], 75 patients were randomized to receive preoperative cisplatin and 5-FU or preoperative chemoradiation with the same drugs at lower doses. The pathological response rate was higher in the combination arm (31% *vs* 8%; $P = 0.01$). The median progression-free survival was 26 mo in the combination arm *vs* 14 mo in the chemotherapy arm ($P = 0.37$). The median OS was 29 mo *vs* 32 mo for the combination arm but did not reach statistical significance ($P = 0.83$).

In the German phase Ⅲ Preoperative Chemotherapy or Radiochemotherapy in Esophago-gastric Adenocarcinoma trial[54,55], 126 patients with GEJ adenocarcinoma were randomly assigned to neoadjuvant chemotherapy alone (cisplatin and 5-FU) for 16 wk *vs* 12 wk of the same regimen followed by low-dose radiotherapy concurrent with cisplatin and etoposide. The pathologic complete remission rate was significantly higher in the induction arm (16% *vs* 2%), with a non-significant trend towards superior three-year survival as well (47% *vs* 28%; $P = 0.07$). A meta-analysis of the two trials[31] favored neoadjuvant chemoradiation but this was not statistically significant.

DISCUSSION

Esophageal cancer is not a common disease with less than 20 000 cases diagnosed in the US every year. Several clinical trials have evaluated different modalities for management of locoregional cancer; however, large phase Ⅲ trials comparing chemotherapy, radiation, surgery or any combination are lacking. Clinical trials reviewed in this article included heterogeneous groups of patients with adenocarcinoma and SCC without uniform staging studies. Stage migration and changes in disease epidemiology impede application of these trials to clinical practice. Comparing outcome (survival or progression free survival) across clinical trials is not recommended in oncology in general and especially in esophageal cancer as the changes in outcome might not be related to the different chemotherapy agents or radiation techniques as much as disease pathology, patient selection and changes in surgical outcomes across more than three decades.

Accumulating evidence suggests that patients whose tumors have invaded beyond the submucosa (T2 or above) and who are surgical candidates should undergo some form of neoadjuvant therapy including chemotherapy, radiation or both prior to surgical resection. Although controversial, esophagectomy remains an essential part of treatment and can lead to improved OS, especially when performed in a high-volume institution. Even in patients with SCC, where definitive chemoradiotherapy is a potentially curative, there remains a high rate of local failure after chemoradiotherapy alone. We therefore recommend surgical resection in all patients with mid to distal esophageal cancer who are surgical candidates. Based on the above trials and meta-analyses, we generally administer neoadjuvant chemoradiotherapy rather than neoadjuvant chemotherapy or surgery alone for LAEC. While neoadjuvant chemotherapy provides

a significant survival benefit, local failure rates are still higher than in patients treated with neoadjuvant chemoradiation. Moreover, data on neoadjuvant chemotherapy without radiation are lacking in SCC.

The optimal neoadjuvant regimen has not yet been established. The above mentioned trials used different drugs, doses, and schedules of chemotherapy and radiotherapy. We recommend platinum-based combination chemotherapy rather than a single agent cisplatin.

Following resection, data on adjuvant therapy are lacking. For patients with completely-resected node-positive disease who have not received neoadjuvant therapy, we suggest postoperative adjuvant therapy with chemotherapy and radiation. In patients with residual lymph node positivity following neoadjuvant chemoradiation, long-term recurrence rates are high; however the potential benefits of further adjuvant chemotherapy in this setting are not clear.

Future trials in LAEC should include neoadjuvant chemoradiotherapy as a control arm. While OS should remain a primary endpoint, secondary endpoints should include local disease control and quality of life. Treatment decisions for individual patients should be based on co-morbidities and effects of neoadjuvant therapy on the patient's performance-status and quality of life. Targeted therapies, such as trastuzumab, should be studied in the neoadjuvant and adjuvant settings to improve long-term outcomes.

Abstract

Regulatory T cells (T_{regs}) are key elements in immunological self-tolerance. The number of T_{regs} may alter in both peripheral blood and in colonic mucosa during pathological circumstances. The local cellular, microbiological and cytokine milieu affect immunophenotype and function of T_{regs}. Forkhead box P3+ T_{regs} function shows altered properties in inflammatory bowel diseases (IBDs). This alteration of T_{regs} function can furthermore be observed between Crohn's disease and ulcerative colitis, which may have both clinical and therapeutical consequences. Chronic mucosal inflammation may also influence T_{regs} function, which together with the intestinal bacterial flora seem to have a supporting role in colitis-associated colorectal carcinogenesis. T_{regs} have a crucial role in the immunoevasion of cancer cells in sporadic colorectal cancer. Furthermore, their number and phenotype correlate closely with the clinical outcome of the disease, even if their contribution to carcinogenesis has previously been controversial. Despite knowledge of the clinical relationship between IBD and colitis-associated colon cancer, and the growing number of immunological aspects encompassing sporadic colorectal carcinogenesis, the molecular and cellular links amongst T_{regs}, regulation of the inflammation, and cancer development are still not well understood. In this paper, we aimed to review the current data surrounding the role of T_{regs} in the pathogenesis of IBD, colitis-associated colon cancer and sporadic colorectal cancer.

INTRODUCTION

Immunological self-tolerance is crucial for preventing autoimmune diseases and maintaining immune homeostasis[1]. Regulatory T cells (T_{regs}) are a subpopulation of T cells including CD4+CD25+ forkhead box P3 (Foxp3)+ T cells, Tr1, Th3, and CD8+ T_{regs}. They serve to suppress the immune system and maintain self-tolerance. Inappropriate T cell response to intestinal microflora has a role in the pathological process of inflammatory bowel diseases (IBD)[2]. Accumulating evidence indicates that the imbalance of immunity, including a discrepancy between the number of T_{regs} in peripheral blood and in inflamed colonic mucosa, an excess of pro-inflammatory stimuli and an altered function of immunoregulatory cells has a central role in the pathogenesis of IBD[3].

Risk for developing cancer rises substantially as a result of poorly regulated inflammatory responses to pathogenic bacteria. T_{regs} function to restore immune homeostasis during chronic inflammation, and therefore it seems logical that T_{regs} would reduce the risk of inflammation-associated colon cancer by down-regulating inflammation. Alteration of T cell phenotype could also have an effect not only on the regulation of the chronic mucosal inflammation[3], but on colitis-associated carcinogenesis as well[4,5].

On the other hand, it is also widely believed, that T_{regs} in cancer primarily suppress protective anticancer immune responses. This alteration of T_{regs} function, together with the tumor-helping chemokine milieu produced by the cancer tissue could support cancer progression[4,5]. T_{regs} role in the carcinogenesis of inflammation-associated colon cancer and sporadic colorectal cancer is paradoxical due to conflicting results.

The bone marrow progenitors of all T cells become committed to their lineage in the thymus. The double negative T cells (CD4-CD8-) will rearrange their T cell receptor (*TCR*) genes to form a unique, functional molecule, which they test against cells in the thymic cortex for a minimal level of interaction with self-major histocompatibility complex (MHC). Upon receiving these signals, they begin to proliferate and express both CD4 and CD8. Then, the double-positive cells are selected by their interaction with thymic cells, begin the transcription of Foxp3, becoming T_{regs}. Foxp3 expression begins at the single-positive stage, at which point they are functional T_{regs}[6].

Foxp3 is a member of the forkhead and winged helix family of transcriptional regulators, and plays a critical role in the development and function of CD4+ T_{regs}[6]. In previous studies, CD4 and CD25 were selected as the markers for T_{regs}, but in recent studies Foxp3 has been proposed as a more reliable and superior biomarker[7,8].

The exact process of T_{reg} cell selection is not well known. It appears to be a process determined by the affinity of interaction with the self-peptide MHC complex[9]. Characteristic features of CD4+CD25+Foxp3+ T_{regs} are their anergic state, and their ability to actively inhibit CD4+CD25- T cells, CD8+ T cells, dendritic cells, natural killer cells, natural killer T cells, and B cells in a cell-to-cell contact and dose-dependent manner[10].

Recent results[3-5] suggest that T_{regs} could have an important, but controversial regulatory role in both the pathogenesis of chronic colonic inflammation and colorectal carcinogenesis. Despite the clinical relationship between IBD and IBD-associated colon cancer, and the growing number of immunological aspects encompassing sporadic colon cancer, the molecular and cellular links between infiltrating immune cells, regulation of the inflammation, and cancer development are not well understood. Therefore, we aimed to review the current information available on the role of T_{regs} in the pathogenesis of IBD, colitis-associated colon cancer and sporadic colorectal cancer.

T_{REGS} IN IBD

Discrepancy in the distribution of T_{regs} in peripheral blood and mucosa

T_{regs} are able to suppress the expansion of effector T cells by interleukin (IL)-10 and transforming growth factor (TGF)-β secretion and cytotoxic T lymphocyte-associated antigen expression[11]. The frequency of circulating T_{regs} was shown to be lower in patients with relapsing than in remitting autoimmune diseases[12,13], therefore leading to the speculation that insufficient levels of T_{regs} in peripheral blood are critical in inducing a relapse of autoimmune disease.

Maul *et al*[14] reported that CD4+CD25+ cells were decreased in the peripheral blood of IBD patients. Moreover, Wang *et al*[3] found the percentage of CD4+Foxp3+ T_{regs} in peripheral blood to be significantly lower in IBD (both ulcerative colitis and Crohn's disease) patients compared with healthy controls. However, at the mucosal level, Maul *et al*[14] and Wang *et al*[3] found the frequency of T_{regs} higher in active and inactive IBD samples compared to healthy controls. Their results and the results of Holmén *et al*[15] indicated that the increased frequency of CD25+ T cells in inflamed mucosa might be associated with the decreased number of circulating CD4+CD25+ T cells. During active inflammation, circulating T_{regs} migrate into the lamina propria to maintain homeostasis. As direct cell-to-cell contact is critical for T_{regs} to function, a low number of T_{regs} may result in a disturbance in the inhibition of the inflammatory reaction[15,16]. The results of Wang *et al*[3] suggest that an insufficient number of T_{regs} in the peripheral blood may be associated with the recurrence of IBD.

While Wang *et al*[3] did not find any alteration in the frequency of mucosal CD4+Foxp3+ T_{regs} in ulcerative colitis and Crohn's disease, Hovhannisyan *et al*[17] showed that the inflammatory environment in the colonic mucosa of Crohn's disease patients (but not in that of ulcerative colitis patients) contributes to the generation of a distinct population of T_{regs} that are Foxp3+ and produce IL-17. These Foxp3+ IL-17-producing cells also produced large amounts of interferon (IFN)-γ, another effector cytokine. On the other hand, Kryczek *et al*[18] observed mucosal Foxp3+IL17+CD4+ T_{regs} in ulcerative colitis that induce proinflammatory cytokines and suppress effector T cell function, exhibiting their dual inflammatory and regulatory function.

The balance between these subpopulations of mucosal T_{reg} cells, which may be regulated by the inflammatory milieu, seems to be crucial in the pathogenesis of IBD.

Phenotypic plasticity of T_{regs} in IBDs

The IL-17-producing CD4+ T (Th17) cells constitute a subset of helper T cells that has been linked to the pathogenesis of IBD[19]. Mucosal Th17 cells are thought to protect the host from infection.

The development of Th17 cells and T_{regs} requires TGF-β which suggests that both cell types may be related

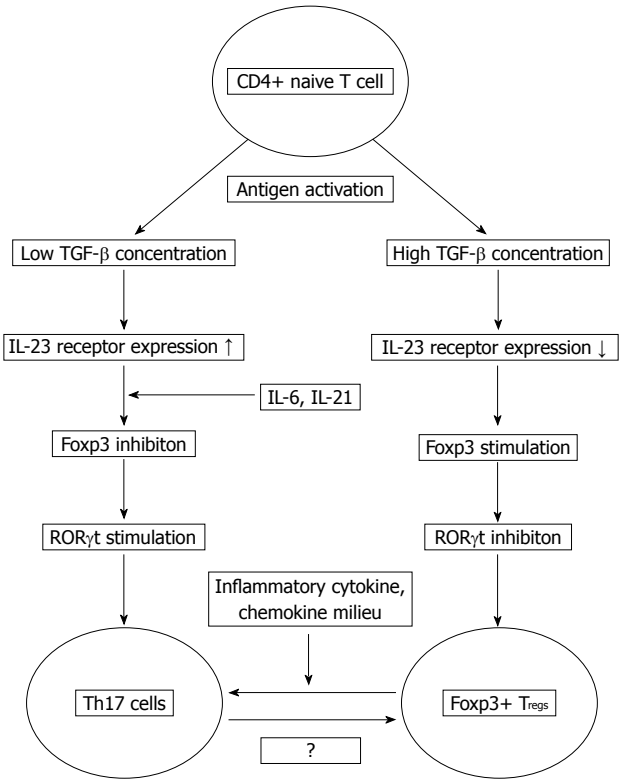

Figure 1 Phenotypic plasticity of T cells in inflammatory bowel disease. The mucosal concentration of transforming growth factor (TGF)-β influences the interleukin (IL)-23 receptor expression of antigen activated CD4+ T cells, which results imbalance in forkhead box P3 (Foxp3) and retinoic acid-related orphan receptor (RORγt) transcription factor activity. The Foxp3 dependent inhibition or stimulation of RORγt may regulate helper T cell (Th) 17 or Foxp3+ regulatory T cell (T_{reg}) differentiation. The inflammatory cytokine/chemokine milieu may also influence the phenotypic changes of T cells.

and may arise from the same precursor based on the distinct cytokine milieus[20-23]. TGF-β exposure of antigen-activated naive CD4+ T cells results in upregulation of Foxp3 and retinoic acid-related orphan receptor (RORγt), two transcription factors that regulate T_{reg} and Th17 cell differentiation[24]. Zhou *et al*[25] showed that at low concentrations, TGF-β synergizes with IL-6 and IL-21 to promote IL-23 receptor (IL23R) expression, favouring Th17 cell differentiation, while in high concentrations it represses IL23R expression and favours Foxp3+ T_{regs} differentiation. *In vitro*, TGF-β-induced Foxp3 inhibits RORγt function, at least in part through their interaction. Consequently, lamina propria Foxp3+RORγt+T cells produce less IL-17 than those that express RORγt alone. IL-6, IL-21 and IL-23 inhibit Foxp3-mediated inhibition of RORγt, therefore promoting Th17 cell differentiation. Based on these data it seems, that the decision of antigen-stimulated cells to differentiate into either Th17 or T_{reg} cell depends on the cytokine-regulated balance of Foxp3 and RORγt[25].

Hovhannisyan *et al*[17] identified such a Foxp3+ IL-17-producing CD4+ T_{reg} cell population in the lamina propria of Crohn's disease patients that shared phenotypic characteristics of both Th17 and T_{reg} cells, and showed potent suppressor activity *in vitro*. Their analysis of the TCR repertoire revealed a similar TCR β-chain variable region usage by Foxp3+IL-17+ and Foxp3+CD4+ T cells, suggesting that Foxp3+ IL-17-producing cells may come from Foxp3+ T_{regs} when exposed to unique inflammatory signals present in Crohn's disease (Figure 1).

Increased mucosal TGF-β and IL-6 expression have been detected in Crohn's disease[26,27]. Similar results were not found in ulcerative colitis associated mucosa[26,27]. These cytokines are supposed to promote the conversion of T_{regs} into effector T cells, while retaining their suppressive properties[17,20]. Despite the presence of cytokines involved in Th17 and T_{reg} cell differentiation, the generation of Foxp3+IL-17+ T_{regs} from normal lamina proprial or peripheral blood CD4+ T cells failed[17]. Therefore it is speculated that additional, presumably local, factors are also required for the induction of these cells *in vivo*. Kryczek *et al*[18] found that these inflammatory T_{regs} are induced from memory chemokine (CC motif) receptor 6+ T cells and T_{regs}. Furthermore, TGF-β, IL-2 and the presence of antigen presenting cells are also essential for their induction.

The better understanding of the origin and function of T_{regs}, and the interaction between effector and regulatory sites of mucosal immune cells in IBD may lead to new therapeutic possibilities.

T_{REGS} IN IBD-ASSOCIATED COLON CANCER

In mice, Faubion *et al*[28] showed that chronic inflammation arising from the bowel may induce thymic involution and T_{reg} cell suppression. This was suggested to lead to the enhancement of inflammation-mediated events that worsen IBD. Restoration of homeostasis through suppression of tumor necrosis factor (TNF)-α production and fortification of T_{regs} were proposed for human IBD patients[4]. These data on IBD may support to the concept that uncontrolled inflammation weakens the T_{reg}-mediated inhibition and increases the risk for inflammation-associated carcinogenesis.

In colitis-associated colon cancer, a high frequency of Foxp3+IL-17+CD4+ T_{regs} was found in the tumor, but not in the adjacent mucosa[18]. Though human tumor-infiltrating T_{regs} express limited effector cytokines[29], colitic Foxp3+IL-17+CD4+ T_{regs} express a moderate amount of IFN-γ, TNF-α and IL-2, and shares similar cytokine profiles to blood Foxp3+IL-17+ T_{regs}[18]. This cytokine profile reveals a phenotype for polyfunctional effector T cells similar to that observed in infectious diseases[30,31] and tumor-infiltrating Th17 cells in multiple human cancers[32]. These data indicate that Foxp3+IL-17+ T_{regs} express effector cytokines and are distinct from T_{regs} within the same inflammatory milieu.

Moreover, in suppressive assays, Foxp3+IL-17+ T cells from colitis-associated colon cancer were able to suppress T cell proliferation and IFN-γ production in a dose-dependent manner[18], which suggests that Foxp3+IL-17+ T cells belong to a functional T_{reg} cell population.

Kryczek *et al*[18] also found that T_{regs} induce the production of IL-1 and IL-6 in ulcerative colitis. IL-17 derived from Foxp3+IL-17+CD4+ T cells may also induce IL-6 expression[33,34]. As IL-1 and IL-6 play a crucial role in ulcerative colitis[35,36], it is possible that IL-17-producing Foxp3+CD4+ T cells together with Th17 cells may potentially contribute to the early tumorigenesis seen in chronic ulcerative colitis.

The role of pathogenic microbial infection in colitis-associated carcinogenesis is also known[4]. After pathogenic microbial challenges, a pro-inflammatory response mediated by effector T cells serves to eliminate pathogenic bacteria. Educated CD4+CD45RB^{low} T_{regs} then subsequently suppress inflammation, offering protection from immunological self-destruction. It was shown that IL-10-dependent T_{regs} protect from malignancy[37,38]. Deficiency in IL-10 increases susceptibility to IBD-associated colorectal cancer (CRC) with poor prognosis[39]. Mice lacking IL-10 were shown to be susceptible to colitis-associated CRC after *Helicobacter hepaticus* (*H. hepaticus*) infection, while their wild type counterparts infected with *H. hepaticus* had only minimal bowel alterations[37,38,40,41]. The lack of IL-10 leads to elevated levels of TNF-α, IL-6 and IL-17, therefore allowing chronic inflammation to persist[42]. After *H. hepaticus* infection, IL-10 insufficient CD4+ T cells preferentially recruit to a Th-17 phenotype in the case of a pro-inflammatory challenge[4-45]. It was also shown in mice that bacteria-triggered inflammation mobilizes neutrophils bearing TGF-β1 and IL-6, which may inhibit T_{regs} and promote Th-17 response, a phenomenon that has been linked to carcinogenesis[40]. Based on these results, one may conclude that colonic bacterial infections supposed to trigger protective IL-10-dependent T_{regs}, while, under hygienic conditions, individuals with insufficiently educated T_{regs} are predisposed to sustained inflammatory reactions and may subsequently developed cancers[4].

Acting downstream of TGF-β1 signaling, Runx proteins are the interacting and functional partners of R-Smad proteins[46]. Among Runx proteins, Runx3 is involved in the differentiation of immune cells[47], and acts as a homeostasis maintainer and tumor suppressor in the gastrointestinal epithelium[48,49]. In mice, Sugai *et al*[47] found that the loss of Runx3 in T cells resulted in suppression of T_{reg} cell function which lead to the development of colitis and colonic tumors (associated with luminal microorganisms) in Runx3$^{-/-}$ animals.

Further studies are needed to reveal the interaction between the commensal intestinal bacterial flora and T_{regs} for the better understanding of colitis-associated colorectal carcinogenesis.

T_{REGS} IN SPORADIC COLORECTAL CANCER

Presence of T_{regs} and disease outcome

Cancer cells have evolved to develop strategies of immunoevasion to escape control by the immune system[50]. There are quite numerous possible immunoevasion mechanisms that appear to affect diverse steps in cancer-specific lymphocyte priming, activation, and effector function. These mechanisms may also operate simultaneously[51,52]. Evidence is accumulating that CD4+CD25+Foxp3+ T_{regs} are crucially involved in cancer immunobiology[10]. The number of Foxp3+ T_{regs} was found to be significantly increased in the peripheral blood, lymph nodes and surrounding tumors of patients with colorectal cancer compared to that of healthy controls[20,53]. Several data show that increased frequencies of T_{regs} prognosticate a worse outcome for colon cancer patients, as this may reflect the inability of the immune system to adequately respond to cancer[54-56]. Moreover, studies aimed at reducing T_{reg} cell frequencies in experimental models have resulted in successful control of cancer[57].

On the contrary, others showed that an increased intratumoral Foxp3+ T_{reg} cell number correlates with a favourable clinical outcome[58]. This can be the result of mast cell-T_{reg} cell interaction, which induces T_{regs} to switch function and escalate inflammation in CRC without losing T-cell-suppressive properties in an IL6 and IL17 independent manner[59].

Szczepanik *et al*[60] found that the absolute number of T_{regs} in the peripheral blood of gastric cancer patients, especially in those with lymph node metastases was significantly decreased in comparison to that of healthy controls. This phenomenon was not observed in CRC patients. Their results suggest that the population of T_{regs} in peripheral blood does not simply mimic intratumoral T_{regs}.

Based on this data, one can conclude that when inflammatory cells that promote tumor progression dominate the immune response, T_{regs} may be beneficial in suppressing carcinogenesis. However, when T cells dominate the immune response, T_{regs} may promote disease progression by suppressing their anti-tumoral immunological effects. The discrepancy between the peripheral blood and local, intratumoral number phenotype of T_{regs} in sporadic CRC may have an effect on this theory, and should be further investigated.

Contribution of T_{regs} to carcinogenesis and cancer cell survival

The colonic adenoma-dysplasia-carcinoma sequence is associated less clearly with inflammation then it is with colitis-associated colon cancer. C57BL/6 mice heterozygous for a mutation in the *Apc* gene (Apc$^{Min/+}$) are genetically at risk for intestinal polyps and mimic early stages of sporadic CRC in humans[61]. It was observed, that Apc$^{Min/+}$ mice have higher serum and intestinal levels of TNF-α, IL-6 and IL-17 than matched wild type animals, which may indicate a subclinical inflammatory condition[4]. Elevated inflammatory cytokine levels were found in human colorectal cancer as well[62].

Using T_{reg} cell titration assay it was also shown, that T_{regs} from *H. hepaticus* infected donor Apc$^{Min/+}$ mice con-

sistently provided complete protection from cancer and more effectively suppressed TNF-α, IL-6 and IL-17 cytokine levels in tumor-prone tissues than T_{regs} from uninfected donor mice[4,63]. It is thought that the protection from cancer is attributable to T_{reg} cell functions, and is more dependent upon the former conditions of T_{regs} than that of the recipient mice.

In humans, Ma *et al*[64] revealed that CD4+CD25+Foxp3+IL-17+ T cells in CRC tissue express TGF-β and IL-10, the functional molecules of T_{regs}. This subset of T cells suppresses anti-tumoral peripheral CD8+ T cells in a tumor antigen-specific manner, therefore contributing to cancer development. If the effector CD8+ T cells could disengage from the suppression of CD4+CD25+Foxp3+IL-17+ T_{regs}, they might again proliferate and fight against tumor development.

It has been shown that chemokine (CC motif) ligand (CCL) 5 is highly expressed in colon tumor tissues from early-stage CRC compared with paired normal tissues[65]. CCL5 promotes tumor growth and metastasis by inducing tumor cell proliferation, angiogenesis, and expression of matrix metalloproteinases[66,67]. It can also diminish anti-tumoral immune responses by increasing the presence of tumor-infiltrating macrophages and T_{regs}[67]. Chang *et al*[68] have recently found that CCL5 expression could not only promote migration of T_{regs} to tumors, but also enhance their killing ability on CD8+ T cells. Furthermore, this enhanced killing ability was associated with an increase in production of TGF-β by T_{regs}. Based on these results, it seems that the production of CCL5 by cancer cells is a part of CRC's immunoevasion repertoire.

Further studies may help us to better understand the interaction between tumor cells and T_{regs} and to identify an unrevealed mechanism by which tumor cells induce immune tolerance in CRC.

CONCLUSION

Targeting T_{regs} may offer an important therapeutic strategy as an adjunct to treatment of patients.

A better understanding of the microenvironmental cues that influence T_{reg} cell commitment toward a given lineage and their balance between regulation and inflammation may result in new therapeutic targets in IBD and colitis-associated cancer.

T_{regs} and IL-10 producing Tr1 cells have the potential to prevent or cure colitis in graft-versus-host disease, a finding supported by a favourable safety profile was demonstrated in phase I clinical trials[69]. Although it must be confirmed in further clinical trials, these results emphasize that T_{regs} may also be promising tools for therapeutic applications in IBD[70]. Changing the distribution of peripheral and mucosal T_{regs} may also have therapeutic potential in colonic inflammations.

We presently lack sufficient data to determine the clinical effect of an immunotherapy targeting T_{regs} in patients with sporadic CRC. The unexpected finding[58] that tumor-infiltrating Foxp3+ T cells could be associated with a favourable prognosis in CRC, suggests the potential in targeting these cells in immune-based anti-cancer therapies. On the other hand, eliminating CD4+CD25+Foxp3+IL-17+ T_{regs} may help the effector CD8+ T cells to fight against cancer cells. Therefore this subset of T cells may offer a novel therapeutic target in the treatment of CRC[64]. In conclusion, these conflicting results should be appreciated with some discretion, as the mechanisms linking tumor-infiltrating Foxp3+ T_{reg} cell density with a favourable outcome remain equivocal.

Abstract

AIM: To investigate the incidence of clinically detected port-site metastasis (PSM) in patients who underwent robotic surgery for biliary malignancies.

METHODS: Using a prospective database, the patients undergoing fully robotic surgery for biliary malignancies between January 2009 and January 2011 were included. Records of patients with confirmed malignancy were reviewed for clinicopathological data and information about PSM.

RESULTS: Sixty-four patients with biliary tract cancers underwent robotic surgery, and sixty patients met the inclusion criteria. The median age was 67 year (range: 40-85 year). During a median 15-mo follow-up period, two female patients were detected solitary PSM after robotic surgery. The incidence of PSM was 3.3%. Patient 1 underwent robotic anatomatic left hemihepatectomy and extraction of biliary tumor thrombi for an Klatskin tumor. She had a subcutaneous mass located at the right lateral abdominal wall near a trocar scar. Patient 2 underwent robotic pancreaticoduodenectomy for distal biliary cancer. She had two metachronous subcutaneous mass situated at the right lateral abdominal wall under a same trocar scar at 7 and 26 mo. The pathology of the excised PSM masses confirmed metastatic biliary adenocarcinoma.

CONCLUSION: The incidence of PSMs after robotic surgery for biliary malignancies is relatively low, and biliary cancer can be an indication of robotic surgery.

INTRODUCTION

Cholangiocarcinoma (CCA) is an epithelial malignant neoplasm arising from the bile ducts with features of cholangiocyte differentiation. CCA is the second most common primary hepatobiliary malignant cancer after hepatocellular carcinoma, and epidemiologic studies suggest its incidence is increasing worldwidely[1]. Advanced unresected CCA has an extremely dismal prognosis, with a median survival of < 24 mo; meanwhile, five-

year survival rates after R0 resection for hilar CCA are 11% to 41% and for distal CCA are 27% to 37%[2]. The treatment of CCA is challenging, and surgical therapy is the only therapeutic option with a chance of cure. Owing to its unique patterns of invasion and metastasis, the disease recurrence rate was very high (> 50%) after R0 resection, either locoregional recurrence or distant metastases[3,4]. Recently, cutaneous or subcutaneous metastasis from CCA and gallbladder cancer was also noted[5-7], especially port-site metastasis (PSM) after laparoscopic surgery[8-14].

Since Mouret performed the first laparoscopic cholecystectomy in 1987, this technique has rapidly become the gold standard for the management of cholelithiasis. In the past decade, laparoscopic and robotic techniques have quickly expanded to the indication of various malignancies[15-17]. The advantages of a minimally invasive surgery are well established, such as shorter convalescence and decreased analgesic requirements, along with better cosmetic results. Laparoscopic oncology continues to be confirmed with favorable outcomes[18,19], however, reports of PSMs, a phenomenon of tumor seeding or implantation at the port-site of entry of the laparoscopic trocars, remain an area of concern[8-14,20-26]. There are very limited reports on the risk of PSMs occurring from robotic surgery for malignancies[27,28].

The goal of our study was to determine the incidence of PSMs in patients undergoing robotic surgery for biliary malignancies, which can somewhat extrapolate whether robotic surgery is indicated for advanced biliary cancers or not.

MATERIALS AND METHODS

This study was conducted with the approval of the institutional review board of PLA Second Artillery General Hospital. We maintain a prospective database of all patients undergoing robotic procedures performed by the Department of Hepatobiliary Surgery, and we reviewed all cases performed between January 2009 and January 2011. All patients with a confirmed biliary malignancy who underwent robotic surgery were included. Patients with benign disease, those who had died postoperatively or lost postoperative following-up, and those whose procedure converted to open or laparotomy were excluded. Data abstracted included the patient's age at diagnosis, site of biliary tumor, primary histological diagnosis, American Joint Committee on Cancer (AJCC) stage, surgical procedures, intraoperative findings, presence of ascites, information regarding adjuvant radiochemotherapy after initial surgery, detection of PSM, time to the development of PSM, findings at the time of the diagnosis of PSM, and the overall survival for patients who developed PSMs. AJCC stage was assigned as delineated in the National Comprehensive Cancer Network Clinial Practice Guidelines on Hepatobliary Cancers (Version 2, 2012)[29]. The medical records were reviewed for all robotic procedures, including operative notes, radiology reports, pathology reports, and all involved progress notes. All patients included in this analysis had a regular every 3-mo follow-up physical examinations.

PSM was defined as subcutaneous tumor recurrence in the abdominal wall, near or within the scar tissue of the previous robotic-trocar site, which was detected either by clinical examination or by radiologic findings.

In all cases, the da Vinci Surgical System (Intuitive Surgical, Inc., Sunnyvale, CA) under a carbon dioxide pneumoperitoneum with the maximum intraabdominal pressure of 14 mmHg was used. On average, 5 or 6 trocars were placed during the procedure, and incision size ranged from 8 mm to 12 mm. One 12-mm trocar, usually infraumbilical, served as the camera port, and 3 robotic 8-mm trocars were placed 8-cm relative to each other. One or two additional 12-mm troars were used as assistant and choledochoscopic access. The entry into the abdominal cavity was achieved under direct visualization. The non-robotic trocar used in all cases was the Versaport trocar system (United States Surgical, North Heaven, Connecticut). The trocars were removed after the abdomen was deflated with the trocars in place. The 12-mm trocar incisions were closed in 2 layers at the fascia and the skin level, and the 8-mm trocar incisions were usually closed at the skin only with an attempt to close all layers. A lavage of the port sites with povidone-iodine solution was performed at the discretion of the surgeon.

Standard statistical analyses were used and performed using SPSS software, Version 17.0 (SPSS Inc., Chicago, IL). Descriptive statistics and proportions were used to report relevant demographic characteristics.

RESULTS

One hundred and ninety-four patients underwent robotic surgery procedures during the study period, including 64 cases with biliary cancers: intrahepatic biliary cystadenocarcinoma in 3, hilar CCA in 39, middle and distal biliary tract cancer in 11, and gallbladder cancer in 11. After exclusion of 2 patients with conversion to open procedures and 2 patients with postoperative death, we finally identified 60 patients who met inclusion criteria. Meanwhile, the 4 patients with open conversion or death were evaluated together when needed. The clinical characteristics of the patients are listed in Table 1.

All patients had no pre- and intra-operative evidence of distant intra-abdominal tumor metastasis. Eight severely jaundiced patients had an intraoperative finding of minor ascites. For retrieval of specimens, we usually applied surgical glove or ladle-like forcep to retrieve the freezing specimen or tumor thrombi intraoperatively, and use of retrieval bags for large specimens at the end of procedure. The postoperative primary histological diagnosis was biliary adenocarcinoma in 59 cases, biliary cystadenocarcinoma in 3, and miscellaneous in 2.

The tumor, node, metastasis stages of primary tumor type are outlined in Table 2. The robotic procedures

performed are listed in Table 3. Among 64 patients with biliary tract cancers, 2 patients converted to open procedures, with a rate of conversion of 3.1%. The postoperative morbidity and mortality are listed in Table 4.

The median follow-up period for all of the patients was 15 mo (range: 11-34 mo). PSMs were detected in 2 (3.3%) of the 60 patients, both of them were absent of intraoperative ascites. The interval between robotic surgery and detection of PSM was 27 mo in patient 1 and 7 mo in patient 2.

Patient 1 was a 51-year-old woman, who admitted with complaints of abdominal pain, jaundice and generalized pruritus in February 2009. A diagnosis of Klatskin tumor (Bismuth classification ⅢⅠb) was suspected. Robotic anatomatic left hemihepatectomy and extraction of biliary tumor thrombi were performed. During the procedures, the glove-fingers were used for retrieval of tumor thrombi specimens (Figure 1). The pathology revealed well-differentiated papillary adenocarcinoma and biliary tumor thrombi arising from the left biliary duct. In order to prevent local tumor recurrence, a prophylactic stereotactic body radiation therapy (SBRT) with total

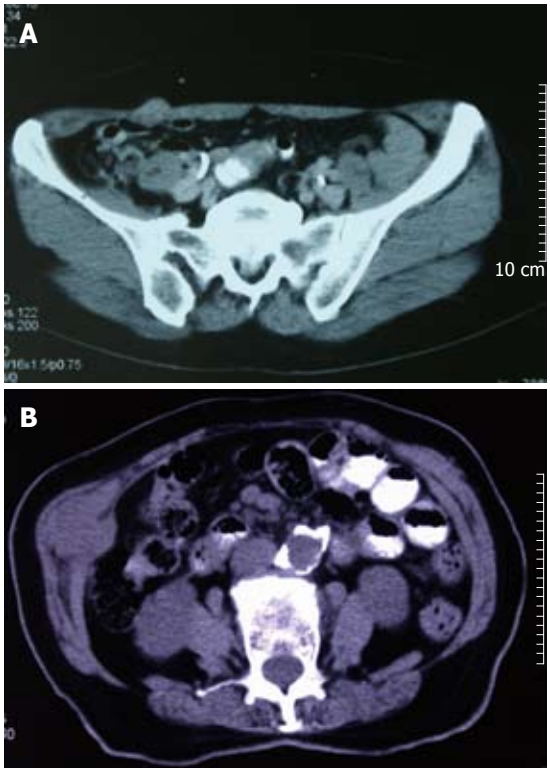

Figure 2 Computerized tomography scans of subcutaneous mass. A: A 2 cm × 1.5 cm subcutaneous mass at right lateral abdominal wall, which near a trocar scar on physical examination; B: A 4 cm × 3 cm × 3 cm subcutaneous mass at right lateral abdominal wall.

dose of 42 Gy (12 times) was given to the hepatic margin at 6th postoperative month.

In May, 2011, she was readmitted to our hospital for noting a subcutaneous mass at right lateral abdominal wall. Upon physical examination, a painless well-circumscribed, hard, subcutaneous mass near a trocar scar was palpated at the right lateral abdominal wall. Computed tomography (CT) scans confirmed a 2 cm × 1.5 cm subcutaneous mass (Figure 2A); no other obvious radiologic abnormalities were discovered. A subcutaneous tumor seeding was considered, and the mass was locally excised from the abdominal wall muscle (Figure 3A). Postoperative pathology confirmed metastatic biliary adenocarcinoma.

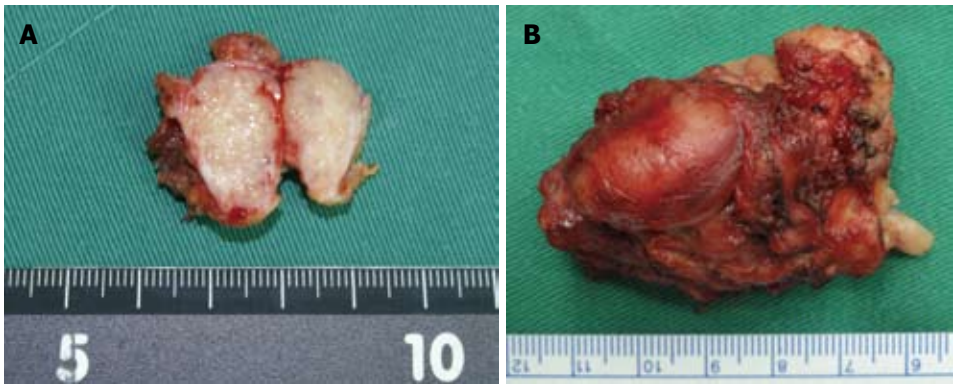

Figure 3 The subcutaneous mass was locally excised (A) and repeated excised locally (B) from abdominal wall muscle.

Mortality	2 (3.1)
Pulmonary infection	1
Acute renal failure	1

In November 2011, about 33-mo after the robotic surgery, she was discovered multiple intraabdominal masses on CT scans, and was managed by SBRT.

Patient 2 was a 75-year-old woman with painless jaundice who was diagnosed as distal biliary tumor, and underwent robotic pylorus-preserving pancreaticoduodenectomy in July 2009. Postoperative pathology revealed poor-differentiated adenocarcinoma arising from the distal biliary duct. The preoperative serum CA199 level was 160 U/mL (normal range: 0-37 U/mL), then it dropped to normal range. An incisional hernia was occurred at infra-umbilical port site 2-mo after operation.

In February 2010, she had complained of a palpable painless subcutaneous mass of 3 cm × 2 cm size at right lateral abdominal wall under a robotic trocar scar, and which was removed by local excision. The pathology revealed seeding nodule of CCA. In September 2011, another 4 cm × 3 cm × 3 cm subcutaneous mass at the same site (Figure 2B) with obvious pain was noted, no other distal metastases were determined on CT scans. Meanwhile, the incisional hernia enlarged rapidly to a size of 13 cm × 13 cm; the serum CA199 level increased to 91.26 U/mL. Repeated local excision of subcutaneous mass (Figure 3B) and simultaneous incisional hernia repair with mesh implantation were performed. She recovered uneventfully. Postoperative pathology confirmed metastatic adenocarcinoma, and the serum CA199 level had returned to normal at that time.

DISCUSSION

Oncology-related laparoscopic PSMs were first reported

in 1978, Döbrönte *et al*[20] described a PSM occurring 2 wk after laparoscopy in a patient with malignant ascites. Since then, a number of PSMs cases after diagnostic or therapeutic laparoscopy have been reported, involving nearly all abdominopelvic malignancies[8-14,20-26]. However, given the sparse published data, and the few events of PSM, the precise incidence of PSM has still not been well defined. Ramirez *et al*[23] estimated that the overall incidence of PSMs after laparoscopic surgery was 1%-2%; and in general laparoscopic surgery the incidence of tumor seeding ranges from 0.8% to 21%[5,30]. Noticeably, the incidence of PSMs after laparoscopic cholecystectomy for incidental gallbladder cancer was as high as 14%-29% within the first 2 years after the initial operation[11-14].

Our study showed that the incidence of PSM in patients undergoing robotic surgery for the management of biliary malignancies is 3.3% (2/60). The 3.3% PSMs incidence in this study seems much lower than the reported incidence after laparoscopic surgery for incidental gallbladder cancer, and a little higher than that in general laparoscopic surgery[23]. The relatively low incidence of PSMs reveals that advanced biliary malignancies can be selected as an indication of robotic or laparoscopic techniques. To the best of our knowledge, this is the first study evaluating the incidence of PSMs after robotic procedures for biliary malignancies. Although there are rare reported cases of PSM after robotic procedures in malignancies[27,28], the risk of PSM between robotic and laparoscopic surgery would be not significantly different, because of procedures and requirements such as CO_2 pneumoperitoneum pressure (12-14 mmHg), the trocars placement are all much similar[28].

There are several postulated mechanisms for developing PSMs[23,30-34]. The most commonly discussed hypotheses include direct wound contamination and implantation, the biological aggressiveness of the primary tumor, haematogenous spread, effects of pneumoperitoneum that including the type of insufflating gas, chimney effect, aerosolization, surgical technique and the local immune response. Likewise the occurrence of PSMs is secondary to the above-mentioned multiple factors. Accordingly, several precautions were adopted with attempt to minimize the risk of PSMs[23,32-38].

The incidence of PSMs is much higher after laparoscopic surgery for incidental gallbladder carcinoma, which is mostly caused by tumor cells contamination due to gallbladder perforation during procedure and retrieval[8-14,39]. In this study, most of our patients had advanced biliary tract cancers. Their bile potentially contains tumor cells exfoliated from the primary tumor; bile ducts mobilization and dissection will probably detach more tumor cells into the bile; the robotic or laparoscopic instruments are inevitably contaminated by the spilled bile and exfoliated tumor cells. These possible scenarios resulted in consequent peritoneal carcinomatosis and PSM, especially in those with tumor thrombus, or undergoing R1 and R2 resection[5-7,40]. For patient 1, the procedures of tumor thrombi exposure and retrieval probably increase the risk of direct wound contamination of tumor cells, during specimen retrieval and instrument transfers.

This study raises a question regarding the indication of robotic or laparoscopic surgery for advanced biliary tract cancers. The initial result of this study justifies robotic surgery for biliary cancer on low incidence of PSMs. However, while either based on the surgical approaches, being robotic, laparoscopic or open, it is less important than the adherence to the principles of oncological surgery. All the procedures of violation of the primary tumor boundaries or damage of tumor-bearing lymph nodes, may promote tumor cell dissemination[41]. The conditions such as a presence of tumor thrombus and extensive intraabdominal metastases, may be a contraindication of robotic surgery for biliary tract cancer, because direct tumor manipulation infringes the oncological principles[41]. To prevent the trocar-site seeding in the case of biliary malignancy, we now routinely extract the specimen intact with the use of an impermeable laparoscopic retrieval bag[39]. Furthermore, we began to perform hyperthermal intraperitoneal chemotherapy at the end of robotic surgery to annihilate potential intraabdominal disseminated tumor cells[42].

In conclusion, the incidence of PSMs after robotic surgery for biliary cancer is relatively low, and biliary malignancies can be selected as an indication of robotic surgery. Although robotic surgery seemed more elaborate than laparoscopic surgery in managing biliary cancer, we should be aware of the risk of PSMs when dealing with malignancies. Emphasis on adhering to strict oncological surgical principles is the best method of prevention. Further studies are mandatory to better determine the role of robotic biliary surgery on the long-term oncological outcomes.

COMMENTS

Background

In the past decade, laparoscopic and robotic techniques have rapidly expanded to the indication of various malignancies. However, reports of port-site metastases (PSMs), a phenomenon of tumor seeding or implantation at the port-site of entry of the laparoscopic trocars, remain an area of concern. It has presumed that gallbladder cancer is a contraindication of laparoscopic technique owing to extremely high incidence of PSMs. This study estimates the incidence of clinically detected PSM in patients undergoing robotic surgery for biliary malignancies, in order to investigate the indication of biliary malignancies for robotic surgery.

Research frontiers

The laparoscopic technique has been little used for biliary malignancies, because the incidence of PSMs after laparoscopic cholecystectomy for incidental gallbladder cancer was as high as 14%-29% within the first 2 years after the initial operation. However, there are very limited reports on the risk of PSMs occurring from robotic surgery for malignancies, especially with no data of PSM incidence after robotic biliary surgery.

Innovations and breakthroughs

This is the largest number of case reports from a single-institution worldwidely. Total to sixty-four patients with biliary tract cancers underwent robotic surgery, and sixty patients met the inclusion criteria. During a median 15-mo follow-up period, two female patients were detected solitary PSM after robotic surgery. The incidence of PSM was 3.3%. The relatively low incidence of PSMs after

robotic surgery for biliary malignancies would arouse the interest of reappraisal the indication of laparoscopic or robotic procedures for biliary cancers.

Applications

Robotic surgery for biliary malignancies can be selected as an indication in selected patients with early or advanced biliary cancers, such as gallbladder cancer, Klatskin tumor and distal biliary cancer. Meanwhile, an emphasis on adhering to strict oncological surgical principles is the best method of prevention of PSMs, and further studies are mandatory to better determine the role of robotic biliary surgery on the long-term oncological outcomes.

Terminology

PSM is a phenomenon of tumor seeding or implantation at the port-site of entry of the laparoscopic trocars after laparoscopic or robotic surgery for malignancies. The high incidence would raise a question on the oncologic safety of laparoscopic or robotic procedures for malignancies.

Peer review

This is an interesting report of the author's experience in the management of patients with biliary malignancies by using robot.

Abstract

AIM: To evaluate the efficacy and safety of traditional Chinese surgical treatment for anal fistulae with secondary tracks and abscess.

METHODS: Sixty patients with intersphincteric or transsphincteric anal fistulas with secondary tracks and abscess were randomly divided into study group [suture dragging combined with pad compression (SDPC)] and control group [fistulotomy (FSLT)]. In the SDPC group, the internal opening was excised and incisions at external openings were made for drainage. Silk sutures were put through every two incisions and knotted in loose state. The suture dragging process started from the first day after surgery and the pad compression process started when all sutures were removed as wound tissue became fresh and without discharge. In the FSLT group, the internal opening and all tracts were laid open and cleaned by normal saline postoperatively till all wounds healed. The time of healing, postoperative pain score (visual analogue scale), recurrence rate, patient satisfaction, incontinence evaluation and anorectal manometry before and after the treatment were examined.

RESULTS: There were no significant differences between the two groups regarding age, gender and fistulae type. The time of healing was significantly shorter (24.33 d in SDPC *vs* 31.57 d in FSLT, $P < 0.01$) and the patient satisfaction score at 1 mo postoperative follow-up was significantly higher in the SDPC group (4.07 in SDPC *vs* 3.37 in FSLT, $P < 0.05$). The mean maximal postoperative pain scores were 5.83 ± 2.5 in SDPC *vs* 6.37 ± 2.33 in FSLT and the recurrence rates were 3.33 in SDPC *vs* 0 in FSLT. None of the patients in the two groups experienced liquid and solid fecal incontinence and lifestyle alteration postoperatively. The Wexner score after treatment of intersphincter fistulae were 0.17 ± 0.41 in SDPC *vs* 0.40 ± 0.89 in FSLT and transsphincter fistulae were 0.13 ± 0.45 in SDPC *vs* 0.56 ± 1.35 in FSLT. The maximal squeeze pressure and resting pressure declined after treatment in both groups. The maximal anal squeeze pressures after treatment were reduced (23.17 ± 3.73 Kpa in SDPC *vs* 22.74 ± 4.47 Kpa in FSLT) and so did the resting pressures (12.36 ± 2.15 Kpa in SDPC *vs* 11.71 ± 1.87 Kpa in FSLT), but there were neither significant differences between the two groups and nor significant differences before or after treatment.

CONCLUSION: Traditional Chinese surgical treatment SDPC for anal fistulae with secondary tracks and abscess is safe, effective and less invasive.

INTRODUCTION

Anal fistulae are common in human beings. Surgery remains one of the most effective therapies. The main objective of surgery for anal fistulae is to eradicate the fistula tract while maintaining anal continence[1]. Fistulotomy (FSLT) and fistulectomy are safe and effective for simple and superficial anal fistulae. When a fistula has secondary tracts or abscess, laying open procedures may have some complications such as longer healing time, larger defects, and higher risk of incontinence[2,3]. In China, many hospitals use traditional Chinese surgical therapies to treat anal fistulae. To some extent, these therapies work well[4-7]. Suture dragging combined with pad compression (SDPC) is a combined dynamic treatment which was invented by Bo-Hua Gu and has been applied to anorectal disease by Jin-Gen Lu since the 1980s[8]. The aim of this study was to evaluate the efficacy and safety of this traditional Chinese surgical treatment SDPC for anal fistulae with secondary tracks and abscess and to compare it with the surgical treatment FSLT in modern medicine.

MATERIALS AND METHODS

Subjects

A total of 60 consecutive patients with intersphincteric or transsphincteric anal fistulae with secondary tracks and abscess were included in the study, who were treated between January 2008 and March 2009 in the department of anorectal surgery, Longhua Hospital affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China. This study was approved by the local ethical committee and performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki. Patients with chronic inflammatory bowel disease, dermatitis, diabetes, tumors and pregnant or lactating women were excluded. Informed consent was obtained from all participants after full explanation of the procedure. None of them were dropped out or lost to follow-up after the study.

Treatment

Preoperative evaluation: Patients were randomly assigned to either the SDPC group or the FSLT group by computer-generated random number. Each group has 30 patients. Clinical evaluation was based on both digital examinations and assessments with perianal and endoanal ultrasonography by an experienced sonographer. All patients were identified to have either intersphincteric or transsphincter anal fistulae with secondary tracts or abscesses. Incontinence evaluation (Wexner score, 0-20) and anorectal manometry (Medtronic Synectics, Sweden) were performed with an 8 channel water-perfused catheter before surgery. Maximal anal squeeze and anal resting pressures were recorded.

Postoperative pain was evaluated using a visual analogue scale (0-10), incontinence evaluation and anorectal manometry were performed when wounds were completely epithelized.

Operative technique: All procedures were carried out by one of two surgeons with significant experience in SDPC and FSLT. Surgeon was told of the intervention one day before surgery. Both groups were operated upon under spinal anaesthesia and in lithotomy or left lateral position. One dose of metronidazole (Shanghai Huazhong Pharmaceutical, Ltd., Shanghai, China) was used intravenously during the operation.

In the SDPC group, internal opening and secondary tracts or abscess were identified by a ball-shape head sliver fistula probe (Figures 1 and 2). The internal opening and inflammatory tissue around were excised with scissors. Mucosa and internal sphincter below the internal opening were laid open and the incision was extended to anal verge for drainage. All secondary tracts and abscesses of intersphincteric fistulae or transsphincteric fistulae were curetted carefully to remove epithelialized and necrotic tissues. Incisions at external openings were made about 1 cm × 0.5 cm for drainage (Figure 3). Then ten silk sutures (4-0, 25 cm length, Shanghai Jinhuan Medical, Ltd., Shanghai, China) were put through every two incisions and knotted in loose state (Figure 4). For complete drainage, one incision was done in the middle of curved (Figure 5) or longer than 5 cm fistulous tract (Figure 6).

In the FSLT group, the internal opening and all tracts were identified with the same ball-shape head sliver fistula probe. The internal opening, extended fistula tracts, abscess and external openings were laid open thoroughly with scissors and curetted carefully. All wounds were left open for drainage.

Postoperative care: Metronidazole was administered intravenously for three days postoperatively in both groups. In the SDPC group, dressings were changed by doctors twice a day at 8 am and 4 pm, respectively. The suture dragging process was started from the first day after surgery during dressing change. Wounds and fistulous track cavities were irrigated with normal saline (Figure 7). Part of the silk sutures inside the fistula tract were dragged

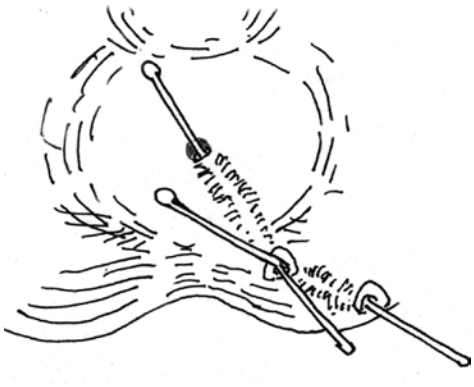

Figure 2 Internal opening and secondary tracts were found by a ball-shape head sliver fistula probe.

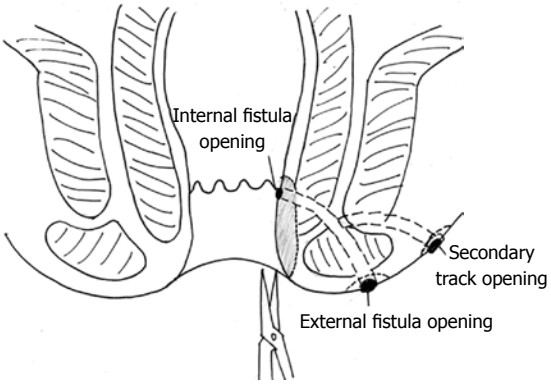

Figure 3 Mucosa and internal sphincter below the internal opening were laid open and a wound was made on anal verge for drainage. Secondary tracts or abscess were curetted.

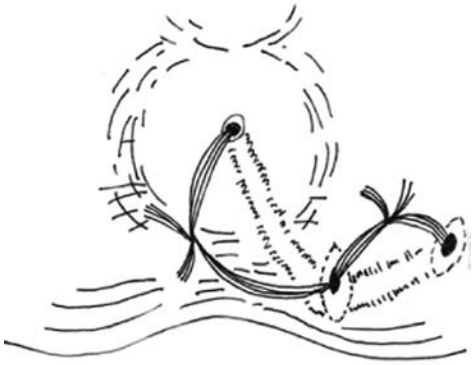

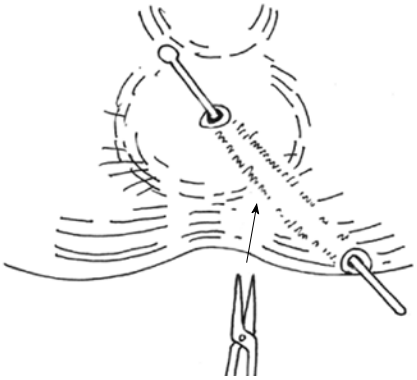

Figure 4 Silk sutures were put through every two incisions and knotted in loose state.

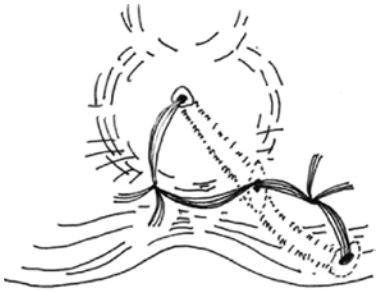

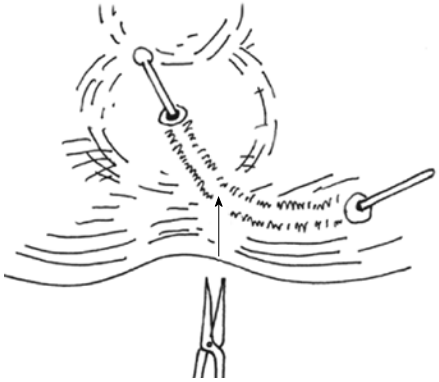

Figure 5 If fistulous track was longer than 5 cm, one incision was done in the middle of tract.

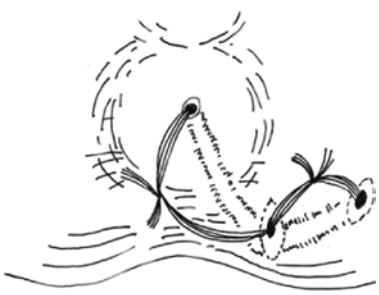

Figure 6 If fistulous track was curved, one incision was done at the top.

Table 1 Demographic characteristics and clinical outcomes of the patients

	SDPC (n = 30)	FIST (s = 30)	P value
Age (yr)	44.25 ± 14.31	41.17 ± 17.58	0.744
Gender (male/female)	22/8	19/11	0.405
Fistulae type			
Intersphincteric	6	5	0.739
Trans-sphincteric	24	25	
Secondary tracts	21	23	0.559
Secondary abscess	9	7	
Time of healing (d)	24.33 ± 4.44	31.57 ± 5.30	< 0.001
Postoperative pain scores	5.83 ± 2.50	6.37 ± 2.33	0.373
Oral analgesics (n)	10	14	0.292
Parenteral analgesics (n)	0	1	0.313
Recurrence rate (%)	3.33	0	0.313
Incontinence score			
Before treatment			
Intersphincteric	0.00 ± 0.00	0.20 ± 0.45	0.148
Trans-sphincteric	0.08 ± 0.28	0.12 ± 0.44	0.366
After treatment			
Intersphincteric	0.17 ± 0.41	0.40 ± 0.89	0.289
Trans-sphincteric	0.13 ± 0.45	0.56 ± 1.35	0.071
Manometry			
Maximal anal squeeze pressure (Kpa)			
Before treatment	24.73 ± 4.39	25.31 ± 3.89	0.590
After treatment	23.17 ± 3.73	23.74 ± 4.47	0.598
Resting pressure (Kpa)			
Before treatment	13.16 ± 2.23	12.66 ± 2.19	0.391
After treatment	12.36 ± 2.15	11.71 ± 1.87	0.212
Patient satisfaction	4.07 ± 0.94	3.37 ± 1.45	0.031

SDPC: Suture dragging combined with pad compression; FIST: Fistulotomy.

out and cleansed with normal saline, then turned back into the tract cavity. Usually the fistulous cavity became smaller at 10 d after surgery while the granulation tissue grew, then five sutures were cut and taken away. The residual sutures were removed one by one every 1-2 d afterwards depending on the space of the cavity. When all sutures were removed as wound tissue became fresh and without discharge, the pad compression process was initiated. One dose of lopramide hydrochloride (Xian-Janssen Pharmaceutical, Ltd., Xi'an, China) was given to the patients at the same time. A thick cotton pad was wrapped over the fistulous cavity and fixed with tape. Patients were asked to sit on a flat chair for 30 min, and relax for 10 min. The total time for pad compression was 6 h a day till the cavity healed.

In the FSLT group, dressings were changed by doctors twice a day at 8 am and 4 pm from the first day after surgery. Normal saline was used to clean the wounds until all wounds were completely epithelized. Patients in both groups were discharged when wounds healed. Success was defined by the absence of bleeding, pain, discharge, and subjective symptomatic relief.

Follow-up

Patients were followed up at outpatient clinic at 1 mo after the wounds were completely healed and by telephone at 12 mo after surgery. Patient's satisfaction was assessed in the outpatient clinic at the first follow-up using scores from -5 to +5 (with -5 being dissatisfied and +5 being very satisfied).

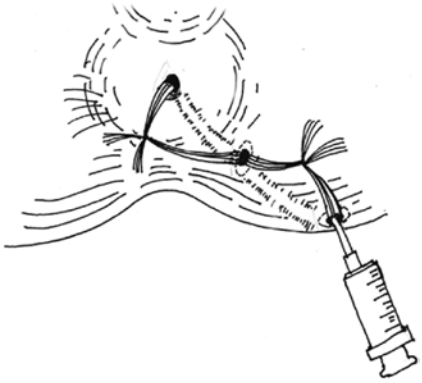

Figure 7 Wounds and fistulous track were irrigated with normal saline.

Statistical analysis

Statistical analysis was performed using SPSS for Windows Version 11.5 (SPSS Inc., Chicago, IL, United States). Descriptive statistics for demographic data were employed. Quantitative data were expressed as the mean ± SD, while χ^2 test was used for categorical data analysis. The two groups were compared with one-sided t test for analysis. $P < 0.05$ was considered significant.

RESULTS

The demographic data and outcomes in the two groups are shown in Table 1.

Time of healing

The mean time of healing in the two groups was 24.33 ± 4.44 d and 31.57 ± 5.30 d, respectively. It was significant shorter in the SDPC group than in the FSLT group.

Postoperative pain

The mean maximal postoperative pain scores were 5.83 ± 2.5 and 6.37 ± 2.33 for the SDPC group and the SDPC group, respectively. Ten (33.33%) patients in the SDPC group used oral analgesics and no patient required additional parenteral analgesics. Fifteen (46.67%) patients in the SDPC group used oral analgesics and one (3.33%) patient received parenteral analgesics due to severe pain.

Recurrence rate

One male patient in the SDPC group had swelling and discharged at week 3 after operation. He became asymptomatic after surgical drainage. All patients in the SDPC group were healed in one stage.

Incontinence evaluation

None of the patients had any incontinence before surgery. Two patients with transphincter fistula in the SDPC group and one with intersphincter and two with transsphincter fistula in the SDPC group used pads to prevent

underwear contamination. Postoperatively, no patient in the SDPC group experienced incontinence, but one intersphincter and two transsphincter fistulae patients used pads in the first two weeks after surgery. One female patient in the SDPC group with transsphincter fistula had transient gas incontinence from the third day after surgery. Symptoms of this patient disappeared 4 wk later without any treatment. Another one intersphincter and three transsphincter patients in the SDPC group wore pads in the first two weeks after surgery. The Wexner score after treatment of trans-sphincter fistulae was 0.13 ± 0.45 in the SDPC group and 0.56 ± 1.35 in the FSLT group (P = 0.071). None of the patients in this study experienced any problem with liquid and solid fecal incontinence and lifestyle alteration postoperatively.

Anorectal manometry

The maximal anal squeeze pressures before operation were 24.73 ± 4.39 Kpa in SDPC and 25.31 ± 3.89 Kpa in FSLT, and reduced to 23.17 ± 3.73 Kpa in SDPC and 22.74 ± 4.47 Kpa in FSLT after operation. The resting pressures before operation were 13.16 ± 2.23 Kpa in SDPC and 12.66 ± 2.19 Kpa in FSLT, and reduced to 12.36 ± 2.15 Kpa in SDPC and 11.71 ± 1.87 Kpa in FSLT after operation. Both of the maximal squeeze pressure and resting pressure declined, but there were neither significant differences between the two groups and nor significant differences before or after treatment.

Patient satisfaction

The mean satisfaction score at 1-mo postoperative follow-up for the SDPC group was 5 in ten patients, 4 in fifteen patients, 3 in three patients, 2 in one patient and 1 in one patient. It was 5 in six patients, 4 in ten patients, 3 in nine patients, 2 in two patients, 1 in one patient, 0 in one patient and -1 in one patient in the SDPC group. The mean satisfaction score was significant higher in the SDPC group (4.07 ± 0.94 in SDPC *vs* 3.37 ± 1.45 in FSLT).

DISCUSSION

The prevalence rate of anal fistulae is 8.6 cases per 100 000 populations[9]. Surgery is the most effective treatment for cryptoglandular fistula. For intersphincteric and low trans-sphincteric fistula, FSLT is a primary therapy[10]. Though complete FSLT is safe, it usually leads to larger wounds that take longer time to heal[11,12]. Recently, Atkin *et al*[13] reported that the laying open technique was still a good option for the management of complex anal fistulas. Ninety-six percent of their patients healed and the incidence rates of incontinence for flatus, soft stools and hard stools were low. But patients were unsatisfied with the postoperative complications of this laying open technique such as severe pain, longer healing time and unsightly scar[7]. More and more surgeons begin to seek less invasive therapies such as fibrin glue, sealant, anal fistula plug, endorectal mucosal advancement flap and ligation of intersphincteric fistula tract. Fibrin glue injection is technically easy, but results have been disappointing, with a success rate as low as 16%[14-16]. Similarly, the use of the anal fistula plug is a simple, low-risk but very expensive technique, and the reported success rates range between 29% and 87%[17-19]. Mucosal advancement flaps are technically difficult and associated recurrence rates vary from 2% to 54%[20-22]. Modified setons as cable-tie seton, silastic tube, silk, linen, braided silk, rubber band, and so forth were used to deal with complex or high anal fistula in recent years. However, incontinence still can not be avoided[23,24]. The latest conservative technique is ligation of intersphincteric fistula trac[25,26], but this procedure does not suit for fistula with abscess. Some novel techniques for treating complex fistula as video-assisted anal fistula treatment[27] and fistula laser closure[28], have been proposed. But these techniques need special equipments although the success rates were up to 80%. In this research, we found that the traditional Chinese surgical treatment SDPC can preserve the integrity of anal sphincter musculature involved by fistulous tract or abscess and maintain anal function with less postoperative pain and shorter healing time. This method has been used to treat fistulae and abscess diseases since the 1980s, which includes two processes. The "suture dragging" process refers to that the sutures which are put through the fistulous tracks or abscesses, are dragged by doctors postoperatively during dressing change. This process usually takes place at the first two weeks postoperatively. Suture dragging not only has the same functions of loose seton as mark and drainage, but also can stimulate granulation tissue to grow. The "pad compression" process means use thick pad to cover the wound and ask patients to sit on flat chair to accelerate the adhesion of wound cavity. Appropriate compression is good for tissue adhesion in wounds with deep cavity. In the last decade, some hospitals in China applied SDPC therapy to treat breast fistulae, acute mastitis, cutaneous abscess, anorectal horseshoe abscesses, necrotic fasciitis, pilonidal sinus disease and have obtained good results[29-32].

In this study, we used SDPC therapy to treat secondary tracts and abscess of intersphincteric and low transsphincteric fistulae. The SDPC therapy did not produce large wounds; the mean time of healing was reduced to 7 d compared with that of the FSLT. For the SDPC group, the postoperative pain mostly happened at dressing change. This was because some patients felt discomfort when doctor dragged sutures. But for the SDPC group, the postoperative pain was severe during bowel movement by stool evacuation. There was one male patient in the SDPC group complicated with edema and pain due to infection 3 wk after surgery during pad compression treatment. He suffered from diarrhea due to taking unhygienic food and not changing dressing regularly. After meticulous debridement and complete wound irrigation, he remained asymptomatic afterwards. One female patient who had gas incontinence

in the SDPC group had a complex trans-sphincteric fistula in which internal opening was at 6 o'clock and external openings at 6 o'clock and 7 o'clock, 1.5 cm and 2 cm from the anal verge respectively. The patient's symptom disappeared while wounds healed at 4 wk postoperatively. Though FSLT is safe in treating low trans-sphincteric fistula, it may damage part of external sphincter, especially for female patients with complex fistula. The Wexner score of trans-sphincteric fistula patients in the SDPC group was higher than in the SDPC group postoperatively. Maximal squeeze pressure and resting pressure after treatment reduced in both groups. This may be because that FSLT divided partial sphincter when managing the internal opening. But no patient experienced any problem concerning solid and liquid incontinence after treatment in both groups. Manometery confirmed that both therapies were safe. Most of the patients were highly satisfied with SDPC therapy for the advantages of less invasiveness, tiny scar, mild pain, shorter healing time and hospitalization.

Notably, the pattern of medical treatment in China is different from that of the Western countries. Doctors take care of patients' wounds postoperatively and patients can be discharged until their wounds are mostly epithelialized. On the contrary, in most developed countries, the procedures for most benign anorectal conditions are usually performed in outpatient settings, and patients can take care of their wounds themselves after hospital discharge. However, the treatment outcomes are quite good in this research, possibly due to this special pattern of treatment.

However, there are some limitations of this study. First, the sample size was small, and follow-up period was not long enough to assess the recurrence. SDPC therapy for complex trans-sphincteric fistulae is superior to that for intersphincteric fistulae. For intersphincteric fistulous tracks are usually short and laying open of this kind of fistulae is easy and safe. But for longer fistulous tracts and secondary abscesses, the advantages of this traditional Chinese surgical treatment are more apparent. In addition, the SDPC and FSLT are different techniques, it is impossible to be blinded to either surgeons or patients. In the future, we will conduct multi-center randomized controlled trials to compare SDPC with "cutting seton" or FSLT for high and low complex trans-sphincteric and supersphincteric anal fistulae.

As one of the traditional Chinese surgical therapies, the SDPC is successful in the treatment of perianal fistulae and abscesses disease. But the rationale of this treatment remains unclear. Why could dragging threads stimulate granulation tissue growth? When is the best time to remove sutures and start pad compression? What kind of appropriate pressure and duration can accelerate tissue adhesion without ischemia? Only when these questions have been clearly answered, can this traditional Chinese surgical sphincter-saving method be well accepted. More rigorous prospective randomized controlled trials with a larger sample size and longer follow-up are urgently needed.

In conclusion, traditional Chinese surgical treatment SDPC is safe, effective and less invasive. It can be used as an alternative to the treatment of complex anal fistulae.

COMMENTS

Background

Surgery is one of the most effective therapies for anal fistulae. More and more surgeons begin to seek less invasive therapies. However, classical procedures such as fistulotomy (FSLT) and fistulectomy, may produce complications such as longer healing time, larger defects, and higher risk of incontinence when dealing with fistulae with secondary tracts or abscess. In China, traditional Chinese surgical method suture dragging combined with pad compression (SDPC) has been used to treat anal fistulae and achieved good results.

Research frontiers

The postoperative complications of anal fistulae mostly include high risk of incontinence, severe pain, longer healing time and unsightly scar. Surgeons begin to seek less invasive therapies such as fibrin glue, sealant, anal fistula plug, endorectal mucosal advancement flap and ligation of intersphincteric fistula tract. The hotspot of anal fistula surgery is how to eradicate the fistula tract while maintaining anal continence and improving patient's quality of life.

Innovations and breakthroughs

There has been few studies about traditional Chinese surgical treatment for fistula diseases. This study reported that the traditional Chinese surgical method is effective and safe compared with the method used in modern medicine. The SDPC used in this study was less invasive with a higher patient's satisfaction.

Applications

The study results suggest that traditional Chinese surgical method SDPC is safe, effective and less invasive. It could be used as an alternative to the treatment of complex anal fistulae.

Terminology

Traditional Chinese surgical treatment SDPC includes two processes. The "suture dragging" refers to that the sutures which were put through the fistulous tracks or abscess during the operation, are dragged by doctor postoperatively during dressing change. The "pad compression" means use thick pad to cover the wound and ask patients to sit on flat chair to accelerate the adhesion of wound cavity. By this method, surgeons can preserve the integrity of anal sphincter musculature involved in fistulous tract or abscess, and maintain anal function with less postoperative pain and shorter healing time.

Peer review

The article presents an interesting novel technique to show the Western world another method of treatment. There was a significant shorter time to healing and higher patients' satisfaction in the study group, without difference in continence or complications. The described technique seems interesting, however it takes a greater deal of postoperative care compared with the traditional FSLT.

Abstract

AIM: To investigate the protective effects of ethyl pyruvate (EP) on acute-on-chronic liver failure (ACLF) in rats.

METHODS: An ACLF model was established in rats, and animals were randomly divided into normal, model and EP treatment groups. The rats in EP treatment group received EP (40 mg/kg) at 3 h, 6 h, 12 h and 24 h after induction of ACLF. Serum endotoxin, high mobility group box-1 (HMGB1), alanine transaminase (ALT), tumor necrosis factor-α (TNF-α), interferon-α (IFN-γ), interleukin (IL)-10 and IL-18 levels, changes of liver histology and HMGB1 expressions in liver tissues were detected at 48 h after induction of ACLF. The effects of EP on the survival of ACLF rats were also observed.

RESULTS: Serum levels of endotoxin (0.394 ± 0.066 EU/mL *vs* 0.086 ± 0.017 EU/mL, $P < 0.001$), HMGB1 (35.42 ± 10.86 μg/L *vs* 2.14 ± 0.27 μg/L, $P < 0.001$), ALT (8415.87 ± 3567.54 IU/L *vs* 38.64 ± 8.82 IU/L, $P < 0.001$), TNF-α (190.77 ± 12.34 ng/L *vs* 124.40 ± 4.12 ng/L, $P < 0.001$), IFN-γ (715.38 ± 86.03 ng/L *vs* 398.66 ± 32.91 ng/L, $P < 0.001$), IL-10 (6.85 ± 0.64 ng/L *vs* 3.49 ± 0.24 ng/L, $P < 0.001$) and IL-18 (85.19 ± 3.49 ng/L *vs* 55.38 ± 1.25 ng/L, $P < 0.001$) were significantly increased, and liver tissues presented severe pathological injury in the model group compared with the normal group. However, EP administration significantly improved hepatic histopathology and reduced the serum levels of endotoxin (0.155 ± 0.045 EU/mL *vs* 0.394 ± 0.066 EU/mL, $P < 0.001$) and inflammatory cytokines (11.13 ± 2.58 μg/L *vs* 35.42 ± 10.86 μg/L for HMGB1, 3512.86 ± 972.67 IU/L *vs* 8415.87 ± 3567.54 IU/L for ALT, 128.55 ± 5.76 ng/L *vs* 190.77 ± 12.34 ng/L for TNF-α, 438.16 ± 38.10 ng/L *vs* 715.38 ± 86.03 ng/L for IFN-γ, 3.55 ± 0.36 ng/L *vs* 6.85 ± 0.64 ng/L for IL-10, and 60.35 ± 1.63 ng/L *vs* 85.19 ± 3.49 ng/L for IL-18, respectively, $P < 0.001$), and the levels of HMGB1 in liver tissues regardless of treatment time after induction of ACLF. EP treatment at the four time points prolonged the median survival time of ACLF rats (60 h) to 162 h, 120 h, 102 h and 78 h, respectively ($\chi^2 = 41.17$, $P < 0.0001$).

CONCLUSION: EP administration can protect against ACLF in rats, and is a potential and novel therapeutic agent for severe liver injury.

INTRODUCTION

Acute-on-chronic liver failure (ACLF) is a severe life-threatening condition with a high fatality, which still lacks effective treatment options[1]. Evidences have indicated that intestinal endotoxemia plays a significant role in the pathogenesis and progression of liver failure[2,3], which results from overgrowth of gram-negative bacteria in gut, and/or bacteria translocation into the peritoneal cavity due to the high permeability of intestinal wall[4,5].

Recent studies have shown that high mobility group box-1 (HMGB1) protein is involved in the progression of endotoxemia[6-8]. HMGB1 can be released into the extracellular milieu by activated macrophages, immunostimulated gut epithelial cells and necrotic or damaged cells in a delayed manner relative to the secretion of tumor necrosis factor-α (TNF-α) and interleukin (IL)-1[9-11]. HMGB1 contributes to the pathogenesis of many diverse inflammatory disorders[12-14]. A growing number of studies have indicated that HMGB1 is a successful therapeutic target in numerous experimental models, such as ischemia/reperfusion[15], acute respiratory distress syndrome[16], rheumatoid arthritis[17], sepsis[18], and cancer[19]. Therefore, we proposed that HMGB1 as an important inflammatory mediator of endotoxemia should also play a significant role in the pathogenesis of liver failure[20].

Ethyl pyruvate (EP), a simple aliphatic ester derived from pyruvic acid, has been shown to improve survival and ameliorate organ dysfunction in a variety of animal models of critical illness, including acute endotoxemia[21], polymicrobial bacterial sepsis[22], postsurgical ileus[23], burn injury[24], acute pancreatitis[25], organ ischemia and reperfusion injury[26,27], and hemorrhagic shock[28]. As an effective anti-inflammatory agent, EP inhibits the activation of key inflammatory signaling pathways[29,30], and down-regulates the secretion of multiple inflammatory proteins, including IL-6, TNF-α and HMGB1[31-33]. These findings suggest that by reducing the levels of proinflammatory mediators, EP could also be a good candidate for treating or protecting against liver failure.

In the present study, we established an ACLF rat model, and investigated whether EP had protective effects on ACLF.

MATERIALS AND METHODS

Experimental animals

Female specific pathogen free Wistar rats, weighing 180-220 g, were purchased from the Experimental Animal Center of Wuhan University. All animals were acclimated to the laboratory for 5 d before experiment and were maintained in a light-controlled room (12-h light/dark cycle) at an ambient temperature of 25 ℃ with free access to water and standard chow. All animals were given humane care in accordance with the institutional guidelines.

Establishment of animal models

The ACLF rat models induced by human serum albumin (HSA), D-galactosamine (D-Gal) and lipopolysaccharide (LPS) were established as described elsewhere[34]. In brief, an immune liver fibrosis rat model was firstly induced by HSA (Octapharma GmbH, Austria)[35,36]. HSA was diluted to a concentration of 8 g/L with physiological saline and emulsified with an equal amount of incomplete Freund's adjuvant. The rats were injected subcutaneously at multipoints with 0.5 mL above solutions containing 4 mg HSA for a total of four times (a 14-d interval between the first and second time; a 10-d interval between the third and fourth time). Then, 4 mg HSA was injected into rat tail vein twice a week for 6 wk. Next, the rats with immune liver fibrosis were injected intraperitoneally with D-Gal (a purity of 98%, Sigma-Aldrich Co., United States) at a dose of 400 mg/kg combined with LPS (a purity of 99%, Sigma-Aldrich Co., United States) at a dose of 100 μg/kg to induce acute liver failure on the basis of chronic liver injury[37,38]. The normal rats were administrated with physiological saline (i.e., the vehicle solution of HSA, D-gal and LPS) at the same time points as did in the model rats, which served as a control.

Experimental design

Animals were randomly divided into normal group (n = 15), model group (n = 15) and EP treatment group (n = 60). The rats of EP treatment group were further divided into four subgroups (each subgroup n = 15), which were injected intravenously with Ringer's EP solution, containing Na^+ 130 mmol/L, K^+ 4 mmol/L, Ca^{2+} 2.7 mmol/L, Cl^- 139 mmol/L, and EP 28 mmol/L, pH = 7.02 (EP with a purity of 98% was purchased from Sigma-Aldrich Co., United States), at a dose of 40 mg/kg[39,40] at 3 h, 6 h, 12 h and 24 h. The time of combined administration of D-Gal and LPS was accepted as baseline (time point 0). EP was administrated subsequently at different time points. The rats of normal and model groups were injected intravenously with the same volume of Ringer's solution at the same time points. Five rats were sacrificed randomly for blood and hepatic tissue sampling at 48 h in each group. The remaining ten rats were observed for survival every 12 h for 7 d after induction of ACLF.

Blood sample examination

The serum levels of endotoxin were examined with Limulus Amebocyte Lysate (LAL, QCL-1000™, BioWhittaker, United States) according to the manufacturer's protocols. The serum levels of HMGB1, TNF-α, IFN-γ, IL-10 and IL-18 were measured using a rat HMGB1

enzyme linked immunosorbent assay (ELISA) Kit (Wuhan EIAab Science Co., Ltd, China) and commercial ELISA kits (Jingmei Biotech Co., Ltd, China) following the manufacturer's instructions, respectively. The alanine transaminase (ALT) level was determined by routine biochemical methods using a Hitachi Automatic Analyzer (Hitachi, Inc., Japan).

Histological examination

Liver samples were fixed in 10% buffered formalin for 24 h, embedded in paraffin, sliced into 5-μm thick sections and stained with hematoxylin and eosin (HE) to evaluate the pathological changes of the liver. The other portions of liver specimens were fixed in 2.5% glutaraldehyde, embedded in epoxy resin, sliced into ultrathin sections (60 nm in thickness) and stained with uranyl acetate and lead citrate to observe the ultrastructural changes of liver tissues under transmission electron microscope.

Real-time reverse transcription-polymerase chain reaction of HMGB1 mRNA

Total RNA was extracted from approximately 100 mg frozen liver tissues using TRIzol reagent (Invitrogen Co., United States). Two μg total RNA was reverse-transcribed into cDNA using a random primer hexamer (Promega Corporation, United States) and a MultiScribe™ Reverse Transcriptase (Applied Biosystems, United States). Gene expression was measured in real-time using primers and QuantiTect SYBR green polymerase chain reaction (PCR) Kit (QIAGEN Co., Ltd., China). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as an internal control. The primers for rat HMGB1 were 5'-CGGATGCTTCTGTCAACTTCT-3' and 5' -AGTTTCTTCGCAACATCACCA-3'; for rat GAPDH, were 5'-TGCACCACCAACTGCTTA-3' and 5'-GGATGCAGGGATGATGTT-3'. Thermal cycling conditions included pre-incubation at 50 ℃ for 2 min, 95 ℃ for 10 min followed by 40 cycles of 95 ℃ for 30 s, 58 ℃ for 30 s and 72 ℃ for 45 s. LightCycler (Roche, Switzerland) was used to collect data automatically and analyze the value of threshold cycle (Ct). The fold change of HMGB1 mRNA expression in the model group or EP treatment group relative to the control group was detected using $2^{-\Delta\Delta Ct}$ method[41].

Western blot analysis of HMGB1 protein

In brief, 50 μg protein extracts from 100 mg liver tissue samples were subjected to 12% sodium dodecyl sulfate polyacrylamide gel electrophoresis and then transferred to a Protran® nitrocellulose membrane (Schleicher and Schuell BioScience GmbH, Germany). The membrane was incubated with primary rabbit anti-rat HMGB1 antibodies (Boisynthesis Biotechnology Co., Ltd., China), and then with horseradish peroxidase-conjugated goat anti-rabbit secondary antibodies (Golden Bridge Biotechnology Co., Ltd., China), and finally detected by chemiluminescence using Enhanced NuGlo™ Chemiluminescent Substrate Kit (Alpha Diagnostic Intl. Inc., United States) followed by autoradiography and densitometric analysis. Membranes were also probed for β-actin as an additional loading control.

Immunofluorescence and confocal microscopy of HMGB1

Briefly, tissue sections were deparaffinized in xylene and rehydrated in a series of alcohol dilutions. The tissue sections underwent antigen retrieval using a commercial regent (Boster Biotechnology Co., Ltd., Wuhan, China), blocked with 10% normal goat serum in a humid chamber at 37 ℃ for 20 min to reduce non-specific binding, and then incubated with primary rabbit anti-rat HMGB1 polyclonal antibodies at 1:200 dilution at 4 ℃ overnight. The sections were then incubated away from light with a secondary fluorescein isothiocyanate-conjugated goat anti-rabbit IgG (Boster Biotechnology Co., Ltd., China) for 60 min at 37 ℃, counterstained with 2 μg/mL propidium iodide (Promoter Bio Co., Ltd., China) for 10 min, and observed under a Leika DM-IRE2 confocal microscope.

Statistical analysis

Results were expressed as mean ± SD. Differences among groups were assessed using unpaired Student *t* test and one-way analysis of variance. Animal survival data were evaluated using the Kaplan-Meier method and compared with the log-rank test. $P < 0.05$ was considered statistically significant.

RESULTS

Effect of EP on serum endotoxin, HMGB1, ALT and inflammatory cytokines

As shown in Figure 1, serum levels of endotoxin, HMGB1, ALT, TNF-α, IFN-γ, IL-10 and IL-18 were all significantly increased in rats of model group (0.394 ± 0.066 EU/mL, 35.42 ± 10.86 μg/L, 8415.87 ± 3567.54 IU/L, 190.77 ± 12.34 ng/L, 715.38 ± 86.03 ng/L, 6.85 ± 0.64 ng/L and 85.19 ± 3.49 ng/L, respectively) at 48 h after induction of ACLF compared with normal group (0.086 ± 0.017 EU/mL, 2.14 ± 0.27 μg/L, 38.64 ± 8.82 IU/L, 124.40 ± 4.12 ng/L, 398.66 ± 32.91 ng/L, 3.49 ± 0.24 ng/L and 55.38 ± 1.25 ng/L, $P < 0.01$). However, compared with model group, the serum levels of endotoxin, HMGB1, ALT, TNF-α, IFN-γ, IL-10 and IL-18 were all markedly lowered in EP treatment group at each time point, even at 24 h (0.327 ± 0.064 EU/mL, 15.73 ± 4.18 μg/L, 4863.78 ± 1864.13 IU/L, 143.24 ± 6.45 ng/L, 526.00 ± 28.68 ng/L, 4.96 ± 0.96 ng/L and 66.66 ± 5.59 ng/L, respectively, $P < 0.01$). There were significant differences in serum levels of endotoxin, HMGB1, TNF-α, IFN-γ, IL-10 and IL-18 in the EP treatment group at 24 h and at 3 h (0.155 ± 0.045 EU/mL, 11.13 ± 2.58 μg/L, 128.55 ± 5.76 ng/L, 438.16 ± 38.10 ng/L, 3.55 ± 0.36 ng/L, 60.35 ± 1.63 ng/L, $P < 0.05$).

Effect of EP on liver histology

HE staining showed a normal structure of hepatic lobule in the rat liver tissues of normal group. Neither de-

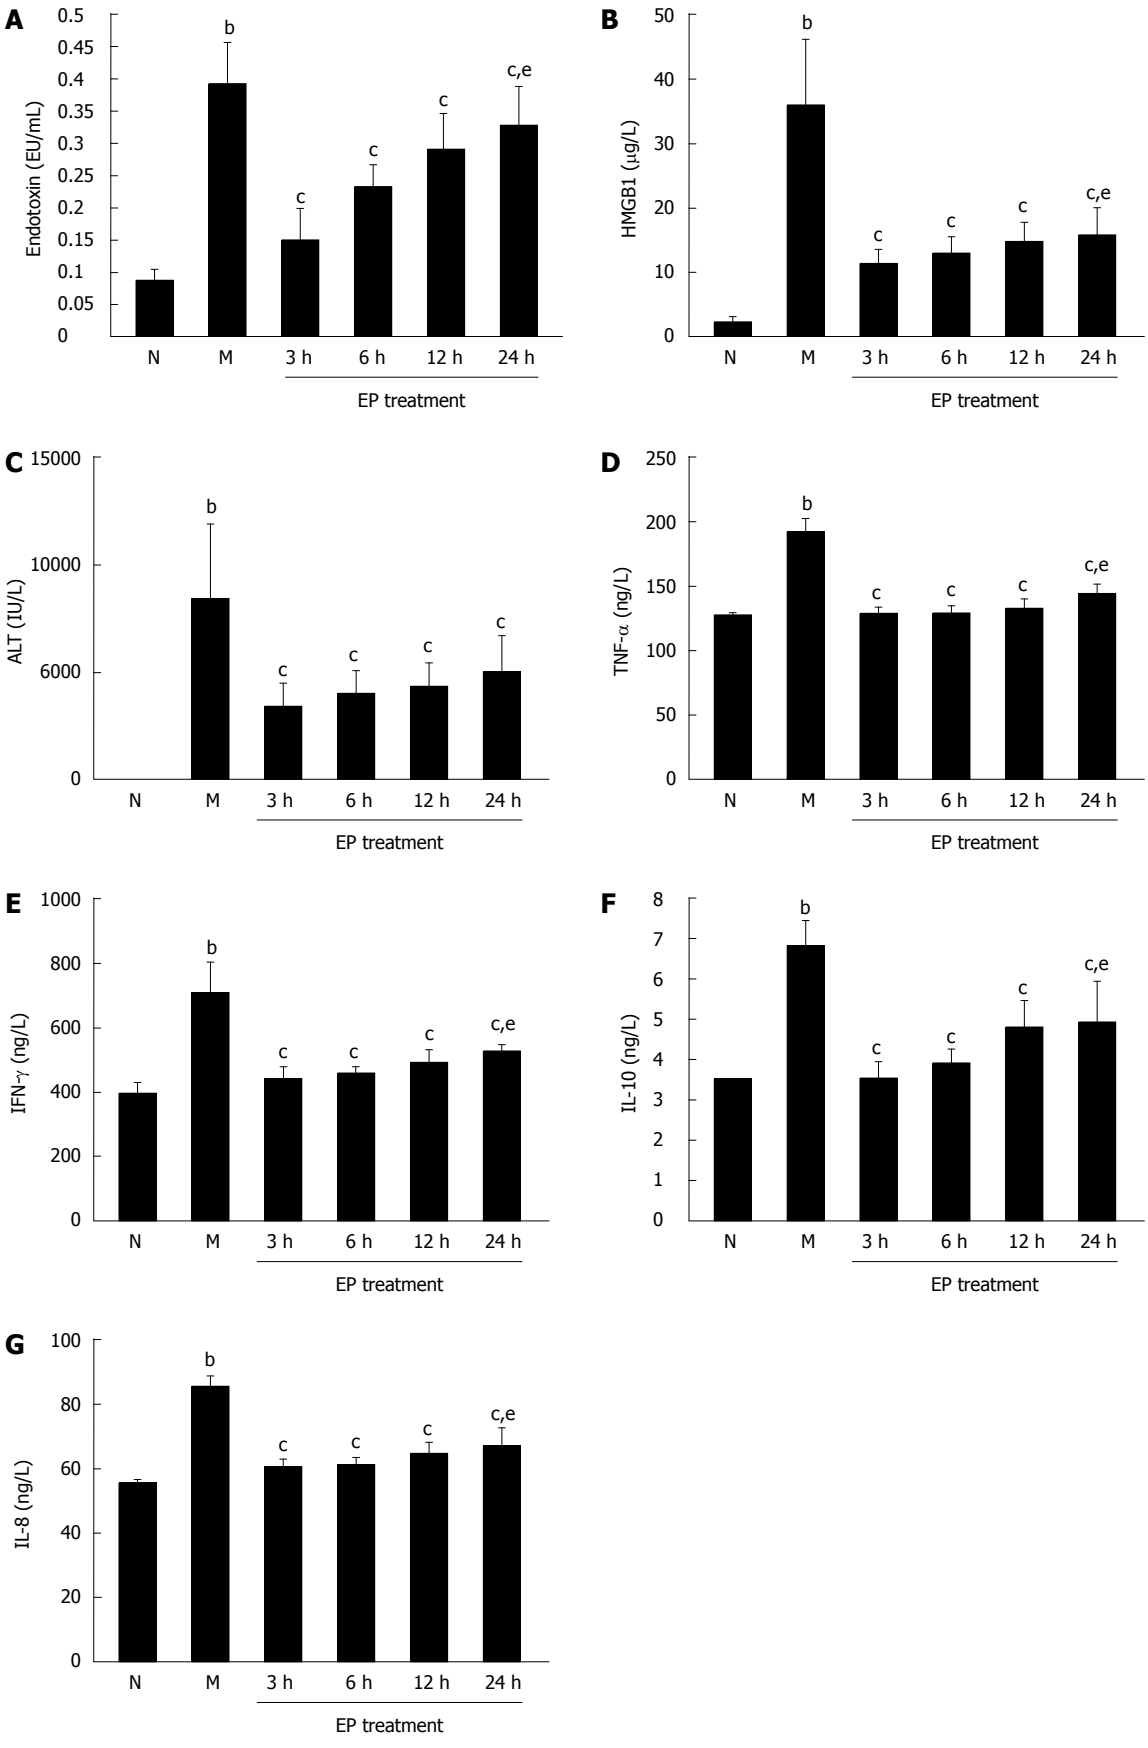

Figure 1 Effect of ethyl pyruvate on serum endotoxin, high mobility group box-1, hepatic enzyme and inflammatory cytokines in rat acute-on-chronic liver failure model. A: Endotoxin; B: High mobility group box-1 (HMGB1); C: Alanine transaminase (ALT); D: Tumor necrosis factor-α (TNF-α); E: Interferon-γ (IFN-γ); F: Interleukin (IL)-10; G: IL-18. $^{b}P < 0.01$ *vs* normal; $^{c}P < 0.05$ *vs* model; $^{e}P < 0.05$ *vs* ethyl pyruvate (EP) treatment at 3 h. Results are expressed as mean ± SD ($n = 5$). N: Normal group; M: Model group.

generation nor necrosis was presented. Hepatocytes were arrayed radiatively around the central vein (Figure 2A1). In the rat liver tissues of model group, the structure of hepatic lobules was in disorder with infiltration of many periportal inflammatory cells, hepatic plate was dissociated, and hepatocytes were swelling or with lytic necrosis. Massive or submassive necrosis of the regenerated nodules was revealed in some areas, while fibrosis septa were intact (Figure 2B1). However, liver histology was significantly improved in rats of EP treatment group as compared with the model group regardless of different time points of treatment. There was an obvious decrease of inflammatory cell infiltration, well-arranged hepatic cords, alleviation of hepatocyte swelling and less pyrenolysis (Figure 2C1, D1, E1 and F1). Under electronic microscope, the hepatocyte ultrastructure of rats in the normal group appeared normal (Figure 2A2), while in the model group, the glycogen granules decreased obviously in cytoplasm, endoplasmic reticulum was dilated and broken, mitochondrion was swollen, mitochondrial cristae were lysed, chromatin appeared vanishing, and even vacuolization occurred in the nuclei (Figure 2B2). Compared with the model group, hepatocyte ultrastructure was significantly improved in rats of EP treatment group, which showed that both endoplasmic reticulum dilation and mitochondrion swelling were alleviated obviously. Mitochondrial cristae and membrane remained clear, chromatin was symmetrical, and nucleoli and nuclear membrane were also legible (Figure 2C2, D2, E2 and F2).

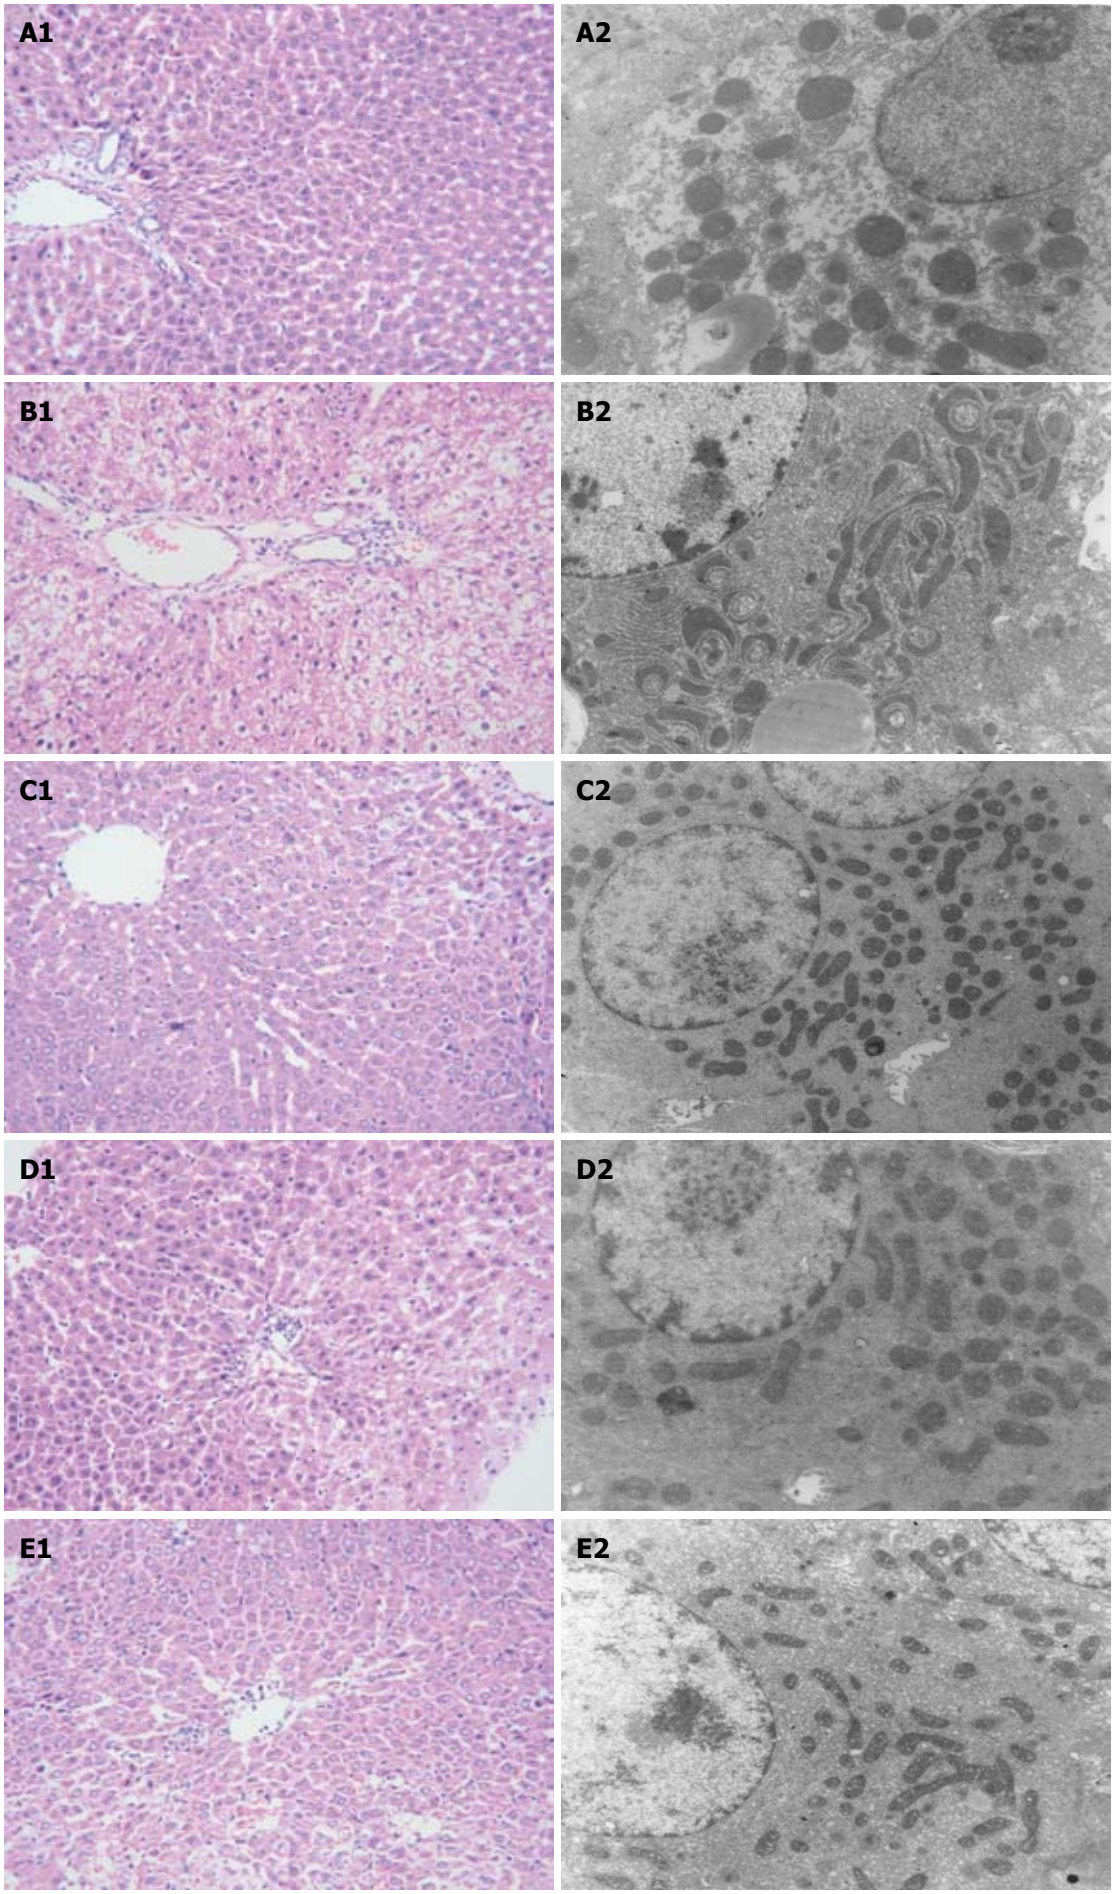
Effect of EP on HMGB1 expression in liver tissues

The real-time reverse transcription-PCR showed that the expression levels of HMGB1 mRNA in the liver tissues of rats in the model group were significantly higher than in the normal group. However, the expression levels of HMGB1 mRNA in EP treatment group were all significantly decreased at 3 h, 6 h, 12 h and 24 h (2.02 ± 0.27, 2.78 ± 1.16, 3.34 ± 0.31 and 4.21 ± 1.22) as compared with the model group (8.84 ± 2.13) (Figure 3A). Western blot assay further found that the expression of HMGB1 protein was significantly increased in the model group compared with the normal group, but significantly decreased in the EP treatment group at 3 h, 6 h, 12 h and 24 h (2.33 ± 0.67, 2.83 ± 1.07, 3.39 ± 1.01 and 4.02 ± 1.02) compared with the models (7.97 ± 1.85) (Figure 3B). There was no significant difference of HMGB1 expression levels in the EP treatment group at 24 h and 3 h (4.21 ± 1.22 *vs* 2.02 ± 0.27 for HMGB1 mRNA; 4.02 ± 1.02 *vs* 2.33 ± 0.67 for HMGB1 protein) (Figure 3).

Effect of EP on survival

Survival curves of each group are shown in Figure 4. The ACLF rats all died within 3 d without EP treatment, and their median survival time was 60 h. EP treatment at 3 h, 6 h, 12 h and 24 h significantly prolonged the median survival time of the ACLF rats to 162 h, 120 h, 102 h and 78 h, respectively. By log-rank test, there was a significant difference among the curves ($\chi^2 = 41.17$, $P < 0.0001$).

Subcellular localization of HMGB1 expression



Under confocal laser scanning microscope, HMGB1 expression in liver cells (green fluorescence) was mainly localized in the cytoplasm. A small number of HMGB1 was also observed in the nuclei (Figure 5).

DISCUSSION

The ACLF model has been widely accepted as a good mimic for pathophysiological process and histological characteristics of ACLF[37,38]. In the present study, an ACLF rat model was established firstly by inducing immune liver injury with HSA, and secondly by inducing acute liver failure with D-Gal and LPS treatment. Most of the rats treated with HSA developed cirrhosis and fibrosis, and 90% of them died of acute liver failure after administration of D-Gal and LPS, with a mean survival time of 60 h. Liver histopathology showed massive or submassive necrosis of the regenerated nodules in some areas, where fibrosis septa were intact. Liver function tests were consistent with massive necrosis of hepatocytes. Serum levels of TNF-α and IL-10 increased significantly, a similar result as seen in the patients with ACLF. These results verified that an ACLF model was successfully established, which was further confirmed by pathological characteristics, biochemical data and inflammatory profiles.

HMGB1 protein is involved in the processes of endotoxemia and multiple inflammatory cytokines actively secreted from monocytes/macrophages in the patients and animal models with liver failure[42,43]. Many studies have shown that HMGB1 stimulates the release of inflammatory cytokines in different cell-lines[44-46]. HMGB1 has been also identified as a successful therapeutic target in diverse inflammatory disorders[7,8]. Previously, we demonstrated that the high expression of HMGB1 and the low percentage of Treg cells play an important role in the pathogenesis of liver failure[20]. In the present study, the serum levels of TNF-α, IFN-γ, IL-10, IL-18 and HMGB1 were significantly increased in the ACLF model compared with the normal group. The tissue levels of HMGB1 were also significantly increased and translocations of HMGB1 from nuclei into cytoplasm were presented in ACLF rats. These findings suggested that the increased expression of HMGB1 and/or translocations of HMGB1 were associated with severe liver injury in ACLF, and blocking the release of HMGB1 may represent one of the novel therapeutic strategies for liver failure.

EP has been shown to be beneficial in a variety of animal models of acute and chronic inflammatory conditions[21-28,47,48]. This study investigated whether EP had protective effects on the ACLF model. The histological examinations of liver tissues in ACLF rats showed severe pathological changes at 48 h after induction of

The time points of 3 h, 6 h, 12 h and 24 h represent four sub-groups of EP treatment group. Results are expressed as mean ± SD ($n = 5$). N: Normal group; M: Model group.

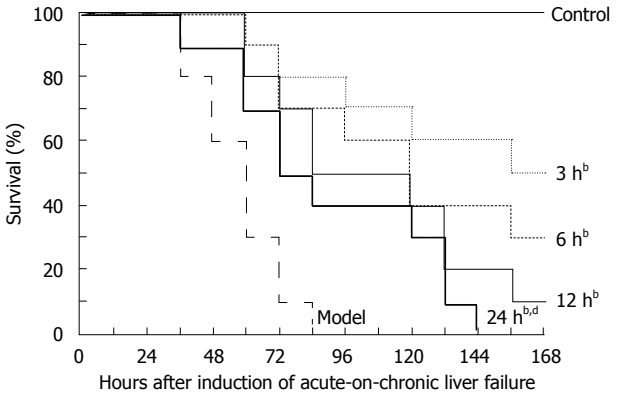

Figure 4 Effect of ethyl pyruvate on survival in rat acute-on-chronic liver failure model. Kaplan-Meier survival curves showed that the median survival time of the model group was 60 h, and the median survival time in ethyl pyruvate treatment group was 162 h, 120 h, 102 h and 78 h, respectively, after treatment at 3 h, 6 h, 12 h and 24 h. By log-rank test, $^{b}P < 0.01$ *vs* model; $^{d}P < 0.01$ *vs* 3 h.

ACLF. However, the hepatic histopathological changes were significantly improved in EP treatment group regardless of treatment time after induction of ACLF. Moreover, serum levels of endotoxin, HMGB1, ALT, TNF-α, IFN-γ, IL-10 and IL-18 were all markedly reduced with EP treatment at different time points. These findings suggested that EP exhibited a protective effect against ACLF rat model through inhibiting the production of inflammatory mediators. Since these inflammatory cytokines, especially the HMGB1, are produced actively by the hepatic macrophage, a major population of monocytes/macrophage lineage, whether EP exerts its inhibitory effects on these inflammatory cytokines through suppressing the hepatic macrophage remains to be further clarified.

A recent study has shown that treatment with anti-HMGB1 antibodies in mice attenuates LPS-induced lethality, even when antibody administration is delayed

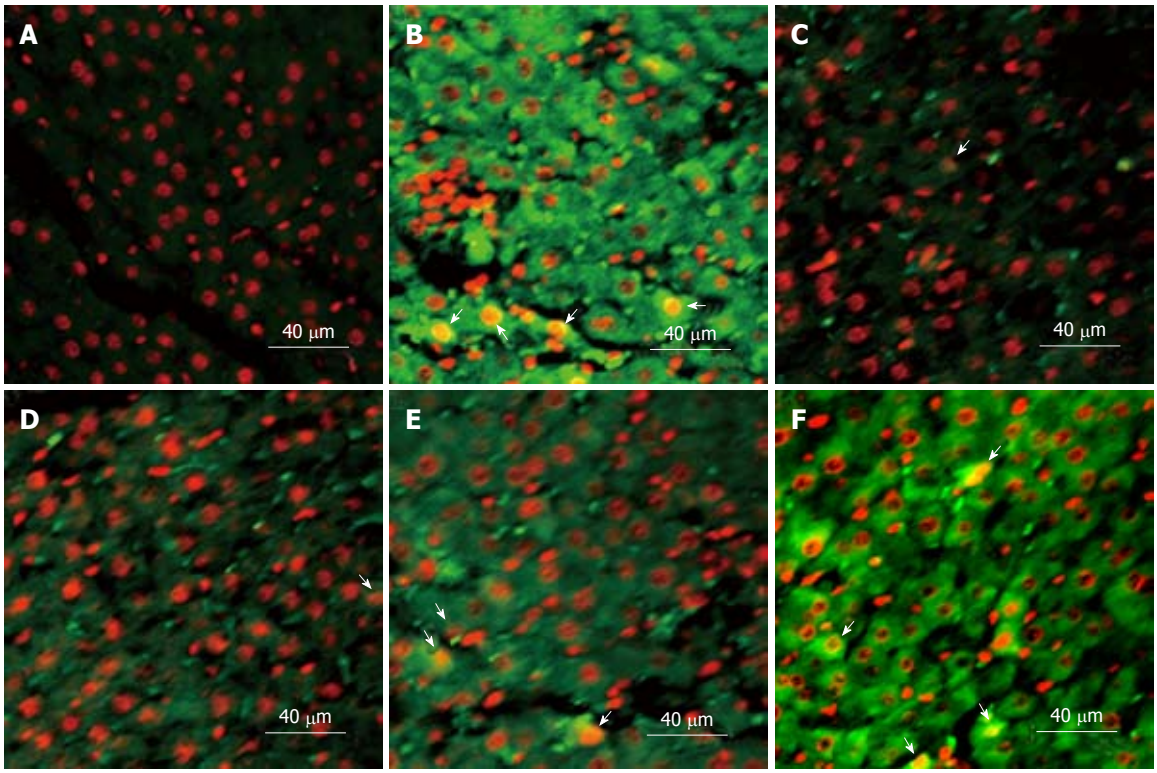

Figure 5 Immunofluorescence and confocal microscopy of high mobility group box-1 expression. Subcellular high mobility group box-1 expression (green fluorescence) was mainly localized in the cytoplasm, and also observed in a small number of nuclei (arrows). A: Normal group; B: Model group; C-F: Ethyl pyruvate treatment at 3 h, 6 h, 12 h and 24 h.

until after the onset of the early proinflammatory cytokine response[6]. In this study, the median survival time of the ACLF rats was 60 h. But EP treatment at 3 h, 6 h, 12 h and 24 h significantly prolonged the median survival time of the model rats to 162 h, 120 h, 102 h and 78 h, respectively, after induction of ACLF. The results showed that HMGB1 expressions in both serum and liver tissues were effectively inhibited in EP treatment group, accompanied with a significant decrease of endotoxin and improvement of hepatic histopathology. In EP treatment group, translocations of HMGB1 from nuclei into cytoplasm were markedly reduced depending on the treatment time points. The inhibitory effect of EP on HMGB1 at 3 h was better than at 24 h after induction of ACLF. It may indicate that early EP treatment could result in more obvious improvement in ACLF rats. However, EP treatment at 24 h after induction of ACLF also improved the liver histological changes and prolonged the survival of ACLF rats. It suggests that EP, as a HMGB1 inhibitor, could improve the ACLF outcome, even when HMGB1 inhibitor administration was delayed until induction of ACLF and after the onset of the early proinflammatory factor response. This indicates that targeted therapy against HMGB1 could be initiated even in the later stage of acute inflammation. It would provide a wider therapeutic time window for the treatment of endotoxemia in ACLF.

In summary, the present study demonstrates that EP administration can inhibit HMGB1 expression, decrease endotoxin level, reduce secretion of inflammatory cytokines, ameliorate hepatocellular injury, improve survival, and protect against ACLF in rats. These findings suggest that EP may be a potential and novel therapeutic agent for severe liver inflammatory injury.

COMMENTS

Background

Acute-on-chronic liver failure (ACLF) is a severe life-threatening condition, for which no effective treatment is available. More and more evidences have indicated that intestinal endotoxemia plays a significant role in the pathogenesis and progression of liver failure. A growing number of studies have also shown that high mobility group box-1 (HMGB1), as an important inflammatory mediator of endotoxemia, is a successful therapeutic target in experimental models of severe inflammatory diseases.

Research frontiers

Ethyl pyruvate (EP), an inhibitor of HMGB1, has been shown to improve survival and ameliorate organ dysfunction in a variety of animal models of critical illness. However, whether EP could also be a good candidate for the treatment of liver failure remains unknown. In this study, an ACLF rat model was treated with EP at different time points. The effects of EP on liver failure were investigated by observing the changes of various parameters, including endotoxin, HMGB1, liver function, cytokines, liver histology and animal survival.

Innovations and breakthroughs

The most common clinical cause of liver failure in Asia, especially in China, is an acute episode of liver function decompensation on the basis of an already impaired liver function caused mostly by chronic hepatitis B virus infection, which is defined as ACLF. Therefore, the traditional animal models of ACLF induced directly by D-galactosamine (D-Gal) or lipopolysaccharide (LPS) in previous studies can not simulate the pathophysiological process of ACLF. In this study, the authors employed an ACLF rat model which was established firstly

by human serum albumin treatment to induce immune liver injury, and secondly by administration of D-Gal and LPS to induce acute liver failure on the basis of chronic liver injury. Since this animal model can well simulate part of the pathophysiological processes of acute liver failure on the basis of chronic liver diseases, the experimental results of treatment with EP turned out to be more persuasive. This study showed that EP administration can inhibit HMGB1 expression, decrease endotoxin level, reduce secretion of inflammatory cytokines, ameliorate hepatocellular injury, and improve the survival of the ACLF rats.

Applications

The study results suggest that EP may be a potential and novel therapeutic agent for severe liver inflammatory injury.

Terminology

ACLF is defined as acute hepatic insult manifesting as jaundice and coagulopathy, complicated within 4 wk with ascites and/or encephalopathy in a patient with previously diagnosed or undiagnosed chronic liver disease according to the consensus recommendations of the Asian Pacific Association for the Study of the Liver; HMGB1 protein, as a late inflammatory mediator, can be released into the extracellular milieu from activated macrophages, immuno-stimulated gut epithelial cells and necrotic or damaged cells in a delayed manner relative to the secretion of other proinflammatory mediators, such as tumor necrosis factor-α and interleukin-1, and contributes to the pathogenesis of diverse inflammatory and infectious disorders; EP, which is a simple aliphatic ester derived from pyruvic acid and is synthesized from pyruvate and ethanol, is stable in Ringer's EP solution through interactions with calcium and potassium ions. Treatment with EP has been shown to be beneficial in animal models of a variety of acute and chronic inflammatory conditions.

Peer review

This is a very well designed study and the literature relating to the rationale for using this compound in this animal model to determine its potential effects has been thoroughly explored. The study is well presented in terms of its goals and purposes. There is convincing data to suggest that EP may be explored as a potential therapeutic agent for severe liver diseases.

Abstract

AIM: To determine whether the carbon monoxide (CO)-releasing molecules (CORM)-liberated CO suppress inflammatory responses in the small intestine of septic mice.

METHODS: The C57BL/6 mice (male, n = 36; weight 20 ± 2 g) were assigned to four groups in three respective experiments. Sepsis in mice was induced by cecal ligation and puncture (CLP) (24 h). Tricarbonyldichlororuthenium (Ⅱ) dimer (CORM-2) (8 mg/kg, *i.v.*) was administrated immediately after induction of CLP. The levels of inflammatory cytokines [interleukin-1β (IL-1β) and tumor necrosis factor-α (TNF-α)] in tissue homogenates were measured with enzyme-linked immunosorbent assay. The levels of malondialdehyde (MDA) in the tissues were determined. The levels of nitric oxide (NO) in tissue homogenate were measured and the expression levels of intercellular adhesion molecule 1 (ICAM-1) and inducible nitric oxide synthase (iNOS) in the small intestine were also assessed. NO and IL-8 levels in the supernatants were determined after the human adenocarcinoma cell line Caco-2 was stimulated by lipopolysaccharide (LPS) (10 g/mL) for 4 h *in vitro*.

RESULTS: At 24 h after CLP, histological analysis showed that the ileum and jejunum from CLP mice induced severe edema and sloughing of the villous tips, as well as infiltration of inflammatory cells into the mucosa. Semi-quantitative analysis of histological samples of ileum and jejunum showed that granulocyte infiltration in the septic mice was significantly increased compared to that in the sham group. Administration of CORM-2 significantly decreased granulocyte infiltration. At 24 h after CLP, the tissue MDA levels in the mid-ileum and mid-jejunum significantly increased compared to the sham animals (103.68 ± 23.88 nmol/mL *vs* 39.66 ± 8.23 nmol/mL, 89.66 ± 9.98 nmol/mL *vs* 32.32 ± 7.43 nmol/mL, $P < 0.01$). *In vitro* administration of CORM-2, tissue MDA levels were significantly decreased (50.65 ± 11.46 nmol/mL, 59.32 ± 6.62 nmol/mL, $P < 0.05$). Meanwhile, the tissue IL-1β and TNF-α levels in the mid-ileum significantly increased compared to the sham animals (6.66 ± 1.09 pg/mL *vs* 1.67 ± 0.45 pg/mL, 19.34 ± 3.99 pg/mL *vs* 3.98 ± 0.87 pg/mL, $P < 0.01$). *In vitro* administration of CORM-2, tissue IL-1β and TNF-α levels were significantly decreased (3.87 ± 1.08 pg/mL, 10.45 ± 2.48 pg/mL, $P < 0.05$). The levels of NO in mid-ileum and mid-jejunum tissue homogenate were also decreased (14.69 ± 2.45 nmol/mL *vs* 24.36 ± 2.97 nmol/mL, 18.47 ± 2.47 nmol/mL *vs* 27.33 ± 3.87 nmol/mL, $P < 0.05$). The expression of iNOS and ICAM-1 in the mid-ileum of septic mice at 24 h after CLP induction significantly increased compared to the sham animals. *In vitro* administration of CORM-2, expression of iNOS and ICAM-1 were significantly decreased. In parallel, the levels of NO and IL-8 in the supernatants of Caco-2 stimulated by LPS was markedly decreased in CORM-2-treated Caco-2 cells (2.22 ± 0.12 nmol/mL *vs* 6.25 ± 1.69 nmol/mL, 24.97 ± 3.01 pg/mL *vs* 49.45 ± 5.11 pg/mL, $P < 0.05$).

CONCLUSION: CORM-released CO attenuates the inflammatory cytokine production (IL-1β and TNF-α), and suppress the oxidative stress in the small intestine during sepsis by interfering with protein expression of ICAM-1 and iNOS.

Wang X, Cao J, Sun BW, Liu DD, Liang F, Gao L. Exogenous carbon monoxide attenuates inflammatory responses in the small intestine of septic mice. *World J Gastroenterol* 2012; 18(40): 5719-5728 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i40/5719.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i40.5719

INTRODUCTION

Sepsis is a complex clinical syndrome resulting from a harmful host inflammatory response to infection. Despite advancements in understanding the pathophysiology of sepsis, clinical outcomes are variable and the mortality rate remains high among the patients[1]. Cecal ligation and puncture (CLP) may induce the activation of an inflammatory cascade, leading to sepsis and multiple organ failure[2]. Some reports have indicated that the inflammatory response syndrome, which contributes to oxidative cell/tissue damage, might frequently be accompanied by leukocyte sequestration in many important organ systems in the body[3]. The increase of production of pro-inflammatory mediators such as interleukin (IL)-1β and tumor necrosis factor-α (TNF-α) is closely associated with activation of leukocytes and macrophages which were sequestrated in the tissue[4,5]. Leukocyte sequestration and its subsequent infiltration in organ tissue can cause leukocyte activation and contribute to vascular damage and the development of systemic inflammatory reaction. As the prerequisite, activation of leukocytes and endothelial cells results in aggregation of leukocytes, platelets and erythrocytes *in vitro*. This may favor disseminated intravasal coagulation and further multiple organ failure.

It has been shown that endogenous carbon monoxide (CO), a bi-product of inducible heme oxygenase (HO-1) can modulates inflammation. Recent studies suggest that exogenously administered CO inhibits lipopolysaccharide (LPS)-induced production of cytokines both *in vivo* and *in vitro*, and consequently exhibits an important cytoprotective function and anti-inflammatory properties which benefit for the resolution of acute inflammation[6].

Recently, transitional metal carbonyls have been identified as potential CO-releasing molecules (CORMs) with the potential to facilitate the pharmaceutical use of CO by delivering it to tissues and organs[7]. Our previous studies[8-14] firstly confirmed that CORM-released CO attenuated leukocytes sequestration in the liver, lung and small intestine of burned mice by interfering with nuclear factor-κB (NF-κB) activation, protein expression of intercellular adhesion molecule-1 (ICAM-1) and therefore suppressing endothelial cells pro-adhesive phenotype. However, to date, little is known if CORM-released CO can down-regulate the inflammatory production and oxidative stress in the small intestine of the septic mice. This study aims to investigate the protective effects and the underlying mechanisms of tricarbonyldichlororuthenium (Ⅱ) dimer (CORM-2), one of the novel groups of CORMs, on the suppression of inflammatory cytokine production and malondialdehyde (MDA) levels as an indicator of oxidative stress index in the small intestine of septic mice induced by CLP.

MATERIALS AND METHODS

Materials

CORM-2 was obtained from Sigma Aldrich and solubilized in dimethyl sulfoxide (DMSO) to obtain a 10 mmol/L stock. Inactive form of the compound (negative control) was also used in some experiments and it was prepared as follows: CORM-2 was "inactivated" (iCORM-2) by adding the compound to DMSO and kept for 18 h at 37 ℃ in a 5% CO_2 humidified atmosphere to liberate CO. The iCORM-2 solution was finally bubbled with nitrogen to remove the residual CO present in the solution. Cell culture reagents were obtained from Gibco (Grand Island, NY) and culture supplies from Corning (Corning, NY) and Falcon (Lincoln Park, NJ). Polyclonal antibody against ICAM-1 and inducible nitric oxide synthase (iNOS) was purchased from Santa Cruz Biotechnology Inc., United States. All the other chemicals were of reagent grade and obtained from Sigma unless otherwise stated.

Animal and CLP protocol

The C57BL/6 mice (male, n = 36; body weight 20 ± 2 g) were fed a standard laboratory diet and water ad libitum. Mice were assigned to four groups in three respective experiments. In each experiment, mice in sham group (n = 9) were underwent sham procedure, whereas mice in CLP group (n = 9) received cecal ligation and puncture, mice in CORM-2 group (n = 9) and iCORM group (n = 9) subjected to the same injury with immediate administration of CORM-2 (8 mg/kg, *i.v.*) and iCORM-2 (8 mg/kg, *i.v.*), respectively. The concentration of CORM-2 used in the present study was based on a previous report in of the use of this compound in mice[15] and the preliminary experiments in our lab[8,9]. The experimental protocol was approved by the Council on Animal Care at Jiangsu University on the Protection and the Welfare of Animals and followed the National

Institutes of Health guidelines for the care and use of experimental animals.

Mice were anesthetized with 2% isoflurane in oxygen *via* a facemask. A 2-cm midline incision was made through the abdominal wall; the cecum was identified and ligated with a 3-0 silk tie 1 cm from the tip. Care was taken not to cause bowel obstruction. A single puncture of the cecal wall was performed with a 20-gauge needle. The cecum was lightly squeezed to express a small amount of stool from the puncture site to assure a full-thickness perforation. Great care was taken to preserve the continuity of flow between the small and large bowels. The cecum was returned to the abdominal cavity, and the incision was closed with surgiclips. Sham mice underwent midline laparotomy under anesthesia; the cecum was exteriorized and returned to the abdomen, and the incision was closed with surgiclips. The animals were sacrificed at 24 h after experimental manipulation.

Histologic studies

The mid-ileum and mid-jejunum specimens harvested from different groups of animals were immersed in 4% formaldehyde solution at 24 h after CLP. The tissue was embedded in paraffin wax, serially sectioned, and stained with hematoxylin-eosin. Tissue morphologic characteristics were evaluated under light microscope. Ileum and jejunum tissues were evaluated for density of granulocytes and degree of hydropic degeneration. Tissues were evaluated in a semi-quantitatively manner by two experienced independent examiners who were blinded to the experimental groups. A scoring system was used for each item using 0 up to 2 points for the different states of organ damage (with 2 being most granulocytes, edema and degeneration). Afterwards, the mean ± SE of each item was calculated.

Preparation of tissue homogenates

The intestine was exposed at 24 h after CLP. Retaining approximately the first 5 cm-long proximal segment of intestine, 3 cm-long segments of jejunum and ileum were removed, cleaned, and snap-frozen in liquid nitrogen. The samples were stored at -70 ℃. Equal weights (100 mg wet weight) of intestine from various groups were suspended in 1 mL phosphate buffered saline and sonicated on ice (30 cycles, twice for 30 s)[8,9]. Homogenates were cleared by centrifuging at 12 000 *r*/min at 4 ℃, and the supernatants were stored at -70 ℃. Protein levels in the homogenates were determined using the Bio-Rad (Hercules, CA) assay kit.

Measurement of IL-1β and TNF-α

The levels of the inflammatory cytokines IL-1β and TNF-α in ileum and jejunum tissue homogenates were measured using enzyme-linked immunosorbent assay kits (R and D Systems, Minneapolis, MN) following the manufacturers instructions.

Cell culture and stimulation

Caco-2, the human adenocarcinoma cell line, was obtained from American Tissue Culture Collection (ATCC, Rockville, MD, United States). The cells were passaged and grown in Dulbecco's modified Egle's medium (DMEM) supplemented with 1% nonessential amino acids, 10% fetal calf serum, 1 mg/L streptomycin, and 1000 U/L penicillin (Complete DMEM). Experiments were performed with cell monolayers that were in culture for 21-25 d. Cells were seeded in the collagen-coated 48-well plates with the same cell density. Medium was replaced every day when each experiment began. Cells were cultured at 37 ℃, 5% CO_2, and 90% related humidity. The supernatants of Caco-2 cell stimulated by LPS (10 g/mL) for 4 h were collected for nitric oxide (NO) and IL-8 levels measurement.

Measurement of NO in tissue homogenate and supernatants of Caco-2 cells

NO was measured as described previously[11]. Briefly, 100 L of supernatants was removed and incubated with 100 L of Griess reagent (10 g/L sulfanilamide and 1 g/L N-1-naphthylethylenediamine dihydrochloride in 25 mL/L phosphoric acid) in a 96-well plate. The plate was incubated for 10 min at room temperature. Nitrite production was quantified spectrophotometrically using an automated colorimetric procedure. Absorbance at 540 nm was measured using a microplate reader (Bio-Tek, United States). The nitrite concentration was calculated by comparing samples with standard solutions of sodium nitrite produced in the culture medium. All samples were assayed in triplicate.

MDA assay

MDA formation was utilized as a lipoperoxidation index. The levels of MDA in the small intestines were determined as described by Sun *et al*[10]. Briefly, tissue was homogenized in 1.15% KCl solution (1:10 volume). An aliquot (0.1 mL) of the homogenate was added to a reaction mixture [200 L of 8.1% SDS, 1500 L of 20% acetic acid (pH 3.5), 1500 L of 0.8% thiobarbituric acid, and 700 L distilled water]. Samples were then boiled for 1 h at 95 ℃ and centrifuged at 3000 × *g* for 10 min. The absorbance of the supernatant was measured by spectrophotometry at 532 nm (Jenway, Mod. 6300, Dunmow, Essex, United Kingdom). Data were expressed in nmol per milligram of wet tissue.

Myeloperoxidase activity

Myeloperoxidase (MPO) activity was measured according to the established method[8,9]. Briefly, tissue was homogenized in 0.5 mL of 50 mmol/L potassium phosphate buffer (pH 7.4) and centrifuged at 10 000 × *g* at 4 ℃ for 30 min. The remaining pellet was resuspended in 0.5 mL of 50 mmol/L potassium buffer at pH 6.0 with 0.5% hexadecyltrimethylammonium bromide, sonicated on ice, and then centrifuged at 12 000 × *g* at 4 ℃ for 10 min. Supernatants were then assayed at a 1:20 dilution in reaction buffer containing 50 mmol/L phosphate buffer, 530 mmol/L o-dianisidine, and 20 mmol/L H_2O_2 solution. One unit of enzyme activity was defined as the amount of MPO that caused a change in absor-

Table 1 Histological scoring of granulocyte infiltration and hydropic degeneration in ileum and jejunum tissue stained with hematoxylin-eosin 24 h after cecal ligation and perforation

	Granulocyte infiltration		Hydropic degeneration	
	Ileum	Jejunum	Ileum	Jejunum
Sham	0.50 ± 0.12	0.51 ± 0.11	0	0
CLP	1.90 ± 0.46[a]	1.67 ± 0.12[a]	1.79 ± 0.34[b]	1.68 ± 0.28[b]
CLP + CORM	0.98 ± 0.12[c]	0.79 ± 0.34[c]	1.67 ± 0.44	1.72 ± 0.36
CLP + iCORM	1.88 ± 0.30[a]	1.61 ± 0.17[a]	1.76 ± 0.67[b]	1.62 ± 0.45[b]

For granulocyte infiltration: 0, no granulocyte infiltration; 1, moderate granulocyte infiltration; 2, severe granulocyte infiltration. For hydropic degeneration: 0, no hydropic degeneration; 1, moderate hydropic degeneration; 2, severe hydropic degeneration. Values are presented as mean ± SE. [a]$P < 0.05$, [b]$P < 0.01$ *vs* sham group; [c]$P < 0.05$ *vs* cecal ligation and perforation (CLP) group. CORM: Carbon monoxide-releasing molecule; iCORM: Inactivated-carbon monoxide-releasing molecule.

bance measured at 460 nm for 3 min. MPO activity was expressed as U/g tissue.

Western blot analysis

Tissues were homogenized for extract preparations in ice-cold mild lysis buffer, containing 1% Nonidet P-40, 0.15 mol/L NaCl, 0.01 mol/L sodium phosphate (pH 7.2), 2 mmol/L ethylene diamine tetraacetic acid, 50 mmol/L sodium fluoride, 0.2 mmol/L sodium vanadate, and 1 g/mL of aprotinin. The tissue homogenates were centrifuged at 20 000 × *g* for 15 min and supernatants were collected. Sodium dodecyl sulphate-polyacrylamide gel electrophoresis was performed on an equivalent amount of protein samples using precast 7% resolving/4% stacking Tris-HCl gels (Bio-Rad, Hercules, CA). Separated proteins were then transferred to polyvinylidene difluoride membranes (Amersham Pharmacia Biotech, Inc., Piscataway, NJ). Membranes were blocked in 5% nonfat milk in TBS buffer containing 0.1% Tween 20 (TBST) for 1 h at room temperature. Blocked membranes were incubated in primary antibody specific for mouse iNOS and ICAM-1 at a concentration of 1:2000 and 1:5000, respectively in TBST overnight at 4 ℃. Then the membranes were washed and probed with horseradish peroxidase-conjugated secondary antibody (Amersham Pharmacia Biotech, Inc., Piscataway, NJ) for 1 h at room temperature. Chemiluminescence detection was performed with the Amersham enhanced chemiluminescence detection kit according to the manufacturer's instructions. To ensure a similar amount of protein in each sample, the membranes were "stripped off", reprobed with actin, developed with horseradish peroxidase-conjugated secondary antibody, and visualized by enhanced chemiluminescence.

Statistical analysis

All the values were presented as mean ± SE. Statistical analysis was performed using the analysis of variance and Student's *t*-test for the comparisons. $P < 0.05$ was considered to be statistically significant.

RESULTS

Histology

Histological analysis showed that the ileum and jejunum from sham mice had the normal architecture of the intestinal epithelium and wall, while CLP induced severe edema and sloughing of the villous tips, as well as infiltration of inflammatory cells into the mucosa. Semiquantitative analysis of histological samples of ileum and jejunum showed that the granulocyte infiltration in the septic mice was significantly increased compared with that in the sham group. Administration of CORM-2 (8 mg/kg, *i.v.*), significantly decreased granulocyte infiltration. However, CORM-2 did not improve the hydropic degeneration induced by sepsis in either the ileum or jejunum (Figure 1 and Table 1).

Effect of CORM-2 on MPO activity in small intestine of septic mice

To determine whether the CLP-induced increase in polymorphonuclear neutrophil (PMN) accumulation in the small intestine was effectively prevented by CORM-2, the activity of MPO, an enzyme in azurophilic granules of neutrophils, was assessed. Extracts of the ileum and jejunum samples were examined for content of MPO 24 h after sepsis. The mean MPO levels are shown in Figure 2. MPO activity in organs obtained from septic mice was markedly increased compared with that in the sham group ($P < 0.01$), while it was significantly decreased by treatment with CORM-2 ($P < 0.05$).

Effect of CORM-2 on tissue MDA in small intestine of septic mice

Tissue MDA levels are considered important markers of lipoperoxidation associated to oxidative stress. The mean MDA levels detected in the mid-ileum and mid-jejunum of mice were significantly affected by CLP injury. At 24 h after CLP, the tissue MDA levels in the mid-ileum and mid-jejunum significantly increased compared with the sham animals. After *in vitro* administration of CORM-2 (8 mg/kg, *i.v.*), tissue MDA levels were significantly decreased (Figure 3A).

Effect of CORM-2 on TNF-α and IL-1β levels in tissue homogenates of septic mice

As shown in Figure 3A, at 24 h after CLP, the expression of TNF-α and IL-1 in mid-ileum and mid-jejunum homogenates of CLP-challenged mice was markedly increased compared with the sham mice. After administration of CORM-2, the elevation levels of TNF-α and IL-1β in tissue homogenates were significantly diminished (Figure 3B and C).

Effect of CORM-2 on NO production in tissue homogenates of septic mice

As shown in Figure 3D, production of nitrite was low in sham group. After CLP challenge, nitrite levels in tissue

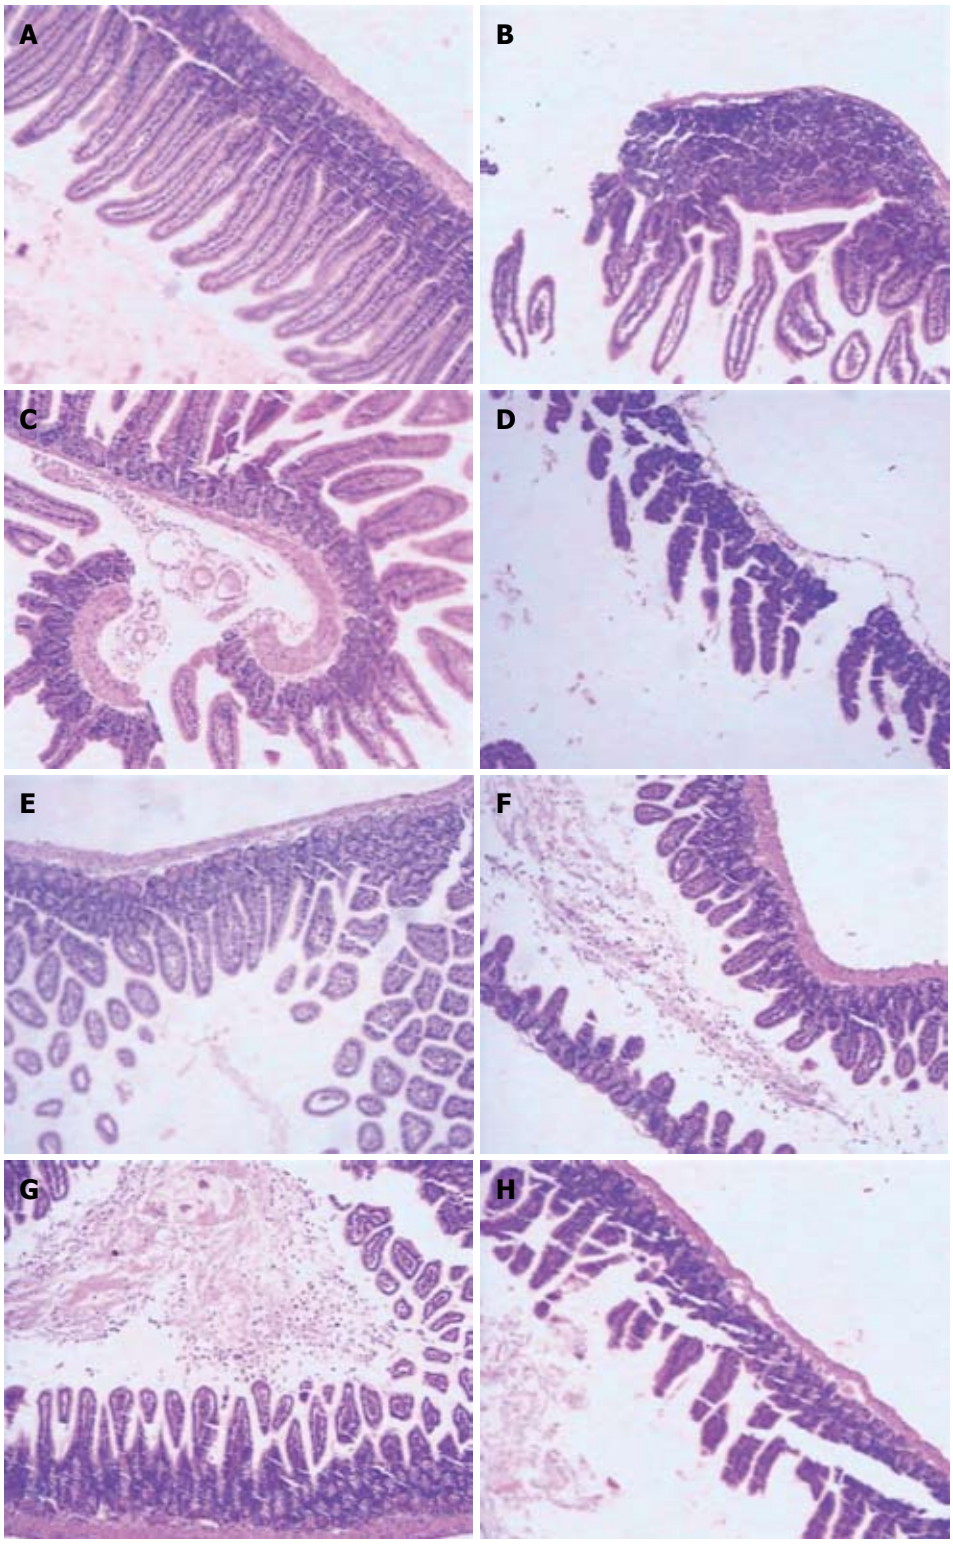

Figure 1 Effects of tricarbonyldichlororuthenium (Ⅱ) dimer carbon monoxide-releasing molecules on small intestine injury in septic mice. Mice were challenged with cecal ligation and perforation (CLP) and treated with tricarbonyldichlororuthenium (Ⅱ) dimer. The mid-ileum (A-D) and mid-jejunum (E-H) specimens harvested from different groups of animals were immersed in 4% formaldehyde solution at 24 h after CLP. The tissue was embedded in paraffin wax, serially sectioned, and stained with hematoxylin-eosin. Tissue morphologic characteristics were evaluated by light microscopy. A, E: Sections from sham mice had normal architecture of the intestinal epithelium and wall; B, F: Sections from septic mice showed inflammatory cell infiltration through the wall, concentrated below the epithelial layer, edema of the distal portion of the villi, and necrosis of the epithelium at the villous tips; C, G: Section from septic mice treated with carbon monoxide-releasing molecules-2 showed a significant decrease in granulocyte infiltration, while no marked improvement of hydropic degeneration. The figure is representative of at least three experiments performed on different days.

homogenates were significantly increased ($P < 0.05$ *vs* sham group). However, nitrite levels were markedly decreased in the CORM-2 group compared with the CLP group ($P < 0.05$).

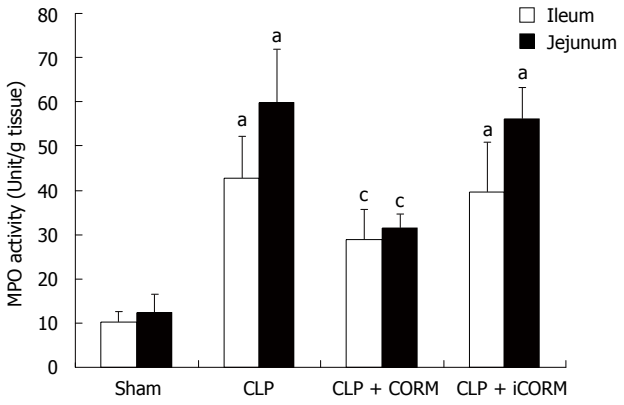

Figure 2 Effects of tricarbonyldichlororuthenium (Ⅱ) dimer carbon monoxide-releasing molecules on myeloperoxidase activity in the small intestine of septic mice. Mice were challenged with cecal ligation and perforation (CLP) and treated with tricarbonyldichlororuthenium (Ⅱ) dimer. Myeloperoxidase (MPO) activity in the mid-ileum and mid-jejunum were assessed 24 h following CLP injury. Results are mean ± SE, $^{a}P < 0.01$ *vs* sham mice; $^{c}P < 0.05$ *vs* CLP mice. CORM: Carbon monoxide-releasing molecule; iCORM: Inactivated-carbon monoxide-releasing molecule.

Effect of CORM-2 on IL-8 and NO production in supernatants of LPS- stimulated Caco-2 cells

Production of IL-8 and nitrite was low in the control Caco-2 cells. After stimulation of LPS, IL-8 and nitrite levels were significantly increased ($P < 0.05$ *vs* control group). CORM-2 significantly reduced IL-8 and nitrite generation in the LPS-stimulated Caco-2 cells ($P < 0.05$ *vs* CLP group, Figure 4).

Effect of CORM-2 on expression of ICAM-1 and *iNOS in the small intestine of septic mice*

The expression of iNOS and ICAM-1 in the mid-ileum of septic mice at 24 h after CLP induction was significantly enhanced compared with the sham animals. After *in vitro* administration of CORM-2 (8 mg/kg, *i.v.*), the expression of iNOS and ICAM-1 was significantly decreased (Figure 5).

DISCUSSION

Sepsis, which frequently occurs after hemorrhage, trauma, burn, or abdominal surgery, continues to be a clinical challenge in clinic as a leading cause of morbidity and mortality in severely ill patients[1,16-19]. Despite the therapeutic strategies focusing on local host defenses and the inhibition of overwhelming inflammation response, little progress has been achieved. CLP may induce the activation of an inflammatory cascade, and cause damage to multiple organs, leading to sepsis and multiple organ failure. This model seems to resemble qualitatively as well as quantitatively the clinical observations of vascular reactivity and inflammation in the course of polymicrobial peritonitis, bacteremia, and systemic sepsis[20-23]. Therefore, this study aims to evaluate the possible role of CORM-derived CO in CLP-induced sepsis.

During sepsis, the most frequent complications within the gastrointestinal tract are small intestinal and mucosal barrier dysfunctions. Our previous data indicated that the intestine is one of the tissues most sensitive to the ischemia and reperfusion (I/R) induced by thermal injury[8-10], and a novel metal carbonyl-based compound (CORM-2) which exerts a protective effect against the pathological changes caused by thermal injury of the small intestine. In this study, we employed the same compound to determine whether it suppresses inflammatory cytokine production and oxidative stress in the small intestine of the septic mice.

Leukocyte sequestration and its subsequent infiltration in tissues can cause leukocyte activation and contribute to vascular damage and the development of systemic inflammatory reaction. MPO is an enzyme that is found predominantly in the azurophilic granules of PMN. Tissue MPO activity is frequently utilized to estimate tissue PMN accumulation in damaged tissues and correlates significantly with the number of PMN determined histochemically in tissues[24-26]. In the present study, we found that MPO activities in small intestine were markedly enhanced after CLP and *in vitro* administration of CORM-2 resulted in significantly downregulation of MPO activity. The direct cause of leukocytes sequestration after CLP is considered to be the higher expression of adhesion molecules (ICAM-1). ICAM-1 activates leukocytes and endothelial cells, which in turn prompt the release of various inflammatory mediators, resulting in systemic inflammatory response syndrome, acute respiratory distress syndrome and multiorgan dysfunction syndrome[27]. At 24 h after CLP, the expression of ICAM-1 in small intestine was markedly upregulated. *In vitro* administration of CORM-2 inhibited the upregulation of ICAM-1 induced by CLP. These findings indicated that CORM-2 can effectively prevent PMN chemotaxis and infiltration in the tissues after CLP, consequently decreasing the production of oxidants and reducing tissue oxidative injury.

Pro-inflammatory cytokines, such as TNF-α and IL-1 have been shown to be released early after an inflammatory stimulus. TNF-α is a pleiotropic cytokine with strong proinflammatory and immunomodulatory properties, and plays a critical role in inflammation and inflammatory bowel disease[28,29]. Various strategies have been explored to inhibit TNF-α. To confirm if prevention of sepsis-induced intestinal dysmotility by CORM-2 was partly through interruption of the cycle of inflammatory events in the local intestine, we investigated the expression of inflammatory cytokines TNF-α in the small intestine of the septic mice. We observed marked increases in TNF-α levels in the tissue homogenates of ileum and jejunum after CLP injury. *In vitro* administration of CORM-2 was able to inhibit the inflammatory production in enteric tissue induced by CLP. Our findings strongly indicated that CORM-2 appears to inhibit upregulation of inflammatory production, and consequently might effectively decrease inflammatory response in the small intestine induced by CLP. Similarly,

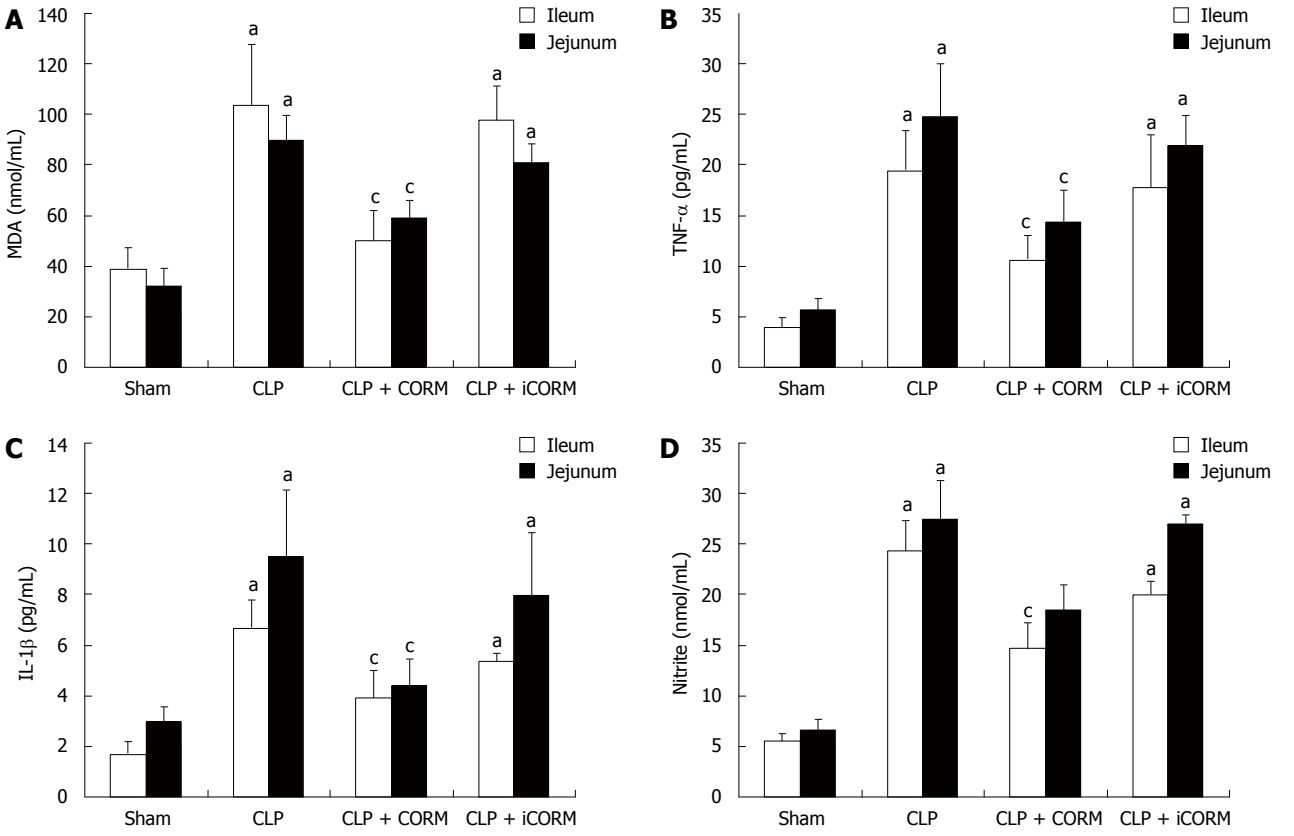

Figure 3 Effects of tricarbonyldichlororuthenium (Ⅱ) dimer carbon monoxide-releasing molecules on malondialdehyde, expression of interleukin-1β and tumor necrosis factor-α and nitrite production in the mid-ileum and mid-jejunum of septic mice. A: Mice were challenged with cecal ligation and perforation (CLP) and treated with tricarbonyldichlororuthenium (Ⅱ) dimer. Malondialdehyde (MDA) in the mid-ileum and mid-jejunum was assessed 24 h following CLP injury; B: Tumor necrosis factor (TNF)-α levels in the mid-ileum and mid-jejunum was assessed 24 h following CLP injury; C: Interleukin (IL)-1β levels in the mid-ileum and mid-jejunum was assessed 24 h following CLP injury; D: Nitrite production in the mid-ileum and mid-jejunum was assessed 24 h following CLP injury. Results are mean ± SE, $^{a}P < 0.01$ *vs* sham mice; $^{c}P < 0.05$ *vs* CLP mice. CORM: Carbon monoxide-releasing molecule; iCORM: Inactivated-carbon monoxide-releasing molecule.

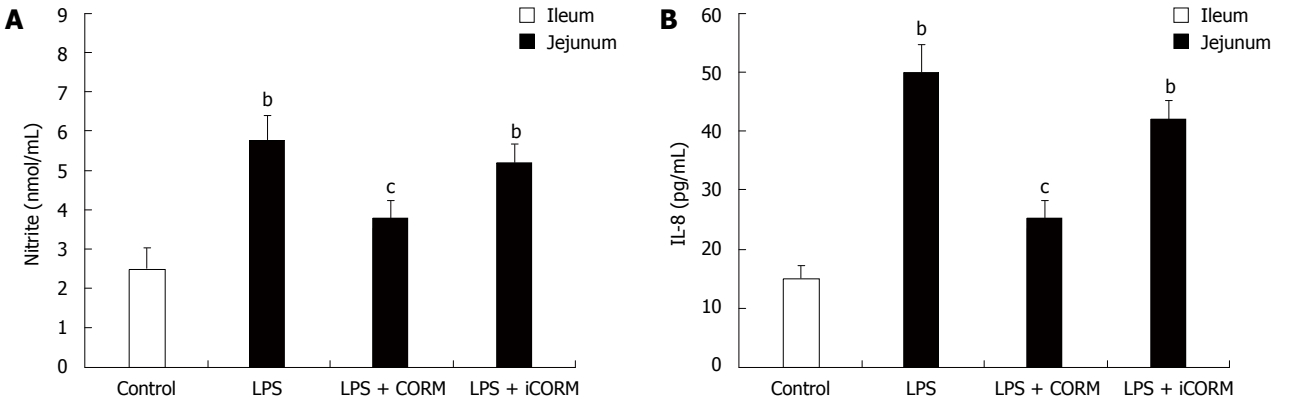

Figure 4 Effects of tricarbonyldichlororuthenium (Ⅱ) dimer carbon monoxide-releasing molecules on interleukin-8 and nitrite production in Caco-2 cells. Caco-2 cells were stimulated by lipopolysaccharide (LPS) and treated with tricarbonyldichlororuthenium (Ⅱ) dimer. Nitrite (A) and interleukin (IL)-8 (B) production in supernatants of Caco-2 cells were assessed 4 h following LPS stimulation. Results are mean ± SE. $^{b}P < 0.01$ *vs* control group; $^{c}P < 0.05$ *vs* LPS-stimulated Caco-2. CORM: Carbon monoxide-releasing molecule; iCORM: Inactivated-carbon monoxide-releasing molecule.

another important cytokine, IL-1, was also found to be markedly upregulated in ileum and jejunum of septic mice. Downregulation of IL-1 levels was most remarkable in the small intestine of septic mice treated with CORM-2. These findings demonstrate that treatment with CORM-2 suppresses the production of IL-1 and TNF-α, and subsequently attenuates the inflammatory response induced by CLP in the small intestine.

Tissue MDA content, the last product of lipid breakdown caused by oxidative stress, is considered to be a good indicator of radical-induced lipid peroxidation[29]. Increased lipid peroxidation in the small intestine of animals with intestinal I/R, was evidenced by significantly increased MDA levels[30]. In the present study, intestinal

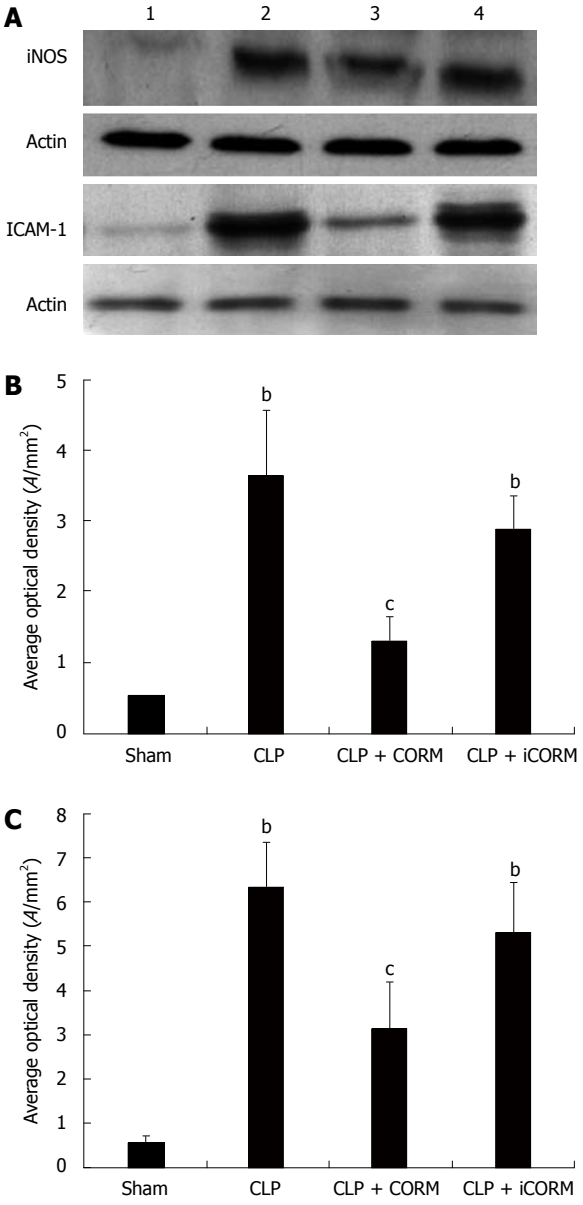

Figure 5 Effects of tricarbonyldichlororuthenium (Ⅱ) dimer carbon monoxide-releasing molecules on protein expression of intercellular adhesion molecule 1 and inducible nitric oxide synthase in the mid-ileum of cecal ligation and perforation-induced mice. A: Representative experiment; B and C: Quantitative results (average optical density, A/mm^2) of three. Mice were challenged with cecal ligation and perforation (CLP) and treated with tricarbonyldichlororuthe-nium (Ⅱ) dimer. Protein expression of intercellular adhesion molecule 1 (ICAM-1) and inducible nitric oxide synthase (iNOS) in the mid-ileum was determined by Western blotting at 24 h after CLP. Lane 1: Sham group; Lane 2: CLP group; Lane 3: CLP + carbon monoxide-releasing molecule (CORM)-2 group; Lane 4: CLP + inactivated-carbon monoxide-releasing molecule (iCORM)-2 group. $^bP < 0.01$ *vs* sham group; $^cP < 0.05$ *vs* CLP group.

MDA levels in CLP groups increased markedly, suggesting that significant increase of oxidative stress occurs at 24 h after experimental manipulation. *In vitro* administration of CORM-2 led to the significantly downregulation of the mean MDA levels in the small intestine of septic mice. This indicated that CORM-2 effectively prevents lipid peroxidation in the small intestine after CLP, consequently decreasing the production of oxidants and reducing the tissue oxidative injury, which contributes to the bowel functional damage to the bowel.

Sepsis alters the concentrations of NO, an inflammatory factor, in plasma and endothelial cells[31]. NO is produced by various types of cells such as macrophages, cardiac myocytes, and vascular smooth muscle and glial cells in response to endotoxin and other inflammatory stimuli. Although it is suggested that NO has a counter-inflammatory activity acting on the cells of the adaptive immune system, in particular, T cells, many studies have well established that NO is indeed a proinflammatory mediator, overproduction of NO plays a major role in the pathophysiology of septic shock, and induction of NOS with consequent excessive NO formation has been proposed as a major factor in pathologic vasodilatation and tissue damage. As an intercellular signaling factor, NO potentially leads to the continuous formation of peroxynitrite. Peroxynitrite damages the organs possibly through lipid peroxidation and/or nitration of cell membrane proteins.

Previously, we demonstrated that thermal injury induced lung neutrophil deposition, lung iNOS expression, and lung damage[9]. We have also shown that NO from iNOS regulated proinflammatory activation, gene expression, and tissue injury in the liver after thermal injury, and CORM-2 inhibited the expression of iNOS in liver tissues, reducing liver injury and tissue PMN infiltration in thermally injured mice[8]. In this study, we measured NO production and expression levels of iNOS in tissue homogenates of the ileum and jejunum of CLP mice following resuscitation to determine whether iNOS was also generated at this site. There was a significant increase of intestinal mucosal iNOS activity within the base of intestinal villi following CLP, while NO production also markedly increased, suggesting that peroxynitrite plays a vital role in CLP-induced intestinal damage. The production of NO and expression of iNOS were significantly inhibited by *in vitro* administration of CORM-2. In parallel, the *in vitro* experiments showed that LPS caused a significant increase of NO production in Caco-2 cells, which was prevented effectively with CORM-2 treatment. These data showed that CORM-2 exhibits, at least partly, an important role in inhibiting iNOS expression, subsequently downregulating the NO production, and attenuating the oxidative stress and tissue damage. NF-κB family members control transcriptional activity of various promoters of proinflammatory cytokines, cellsurface receptors, transcription factors, and adhesion molecules that are involved in intestinal inflammation. Previously, using a thermal injury model in mice, we have shown that CORM-2 plays a pivotal role in inhibition of NF-κB activity in the liver, which subsequently decreases hepatocellular secretion of inflammatory cytokines and burn-related hepatic dysfunction[11]. In this study, NF-κB activity in mid-ileum was elevated by CLP, while it was markedly inhibited by administration of CORM-2 (data not shown). These results show that CORM-2 plays, at least partly, an important role in

inhibition of NF-κB activity in the small intestine.

In conclusion, the data presented in this study suggest a protective role of CORM-2, one of the novel CORMs, in the small intestine of the septic mice. The potential mechanism of this beneficial effect of CORM-2 appears to suppress oxidative stress, and decrease the production of IL-1 and TNF-α. This was accompanied by a decrease of NO production and protein expression of ICAM-1 and iNOS, thus suppressing the tissue damage in the small intestine. However, the therapeutic potential of anti-inflammation or anti-oxidative stress strategies in this setting should be further validated by future studies.

COMMENTS

Background

Sepsis is a complex clinical syndrome resulting from a harmful host inflammatory response to infection. Cecal ligation and puncture (CLP) may induce the activation of an inflammatory cascade, and may lead to sepsis and multiple organ failure. There have been several reports indicating that the inflammatory response syndrome, which contributes to oxidative cell/tissue damage, might frequently be accompanied by leukocyte sequestration in many important organ systems in the body. The increase of production of pro-inflammatory mediators such as interleukin (IL)-1β and tumor necrosis factor-α (TNF-α) is closely associated with activation of leukocytes and macrophages which were sequestrated in the tissue. During sepsis, the most frequent complications within the gastrointestinal tract are small intestine and mucosal barrier dysfunction. Their previous data indicated that the intestine is one of the most sensitive tissues to ischemia and reperfusion induced by thermal injury.

Research frontiers

Sepsis, which frequently occurs after hemorrhage, trauma, burn, or abdominal surgery, continues to be a challenge in clinic as a leading cause of morbidity and mortality in severely ill patients. Despite therapeutic strategies focus on local host defenses and the inhibition of overwhelming inflammation response, little progress has been achieved. Their previous studies firstly confirmed that carbon monoxide (CO)-releasing molecules (CORM)-released CO attenuated leukocytes sequestration in the liver, lung and small intestine of burned mice by interfering with nuclear factor κB activation, protein expression of intercellular adhesion molecule 1 (ICAM-1) and therefore suppressing endothelial cells pro-adhesive phenotype. However, to date, little is known if CORM-released CO can down-regulate the inflammatory production and oxidative stress in the small intestine in septic mice.

Innovations and breakthroughs

In the present study, the authors found that a protective role of tricarbonyldichlororuthenium (Ⅱ) dimer (CORM-2), one of the novel CORMs, on the small intestine during sepsis. The potential mechanism of this beneficial effect of CORM-2 appears to suppress oxidative stress, decrease the myeloperoxidase activities and production of IL-1 and TNF-α. This was accompanied by a decrease of nitric oxide (NO) production and protein expression of ICAM-1 and inducible NO synthase, and therefore suppress tissue damage in the small intestine. These data indicated that CORM-2 effectively prevents polymorphonuclear neutrophil chemotaxis and infiltration in the tissue after CLP, consequently decreased the production of oxidants, reduced tissue oxidative injury.

Applications

The protective role of CORM-2, one of the CORMs, on the organs during sepsis, and its therapeutic potential in anti-inflammation or anti-oxidative stress will be the novel strategies in the future.

Peer review

The authors report the protective role of CORM-2, one of the CORMs, on the organs during sepsis, and its therapeutic potential in anti-inflammation or anti-oxidative stress. This is a well-written article. The study is interesting and goes along with previous data on modulation of inflammation by CO.

Abstract

AIM: To compare intradermal (ID) and intramuscular (IM) booster doses, which have been used in healthy and high risk subjects, such as healthcare workers, haemodialysis patients, human immunodeficiency virus patients, and renal transplant recipients unresponsive to initial hepatitis B vaccination, in celiac individuals.

METHODS: We conducted our study on 58 celiac patients, vaccinated in the first year of life, whose blood analysis had showed the absence of protective hepatitis B virus (HBV) antibodies. All patients had received the last vaccine injection at least one year before study enrolment and they had been on a gluten free diet for at least 1 year. In all patients we randomly performed an HBV vaccine booster dose by ID or IM route. Thirty celiac patients were revaccinated with recombinant hepatitis B vaccine (Engerix B) 2 μg by the ID route, while 28 celiac patients were revaccinated with Engerix B 10 μg by the IM route. Four weeks after every booster dose, the anti-hepatitis B surface (HBs) antibody titer was measured by an enzyme-linked immune-adsorbent assay. We performed a maximum of three booster doses in patients with no anti-HBs antibodies after the first or the second vaccine dose. The cut off value for a negative anti-HBs antibody titer was 10 IU/L. Patients with values between 10 and 100 IU/L were considered "low responders" while patients with an antibody titer higher than 1000 IU/L were considered "high responders".

RESULTS: No significant difference in age, gender, duration of illness, and years of gluten intake was found between the two groups. We found a high percentage of "responders" after the first booster dose (ID = 76.7%, IM = 78.6%) and a greater increase after the third dose (ID = 90%, IM = 96.4%) of vaccine in both groups. Moreover we found a significantly higher number of high responders (with an anti-HBs antibody titer > 1000 IU/L) in the ID (40%) than in the IM (7.1%) group, and this difference was evident after the first booster dose of vaccination ($P < 0.01$). No side effects were recorded in performing delivery of the vaccine by either the ID or IM route.

CONCLUSION: Our study suggests that both ID and IM routes are effective and safe options to administer a booster dose of HBV vaccine in celiac patients. However the ID route seems to achieve a greater number of high responders and to have a better cost/benefit ratio.

INTRODUCTION

In literature there are several reports describing a non-responsiveness to hepatitis B vaccine in celiac patients[1-4], although the pathogenic mechanism is still unclear. As a matter of fact it seems that this failed response could be linked to the "major histocompatibility complex" (MHC) and human leucocyte antigen (HLA)-Ⅱ pattern characterizing the disease[5-7], while other studies indicate that gluten intake at the time of vaccination could influence the vaccine-induced immune response[8].

However it is not completely understood whether the unresponsiveness to hepatitis B vaccine in celiac patients is also linked to a weakened immune response in healthy older people or to a physiological loss of humoral immunity with the flow of time[9]. Fisman *et al*[10] published a meta-analysis on the increased risk of unresponsiveness to hepatitis B vaccination in older subjects, finding a low response even in 30-year-old patients.

An important consideration is that the titer of anti-hepatitis B surface (anti-HBs) antibodies that should be considered as cut-off for "non-response" to hepatitis B virus (HBV) vaccine is < 10 IU/L, when the measurement is performed a long time after the vaccination. The responsiveness to hepatitis B vaccine should usually be determined by antibody measurement within 2-6 mo after the third vaccine dose. In those patients with anti-HBs < 10 IU/L a booster vaccine schedule should be proposed, but until now there is no consensus on this kind of management.

In the present study we administered a vaccine booster dose against HBV by the intradermal (ID) or intramuscular (IM) route in celiac patients, whose antibodies levels against the HBV were low after the first regimen of hepatitis B vaccine performed in the first year of life.

The aim of our study was to evaluate the possibility to provide a satisfactory immune response against HBV by these procedures, comparing their efficacy.

MATERIALS AND METHODS

Our study was a prospective, randomized study, conducted on 58 celiac patients (age, mean ± SD, 9.8 ± 6.2 years) of 116 celiac subjects (age, mean ± SD, 10.2 ± 5.7 years) referred to our Pediatric Department, University of Catania, Italy, whose blood analysis showed the absence of protective HBV antibodies (anti-HBs). In all included patients, the diagnosis of celiac disease was made after one year of age, based on clinical signs and standard serological markers (antigliadin IgA and IgG, tissue trans-glutaminase IgA antibody, anti-endomysial antibody) and on typical histological findings on small bowel biopsies (villous atrophy with crypt hyperplasia and increased intraepithelial lymphocytes).

All patients received the anti-HBV vaccine at 3, 5 and 11 mo of age by IM injection on the front-lateral area of their quadriceps muscle (10 μg of Engerix B, GlaxoSmith and Kline, Belgium), as planned by the Italian standard vaccination schedule.

All patients had received the last vaccine injection at least one year before the study enrolment and they had been on a gluten free diet for at least 1 year. None of the patients had ever been affected by HBV infection.

In all patients we randomly performed an HBV vaccine booster dose by the ID or IM route. Thirty celiac patients were revaccinated by the ID route with a 2 μg dose of recombinant hepatitis B vaccine (Engerix B) administered on the flexor surface of the forearm, using a 1 mL syringe and 26-gauge needle. In all the patients a visible skin weal was noticed as evidence of the ID inoculation.

Twenty-eight celiac patients were revaccinated by the IM route with a 10 μg dose of Engerix B administered in the lateral region of their deltoid muscle, using a 5 mL syringe and 26-gauge needle.

Four weeks after every booster dose, the anti-HBs antibody titer was measured by enzyme-linked immune-adsorbent assay (hepanostica anti-HBs, bioMeriuex, Netherlands). We performed a maximum of three booster doses in patients with no anti-HBs antibodies after the first or the second vaccine dose. The cut off value for a negative anti-HBs antibody titer was 10 mIU/mL. Patients with values between 10 and 100 IU/L were considered "low responders" while patients with an antibody titer higher than 1000 IU/L were considered "high responders"[11].

Statistical analysis

The Mann-Withney *U*-test was performed to compare age, duration of illness, years of gluten intake and HBs antibody titer between the two groups of patients. The Fisher exact test was used to compare the gender, the number of non responders, low responders and high responders between the ID and IM groups. *P* value < 0.05 was considered statistically significant.

RESULTS

The main features of the two groups of patients are reported in Table 1. No significant difference of age, gender, duration of illness, and years of gluten intake was found between the two groups.

The number and the percentage of responders to ID and IM hepatitis B vaccination after every dose injection are reported in Table 2, together with the mean and SD of the anti-HBs titer in the two groups after the first and the third booster.

Both groups of patients showed a similar percentage of responders after the first dose of vaccine (ID = 76.7%, IM = 78.6%) and a major increase after the third dose (ID = 90%, IM = 96.4%). However, we did not find any statistically significant difference between the two groups. We found no statistically significant difference in anti-HBs titer between the two groups, after the first and the third doses.

Finally we found a significantly higher number of high responders (with an anti-HBs antibody titer > 1000 IU/L) in the ID (40%) than in the IM (7.1%) group, and this difference was evident after the first booster dose of

Table 1 Comparison of age, gender, duration of illness and gluten intake in patients receiving vaccine booster by the intradermal or intramuscular route

vaccination (Figure 1). No side effects were recorded in performing both ID and IM injections.

DISCUSSION

Literature data describe that 4%-10% of healthy, immune competent individuals fail to elicit protective levels of antibodies to recombinant HBs antigen after completing the standard hepatitis B vaccination schedule[12]. Even though the pathogenic mechanism leading to a failed response to hepatitis B vaccine is still unknown, there are several hypotheses trying to explain this link. Recently Zingone *et al*[8] reported a possible association with gluten intake at the time of vaccination that may influence the vaccine-induced immune response. Nevertheless the most likely hypothesis is related to a specific pattern of MHC[13] and HLA-Ⅱ antigens linked to the disease. As a matter of fact, homozygosis for HLA-B8, DR3 and DQ2 alleles was found to have a significantly higher incidence in hepatitis B vaccine non responders[5-7].

This HLA-DQ2 haplotype is present in 90%-95%[14,15] of celiac patients and it seems to explain the relationship between the disease and the non-responsiveness to hepatitis B vaccine. Thus, in celiac non responders a re-vaccination should be recommended because of the worldwide spread of the disease.

Nowadays, there is no consensus on the management of celiac patients with anti-HBs antibody levels < 10 IU/L after the IM vaccine. In healthy people a common practice is to administer a higher dose of HBV re-

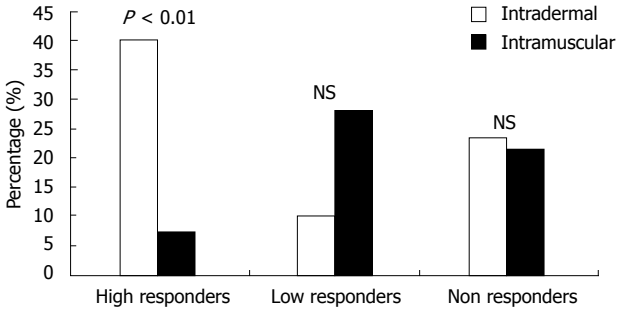

Figure 1 Percentage of high responders, low responders and non responders after the first booster dose. *P* value was calculated by Fisher exact test. NS: Not significant.

combinant vaccine (HBRV) or a second course of three doses of IM recombinant vaccine (IMRV)[16], but it does not seem to be successful. In fact it has been reported that more than 50% of non responders are not able to acquire an protective anti-HBs titer with at least two additional IMRV booster doses in the primary course[17,18].

In human immunodeficiency virus patients, repeated vaccination is commonly considered as a first satisfactory strategy[19]. Some investigators have even increased the dose of hepatitis B vaccine with varying success[20,21] or have used a double dose of a combined hepatitis A and B vaccine[22].

The United States Center for Disease Control and Prevention recommends the administration of an additional series of three doses of IM vaccine in chronic hemodialysis patients[23]. For those non-responders after two series (six doses of vaccine in total), there is no data to support the use of additional doses to induce an immune response.

Another approach is to administer HBRV vaccine by the ID route. In fact a recent meta-analysis by Fabrizi *et al*[24] concluded that the ID route is associated with higher anti-HBs antibody levels, although this is not sustained over time. Recently in a pilot study we found an effective response after ID administration of HBRV in celiac patients too[25].

At present this is the first study comparing the ID and IM routes in these patients. In our study we found a high percentage of response after the first dose of vaccination in both groups (ID 76.7% *vs* IM 78.6%) and a higher response after the third booster dose (ID 90% *vs* IM 96.4%). Moreover, the percentage of responders in both groups after the three doses of vaccine was similar to those found in vaccinated healthy people[12].

Our data confirms that both routes are effective to perform a booster strategy in celiac patients with low anti-HBs antibodies, as 90% of ID patients and 96.4% of IM subjects showed a protective anti-HBs titer after the third booster dose. However the ID route seems to produce a significantly higher percentage (40%) of high responders (anti-HBs > 1000 IU/L) than the IM route (7.1%).

In our opinion, this result may have an important clinical significance, because a protective anti-HBs titer

may persist to 64% after 10 years in normal children if there is a high value of anti-HBs antibody titer at the end of the initial schedule[9].

However, whether the ID route is a better strategy than IM hepatitis B vaccine still remains an open question. In fact several studies in high-risk groups[26-28] showed that low dose ID injections resulted in long term sero-protection in a large number of subjects non responsive to IM vaccination. However, a recent meta-analysis of 757 adults by Sangaré *et al*[29] demonstrated that ID hepatitis B vaccination was less effective to achieve sero-protection than IM vaccination.

Recently a randomized study on ID *vs* IM hepatitis B vaccination in human immunodeficiency virus-infected children, without severe immunosuppression, confirmed this issue[30]. In particular, in the study by Medeiros *et al*[31] on hemodialysis patients, the percentage of responders was very low (13.3%).

Our data seem to suggest that the use of the ID route for the booster dose of hepatitis B vaccine in celiac patients is a better option to obtain an higher titer of antibodies against HBV. Moreover the ID route allows a better cost/efficacy ratio, because of the cost reduction exceeding 50% (2 μg per dose) compared with a standard IM vaccine regimen (10 μg per dose)[32]. In conclusion, it is important to highlight that the ID route could represent an efficacious and cost-saving option for difficult-to-vaccinate and high-risk patients, as reported in other studies[33-35] and also for the observed 4%-10% of healthy people who normally fail to respond to the standard HBV vaccination regimen[36].

COMMENTS

Background

The hepatitis B vaccine is a mandatory vaccine for all children. Nevertheless around 4%-10% of healthy subjects and a higher percentage of patients affected by celiac disease do not respond to the standard cycle of vaccination provided by the Ministry of Health. As a matter of fact they show an antibody titer less than 10 IU/L after the standard vaccination doses. This population could be considered at risk for potential exposure to hepatitis B virus (HBV) infection. Thus, it is proposed that the revaccination of "non-responders" at the first cycle of scheduled HBV vaccination, by booster doses, could improve HBV antibody titer and this study compared the efficacy of intramuscular (IM) boosters *vs* intradermal (ID) vaccination.

Research frontiers

The ID route of vaccination is an effective way to vaccinate people, it is safe and it seems to be easier to practice than the IM route. This way should be considered in "non-responder" celiac patients, not only for the high response to vaccination, but also because it allows a better cost/efficacy ratio, with a cost reduction exceeding 50% compared with an IM vaccine regimen. This cost decrease is linked to the lower dosage of vaccine used in the ID route (2 μg per dose) than in the IM route (10 μg per dose).

Innovations and breakthroughs

The problems of responsiveness to vaccinations such as anti HBV vaccine have been widely studied, and researchers have demonstrated how this lack of response could be linked to genetic and environmental factors. Actually there are few studies that respond to the question on how to solve this non-responsiveness to HBV vaccine. Some studies found a good strategy was re-vaccination by the IM route, others demonstrated a better outcome with the ID route. Moreover, other researchers find the practice of applying booster doses to "non-responders" not useful, as they conserve their intra-cellular immunity. Nevertheless, as the problem has widely interested the scientific community in these last years, it could be useful to establish a common behavior to solve this question. For this reason, studies on new vaccination schedules could be useful and this study is the first one that compares two vaccination routes in order to better understand the way the research should address its efforts.

Applications

The study results suggest that ID route of HBV vaccination is a potential therapeutic strategy that could be used in improving responsiveness to HBV vaccine and in preventing a potential infection in a "non-responders" population.

Peer review

This is a good prospective, randomized study in which the authors analyzed the efficacy of ID and IM routes in HBV vaccinated children to improve their responsiveness to standard vaccination. The results are interesting and suggest that the ID route of booster vaccination is not only as effective as the IM one, but it is also less expensive, so it could easily be considered as a successful strategy for booster doses of HBV vaccine in "non-responder" patients.

Abstract

AIM: To analyze the effectiveness of the endoscopic therapy and to identify prognostic factors for recurrent bleeding.

METHODS: Retrospective study of patients with gastrointestinal bleeding secondary to Dieulafoy's lesion (DL) from 2005 to 2011. We analyzed the demographic characteristics of the patients, risk factors for gastrointestinal bleeding, endoscopic findings, characteristics of the endoscopic treatment, and the recurrence of bleeding. We included cases in which endoscopy described a lesion compatible with Dieulafoy. We excluded patients who had potentially bleeding lesions such as angiodysplasia in other areas or had undergone other gastrointestinal endoscopic procedures.

RESULTS: Twenty-nine patients with DL were identified. Most of them were men with an average age of 71.5 years. Fifty-five percent of the patients received antiaggregatory or anticoagulant therapy. The most common location for DL was the stomach (51.7%). The main type of bleeding was oozing in 65.5% of cases. In 27.6% of cases, there was arterial (spurting) bleeding, and 6.9% of the patients presented with an adherent clot. A single endoscopic treatment was applied to nine patients (31%); eight of them with adrenaline and one with argon, while 69% of the patients received combined treatment. Six patients (20.7%) presented with recurrent bleeding at a median of 4 d after endoscopy (interquartile range = 97.75). Within these six patients, the new endoscopic treatment obtained a therapeutic success of 100%. The presence of arterial bleeding at endoscopy was associated with a higher recurrence rate for bleeding (50% *vs* 33.3% for other type of bleeding) [P = 0.024, odds ratio (OR) = 8.5, 95% CI = 1.13-63.87]. The use of combined endoscopic treatment prevented the recurrence of bleeding (10% *vs* 44.4% of single treatment) (P = 0.034, OR = 0.14, 95% CI = 0.19-0.99).

CONCLUSION: Endoscopic treatment of DL is safe and effective. Adrenaline monotherapy and arterial (spurting) bleeding are associated with a high rate of bleeding recurrence.

INTRODUCTION

Dieulafoy's lesion (DL) was first described in 1884 by Gallarden[1-3], and characterized in 1898 by the French surgeon George Dieulafoy, who described its characteristics in three patients and gave it its name. It is a rare but important cause of gastrointestinal bleeding. Up to 6% of the cases of nonvaricose bleeding in the upper gastrointestinal tract[4,5] and 1%-2% of all gastrointestinal hemorrhages are caused by DL[6,7]. In spite of this, its mortality rates are similar to those of other causes for gastrointestinal bleeding[8]. This lesion is defined by the presence of an abnormally thick arteriole (1-3 mm in diameter, 10 times higher than the diameter of submucosal capillaries at that level) that maintains the caliber of the feeding vessel when it reaches the mucous membrane[3,9]. Histologically, it is characterized by subintimal fibrosis of the artery and a lack of inflammation at the edge of the mucosal defect, which sets it apart from peptic ulcers. The exact mechanism that triggers the bleeding is unknown. Some authors have speculated on the combined effect of atrophy and ischemia of the mucosa[2]. It is believed that this thick vessel applies pressure to the mucosa and leads to a small erosion and rupture of the vessel towards the lumen. Clinically, it appears with intermittent and painless gastrointestinal bleeding[10,11]. The most common location is the stomach[6,8]; specifically the lesser curvature[1,8,12]. In 80%-95% of these cases it is located within 6 cm of the gastroesophageal junction, because the arterial flow in this area emerges directly from the left gastric artery[2,13,14]. Approximately one third of the lesions are located outside the stomach, most of them in the duodenum[15], followed by the colon[3,16]. They have also been described in the esophagus, jejunum and ileum[13,17], rectum[18,19] and anal canal[20]. There have also been some cases in which the lesion was outside the gastrointestinal tract (bronchial tubes)[21].

The diagnostic procedure of choice is endoscopy, which is effective in > 90% of patients[7,8]. The endoscopic diagnosis may be difficult, especially during the first episode, due to the size of the lesion and the intermittent nature of the hemorrhage. For this reason, up to 6% of patients require three or more endoscopies in order to reach a diagnosis[8]. Endoscopic ultrasound has been highlighted as a useful technological resource that can support the diagnosis of this condition, because it can locate the submucosal vessel with great accuracy[22].

Traditionally, the treatment of DL was surgical. However, with the development of endoscopic hemostasis techniques, the need for surgery has been reduced, and the mortality rates have decreased from 80% to 8.6%[23]. Therefore, the current treatment of choice in accessible lesions is endoscopy[13], with a success rate of > 90%[7,24-26] and low rates of recurrence and complications[27-33]. The endoscopic hemostasis procedures are classified into three groups: (1) thermal: electrocoagulation, heater probe and argon plasma coagulation; (2) local injection of substances, such as adrenaline or sclerosing solutions; and (3) mechanical: hemostatic clips and bands[6,7,12].

All these procedures achieve high rates of primary hemostasis, with low rates of recurrence (generally < 10%)[27-33]. However, in the clinical field, the choice of a procedure depends on the experience and the decision of the endoscopist.

The objectives of our study were to assess the effectiveness of endoscopic treatment of DL, and to identify potential prognostic factors for recurrence of bleeding in patients with this kind of lesion.

MATERIALS AND METHODS

Patients

This was a retrospective study of patients who were admitted to the University Hospital of Salamanca with a diagnosis of gastrointestinal bleeding caused by DL between 2005 and 2011. We collected data regarding clinical presentation of the disease, diagnosis, and effectiveness of medical and endoscopic treatment of gastrointestinal bleeding caused by DL. We included cases in which endoscopy described a lesion compatible with Dieulafoy. We excluded patients who had potentially bleeding lesions such as angiodysplasia in other areas or had undergone other gastrointestinal endoscopic procedures.

Descriptive analysis

In the descriptive analysis of the sample, we used percentages for the qualitative variables and measures of central tendency (mean and/or median when there was a large asymmetry or dispersion) and of dispersion (SD) for the quantitative variables.

Statistical analysis

We used the SPSS Version 15.0 (Chicago, IL, United States) for the analysis. The dichotomous variables were analyzed with the χ^2 test on contingency tables in order to compare the distribution of categorical variables, and we calculated the odds ratios (ORs) and 95% CIs. The analysis of variance test was used in the analysis of continuous and categorical variables. The multivariate analysis was done using binary logistic regression. Statistical significance was established at $P < 0.05$.

RESULTS

Out of the 2582 patients admitted in the endoscopy unit with upper gastrointestinal bleeding, we identified 29 with DL (1.12%). In this group, 21 (72.4%) patients were

Table 1 Prognostic factors analyzed in cases of bleeding recurrence caused by Dieulafoy's lesion *n* (%)

Factor	Bleeding recurrence	No bleeding recurrence	*P* value
Male patients	4 (66.7)	17 (73.9)	0.54
Arterial hypertension	5 (83.3)	13 (56.5)	0.23
Ischemic heart disease	3 (33.3)	6 (20.1)	0.54
Valvular heart disease	1 (16.7)	5 (21.7)	0.63
Renal failure	1 (16.7)	-	-
Anticoagulant or antiaggregant	3 (50)	13 (56.5)	0.56
Antiaggregant	6 (100)	7 (30.4)	0.62
Anticoagulant	1 (16.7)	11 (47.8)	0.18
Location in the stomach	3 (50)	12 (52.2)	0.63
Mean systolic arterial pressure (mmHg)	107.3	112	0.62
Mean heart rate (beats/min)	83	85.7	0.77
Urea (mg/dL)	76.8	84.3	0.66
Hemoglobin (mg/dL)	8.76	8.75	0.98
Need of transfusion	6 (100)	20 (87)	0.48
PPI perfusion	2 (33.3)	11 (47.8)	0.43
Arterial bleeding type	4 (66.7)	4 (19)	0.02
Combined endoscopic treatment	2 (33.3)	18 (78.3)	0.03

PPI: Proton-pump inhibitor.

men with an average age of 71.5 ± 14.5 years. Their personal records showed arterial hypertension (62.1%), ischemic heart disease (27.6%), valvular heart disease (20.7%), and chronic liver disease (3.4%). Sixteen patients (55.2%) were receiving antiaggregatory or anticoagulant therapy, and five (17.2%) a combination of both therapies.

Among the patients treated with antiaggregatory agents, five (55.5%) were being treated with acetylsalicylic acid (ASA), and the remainder with clopidogrel. Among the anticoagulant patients, 11 (91.6%) were being treated with acenocoumarol, and one patient was being treated with low molecular weight heparin. No patient was receiving triple therapy (ASA/clopidogrel/acenocoumarol). Only three (10.3%) of the patients were being treated with a proton-pump inhibitor (PPI) before the bleeding episode.

Symptoms of clinical instability were present in 10 (34.5%) patients (systolic arterial pressure < 100 mmHg and/or heart rate > 100 beats/min) and the average hemoglobin levels before gastroscopy were 8.6 ± 2.48 mg/dL.

The most common location for DL was the stomach (51.7%), followed by duodenum (31%) and esophagus (13.8%). In one patient, the lesion was located on the colon. The main type of bleeding was oozing, in 65.5% of the cases. In 27.6% of the cases there was arterial (spurting) bleeding (Figure 1), and 6.9% of the patients presented with an adherent clot. A single endoscopic treatment was applied to nine patients (31%); eight of them with adrenaline and one with argon, while 69% of the patients received combined treatment (several different combinations with clip, adrenaline, sclerosing therapy and argon). Hemostatic bands were not used in any of the cases. All medical treatments were initiated before endoscopy, 16 patients (55.2%) received continuous intravenous perfusion of PPI with an average dose of 156.92 ± 62.1 mg/24 h for an average period of 3 ± 1.82 d, and 13 (44.8%) patients received treatment with oral PPI, with an average dose of 57.5 ± 34.93 mg/24 h. Most of the patients (n = 26) required red blood cell transfusion, with a median value of 2 U concentrate per patient [interquartile range (IQR) = 2].

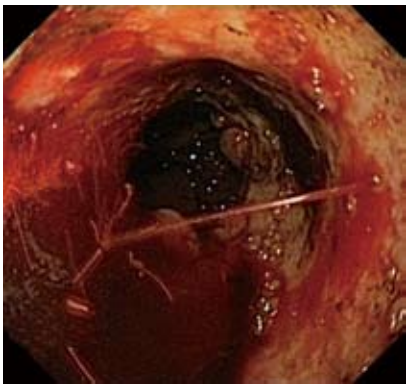

Figure 1 Dieulafoy's lesion located on the esophagus with arterial (spurting) bleeding.

Bleeding reappeared in six patients (20.7%), at a median 4 d after endoscopy (IQR = 97.75). In this group of patients, the second endoscopic treatment achieved a therapeutic success rate of 100%. The recurrence of bleeding was not associated with age, sex, personal record, previous medical treatment (including antiaggregants and/or anticoagulants), the seriousness of the hemorrhage or its location, or the medical treatment used (Table 1). However, the presence of arterial (spurting) bleeding at endoscopy was associated with a higher rate of bleeding recurrence (50% *vs* 33.3% for other types of bleeding) (P = 0.024, OR = 8.5, 95% CI = 1.13-63.87). Multivariate analysis adjusted for age, sex, type of antiaggregant, type of anticoagulation and single or combined endoscopic treatment, confirmed the association (P = 0.039). The use of combined endoscopic treatment prevented recurrence of bleeding (10% *vs* 44.4% with monotherapy) (P = 0.034, OR = 0.14, 95% CI = 0.19-0.99), and multivariate analysis confirmed this association (P = 0.049). Two patients died; one due to postoperative septic shock and the other to complications of previous heart disease.

DISCUSSION

In our hospital, the prevalence of gastrointestinal bleeding due to DL was 1.12%. This percentage was similar to that in other studies[23,31,34]. The demographic characteristics of our patients were similar to those in other studies; we found a higher prevalence of the condition in men, compared to women, with a ratio of 3:1, and an average age of 71.5 years. DL usually affects patients with associated comorbidity[25], such as cardiovascular disease, arterial hypertension or renal failure. Some authors have proposed that these conditions alter the normal process of angiogenesis and trigger the formation of aberrant ves-

sels with a constant caliber that increase the incidence of DL[35]. In our study, most of the patients presented with comorbidity; mainly hypertension (62.1%) and ischemic heart disease (27.6%). Similarly, some researchers have proposed a causal relation with the use of nonsteroidal anti-inflammatory drugs and aspirin, and they argue that the erosive gastritis and the subsequent necrosis of the vascular wall induced by these drugs may lead to rupture of the submucosal vessels, although there is little evidence in the literature that supports this relationship[1,2]. In our study, although a high percentage of the patients received antiaggregant therapy, only three patients (10%) received some additional PPI.

Gastrointestinal bleeding caused by DL can be serious. In our study, 10 patients (34.5%) presented with symptoms of hemodynamic instability, and 27 (93.1%) showed active bleeding at the moment of endoscopic exploration. Two patients died; one due to postoperative complications (septic shock) and the other to complications of previous heart disease.

Most of the studies have shown that the most common location of DL is the stomach. In our series this was also the most common location, followed by the duodenum and the esophagus, plus one case in which the lesion was in the colon and two cases in which it was located on the gastric anastomosis caused by gastrectomy.

The first endoscopy was diagnostic in 93% of cases. Early exploration seems to increase sensitivity due to the intermittent nature of bleeding caused by DL[31] but we did not study this factor.

The success rate of endoscopic treatment in our study was high, similar to that reported in other studies[23,36,37]. Primary hemostasis was achieved in 89% of the cases ($n = 26$).

The endoscopic methods used were: injection (adrenaline, aethoxysklerol), thermal techniques (argon), and mechanical techniques (clip). In most of the cases, combined endoscopic treatment was applied (69%), and the technique was chosen according to the criteria of the endoscopist. The most commonly used technique was a combination of adrenaline injection and a sclerosing agent. Recurrent bleeding was found in six cases (20.7%), compared with other studies that have described rates of 9%-40%[23]. The recurrence of bleeding was associated with monotherapy with adrenaline and endoscopic findings of arterial (spurting) bleeding. Although there is no consensus on the endoscopic treatment of choice, several studies have compared the effectiveness of different techniques. Adrenaline injection is the most commonly used method due to its availability, low cost and safety. Some studies have shown a higher effectiveness of mechanical methods compared with injection techniques. In recent years, several studies have proven that the hemoclip[35] and endoscopic ligature improve the rates of primary hemostasis and reduce the need for subsequent endoscopy[38,39]. Theoretically, the mechanical hemostasis leads to a smaller lesion of the surrounding tissue than thermal therapy or injection techniques, which suggests that these procedures could be a first-line approach for the management of DL[33,36,40]. Another study has shown better results for thermocoagulation *vs* injection of a single substance[37]. A recent study has concluded that combined therapy with hemoclip and aethoxysklerol injection is the most effective[41], while other studies have shown that sclerosis with adrenaline was associated with a higher risk of bleeding recurrence[29,42]. Similar to endoscopic treatment of bleeding due to peptic ulcer, a lower rate of bleeding recurrence has been described with the use of combined endoscopic treatment compared with monotherapy, as could be seen in our study.

With regard to the limitations of our study, we must first mention the small size of the sample, and the retrospective design. The low number of prospective studies may be due to the low incidence of DL.

In conclusion, endoscopic treatment of DL is effective. Treatment with adrenaline monotherapy, and arterial (spurting) bleeding, are associated with a higher rate of bleeding recurrence. For this reason, combined treatment is recommended.

COMMENTS

Background

The Dieulafoy's lesion (DL) is a rare condition that causes gastrointestinal bleeding and treatment is difficult. It is a small aberrant vessel and the diagnosis is only obtained after surgery and pathological analysis. Recurrent bleeding is common and we have many endoscopic therapeutic options.

Research frontiers

Because it is very rare, there have been few prospective studies with few patients to analyze the characteristics of the bleeding, factors associated with recurrence, and treatment success. Although there is no consensus on the endoscopic treatment of choice, several studies have compared the effectiveness of different techniques.

Innovations and breakthroughs

The authors showed that combined treatment with two endoscopic techniques was more effective in controlling bleeding than adrenaline monotherapy, as occurs for gastrointestinal ulcer bleeding. Furthermore, it is important to consider the type of presentation of bleeding. Arterial (spurting) bleeding is associated with a higher rate of recurrence.

Applications

This study suggests that when a DL with active bleeding is present, combination therapy should be performed with at least two endoscopic techniques, especially if the bleeding is arterial.

Peer review

The authors have retrospectively analyzed patients with bleeding from DL in whom endoscopic therapy in the form of single or combination treatment was applied. The authors have then tried to establish factors responsible for rebleeding. Interesting paper on an interesting topic.

Abstract

AIM: To assess the prevalence of human papilloma virus (HPV) in esophageal squamous cell carcinoma (ESCC) in the south-eastern region of Poland.

METHODS: The study population consisted of 56 ESCC patients and 35 controls. The controls were patients referred to our department due to other non-esophageal and non-oncological disorders with no gross or microscopic esophageal pathology as confirmed by endoscopy and histopathology. In the ESCC patients, samples were taken from normal mucosa (56 mucosa samples) and from the tumor (56 tumor samples). Tissue samples from the controls were taken from normal mucosa of the middle esophagus (35 control samples). Quantitative determination of DNA was carried out using a spectrophotometric method. Genomic DNA was isolated using the QIAamp DNA Midi Kit. HPV infection was identified following PCR amplification of the *HPV* gene sequence, using primers MY09 and MY11 complementary to the genome sequence of at least 33 types of HPV. The sequencing results were computationally analyzed using the basic local alignment search tool database.

RESULTS: In tumor samples, HPV DNA was identified in 28 of 56 patients (50%). High risk HPV phenotypes (16 or/and 18) were found in 5 of 56 patients (8.9%), low risk in 19 of 56 patients (33.9%) and other types of HPV (37, 81, 97, CP6108) in 4 of 56 patients (7.1%). In mucosa samples, HPV DNA was isolated in 21 of 56 patients (37.5%). High risk HPV DNA was confirmed in 3 of 56 patients (5.3%), low risk HPV DNA in 12 of 56 patients (21.4%), and other types of HPV in 6 of 56 patients (10.7%). In control samples, HPV DNA was identified in 4 of 35 patients (11.4%) with no high risk HPV. The occurrence of HPV in ESCC patients was significantly higher than in the controls [28 of 56 (50%) *vs* 4 of 35 (11.4%), $P < 0.001$]. In esophageal cancer patients, both in tumor and mucosa samples, the predominant HPV phenotypes were low risk HPV, isolated 4 times more frequently than high risk phenotypes [19 of 56 (33.9%) *vs* 5 of 56 (8.9%), $P < 0.001$]. A higher prevalence of HPV was identified in female patients (71.4% *vs* 46.9%). Accordingly, the high risk phenotypes were isolated more frequently in female patients and this difference reached statistical significance [3 of 7 (42.9%) *vs* 2 of 49 (4.1%), $P < 0.05$]. Of the pathological characteristics, only an infiltrative pattern of macroscopic tumor type significantly correlated with the presence of HPV DNA in ESCC samples [20 of 27 (74.1%) *vs* 8 of 29 (27.6%) for ulcerative or protruding macroscopic type, $P < 0.05$]. The occurrence of total HPV DNA and both HPV high or low risk phenotypes did not significantly differ with regard to particu-

lar grades of cellular differentiation, phases in depth of tumor infiltration, grades of nodal involvement and stages of tumor progression.

CONCLUSION: Low risk HPV phenotypes could be one of the co-activators or/and co-carcinogens in complex, progressive, multifactorial and multistep esophageal carcinogenesis.

INTRODUCTION

Esophageal cancer is the eighth most common cancer and the sixth leading cause of cancer-related death worldwide[1-3]. Overall survival rates range between 5% and 16%[2]. Thus, esophageal cancer poses a considerable medical and public health challenge in many parts of the world. Although there is a marked tendency for increasing incidence rates of esophageal adenocarcinoma in industrialized Western countries, the world leading pathological type of esophageal cancer is still squamous cell carcinoma[2]. Marked geographic, cultural and ethnic variations suggest the importance of environmental influences in the development of this condition. In China, India and Central Asia (the Esophageal Cancer Belt), squamous cell carcinoma still predominates[2]. Significantly high incidence rates have been reported in France, South Africa, Chile, Brazil and the north-eastern Himalayan region[1-3]. The North American and European countries have been found to be low-risk areas[1-3]. The highest incidence and mortality have been reported in Kazakh populations, especially in Xinjiang, China[1-3]. In Europe, the incidence of esophageal cancer is increasing and seems to parallel the decrease in gastric cancer incidence[1-3]. Poland is a low-incidence country with the reported age-standardized annual incidence of 4.5 and 0.7/100.0, for men and women, respectively[4].

In Western countries, esophageal carcinomas with squamous cell differentiation typically arise after many years of tobacco and alcohol abuse[5]. Other causes include chronic mucosal injury due to hot beverages and malnutrition[5]. An etiologic role of different microorganisms such as fungi, bacteria and viruses has also been proposed for the pathogenesis of esophageal squamous cell cancer (ESCC)[5,6]. Of these microorganisms, human papilloma virus (HPV), cytomegalovirus (CMV) and Epstein-Barr virus (EBV) have been investigated[5,6]. The role of HPV in the etiology of ESCC has been debated for the past 30 years[7]. The prevalence of HPV in esophageal cancer seems to be higher in areas with a high incidence of ESCC, such as China and South Africa. In 1982, Syrjanen *et al*[7] found that HPV infection caused pathological lesions in esophageal cancer specimens. The prevalence of HPV in ESCC in subsequent studies has shown high variability ranging from 0% to 67%[8-12]. The issue of HPV incidence in ESCC patients in the Polish population has not yet been addressed. In this study we evaluated the prevalence of HPV DNA in patients treated in a regional specialized center for esophageal cancer surgery in Poland, where squamous cell type differentiation of esophageal cancer still predominates.

MATERIALS AND METHODS

Study population

HPV identification was carried out on 147 esophageal tissue samples taken from 91 patients treated between 2007 and 2010 in the Second Department of General and Gastrointestinal Surgery and Oncological Surgery of the Alimentary Tract, Medical University of Lublin, Poland. The study population consisted of 56 patients with ESCC (49 males aged 56.22 ± 7.34 years; 7 females aged 58.85 ± 7.77 years) and 35 controls with normal esophageal mucosa (30 males aged 33.73 ± 9.62 years; 5 females aged 45.91 ± 5.72 years). The detailed pathological characteristics of the ESCC patients are shown in Table 1. The controls were patients referred to our department due to other non-esophageal and non-oncological disorders with no gross and microscopic esophageal pathology as confirmed by endoscopy and histopathology. All investigated patients and controls were smokers.

The study was approved by the Ethics Committee of the Medical University of Lublin (0254/212/2007) and carried out in accordance with the principles of the Helsinki Declaration. Written informed consent was obtained from all the subjects.

Tissue samples in ESCC patients were taken during surgery from the specimen or during preoperative esophagoscopy. The first set of samples was taken from normal esophageal mucosa 10 cm proximal to the edge of the tumor (56 mucosa samples). A second set of samples was then taken from the tumor (56 tumor samples). Tissue samples in the controls were taken during esophagogastro-duodenoscopy from normal mucosa of the middle esophagus (35 control samples). Tissue samples were divided into two parts: one part was sent

for histopathological assessment and the other was stored in a freezer at -70 ℃ for molecular testing. Before molecular testing for HPV, histopathological assessment of all samples was carried out by two independent experienced pathologists. ESCC was confirmed in all tumor samples and no microscopic pathology was identified in the mucosa and control samples.

DNA isolation

Genomic DNA was isolated from esophageal cancer tissue and healthy esophageal mucosa by proteinase digestion and phenol extraction or using the QIAamp DNA Mini Kit (Qiagen) according to the manufacturer's instructions.

The esophageal tissue samples were homogenized following the addition of 1 mL buffer with the following composition: 0.01 mol Tris-HCl pH 7.5; 0.01 mol ethyl enediaminetetraacetic acid; 0.6% odium dodecyl sulfate. The homogenate was incubated for 30 min at room temperature. Then, K proteinase was added reaching a final concentration of 50 mg/L and incubated for 24 h at 37 ℃. Following incubation, half the volume of phenol: chloroform: isoamyl alcohol (in a ratio of 25:24:1) mixture was added to the solution; it was shaken for 15 min at room temperature and centrifuged for 15 min at 3000 *r*/min. The remaining volume of phenol, chloroform, isoamyl alcohol mixture was added to the water phase obtained, shaken energetically and then centrifuged. The above procedures were repeated until complete purification of DNA manifested as a lack of interphase was achieved. Then, half the volume of isopropylene alcohol and 0.1 volume of 3 mol acetate at pH 7.0 were added to the water phase obtained.

The DNA samples obtained in this manner were then rinsed in 80% ethanol and dissolved in distilled water after drying. The samples with dissolved DNA were stored at 20 ℃. Quantitative determination of the DNA obtained was carried out by spectrophotometry using an automatic spectrophotometer manufactured by Pharmacia Co. In order to determine the amount of DNA in a given sample, 1 μL of the sample was dissolved in 69 μL of re-distilled water and after calibration of the spectrophotometer, the sample was placed in its measuring chamber. After automatic processing of the data measured, the result was read in mg/L.

HPV: Human papilloma virus.

HPV identification

Genomic DNA was isolated from study tissues using the QIAamp DNA Midi Kit (QIAGEN) according to the manufacturer's protocol. HPV infection was identified following polymerase chain reaction (PCR) amplification of the *HPV* gene sequence, using primers MY09 and MY11 (Table 2) complementary to the genome sequence of at least 33 types of HPV viruses as described previously[13]. The reaction mixture contained 15 mg/L DNA and the following reagents: 0.5 U Taq DNA polymerase (Fermentas), PCR buffer and magnesium chloride at a final concentration of 1.5 mmol (Fermentas), primers at a final concentration of 0.25 mmol each and dNTPs (Promega) at a final concentration of 0.2 mmol. PCR products were run in 1.2% agarose gel electrophoresis with ethidium bromide and visualized in ultraviolet light. The product length was assessed according to the MassRuler marker (Fermentas). PCR products were randomly eluted from agarose gel using QIAGEN and sequenced in order to confirm the presence of the expected product. The sequencing results were computationally analyzed using the basic local alignment search tool database. These were sequenced in the Sequencing Laboratory Adam Mickiewicz University Poznań.

Statistical analysis

From the statistical analysis of the results obtained from

Table 3 Human papilloma virus status in esophageal squamous cell carcinoma patients investigated from Lublin region

HPV risk	*n* (%)	χ^2
Tumor samples (*n* = 56)		
High risk	5 (8.9)	
Low risk	19 (33.9)[b]	24.487
Others	4 (7.1)	
Total	28 (50.0)[d]	21.185
Mucosa samples (*n* = 56)		
High risk	3 (5.3)	
Low risk	12 (21.4)[b]	23.451
Others	6 (10.7)	
Total	21 (37.5)[d]	27.521
Control samples (*n* = 35)		
High risk	0 (0)	
Low risk	2 (5.7)	
Others	2 (5.7)	
Total	4 (11.4)	

[b]$P < 0.01$ *vs* human papilloma virus (HPV) high risk, Fisher test; [d]$P < 0.01$ *vs* control, Fisher test.

HPV (+) and HPV (-) patients, correlation tables containing structure indices were compiled. A method of statistical interference, verification of hypotheses based on homogeneity and independence test χ^2, was used. The differences between groups of ESCC samples according to analyzed clinico-pathological parameters were compared using the Mann-Whitney *U* test or the Kruskal-Wallis test depending on the distribution of the grouping variable. Statistical significance was found at $P < 0.05$. The statistical analyses were performed on an IBM PC, using SPSS 8.0 PL for Windows 95 and Statistica 5.0.

RESULTS

The results of molecular testing which evaluated the occurrence of HPV in 147 esophageal tissue samples from patients with ESCC and controls are shown in Table 3. In tumor samples, HPV DNA was identified in 28 of 56 samples (50%). High risk HPV DNA (16 or/and 18) was found in 5 of 56 samples (8.9%), low risk in 19 of 56 samples (33.9%) and other types of HPV (37, 81, 97, CP6108) in 4 of 56 samples (7.1%). In mucosa samples, HPV DNA was isolated in 21 of 56 samples (37.5%). High risk HPV DNA was confirmed in 3 of 56 samples (5.3%), low risk HPV DNA in 12 of 56 samples (21.4%), and other types of HPV in 6 of 56 samples (10.7%). In control samples, HPV DNA was identified in 4 of 35 samples (11.4%). In control samples, no high risk HPV DNA was isolated. Two samples contained low risk HPV DNA (5.7%) and other types of HPV were found in 2 of 56 cases (5.7%).

The occurrence of HPV DNA in ESCC tissue and unaffected esophageal mucosa taken from patients with esophageal cancer was significantly higher than in control samples taken from healthy esophageal mucosa [28 of 56 (50%) *vs* 4 of 35 (11.4%), $P < 0.001$]. In esophageal cancer patients, both in tumor and mucosa samples, the predominant HPV phenotype was low risk HPV DNA, and was isolated approximately 4 times more frequently than high risk phenotypes. This difference reached statistical significance [19 of 56 (33.9%) *vs* 5 of 56 (8.9%), $P < 0.001$].

[1]Mann-Whithey *U* test; [2]Kruskal-Wallis test. HPV: Human papilloma virus; ULC: Ulcerative; INF: Infiltrative; PROT: Protruding.

A higher prevalence of HPV DNA was identified in female patients (71.4% *vs* 46.9%). Accordingly, high risk HPV phenotypes were isolated more frequently in female patients and this difference reached statistical significance [3 of 7 (42.9%) *vs* 2 of 49 (4.1%), $P < 0.05$] (Table 4). Of the pathological characteristics, only an infiltrative pattern of macroscopic tumor type significantly correlated with the presence of HPV DNA in ESCC samples [20 of 27 (74.1%) *vs* 8 of 29 (27.6%), $P < 0.05$] (Table 4). The occurrence of total HPV DNA and both HPV high or low risk phenotypes did not significantly differ with regard to particular grades of cellular differentiation, phases in depth of tumor infiltration, grades of nodal involvement and stages of tumor progression. The detailed distribution of total HPV DNA, high and low risk HPV phenotypes according to particular clinico-pathological characteristics are shown in Table 4.

DISCUSSION

The role of HPV in the etiology of ESCC is not clear. To date, over 70 studies have tested for HPV in esophageal cancer tissue[13] and the reported HPV detection rate ranged from 0% to 67%[8-12]. The data from China[14] pro-

vided the most convincing evidence to date that HPV is not directly involved in ESCC carcinogenesis, at least in China. HPV DNA contamination cannot be ruled out as an explanation for high HPV occurrence in ESCC tissue studies with less stringent tissue procurement and processing protocols. A few possible reasons for this variation between studies include small study sites, different HPV detection assays, interlaboratory variability and suboptimal sample collection and handling leading to contamination[1,15].

The incidence of HPV infection in ESCC patients was significantly higher in comparison to controls with normal esophageal mucosa. In our study we identified HPV DNA in 50% of ESCC patients, but contrary to the Chinese data[1], the detected HPV types had low oncogenic potential. A high risk 16 or/and 18 HPV DNA type was only detected in 5 of 56 cases (8.92%). HPV types with low oncogenic potential were found 4 times more frequently than high risk HPV types both in tumor tissue and distant mucosa in patients with ESCC. These differences reached statistical significance.

HPV type 16 was detected in 16% of ESCC patients in Uppsala, Sweden[16] and this was higher than in our population. Xu *et al*[17] reported that the detection rate of infection with all HPV types (16, 18 and 58) in ESCC tissue in Chinese patients was 50%. This number corresponded well with data observed in our study. When investigated by nested polymerase chain reaction, HPV DNA was identified in all ESCC tumor tissue in German patients[18]. Concomitantly, another potentially oncogenic virus considered to be involved in ESCC malignant transformation was EBV DNA which was detected in 35% of these patients.

A search of the most frequently used databases (Medline, PubMed) using the terms esophageal squamous cell carcinoma, HPV and Poland, revealed a lack of studies investigating the occurrence of HPV DNA in ESCC in the Polish population. To our knowledge this is the first report from Poland elaborating this issue.

Analysis of the prevalence of HPV DNA in ESCC samples according to different clinico-pathological parameters revealed that HPV was more frequently isolated in female patients and in tumors showing an infiltrative growth pattern (Table 4). In the majority of studies, investigators did not confirm statistically significant differences between HPV-positive and HPV-negative cases with regard to clinical and pathologic findings[19-26]. Nevertheless, Antonsson *et al*[20] reported that patients with HPV-positive ESCC tumors were younger than those with HPV-negative tumors and had higher body mass index. In turn, Harrera *et al*[21] in a Mexican population found that male patients were most commonly affected and the male:female ratio in HPV-positive ESCC increased two-fold in comparison with HPV-negative cases. Dreilich *et al*[16] found a significantly higher rate of the HPV 16 phenotype in advanced compared with localized cancer but this did not translate into prognostic significance. Although isolated data may suggest some association between HPV and aggressiveness and prognosis of ESSC, generalized and coherent conclusions concerning the influence of HPV and its particular phenotypes on clinico-pathological characteristics of ESCC cannot be drawn.

In summary, we identified low risk HPV DNA types in ESCC patients significantly more frequently than other types (37, 81, 97, CP6108). This may suggest that low risk HPV types could be one of the co-activators or/and co-carcinogens in complex, progressive, multifactorial and multistep esophageal carcinogenesis. HPV DNA occurrence does not preclude development of the squamous cell phenotype of esophageal carcinoma.

COMMENTS

Background

Esophageal cancer is the eighth most common cancer and the sixth leading cause of cancer-related death worldwide. Overall survival rates range between 5% and 16%. Although there is a marked tendency for increasing incidence rates of esophageal adenocarcinoma in industrialized Western countries, the world leading pathological type of esophageal cancer is still squamous cell carcinoma. Marked geographic, cultural and ethnic variations suggest the importance of environmental influences in the development of this condition. In Europe, the incidence of esophageal cancer is increasing and seems to parallel the decrease in gastric cancer incidence. Poland is a low-incidence country with the reported age-standardized annual incidence of 4.5 and 0.7/100.0, for men and women, respectively.

Research frontiers

Esophageal carcinoma is multifactorial in origin and typically arises after many years of tobacco and alcohol abuse. Other causes include chronic mucosal injury due to hot beverages and malnutrition. An etiologic role of different microorganisms such as fungi, bacteria and viruses has also been proposed for the pathogenesis of esophageal squamous cell cancer (ESCC). Of these microorganisms, human papilloma virus (HPV), cytomegalovirus and Epstein-Barr virus have been investigated. The role of HPV in the etiology of ESCC has been debated for the past 30 years.

Innovations and breakthroughs

In this study, the authors found HPV DNA in 50% of ESCCs. High risk HPV phenotypes (16 or/and 18) were found in 8.9%, low risk in 33.9% and other types of HPV (37, 81, 97, CP6108) in 7.1% of the patients. Low risk HPV DNA types were identified significantly more frequently than other types (37, 81, 97, CP6108). This may suggest that low risk HPV types could be one of the co-activators or/and co-carcinogens in complex, progressive, multifactorial and multistep esophageal carcinogenesis.

Applications

The data on the prevalence of different types of HPV may contribute to the design of future strategies for the prevention of HPV-related malignancies, including the development of effective vaccines.

Terminology

HPVs are DNA viruses that infect basal skin and mucosal cells. HPVs are categorized according to their cervical oncogenicity-based risk, with high, probably high, low and undetermined risks.

Peer review

In this manuscript, the authors investigated the prevalence of HPV in esophageal squamous cell carcinoma in Poland. Overall positive rate of HPV was similar to the previous reports. However HPV DNA type was different from other countries. Since this is the first report to investigate about relationship between HPV DNA type and esophageal squamous cell carcinoma, this study is certainly valuable in this research field.

Abstract

AIM: To give an overview of the literature on intussusception due to inflammatory fibroid polyp (IFP).

METHODS: We present a new case of ileal intussusception due to IFP and a literature review of studies published in English language on intussusception due to IFP, accessed *via* PubMed and Google Scholar databases. For the search, the keywords used were: intussusception, IFP, intussusception and IFP, intussusception due to IFP, and IFP presenting as intussusception. The search covered all articles from 1976 to November 2011.

RESULTS: We present a 38-year-old woman who was admitted 10 d after experiencing abdominal pain, vomiting, and nausea. Ultrasonography demonstrated small bowel intussusception. An ileal intussusception due to a mass lesion 50 cm proximal to the ileocecal junction was found during laparotomy. Partial ileal resection and anastomosis were performed. A diagnosis of ileal IFP was made based on the immunohistochemical findings. In addition, a total of 56 reports concerning 85 cases of intussusception due to IFP meeting the aforementioned criteria was included in the literature review. The patients were aged 4 to 81 years (mean, 49 ± 16.2 years); 44 were women (mean, 51.8 ± 14.3 years) and 41 were men (mean, 46 ± 17.5 years). According to the location of the IFP, ileal intussusception was found in 63 patients, while 17 had jejunal, three had colonic, and two had ileojejunal intussusception.

CONCLUSION: Although IFPs are rare and benign, surgery is the only solution in case of intestinal obstruction. Differential diagnosis should be made *via* immunohistochemical examination.

INTRODUCTION

Intussusception occurs when a more proximal portion of the bowel (intussusceptum) invaginates into the more distal bowel (intussuscipiens)[1-5]. The pathomechanism is thought to involve altered bowel peristalsis at the intraluminal lesion, which is then a lead point for the intussusceptum[1]. Although intussusception is a common condition in children, it is rare in adults. Adult intussusception differs from pediatric intussusception in various respects, including etiology and clinical characteristics[1-4]. Adult intussusception represents 5%-16% of all cases of intussusception and 1%-5% of all cases of intestinal

obstruction in adults[1-3,5-11]. In children, 90% of cases are idiopathic, whereas 70%-90% of cases of adult intussusception are secondary to an underlying pathology, with approximately 65% being due to benign or malignant neoplasms[1,4,12]. Non-neoplastic processes represent 15%-25% of cases, while idiopathic intussusception accounts for about 10% of cases[2,5,6,12-14]. The presentation of pediatric intussusception is often acute with sudden onset of intermittent colicky pain, vomiting, and bloody mucoid stools, and the presence of a palpable mass. In contrast, adults may present with acute, subacute, or chronic nonspecific symptoms[2-4].

Up to 90% of occurrences in adults have a lead point, defined as a well-definable pathological abnormality. Most lead points in the gastrointestinal tract involve primary or metastatic malignancy, lipomas, leiomyomas, adenomas, neurofibromas, postoperative adhesions, Meckel's diverticulum, foreign bodies, vascular anomalies, lymphoid hyperplasia, trauma, celiac disease, cytomegalovirus colitis, lymphoid hyperplasia secondary to lupus, Henoch-Schönlein purpura, Wiskott-Aldrich syndrome, appendiceal stump, or inflammatory fibroid polyps (IFP)[1,4,14-16].

IFPs are rare, benign, tumor-like lesions of the gastrointestinal tract. They are most commonly localized to the gastric antrum, but can develop anywhere in the gastrointestinal tract. The small bowel is the second most common site of origin, where IFPs usually present as intussusception or obstruction[15,17-20]. Here, we present a rare case of ileoileal intussusception due to IFP in a 38-year-old woman. A review of 85 cases reported in the English literature is also presented.

MATERIALS AND METHODS

Here, we present and discuss a new case of ileo-ileal intussusception caused by IFP. In addition, a search of the English-language medical literature using PubMed and Google Scholar was conducted for articles related to gastrointestinal intussusception due to IFP; the key words used were intussusception, IFP, inflammatory fibrous tumor, intussusception and IFP, intussusception due to IFP, and IFP presenting as intussusception. The search covered all articles from 1976 to November 2011. If there were any missing data, the corresponding authors of the articles in question were contacted by email. Articles containing adequate information, such as publication year, patient age, sex, duration of complaint, radiological tools, presence of palpable mass, surgical approach, tumor location, and tumor size, were included, while studies and comment articles with insufficient clinical and demographic data were excluded.

RESULTS

Case report

A 38-year-old female patient presented to our emergency clinic with a 10-d history of abdominal pain, vomiting, and nausea. Upon auscultation of the abdomen, bowel sounds were found to be consistent with mechanical bowel obstruction. Physical examination revealed muscular defense and rebound tenderness. Digital rectal examination did not reveal the presence of feces, mucus, or blood. Laboratory investigations showed blood urea nitrogen, 38 mg/dL (normal: 5-23 mg/dL); creatinine, 1.7 mg/dL (normal: 0.6-1.2 mg/dL); and C-reactive protein, 58 mg/L (normal: 0-0.5 mg/L). Blood cell counts revealed a leukocyte count of 8.77/L (normal: 4-11.000/L), a hemoglobin level of 11.4 g/dL (normal: 12-16 g/dL), and a platelet count of 275/L (150-450 000/L). Other serum parameters were within the normal limits. An upright plain abdominal film revealed small bowel obstruction, with marked small bowel air-fluid levels (Figure 1). Abdominal ultrasound revealed a hypoechoic, round, soft tissue mass measuring 35 mm × 38 mm at the end of a dilated, thick-walled ileal loop at the right iliac fossa. The clinical symptoms and ultrasonographic images were consistent with intussusception or mechanical intestinal obstruction caused by a tumoral mass. Thus, laparotomy with midline incision was performed. On exploration, an ileoileal intussusception was found 50 cm proximal to the ileocecal valve. The intussuscepted intestinal segments were obstructing the lumen, causing dilatation in the intestine proximal to the intussusception (Figure 2). Segmental resection of the intussuscepted ileum and end-to-end anastomosis were performed. Macroscopically, the resected segment of the ileum was 20 cm in length. Histopathological examination showed an IFP measuring 4 cm × 4 cm, composed of an edematous stroma containing spindle-shaped stromal cells, lymphoid nodules and eosinophils. On immunohistochemical analysis, the

Figure 1 Upright plain abdominal radiography revealed small bowel obstruction with marked small bowel air-fluid levels.

Figure 2 Intraoperative photograph of ileoileal intussusception.

spindle cells were negative for CD117, smooth muscle actin, desmin, S100 protein and CD34. A diagnosis of IFP (Vanek's polyp) of the ileum was made. The patient recovered without complications and has remained well and symptom-free until at least 6 mo after discharge.

Literature review

The English-language medical literature published between 1976 and November 2011 was searched using PubMed and Google Scholar. A total of 56 reports concerning 85 cases of intussusception due to IFP meeting the aforementioned criteria were included in this review. The patients were aged from 4 to 81 years (mean, 49 ± 16.2 years); 44 were women (mean, 51.8 ± 14.3 years) and 41 were men (mean, 46 ± 17.5 years). According to the localization of the IFP, 63 patients had ileal intussusception, while 17 had jejunal, three had colonic, and two had ileojejunal intussusception. The clinicopathological characteristics of the 85 patients are summarized in Table 1.

DISCUSSION

Intussusception was first described by Barbette in 1674 and later by Hunter in 1789. Sir Jonathan Hutchinson was the first surgeon who operated on intussusception in a child in 1871[2,5,6,17,21]. Intussusception, defined as invagination of a proximal part of small bowel along with its mesentery into an adjacent segment, can lead to impaired peristalsis, obstruction, and possible vascular compromise[3,6,11,15,17]. The precise mechanism of intestinal intussusception remains unclear. However, it is believed that any lesion in the bowel wall or irritant within the lumen that alters normal peristaltic activity, forming leading edges for the intussusceptum, may initiate invagination. Ingested food and subsequent peristaltic activity of the bowel produces an area of constriction above the stimulus and relaxation below, thus telescoping the lead point through the distal bowel lumen[3-5].

Intussusceptions have been classified according to location into three major categories, i.e., enteroenteric, ileocolic or ileocecal, and colocolic. Enteroenteric intussusception is confined to the small bowel. In ileocolic intussusception, the ileum invaginates through the ileocecal valve. Colocolic intussusception is confined to the colon[1,5]. Adult intussusception occurs more frequently in the small bowel (50%-88%) than in the large bowel (12%-50%)[1].

Intussusception can be classified according to the underlying etiological factors as primary (idiopathic) or secondary (benign or malignant lesion). Primary or idiopathic adult intussusception accounts for about 10% of cases and is more likely to occur in the small intestine. Secondary intussusception, which is more common in the adult population, is associated with a pathological condition involving a lead point. The etiologies of intussusception in the small bowel and the colon are quite different. In the small intestine there is a predominance of benign processes, with up to 90% of cases, including hamartomas, lipomas, leiomyoma neurofibromas, adenomas, Peutz-Jeghers syndrome, IFP, adhesions, Meckel's diverticulum, lymphoid hyperplasia, trauma, celiac disease, intestinal duplication, Henoch-Schönlein purpura, appendiceal stump, and tuberculosis. Malignant lesions (either primary or metastatic) account for 14%-47% of cases of intussusception in the small intestine. On the other hand, intussusception occurring in the large bowel is more likely to have a malignant etiology and accounts for 43%-80% of cases[4,8,12,21]. Colon adenocarcinoma is the most important cause of malignant large bowel intussusception. Benign lesions provoking large bowel intussusception include lipomas, leiomyomas, adenomatous polyps and endometriosis. We reviewed the published literature regarding intussusception, and the underlying cause in most cases of enteroenteric intussusception was benign, whereas it was mostly malignant in the ileocolic and colocolic cases. That is, the potential for malignancy increased from proximal to distal intussusception. Thus, the most important factors in the surgical decision process in an adult patient without a histopathological diagnosis in the preoperative period and intussusception was detected during a surgical operation are the location and size of the mass and viability of the invaginated segment. Benign tumors, often lipomas, are the most common specific causes of adult intussusception. IFPs have been reported as a rare cause of adult intussusception[22,23]. As the main topic of this report is intussusception due to IFPs, a discussion of the general features of gastrointestinal IFPs is presented below.

IFPs are rare, idiopathic pseudotumorous lesions of the gastrointestinal tract, which were first described by Vanek in 1949 as an eosinophilic submucosal granuloma. In that first report of six gastric lesions, Vanek called attention to the inflammatory nature of the lesions and their submucosal origin[24-28]. Various names for IFPs have been suggested, including eosinophilic granuloma, submucosal fibroma, hemangiopericytoma, inflammatory pseudotumor and fibroma. However, the term IFP first proposed by Helwig and Ranier in 1953 for gastric polyps has gained acceptance for similar lesions throughout the gastrointestinal tract[15,16,26,29,30].

IFPs can develop in many different locations in the gastrointestinal tract. The most common site is the gastric antrum (66%-75%), followed by the small bowel (18%-20%), colorectal region (4%-7%), gallbladder (1%), esophagus (1%), duodenum (1%), and appendix (< 1%)[18,21,26,31,32]. However, the ileal segment is the most common site where these polyps cause intussusception[21].

The precise etiopathogenesis of IFPs remains unknown, but trauma, allergic reaction, genetic tendency, bacterial, physical, chemical and even metabolic stimuli have been suggested as initiators of the process. The more common occurrence of these lesions in the stomach, with its coarse food content and active muscular contractions, supports a traumatic etiology, but it is dif-

ficult to account for lesions in the lower ileum on this basis[33-39].

IFPs are usually asymptomatic, and are typically identified during endoscopic procedures and laparotomy. When they are symptomatic, the clinical symptoms depend on the location and size of the tumor[9,27,40-42]. Abdominal pain is the main symptom in patients with lesions in the stomach. Intussusception and obstruction are the most frequent initial symptoms when the polyp is located in the small intestine[10,26-28,40,43,44]. Other gastrointestinal symptoms, such as vomiting, diarrhea, bloody stools, tenesmus, and alterations in bowel habits, are also seen although their frequencies are low[30]. At the time of diagnosis, most IFPs usually measure between 2 and 5 cm in diameter. However, giant IFPs up to 20 cm in diameter have also been reported[9,10,15-17,26,27,33]. IFPs usually present in the sixth or seventh decade, but cases have been reported over a wide age range from 5 mo to 92 years old[35-38,45-47]. There is a slight predominance of the condition in men. Macroscopically, these tumors are pedunculated or sessile, measure 0.2-20 cm in diameter, arise from the submucosa, and project into the bowel lumen. The mucosal surface is usually ulcerated and pale. Microscopically, it is composed of mononuclear, spindle-shaped cells, forming a confused or whirl-like structure. The inflammatory infiltration also includes blood vessels, eosinophils, lymphocytes, macrophages, and mastocytes[10,14,18,19,25-27].

IFPs can mimic several other tumor and non-tumor processes of the gastrointestinal tract. Differential histopathological diagnoses include spindle cell lesions, such as inflammatory fibrosarcoma, spindle-cell carcinoids, and gastrointestinal stromal tumors (GISTs). Differentiation can be difficult, especially between IFPs and GISTs[10,15-17,22,26,48]. GISTs are common in the stomach and frequently present as polypoid masses. In the intestine, these tumors can present with intussusception similar to IFP. Immunohistochemistry is used to distinguish between IFPs and GISTs. Both tumors are positive for CD34 and vimentin, but GISTs are positive for CD117, while IFPs are not[13,24,26,49].

The preoperative diagnosis of intussusception is controversial. An accurate diagnosis is based on a good medical history, thorough physical examination, and specific imaging modalities, such as X-ray, ultrasonography (US), computed tomography (CT), magnetic resonance imaging (MRI), enteroclysis, endoscopic procedures, angiography, and capsule endoscopy[6,50-55]. Typically, abdominal X-ray examination is the first diagnostic tool used, because obstructive symptoms dominate the clinical picture in most cases[56-60]. Barium enema was the gold standard for diagnosis of intussusception until the mid-1980s when studies established that US could be used to diagnose the condition accurately. Around the same time, it was found that air could be used to diagnose and treat intussusception[5,61,62]. Today, enteroclysis is rarely used in the diagnosis of intussusception. This invasive double-contrast imaging method requires intubation using a special catheter with a double lumen and balloon to the proximal jejunum and is performed under fluoroscopy, MRI, or CT imaging. Although enteroclysis shows not only the inside of the lumen but also has high sensitivity and specificity for revealing small and mucosal lesions, its invasive nature limits its use[40]. Colonoscopy is useful only in cases in which colonic involvement is strongly suspected, and it allows the lesion to be diagnosed and biopsied. On colonoscopy, intussusception is seen as an intraluminal mass directed centrally and distally. However, diagnosis is rarely made by colonoscopy, and the diagnosis is usually made during surgery[4,48].

Capsule endoscopy and digital balloon endoscopy are newer means of diagnosing various gastrointestinal disorders[4,7]. Capsule endoscopy is a non invasive diagnostic test used to locate the source of gastrointestinal bleed-

ing and to identify the causes of other intestinal disorders, including intussusception and various tumors. On capsule endoscopy, intussusception has been reported to appear as mass lesion of the small bowel. Although obstructive symptoms are contraindicated for capsule endoscopy, this new method for evaluating the small bowel could be helpful in cases with long-standing abdominal pain and negative results on radiological examination, CT, or barium studies, to exclude the possibility of malignancy. Double-balloon enteroscopy, also known as "push-and-pull" enteroscopy, can be used to examine approximately 70-150 cm of the small bowel, and double balloon enteroscopy can examine the full length of the small bowel, both antegrade and retrograde[7,44]. Diagnostic laparoscopy (DL) may assist in the diagnosis of intussusception in cases in which the diagnosis is suspected but not confirmed by preoperative workup. Moreover, DL can help to establish the cause and is less traumatic than an exploratory laparotomy. US is considered a useful tool in the diagnosis of intussusception in both pediatric and adult cases[5-7,15,46]. Its classical imaging features include the target or doughnut sign in the transverse view and the pseudokidney, sandwich, or hayfork sign in longitudinal view[4,5,7,40]. However, obesity and the presence of a large amount of air in the distended bowel loops can limit image quality and subsequent diagnostic accuracy. Overall, US has a sensitivity of 98%-100% and a specificity of 88%-89% for diagnosing intussusception[3,17,29,40]. Abdominal CT is currently considered the most sensitive radiological method for confirming intussusception, with a reported diagnostic accuracy of 58%-100%[1-3,5,7,21]. On CT, a bowel-within-bowel configuration suggested by mesenteric fat and vessels compressed between the walls of the small bowel is pathognomonic of intussusception[3-6]. In contrast to US, CT is unaffected by the presence of gas in the bowel lumen. Therefore, we suggest that all patients presenting with an intestinal obstruction should undergo a CT scan as a routine diagnostic measure[3]. MRI is not applied routinely in diagnosis of intussusception in either children or adults. However, MRI can contribute to the radiological diagnosis of intussusception by demonstrating the "bowel-within-bowel" or "coiled-spring" appearance. This pattern can be seen more clearly with the use of the recently developed half-Fourier acquisition single-shot turbo spin-echo MRI modality. A polyp can be detected as a leading point using a combination of breathing-independent T2-weighted MRI and gadolinium-enhanced breath-hold T1-weighted imaging[4,23,30,34,40].

The appropriate management of adult intussusception remains controversial, with the debate focusing mostly on the issue of primary *en bloc* resection *vs* initial reduction followed by more limited resection. Reduction by surgery before resection may theoretically permit more limited resection; however, the risk of potential intraluminal seeding or venous tumor dissemination during the manipulation of a malignant lesion should also be taken into consideration. The incidence of malignancy as the cause of small intestinal intussusception ranges from 1% to 47%, and the majority of lesions are metastatic. Therefore, recent reports have recommended initial reduction of externally viable small bowel prior to resection. The likelihood of cancer in ileocolic and colocolic intussusception is 43%-100%. The vast majority of these lesions arise as a primary lesion, in which resection without reduction is recommended[1,2,4,5,48].

COMMENTS

Background

Intussusception occurs when a more proximal portion of the bowel invaginates into the more distal bowel. The pathomechanism is thought to involve altered bowel peristalsis at the intraluminal lesion, which is then a lead point for the intussusceptum. Inflammatory fibroid polyp (IFP) is a rare benign cause of intussusception.

Research frontiers

IFP is a benign gastrointestinal tumor that appears grossly as a localized, submucosal, sessile polypoid mass, occasionally involving the entire thickness of the gastrointestinal tract wall. In this study, the author performed an overall evaluation of the literature published in English language regarding the management approaches and diagnostic process in cases of intussusception related to IFPs and presented his own experience.

Innovations and breakthroughs

This study is the largest literature screening on intussusception due to IFPs.

Applications

This literature review demonstrates the importance of radiological assessment, surgical experience, and immunhistochemical staining in the differential diagnosis of IFPs.

Terminology

Intussusception is defined as invagination of a proximal part of the small bowel along with its mesentery into an adjacent segment; IFPs are rare, idiopathic pseudo tumorous lesions of the gastrointestinal tract, which were first described by Vanek in 1949 as an eosinophilic submucosal granuloma.

Peer review

The authors have prepared a literature review of 56 papers about IFP and intussusception published between 1976 and 2011 with a case that was treated in their clinic. Looking to the study in general, it seems simple and informative.

Abstract

AIM: To determine the usefulness of arrival time parametric imaging (AtPI) using contrast-enhanced ultrasonography (CEUS) with Sonazoid in evaluating early response to sorafenib for hepatocellular carcinoma (HCC).

METHODS: Fourteen advanced HCC patients who received sorafenib 400/800 mg/d for at least 4 wk and were followed up by CEUS were enrolled in this study. CEUS was performed before treatment and 2 and 4 wk after treatment, and images of the target lesion in the arterial phase were recorded for each patient. The images were analyzed by AtPI. Color mapping (CM) images obtained by AtPI were compared before and after the treatment. In these CM images, the mean arrival time of the contrast agent in the region of interest from the starting point [mean time (MT)] was calculated. In each patient, differences between MT before and MT 2 and 4 wk after the treatment were compared with responses evaluated 4-8 wk after the treatment by dynamic computed tomography (CT), and statistical analysis was performed. Modified response evaluation criteria in solid tumors was used for the response evaluation.

RESULTS: In CM images both 2 and 4 wk after the treatment, delays in the arrival time of the contrast agent were noted in 8 of the 14 patients. In the other 6 patients, no color changes were observed in the tumor, or red and/or yellow increase, suggesting a decrease in blood flow velocity between images 2 and 4 wk after the treatment and those before the treatment. Dynamic CT could be performed 4-8 wk after the treatment in 13 of the 14 patients. Median differences in the MT were 1.13 s and 1.015 s, 2 and 4 wk after the treatment, respectively, in the 8 patients who showed stable disease (SD)/partial response (PR) on dynamic CT. Median differences in the MT were -0.39 s and -0.95 s, 2 and 4 wk after the treatment, respectively, in the 5 patients who showed progressive disease (PD). Differences in the median MT between SD/PR and PD groups were significant 2 and 4 wk after the treatment with $P = 0.019$ and $P = 0.028$, respectively.

CONCLUSION: AtPI by CEUS using Sonazoid is suggested to be useful for evaluating early responses to sorafenib.

INTRODUCTION

We previously evaluated the hemodynamics of hepatocellular carcinoma (HCC) and metastatic liver tumors based on the time intensity curve (TIC)[1] and arrival time parametric imaging (AtPI)[2,3] employing contrast-enhanced ultrasonography (CEUS) using Sonazoid (Daiichi Sankyo, Tokyo, Japan). As a result, CEUS using Sonazoid has been suggested to allow continuous observation of hemodynamics and is applicable to evaluate the hemodynamics of HCC and the effects of therapeutics on metastatic liver tumors[1,2]. Recently, molecular biological characteristics related to the progression and proliferation of HCC have been clarified, accelerating the development of various molecular-targeting agents[4-6]. Sorafenib[7-9] (Bayer, Leverkusen, Germany) is a multikinase inhibitor that targets multiple molecules, and was approved for use in the treatment of unresectable advanced HCC in Japan in May, 2009. Since it targets tumor growth (RAF-MEK-ERK) and angiogenesis (vascular endothelial growth factor receptor and platelet-derived growth factor receptor) signal transduction pathways, it is expected to be useful for the treatment of HCC[10-14].

The evaluation of chemotherapeutic agents that exert their cytotoxic effects against advanced HCC by inhibiting nucleic acid metabolism has been conducted mainly based upon the tumor volume-reducing effect, according to the response evaluation criteria in solid tumor (RECIST)[15]. The tumor volume-reducing effect of molecular-targeting agents such as sorafenib appears to be slow, although the survival period is considered to be prolonged, even with only a minor volume-reducing effect. Indeed, in the Sorafenib HCC Assessment Randomized Protocol trial in advanced HCC, while the response rate based upon RECIST was only 2%, the survival period in the sorafenib group was significantly longer than in the placebo group, demonstrating its clinical efficacy[10]. Therefore, evaluation of the antineoplastic effect of sorafenib, which exhibits an antitumor effect primarily by inhibiting angiogenesis, is difficult by conventional criteria, and the evaluation of hemodynamics is expected to become important in the assessment of its efficacy[16]. Recently, the modified RECIST (mRECIST)[17] and Choi criteria[18] have been recommended for the evaluation of therapeutic effects[19]. Also, in consideration of the serious complications of sorafenib reported to date[10], and moreover the fact that sorafenib is an expensive drug, early evaluation of its therapeutic effects is considered to be necessary to assess whether the treatment should be continued.

In this study, we performed image analysis by AtPI using CEUS with Sonazoid before and after the sorafenib administration and evaluated the usefulness of AtPI in evaluating early responses to sorafenib.

MATERIALS AND METHODS

Of the 45 patients with advanced HCC in whom treatment with sorafenib was initiated at our hospital between June 2009 and October 2011, 14 who consented to the study and were orally treated with sorafenib for at least 4 wk, and who could be followed up by CEUS, were selected as subjects. All patients were males with a mean age of 70.4 years (62-82 years). Underlying liver disease was hepatitis C in 8, alcoholic hepatitis in 4, and others in 2. Child-Pugh liver function class was A in all subjects, median alpha-fetoprotein level before administration was 150.9 ng/mL (7.1-22 516 ng/mL), and median protein induced by vitamin K absence-Ⅱ level was 1781 mAU/mL (12-259 000 mAU/mL). The initial dose of sorafenib was 800 mg/d for 5 patients and 400 mg/d for 9 patients.

Methods

CEUS was performed before and 2 and 4 wk after the sorafenib administration. One lesion or portal vein tumor thrombus (PVTT) that could be followed for a period was selected on employing ultrasonography in each patient to standardize evaluations, and CEUS was performed in the same cross-section and under the same conditions at all time points. The ultrasound equipment used in this examination was SSA-790A (Toshiba Medical Systems, Tokyo, Japan) with a convex probe (PVT-375BT, 3.75-MHz center frequency). The imaging mode used was wideband harmonic imaging (pulse subtraction) with transmission/reception frequencies of 1.8 and 3.5 MHz, respectively. The mechanical index for acoustic output was set to 0.2; the dynamic range was set to 60-65 dB. A single focus point was set at the deep site of the lesion, and a bolus intravenous injection of Sonazoid (0.5 mL) was administered *via* a left cubital venous line followed by 10 mL normal saline flush. After injection of Sonazoid, the patients were asked to hold their breaths. The arterial phase (0-40 s) was observed and video images were recorded and analyzed by an off-line procedure using AtPI.

AtPI was performed using image analysis software for Aplio/Xario on the basis of the report by Watanabe *et al*[2]. It was performed by determining a starting point at an appropriate site such as an intrahepatic artery and a tumor vessel, regarding the time when the contrast agent reached this site as the zero point, measuring the difference in the arrival time between the target and starting points throughout the entire diagnostic image, and coloring the time differences [color mapping (CM)]. In this study, the moment of arrival of the contrast agent at a

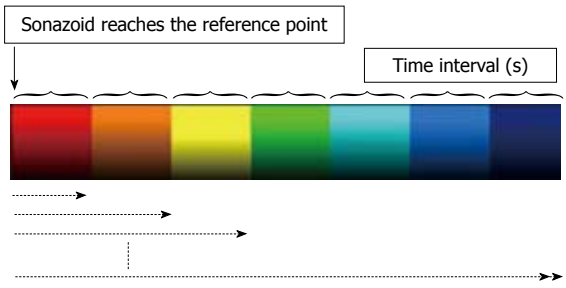

Figure 1 Delays in the arrival of the contrast agent at the target site compared with that at the reference point (0 s) are represented by red, orange, yellow, green, light blue, blue and dark blue at 0.5 s intervals.

large artery near the tumor or PVTT was regarded as starting point.

Qualitative analysis: Delays in the arrival of the contrast agent at the target site compared with that at the reference point (0 s) were represented by red→orange →yellow→green→light blue→blue→dark blue at 0.5 s intervals (Figure 1). CM images obtained were grossly compared in each patient before and after the treatment.

Quantitative analysis: In prepared CM images, a maximum region of interest (ROI) was determined for each subject, and the mean arrival time of the contrast agent in the ROI from the starting point [mean time (MT)] was calculated. In each patient, differences in the MT 2 and 4 wk after the initiation of the treatment compared with the MT before treatment were determined. Blood flow velocity was judged to have been reduced when the difference was zero or greater [MT (+) group] and to have been increased when the difference was less than zero [MT (-) group]. Differences in the MT 2 and 4 wk after the treatment were compared with responses evaluated 4-8 wk after the treatment by dynamic computed tomography (CT), and statistical analysis was performed. mRECIST[7] was used for the response evaluation. The Mann-Whitney test was performed for statistical analyses at the $P < 0.05$ level of significance. This study was approved by the Ethical Review Board of Toho University Medical Center, Omori Hospital.

RESULTS

In 14 patients, the mean duration of sorafenib administration was 177 d, and the mean daily dose was 542.9 mg/d.

Qualitative analysis

In CM images 2 wk after the treatment, color in the tumor changed to primarily blue or dark blue from primarily red or yellow before the treatment in 8 of the 14 patients, and time-dependent changes (delays in the arrival time of the contrast agent) were noted. These 8 patients also showed similar changes in CM images 4 wk after the treatment (Figure 2). In the other 6 patients, no color changes were observed in the tumor, or red and/or yellow increases, between images 2 wk after the treatment and those before the treatment. These 6 patients also showed similar CM images 4 wk after the treatment.

Quantitative analysis

The MT was (+) in 8 patients but (-) in 6 two weeks after the treatment, and mean differences in MT were 1.21 ± 0.75 s and -0.85 ± 0.78 s, respectively. Four weeks after the treatment, the MT was (+) in 7 and (-) in 7, and the mean difference in MT was 1.18 ± 0.4 s and -1.11 ± 0.62 s, respectively. The MT was (+) but changed to (-) from 2 to 4 wk after the treatment in 1 of the 8 patients in whom CM images showed gross delays in the arrival time of the contrast agent in the tumor 2 and 4 wk after the treatment.

Dynamic CT could be performed 4-8 wk after the treatment in 13 of the 14 patients. Median differences in the MT were 1.13 s and 1.015 s, 2 and 4 wk after the treatment, respectively, in the 8 patients who showed stable disease (SD)/partial response (PR) on dynamic CT. Median differences in the MT were -0.39 s and -0.95 s, 2 and 4 wk after the treatment, respectively, in the 5 patients who showed progressive disease (PD). Differences in the median MT between SD/PR and PD groups were significant 2 and 4 wk after the treatment with $P = 0.019$ and $P = 0.028$, respectively (Figure 3). The finding on dynamic CT after treatment was SD in the above patient in whom the MT changed from (+) to (-) 4 wk after the treatment.

DISCUSSION

Some studies have evaluated the responses of gastrointestinal stromal tumor (GIST) and metastatic lesions of renal cell carcinoma to molecular-targeted agents by CEUS using Levovist (Schering, Berlin, Germany) and SonoVue (Bracco, Milan, Italy)[20-24]. Lassau *et al*[20] evaluated the responses of GIST to imatinib by CEUS using Levovist and SonoVue, and suggested that CEUS was useful for detailed evaluation early after the treatment, and that decreases in tumor staining early after the treatment were related to progression-free survival (PFS) and may serve as a response-predicting factor. Lamuraglia *et al*[21] also evaluated the efficacy of sorafenib against liver metastases of renal cell carcinoma by CEUS using SonoVue, and suggested that PFS or overall survival (OS) may be prolonged by the suppression of vascularization.

In this study, we evaluated the early responses of advanced HCC to sorafenib by AtPI using CEUS with Sonazoid. Differences in the arrival time of the contrast agent between a large artery near the target lesion and ROI were evaluated according to CM images or the MT. Evaluations of differences in the arrival time are considered equivalent to evaluations of blood flow velocity to the tumor or inflow volume of blood flow in the tumor.

In this study, a delay in the arrival time of the contrast agent, i.e., a decrease in blood flow velocity, could be detected visually and readily in CM images as early as 2 wk after the treatment in 8 of the 14 patients. A decrease in blood flow velocity could also be confirmed

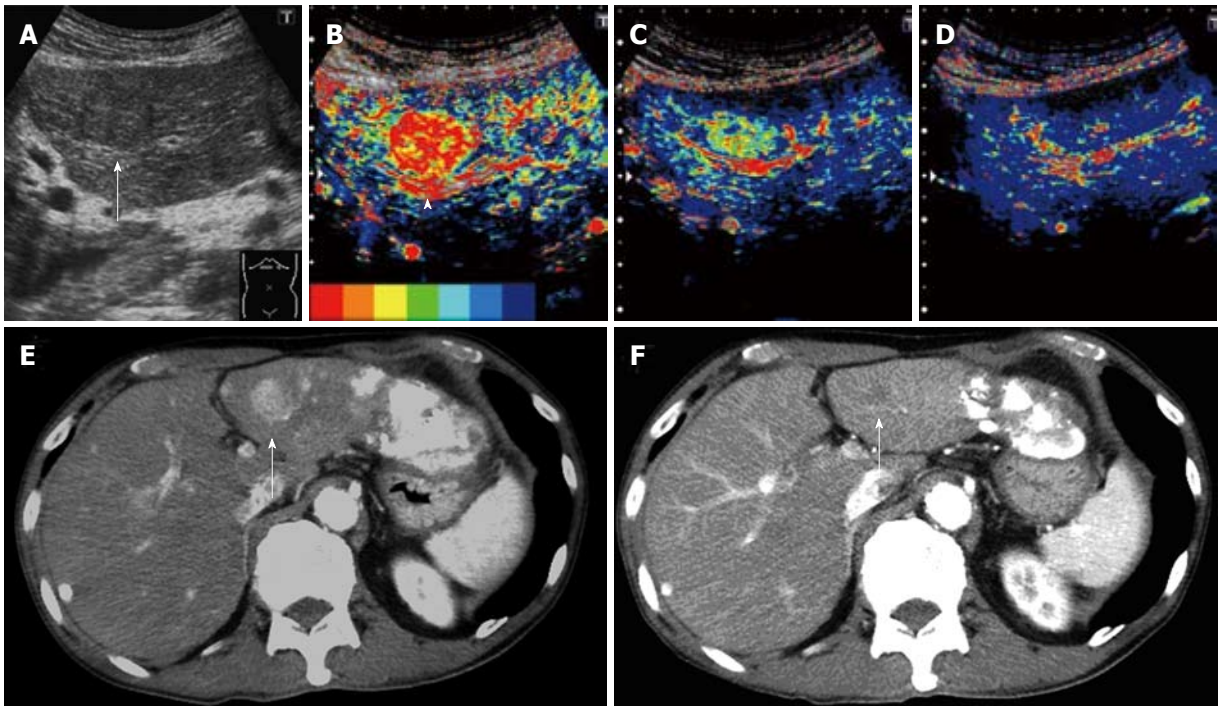

Figure 2 Clinical example of good responder patient. A 74-year-old man with a history of hepatitis C virus cirrhosis underwent transcatheter arterial chemoembolization (TACE) for advanced hepatocellular carcinoma three times, after which sorafenib administration (400 mg/d) was started for this patient because the tumor was TACE-refractory. A: Gray-scale ultrasonography showed a mosaic-pattern tumor sized 20 mm in diameter in S3 (arrow). This tumor was established as a target lesion; B: A large artery near this tumor was regarded as starting point (arrow head). The color mapping (CM) image before the treatment showed primarily red or orange in the tumor; C: The CM image 2 wk after the treatment showed primarily green in the tumor; D: The CM image 4 wk after the treatment showed primarily dark blue in the tumor, the same as the surrounding parenchyma; E: Dynamic computed tomography (CT) scan in arterial phase before the treatment showed a hypervascular lesion in S3 (arrow) which was the target lesion and accumulation of iodized oil in the left lobe and S7; F: Dynamic CT scan in arterial phase 4 wk after the treatment showed a hypovascular lesion in S3 (arrow) and this lesion reduced. This therapeutic response was described as a partial response.

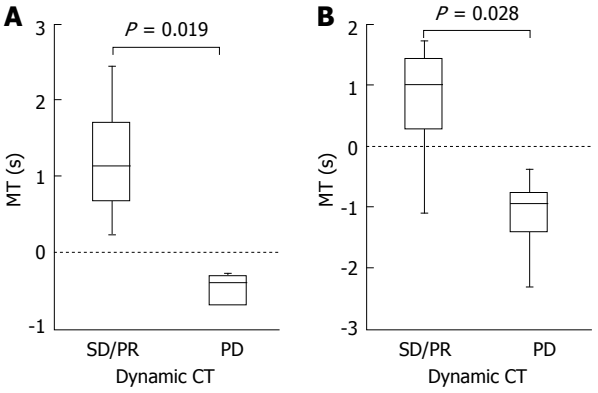

Figure 3 Comparisons between the mean time and therapeutic effects according to modified response evaluation criteria in solid tumors evaluated by dynamic computed tomography. A: Median difference in the mean time (MT) was 1.13 s, 2 wk after the treatment in the 8 patients who showed stable disease (SD)/partial response (PR) on dynamic computed tomography (CT). Median difference in the MT was -0.39 s, 2 wk after the treatment in the 5 patients who showed progressive disease (PD); B: Median difference in the MT was 1.015 s, 4 wk after the treatment, in the 8 patients who showed SD/PR on dynamic CT. Median difference in the MT was -0.95 s 4 wk after the treatment in the 5 patients who showed PD. Differences in the median MT between SD/PR and PD groups were significant 2 and 4 wk after the treatment with $P = 0.019$ and $P = 0.028$, respectively.

after 4 wk. However, as changes in blood flow in the tumor due to sorafenib administration were uneven, we set a ROI in the target HCC, calculated the mean arrival time of the contrast agent into the ROI, i.e., MT, and evaluated differences in the MT before and after the treatment as an objective method, not dependent on vision. In the 8 patients in whom delays in the arrival time of the contrast agent could be confirmed visually in CM images both 2 and 4 wk after the treatment, the MT was (+) in all 8 after 2 wk and in 7 after 4 wk. This suggests the possibility of quantification and objective evaluation of changes in blood flow velocity in the tumor visually detected in CM images. Comparisons between the MT and therapeutic effects according to mRECIST evaluated by dynamic CT showed significant differences in the MT between SD/PR and PD groups both 2 and 4 wk after the treatment, indicating general agreement between these parameters. The results of this study suggest that a delay in the arrival time of the contrast agent visually detected in CM images, i.e., a change of CM images, reflect the response and that changes in hemodynamics visually represented in CM images may be quantified and objectively evaluated using the MT.

Responses of HCC have been evaluated primarily using dynamic CT and magnetic resonance imaging as well as CEUS, but it has often been difficult to repeat the examination frequently during the course due to exposure, iodine allergies, and renal dysfunction. On the other hand, Sonazoid is effective at a low dose, causes few adverse reactions, and can be used safely even in patients with iodine allergies or renal dysfunction, with the

exception of those with egg shell allergies. Since changes in CM images were noted in this study, and the MT showed differences from values before the treatment by 2 wk after the treatment, AtPI using CEUS with Sonazoid may be useful for the early evaluation of responses to sorafenib.

Lassau *et al*[22] reported that evaluation of the time to peak intensity and slope of the wash-in obtained by TIC using CEUS with SonoVue was useful for the predication of early responses of metastatic lesions of renal cell carcinoma to molecular-targeted agents. These techniques including AtPI reflect tumor hemodynamics, and their relative usefulness is impossible to discuss, but AtPI may be equally predictive of responses compared to the TIC.

This study raises the following questions: (1) Since tumors have a three-dimensional structure, can they be evaluated accurately by examination of a single cross-sectional ultrasonography image? (2) Since HCC shows multicentric carcinogenesis[25,26] and intrahepatic metastasis, the degree of differentiation may vary among lesions of multiple HCC. Therefore, is it possible to apply the findings in a single target lesion uniformly to all other lesions? (3) Visual evaluation of CM images obtained 4 wk after the treatment disagreed with the MT value in 1 patient. While CM images were found to be useful for simple comparison between conditions before and after the treatment, measurement of the MT is still a complex process, and further improvements are considered necessary in the method to determine the ROI and other aspects; and (4) Do the results obtained by this study, i.e., the MT calculated by AtPI, contribute to improvements in the OS? These problems are considered to need careful evaluation by further accumulation of cases.

In conclusion, AtPI by CEUS using Sonazoid is suggested to be useful for evaluating early responses to sorafenib. Changes in hemodynamics in advanced HCC over the course of its treatment could be visually represented in a single static CM image obtained by AtPI. By further quantification, hemodynamic changes over the course of treatment could be evaluated more objectively. Since the number of patients in this study was small, and the observation period was short, the usefulness of the procedure in evaluating the time to progression or OS cannot be discussed, but evaluation of tumor hemodynamics using AtPI is considered to contribute to the prediction of responses early after treatment.

COMMENTS

Background

Recently, molecular biological characteristics related to the progression and proliferation of hepatocellular carcinoma (HCC) have been clarified, accelerating the development of various molecular-targeted agents. Since sorafenib is a multikinase inhibitor and it targets tumor growth and angiogenesis signal transduction pathways, it is expected to be useful for the treatment of HCC.

Research frontiers

Therapeutic efficacy has been assessed by Response Evaluation Criteria in Solid Tumor using dynamic computed tomography (CT) and overall survival in previous studies. Since sorafenib produces an antitumor effect primarily by inhibiting angiogenesis, evaluation of its antineoplastic effect is difficult by conventional criteria, and evaluating hemodynamics is expected to become important for its efficacy evaluation. In this study, the authors verified that arrival time parametric imaging (AtPI) by contrast-enhanced ultrasonography (CEUS) using Sonazoid is useful for evaluating early responses to sorafenib.

Innovations and breakthroughs

Dynamic CT and magnetic resonance imaging are generally used to evaluate the antineoplastic effect, but tumor hemodynamics are difficult to evaluate by these methods. AtPI by CEUS can evaluate the changes of hemodynamics in HCC over a course of treatment visually and objectively.

Applications

AtPI by CEUS using Sonazoid is suggested to be useful for evaluating early responses to sorafenib. This was a pilot study with a small series of patients. Similar studies with much larger numbers of patients are awaited.

Terminology

Ultrasound contrast agents consist of microbubbles that visualize the hemodynamics. AtPI is a method using CEUS, which utilizes the arrival time of each pixel in the diagnostic image.

Peer review

This is an interesting manuscript on a small series of patients followed with CEUS under treatment with sorafenib. As a pilot, it provides an interesting hypothesis to be tested in a larger series of patients. It is well conducted and also well presented.

Abstract

AIM: To assess the nourishment status and lifestyle of non-hospitalized patients with compensated cirrhosis by using noninvasive methods.

METHODS: The subjects for this study consisted of 27 healthy volunteers, 59 patients with chronic viral hepatitis, and 74 patients with viral cirrhosis, from urban areas. We assessed the biochemical blood tests, anthropometric parameters, diet, lifestyle and physical activity of the patients. A homeostasis model assessment-insulin resistance (HOMA-IR) value of $\geqslant$ 2.5 was considered to indicate insulin resistance. We measured height, weight, waist circumference, arm circumference, triceps skin-fold thickness, and handgrip strength, and calculated body mass index, arm muscle circumference (AMC), and arm muscle area (AMA). We interviewed the subjects about their dietary habits and lifestyle using health assessment computer software. We surveyed daily physical activity using a pedometer. Univariate and multivariate logistic regression modeling were used to identify the relevant factors for insulin resistance.

RESULTS: The rate of patients with HOMA-IR $\geqslant$ 2.5 (which was considered to indicate insulin resistance) was 14 (35.9%) in the chronic hepatitis and 17 (37.8%) in the cirrhotic patients. AMC (%) (control *vs* chronic hepatitis, 111.9% ± 10.5% *vs* 104.9% ± 10.7%, P = 0.021; control *vs* cirrhosis, 111.9% ± 10.5% *vs* 102.7% ± 10.8%, P = 0.001) and AMA (%) (control *vs* chronic hepatitis, 128.2% ± 25.1% *vs* 112.2% ± 22.9%, P = 0.013; control *vs* cirrhosis, 128.2% ± 25.1% *vs* 107.5% ± 22.5%, P = 0.001) in patients with chronic hepatitis and liver cirrhosis were significantly lower than in the control subjects. Handgrip strength (%) in the cirrhosis group was significantly lower than in the controls (control *vs* cirrhosis, 92.1% ± 16.2% *vs* 66.9% ± 17.6%, P < 0.001). The results might reflect a decrease in muscle mass. The total nutrition intake and amounts of carbohydrates, protein and fat were not significantly different amongst the groups. Physical activity levels (kcal/d) (control *vs* cirrhosis, 210 ± 113 kcal/d *vs* 125 ± 74 kcal/d, P = 0.001), number of steps (step/d) (control *vs* cirrhosis, 8070 ±

3027 step/d *vs* 5789 ± 3368 step/d, P = 0.011), and exercise (Ex) (Ex/wk) (control *vs* cirrhosis, 12.4 ± 9.3 Ex/wk *vs* 7.0 ± 7.7 Ex/wk, P = 0.013) in the cirrhosis group was significantly lower than the control group. The results indicate that the physical activity level of the chronic hepatitis and cirrhosis groups were low. Univariate and multivariate logistic regression modeling suggested that Ex was associated with insulin resistance (odds ratio, 6.809; 95% CI, 1.288-36.001; P = 0.024). The results seem to point towards decreased physical activity being a relevant factor for insulin resistance.

CONCLUSION: Non-hospitalized cirrhotic patients may need to maintain an adequate dietary intake and receive lifestyle guidance to increase their physical activity levels.

INTRODUCTION

Chronic infection with hepatitis virus is one of the most common causes of liver cirrhosis worldwide. About 3.5 million people worldwide are chronically infected with hepatitis B virus (HBV). More than 70% of all newly diagnosed liver cancer patients are found in Asia, a region accounting for 75% of all patients with chronic HBV infection[1]. Hepatitis C virus (HCV) has infected approximately 1.3 million people worldwide. In the Asia-Pacific region, the prevalence of HCV infection ranges from 0.3% to 12%, with geographical variation[2]. The major cause of liver cirrhosis in Japan is the hepatitis virus. In particular, chronic HCV infection accounts for 60.9% of all liver cirrhosis cases[3].

Cirrhosis is an end-stage chronic liver disease, and the damage to the hepatocytes decreases the function of the liver, leading to a variety of nutritional metabolic disorders. Therefore, protein energy malnutrition (PEM) is frequently seen in patients with cirrhosis[4-7]. A study of subjects with cirrhosis conducted in Western countries reported that 11% had energy malnutrition, 22% had protein malnutrition, 32% had both complications of PEM, and 35% had a normal nourishment status[8]. In 2002, a study of Japanese patients with cirrhosis reported that 12% had energy malnutrition, 25% had protein malnutrition, 50% had PEM, and only 13% had a normal nourishment status[9]. Currently, the lifestyles of people in urban areas of several Asian countries are changing due to westernization and motorization, resulting in excessive food intake, decreased intensity of daily activities, and a lack of exercise (Ex). These changes may lead to obesity, metabolic syndrome, and lifestyle diseases. Is there a possibility that this lifestyle transition (over-nourishment and decline in the intensity of daily activities) has an effect on the nutrition of cirrhosis? In 2006, a study reported that body mass index (BMI) in patients with cirrhosis was almost the same as those of the same age group in the normal Japanese population[10]. Moreover, both experimental and clinical studies found that over-nutrition, fatty liver, and glucose intolerance are significant risk factors of hepatic carcinogenesis[11,12]. The combination of over-nutrition and obesity in cirrhosis patients also indicates the possibility of an impaired pathogenesis. These findings suggest that high calorie and protein intake (i.e., old dietary interventions of cirrhosis) promotes obesity, fatty liver, and hepatic carcinogenesis. Almost all subjects in Japanese reports were hospitalized having decompensated cirrhosis with hepatic failure. Patients with severe decompensated cirrhosis tend to develop a reduced food and protein intake because of abdominal ascites and hepatic encephalopathy. However, the majority of cirrhotic patients have compensated cirrhosis and so do not need to be hospitalized, and thus their daily lives may be almost the same as that of healthy people. Few researchers have studied the effect of dietary habits and lifestyle in non-hospitalized cirrhotic patients on their conditions.

If we consider cirrhosis from the point of view of a lifestyle disease, we should know the patients' actual condition in order to provide adequate lifestyle and dietary guidance. The purpose of this study is to assess the nourishment status of non-hospitalized patients with compensated cirrhosis and to create a database on nutritional and lifestyle education for these patients by analyzing their lifestyle, food intake and physical activity.

MATERIALS AND METHODS

Subjects

We interviewed 155 patients (age range: 45-79 years) with chronic liver disease living in urban areas. Patients with chronic viral liver disease who regularly visited the Osaka City University Hospital between March 2009 and December 2010 were enrolled. Written consent was received from all study participants. After excluding patients with non-viral liver disease, abdominal ascites and hepatic encephalopathy, 133 patients were enrolled. Next, the

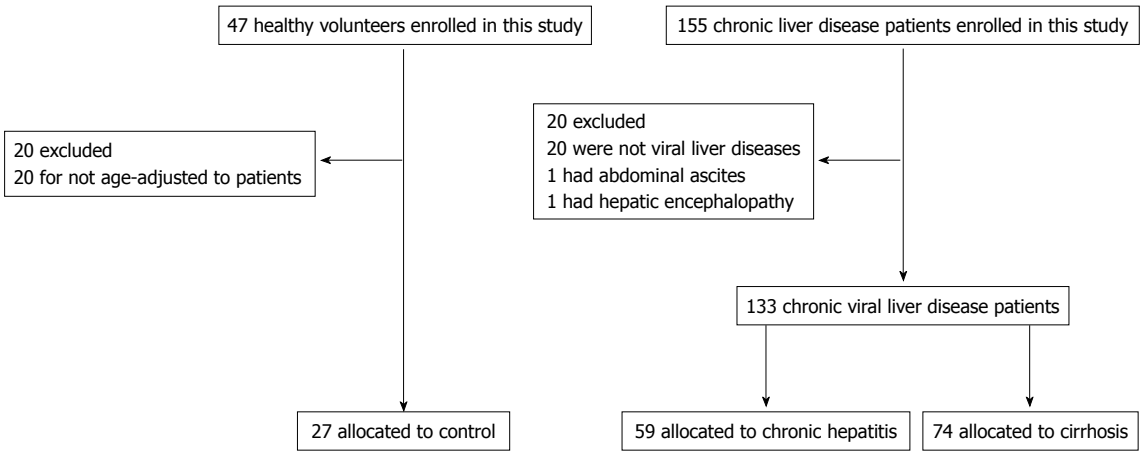

Figure 1 Flow chart of the participants in the study.

patients were divided into 2 groups of chronic hepatitis and cirrhosis on the basis of the clinical diagnosis made by the attending physicians. We enrolled 47 healthy volunteers from an urban area (local residents around the Osaka City University) who underwent a health check after providing their consent. The results were age-adjusted and, finally, data of 27 healthy volunteers were used for the comparison of the subjects (Figure 1). Complication of diabetes mellitus, hypertension, and hyperlipidemia were defined by taking medication for each disease. The degree of liver disease was assessed using the Child-Pugh classification. This trial was conducted in accordance with the guidelines of the World Medical Association's Declaration of Helsinki (1996) and was approved by the ethics committee of our institution (No. 1906).

Laboratory evaluation

Both chronic hepatitis and cirrhosis patients were examined, and we measured the number of white blood cells (WBC; × 100/μL), number of red blood cells (RBC; × 10^2/μL), hemoglobin (Hb; g/dL), hematocrit level (Ht; %), platelet count (Plt; × 10^2/μL), prothrombin time (PT; %); total protein (TP; g/dL), albumin (Alb; g/dL), blood urea nitrogen (mg/dL), creatinine (mg/dL), total bilirubin (T-bil; mg/dL), direct bilirubin (D-bil; mg/dL), aspartate aminotransferase (AST; IU/L), alanine aminotransferase (IU/L), leucine aminopeptidase (LAP; IU/L), γ-glutamyl transpeptidase (IU/L), alkaline phosphatase (ALP; IU/L), cholinesterase (ChE; IU/L), triglycerides (TG; mg/dL), total cholesterol (Total-C; mg/dL), fasting blood sugar (FBS; mg/dL), hemoglobin A1c (HbA1c; %), immunoreactive insulin levels (IRI; μU/mL), plasma branched-chain amino acid levels (BCAA; μmol/mL), plasma tyrosine levels (Tyrosine; μmol/mL), and the molar ratio of BCAA to tyrosine (BTR). The insulin resistance index was calculated according to homeostasis model assessment-insulin resistance (HOMA-IR) from the FBS and IRI values using the following formula[13]: HOMA-IR = FBS × IRI/405.

A HOMA-IR value of ⩾ 2.5 was considered to indicate insulin resistance. The data of subjects with complicated diabetes mellitus were excluded in the comparison of the HOMA-IR values.

Anthropometric assessment

To evaluate nourishment status in the subjects, we assessed their height (cm) and weight (kg) and calculated BMI (kg/m^2). We classified patients with a BMI of < 18.5 kg/m^2 as underweight, 18.5 kg/m^2 to 25 kg/m^2 as normal, and ⩾ 25 kg/m^2 as obese to estimate the rate of obesity in the subjects[14]. We measured the waist circumference (cm) by using a measuring tape to estimate the intra-abdominal fat. Arm circumference (AC; cm) and triceps skin-fold thickness (TSF; mm) were measured with Inser-Tape and Adipometer (Abbott Japan Co., Ltd., Tokyo, Japan). To minimize intra-operator variability, the averages of 3 consecutive measurements were recorded. Arm muscle circumference (AMC; cm) and arm muscle area (AMA; cm^2) were calculated by using the following formula: AMC = AC - (π × TSF), AMA = (AMC)^2/4π.

Age and sex difference were considered; the mean value of measured anthropometric measurements were divided by the respective age-sex-adjusted medians, which were obtained from the Japanese Anthropometric Reference Data 2001[15]. The results were expressed as a percentage (%TSF, %AC, %AMC, %AMA). In addition, right and left handgrip strength were measured once by using the Smedley Type Hand Dynamometer Grip D (Takei Kiki Kogyo Co., Ltd., Japan). The mean value of both hand grip strength measurements were expressed as a percentage by dividing the average of each age acquired from the Japanese Ministry of Education, Culture, Sports, Science and Technology, which performed a test of physical strength and Ex capacity in 2009. The obtained results were used as a qualitative evaluation index of the skeletal muscle.

Dietary and lifestyle survey

Dietary habits and lifestyle of the interviewed subjects were evaluated by using the specific health guideline support software Health Check for Metabolic Syndrome (Su-

zuken Co., Ltd., Nagoya, Japan). Originally, this software was developed as a tool for specific health guidelines to study metabolic syndromes and reserves. The software was modified so that it could be used for chronic liver disease patients. The survey consisted of 50 questions concerning daily life and dietary habits. The results were expressed as total energy or protein intake per body (BW). To compare the results of this study with the guideline of the European Society for Parenteral and Enteral Nutrition (ESPEN) Nutritional Management[16], total energy and protein intake were divided by BW. The results were expressed as total energy or protein intake per BW.

Physical activity survey

The lifestyle recorder, Lifecorder (Suzuken Co., Ltd., Nagoya, Japan), is an activity observation machine that functions as an acceleration sensor. The physical activity pattern was objectively obtained by continuously measuring activity intensity, period and frequency. This is one means to evaluate physical activity-related energy expenditure. It is possible to estimate total energy expenditure (TEE), including involuntary activities such as slow or small erratic movements performed when sedentary and during very low-level activities, by attaching the Lifecorder for 24 h. The quantity and intensity of physical activity could then be accurately determined. This was confirmed in a paper that reported the use of the metabolic chamber[17], showing correlation with the measured values of TEE. The Lifecorder was used for 1 wk (7 d). Data of daily TEE (kcal/d), physical activity (kcal/d), the number of steps (step/d), and Ex (Ex/wk) were obtained. Ex is a unit to express the quantity of physical activity, calculated by multiplying metabolic equivalents (METs) by the duration of the activity (h) as proposed in the Physical Activity Guide for Health Promotion 2006, which was published by the Ministry of Health, Labor and Welfare of Japan. The METs is an index for the intensity of physical activity, calculated as energy expenditure (oxygen uptake, mL/kg per minute) during a specific physical activity divided by sitting/ resting energy expenditure (REE). The goal for the quantity of physical activity for health promotion was set at 23 Ex or more per week to be achieved by active physical activities (including both Ex and non-Ex activities), of which 4 Ex or more should be achieved by active Ex[18].

Logistic regression analysis

Univariate and multivariate logistic regression modeling were used to identify the relevant factors for insulin resistance in patients with chronic liver disease. The degree of chronic hepatitis, HCV infection, the presence or absence of hepatocellular carcinoma, sex, age, %AC, %TSF, handgrip strength, Ex, Plt, Alb, BTR, total energy intake per BW, protein intake per BW, and the percentage fat in nutrition intake were chosen as potential factors. Continuous variables were divided into 2 groups according to each standard as described below. HCV infection has been reported to cause insulin resistance[19]. Therefore, patients were categorized into 2 groups according to HBV and HCV infection. Patients were categorized into 2 groups by age, with those over 65 years considered elderly. Both %AC and %TSF were divided using 100 as a standard value. Handgrip strength was divided using 69, which was the median value. Ex was divided using a value of 4.0, which is the desired amount of active Ex. Plt was divided according to a value of 100 000, with less than 100 000 as the standard for liver cirrhosis. It has been reported that Alb of 3.5 or less is related to prognosis[9]. Therefore, Alb was divided using a value of 3.5, with less than 3.5 considered malnutrition. BTR was divided into 2 groups based on 4.41, which is the lower limit of the standard range. In this study, energy intake per BW was divided based on a value of 30, which is the median of the standard range in the ESPEN nutritional management guidelines[16]. Protein intake per BW was divided based on a value of 1.2, which is the upper limit of the standard range in the ESPEN nutritional management guidelines. The percentage of fat in daily food intake was divided using 25, which is the upper limit of the standard range.

Statistical analysis

Outcomes are presented as mean ± SD, number of patients, or a percentage. The statistical analyses were performed using the Mann-Whitney *U*, Kruskal-Wallis, and Scheffe's multiple comparison tests, or Spearman's rank correlation coefficient. Univariate and multivariate logistic regression modeling were used to obtain the crude and adjusted odds ratios and 95% CI for the association between each factor and insulin resistance. The statistical software Dr. SPSS Ⅱ for Windows Version 11.0.1J (SPSS Inc.) was used for the analysis. P value < 0.05 was considered statistically significant.

RESULTS

Subjects characteristics

One hundred and thirty-three patients with chronic liver disease were included in the analysis. Their characteristics are summarized in Table 1. Sex was not significantly different among the groups. Age in cirrhotic patients was significantly higher than that in patients with chronic hepatitis. Seventeen patients with chronic hepatitis and 11 patients with cirrhosis were infected with HBV, while 42 patients with chronic hepatitis and 63 patients with cirrhosis were infected with HCV. Eleven patients had diabetes mellitus, 20 had hypertension, and 4 had hyperlipidemia in the chronic hepatitis patients. The cirrhotic patients were involved with complications of diabetes mellitus in 11 patients, hypertension in 20, and hyperlipidemia in 4. When cirrhotic patients were assessed by using Child-Pugh classification of the severity of liver disease, 62 patients were classified into class A, and 12 into class B.

Laboratory evaluation

The results of laboratory evaluation are shown in Table

Table 1 Subjects characteristics

	Control	Chronic hepatitis	Cirrhosis
Sex (male/female)	12/15	26/33	25/49
Age (yr)	65.9 ± 6.1	63.5 ± 10.1	68.3 ± 7.5[b]
Viral infection (HBV/HCV)	-	17/42	11/63
Child-Pugh classification (A/B)	-	-	62/12
Diabetes mellitus	-	11	11
Hypertension	-	20	24
Hyperlipidemia	-	4	6

[b]$P < 0.01$ *vs* chronic hepatitis. Data are expressed as mean ± SD or as number of patients. Statistical differences among the 3 groups were determined by the Kruskal-Wallis and Scheffe's multiple comparison tests. HBV: Hepatitis B virus; HCV: Hepatitis C virus.

Table 3 Anthropometric assessments of all subjects

	Control	Chronic hepatitis	Cirrhosis
Height (cm)[1]			
Male	168.2 ± 6.3	168.0 ± 7.6	165.8 ± 6.0
Female	151.0 ± 3.5	152.8 ± 4.1	151.6 ± 6.5
Weight (kg)[1]			
Male	67.0 ± 8.5	67.5 ± 11.0	64.5 ± 9.0
Female	54.5 ± 6.7	54.6 ± 9.4	50.8 ± 8.8
BMI (kg/m^2)[1]			
Male	23.7 ± 3.1	23.9 ± 3.1	23.4 ± 2.6
Female	23.9 ± 2.6	23.4 ± 4.0	22.1 ± 3.5
BMI (underweight/normal/obese)[2]			
Male	1/5/5	1/17/9	0/16/8
Female	1/8/7	2/17/13	6/36/8[h]
Abdominal circumference (cm)[1]			
Male	86.3 ± 7.8	90.0 ± 8.0	87.7 ± 8.6
Female	84.6 ± 10.0	86.0 ± 9.9	85.1 ± 9.2
%AC[1]	108.1 ± 8.4	107.4 ± 11.8	103.9 ± 11.5
%TSF[1]	96.0 ± 37.0[a]	129.0 ± 50.2	116.5 ± 48.4
%AMC[1]	111.9 ± 10.5[b,e]	104.9 ± 10.7	102.7 ± 10.8
%AMA[1]	128.2 ± 25.1[c,f]	112.2 ± 22.9	107.5 ± 22.5
Hand grip strength (%)[1]	92.1 ± 16.2[d,g]	74.4 ± 20.9	66.9 ± 17.6

[a]$P = 0.013$, [b]$P = 0.021$, [c]$P = 0.013$, [d]$P < 0.001$ *vs* chronic hepatitis; [e]$P = 0.001$, [f]$P = 0.001$, [g]$P < 0.001$ *vs* liver cirrhosis; [h]$P = 0.007$. Data are expressed as mean ± SD or as number of patients. [1,2]Statistical differences among the 3 groups were determined by the Kruskal-Wallis and Scheffe's multiple comparison tests[1] or Spearman's rank correlation coefficient[2]. BMI: Body mass index; AC: Arm circumference; TSF: Triceps skin fold thickness; AMC: Arm muscle circumference; AMA: Arm muscle area.

2. The values of WBC, RBC, Hb, Ht, Plt, PT, TP, Alb, Total-C, TG, ChE, HbA1c and BTR in cirrhotic patients were significantly lower than those in patients with chronic hepatitis. Furthermore, the values of AST, T-bil, D-bil, ALP and LAP were also significantly higher in the latter group. The IRI of both the groups was slightly high, and the mean value of HOMA-IR was ⩾ 2.5. Twenty-two of the 106 patients who had obvious diabetes, based on their measured FBS level and insulin level, were excluded. We used the remaining 84 patients as the subjects for the analysis. The number of patients with a HOMA-IR ⩾ 2.5, which was considered to indicate insulin resistance, was 14 (35.9%) in the chronic hepatitis patients and 17 (37.8%) in the cirrhotic patients.

Table 2 Laboratory evaluations for the patients (mean ± SD)

	Chronic hepatitis	Cirrhosis
WBC (× 100/μL)	55.5 ± 19.2	37.9 ± 13.6[a]

Anthropometric assessment

Table 3 presents the outcomes of anthropometric assessments in the subjects. The skeletal muscle index (measured as %AMC and %AMA) was significantly lower in the chronic hepatitis and cirrhotic patients than in the controls. The body fat indicator (measured as %TSF) in the chronic hepatitis patients was significantly higher than in the controls. The handgrip strength in both the patient groups was significantly lower than that in the controls. We divided the subjects into male and female subgroups when comparing height, weight, BMI and abdominal circumference. There were no significant differences among the 3 groups. Among the men, the rate of obesity was 45.5% in the control, 33.3% in those with chronic hepatitis, and 33.3% in those with liver cirrhosis. Among the women, the rate of obesity was 43.8% in the control, 40.6% in those with chronic hepatitis, and 16.0% in those with liver cirrhosis. The difference in the obesity rate was not significant in the men; however, the obesity rate in

Statistical differences among the 3 groups were determined by the Kruskal-Wallis and Scheffe's multiple comparison tests. BW: Body weight; RE: Retinol equivalents.

women was significantly lower as liver disease advanced.

Dietary survey

The results of the dietary survey are presented in Table 4. The total nutrition intake and amounts of carbohydrates, protein, and fat were not significantly different among the groups. These results showed that the average food intake of patients was not different compared to that of the controls. Moreover, the intake of important micro-elements such as calcium, iron, salt, vitamins A, B1, B2, and C; and dietary fibers was almost the same in these 3 groups. The food intake and its contents seemed to be sufficient in cirrhotic patients.

Lifestyle survey

The outcomes of the lifestyle survey are described in Table 5. The lifestyle-related questionnaire survey revealed that the amount of alcohol consumed by cirrhotic patients was significantly lower than that of control subjects. Chronic hepatitis patients tended to consume less alcohol compared with control subjects. With regard to drinking habits, significantly more subjects in each patient group replied that they drank less compared to the controls. Significantly more subjects in both patient groups reported that they had enough rest compared to the control group. Furthermore, the sleeping time in patients of the cirrhosis group was significantly longer than that in the other 2 groups. The perceived health status in each patient group was significantly lower than in the control group.

Physical activity survey

Table 6 shows the results of the physical activity survey. The physical activity levels, number of steps, and Ex in the chronic hepatitis and cirrhosis groups were significantly lower than those of the control group. Moreover, TEE in cirrhotic patients was significantly lower than that in control subjects and chronic hepatitis patients.

Results of logistic regression analysis

Table 7 shows the results of univariate and multivariate logistic regression modeling, which were used to determine the relevant factors for insulin resistance. Unadjusted univariate logistic regression modeling suggested that 6 factors, including the presence or absence of hepatocellular carcinoma, AC, Ex, BTR, total energy intake per BW, and percentage fat, were significantly associated with insulin resistance. In the multivariate logistic regression modeling adjusted for sex, age, the presence or absence of hepatocellular carcinoma, AC, Ex, BTR, total energy intake per BW and percentage fat, Ex was a significant factor associated with insulin resistance.

DISCUSSION

In this study, we carried out laboratory evaluations, an-

thropometric assessments, a diet, lifestyle, and physical activity survey in chronic liver disease patients. The results were compared with the data of healthy subjects. As shown in Table 2, a considerable number of the chronic hepatitis patients presented insulin resistance without obvious elevation of FBS. Thirty-three point nine percent in the chronic hepatitis and 37.8% in cirrhotic patients indicated insulin resistance. Insulin resistance has been reported to be correlated with liver fibrosis[20,21], carcinogenesis[22] and mortality[23] of liver cancer in chronic liver disease patients. FBS as well as IRI should be measured and HOMA-IR should be calculated for an early diagnosis and for improving insulin resistance by diet and Ex therapy.

The rate of obesity in men and women was 30.5% and 20.8%, respectively, according to the national health and nutrition examination survey conducted by the Japanese Ministry of Health, Labour and Welfare in 2009. In this study, the incidence of obesity in men with liver cirrhosis was almost the same as that in the general adult male population. However, the rate of obesity in women was significantly lower as liver disease advanced. However, BMI was not significantly different among the 3 groups, and 72.0% of the women with liver cirrhosis had a normal BMI. These results suggested that almost all women with liver cirrhosis might have normal weight. Complications such as metabolic syndrome, obesity, and fatty liver in patients with chronic liver disease were risk factors of liver fibrillization[24] and carcinogenesis[25]. These complications are related to increasing mortality of carcinoma[11] and decreased response to antiviral therapy[26]. If the condition of patients with obesity or fatty liver could be improved by correcting their diet and lifestyle, these approaches might be effective to curb the progression of the disease, carcinogenesis, and to improve the efficacy of interferon therapy. However, malnutrition in cirrhotic patients is caused by the decreased protein synthesis and disturbed energy metabolism that result from liver failure. Protein malnutrition can cause a decrease in skeletal muscle mass in cirrhotic patients. In fact, AMC and AMA in patients with chronic hepatitis and liver cirrhosis were significantly lower than those in the control subjects, while AC was not significantly different among all groups. Moreover, TSF in the chronic hepatitis group was significantly higher than that in the control group. These results suggest the possibility of a decrease in skeletal muscle mass and a relative increase in fat mass in patients with chronic liver disease. However, anthropometry might underestimate the prevalence and severity of malnutrition in patients with cirrhosis. In particular, the underestimation was more pronounced in patients with Child-Pugh A and B cirrhosis, although anthropometry is a simple and non-invasive method[27]. More attention needs to be paid to the method of nutrition assessment. In the future, the body composition of cirrhotic patients might have to be evaluated again by using more accurate methods such as dual-energy X-ray absorptiometry.

In this study, the handgrip strength in the patient groups was significantly lower than that in the control group. Handgrip strength has been reported to be strongly correlated with muscle mass[28]. Decreased handgrip strength corresponded with lower %AMC and %AMA values. These results might reflect a decrease in muscle mass. Furthermore, the handgrip strength can be used to predict morbidity of complications in cirrhotic patients[29]. Therefore, it may be a valuable predictive factor of malnutrition and its accompanying complications. Although not specific to patients with liver disease, a Japanese study published in 2007 reported that the multivariate-adjusted reactive risk of all causes of death, excluding external causes, for each 5-kg increment of grip strength was significantly lower in middle-aged and elderly individuals[30]. Maintaining grip strength might benefit cirrhotic patients.

In the dietary survey, there were no significant differences in nutrition intake between the groups. Furthermore, patients did not show a deficiency in total energy and protein intake per BW, as per the guidelines of ESPEN Nutritional Management. This finding suggests that dietary intake was almost sufficient to fulfill the

nutritional requirements. The results of the biochemical blood tests and anthropometric assessments showed that cirrhotic patients were malnourished, leading to reduced values of serum albumin, AMC, AMA and handgrip strength. Although protein intake was adequate in the cirrhosis group, the BTR was low. This result suggests that improving the amino acid imbalance by dietetic treatment is difficult. Therefore, oral BCAA supplementation in cirrhotic patients has been shown to be effective in improving BTR and maintaining serum albumin and their quality of life (QoL)[31]. In addition, oral BCAA supplementation could decrease the risk of specific hepatic carcinogenesis in cirrhotic patients[10].

In the lifestyle survey, chronic liver disease patients

consumed significantly less alcohol and had a lower drinking frequency. These results suggested that the patients were aware of the adverse effect of alcohol drinking. Cirrhotic patients had a significantly longer sleeping time, and more patients reported that their resting time was sufficient than the other 2 groups. This shows that patients with cirrhosis are careful in maintaining rest. Perceived health status in the patient groups was significantly lower than that in the control group; progression of the liver disease might influence the QoL of the patients.

The result of the physical activity survey suggested that cirrhotic patients in urban areas had significantly lower TEE than the control and chronic hepatitis groups. In a study that determined REE by using an indirect calorimeter, the REE of cirrhotic patients was found to vary[32]. However, the REE in cirrhotic patients was significantly higher than that in the control and chronic hepatitis groups when measured using a direct calorimeter[33]. The Lifecorder of TEE was conjectured by body motion, but this measured value does not consider the increased REE in cirrhotic patients. This suggested that the TEE of cirrhotic patients in this study might be underestimated. However, a study that validated the Lifecorder reported that there was a strong correlation between physical activity levels and measured METs while walking[17]. At the very least, this result suggested that the level of physical activity of chronic hepatitis and cirrhosis group was low. As mentioned above, the perceived health status in cirrhotic patients was also low. We think that all physical activity might be suppressed by stressing about the need for rest in the usual life guidelines for cirrhosis. Some reports stated that maintenance of weight loss and Ex in overweight patients with liver disease resulted in a sustained improvement in liver function, insulin resistance and QoL[34,35]. Obese cirrhotic patients would rather try to increase the intensity of daily activities involving Ex than continue to maintain excessive resting. However, since patients with decompensated cirrhosis with ascites, hepatic encephalopathy, and jaundice need to lie quietly and consume sufficient amounts of nutrients, we should probably exclude them from the patients with chronic hepatitis and compensated cirrhosis enrolled in this study.

In this study, univariate and multivariate logistic regression modeling were used to identify the relevant factors for insulin resistance. The results show that decreased Ex was a significant factor for insulin resistance. For patients with chronic liver disease, increasing the amount of physical activity might improve insulin resistance. Insulin resistance tended to decrease at low values of %AC, which is an index of muscle and fat mass. In this study, the muscle mass in patients with chronic liver disease was lower than in the control group. While the amount of fat mass in the liver cirrhosis group was not significantly different from that of the control group, the amount of fat mass in the chronic hepatitis group was higher than that of the control group. In patients with chronic liver disease, obesity or muscle wasting might be related to insulin resistance. Insulin resistance tended to decrease at higher fat percentages. Insulin secretion might not be as easily stimulated when fat is ingested compared with when carbohydrates are ingested. This might be associated with the insulin resistance observed in chronic liver disease. However, this study has limitations. We have not completely verified a causal relationship between Ex and insulin resistance as this is a cross sectional study. It will thus be necessary to perform a future cohort study to verify whether insulin resistance in patients with cirrhosis is directly induced by decreased physical activity.

In summary, the results of this study suggested that chronic liver disease patients in urban areas have lower skeletal muscle mass and higher relative body fat percentage. We think that the lower skeletal muscle mass may result from the decline in BTR, which indicates an amino acid imbalance, and that the intensity of daily activities was lower because of excessive resting instead of a decrease in dietary intake. Moreover, this study showed that insulin resistance might exist in early-stage chronic liver disease patients. Ex was a relevant factor for insulin resistance, and decreased physical activity was associated with insulin resistance.

Therefore, non-hospitalized cirrhotic patients in urban areas need to maintain an adequate dietary intake and receive lifestyle guidance to increase their physical activity levels.

COMMENTS

Background

Cirrhosis is an end-stage chronic liver disease, and one of the typical diseases that is associated with malnutrition. However, the combination of over-nutrition and obesity in cirrhosis patients indicates the possibility of an impaired pathogenesis. These findings suggest that excessive food intake, decreased intensity of daily activity, and a lack of exercise (Ex) in cirrhotic patients promotes obesity, fatty liver, and hepatic carcinogenesis. Few researchers have studied the effect of dietary habits and lifestyle in non-hospitalized cirrhotic patients on their conditions.

Research frontiers

Recently, both experimental and clinical studies found that over-nutrition, fatty liver, and glucose intolerance are significant risk factors of hepatic carcinogenesis. Moreover, insulin resistance has been reported to be correlated with liver fibrosis and mortality of liver cancer in chronic liver disease patients. Some reports have said that maintenance of weight loss and Ex in overweight patients with liver disease resulted in a sustained improvement in liver function, insulin resistance, and quality of life. To improve insulin resistance or the loss of excess weight, correction of malnutrition and the addition of moderate Ex are effective methods of therapy. However, it is not clear if Ex that is moderate in intensity or quantity will be effective therapy for cirrhotic patients. The purpose of this study is to assess the nourishment status of non-hospitalized patients with compensated cirrhosis.

Innovations and breakthroughs

The results of this study suggested that chronic liver disease patients in urban area have lower skeletal muscle mass and higher relative body fat percentage. Moreover, this study showed that insulin resistance might exist in early-stage chronic liver disease patients. Ex was a relevant factor for insulin resistance, and decreased physical activity was associated with insulin resistance.

Applications

The results of this study suggest that non-hospitalized cirrhotic patients in urban areas need to maintain an adequate dietary intake and receive lifestyle guidance to increase their physical activity levels. Decreased physical activity was

associated with insulin resistance. Therefore, increasing physical activity may improve insulin resistance and suppress hepatocellular carcinogenesis.

Terminology

Ex is a unit to express the quantity of physical activity, calculated by multiplying metabolic equivalents (METs) by the duration of the activity (h) as proposed in the Physical activity guide for Health Promotion 2006, which was published by the Ministry of Health, Labor and Welfare of Japan. METs is an index for the intensity of physical activity, calculated as energy expenditure (oxygen uptake, mL/kg per minute) during a specific physical activity divided by sitting/resting energy expenditure.

Peer review

In this paper, the authors investigated the nourishment status and lifestyle of non-hospitalized patients with compensated cirrhosis by using non-invasive methods in Japan. They found that insulin resistance was seen in more than 35% of patients with chronic liver disease. In addition, the handgrip strength, physical activity levels, number of steps and Ex were significantly lower in the cirrhotic group than in the control group. The authors concluded that non-hospitalized cirrhotic patients may need to maintain an adequate dietary intake and receive lifestyle guidance in order to increase their physical activity levels. Overall, theseindings are interesting.

Abstract

AIM: To develop a novel endoscopic severity model of intestinal Behcet's disease (BD) and to evaluate its feasibility by comparing it with the actual disease activity index for intestinal Behcet's disease (DAIBD).

METHODS: We reviewed the medical records of 167 intestinal BD patients between March 1986 and April 2011. We also investigated the endoscopic parameters including ulcer locations, distribution, number, depth, shape, size and margin to identify independent factors associated with DAIBD. An endoscopic severity model was developed using significant colonoscopic variables identified by multivariate regression analysis and its correlation with the DAIBD was evaluated. To determine factors related to the discrepancy between endoscopic severity and clinical activity, clinical characteristics and laboratory markers of the patients were analyzed.

RESULTS: A multivariate regression analysis revealed that the number of intestinal ulcers ($\geqslant$ 2, P = 0.031) and volcanoshaped ulcers (P = 0.001) were predictive factors for the DAIBD. An endoscopic severity model (Y) was developed based on selected endoscopic variables as follows: Y = 47.44 + 9.04 × non-Ileocecal area + 11.85 × $\geqslant$ 2 of intestinal ulcers + 5.03 × shallow ulcers + 12.76 × deep ulcers + 4.47 × geographic-shaped ulcers + 26.93 × volcano-shaped ulcers + 8.65 × $\geqslant$ 20 mm of intestinal ulcers. However, endoscopic parameters used in the multivariate analysis explained only 18.9% of the DAIBD variance. Patients with severe DAIBD scores but with moderately predicted disease activity by the endoscopic severity model had more symptoms of irritable bowel syndrome (21.4% *vs* 4.9%, P = 0.026) and a lower rate of corticosteroid use (50.0% *vs* 75.6%, P = 0.016) than those with severe DAIBD scores and accurately predicted disease by the model.

CONCLUSION: Our study showed that the number of intestinal ulcers and volcano-shaped ulcers were predictive factors for severe DAIBD scores. However, the correlation between endoscopic severity and DAIBD (r = 0.434) was weak.

INTRODUCTION

Behcet's disease (BD) is a chronic, relapsing, multi-systemic inflammatory disorder characterized by recurrent oral and genital ulcers combined with other systemic manifestations. The systemic manifestations are due to involvement of many other organs including the skin, joints, blood vessels, nervous system, epididymis, and gastrointestinal tract[1,2]. In particular, when patients with BD have predominant gastrointestinal symptoms and show intestinal ulcerations according to objective measures, the disease is then diagnosed as "intestinal BD"[3,4].

Intestinal BD is generally accepted as a type of inflammatory bowel disease (IBD), a group of diseases that includes ulcerative colitis (UC) and Crohn's disease (CD). Because IBD has various, fluctuated clinical courses with repeated remission and relapse, the disease activity index is helpful for disease management and therefore has been commonly used in monitoring treatment response. For example, disease activity is usually defined according to the Truelove and Witts' criteria[5] or the Mayo score system[6] as mild, moderate, or severe disease for UC and measured by the Crohn's disease activity index (CDAI)[7] or the Harvey-Bradshaw index[8] for CD.

Endoscopy is by far the best and most widely used modality for assessment of the disease extent and severity of IBD[9]. A study investigating a cohort of CD patients under long-term treatment with infliximab recently reported that mucosal healing was associated with a significantly lower need for abdominal surgery[10]. Furthermore, data from the Active Ulcerative Colitis Trials 1 and 2[11] have suggested that mucosal healing was associated with a better outcome in UC, more specifically, a decreased risk of relapse. Therefore, the macroscopic mucosal appearance is considered a valuable indicator of disease activity. In this regard, colonoscopic activity has been assessed using a modified version of Baron's criteria[12] for UC and the Crohn's disease endoscopic index of severity (CDEIS)[13] for CD.

Although the disease activity index for intestinal Behcet's disease (DAIBD), a relatively simple eight-point system, was recently introduced[14], there are no specific tools for the measurement of endoscopic severity in intestinal BD. There have been several descriptions of clinical outcomes according to colonoscopic findings[15,16], however, endoscopic appearance has never been taken into account in evaluating disease activity in intestinal BD. Therefore, the aim of this study was to identify endoscopic factors associated with the DAIBD, to develop a novel endoscopic severity model of intestinal BD using these factors, and to evaluate the correlations between the actual DAIBD and endoscopic severity.

MATERIALS AND METHODS

Patients

We reviewed the medical records of patients with intestinal BD at Severance Hospital, Yonsei University College of Medicine, Seoul, South Korea, between March 1986 and April 2011. Patients with a history of previous colon operations were excluded from the study and those diagnosed or suspected as having UC, CD, intestinal tuberculosis, infectious colitis, or malignancy were not included in our study.

BD was diagnosed according to the criteria from the 1987 Behcet's Disease Research Committee of Japan[17] and was divided into the following three types: complete, incomplete and suspected BD. Intestinal involvement of BD was evaluated using colonoscopy for the large bowel and terminal ileum involvement and small bowel follow-through or computed tomography enterography for the small bowel involvement in patients with BD who had gastrointestinal symptoms. Diagnosis of intestinal BD was made according to the criteria as previously described using a modified Delphi process[2,18]. Patients were categorized into three groups as definite, probable, and suspected on the basis of colonoscopic findings and extraintestinal systemic manifestations. Clinical activity of intestinal BD was judged by the DAIBD composed of the following eight variables: general well-being, fever, extraintestinal manifestations, abdominal pain, abdominal mass, intestinal complications, and number of liquid stools in one week. The DAIBD was classified into quiescent ($\leqslant$ 19), mild (20-39), moderate (40-74), and severe disease ($\geqslant$ 75)[14].

Methods

We collected demographic data including initial gastrointestinal symptoms and other extraintestinal manifestations related to systemic BD at the time of colonoscopy. We also investigated all colonoscopic findings with respect to location, distribution, number, depth, shape, size, and ulcer margin. Patients with < 5 ulcers that were oval in shape, deep, with discrete borders, and located in the ileocecal area including the terminal ileum, ileocecal valve, and cecum were considered as having typical intestinal BD lesions[19]. When the colon was divided into five segments (ileocecal area, ascending colon, transverse colon, descending colon, and rectosigmoid colon), a localized type was defined when lesions were restricted to only one segment and a diffuse type was defined when lesions were scattered in more than two colonic segments[15]. Furthermore, when two or more ulcers were observed, the largest diameter of the biggest ulcer was

used for the measurement of depth, shape, size and margin for analysis. This study was approved by the Institutional Review Board of Yonsei University College of Medicine and was conducted in accordance with the ethical principles of the Declaration of Helsinki.

Statistical analysis

Continuous variables are presented as mean ± SD and categorical variables as frequency and percentage. An endoscopic severity model was constructed using the DAIBD as a dependent variable and the following endoscopic parameters as explanatory variables: ulcer location, distribution, number, depth, shape, size, and margin. To identify independent factors associated with disease activity for intestinal BD, we selected explanatory items using univariate analysis ($P < 0.05$) and also items that were recommended to be included by experts, which were followed by multiple linear regression analysis. The independent variables were evaluated using Student's *t*-test or one-way analysis of variance, with post hoc tests for confirmation of significance (Tukey's test at $\alpha = 0.05$). R^2 in the regression is used for how much the variance of the DAIBD can be explained by the endoscopic parameters. Moreover, relationships between predicted scores and the DAIBD were evaluated using Spearman's correlation coefficients.

Using an endoscopic severity model, we sought to predict actual disease activity for intestinal BD. To evaluate factors associated with any discrepancy between the predicted score using an endoscopy severity model and the actual DAIBD, we divided patients into four groups (quiescent, mild, moderate, and severe groups) according to their actual DAIBD cutoff scores and analyzed clinical characteristics and laboratory markers in each group. They were further classified according to their predicted DAIBD scores using the endoscopic model. Two of the groups of patients with the actual DAIBD scores showed values consistent with the predicted scores by the endoscopic model, while the other two groups of patients showed disagreement between the actual DAIBD and predicted scores; one with lower predicted scores than the actual DAIBD scores and the other with higher predicted scores than the actual DAIBD scores. Student's *t*-test was used to compare continuous variables and chi-squared test was used to compare categorical variables for each group.

$P < 0.05$ was considered statistically significant for all tests. All statistical analyses were performed using SPSS Version 17.0 for Windows (SPSS Inc., Chicago, IL, United States) and/or SAS Version 9.1 (SAS Institute, Gary, NC, United States).

RESULTS

Baseline clinical and colonoscopic characteristics of patients with intestinal BD

A total of 243 patients with intestinal BD were recruited during the study period, and 72 of 243 patients were excluded because they underwent operations such as ileocecectomy, right hemicolectomy, or small bowel resection before undergoing colonoscopy. One patient was excluded after finally being diagnosed with CD after follow-up colonoscopy, and 3 patients were further excluded who were confirmed not to have intestinal BD at the end of the follow-up period. The remaining 167 patients were included in this study. Their clinical and colonoscopic characteristics are summarized in Tables 1 and 2, respectively.

The mean age at diagnosis was 38.5 years (range:15-73 years) for BD and 41.4 years (range: 16-73 years) for intestinal BD. Ninety-six patients (57.5%) were female. According to the diagnostic criteria for BD, 3 patients (1.8%) had the complete type, 78 (46.7%) had the incomplete type, and 53 (31.7%) had the suspected type of disease. Twenty-five patients (15.0%) presented with only typical oral ulcers and 8 (4.8%) had only gastrointestinal lesions without any extraintestinal manifestations. The chief complaints of patients were diarrhea (85.0%), abdominal pain (71.8%), and abdominal tenderness (71.2%). At the time of colonoscopy, 5-aminosalicylic acids or sulfasalazine were prescribed to almost all the patients with intestinal BD (97.6%), azathioprine or 6-mercaptopurine to 24 patients (14.4%), colchicine to 80 (47.9%), and corticosteroids to 72 (43.1%).

On colonoscopy, the ileocecal area was the most common location for intestinal lesions (156 patients, 93.4%), with ileal ulcers present in 4 (2.4%). Localized intestinal involvement was found in 142 patients (85.0%) and 86 (51.5%) had a solitary intestinal ulcer. Regarding the depth and shape of intestinal ulcers, 109 patients (65.3%) had deep ulcers and 79 (47.3%) had oval-shaped ulcers. Patients with intestinal BD had relatively large ulcers; ulcers larger than 20 mm were noted in 82 patients (49.1%). The ulcer margins were usually discrete (75 patients, 44.9%), and 94 patients (56.3%) had typical ulcers. With regard to the intestinal BD diagnostic criteria, 69 (41.3%), 82 (49.1%), and 16 patients (9.6%) were classified as definite, probable, and suspected types, respectively.

Endoscopic factors associated with disease activity for intestinal BD

Univariate analysis revealed that the depth of intestinal ulcers ($F = 5.03$, $P = 0.008$), ulcer shape ($F = 13.33$, $P < 0.001$), and ulcer size ($F = 6.62$, $P < 0.001$) were significantly associated with disease activity for intestinal BD (Table 3). The mean DAIBD score of deep ulcers was significantly greater than that of shallow ulcers as shown by Tukey's multiple comparison test ($P = 0.027$) and the mean DAIBD score of volcano-shaped ulcers was also greater than that of oval-shaped or geographic ulcers ($P < 0.001$ and $P = 0.001$, respectively). The mean DAIBD score of ulcers larger than 20 mm was significantly greater than that of ulcers less than 5 mm or ulcers ranging from 10 mm to 20 mm ($P = 0.014$ and $P = 0.002$, respectively). No difference in the DAIBD

Table 1 Baseline clinical characteristics of patients with intestinal Behcet's disease

Characteristic	No. of patient (%)
Age at diagnosis of BD (yr)	38.5 ± 12.2

BD: Behcet's disease.

score was observed with regard to any other endoscopic variables including location, distribution, number, or pattern of ulcer margin.

Significant variables ($P < 0.05$) found on univariate analysis were included in the multivariate analysis to identify independent factors associated with disease activity. Location and number of ulcers that experts have recommended as potentially important predictive factors were also included in the multivariate analysis. Multivariate regression analysis showed that the number of intestinal ulcers (≥ 2, $P = 0.031$) and that of volcano-shaped ulcers ($P = 0.001$) were independent predictive factors for the DAIBD (Table 4).

Using the coefficients from the estimated regression model (Table 4), we generated an endoscopic severity model to predict DAIBD scores (Y) based on five optimal selected endoscopic variables. The final model was as follows: Y = 47.44 + 9.04 × non-ileocecal area + 11.85 × ≥ 2 of intestinal ulcers + 5.03 × shallow ulcers + 12.76 × deep ulcers + 4.47 × geographic-shaped ulcers + 26.93 × volcano-shaped ulcers + 8.65 × ≥ 20 mm of intestinal ulcers.

Predictive factors for discrepancies between predicted endoscopic score and actual DAIBD

However, the five most predictive endoscopic parameters in the multiple linear regression analysis explained only 18.9% of the DAIBD variance. Therefore, we attempted to find out the reasons for this unexpected discrepancy. Using the endoscopic severity model, the predicted DAIBD severity distribution was as follows: 108 patients (64.7%) had moderate disease activity and 59 (35.3%) had severe disease activity (Table 5). Conversely, in this study, the actual DAIBD scores demonstrated that disease activity was quiescent in 2 patients (1.2%), mild in 32 (19.2%), moderate in 50 (29.9%), and severe in 83 (49.7%).

DAIBD: Disease activity index for intestinal Behcet's disease.

To find out which predictive factors are causing discrepancies between the predicted endoscopic scores and the actual DAIBD scores, we first analyzed 83 patients with severe actual DAIBD scores. Among the 83 patients, 42 (50.6%) had moderate and 41 (49.4%) had severe predicted disease activity based on the endoscopic severity model. Moderately predicted group had more irritable bowel syndrome symptoms (21.4% *vs* 4.9%, $P = 0.026$) and a lower rate of corticosteroid use (50.0% *vs* 75.6%, $P = 0.016$) than severely predicted group. However, infection rates (16.7% *vs* 12.2%, $P = 0.562$) and rates of systemic BD presentation (57.1% *vs* 46.3%, $P = 0.325$) were not significantly different between the two groups.

Among the remaining 84 patients with mild or moderate DAIBD, 37 patients (44.0%) showed consistent results between the actual DAIBD and their predicted scores, while 47 (56.0%) showed inconsistent results. Clinical or laboratory variables including rate of corticosteroid use (25.5% *vs* 21.6%, $P = 0.676$), erythrocyte sedimentation rate (ESR) (39.15 ± 27.66 mm/h *vs* 33.74 ± 27.98 mm/h, $P = 0.421$), or C-reactive protein (CRP) level (7.11 ± 18.33 mg/L *vs* 2.81 ± 3.99 mg/L, $P = 0.162$) were not significantly different between the two groups.

DISCUSSION

To the best of our knowledge, there have been no studies concerning endoscopic factors associated with disease activity for intestinal BD. Moreover, there is currently no available endoscopic severity model for intestinal BD. To date, the management of intestinal BD and the assessment of its response to treatment depend heavily on expert opinions. Although recently, the DAIBD was proposed to objectively evaluate disease activity, which would be useful to physicians in clinical practice[14], endoscopy has rarely been investigated as a predictor of disease activity in intestinal BD. Accordingly, we aimed to identify endoscopic factors related to disease activity of intestinal BD, to develop a novel scoring model for predicting a severe course of disease, and to clarify the correlation between the DAIBD and endoscopic severity.

In the present study, we first sought to identify the endoscopic factors associated with disease activity for intestinal BD. On univariate analysis, the significant endoscopic predictors of disease activity were depth of intestinal ulcers, ulcer shape and ulcer size. Multivariate analysis revealed that the number of intestinal ulcers and volcano-shaped ulcers were independent predictors of the DAIBD. These results were consistent with those of several prior studies. A Korean study[15] reported that volcano-shaped ulcers responded least to medical treat-

ment, required surgery more frequently, and showed more frequent recurrences than geographic and aphthous-shaped ulcers. Another Korean study[16] revealed that individuals with deep ulcers and ulcers larger than 20 mm had an increased rate of steroid use and more frequent intestinal surgery. Moreover, a recent study by Jung *et al*[20] suggested that those with volcano-shaped ulcers demonstrated a less favorable response to surgical treatment, had more frequent recurrences, and more frequently required reoperation. In addition to volcano-shaped, deep, and larger than 20 mm ulcers, this study showed for the first time that having two or more intestinal ulcers was related to an increased disease severity when compared to solitary ulcers. Although there have been no reports regarding the correlations between the number of ulcers and disease activity in IBD, our results can be explained by the fact that an increase in the extent of mucosal involvement reflects the multiplicity of ulcers because patients with extensive and multiple ulcers are less likely to respond to local or systemic treatments. In systemic BD, the number, frequency, and healing time of oral ulcers and pain have been used to evaluate disease activity in clinical practice and studies[21]. In addition, in our study, ulcers in the ileocecal area showed a lower DAIBD score than ulcers in other location. A recent study on free bowel perforation in intestinal BD patients[22] reported that small bowel perforation was observed in 21.2%. Ileal ulcers might be at higher risk of complications such as perforation, which could be therefore related to severe disease activity. Further studies are required to validate whether the number of intestinal ulcers and ulcer location are truly associated with disease activity in intestinal BD.

Based on the predictive endoscopic factors for disease activity identified on multivariate analysis, we sought to develop an endoscopic severity model for intestinal BD. In multivariate analysis, besides the factors found to be significantly associated with the DAIBD in univariate analysis, potential factors that could achieve the optimized R^2 were also included, reflecting experts' suggestions. Initially, we hypothesized that endoscopic severity would have a highly significant correlation with clinical activity. However, the correlation between endoscopic severity and the DAIBD (r = 0.434) was unexpectedly found to be substantially weak. These results suggest that endoscopic severity might not correlate with clinical disease activity; thus, we cannot precisely judge a patient's condition using only the clinical activity index. Another potential reason for the lack of correlation may be that improvement in endoscopic lesions appeared later than the patient's clinical status. Although there have been no reports on correlations between endoscopic severity and disease activity in intestinal BD, many previous studies have described a poor association between endoscopic severity and clinical activity in IBD. In CD, the Groupe d'Etudes Therapeutiques des Affections Inflammatoires Digestives have shown that endoscopic severity patterns assessed by the CDEIS correlated poorly (r = 0.32) with clinical activity measured by the CDAI[23]. Daperno *et al*[24] indicated that the correlation of the simple endoscopic score for CD with CDAI (r = 0.39) was better than for the CDEIS, but still far from optimal. In contrast, Allez *et al*[25] observed that patients with CD exhibiting deep and extensive ulcerations on colonoscopy have a more aggressive clinical course with an increased rate of penetrating complications and increased likelihood of surgery. In UC, Carbonnel *et al*[26] demonstrated that extensive and deep ulcerations observed on colonoscopy were associated with an increased risk of colectomy, and another study by Daperno *et al*[27] reported that severe endoscopic lesions were significantly more frequent in non-responders to medical treatment compared with responders. These findings suggest that clinical disease activities might not highly correlate with concrete progress of patients. Endoscopic activity indexes could complement this drawback of clinical indices of IBD including intestinal BD. Further large-scale studies are needed to conclude whether endoscopic severity is superior to clinical disease activity in intestinal BD in terms of reflecting exactly the patient's current condition and predicting prognosis.

Because the correlation between endoscopic severity and the DAIBD was weak, recognizing reasons for the disagreement would be useful for clinicians in practice. To determine possible explanatory factors for the discrepancy between endoscopic severity and clinical activity, we considered laboratory results as well as clinical findings. These unexpected results might be explained that many systemic manifestations of the inflammatory process that result in the appearance of symptoms, but are not necessarily reflected in the mucosal lesions. Patients with systemic BD symptoms including oral and genital ulcers, eye and skin lesions, or arthralgia or concomitant infections may present with higher DAIBD scores than the predicted scores. Moreover, patients with predominant irritable bowel syndrome symptoms might present with higher clinical activity scores because symptoms of irritable bowel syndrome include nonspecific abdominal pain or discomfort and changes in stool frequency and appearance with the onset of symptoms, which might mimic IBD symptoms[28]. In the present study, patients with higher DAIBD scores than predicted scores had more irritable bowel syndrome symptoms and a lower rate of corticosteroid use. It is possible that clinical symptoms improve more quickly with the use of corticosteroids.

Moreover, in a group of patients with a higher endoscopic severity than actual clinical activity, we anticipated that serum biomarkers such as CRP and ESR would explain the discrepancy because the utility of laboratory markers for assessment of IBD activity, risk of complications, prediction of relapse and for monitoring the effect of therapy have been investigated. Consigny *et al*[29] reported that CRP levels (> 20 mg/dL) and ESR (> 15 mm/h) were predictive of relapse in CD, and Travis *et al*[30] revealed that elevated CRP (> 45 mg/L) could predict an

increased risk of colectomy in severe UC. Although many studies in the past few decades have noted that CRP and ESR are associated with systemic BD activity[31,32], the role of CRP and ESR in intestinal BD is still unknown. In the current study, the CRP and ESR levels were numerically higher in the severe predicted DAIBD group without any statistical difference. A recent study by Jung *et al*[33] also demonstrated that CRP or ESR levels were not highly correlated with disease activity in intestinal BD patients. Further studies are needed to evaluate the precise role of laboratory markers in intestinal BD.

The main strength of our study is that this is the first study to consider the use of endoscopy as a measurement tool of disease status in intestinal BD. However, because we retrospectively analyzed clinical and colonoscopic characteristics, our results might have been affected by the limitations of its retrospective design. In addition, the correlations between the predicted endoscopic severity model and the disease activity of intestinal BD were far below the expected values. Further studies to predict the clinical outcomes more accurately by taking into account endoscopic factors and the DAIBD together are required to verify our results.

In conclusion, we evaluated endoscopic factors related to disease activity of intestinal BD and the correlations between clinical activity and endoscopic severity. Our findings indicate that clinicians should closely observe patients with two or more intestinal ulcers and those with volcano-shaped ulcers and that these endoscopic findings could help clinicians make decisions regarding medical strategies for the treatment of intestinal BD. Finally, the understanding of discrepancy between actual and predicted DAIBD by the endoscopic severity model could be helpful in making an appropriate decision regarding medical strategies.

COMMENTS

Background

Because inflammatory bowel disease (IBD) has various, fluctuated clinical courses with repeated remission and relapse, the disease activity index is helpful for disease management. Moreover, recent studies suggested that mucosal healing was associated with a better outcome. Therefore, the macroscopic mucosal appearance is also considered a valuable indicator of disease activity. In this regard, disease activity index including endoscopic severity has been used in ulcerative colitis and Crohn's disease (CD).

Research frontiers

A study investigating a cohort of CD patients under long-term treatment with infliximab recently reported that mucosal healing was associated with a significantly lower need for abdominal surgery and data from the Active Ulcerative Colitis Trials 1 and 2 have suggested that mucosal healing was associated with a decreased risk of relapse. Moreover, because endoscopy could provide a direct assessment of the disease extent and severity, endoscopic severity has been estimated in IBD. However, although the disease activity index for intestinal Behcet's disease (DAIBD) was recently introduced, there are no specific tools for the measurement of endoscopic severity in intestinal Behcet's disease (BD).

Innovations and breakthroughs

This is the first study to consider the use of endoscopy as a measurement tool of disease status in intestinal BD. Their study demonstrated that the number of intestinal ulcers and volcano-shaped ulcers were predictive factors for severe DAIBD scores. However, the correlation between endoscopic severity and DAIBD (r = 0.434) was weak. Patients with severe DAIBD scores but with moderately predicted disease activity by the endoscopic severity model had more symptoms of irritable bowel syndrome and a lower rate of corticosteroid use than those with severe DAIBD scores and accurately predicted disease by the model.

Applications

This study suggests that clinicians should closely observe patients with two or more intestinal ulcers and those with volcano-shaped ulcers and that these endoscopic findings could help clinicians make decisions regarding medical strategies for the treatment of intestinal BD. Furthermore, the understanding of discrepancy between actual and predicted DAIBD by the endoscopic severity model could be helpful in making an appropriate decision regarding medical strategies.

Terminology

BD is a chronic, relapsing, multi-systemic inflammatory disorder and intestinal BD is diagnosed when patients with BD have predominant gastrointestinal symptoms and show intestinal ulcerations according to objective measures.

Peer review

In the present study, the authors showed that the number of intestinal ulcers and volcano-shaped ulcers were predictive factors for severe DAIBD scores, and that the correlation between endoscopic severity and DAIBD (r = 0.434) was weak. This study was well-investigated and will give us interesting information about the clinical indices of intestinal Behcet's disease.

Abstract

AIM: To perform a meta-analysis of observational studies to further elucidate the relationship between oral bisphosphonate use and gastrointestinal cancer risk.

METHODS: Systematic literature search was conducted in MEDLINE, EMBASE, and the Cochrane Library to identify studies through January 2011. Search terms were "bisphosphonates" or trade names of the drugs, and "observational studies" or "cohort studies" or "case-control studies". Two evaluators reviewed and selected articles on the basis of predetermined selection criteria as followed: (1) observational studies (case-control or cohort studies) on bisphosphonate use; (2) with at least 2 years of follow-up; and (3) reported data on the incidence of cancer diagnosis. The DerSimonian and Laird random effects model were used to calculate the pooled relative risk (RR) with 95% confidence interval (CI). Two-by-two contingency table was used to calculate the outcomes not suitable for meta-analysis. Subgroup meta-analyses were conducted for the type of cancer (esophageal, gastric and colorectal cancers). Sensitivity analyses were performed to examine the effect sizes when only studies with long-term follow-up (mean 5 years; subgroup 3 years) were included.

RESULTS: Of 740 screened articles, 3 cohort studies and 3 case-control studies were included in the analyses. At first, 4 cohort studies and 3 case-control studies were selected for the analyses but one cohort study was excluded because the cancer outcomes were not categorized by type of gastrointestinal cancer. More than 124 686 subjects participated in the 3 cohort studies. The mean follow-up time in all of the cohort studies combined was approximately 3.88 years. The 3 case-control studies reported 3070 esophageal cancer cases and 15 417 controls, 2018 gastric cancer cases and 10 007 controls, and 11 574 colorectal cancer cases and 53 955 controls. The percentage of study participants who used bisphosphonate was 2.8% among the cases and 2.9% among the controls. The meta-analysis of all the studies found no significant association between bisphosphonate use and gastrointestinal cancer. Also no statistically significant association was found in a meta-analysis of long-term follow-up studies. There was no negative association between bisphosphonate use and the incidence of esophageal cancer in the overall analysis (RR 0.96, 95% CI: 0.65-1.42, I^2 = 52.8%, P = 0.076) and no statistically significant association with long-term follow-up (RR 1.74, 95% CI: 0.97-3.10, I^2 = 58.8%, P = 0.119). No negative association was found in the studies reporting the risk of gastric cancer (RR 0.89, 95% CI: 0.71-1.13, I^2 = 0.0%, P = 0.472). In case of colorectal cancer, there was no association between colorectal cancer and bisphosphonate use (RR 0.62, 95% CI: 0.30-1.29, I^2 = 88.0%, P = 0.004) and

also in the analysis with long-term follow-up (RR 0.61, 95% CI: 0.28-1.35, I^2 = 84.6%, P = 0.011).

CONCLUSION: Oral bisphosphonate use had no significant effect on gastrointestinal cancer risk. However, this finding should be validated in randomized controlled trials with long-term follow-up.

INTRODUCTION

Bisphosphonates are commonly used in postmenopausal women with osteoporosis. *In vitro* and *in vivo* studies have suggested that bisphosphonate has anticancer properties[1]: promoting apoptosis[2], inhibiting tumor cell adhesion and invasion[3], inhibiting angiogenesis[4], altering tumor-associated macrophage function[4], and enhancing immune surveillance[1,5]. However, it was recently reported that the Food and Drug Administration received reports of 23 cases of esophageal cancer in the United States and another 31 cases in Europe and Japan, all occurring from 1995 through 2008 among patients using oral bisphosphonates[6]. Since then, there have been several cohort studies and case-control studies to elucidate the association between the use of bisphosphonate and the risk of gastrointestinal tract cancer. However, results of the observational studies are inconsistent[7,8].

As yet, there have been no randomized controlled trials demonstrating a causal relationship between bisphosphonate use and gastrointestinal track cancer. Moreover, no meta-analysis has been performed despite the inconsistent results of observational studies. Therefore, in the present study, we aimed to investigate the association between the use of oral bisphosphonate and the risk of gastrointestinal cancer *via* meta-analysis of cohort studies and case-control studies.

MATERIALS AND METHODS

Study selection

We conducted a systematic literature search of MEDLINE, 1977 April 2011; EMBASE, 1971 April 2011; and the Cochrane Database of Systematic Reviews in the Cochrane Library, 1973 April 2011. We identified observational studies of bisphosphonate use whose primary or secondary outcomes included gastrointestinal tract cancer. The search terms were "bisphosphonates" or trade names of the drugs, and "observational studies" or "cohort studies" or "case-control studies" (Table 1). All the searches were restricted to human studies. In addition, a manual review of references from primary and review articles was performed to locate any additional relevant studies. All the potentially relevant articles were independently reviewed by 2 investigators (Oh YH and Yoon C). Disagreements between evaluators were resolved by discussion or consultation with a third author (Park SM).

The inclusion criteria were: (1) observational studies (case-control or cohort studies) on bisphosphonate use; (2) with at least 2 years of follow-up; and (3) reported data on the incidence of cancer diagnosis.

Data synthesis

To compute a pooled relative risk (RR) with 95% confidence interval (CI), we used the RRs or odds ratios and 95% CIs that were adjusted for most confounders. Because the incidence of cancer is generally low, we did not distinguish between the various measures of RR. If the outcome measures were unsuitable for meta-analysis, we calculated a crude estimate using a two-by-two contingency table.

We also assessed the heterogeneity for each meta-analysis by using the I^2 value which measures the percentage of total variation across that is attributable to heterogeneity rather than chance. High value of I^2 index suggests increased heterogeneity. We also calculated P value of Q-test which represents heterogeneity. If P value is less than 0.10, it represents there is heterogeneity.

Because of the known clinical and methodological heterogeneity of the studies we analyzed, we calculated the pooled RR with 95% CI based on the DerSimonian and Laird random effects model. We used Stata Version 11.0 (Stata Corp., College Station, Texas) for the statistical analysis.

Statistical analysis

Subgroup meta-analyses were carried out for the study design (cohort and case-control) and type of cancer. For the cancer subgroup analyses, esophageal, gastric and colorectal cancers were analyzed independently.

We also performed sensitivity analyses to examine the effect sizes when only studies with long-term follow-up (mean 5 years; subgroup 3 years) were included.

RESULTS

Identification of relevant studies

Figure 1 is a flow diagram of how we identified the relevant studies. Of the 740 articles identified, 4 cohort studies[7,9-11] and 3 case-control studies[8,12,13] were selected for the analyses. Many of initial 742 articles are not in

our scope. They are mainly about effect of bisphosphonates, effects of several types of bisphosphonate regimen, other adverse effects of bisphosphonate, such as atrial fibrillation, osteonecrosis of jaw syndrome, and anti-cancerous bisphosphonate use for breast cancer and prostate cancer. We performed review of titles and abstract of the articles, then excluded irrelevant for our study. Thirty articles were remained after overall process, but 23 of 30 articles included no available data for outcome measures. One cohort study[9] was excluded because the cancer outcomes were not categorized by type of gastrointestinal cancer.

We also contacted Dr. Chris Cardwell to ask the data for the adjusted hazards ratio and 95% CI for gastric cancer only in bisphosphonate users[7].

Characteristics of the studies included in the analyses

More than 124 686 subjects participated in the 3 cohort studies[7,10,11] used in our meta-analyses. The mean follow-up time in all of the cohort studies combined was approximately 3.88 years (range: 0.5-13 years). The 3 case-control studies[8,12,13] used in our meta-analyses reported the number of cases and controls: 3070 esophageal cancer cases and 15 417 controls, 2018 gastric cancer cases and 10 007 controls, and 11 574 colorectal cancer cases and 53 955 controls. The percentage of study participants who used bisphosphonate was 2.8% among the cases and 2.9% among the controls. Tables 2 and 3 summarize the general characteristics of the studies included in our analyses.

The methods of the studies we included were assessed on the basis of 5 predetermined quality assessment items (Table 4). All of the studies included in our analyses were based on the secure record linkage regarding medication use and cancer diagnosis.

Association between bisphosphonate use and the risk of gastrointestinal tract cancer

There was no negative association between bisphosphonate use and the incidence of esophageal cancer in the overall analysis (RR 0.96, 95% CI: 0.65 1.42, I^2 = 52.8%, P = 0.076; Figure 2A). In 2 studies with long-term follow-up, there was a tendency for bisphosphonate users to develop esophageal cancer; however, this finding was not statistically significant (RR 1.74, 95% CI: 0.97-3.10, I^2 = 58.8%, P = 0.119). No significant association was

found in the studies[8,14] reporting the risk of gastric cancer (RR 0.89, 95% CI: 0.71-1.13, I^2 = 0.0%, P = 0.472; Figure 2B).

Bisphosphonate users were less likely to receive a diagnosis of colorectal cancer; however, this finding was not statistically significant in the overall analysis (RR 0.62, 95% CI: 0.30-1.29, I^2 = 88.0%, P = 0.004) or in the analysis limited to studies with long-term follow-up (RR 0.61, 95% CI: 0.28-1.35, I^2 = 84.6%, P = 0.011; Figure 2C).

DISCUSSION

Main findings

In the present study, we examined the association between oral bisphosphonate use and the incidence of gastrointestinal tract cancer by analyzing the results of previ-

ous observational studies. Our meta-analyses found no significant association between the use of oral bisphosphonate and the overall gastrointestinal cancer incidence.

In the study design subgroup meta-analysis, no statistically significant association was found for the cohort studies or case-control studies. The cancer type subgroup analysis identified no association between bisphosphonate use and esophageal cancer or gastric cancer. Colorectal cancer was less likely to be diagnosed in bisphosphonate users; however, this finding was not statistically significant. The results of the sensitivity analyses of the studies with more than 3 years of oral bisphosphonate use were similar to those of the overall analyses.

According to our analyses, oral bisphosphonate seems to have little association with the incidence of gastrointestinal cancer.

It is well known that the use of oral bisphosphonate induces gastrointestinal problems, such as erosive esophagitis[15]. The endoscopic and histological findings of mucosal injury of the esophagus in patients using oral bisphosphonates[15-20] suggest that prolonged use may increase the risk of esophageal cancer. Green *et al*[8] analyzed the United

Kingdom General Practice Research Database and reported that bisphosphonate use increases esophageal cancer risk (RR 1.30, 95% CI: 1.02-1.66). The cancer-promoting effect was even greater in patients who used the drug for more than 3 years (RR 2.24, 95% CI: 1.47-3.43). We can infer from this result that bisphosphonate should be restricted among people with risk factors for esophageal cancer, such as Barrettv's esophagus. However, according to the study of Nguyen *et al*[12], the use of oral bisphosphonate does not increase the risk of esophageal adenocarcinoma in patients with Barrett's esophagus (incidence density ratio 0.92; 95% CI: 0.21-4.15). The risk of esophageal adenocarcinoma in patients with Barrett's esophagus is 30- to 125-fold greater than the risk in the general population[21]. The carcinogenic effect of oral bisphosphonate, including damage to the esophagus due to the toxicity of the drug itself and the effect of contact between the pill and the esophageal mucosa[15], may expedite the development of esophageal cancer in patients with Barrett's esophagus. However, a correlation between the risk of esophageal adenocarcinoma and use of oral bisphosphonate by patients with Barrett's esophagus is inconsistent with the concept of the so-called Barrett pathway.

Several *in vivo* and *in vitro* studies suggest that bisphosphonate has anticancerous properties[1-5]. Clinical studies also implicate the anticancerous effect of bisphosphonate in breast cancer[22]. It can be inferred from these

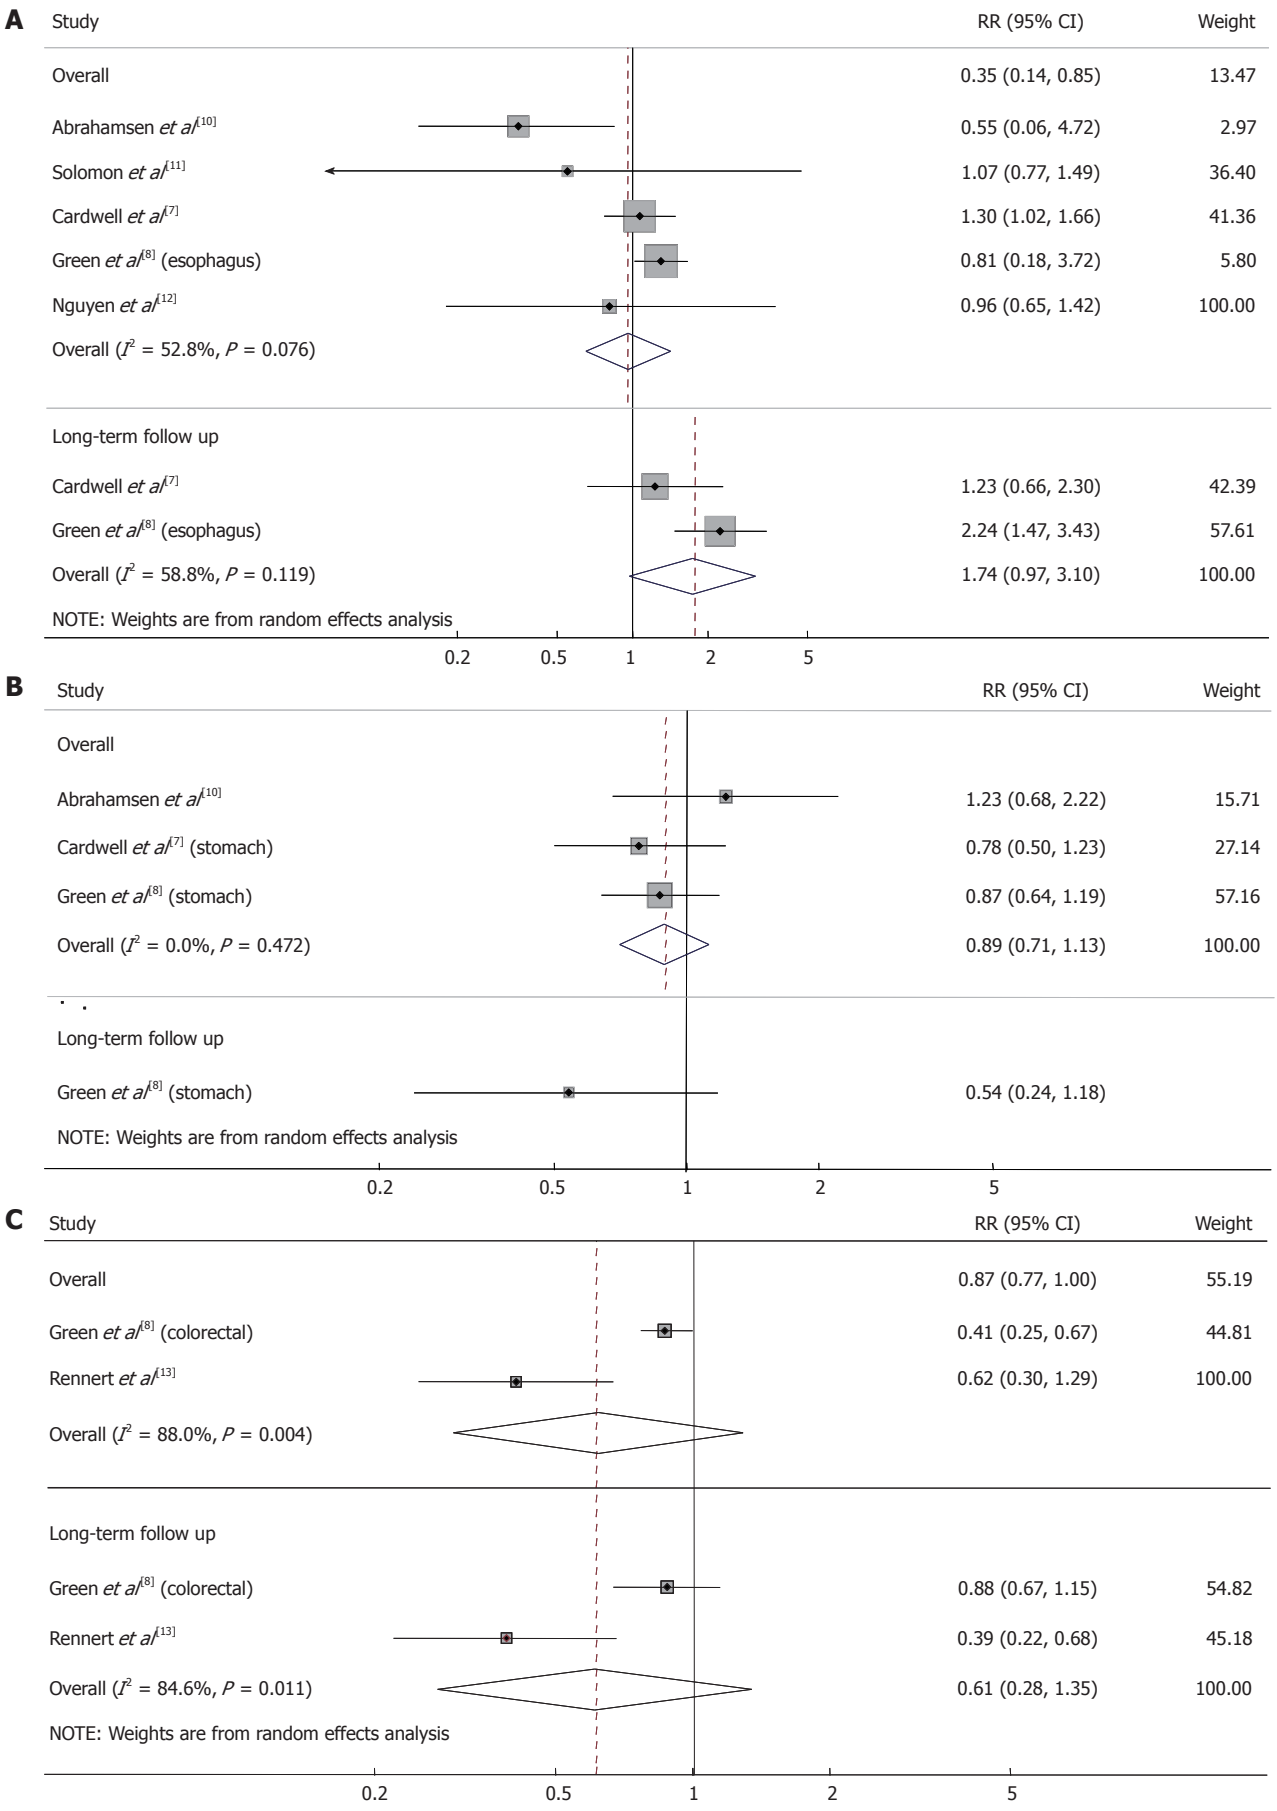

Figure 2 Association between bisphosphonate use and some cancer risk using the meta-analysis of the random effects model. A: Esophageal cancer risk; B: Gastric cancer risk; C: Colorectal cancer risk.

studies that there is no significant association between the use of oral bisphosphonate and the risk of esophageal cancer because bisphosphonate has anticancerous effects. As for procancerous effects, oral bisphosphonate directly irritates the esophageal mucosa and induces erosive esophagitis. On the contrary, bisphosphonate directly and indirectly interferes with cancer cell growth. Our finding about the correlation between the risk of esophageal cancer and oral bisphosphonate use suggests that the procancerous and anticancerous effects of bisphosphonate may cancel each other out.

There is also an implication about esophageal cancer within the statistical results in our study. Two observational studies that have great significance in our meta-analyses Caldwell *et al*[7] and Green *et al*[8], reported discrepant results (Figure 2A). According to the analyses of Dixon *et al*[23], the time-dependent RRs of esophageal cancer and oral bisphosphonate indicate no significant increased risk for esophageal cancer within 3 years of oral bisphosphonate use. However, when these investigators restricted their analyses to bisphosphonate use for more than 3 years, their results were different[23]. The Caldwell study[7] reported a RR of 1.01 (95% CI: 0.48-2.12); Green *et al*[8] reported a RR of 2.24 (95% CI: 1.47-3.43). The result of our meta-analysis was a RR of 1.74 (95% CI: 0.97-3.10) for the follow-up longer than 3 years. Our results show no statistical correlation between the long-term oral bisphosphonate use and the risk of esophageal cancer. However, in the study of Caldwell *et al*[7], the RR increased to 1.23 (95% CI: 0.66-2.3) when the analysis was restricted to a group of patients with a mean bisphosphonate use duration of 6.8 years. These results indicate that there is somewhat an association between prolonged oral bisphosphonate use and risk of esophageal cancer. Both studies used data from the Uinted Kingdom General Practice Research Database. Inconsistency between the 2 studies may be explained by differences in study design and confounding that could not be measured.

As stated previously, oral bisphosphonates induce esophagitis[15] and esophageal cancer that can be developed from reflux esophagitis through the Barrett pathway[19,20], and this is not a one-time process; it takes time. For this reason, recurrent injuries and healing processes induced by prolonged oral bisphosphonate use could be clinically meaningful factors. The long-term effect of oral bisphosphonate could be confirmed by an observational study that focuses on much longer periods of oral bisphosphonate use.

Regarding gastric cancer, our results show no significant association with oral bisphosphonate use. There is only 1 study that estimates RR dependent on duration of oral bisphosphonate use. Although there is no statistical significance, Green *et al*[8] found that RR is less for those using oral bisphosphonate longer than 3 years (RR 0.54, 95% CI: 0.24-1.18) than for those using oral bisphosphonate shorter than 3 years (RR 1.03, 95% CI: 0.67-1.59 for less than 1 year; RR 0.89, 95% CI: 0.52-1.53 for 1-3 years). This implies that there is no cumulative effect of oral bisphosphonate on the risk of gastric cancer. If bisphosphonate has competing procancerous and anticancerous properties, it may not affect the risk of cancer.

We performed a random-effects model analysis of the data on colorectal cancer because of high heterogeneity (I^2 = 88.0%, P = 0.004). According to our meta-analysis, oral bisphosphonate use demonstrates no effect on the risk of colorectal cancer (RR 0.62, 95% CI: 0.30-1.29). The analysis of the long-term use (more than 3 years) revealed that there is no statistically significant association between oral bisphosphonate use and colorectal cancer (RR 0.61, 95% CI: 0.28-1.35). However, the subgroup analysis shows a significant negative association between oral bisphosphonate use and the incidence of colorectal cancer (RR 0.87, 95% CI: 0.77-1.00; RR 0.41, 95% CI: 0.25-0.67). Therefore, it may be hasty to conclude on the basis of overall meta-analysis that oral bisphosphonate use does not affect colorectal cancer. In the study by Rennert *et al*[13], cases and controls were matched for age, ethnicity, family history of colorectal cancer, sports activity, vegetable consumption, body mass index (BMI), low-dose aspirin use, statin use, postmenopausal hormone use, calcium supplement use, and vitamin use, all of which can affect the risk of colorectal cancer. However, in Green *et al*[8], RRs were only adjusted for smoking status, alcohol intake and BMI. Thus, there were important differences in the study design and quality of methods.

The study by Rennert *et al*[13] implies that oral bisphosphonate has a protective effect against colorectal and breast cancers. The anticancerous effects of bisphosphonate, such as promoting apoptosis[2], inhibiting tumor cell adhesion and invasion[3], inhibiting angiogenesis[4], altering tumor-associated macrophage function[4], and enhancing immune surveillance, as previously mentioned, may have a key role in such a protective effect. One study reported that ibandronate reduces the incidence of colorectal dysplasia in mice with induced ulcerative colitis[24]. In colorectal cancer, different from esophageal cancer, oral bisphosphonate does not directly injure the intestinal mucosa or induce chronic mucosal inflammation and healing processes.

Considering this background, the results of our meta-analyses should be interpreted as inconclusive. A well-designed randomized controlled study or prospective cohort study is needed to confirm the preventive effect of oral bisphosphonate against colorectal cancer.

Our study has a few limitations. First, the number of studies we analyzed is small. There have been few studies about the correlation between oral bisphosphonate use and the risk for gastrointestinal cancer. For this reason, each study that reported on colorectal cancer reported a negative association, but the overall meta-analysis showed no statistical significance. Thus, oral bisphosphonate use is seemingly irrelevant to colorectal cancer. Second, the quality of our study depends on data from

original publications. Our study inevitably inherits some problems from the observational studies, such as selection bias, surveillance bias, and confounding. For example, more esophageal and gastric abnormalities might be observed in bisphosphonate users simply because they receive more endoscopic exams for abdominal discomfort caused by oral bisphosphonate.

We discussed the small number of studies regarding bisphosphonate use and development of gastrointestinal cancer in our article as a limitation. However, the actual number of overall subjects in our meta-analysis is not too small. In cohort studies, 124 686 subjects with mean follow up of 3.88 years were included in the final analysis. In case of case-control studies, there were 3070 esophageal cancer cases, 2018 gastric cancer cases and 11 574 colorectal cancer cases were included as well. Moreover, the results of two large observational studies were inconsistent. Caldwell *et al*[7] showed no significant association between bisphosphonate use and esophageal cancer. On the other hand, Green *et al*[8] had revealed the significant association. The inconsistent results of observational studies suggest the need of further studies as well as a meta-analysis.

Despite the negative results, our study is meaningful since it provides not an ultimate but a reasonable interim conclusion regarding the safety of bisphosphonate use before definite accumulation of long-term observational studies.

In summary, our meta-analyses indicate that there is no significant association between oral bisphosphonate use and the risk of gastrointestinal cancer. Oral bisphosphonate use has no significant association with the risk of esophageal cancer. There is an increased, though not statistically significant, risk of esophageal cancer in long-term users of oral bisphosphonate. An observational study focused on long-term use of bisphosphonate is needed to confirm this finding. The risk of gastric cancer is not associated with oral bisphosphonate use. Each study reporting on colorectal cancer indicates a negative association between the risk of colorectal cancer and oral bisphosphonate use, but our meta-analysis showed no statistically significant association. The confidence intervals were large (95% CI: 0.30-1.29). Thus, a randomized controlled trial or prospective cohort study should be performed to confirm the preventive effect of oral bisphosphonate.

COMMENTS

Background

There rises concerns about bisphosphonate use after the reports of 23 cases of esophageal cancer in the United States and another 31 cases in Europe and Japan, all occurring from 1995 through 2008 among patients using oral bisphosphonates. Bisphosphonate induced esophagitis, Barrett's esophagus and gastric ulcer can be the precancerous condition. There were observational studies to evaluate the risk between esophageal cancer and bisphosphonate use. But the results were inconsistent. So the overall evaluation of the association between gastrointestinal cancer and bisphosphonate is required.

Research frontiers

Meta-analysis was used to evaluate the risk of bisphosphonate for gastrointestinal cancer (esophageal, stomach, and colorectal cancer) in this study.

Innovations and breakthroughs

This meta-analysis systemically assessed the relation between bisphosphonate use and gastrointestinal cancer risk, and also showed site specific, long-term follow up results.

Applications

The results of meta-analysis in this study show that use of bisphosphonate has no significant association with gastrointestinal cancers. According to the results, bisphosphonate can be used without charge of carcinogen for now. But there should be a far more long-term observational studies to guarantee the long-term safety.

Terminology

Meta-analysis is method focused on contrasting and combining results from different studies to show the overall conclusion. It is essential component of a systematic review procedure.

Peer review

This is a good descriptive study in which authors perform a meta-analysis of observational studies to further elucidate the relationship between oral bisphosphonate use and gastrointestinal cancer risk. The results are interesting and suggest that oral bisphosphonate use had no significant effect on gastrointestinal cancer risk.

Abstract

AIM: To investigate the prevalence of cholelithiasis among patients treated with ezetimibe.

METHODS: A retrospective, case-control study based on computerized medical records from patients of the Clalit Health Services, Sharon-Shomron region, from 2000 to 2009. Patients 20-85 years of age, who had been treated with ezetimibe and statins or statins only for at least 6 mo, and who had an abdominal ultrasound were included in the study. Collected data included age, gender, ezetimibe treatment duration, presence of hypothyroidism or diabetes, and existence of cholelithiasis as determined by ultrasound. Excluded were subjects after gallbladder resection, with hemolysis, myeloproliferative or inflammatory bowel diseases, and those treated with ursodeoxycholic acid and fibrates. Patients treated with statins and ezetimibe (study group) were compared to patients treated with statins only (control group).

RESULTS: The study group included 25 patients and the control group 168. All patients in the study were treated with statins. The study group included 13 males (52%) and 12 females (48%), the control group 76 males (45%) and 92 (55%) females (P = 0.544). The groups did not differ in age (mean age: 68 ± 8 years, range 53-85 years *vs* mean age: 71 ± 8 years, range 51-85 years; P = 0.153) or in the rate of diabetic and hypothyroid patients [11 (44%) *vs* 57 (33%), P = 0.347 in the study group and 5 (20%) *vs* 23 (14%), P = 0.449 in the control group, respectively]. Patients in the study group were treated with ezetimibe for an average of 798 ± 379 d. Cholelithiasis was found in 4 (16%) patients in the study group and in 33 (20%) patients in the control group (P = 0.666).

CONCLUSION: Ezetimibe does not appear to influence the prevalence of gallstones.

INTRODUCTION

Cholelithiasis is one of the most common diseases of the digestive system in the developed world. Its prevalence according to ultrasound-based studies is estimated to be 18.8% in females and 9.5% in males. Cholesterol stones make up 80%-90% of the gallstones in the Western world[1-8].

A delicate balance exists in the bile between the con-

centration of cholesterol and its main solubilizers, bile acids and phospholipids. Once the carrying capacity of cholesterol is exceeded, it can crystallize and initiate the formation of gallstones[5].

The treatment of hyperlipidemia consists of the inhibition of the two cholesterol sources in the body. Statins reduce cholesterol synthesis by inhibiting the key enzyme hydroxy methylglutaryl coenzyme A reductase, while ezetimibe decreases intestinal cholesterol absorption[9-12].

Ezetimibe blocks the mucosal Niemann-Pick C1-like1 receptor (NPC1L1)[12-18]. This causes a decrease in cholesterol absorption from the small intestine[16,19-22], loss of cholesterol into the stool and a decrease in the amount of cholesterol delivered to the liver and bile, thereby reducing the amount of cholesterol available for the formation of gallstones. Human liver cells also express the NPC1L1 receptor, which is located on the canalicular membrane and retains cholesterol by preventing its loss into bile and stool[12,13]. Thus, an opposite effect on bile is expected: biliary cholesterol enrichment and the formation of crystals and stones may occur when the receptor is inhibited by ezetimibe[12].

A few recent studies have evaluated the effects of hypocholesterolemic medication on gallstone formation. One study addressed the role of the hepatocyte NPC1L1 receptor and its function in cholesterol absorption from the biliary tract[12,13]. Transgenic mice with Hepatic NPC1L1receptor over-expression had a 10-30 fold decrease in biliary cholesterol without any effect on phospholipids or bile acid concentration. Biliary and plasma cholesterol concentrations returned to normal when ezetimibe was added[12]. In another study, Altmann *et al*[13] evaluated the effect of ezetimibe on gallstone formation in gallstone-susceptible mice. Ezetimibe prevented the formation of gallstones by effectively reducing intestinal cholesterol absorption. In the same study, 30 d of ezetimibe treatment was reported to decrease the biliary cholesterol concentrations and cholesterol saturation index in overweight patients with and without gallstones. Another study reported fewer cholecystectomies among subjects treated with statins compared to those not treated with the drug[14].

The aim of this study was to evaluate the prevalence of cholelithiasis among patients treated with ezetimibe. Since ezetimibe is usually not prescribed as monotherapy, we addressed the question in patients treated with concomitant statins.

MATERIALS AND METHODS

This retrospective case-control study was based on a review of computerized medical records of patients in the Sharon-Shomron region of Clalit Health Services (CHS), the largest health maintenance organization in Israel (and the second largest in the world), from 2000 to 2009.

The demographic and clinical data of all CHS members are contained in a central computer. This database is automatically updated with hospitalizations, invasive procedures, laboratory and imaging results, prescribed and purchased medications and mortality data.

The study inclusion criteria were patients 20 to 85 years of age, taking statins or statins and ezetimibe, with abdominal ultrasound results that included the presence or absence of gallstones. Statin or statin and ezetimibe treatment must have begun at least six months prior to the ultrasound. Subjects after gall bladder resection, with hemolysis, myeloproliferative or inflammatory bowel diseases, and those treated with ursodeoxycholic acid and fibrates were excluded.

The extracted data included age, gender, ezetimibe treatment duration, comorbidity with diabetes mellitus or hypothyroidism and the presence of gallstones based on abdominal ultrasound.

Patients were eligible for the study regardless of the indication for the ultrasound. In cases where a patient had more than one ultrasound, the most recent result was considered. All the scans were reviewed by an experienced radiologist.

Patients treated with ezetimibe and statins were compared to a matched control group of patients treated with statins only, to evaluate the prevalence of cholelithiasis.

The work was approved by the ethics committee of our institution (Helsinki Committee, Meir Medical Center, Israel, approval No. 020-09).

Statistical analysis

Data from the study groups were analyzed using the Pearson χ^2 test or the Fisher's exact test (each when appropriate) for non-parametric data and *t* test for continuous parametric data.

RESULTS

The study group included 25 patients treated with statins and ezetimibe. The control group consisted of 168 patients treated with statins only. Clinical and demographic data are presented in Table 1.

There were 13 males (52%) and 12 females (48%) in the study group and 76 males (45%) and 92 (55%) females ($P = 0.544$) in the control group. The groups did not differ in age (mean age: 68 ± 8 years, range 53-85 years *vs* 71 ± 8 years, range 51-85 years; $P = 0.153$) or in the rate of diabetic and hypothyroid patients [11 (44%) *vs* 57 (33%), $P = 0.347$ in the study group and 5 (20%) *vs* 23 (14%), $P = 0.449$ in the control group, respectively]. The mean duration of ezetimibe treatment was 798 ± 379 d. All patients were treated with statins. In the study group: simvastatin in 6 patients, atorvastatin 8, rosuvastatin 7 and pravastatin 4.

Cholelithiasis was found in 4 study group patients; 1 taking simvastatin and 3 treated with atorvastatin. In the control group: simvastatin 119, atorvastatin 19, rosuvastatin 11, and pravastatin 17 patients. Among the control group, 28 of the 33 gallstone positive patients had been

Table 1 Demographic and clinical characteristics of the patient groups

Study parameters	Study group (statins + ezetimibe) (n = 25)	Control group (statins only) (n = 168)	P value
Male/female	13 (52)/12 (48)	76 (46)/92 (55)	0.544
Mean age (yr)	68 ± 8	71 ± 8	0.153
Co-morbidities			
Diabetes	11 (44)	57 (34)	0.347
Hypothyroidism	2 (20)	23 (14)	0.449
Ezetimibe treatment			
Mean period (d)	799 ± 379		
Range (d)	183-1540		
Patients with gallstones	4 (16)	33 (20)	0.666

Data are presented as mean ± SD or n (%).

treated with simvastatin, 4 with atorvastatin, and 1 with rosuvastatin.

No statistically significant difference was found in the prevalence of gallstones in the study group (4, 16%) compared to the control group (30, 20%), $P = 0.666$.

No statistically significant differences were found in the prevalence of gallstones when controlling for age. Among patients ≤ 65, gallstones were present in 2 (18%) in the study group compared to 8 (17%) in the control group, $P = 0.619$. Among patients older than 65 years of age cholelithiasis was present in 2 (14%) study group patients and 25 (21%) control group patients, $P = 1$ by Fisher's exact test.

DISCUSSION

The results of this study show that treatment with ezetimibe in addition to statin therapy did not influence the prevalence of cholelithiasis. We compared patients treated with ezetimibe and statins to those treated with statins only because ezetimibe, which is not effective when used as monotherapy [low-density lipoprotein cholesterol (LDL-C) reduction of only about 16%], is usually given in combination with statins to patients who do not reach the recommended LDL-C levels with statin treatment (where it provides an additional reduction of 25% in LDL-C levels)[16,19-25].

The study was initiated because of two contradictory findings concerning the effect of ezetimibe on bile composition and gallstone formation[12,13]. Temel *et al*[12] addressed the inhibition of the hepatic canalicular membrane NPC1L1 receptor, which absorbs cholesterol from the bile. Inhibition of the receptor increases biliary cholesterol levels and the possibility of gallstone formation. In contrast, Altmann *et al*[13] reported that ezetimibe treatment resulted in decreased cholesterol bowel absorption and a net change in the bile composition to a less lithogenic type, when used in a mouse model as well as in human subjects[13].

To date, it is not clear whether statin-ezetimibe treatment over time leads to an increase or decrease in the prevalence of gallstones. A recent study revealed that statin-treated patients had fewer cholecystectomies compared to patients who did not take statins[14]. However, that study did not address the presence of gallstones or ezetimibe treatment[14]. Our study showed that the combination of statin and ezetimibe did not affect gallstone formation. A possible explanation could be the fact that statin treatment reduces the prevalence of gallstones, which masks the effect of ezetimibe on cholelithiasis.

The study has limitations, including the small number of patients who received ezetimibe and lack of information regarding the presence of gallstones prior to treatment with ezetimibe. However, this lack of information was true for both study groups. Another possible weakness might be the duration of ezetimibe treatment. Nevertheless, a mean duration of over two years seems a reasonable period in which to assess both gallstone formation and dissolution.

In conclusion, adding ezetimibe to statin therapy did not affect the prevalence of gallstones compared to treatment with statins alone.

ACKNOWLEDGMENTS

This study has been presented in abstract form at the Digestive Disease Week in Chicago May 8, 2011.

COMMENTS

Background

Hyperlipidemia treatment consists of the inhibition of the two cholesterol sources in the body. Statins reduce cholesterol synthesis by inhibiting the key enzyme hydroxy methylglutaryl coenzyme A reductase, while ezetimibe decreases intestinal cholesterol absorption. This study was initiated because of two contradictory findings concerning the effect of ezetimibe on bile composition and gallstone formation. To date, it is not clear whether statin-ezetimibe treatment over time leads to an increase or decrease in the prevalence of gallstones.

Research frontiers

When using a combination of a statin and ezetimibe for the treatment of hyperlipidemia, it is unclear whether statin-ezetimibe treatment leads to an increase or decrease in the prevalence of gallstones over time. In this study, the authors did not demonstrate a reduction in gallstone prevalence.

Innovations and breakthroughs

This study shows that ezetimibe in combination with a statin does not affect gallstone formation.

Applications

Despite promising data in animal models, ezetimibe seems to have no potential in treating human gallstone disease.

Peer review

This is a good descriptive study in which authors investigate the prevalence of cholelithiasis among patients treated with ezetimibe. It is a retrospective study with negative results, yet it does convey a logical reason for the study. Hence, it may be accepted as a short paper.

Abstract

AIM: To observe the efficacy of peg-interferon in the treatment of hepatitis delta virus (HDV) and to identify the factors that would be predictive of the sustained viral response (SVR).

METHODS: This prospective study was conducted in Medical Unit Ⅳ of the Liaquat University of Medical and Health Sciences Hospital Jamshoro from June 2008 to September 2011. This study cohort included all patients of either sex who presented during this time with hepatitis B surface antigen positivity, hepatitis B virus DNA > 20 000 IU/mL, serum glutamic pyruvic transaminase (SGPT) > 2(upper limit of normal), HDV-RNA positivity with fibrosis stage ≥ 2. Informed consent was obtained from each of these individuals. Patients were diagnosed with hepatitis D on the basis of detectable viral antibodies and the presence of HDV-RNA in their serum. A liver biopsy was performed in all cases and fibrosis staging was performed in accordance with the METAVIR scoring system. All eligible patients were administered peg-interferon at a weekly dosage of 1.5 μg/kg body weight for 48 wk. HDV-RNA was assayed at the end of this treatment period and again at 24 wk later. A biochemical response was determined by a normalization of SGPT at the end of the treatment or during follow up. The end of treatment response was defined by a HDV-RNA negative status. A sustained virological response was defined by undetectable serum HDV-RNA at six months after the end of treatment.

RESULTS: Among the 277 patients enrolled in our present study, 238 completed a course of peg-interferon therapy of which 180 (75.6%) were male and 58 (24.4%) female. Biochemical responses were achieved in 122/238 (51.3%) patients. End of treatment responses were achieved in 71/238 (29.8%) cases. A SVR was achieved in 70 of these patients (29.4%). A strong association was found between the SVR and the end of treatment responses (P = 0.001), biochemical responses (P = 0.001) and the degree of fibrosis (P = 0.002).

CONCLUSION: Peg-interferon therapy can induce remission in nearly one third of patients harboring HDV.

INTRODUCTION

Hepatitis delta virus (HDV) is a defective RNA virus that requires hepatitis B virus (HBV) to achieve replication. In long-term carriers of HBV, HDV infection can result in acute fulminant hepatitis or severe chronic hepatitis often progressing to cirrhosis and hepatocellular carcinoma[1]. Nearly 15-30 million people worldwide are infected with HDV[2]. Hepatitis D is dependent on hepatitis B for its prevalence. In Pakistan, the prevalence of hepatitis B is about 2.5% but in certain areas of Sindh province is much higher, in the range of 4.5% to 6.4%, with consequent increases in the prevalence of hepatitis D[3]. These areas are collectively referred to as the delta belt.

The introduction of a vaccination program for HBV, blood testing including that of pregnant women, the application of safety measures against blood born infections, the use of disposable syringes, and an increased public awareness of hepatitis B has markedly reduced the prevalence of this disease in many countries. However, hepatitis B is still a major health problem in several countries including Pakistan where HDV was found in 16.6% of hepatitis B carriers[4,5]. Indeed, a recently published study has detected HDV in 36.6% to 69.5% of hepatitis B patients in different parts of Pakistan[6].

The treatment options for HDV have remained disappointing over many years. Oral agents such as ribavirin, lamivudine, and famciclovir have been found to be ineffective against HDV[7]. The effectiveness of currently available and seemingly more potent oral antiviral drugs against hepatitis B such as adefovir, dipivoxil, entecavir, telbivudine and tenofovir is difficult to assess due to a lack of adequate clinical data[8]. The only medication which has proved effective to date against HDV infection is interferon. Up to 70% of affected patients can achieve biochemical responses using this drug, among which significant numbers achieve a virological response[9]. The efficacy of interferon based treatments is dose related, as a 12 mo treatment at 9 MU was found to be more effective than lower dose regimens. Unfortunately because of the dose-related side effects of standard interferon, patient compliance has tended to be very poor[10]. Recently however, peg-interferon, a product of the conjugation of interferon with polyethylene glycol has replaced standard interferon in clinical use because its prolonged half life allows for a single weekly dose to be administered. There are few previous studies of peg-interferon variant to date and it is difficult to draw any conclusions regarding its efficacy[11]. An evaluation of this drug in a large number of patients is therefore required and is also necessary to assess the factors that are predictive of a viral response in the treated patients.

The aim of our current study was to observe the efficacy of peg-interferon in the treatment of HDV and to evaluate the factors that are predictive of an sustained viral response (SVR) in the treated patients.

MATERIALS AND METHODS

Patients and clinical setting

This prospective study was conducted in Medical Unit Ⅳ of the Liaquat University of Medical and Health Sciences Hospital, Jamshoro, from June 2008 to September 2011. The patient cohort comprised consecutive cases of either sex who were hepatitis B surface antigen (HBsAg) positive, had HBV DNA > 20 000 IU/mL, a serum glutamic pyruvic transaminase (SGPT) > 2 (upper limit of normal), and were HDV-RNA positive with a fibrosis stage ⩾ 2. Informed consent was obtained from each patient and the study was performed in accordance with the ethical guidelines of the 1975 Declaration of Helsinki. All of the subject patients were received from Hepatitis Prevention and Control Program, Sindh Chief Minister's initiative.

Exclusion criteria

We did not include patients below 18 or above 65 years age; with concomitant hepatitis C virus infection; fibrosis stage < 2 on liver biopsy; or with decompensated cirrhosis of the liver, i.e., history of ascites, variceal bleeding or hepatic encephalopathy. Also excluded were pregnant women or nursing mothers and cases of metabolic liver disease such as Wilson disease or hemochromatosis. Leukopenia (< 2500/mm^3), neutropenia (< 1000/mm^3), hemoglobin < 10 g/dL, and the presence of other severe diseases (cardiomyopathy, diabetes mellitus, arterial hypertension, neoplasia, neurologic diseases, depression and/or psychiatric disorders were additional exclusion criteria.

Methods

Patients were diagnosed with hepatitis D on the basis of antibodies and HDV-RNA in the serum. Patients in our cohort were also positive for HBsAg and had hepatitis B DNA levels > 20 000 IU/mL. Routine serological tests such as complete blood counts, liver function test, prothrombin time, SGPT, serum albumin, anti hepatitis D antibodies, HBsAg and an ultrasound of the abdomen were performed by the research laboratory of the Liaquat university of Medical and Health Sciences. Hepatitis D RNA and HBV-DNA tests were performed by the molecular laboratory of Liaquat university of Medical and Health Sciences. Liver biopsies were performed for all patients upon obtaining written consent and having fully explained the procedure to each individual. The biopsy procedure was performed in each case under ul-

SGPT: Serum glutamic pyruvic transaminase.

trasound guidance with a 14 gauge tru-cut biopsy needle. The biopsy sample was considered adequate if it was greater than 10 mm in size and contained more than 5 portal tracts[12]. Biopsy samples were sent to a pathologist who had no knowledge of the clinical status of the patient. The staging of fibrosis was performed in accordance with the METAVIR scoring system as follows: F0, no fibrosis; F1, portal fibrosis without septa; F2, few septa; F3, numerous septa without cirrhosis; or F4, cirrhosis[13].

Treatment and follow up

All eligible patients were administered peg-interferon weekly at 1.5 μg/kg body weight for 48 wk as part of the Hepatitis Prevention and Control Program, Sindh Chief Minister's initiative. This program was initiated by the Government of Sindh province in Pakistan and provides free peg-interferon-base treatments to all affected patients. This program covers a population of 55.24 million in the Sindh province of Pakistan.

Patients were followed up every month to obtain complete blood picture and SGPT. All patients were evaluated for possible complications of interferon therapy. HDV-RNA was assayed at the end of treatment and at 24th wk later. A biochemical response was confirmed if there was a normalization of the SGPT levels at the end of treatment or during follow up. An end of treatment response was defined as a HDV-RNA negative result at the end of treatment. An SVR was defined as undetectable HDV-RNA in the serum at six months after the end of treatment. A non responder was defined as a patient with persistent detectable HDV-RNA at the end of treatment[14].

Continuous variables such as age, SGPT and platelet count were computed as the mean ± SD. Categorical variables such as sex, end of treatment response, biochemical response, SVR and stage of fibrosis were expressed as a percentage. Receiver operating characteristic (ROC) curve comparisons were performed between the end of treatment response, biochemical response, stage of fibrosis with SVR by calculating the area under the curve and 95% confidence intervals (CIs) as described by Hanley *et al*[15]. A P value of 0.05 was considered statistically significant. All data were processed on SPSS Version 16.

Table 2 Relation between biochemical response, end of treatment response and stage of fibrosis with sustained viral response n (%)

Variable	SVR achieved	SVR not achieved	P value
BR	60/122 (49.1)	62/122 (50.9)	0.001
ETR	70/71 (98.5)	1/71 (1.5)	0.001
Stage of fibrosis			0.002
Stage 2	39/172 (22.6)	133/172 (77.3)	
Stage 3	18/44 (40.9)	26/44 (59.09)	
Stage 4	13/22 (59)	9/22 (40.9)	

SVR: Sustained viral response; BR: Biochemical response; ETR: End of treatment response.

RESULTS

Of the 277 patients enrolled in this study, 238 completed the course of interferon therapy. Among the remaining 39 patients, 31 were excluded from the study because of minimal (stage 0 and 1) fibrosis and eight patients were dropped because of interferon-induced complications early in study period. Of the remaining 238 patients who were analyzed, 180 (75.6%) were male and 58 (24.4%) female. The mean age was 29.6 ± 8.5 years, hemoglobin (g/dL) was 11.49 ± 2.45, platelet count (10^3/mm^3) was 145.6 ± 14.3, and SGPT (IU/L) was 134.18 ± 14.3. Hepatitis B DNA level (IU/mL) 155.1 ± 70.1. Fibrosis stage 2 was present in 172 (72.3%), stage 3 in 44 (18.5%) and stage 4 in 22 (9.2%) patients. A biochemical response was achieved in 122/238 (51.3%) patients and not in 116 (48.7%) cases. End of treatment responses were achieved in 71/238(29.8%) cases and not in 167 (70.2%) patients. SVR was achieved in 70 (29.4%) patients.

The baseline characteristics of the patients in the study cohort are listed in Table 1. A strong association was found between SVR and end of treatment response (P = 0.001) as 70/71 (98.5%) patients who obtained an end of treatment response also achieved an SVR. The association between an SVR and the stage of fibrosis was also significant (P = 0.002) as 39/172 (22.6%) patients with fibrosis stage 2, 18/44 (40.9%) patients with fibrosis stage 3 and 13/22 (59%) patients with fibrosis stage 4 achieved SVR, and with the biochemical response (P = 0.001) as 60/122 (49.1%) of such patients also achieved SVR. Table 2 shows relation of end of treatment response, biochemical response and stage of fibrosis with SVR. ROC curve comparing the end of treatment response, biochemical response, stage of fibrosis and SVR is shown in Figure 1. The end of treatment response was found to be predictive of an SVR with a sensitivity of 98%, specificity of 94%, positive

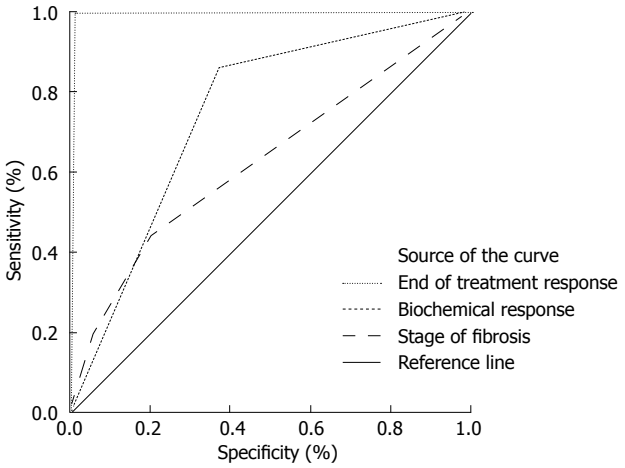

Figure 1 Receiver operating characteristic curve comparing end of treatment response, biochemical response, stage of fibrosis with sustained viral response. Receiver operating characteristic curve showing comparison between end of treatment response [area under curves (AUC) 0.997, 95% CI: 0.99-1.004], biochemical response (AUC 0.744, 95% CI: 0.67-0.81), stage of fibrosis (AUC 0.625, 95% CI: 0.54-0.70). The best predictor was end of treatment response at 99.7% (P = 0.001), followed by biochemical response 74.4% (P = 0.001) and stage of fibrosis 62.5% (P = 0.002).

predictive value (PPV) of 94.45, and negative predictive value (NPV) of 98% (P = 0.001). A biochemical response was also predictive of an SVR with a sensitivity of 85.7%, specificity of 63.2%, PPV of 69.9% and NPV of 81.5% (P = 0.001). The degree of fibrosis predicted an SVR with a sensitivity of 44.3%, specificity of 46%, PPV of 45% and NPV of 45.3% (P = 0.002).

DISCUSSION

This is the largest prospective study yet reported on the efficacy of peg-interferon monotherapy treatment for hepatitis D. The 238 patients included in the study cohort was far larger than the population analyzed in the previous hep-net-international delta hepatitis intervention trial, a multicenter trial comprising 90 patients in three arms. In our current prospective study, a biochemical response was achieved in 51.3%, end of treatment in 29.8% and SVR in 29.4% of the 238 patients with hepatitis D after 48 wk of peg-interferon therapy. Niro *et al*[16] previously studied 16 patients receiving peg-interferon for 72 wk and found biochemical response in 6 (37.5%) patients with 5 patients showing an end of treatment response and maintaining an SVR. In another earlier study by Wedemeyer *et al*[17] conducted on 29 patients receiving peg-interferon for 48 wk, a biochemical response was found in 8 (24%) cases and 9 (28%) patients showed an end of treatment response. When the therapy was extended to 72 wk, 13 (45%) patients achieved a complete biochemical response and 9 (31%) had an end of treatment response and SVR of 23% at 48 wk was improved to 28% at 72 wk. Erhardt *et al*[18] have reported that among 12 patients treated using peg-interferon, biochemical normalization occurred in 3 (25%) patients and an SVR in 2 (17%) patients. Castelnau *et al*[19] in their study of 12 patients treated for 12 mo with peg-interferon observed complete biochemical response in 8 (57%) patients, and an end of treatment response in 8 (57%) cases of whom 6 (43%) obtained an SVR. The discrepancies between the results of these various studies are likely due to the small number of patients analyzed.

In our present study, strong predictors of an SVR were an end of treatment response, biochemical response and the stage of fibrosis. We observed a strong association between the end of treatment response (P = 0.001) and an SVR as 70/71 (98.5%) patients achieved both responses. Indeed, an end of treatment response was predictive of an SVR with a PPV of 94.45% and an NPV of 98% (P = 0.001). Niro *et al*[16] also confirmed the importance of an end of treatment response as the 3/16 (19%) of their patients who achieved end of treatment response increased to 4/16 (25%) at the 24 wk follow up point. Wedemeyer *et al*[17] observed an end of treatment response in 9/29 (31%) of the patients in their cohort after 72 wk of treatment, out of which 5 patients maintained clearance of HDV-RNA at the end of follow up. However, the outcomes of the remaining four patients was unknown, making the end of treatment response an important predictor of SVR or end of follow up response.

Erhardt *et al*[18], in a study of 10 patients, found end of treatment response to peg-interferon in 2/10 (17%) cases that were maintained after 24 wk of follow up. Castelnau *et al*[19], in a study of 14 hepatitis D patients, report an SVR in all 8 (57%) patients who achieved an end of treatment virological response.

Based on our current findings, the biochemical response is an important predictor of an SVR as 60/70 (85.7%) (P = 0.001) of our hepatitis D patients achieved both responses. Niro *et al*[16] previously reported a biochemical response in 6 patients out of which 3 achieved SVR during a follow up of 11 patients for 72 wk. According to the study of Wedemeyer *et al*[17], 7 hepatitis D patients achieved SVR out of 13 (53.8%) patients who achieved a biochemical response after 72 wk of peg-interferon treatment. Castelnau *et al*[19] have reported that 75% of hepatitis D patients who achieved an end of treatment response were HDV-RNA negative six months after of the discontinuation of their treatment.

In our current analyses, the response to treatment increased with the degree of fibrosis (P = 0.002) as 39/172 (22.6%) patients with fibrosis stage 2, 18/44 (40.9%) patients with fibrosis stage 3 and 13/22 (59%) patients with fibrosis stage 4 achieved SVR. Reports on hepatitis D are sparse at present but the two publications recently presented at the 62nd Annual Meeting of the American Association for the Study of Liver Disease (2011) in San Francisco on hepatitis B has shed some new light on the importance of the stage of fibrosis for the treatment response outcome. Marcellin *et al*[20] treated 641 hepatitis B patients with tenofovir for five years and performed paired biopsies in 348 of these cases, one at baseline and a second at 5 years after the start of

treatment. These authors found an overall histological improvement in 98% of their patients, which was more marked in patients with advanced fibrosis. In another study by Gane *et al*[21], paired biopsies were performed in 72 Asian patients with hepatitis B receiving tenofovir treatment for five years. A histological regression of fibrosis of ⩾ 1 point decrease in the Ishak score was noted in 42/72 (58.3%) patients at five years which was more marked in 6/18 patients with liver cirrhosis. These two observations and our present findings indicate that the response to treatment will increase as the degree of fibrosis increases. This result will be of definite benefit in deciding the time of treatment.

Niro *et al*[16] in his study performed a baseline biopsy in 11 of 16 hepatitis D patients, of which 6 patients consented for paired biopsy after 72 wk of peg-interferon treatment. These authors reported an improvement of more than 1 point in Necro inflammatory activity as well as fibrosis in 4 out of 6 patients. Erhardt *et al*[18] report in their study of 12 patients that 11 allowed a baseline biopsy and 7 a followed biopsy after six months of treatment. An improvement in the stage of fibrosis was observed in responders as well as in non-responders. In contrast to previous studies however, no improvement was found in cases of cirrhosis of the liver.

In conclusion, peg-interferon therapy can induce remission in nearly one third of patients infected with HDV. Patients who achieve a biochemical response or an end of treatment response with a high stage fibrosis on liver histology, also achieved SVR.

ACKNOWLEDGMENTS

We are thankful to Dr. Majeed Chutto, Program Manager Hepatitis Prevention and Control Program Sindh Chief Minister's initiative for providing peg-interferon based treatment to patients. We are thankful to Dr. Mehtab Abbasi, Dr. Zareen, Dr. Faizan, Dr. Manan for assisting during the liver biopsy and follow up of the patients. We appreciate the efforts of Mr. Ali Jan, Assistant Computer Operator for record keeping.

COMMENTS

Background

Nearly 150 million people worldwide are infected with hepatitis delta virus (HDV). Hepatitis D is dependent on hepatitis B for its prevalence. In Pakistan, the prevalence of hepatitis B is about 2.5% but in certain areas of Sindh province is much higher, in the range of 4.5% to 6.4%, with consequent increases in the prevalence of hepatitis D.

Research frontiers

The treatment options for HDV have remained disappointing over many years. Recently however, peg-interferon, a product of the conjugation of interferon with polyethylene glycol has replaced standard interferon in clinical use because its prolonged half life allows for a single weekly dose to be administered. Although the previous studies has shown sustained viral response (SVR) in substantial number of patients but the number of patient studied were so small that it was very difficult to draw any conclusion.

Innovations and breakthroughs

The above mentioned studies are on such small scale that's it is difficult to draw any conclusion. An evaluation of this drug in a large number of patients is therefore required and is also necessary to assess the factors that are predictive of a viral response in the treated patients. This is the largest prospective study yet reported on the efficacy of peg-interferon monotherapy treatment for hepatitis D. The 238 patients included in the study cohort was far larger than the population analyzed in the previous hep-net-international delta hepatitis intervention trial, a multicenter trial comprising 90 patients in three arms. In the authors' current prospective study, a biochemical response was achieved in 51.3%, end of treatment in 29.8% and SVR in 29.4% of the 238 patients with hepatitis D after 48 wk of peg-interferon therapy.

Applications

The present study has been conducted on larger scale. One of very important observation seen was better response of patients with more aggressive disease. This will further open the debate as this finding is in contrast to what was previously being observed that milder disease respond better. The present study will help with selecting the patients in future at proper time as well as those who can better response to treatment.

Peer review

This is a large study of 277 patients with delta virus infection. A total of 238 patients completed a full course of 48 wk of treatment with pegylated interferon. The SVR rate was 29.4%. The data is interesting.

Abstract

AIM: To evaluate the feasibility and efficacy of endoscopic submucosal dissection (ESD) for foregut neuroendocrine tumors (NETs).

METHODS: From April 2008 to December 2010, patients with confirmed histological diagnosis of foregut NETs were included. None had regional lymph node enlargement or distant metastases to the liver or lung on preoperative computerized tomography scanning or endoscopic ultrasonography (EUS). ESD was attempted under general anesthesia. After making several marking dots around the lesion, a mixture solution was injected into the submucosa. The mucosa was incised outside the marking dots. Dissection of the submucosal layer beneath the tumor was performed under direct vision to achieve complete *en bloc* resection of the specimen. Tumor features, clinicopathological characteristics, complete resection rate, and complications were evaluated. Foregut NETs were graded as G1, G2, or G3 on the basis of proliferative activity by mitotic count or Ki-67 index. All patients underwent regular follow-up to evaluate for any local recurrence or distant metastasis.

RESULTS: Those treated by ESD included 24 patients with 29 foregut NETs. The locations of the 29 lesions are as follows: esophagus (n = 1), cardia (n = 1), stomach (n = 23), and duodenal bulb (n = 4). All lesions were found incidentally during routine upper gastrointestinal endoscopy for other indications, and none had symptoms of carcinoid syndrome. Preoperative EUS showed that all tumors were confined to the submucosa. Among the 24 gastric lesions, 16 lesions in 11 patients were type I gastric NETs arising in chronic atrophic gastritis with hypergastrinemia, while the other 8 solitary lesions were type Ⅲ because of absence of atrophic gastritis in these cases. All of the tumors were removed in an *en bloc* fashion. The average maximum diameter of the lesions was 9.4 mm (range: 2-30 mm), and the procedure time was 20.3 min (range: 10-45 min). According to the World Health Organization 2010 classification, histological evaluation determined that 26 lesions were NET-G1, 2 gastric lesions were NET-G2, and 1 esophageal lesion was neuroendocrine carcinoma (NEC). Complete resection was achieved in 28 lesions (28/29, 96.6%), and all of them were confined to the submucosa in histopathologic assessment with no lymphovascular invasion. The remaining patient with NEC underwent additional surgery because the resected specimens revealed angiolymphatic and muscularis invasion, as well as incomplete

resection. Delayed bleeding occurred in 1 case 3 d after ESD, which was managed by endoscopic treatment. There were no procedure-related perforations. During a mean follow-up period of 24.4 mo (range: 12-48 mo), local recurrence occurred in only 1 patient 7 mo after initial ESD. This patient successfully underwent repeat ESD. Metastasis to lymph nodes or distal organs was not observed in any patient. No patients died during the study period.

CONCLUSION: ESD appears to be a safe, feasible, and effective procedure for providing accurate histopathological evaluations and curative treatment for eligible foregut NETs.

INTRODUCTION

Depending on the point of origin in the disseminated endocrine system, gastrointestinal neuroendocrine tumors (NETs) can be classified as a tumor of the foregut (esophagus, stomach and duodenum), midgut (distal ileum and proximal colon), or hindgut (distal colon and rectum). Foregut NETs are considered rare, and the reported incidence is 10%-30% of all gastrointestinal NETs, but their incidence has been increasing in most countries over the last 50 years[1]. These increases in diagnosed incidence and prevalence are likely attributable, in part, to better awareness and improved diagnostic strategies regarding NETs, as well as the increasingly widespread use of upper gastrointestinal endoscopy[2].

Foregut NETs can show a broad range of clinical behavior, ranging from benign and asymptomatic to disseminated and metastatic. This clinical behavior is a reflection of tumor location, type, grade and stage. With the advent of screening gastroscopy, we currently can diagnose and treat small foregut NETs at a very early stage. Foregut NETs that are limited to the mucosa/submucosa and are less than 11-20 mm in size demonstrate a low frequency of lymph node and distant metastasis, and thus have been managed with local excision (including endoscopic treatment), which offers improved quality of life compared with surgery[3,4]. Nowadays traditional polypectomy and endoscopic mucosal resection (EMR) are most commonly employed for some foregut NETs[5-12]. However, complete histological resection may not always be easy to achieve by using EMR because most gastrointestinal NETs are not confined to the mucosa but, rather, invade the submucosa[13], which results in frequent involvement of the resection margin.

Endoscopic submucosal dissection (ESD) is a method of endoscopic resection that involves circumferential cutting of the mucosa surrounding the tumor followed by dissection of the submucosa under the lesion. ESD has the advantage of a high probability of *en bloc* and histologically complete resection even in huge lesions because the technique involves dissection of the submucosal tissue beneath the lesion[14-16]. To date, the fact that ESD can facilitate a histologically complete resection of NETs has been verified for the use of ESD for treatment of rectal carcinoid tumors (now referred to as NETs)[17-19]. However, no systematic data have yet been published in which ESD has been applied to foregut NETs. Thus, we retrospectively evaluated the feasibility and efficacy of ESD for foregut NETs in this study.

MATERIALS AND METHODS

Patients

With the approval of the institutional review board, 24 patients with confirmed histological diagnosis of foregut neuroendocrine neoplasms were treated with ESD from April 2008 to December 2010. None had regional lymph node enlargement or distant metastases to the liver or lung on computerized tomography (CT) scanning or endoscopic ultrasonography (EUS) before ESD. Tumor characteristics, complete resection rate, complications, local recurrences, and distant metastases were evaluated in all patients. Informed patient consent was obtained prior to the procedures. The procedures were in accordance with the Helsinki Declaration (1964, and amended in 1975, 1983, 1989, 1996 and 2000) of the World Medical Association.

ESD procedures

Preoperative EUS (high-frequency miniprobe, UM-2R, 12 MHz; UM-3R, 20 MHz, Olympus) was performed to evaluate the depth of tumor invasion and the involvement of regional lymph nodes. The existence of lymph node and distant metastasis was surveyed by contrast-enhanced CT, abdominal ultrasound, and chest X-ray.

To dissect the tumor, ESD was attempted with a single-channel gastroscope (GIF-H260, Olympus) and an insulated-tip electrosurgical knife (KD-611L, Olympus) or hook knife (KD-620LR, Olympus). A transparent cap (D-201-11304, Olympus) was attached to the tip of the gastroscope to provide direct views of the submucosal layer. Other equipment included an injection needle

Table 1 World Health Organization 2010 classification and suggested grading of neuroendocrine neoplasms of the digestive system[20]

Classification	Grading		
	Grade	Mitotic count (per 10 HPF)	Ki-67 index (%)
NET	G1	< 2	< 2
NET	G2	2–20	3-20
NEC	G3	> 20	> 20

HPF: High-power field; NEC: Neuroendocrine carcinoma; NET: Neuroendocrine tumor; G1: Low-grade tumors; G2: Intermediate-grade tumors; G3: High-grade tumors.

(NM-4L-1, Olympus), grasping forceps (FG-8U-1, Olympus), snare (SD-230U-20, Olympus), hot biopsy forceps (FD-410LR, Olympus), clips (HX-610-90, HX-600-135, Olympus), high-frequency generator (ICC-200, ERBE), and argon plasma coagulation unit (APC300, ERBE).

Patients were treated under general anesthesia. After making several marking dots with argon plasma coagulation around the lesion, a mixture solution (including 100 mL normal saline, 1 mL indigo carmine, and 1 mL epinephrine) was injected into the submucosa. The mucosa was incised outside the marking dots. Direct dissection of the submucosal layer beneath the tumor was then performed under direct vision to achieve a complete *en bloc* resection of the specimen. The tumor was dissected along the capsule, and saline solution was injected repeatedly during the dissection when necessary. The resultant artificial ulcer was managed routinely with argon plasma coagulation to prevent delayed bleeding and hemoclips were used to close the deeply dissected areas as needed.

Pathological evaluation

The World Health Organization (WHO) 2010 classification of tumors of the digestive system was used for histopathologic evaluation[20] (Table 1). Immunohistochemistry with the two robust neuroendocrine markers chromogranin A and synaptophysin was used to reach an accurate diagnosis. The mitotic count per 10 high-power fields or the Ki-67 index per 400 cells-2000 cells was used for grading and staging. On the basis of proliferative activity, foregut neuroendocrine neoplasms were graded as G1, G2 or G3. Low to intermediate grade tumors (G1-G2) were defined as NETs (previously referred to as carcinoids) whereas high-grade carcinomas (G3) were termed neuroendocrine carcinomas (NECs).

en bloc resection refers to a resection in one piece. A resection with a tumor-free margin in which both the lateral and basal margins were free of tumor cells was considered as a complete resection. A resection was considered as an incomplete resection in which the tumor extended into the lateral or basal margin, or the margins were indeterminate because of artificial burn effects.

Types of gastric NET

There is a clinicopathological categorization of gastric NETs which distinguishes the four types of neuroendocrine neoplasms of the stomach[3]: type Ⅰ are those arising in chronic atrophic gastritis with hypergastrinemia; type Ⅱ occurs in patients with hypergastrinemia due to Zollinger-Ellison syndrome in association with multiple endocrine neoplasia type Ⅰ; type Ⅲ are gastric NETs not associated with any specific pathogenetic background; and poorly differentiated NECs are nowadays classified as type Ⅳ neuroendocrine neoplasms of the stomach.

Indications for additional surgery

Additional surgical intervention was recommended in the case of type Ⅰ or type Ⅱ gastric NETs with positive margins, size > 20 mm, G2-G3 histological grading, invasion into the muscularis propria, or vessel infiltration of tumor cells. Additional surgery was also recommended in the case of type Ⅲ gastric NETs with a size > 10 mm irrespective of other risk factors. Surgery was the only treatment of choice in case of a localized type Ⅳ gastric NET.

Surgical indication for esophageal and duodenal NETs is controversial. The indication used in our study corresponded with that of type Ⅲ gastric NETs.

Follow-up

Patients underwent follow-up endoscopy and/or EUS at 1, 3, 6 and 12 mo after ESD and annually thereafter to view the wound healing and evaluate for any residual tumor or recurrence. Close follow-up was also carried out to evaluate for distant metastasis every 6 mo by abdominal ultrasound, contrast-enhanced CT, and chest radiography.

RESULTS

Patient characteristics, lesion features, and clinical outcomes are summarized in Table 2. The study cohort consisted of 9 men (ages 35 to 71 years) and 15 women (ages 35 to 82 years). Of these, 3 cases had 2 tumors and 1 case had 3 tumors (case nos. 12, 14, 20 and 24). The 29 lesions were found in the esophagus (n = 1), gastric cardia (n = 1), stomach (n = 23), or duodenal bulb (n = 4; Figure 1).

All lesions were found incidentally during routine upper gastrointestinal endoscopy for other indications such as anemia, reflux symptoms, or nonspecific abdominal symptoms. None had symptoms of carcinoid syndrome. With respect to macroscopic appearance, 15 patients had submucosal tumors with a central depression or erosion on top, 8 patients had sessile polyps with a reddened surface, and 1 patient had an erosion-type tumor.

EUS showed that all tumors were confined to the submucosa. Before ESD procedures, histological diagnosis of foregut NETs had been confirmed via biopsies in 4 cases (case nos. 8, 13, 15 and 22), suspected diagnosis of NETs were made based upon specific macroscopic appearances and EUS characteristics in 15 cases, and an indefinite diagnosis was made in 5 cases (case nos. 5, 7, 16, 18 and 23).

"Reject" means the patient rejected the additional surgery. NA: Not applicable; NEC: Neuroendocrine carcinoma; NET: Neuroendocrine tumor; M: Male; F: Female; WHO: World Health Organization.

Among the 24 gastric lesions, 16 lesions in 11 patients were type I gastric NETs arising in chronic atrophic gastritis with hypergastrinemia, while the other 8 solitary lesions were type Ⅲ because of absence of atrophic gastritis. No patient had metastatic disease to lymph nodes or distal organs on preoperative examinations.

All of the tumors were removed in an *en bloc* fashion (29/29, 100%). The average maximum diameter of the lesions was 9.4 mm (range: 2-30 mm), and the average procedure time was 20.3 min (range: 10-45 min) (Figure 2A-H).

According to the WHO 2010 classification, results of pathological studies determined that 26 lesions were NET-G1, 2 gastric lesions were NET-G2 (case nos. 5 and 18), and 1 esophageal lesion was NEC (case no. 16). In the esophageal lesion defined as NEC, the tumor invaded the muscularis propria and the vertical margin was affected by tumor cells. Lymphatic and vascular invasion were also observed in the resected specimens. This

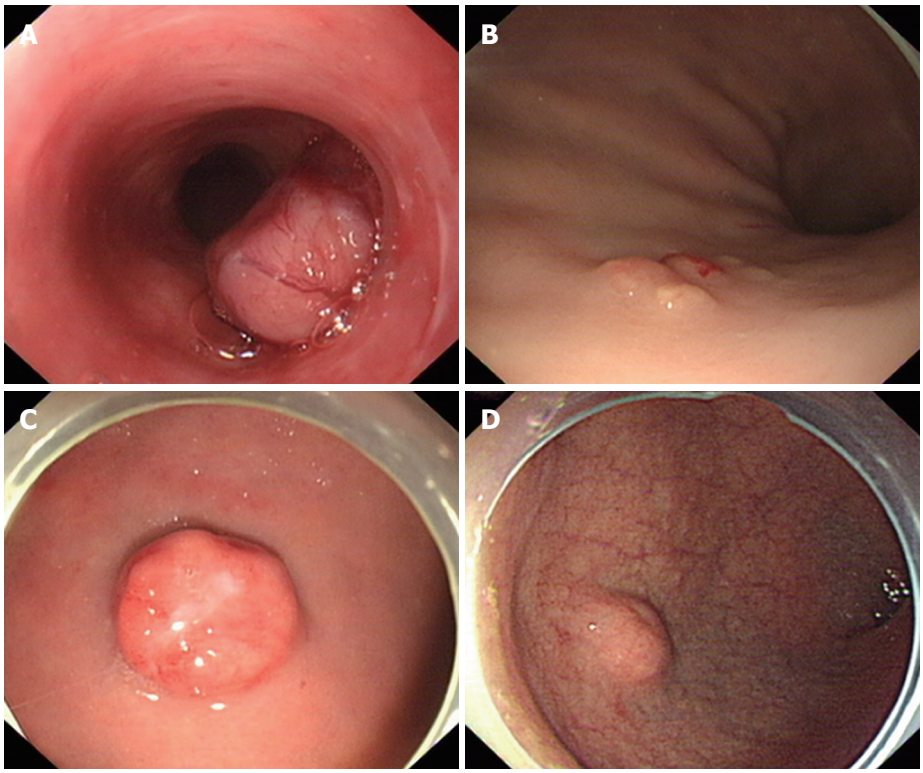

Figure 1 Macroscopic appearance of foregut neuroendocrine tumors in representative cases. A: An esophageal neuroendocrine tumor (NET; case no. 16); B: A type Ⅰ gastric NET (case no. 14); C: A type Ⅲ gastric NET (case no. 17); D: A duodenal NET (case no. 11).

patient thus underwent esophagectomy and excision of regional lymph nodes. Complete resection was achieved for the remaining 28 lesions (28/29, 96.6%), all of which were confined to the submucosa without lymphovascular invasion upon histopathologic assessment (Figures 2I-K).

Delayed bleeding occurred in 1 case 3 d after ESD (case no. 17). Successful hemostasis was achieved by coagulating forceps and spraying with thrombin during emergency endoscopy, and no blood transfusion was necessary. There were no procedure-related perforations.

Additional surgical intervention was considered in 6 cases (case nos. 3, 5, 7, 17, 18 and 23) because duodenal and type Ⅲ gastric NETs with a diameter larger than 10 mm may have a high risk of metastasis. However, only 1 of the 6 underwent additional surgery (case no. 18), and we could not reveal residual lesions or metastatic lymph nodes in the surgical specimens. The remaining 5 cases refused additional surgery, citing their age, physical condition, or other personal reasons. These patients remained under careful follow-up.

During a mean follow-up period of 24.4 mo (range: 12-48 mo), local recurrence occurred in only 1 patient 7 mo after initial ESD (case no. 14). This patient underwent successful repeat ESD. Metastasis to lymph nodes or distal organs was not observed in any patient, and no patient died during the study period.

DISCUSSION

Though rare, primary foregut NETs may now be discovered more often with the advent of screening gastroscopy[1]. Nowadays more and more foregut NETs are usually diagnosed at an early stage (tumor size < 11-20 mm and limited to the mucosa/submucosa)[1,3], and thus can be managed with local excision (including endoscopic treatment) because of a low frequency of lymph node and distant metastasis.

As a minimally invasive technique, endoscopic resection may benefit patients diagnosed with foregut NETs. This approach offers the promise of localized treatment of these tumors with relatively few complications and low mortality. Various endoscopic resection procedures have been described as potential treatment procedures for foregut NETs, such as endoscopic polypectomy, strip biopsy, aspiration resection, and band-snare resection[5-12]. However, complete resection of NETs is difficult with conventional polypectomy because most gastrointestinal NETs are not confined to the mucosa but, rather, invade the submucosa[13], which results in frequent involvement of the resection margin. As such, polypectomy may not provide adequate resection margins and additional surgical intervention may be needed.

In the current study we applied ESD to remove foregut NETs. Most of the lesions extended into the submucosa (96.6%, 28/29), and *en bloc* resection was achieved for all of the tumors in this study. Moreover, a histologically complete resection was achieved for 96.6% (28/29) of the current series. This is important as a high rate of histologically complete resections with ESD may give several advantages for the treatment of foregut NETs[17-19]. First, a histologically complete resection

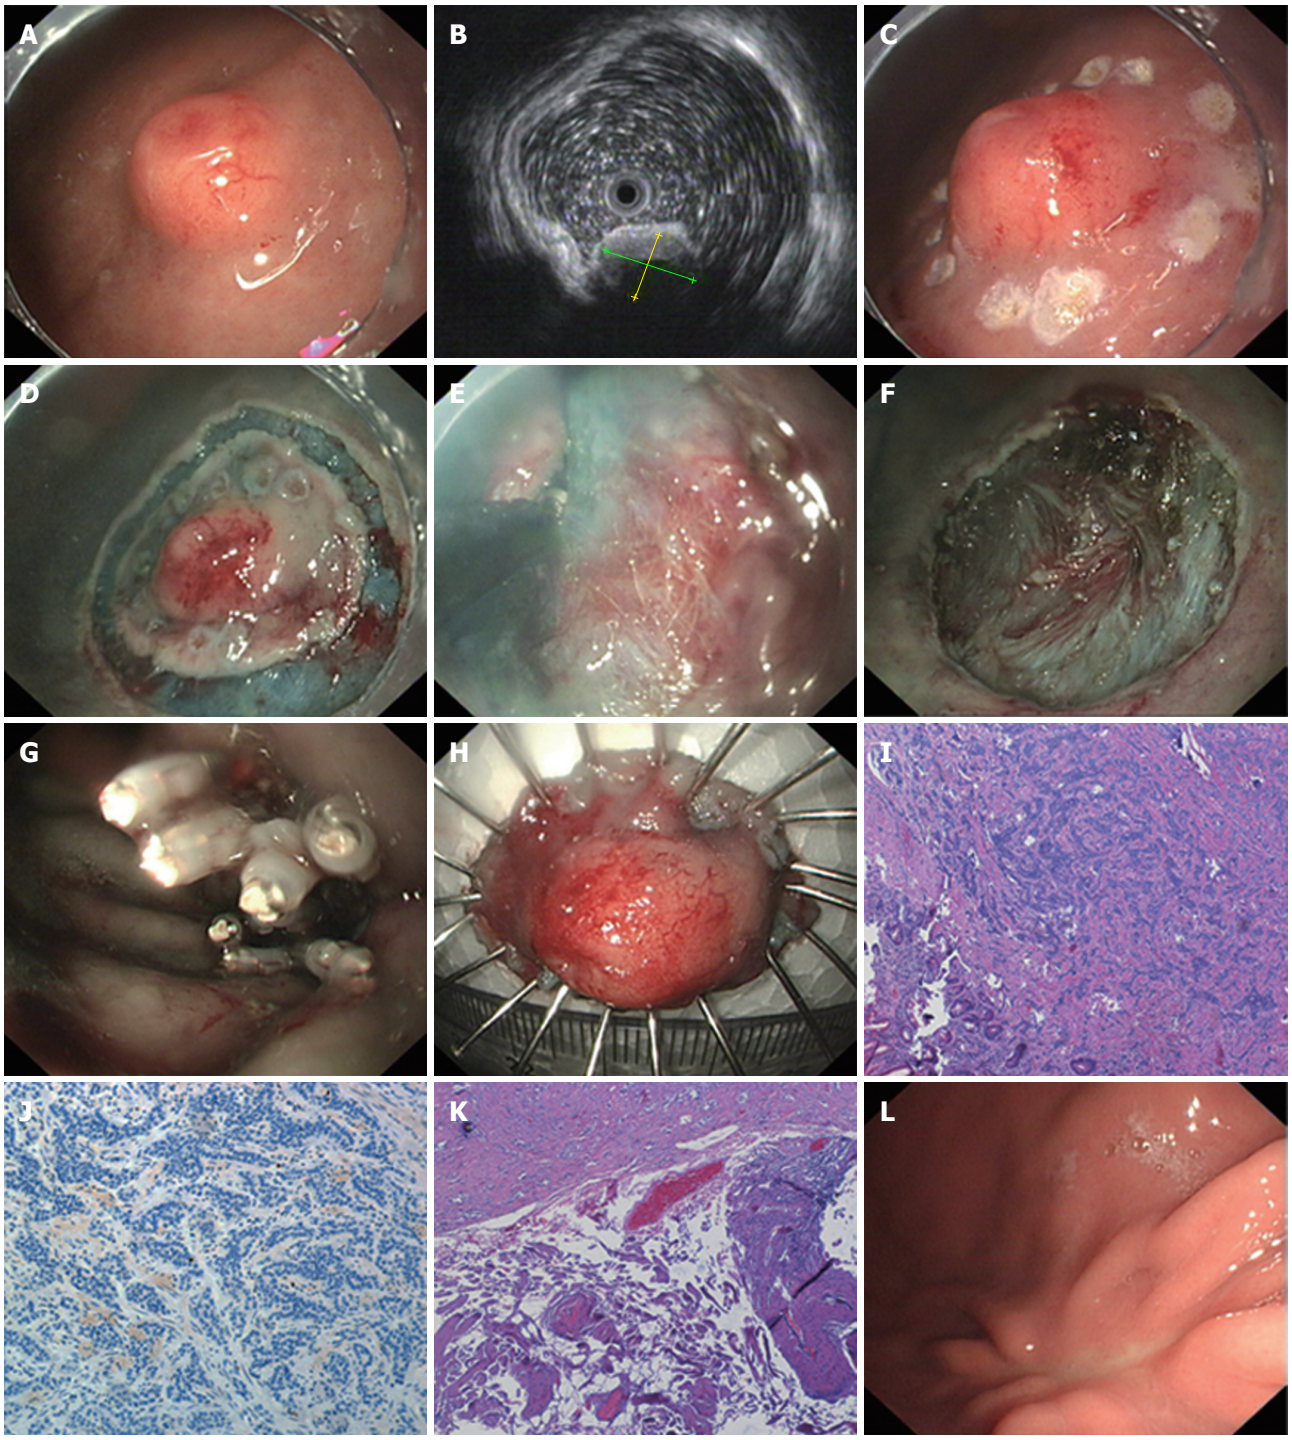

Figure 2 Endoscopic submucosal dissection of a type Ⅲ gastric neuroendocrine tumor in a 71 year-old man (case no. 3). A: A submucosal tumor with a central depression of the gastric body; B: Endoscopic ultrasonography shows a mass invading the submucosa (maximum diameter, 18 mm); C-G: Processes of endoscopic submucosal dissection with the use of a soft transparent hood; H: Completely resected specimen; I: Microscopic examination of the completely resected specimen reveals a neuroendocrine tumor (NET) within the submucosa of the stomach (hematoxylin-eosin staining, × 40); J: The lesion was NET-G1 on the basis of proliferative activity (Ki-67 index < 2%, × 100); K: The basal margin was free of tumor invasion (hematoxylin-eosin staining, × 40); L: Endoscopic findings of scar 12 mo after endoscopic submucosal dissection.

can provide a substantial amount of submucosal tissue, such that an accurate determination of lymphovascular invasion and histological grading is possible, which can inform decisions regarding subsequent therapy. Second, incomplete resection of tumors results in the need for additional surgery, and complete resection for a reduced frequency of unnecessary surgery. Third, repeat endoscopic resection of remnant tumor after an initial incomplete endoscopic resection may be difficult because of fibrosis that prevents lifting the lesion by submucosal injection. Therefore, we recommend histologically complete resection of foregut NETs even when lesions are

small, and the present study indicates that ESD may maximize the likelihood of such an outcome because of complete resection.

Bleeding and perforation are the two main complications of ESD. In this study, only 1 case had delayed bleeding 3 d after ESD. Successful hemostasis was achieved by coagulating forceps and spraying with thrombin during emergency endoscopy. No patient had immediate or delayed perforation. The relatively low ESD complication rate most likely reflects the small size of the lesions. Furthermore, we focus heavily on preventing and handling bleeding during the procedure because hemostasis may take a long time to establish and the endoscopic view may be affected. This is important because blind hemostasis may eventually lead to perforation. In our study, immediate minor bleeding was treated successfully by grasping the bleeding vessels with hot biopsy forceps and coagulating them during ESD. Direct coagulation with the hook knife was done for small vessels in the submucosa, and metallic clips were often deployed for more brisk bleeding.

Certain properties of foregut NETs should be considered for rescue surgery after endoscopic resection. The indication for this is usually based on the location, type, grade, and stage of the foregut NET disease. Considering the review of Scherübl *et al*[3] for the treatment of gastric NETs, in this study additional surgical intervention was recommended in the case of type I or type II gastric NETs with positive margins, size > 20 mm, G2-G3 histological grading, invasion into the muscularis propria, or vessel infiltration of tumor cells. Additional surgery was also recommended in the case of type III gastric NETs with a size > 10 mm irrespective of other risk factors. Surgery was the only treatment of choice in case of a localized type IV gastric NET. As for the endoscopic treatment of esophageal and duodenal NETs, the indication is controversial. In correspondence to a systemic review[4], additional surgery was recommended in our study in patients with duodenal NETs larger than 10 mm. According to these indications, additional surgical intervention should have been undertaken 7 cases; however, 5 of them refused additional surgery, citing their age, physical condition, or other personal reasons. Nonetheless, during a 2-year follow-up period, local recurrence or distal metastasis didn't occur in these 5 patients.

Thus, the appropriate selection criteria of foregut NETs for endoscopic resection is still controversial and is in need of further investigation. Because of complete resection, the present study indicates that ESD may reasonably serve as a curative treatment for foregut NETs when lesions are within the existing criteria. ESD also provides enough histological information for tumor grading and staging even when lesions are beyond the selection criteria, which informs decisions regarding subsequent surgery. In addition, endoscopic treatment might also be considered in particular in patients with a high risk of perioperative complications due to old age or advanced comorbidity, for example, or if there are other contraindications to major surgery, even though the lesions are a little beyond the existing criteria. If EUS is able to rule out invasion of the muscularis propria, the upper size limit for the lesion would only be restricted by what is endoscopically practicable[4]. If endoscopy is deemed unsuitable, laparoscopic techniques could be another attractive alternative[21,22].

In conclusion, ESD may be considered for the treatment of eligible foregut NETs because the technique shows a high histologically complete resection rate, provides accurate histopathological evaluation, has a low complication rate, and can be performed within a reasonable timeframe. Issues to be addressed in future prospective studies include identification of appropriate selection criteria and analysis of long-term results after ESD treatment of foregut NETs.

COMMENTS

Background

With the advent of screening gastroscopy, foregut neuroendocrine tumors (NETs) can be diagnosed at a very early stage and thus managed with local excision, including endoscopic treatment. However, complete resection of NETs is difficult with conventional polypectomy because most gastrointestinal NETs are not confined to the mucosa but, rather, invade the submucosa, which results in frequent involvement of the resection margin.

Research frontiers

Endoscopic submucosal dissection (ESD) is a method of endoscopic resection that involves circumferential cutting of the mucosa surrounding the tumor followed by dissection of the submucosa under the lesion. ESD has the advantage of a high probability of *en bloc* and histologically complete resection even in huge lesions because the technique involves dissection of the submucosal tissue beneath the lesion. To date, the fact that ESD can facilitate histologically complete resection of NETs has been verified on the use of ESD for the treatment of rectal carcinoid tumors (now referred to as NETs). However, no systematic studies have yet been published in which ESD has been applied for foregut NETs.

Innovations and breakthroughs

In the current study, the authors reported for the first time that ESD can reasonably serve as curative treatment for eligible foregut NETs when lesions are within the existing criteria. ESD also provides enough histological information for tumor grading and staging even when the lesions are beyond the selection criteria, which informs decisions regarding subsequent surgery.

Applications

The study suggests that ESD should be considered for treatment of eligible foregut NETs. Issues to be addressed in future prospective studies include identification of appropriate selection criteria and analysis of long-term results after ESD treatment of foregut NETs.

Terminology

Gastrointestinal NETs can be classified as tumor of the foregut (esophagus, stomach, and duodenum), midgut (distal ileum and proximal colon), or hindgut (distal colon and rectum).

Peer review

This is a good descriptive study reporting the results of endoscopic treatment for the resection of foregut NETs. The results are interesting and suggest that ESD may be considered for treatment of eligible foregut NETs because the technique shows a high histologically complete resection rate, provides accurate histopathological evaluation, has a low complication rate, and can be performed within a reasonable timeframe.

Abstract

AIM: To evaluate the status of anorectal function after repeated transanal endoscopic microsurgery (TEM).

METHODS: Twenty-one patients undergoing subtotal colectomy with ileorectal anastomosis were included. There were more than 5 large (> 1 cm) polyps in the remaining rectum (range: 6-20 cm from the anal edge). All patients, 19 with villous adenomas and 2 with low-grade adenocarcinomas, underwent TEM with submucosal endoscopic excision at least twice between 2005 and 2011. Anorectal manometry and a questionnaire about incontinence were carried out at week 1 before operation, and at weeks 2 and 3 and 6 mo after the last operation. Anal resting pressure, maximum squeeze pressure, maximum tolerable volume (MTV) and rectoanal inhibitory reflexes (RAIR) were recorded. The integrity and thickness of the internal anal sphincter (IAS) and external anal sphincter (EAS) were also evaluated by endoanal ultrasonography. We determined the physical and mental health status with SF-36 score to assess the effect of multiple TEM on patient quality of life (QoL).

RESULTS: All patients answered the questionnaire. Apart from negative RAIR in 4 patients, all of the anorectal manometric values in the 21 patients were normal before operation. Mean anal resting pressure decreased from 38 ± 5 mmHg to 19 ± 3 mmHg (38 ± 5 mmHg *vs* 19 ± 3 mmHg, $P = 0.000$) and MTV from 165 ± 19 mL to 60 ± 11 mL (165 ± 19 mL *vs* 60 ± 11 mL, $P = 0.000$) at month 3 after surgery. Anal resting pressure and MTV were 37 ± 5 mmHg (38 ± 5 mmHg *vs* 37 ± 5 mmHg, $P = 0.057$) and 159 ± 19 mL (165 ± 19 mL *vs* 159 ± 19 mL, $P = 0.071$), respectively, at month 6 after TEM. Maximal squeeze pressure decreased from 171 ± 19 mmHg to 62 ± 12 mmHg (171 ± 19 mmHg *vs* 62 ± 12 mmHg, $P = 0.000$) at week 2 after operation, and returned to normal values by postoperative month 3 (171 ± 19 *vs* 166 ± 18, $P = 0.051$). RAIR were absent in 4 patients preoperatively and in 12 ($\chi^2 = 4.947$, $P = 0.026$) patients at month 3 after surgery. RAIR was absent only in 5 patients at postoperative month 6 ($\chi^2 = 0.141$, $P = 0.707$). Endosonography demonstrated that IAS disruption occurred in 8 patients, and 6 patients had temporary incontinence to flatus that was normalized by postoperative month 3. IAS thickness decreased from 1.9 ± 0.6 mm preoperatively to 1.3 ± 0.4 mm (1.9 ± 0.6 mm *vs* 1.3 ± 0.4 mm, $P = 0.000$) at postoperative month 3 and increased to 1.8 ± 0.5 mm (1.9 ± 0.6 mm *vs* 1.8 ± 0.5 mm, $P = 0.239$) at postoperative month 6. EAS thickness decreased from 3.7 ± 0.6 mm preoperatively to 3.5 ± 0.3 mm (3.7 ± 0.6 mm *vs* 3.5 ± 0.3 mm, $P = 0.510$) at month 3 and then increased to 3.6 ± 0.4 mm (3.7 ± 0.6 mm *vs* 3.6 ± 0.4 mm, $P = 0.123$) at month 6 after operation. Most patients had frequent stools per day and relatively high Wexner scores in a short time period. While actual fecal incontinence was exceptional, episodes of soiling were reported by 3 patients. With regard to the QoL, the physical and mental health status scores (SF-36) were 56.1 and 46.2 (50 in the general population), respectively.

CONCLUSION: The anorectal function after repeated TEM is preserved. Multiple TEM procedures are useful for resection of multi-polyps in the remaining rectum.

INTRODUCTION

Familial adenomatous polyposis (FAP) is an autosomal dominant disease that is classically characterized by the development of hundreds to thousands of adenomas in the rectum and colon during the second decade of life. Almost all patients will develop colorectal cancer if they are not identified and treated at an early stage. The incidence of FAP at birth is approximately 1/8300[1] in both men and women, and less than 1% of them develop colorectal cancer[1].

Twenty years ago, many patients with FAP underwent subtotal colectomy in China. Currently, some of the older patients refused to undergo a complicated operation (such as ileal pouch-anal anastomosis) because of old age or poor physical status. However, polyps are still present in the remaining rectum of patients and some of these polyps are too large to be extirpated by a colonoscope. These large polyps often cause bleeding and discomfort in old patients and anxiety about the risk of cancer in relatively younger patients. These patients desire a minimally invasive procedure.

Transanal endoscopic microsurgery (TEM) was developed in 1983 by Büess *et al*[2-6]. It is a minimally invasive procedure to manage anorectal villous adenomas and early rectal adenocarcinomas[7,8]. TEM can be used to excise tumors located in the middle and upper rectum, and to manage other lesions, such as adenomas, which are not amenable to colonoscopic excision and can spare some patients the risks and side effects of major rectal surgery. In this study, patients had several large polyps and many small polyps. We performed TEM repeatedly to excise large polyps and fulgerize small polyps. The patients were satisfied with the clinical and anorectal functional outcome after TEM.

Generally, several factors from a single TEM procedure may cause internal anal sphincter (IAS) damage, which results in a decrease in mean anal resting pressure (ARP) and absence of rectoanal inhibitory reflexes (RAIR)[9]. It is unknown if repeated TEM will cause more severe IAS damage than a single TEM. The current study assessed anorectal function by anorectal manometry. Anorectal manometry provides objective data, which are necessary to determine sphincter function postoperatively.

MATERIALS AND METHODS

From January 2005 to June 2011, 21 patients (13 females and 8 males) who had been diagnosed with FAP and underwent TEM 2 or 3 times were included in the study. All the patients had undergone subtotal colectomy with ileorectal anastomosis previously. When there were more than 5 large (> 1 cm) polyps in the remaining rectum (range: 6-20 cm from the anal edge), including 19 villous adenomas and 2 adenocarcinomas (2 uT1N0M0), these patients underwent TEM at least twice (19 underwent TEM twice and 2 underwent TEM 3 times) in our department using the technique designed by Buess *et al*[2,10].

All these patients were followed up for more than 6 mo (range: 6-24 mo). The median age of these patients at the time of the operation was 66 years (range: 49-82 years). All of the 21 patients underwent colonoscopy, biopsy and anorectal manometry before operation, and 2 patients with malignant lesions underwent endosonography and magnetic resonance imaging for preoperative staging. The inclusion criteria for this study were: those patients who had documentation for TEM, with villous adenomas, and uT1N0M0 adenocarcinomas located 5-18 cm from the anal verge. The exclusion criteria were preoperative defects of IAS as shown by endosonography or preoperational anal incontinence.

For patients with benign or low-grade malignant polyps in the remaining rectum, we performed submucosal endoscopic excision with TEM. Intraoperative pathological examination was performed to ensure that no malignant lesion remained. We closed the defect with sutures for the large polyps (> 1 cm).

There are a variety of approaches for anorectal manometry and determining RAIR. In our study, anorectal manometry was performed with an 8-channel water-perfused catheter (MMS Corporation, Holland) with an external diameter of 5.5 mm. A computer system with menu-driven software (MMS Corporation, Holland) was used. The patients assumed the left lateral decubitus position. The stationary technique (the catheter was left in one position) was used in our laboratory. Anorectal manometric parameters, such as ARP, maximum squeeze pressure (MSP), maximum tolerable volume (MTV) and RAIR were recorded. Endoanal ultrasonography was used to study the integrity and thickness of the IAS and external anal sphincter (EAS). Manometry and a stan-

dardized questionnaire about incontinence were carried out at preoperative week 1 and postoperative week 2, months 3 and 6.

We used the SF-36 score, which summarizes physical and mental health status, to assess the effect of multiple TEM on patient quality of life (QoL).

SPSS 17.0 software was used for statistical analysis. Paired Student's *t* test was used to analyze the manometric data.

RESULTS

Apart from negative RAIR in 4 patients, all of the anorectal manometric values in the 21 patients were normal before the operation. However, all anorectal manometric parameters changed to different degrees after TEM. The mean ARP decreased from 38 mmHg ± 5 mmHg to 19 ± 3 mmHg (38 ± 5 mmHg *vs* 19 ± 3 mmHg, $P = 0.000$) and MTV decreased from 165 ± 19 mL to 60 ± 11 mL (165 ± 19 mL *vs* 60 ± 11 mL, $P = 0.000$) at month 3 after TEM. MSP decreased from 171 ± 19 mmHg to 62 ± 12 mmHg (171 ± 19 mmHg *vs* 62 ± 12 mmHg, $P = 0.000$) at week 2 after operation, and returned to normal values at postoperative month 3 (171 ± 19 *vs* 166 ± 18, $P = 0.051$). ARP and MTV were 37 ± 5 mmHg (38 ± 5 mmHg *vs* 37 ± 5 mmHg, $P = 0.057$) and 159 ± 19 mL (165 ± 19 mL *vs* 159 ± 19 mL, $P = 0.071$), respectively, at month 6 after TEM, which were up to the normal values (Figure 1). Among them, ARP in 18 patients, MSP in 19 patients and MTV in 21 patients were decreased by more than 50% at wk 2 after TEM (Table 1).

RAIR was absent in 4 patients preoperatively and in 12 ($\chi^2 = 4.947$, $P = 0.026$) patients at 3 mo after surgery while RAIR was absent only in 5 patients (including 4 patients whose RAIR was absent preoperatively) at postoperative month 6 ($\chi^2 = 0.141$, $P = 0.707$).

Endosonography demonstrated that disruption to the IAS occurred in 8 patients, with full integrity of the EAS in all patients. Of these 8 patients, 6 had incontinence to flatus at postoperative week 2, which disappeared at postoperative month 3. IAS thickness decreased from 1.9 ± 0.6 mm preoperatively to 1.3 ± 0.4 mm (1.9 ± 0.6 mm *vs* 1.3 ± 0.4 mm, $P = 0.000$) at postoperative month 3 and increased to 1.8 ± 0.5 mm (1.9 ± 0.6 mm *vs* 1.8 ± 0.5 mm, $P = 0.239$) at postoperative month 6. EAS thickness decreased from 3.7 ± 0.6 mm preoperatively to 3.5 ± 0.3 mm (3.7 ± 0.6 mm *vs* 3.5 ± 0.3 mm, $P = 0.510$) at month 3 and then increased 3.6± 0.4 mm (3.7 ± 0.6 mm *vs* 3.6 ± 0.4 mm, $P = 0.123$) at month 6, as demonstrated by endoanal ultrasonography.

Twenty patients had frequent stools per day and relatively high Wexner scores in a short time period after repeated TEM. Two-thirds of the patients had more than 5 bowel movements per day and 1 bowel movement at night. Bowel movements almost returned to the preoperative frequency in 17 of these patients 3-6 mo after surgery. Actual fecal incontinence was uncommon, but episodes of soiling were reported by 3 patients. Overall, the number of stools per day increased from 1.5 ± 0.7 before surgery to 5.6 ± 1.8 (1.5 ± 0.7 *vs* 5.6 ± 1.8, $P = 0.000$) at postoperative week 2 and then decreased to 1.7 ± 0.7 (1.5 ± 0.7 *vs* 1.7 ± 0.7, $P = 0.329$) at postoperative month 6. The Wexner scores increased from 0 before surgery to 4.1 ± 0.8 (0 *vs* 4.1 ± 0.8, $P = 0.000$) at postoperative week 2, and then they decreased to 2.0 ± 0.5 (0 *vs* 2.0 ± 0.5, $P = 0.002$) and 0.7 ± 0.1 (0 *vs* 0.7 ± 0.1, $P = 0.261$) at postoperative mos 3 and 6, respectively (Figure 2).

With regard to the QoL of the patients, the 2 scores of the SF-36, which summarizes the physical and mental health status, were 56.1 ± 6.1 and 46.2 ± 5.9, respectively (both are 50 in the general population). The scores were not significantly different compared with the general population.

All the patients were followed up for 6-24 mo, and no case of relapse was found.

DISCUSSION

FAP is a genetic disorder that results from a mutation in the adenomatous polyposis gene. In the majority of patients, polyps arise during childhood, mostly in the distal colon (rectosigmoid) as small intramucosal nodules. At adolescence, the polyps are usually identified throughout the colon and, thereafter, increase in size and number. Approximately half of FAP patients develop adenomas by 15 years of age and 95% develop by 35 years.

Given the substantial risk of rectal cancer developing after colectomy and ileorectal anastomosis, total proctocolectomy was recommended mostly for the typical FAP patients with multiple rectal adenomas. Currently, surgical options for FAP include subtotal colectomy with IRA, total proctocolectomy with ileostomy, and proctocolectomy with or without mucosectomy and ileal pouch anal anastomosis.

Therefore, TEM has gradually been accepted. TEM is a new technique used only in a few well-known hospitals in China, and excellent outcome in morbidity and a low relapse rate have been achieved. A few studies have addressed its functional results[11-17] and suggest that several factors during a single TEM may cause IAS damage. This damage results in a decrease in mean ARP and absence of RAIR[9]. There have been no studies on clinical and anorectal functional results after repeated TEM. It is unknown whether repeated TEM causes more severe IAS damage.

Several studies have shown that the IAS is the main contributor to ARP[18-20]. Division or damage of the IAS may be associated with troublesome soiling[21] and accounts for approximately 50%-85% of ARP, and EAS contributes to the other 25%-30% of ARP[22-24]. On the other hand, MSP is largely related to contraction of the EAS. Use of a wide rectoscope during TEM may result in rupture of the IAS because of significant anal dilatation, followed by a temporary decrease in ARP and MSP.

A fall in anorectal pressures because of anal dilatation can occur after using anal separators and stapling instruments in coloproctological procedures for hemorrhoids, fistula, or cancer[25-27]. According to our study results, the decrease in sphincteric thickness at postoperative month 3 due to anal dilatation may be another factor contributing to a temporary fall in anorectal pressure. Both ARP and MSP were decreased at postoperative week 2. However, MSP turned normal at postoperative month 3, which was faster than that of ARP and MTV at postoperative month 6. The integrity of both EAS and IAS could be explained by the finding that patients were continent, even though ARP and MSP were decreased in a short time period after surgery. Six of 8 patients with rupture of the IAS in our study presented with some degree of incontinence. We consider that a damaged IAS may result in temporary incontinence. MTV was decreased at postoperative week 2 and was returned to normal at postoperative month 6. Partial excision and reconstruction of the anorectal wall during TEM resulted in a decrease in anorectal volume and compliance, which may lead to a decrease in MTV.

RAIR is defined as transient relaxation of the IAS in response to rectal distension as confirmed by Denny-Brown and Robertson[28]. RAIR has been postulated as a factor in maintenance of continence[29,30], but the exact role of RAIR is unknown. Therefore, the upper anal canal is able to discriminate between flatus and fecal material. It is absent initially after low anterior resection and the ileoanal pouch procedure. Regeneration may occur after hand-sewn coloanal anastomosis and low stapled anastomosis[31-34]. RAIR disappears when the anorectal wall is removed[35] and when there are changes with depth if the IAS is excised[10]. According to our study results, RAIR was absent in 4 patients preoperatively and absent in only 5 patients (including the 4 patients whose RAIR was absent preoperatively) at postoperative month 6. Patients whose RAIR was absent after TEM had a deeper IAS excision. Only one patient (excluding the 4 patients whose RAIR was absent preoperatively) whose RAIR was absent postoperatively was treated with TEM 3 times and the excision of the anorectal wall was deeper.

We used the Wexner score to assess continence[36]. Most patients had more frequent stools per day (15 patients had more than 5 bowel movements per day and 1 bowel movement at night) and relatively higher Wexner scores (range: 6-13) at postoperative week 2 after multiple TEMs. There was remarkable improvement in these incontinence scores at 6 mo after operation, with most patients reporting satisfactory anorectal function. While actual fecal incontinence was unusual, episodes of soiling were reported by 3 patients.

With regard to the QoL of patients who had multiple TEM procedures, at 6 mo after operation, the physical and mental health status scores were not significant compared with the general population. The FAPs, multiple-operations, postoperative discomfort were possible explanations for the low mental health status scores. A good QoL is a surrogate for good functional outcome. In the current study, anorectal function was well-preserved, even though some anorectal manometric parameters changed over time.

In conclusion, we found that anorectal function is well-preserved when TEM is performed repeatedly and patients have a good QoL. Repeated TEM is a good choice of treatment for resection of multi-polyps in the remaining rectum of FAP patients who underwent subtotal colectomy.

COMMENTS

Background

Familial adenomatous polyposis (FAP) can cause colorectal cancer. Some of the patients with FAP who underwent subtotal colectomy in China twenty years ago refuse to undergo a complicated operation because of old age or poor physical status. The authors have used transanal endoscopic microsurgery (TEM) repeatedly to excise large polyps and fulgerize small polyps for preventing the canceration of the disease.

Research frontiers

TEM has been suggested as a minimally invasive procedure to manage ano-

rectal villous adenomas and early rectal adenocarcinomas. However, TEM procedure may cause internal anal sphincter (IAS) damage. It is unknown if several procedures of TEM cause more severe IAS damage than a single TEM. There had been no studies on clinical and anorectal functional outcome after repeated TEM.

Innovations and breakthroughs

It is unknown whether TEM that is performed multiple times causes more severe IAS damage. This is the first study to report that repeated TEM is a good choice of treatment for resection of multi-polyps in the remaining rectum of FAP patients who undergo subtotal colectomy. Furthermore, the study showed that a good anoretal functional outcome with little IAS damage was achieved after repeated TEM.

Applications

Repeated TEM is a good choice of treatment for resection of multi-polyps in the remaining rectum of FAP patients who underwent subtotal colectomy.

Peer review

This is a clinical report on anorectal function measured before and 2 to 3 after TEM excision of recurrent polyps in the rectal stump of FAP patients who underwent subtotal colectomy. This is a very interesting article which evaluates the short and long-term anorectal function (as measured by anorectal manometry) following repeat TEM procedures. TEM is very helpful tool in the management of recurrent polyps in FAP patients who have a residual rectal stump. There is little data on its use in this clinical setting, and no data on the impact of serial TEM procedures on anorectal function, so this work is important.

Abstract

The exact aetiology of sigmoid volvulus in Parkinson's disease (PD) remains unclear. A multiplicity of factors may give rise to decreased gastrointestinal function in PD patients. Early recognition and treatment of constipation in PD patients may alter complications like sigmoid volvulus. Treatment of sigmoid volvulus in PD patients does not differ from other patients and involves endoscopic detorsion. If feasible, secondary sigmoidal resection should be performed. However, if the expected surgical morbidity and mortality is unacceptably high or if the patient refuses surgery, percutaneous endoscopic colostomy (PEC) should be considered. We describe an elderly PD patient who presented with sigmoid volvulus. She was treated conservatively with endoscopic detorsion. Surgery was consistently refused by the patient. After recurrence of the sigmoid volvulus a PEC was placed.

INTRODUCTION

Gastrointestinal symptoms are common in Parkinson's disease (PD) and may give rise to life threatening conditions such as sigmoid volvulus. Early recognition and treatment of constipation in PD patients may alter complications such as sigmoid volvulus. We describe a patient known to have PD with recurrent bowel dilatation associated with sigmoid volvulus. Furthermore, we review the relevant literature concerning volvulus in patients with PD and treatment of this condition.

CASE REPORT

A 73-year-old female patient was admitted three times within three months to the gastrointestinal ward with recurrent painless abdominal distension. A week before her first admission she noticed progressive abdominal distension. Apart from nausea she experienced no other symptoms.

Her past medical history revealed breast carcinoma for which she had undergone a modified radical mastectomy in 1997 and resection of local recurrence combined with hormonal therapy in 2005. She was also known to have severe PD for more then twenty years.

Figure 1 Typical "bean-shaped" sigmoid with distension up to 11 cm representing sigmoid volvulus.

Figure 3 Colonic dilatation resolved after endoscopic detorsion with large bore rectal tube placement.

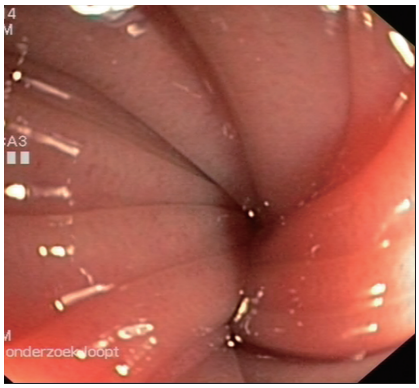

Figure 2 Endoscopic image of torsion of sigmoid: "Toffee-sign".

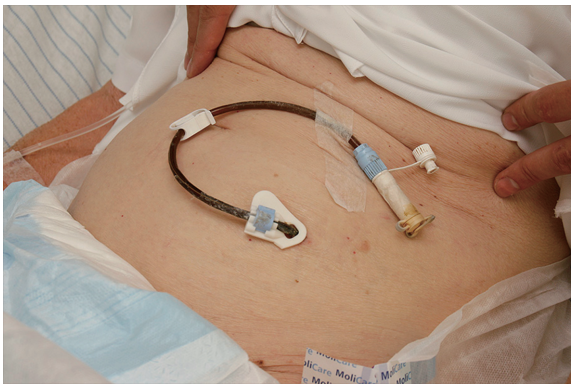

Figure 4 Percutaneous endoscopic colostomy has been placed.

Medication consisted of levodopa/carbidopa and amantadine.

On physical examination at admission the patient was not very ill and had normal vital parameters. Her abdomen was grossly distended and high pitched bowel sounds were heard. The clinical diagnosis of an ileus was made. Laboratory tests were unremarkable without any sign of inflammation. An abdominal X-ray revealed a typical coffee bean-shaped sigmoid with gross dilatation up to 11 cm (Figure 1).

The patient was treated with enemas and laxatives. A colonoscopy was performed which did not reveal any mucosal irregularities. At 40 cm from the anus a strangulation of the sigmoid was seen with proximal dilatation of the colon which is pathognomonic for volvulus (Figure 2). Surgical treatment was repeatedly considered but consistently refused by the patient. Decompression of the colon was finally established by a large (11 French) cannula inserted proximal from the evident torsion of the sigmoid (Figure 3). Ten days after admission the patient was discharged in good clinical condition.

However, two months later she was readmitted with a recurrence of sigmoid volvulus. For the second time, conservative treatment with endoscopic derotation of the affected sigmoid and placement of a cannula for decompression was performed. To prevent further recurrence, a percutaneous endoscopic colostomy (PEC) was placed in the distal colon to achieve fixation to the abdominal wall (Figure 4). No complications occurred. The patient was discharged a few days later. Two years later she was admitted with a third recurrence of sigmoid volvulus and was again successfully treated with endoscopic derotation. The patient still persists in her wish not to be operated on.

DISCUSSION

Colonic dysfunction in PD

Parkinsonism is an extrapyramidal syndrome with symptoms consisting of a variable combination of general rigidity, disturbance of posture, gait and tremor. The signs of this chronic and progressive disease, affecting mostly people of sixty-five years and older, are caused by loss of nerve cells in the pigmented substantia nigra pars compacta and the locus coeruleus in the midbrain. Apart from typical parkinsonian features as mentioned above, gastrointestinal symptoms are common, especially motility disorders, varying from swallowing disorders, gastroparesis to bowel dysmotility and anorectal dysfunction[1-3]. Constipation is one of the most common gastrointestinal features in PD patients. Constipation may even precede typical symptoms 10 or 20 years before the onset of PD[4-7]. Several reports have revealed that constipation occurs in up to 50% of patients with PD. The severity of constipation seems be directly related to the severity and duration of PD[1].

There is a multiplicity of factors contributing to constipation in PD patients. Reduced physical activity and a decrease in swallowing saliva may play a role in constipation. Antiparkinsonian drugs are thought to contribute

to diminished bowel motions[8], although an association between constipation and PD was noted even before the introduction of antiparkinsonian drugs by Parkinson in 1817. Several studies did not confirm the correlation between medication and delayed colonic transit time[1,9]. In PD, colonic transit time is prolonged in all segments of the colon[8-11]. Defecation itself can be impaired by decreased phasic rectal contractions, weak abdominal strain and/or paradoxical sphincteric contractions during defecation[10]. However, the exact pathophysiology of autonomic gut dysfunction remains obscure.

Constipation may result from both peripheral as well as central nerves. Depletion of dopamine-containing neurons in the central nervous system is a basic defect in PD. On the other hand, a substantial decrease in dopaminergic myenteric neurons has been documented[12]. Deposition of intracytoplasmic hyaline inclusions, so-called Lewy bodies, can be found not only centrally in the pigmented nuclei but also in the myenteric and submucosal plexus[13]. Conditions associated with constipation in PD patients include megacolon and sigmoid volvulus[14,15].

Volvulus and PD

In sigmoid volvulus there is twisting of the sigmoid around its mesenteric axis. Apart from obstruction it may also involve strangulation of the main vessels at the base of the affected mesentery. Sigmoid volvulus is the third leading cause of large bowel obstruction in adults and is even more common in the elderly[16-18]. It can be a life threatening condition with high mortality rates of up to 50%[19].

The incidence of sigmoid volvulus in PD is not known. Only a few reports have been published concerning this association[14,20-22]. A longstanding history of constipation is, amongst anatomic variations and neuropsychiatric diseases, one of the risk factors for the development of volvulus because of an abnormally loaded loop of bowel[23,24]. The diagnosis of volvulus is based on physical examination in combination with an abdominal X-ray revealing a typical "coffee bean" shaped sigmoid. In the majority of cases no further investigation is required to confirm the diagnosis of volvulus[25]. If there is any doubt about possible obstructive disease, an abdominal computed tomography-scan can be considered. However, colonoscopy is the most favourable diagnostic tool to visualize obstructive colonic moments. The endoscopic picture of volvulus shows a pinpoint lumen with wrenched sides. When passing the pinpoint opening one sees a grossly dilated lumen (Figure 2). In the case of volvulus, endoscopy allows immediate treatment.

Management of sigmoid volvulus

Awareness of the high incidence of gastrointestinal disorders, and especially constipation, in PD patients is mandatory in order to recognise a condition such as sigmoid volvulus. The question remains as to whether the aetiology of sigmoid volvulus in this specific group of patients is different. If constipation is the main cause, the primary focus should be on medical prophylactic treatment with laxatives. However, if patients with PD have redundant sigmoid, surgery remains the first choice of treatment. No data have been published related to this question. Even for volvulus in general, the published data are too scarce to allow high level evidence-based judgement.

Early aggressive treatment of constipation with dietary adjustments, physiotherapy, bulk-forming agents and laxatives should be the aim in all PD patients. The prokinetic agent, cisapride, has been shown to reduce colonic transit time in PD patients, but seemed to be ineffective after long-term use[9] and is no longer regularly available. Tegaserod, a 5-hydroxytryptamine type 4 agonist, has shown to improve bowel movement frequency and stool consistency[26]. In addition, improvement in subjective experience of symptoms by PD patients has been observed[27]. Further trials are not expected since this drug was also withdrawn because of an increased risk of serious cardiovascular adverse events.

In patients with alarming signs of possible necrosis or perforation, immediate surgical intervention is needed. When symptoms are mild and not worrisome, urgent endoscopic detorsion should be considered as the first choice of treatment[16,25,28]. Endoscopy enables direct assessment of the viability of the colonic mucosa. Although endoscopic detorsion has high recurrence rates, varying from 3.3% to over 60%[29,30] , it is a relatively safe procedure with mortality rates of 1%-3%[29,31].

In cases of successful endoscopic detorsion, semi-elective sigmoidectomy can be performed. This allows an appropriate workup to achieve optimal preoperative conditions. Mortality rates vary between 0% and 10%[16,23,32,33].

In recurrent volvulus, surgery is the first choice of treatment as endoscopy in recurrent volvulus is accompanied by a raised mortality rate of up to 20%[16]. However, surgical treatment in the acute phase of volvulus is also known to have high mortality[16,17,23,29,31].

There are several surgical options to treat volvulus, ranging from operative detorsion alone to retroperitoneal fixation and partial resection with or without primary anastomosis. Detorsion alone has a very high recurrence rate of up to 74%[16,31].

Resection performed with primary anastomosis is advocated by some authors as it has the advantage of avoiding a second operation to restore continuity[25,28,32]. Mortality in this group ranges from 0%-19%[23,28,33]. If the expected surgical morbidity and mortality is unacceptably high or if patients refuse surgery, as in our case, PEC can be considered. Under endoscopic vision, a tube is placed percutaneously in the distal colon. This allows fixation of the colon to the abdominal wall and if necessary offers direct access for laxatives and desufflation. Complications following PEC such as infection, faecal leakage and buried internal bolster can cause significant

morbidity, but is a good alternative in selected cases[34,35]. There are few available publications on recurrence rate after PEC[34,35].

In conclusion, gastrointestinal dysfunction is a common feature in elderly patients, and especially in those affected by PD. Patients with chronic constipation are more likely to develop a complication like sigmoid volvulus. The association between sigmoid volvulus and PD has been described previously. There are no data available suggesting different treatment for sigmoid volvulus in PD patients. In general, endoscopic detorsion can be performed as the first choice of treatment in acute sigmoid volvulus if signs of an acute abdomen are absent. This should be followed by resection at a later stage if the condition of the patient allows surgical intervention. However, if there are signs of gangrene, an emergency operation is the only therapeutic option and endoscopic treatment should not delay surgery. PEC is an alternative treatment for selected cases if surgical intervention is not an option.

Abstract

Several case reports deal with the relationship between hepatitis C virus (HCV) infection and pulmonary or hepatic sarcoidosis. Most publications describe interferon α-induced sarcoidosis. However, HCV infection *per se* is also suggested to cause sarcoidosis. The present case report describes a case of biopsy-verified lung and liver sarcoidosis and HCV infection, and the outcome of antiviral therapy. In March 2009, a 25-year-old man presented with moderately elevated liver enzymes without any clinical symptoms. The patient was positive for HCV antibodies and HCV RNA of genotype 1b. Four months later the patient became dyspnoic and pulmonary sarcoidosis was diagnosed by lung biopsy and radiography. A short course of corticosteroid treatment relieved symptoms. Three months later, liver biopsy showed noncaseating granulomas consisting of epithelioid histiocytes and giant cells with a small amount of peripheral lymphocyte infiltration, without any signs of fibrosis. Chronic HCV infection with coexistence of pulmonary and hepatic sarcoidosis was diagnosed. Antiviral therapy with peginterferon α and ribavirin at standard doses was started, which lasted 48 wk, and sustained viral response was achieved. A second liver biopsy showed disappearance of granulomas and chest radiography revealed normalization of mediastinal and perihilar glands. The hypothesis that HCV infection *per se* may have triggered systemic sarcoidosis was proposed. Successful treatment of HCV infection led to continuous remission of pulmonary and hepatic sarcoidosis. Further studies are required to understand the relationship between systemic sarcoidosis and HCV infection.

INTRODUCTION

The estimated global prevalence of hepatitis C virus (HCV) infection is around 3%, corresponding to 170

million infected people[1]. As estimated, up to 1% of 1.34 million of the Estonian population are infected with HCV and this virus was reported to be the main etiological agent for chronic hepatitis and liver cirrhosis in Estonian patients[2]. After acute infection, chronic hepatitis develops in up to 80% of cases and may lead to hepatic and extrahepatic complications. There have been reported more than 30 extrahepatic manifestations of chronic HCV infection[3]. The best documented manifestation is essential mixed cryoglobulinemia. Non-cryoglobulin diseases having a relationship with HCV include idiopathic pulmonary fibrosis, lichen planus, Sjogren syndrome, autoimmune thyroiditis, porphyria cutanea tarda, chronic polyarthritis and some others[4].

Sarcoidosis is a systemic inflammatory disease of unknown etiology with the presence of noncaseating epithelioid cell granulomas in many organs. The diagnosis of sarcoidosis is based on a compatible clinical and/or radiological picture, histological evidence of noncaseating granulomas and the exclusion of other diseases having a similar histological or clinical picture[5].

The prevalence of sarcoidosis in the general population varies throughout the world from less than one case to 40 cases per 100 000 people or 0.001%-0.04%[5,6]. The prevalence of sarcoidosis in HCV-infected patients is reported to be 0.1%-0.2%[7,8]. A relationship between systemic sarcoidosis and HCV infection may emerge due to antiviral therapy with interferon α and ribavirin (in 75% of cases), or owing to unknown factor(s)[9]. Coexistence of sarcoidosis and untreated HCV infection prompted some authors to suggest that HCV infection *per se* can induce sarcoidosis[10]. The decision to start antiviral therapy for HCV infection in patients with pre-existing sarcoidosis is a delicate challenge for the clinician, calling for close monitoring[9].

This case report describes the clinical and histological characteristics of systemic sarcoidosis and chronic HCV infection, and the successful outcome of antiviral therapy.

CASE REPORT

In March 2009, a 25-year-old male patient was referred to the gastroenterologist at the West-Tallinn Central Hospital with moderately elevated liver enzymes: alanine aminotransferase (ALAT) 111 U/L (reference range < 42 U/L), aspartate aminotransferase 44 U/L (reference range < 37 U/L); and with positive HCV antibodies. According to his case history, elevated liver enzymes were also observed during a routine visit to the family doctor in December 2008.

The patient denied intravenous drug abuse, any occupational exposures and blood transfusions in the past. The time and manner of acquisition of HCV infection remained uknown. The patient did not have any symptoms of liver disease. Human immunodeficiency virus, surface antigen of the hepatitis B virus and autoantibodies; i.e., antinuclear antibodies, anti-mitochondrial M2-antibodies, anti-liver-kidney microsome antibodies and anti-smooth muscle antibodies, were negative. The values of ferritin, thyroid-stimulating hormone and ceruloplasmin were within the reference ranges. The patient was infected with HCV genotype 1b determined by the hybridization technique (VERSANT HCV genotype assay); the viral load was 723 000 IU/mL as analysed by the polymerase chain reaction assay (COBAS® AmpliPrep/COBAS® TaqMan). Abdominal ultrasound revealed no changes in liver size and appearance, nor was there noted any pathology in the other internal organs.

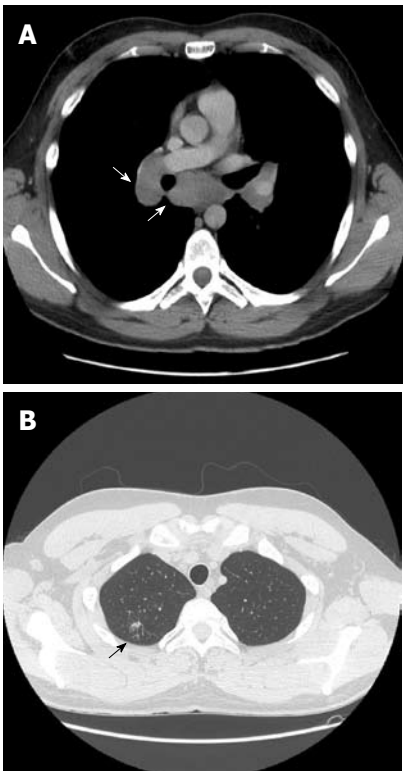

Figure 1 Thoracic computer tomographic scans of mediastinal, hilar lymph nodes and pulmonary nodules. Enlarged lymph nodes (A, white arrows) and small pulmonary nodules in the right upper lobe before prednisolone treatment (B, black arrow; July 2009) are revealed.

The diagnosis was chronic hepatitis C of unknown origin. Antiviral treatment was offered, but the patient for some reason postponed treatment and decided to start it several months later.

In July 2009, the patient was referred to the pulmonologist due to erythema nodosum on his legs, and dyspnea and cough. Computer tomography (CT) scans of the chest showed mediastinal and hilar adenopathy and focal lesions in the right upper lung lobe (Figure 1). Transbronchial biopsy of pulmonary lymph nodes was performed, which revealed epithelioid cell granulomas (Figure 2). Systemic sarcoidosis was diagnosed and corticosteroid treatment with prednisolone 20 mg orally was started. After one month of corticosteroid therapy the skin lesions disappeared. As the patient did not experience any symptoms, he discontinued prednisolone treatment.

In October 2009, the patient still had elevated ALAT (60 U/L) and the viral load was 687 000 IU/mL. Ultra-

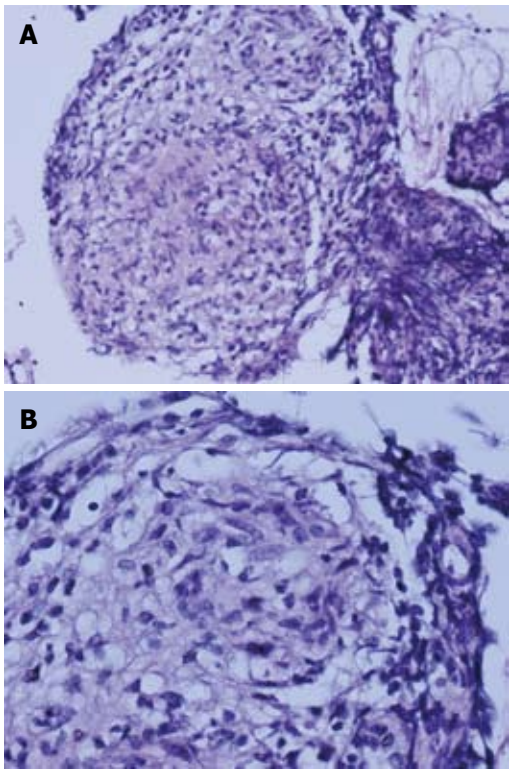

Figure 2 Biopsy taken from a pulmonary lymph node. Two tight naked round well-formed granulomas are surrounded by a small amount of lymphocytic infiltration. The granulomas consist of epithelioid cells; there are no necrosis, giant cells, Shaumann or asteroid bodies. Stained with hematoxylin and eosin, magnification × 200 (A) and × 400 (B).

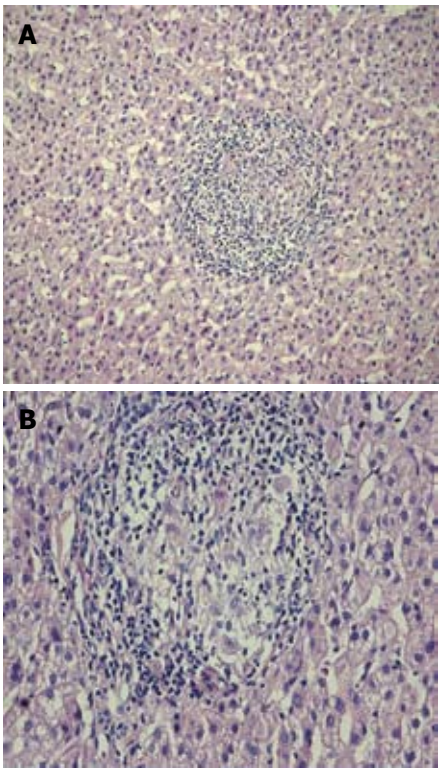

Figure 3 Liver biopsy revealing a noncaseating granuloma consisting of epithelioid histiocytes and giant cells with a small amount of peripheral lymphocyte infiltration. Stained with hematoxylin and eosin, magnification × 200 (A) and × 400 (B).

sound-guided liver biopsy was performed. It revealed 3 noncaseating granulomas consisting of epithelioid histiocytes and giant cells with weak peripheral lymphocyte infiltration, without any signs of fibrosis specific for chronic hepatitis C (Figure 3). His chest CT scans showed mild regression of lung sarcoidosis: mediastinal lymph nodes had became smaller while all other pathological findings remained the same (Figure 4A and B). The patient was diagnosed with chronic hepatitis C with coexisting pulmonary and hepatic sarcoidosis.

Taking into consideration that there was no exacerbation of pulmonary sarcoidosis and that the patient had chronic hepatitis C, antiviral therapy was opted for: peginterferon α-2a (Pegasys, F.Hoffmann La Roche Ltd, Basel, Switzerland) at a dose of 180 μg once a week subcutaneously and 1200 mg of ribavirin (Copegus, F.Hoffmann La Roche Ltd, Basel, Switzerland) daily orally was started. At week 4, the viral load decreased to 4755 IU/mL and no HCV RNA was found at weeks 12 and 24. The patient completed antiviral therapy at week 48 with normal liver enzymes and negative HCV RNA. At the end of treatment, chest CT scans showed a decrease in mediastinal and hilar adenopathy with disappearance of focal lesions in the upper lobe of the right lung (Figure 4C and D).

During treatment the patient experienced some side effects (fatigue, weight loss of 5 kg); he developed neutropenia and anemia but there was no need to change the doses of antiviral medications.

Six months after the end of treatment the patient had negative HCV RNA and his liver enzymes were normal. Sustained viral response (SVR) was documented. CT scans showed small mediastinal lymph nodes about 0.5 cm in diameter, and absence of hilar adenopathy and focal lesions in the upper lobe of the right lung.

Five months after SVR was confirmed, a new liver biopsy was performed which showed no remnant granulomas and mild steatosis in the liver tissue (Figure 5). No corticosteroid treatment was given after the first treatment course in July.

DISCUSSION

Sarcoidosis is a chronic multi-systemic granulomatous disease of unknown etiology related to exaggerated cellular immunological reactions[11]. The lungs, the liver, the lymph nodes, and the skin are commonly involved.

Here, we present a case of systemic sarcoidosis with the example of a treatment-naive patient with HCV 1b infection. The patient was first diagnosed as symptom-free with chronic HCV infection. Four months later, lung symptoms developed and the diagnosis was pulmonary sarcoidosis. The complaints - cough and dyspnea, as well as erythema nodosum - were relieved by the administration of oral corticosteroids. Three months later a liver biopsy revealed hepatic granulomas. Chronic HCV infection with coexistence of pulmonary and he-

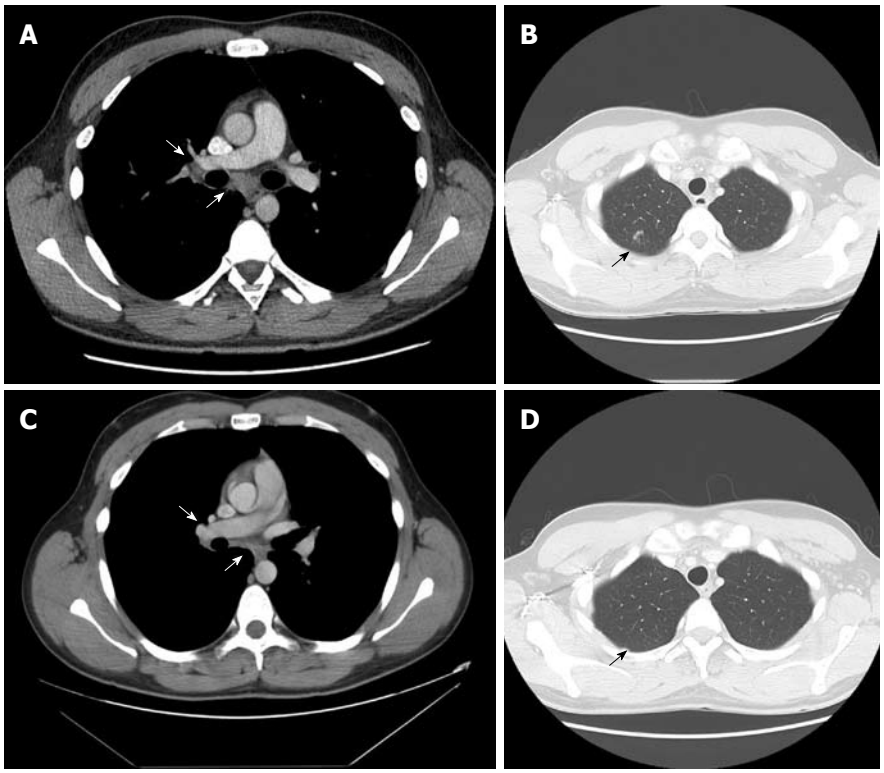

Figure 4 Thoracic computer tomographic scans of mediastinal, hilar lymph nodes and pulmonary nodules. A significant decrease in size of mediastinal and hilar lymph nodes (A, white arrows) is shown before initiation of antiviral treatment but pulmonary nodules remain at the same levels (B, black arrow; October 2009). At the end of treatment no progression of lymph nodes is revealed (C, white arrows) and pulmonary nodules are absorbed (D, black arrow; December 2010).

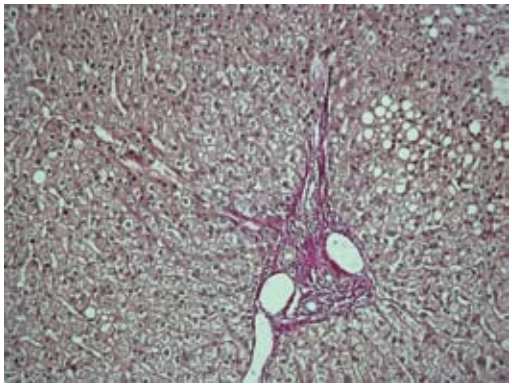

Figure 5 Liver biopsy revealing the absence of granuloma formation with vesicles of steatosis. Stained with van Geason, magnification × 200.

patic sarcoidosis was diagnosed. The patient started and completed a full 48-wk course of antiviral therapy without aggravating lung symptoms.

According to Ramos-Casals *et al*[9], sarcoidosis during antiviral therapy (in 75% of cases) has mainly a benign uncomplicated evolution, while more complicated cases are observed especially in HCV patients with preexisting sarcoidosis both with and without previous antiviral therapy.

In our studied HCV treatment-naive patient, systemic sarcoidosis was unrelated to antiviral therapy. In sarcoidosis observed in treatment-naive patients with HCV infection, skin involvement is less frequent than in sarcoidosis triggered by antiviral therapy. In the former case, systemic corticosteroids have to be used more often and the outcome appears less favorable[8]. In our patient, corticosteroid therapy for sarcoidosis was given for only a month when the patient discontinued therapy. Despite this, the outcome of therapy was favorable: the skin lesions disappeared, and progression of lung sarcoidosis or exacerbation of HCV infection was not noted.

In the case of pre-existing sarcoidosis the decision about starting antiviral therapy under close monitoring should be made very cautiously[8,9]. According to Charlier *et al*[12], reactivation of pre-existing sarcoidosis in HCV patients is rare and the manifestations of the disease are not very severe. Bearing these aspects in mind, antiviral therapy with peginterferon α and ribavirin for treatment of chronic HCV infection was opted for in the present case. The therapy was successful and the patient achieved SVR. No reactivation of systemic sarcoidosis with skin, lung or hepatic involvement was observed. The absence of hepatic granuloma on the second liver biopsy, performed five months after SVR, demonstrated a favorable treatment result possibly preventing hepatic granuloma in our patient, which develops into liver cirrhosis with life-threatening variceal bleeding in about 1% of these cases[13].

Our case report, as it considers hepatic involvement, is interesting in several aspects. Firstly, for sarcoidosis in the liver, the course of which is usually mild and tran-

sient, and clinically silent, granulomatous lesions are usually very small and asymptomatic[14,15]. In our patient the manifestations of liver disease were asymptomatic.

Corticosteroid treatment of hepatic sarcoidosis is used only for patients with severe liver lesions, such as chronic cholestatic disease, portal hypertension and cirrhosis[16].

Secondly, hepatic granulomas are not very rare in HCV disease. The prevalence of hepatic granulomas in liver biopsies of patients with chronic hepatitis C have been reported to be from 0.8% up to 9.5%[17-19] and only when other etiological factors of granuloma formation are excluded may it be considered as a part of the histologic spectrum of HCV[19]. In our treatment-naive HCV patient, noncaseating granuloma was found first in the lung lymph node and later liver biopsy also revealed granulomas, so coexistence of systemic sarcoidosis and chronic hepatitis C was diagnosed.

All these facts show that some similar specific immune pathogenic mechanisms may be involved in the course of systemic sarcoidosis and chronic HCV. It is possible that complex dysregulation of the cytokine/chemokine network in patients with HCV infection along with some other host factors might induce the release of certain mediators and activation of mononuclear phagocytes that finally cause a granulomatous reaction[20]. Although coexistence of both diseases in our case may be a coincidence, we, like Bonnet *et al*[10], suggest that HCV *per se* could be an antigenic trigger for development of sarcoidosis.

As systemic sarcoidosis may be reactivated after antiviral treatment, further close follow-up of our patient is needed.

In conclusion, physicians should be aware that HCV-infected patients may have systemic sarcoidosis unrelated to antiviral treatment. Also, it is obvious that further case-control studies focusing on sarcoidosis in patients with HCV infection and the relationship between sarcoidosis and antiviral therapy are needed.

CONSENT

Written informed consent was obtained from the patient for publication of this case report and accompanying images.

Abstract

Inflammatory myofibroblastic tumor (IMT) in the liver is an uncommon lesion of uncertain pathogenesis. In most cases, symptomatological imaging and clinical studies suggest malignancy. We report a case of liver IMT with imaging findings from positron emission tomography/computed tomography (PET/CT), contrast-enhanced computed tomography (CECT) and contrast-enhanced ultrasonography (CEUS). This report was the first to depict a PET/CT scan of a liver IMT that revealed an inhomogeneous, intense (fluorine 18)-fluoro-2-deoxy-D-glucose uptake. The CECT and CEUS images showed a hepatic artery supplying blood to the mass and necrosis. The characteristic histopathological features and the presence of spindle cells expressing smooth muscle actin, collagen fibers and lymphocytes allowed for the diagnosis of liver IMT. Recognizing such findings will help to achieve a correct diagnosis and may prevent inappropriate treatment.

INTRODUCTION

Inflammatory myofibroblastic tumor (IMT) is rare. Although IMT was once considered a soft tissue lesion, it has also been reported in the mesentery, omentum, major salivary glands, larynx, breast and thyroid gland, and in visceral organs, such as the lung, small intestine and kidney. To date, the appearance of IMT in the liver has been minimal[1]. Because of how it appears on different types of imaging, IMT is difficult to clinically differentiate from malignant tumors. IMT may regress spontaneously; therefore, indications for surgery must be carefully assessed. Cases involving (fluorine 18)-fluoro-2-deoxy-D-glucose positron emission tomography and computed tomography (^{18}F-FDG-PET/CT) examinations of liver IMT have never been reported. Here, we report a case of liver IMT using ^{18}F-FDG-PET/CT, contrast-enhanced computed tomography (CECT) and contrast-enhanced ultrasonography (CEUS). The imaging findings showed a hepatic artery supplying blood to the mass in the presence of necrosis. An inhomogeneous, intense ^{18}F-FDG uptake was also noted. The characteristic histopathological features, along with the presence of spindle cells expressing smooth muscle actin (SMA), collagen fibers and lymphocytes, allowed for the IMT diagnosis. Recognizing such findings will improve correct diagnosis and may prevent inappropriate treatment.

CASE REPORT

A 42-year-old Chinese woman presented with high fever (39 ℃) and denied having abdominal pain, fatigue and weight loss. On physical examination, the right upper quadrant of the patient's liver was tender at palpation. After being placed on anti-infection medicine, her body temperature decreased to a maintainable range (within normal limits). However, when the treatment ceased, the original fever returned. The laboratory results revealed a white blood cell count of 10 900/mL with segmental neutrophilia (73.4%) and slightly elevated levels of C-reactive protein (CRP, 116.2 mg/L) and fibrinogen (5.191 g/L); the erythrocyte sedimentation rate (ESR) and hemoglobin level (7.4 g/dL) were normal. The liver function tests were within the normal limits, as were the tests for alpha-fetoprotein (AFP, 2.0 ng/mL), carbohydrate antigen 19-9 (CA19-9, 13.84 U/mL), CA125 (17.71 U/mL), CA50 (12.4 U/mL) and carcinoembryonic antigen (CEA, 1.91 ng/mL). The serology markers for hepatitis and infectious agents such as echinococcus were also negative.

Conventional ultrasonography (CUS, ProSound SSD Alpha 10 system designed by Aloka Co, Ltd, Tokyo, Japan) revealed that there was a 3.8 cm × 4.6 cm hypoechoic mass in the right anterior lobe of the liver that had a clearly defined border and a heterogeneous echo texture. CEUS examinations were performed after the CUS by administering a sulfur hexafluoride-filled microbubble contrast agent (SonoVue; Bracco SpA, Milan, Italy). After administering the contrast agent, the arterial phase images showed hyperenhancement of the mass. The portal phase and parenchymal phase images revealed wash-out that corresponded to that on the arterial phase images. On the edge of the mass, there was a 1.3 cm × 1.5 cm solid nodule with a strong echo and a clear border that did not show signs of either parenchymal or arterial phases. CEUS indicated that the mass had a rich blood supply and necrosis, which is typical of a malignant tumor (Figure 1).

The patient had a whole-body ^{18}F-FDG PET/CT (Discovery VCT, GE, American) scan that returned normal results for all of the organs except the liver. The imaging showed an inhomogeneous, intense uptake of ^{18}F-FDG with SUVmax 9.1 (SUV standardized uptake value) in the anterior segment of the right lobe of the liver (Figure 2). The inhomogeneous uptake of the mass was more intense at its periphery. The mass size was approximately 4.9 cm × 4.6 cm × 5.0 cm. An abdominal CECT confirmed tumor localization in the anterior segment of the right lobe of the liver and showed that enhancement of the mass was broad and well defined at its periphery in the arterial phase. Portal venous phase images depicted a further enhancing mass, while the delayed-phase images revealed a quick wash-out that corresponded to the observations from the arterial-phase images. They were not as prevalent as those reported during the portal venous phase. There was evidence of necrosis in front of the mass and a liver lobe artery at the periphery of the mass. A 1.6 cm × 1.5 cm low-density nodule that had not been illuminated during either of the phases was present on the front edge of the mass (Figure 3).

Laparoscopy indicated that the mass was protruding from the liver surface and was slightly adhered to the surrounding tissue. The mass color was yellowish; however, it did not cause congestion or edema, and the common bile duct was not enlarged. The gall bladder, stomach, spleen, colon, small intestine and other organs were normal. A right lobectomy of the liver was performed by laparoscopy, and the mass was completely resected because the minimal contact it had with the large vessels minimized the risk. A portion of the free necrotic liver tissue was removed. Doctors dissected the specimen, which was approximately 6 cm in diameter.

Upon closer pathological examination, the mass measured 4.5 cm × 4.3 cm × 3.5 cm and weighed 1.6 kg; it was easily removed from the surrounding parenchyma. A microscopic examination revealed that the mass was composed of collagen fibers, chronic inflammatory cells lying on loose T-lymphocytes and ganglion-like cells. The chronic inflammatory infiltrate was characterized by the predominant proliferation of plasma cells in addition to lymphocytes and collagen fibers. An immunohistochemical analysis revealed that the spindle cells were positive for SMA and that the ganglion cell-like cells were positive for neuron-specific enolase and S-100. Staining for P53, desmin and epithelial membrane antigen was negative. The histological patterns were fibrous histiocytoma-like and desmoid-type (Figure 4).

DISCUSSION

IMT is a lesion with intermediate biological behavior that may recur with local or surrounding infiltration or, in rare cases, metastasis. IMT has been observed in almost all solid organs; however, its incidence in the liver has been low[1]. The case presented here involved a 42-year-old woman with a mass located on the right lobe of the liver; according to the pathological and immunohistochemical findings, the mass was diagnosed as IMT. One and a half years after surgery, no recurrence or metastasis have been identified.

This case contradicted the frequent male predilection of the lesion (male/female: 1.5/1), demonstrating that liver IMT was not limited to younger age groups and males[1]. Clinical findings indicate that symptoms in most cases include fever, abdominal pain, weight loss, weakness, and anorexia. Laboratory investigations usually suggest an inflammatory process: leukocytosis, neutrophilia, elevated ESR and CRP, anemia, thrombocytosis, polyclonal hypergammaglobulinemia, and slightly elevated levels of liver enzymes. Tumor markers, such as serum AFP and CEA, are always normal. Although these markers are valuable in the discrimination of liver IMT from malignant tumors, they cannot completely rule out some malignancies in which AFP levels may also be normal, such as fibrolamellar hepatocellular carcinoma. In this

A: Axial arterial phase images showing a hyperenhanced mass well defined at the periphery of the mass; B: Arterial phase images showing a liver lobe artery (dash arrow) around the mass and the front edge of the mass lay a low density nodule (solid arrow) not enhancing in three phase images; C: Axial portal venous phase images showing a further enhanced corresponding to the arterial phase images; D: Axial delayed images showing obviously wash-out corresponding to the arterial phase images.

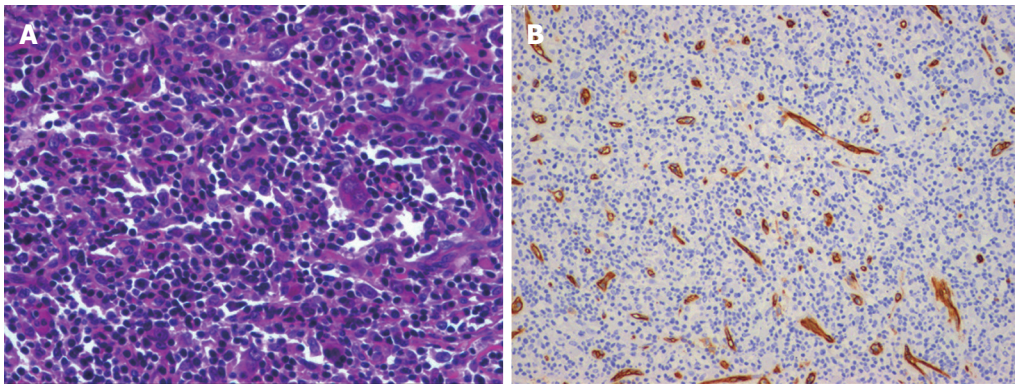

Figure 4 Histopathology findings of the liver inflammatory myofibroblastic tumor. A: Lesion was composed of chronic inflammatory cells and spindle cells (hematoxylin and eosin stain, × 200); B: Spindle cells were positive in smooth muscle actin tumor (immunostaining, × 100).

case, the clinical symptoms were nonspecific. The patient denied having abdominal pain, fatigue and weight loss. As described in the laboratory setting, the aminotransferases were all normal.

Furthermore, radiological aspects of IMT are usually similar to those of a malignant neoplasm[2]. Mali *et al*[3] reported a homogeneous mass without calcification or contrast enhancement. Megumi *et al*[4] reported that CECT revealed a soft, deeply stained image on the margin of the mass in the early phase. In the late phase, enhancement of the center of the mass was poor, and there was a soft, deeply stained image around the center. In this case, the CECT showed a hyperenhanced image in the arterial phase and a further developing mass in the portal venous phase; the contrast was obviously washed out in the delayed phase. On the front edge of the mass lay a low-density nodule, indicating the necrotic liver tissue that was removed by the surgeon, which has never been reported. However, the CECT image results of our case conflicted with the above case reports. These findings support the notion that the IMT CT image findings were nonspecific and could mimic many diseases.

Nam *et al*[5,6] observed two different appearances of the hepatic IMT. The enhancement was broad and ill-

defined at the periphery of the mass. In our case, the enhancement was broad and well defined at the periphery of the mass. In agreement with the histopathologic findings, the hypo-enhanced areas identified in the CECT correlated with the concentrated fibrous tissue, and the hyper-enhanced area corresponded predominantly with the cellular infiltration that contained foamy histiocytes, plasma cells, and lymphocytes. These image and pathological results corresponded to the findings in this study. To our knowledge, there has been no report on liver IMT with PET/CT. Wan *et al*[7] reported that inflammatory tissue has high metabolic activity. In addition, this case demonstrated an inhomogeneous, intense ^{18}F-FDG uptake with SUVmax 9.1. The inhomogeneous ^{18}F-FDG uptake of the mass corresponded to the different mass components (collagen fibers, chronic inflammatory cells, T-lymphocytes, ganglion-like cells).

IMT may be more difficult to clinically differentiate from malignant tumors, and different types of image findings and an excision biopsy may frequently be needed to make the diagnosis. The postoperative prognosis of liver IMT is favorable[4]. Some reports have shown that percutaneous needle biopsies are efficient for making the diagnosis[8]. When malignant tumors are suspected, a needle biopsy is not necessarily recommended because there is a risk of tumor cell dissemination. Because it may show spontaneous regression, indications for surgery must be carefully assessed. It is important that similar clinical cases perform ^{18}F-FDG PET/CT, CECT or MRI.

The pathogenesis of IMT is uncertain. Some authors have suggested an infectious origin; however, few cases have provided positive cultures or microorganisms isolated from tissue sections[2]. It was suggested that the chronic xanthogranulomatous pattern was a response to a previous infectious process. IMT can occur after surgery, trauma, radiotherapy or steroid use; it can also occur in connection with ventriculo-peritoneal shunts or infectious agents, such as *Mycobacterium avium intracellulare*, *Corynebacterium equi*, *Campylobacter jejuni*, *Bacillus sphaericus*, *Coxiella burnetii*, *Epstein-Barr* virus, *Escherichia coli*, *human herpes* virus 8 and *Actinomycosis*[3,9,10]. Some IMT cases are related to infectious or reparative processes, and the association of IMT with some infectious agents has been related to its pathogenesis, although it is rarely observed. According to some authors[6], IMT could develop secondary portal venous infection, and the inflammatory mass might enlarge together with the obliterative phlebitis, which may explain the tumoral development in the patient. As previously described in the literature, this tumor was found in the right lobe of the liver and was characterized by a well-circumscribed firm lesion with myxoid areas and a yellow or whitish color. Fleshy or myxoid surfaces suffering from lacerations rarely exhibit hemorrhage, necrosis or calcification[1]; however, this case showed necrotic liver tissue on the CECT and the CEUS, and this necrotic tissue was removed by our surgeon. The differential diagnosis depends upon the histological patterns observed; although we observed a hypocellular fibrous pattern with some inflammatory cells, the SMA immunoreactivity in the spindle cells was important in the diagnosis. CD34, CD23 and CD117 were non-immunoreactive in the spindle cells, which excluded the diagnosis of a fibrous solitary tumor. Although ganglion-like cells were positive in this case, there was no malignant tendency.

In this case, there was notable evidence of necrosis in front of the mass and a lobe artery at the periphery of the mass, which sometimes relates to malignant tumors. Although clinical, histopathological or molecular features do not predict biological behavior[10], recurrences are associated with the abdominal site, large size of the tumor and older age. Because the tumor may regress spontaneously, indications for surgery must be carefully assessed. Although ^{18}F-FDG PET/CT examinations can successfully differentiate IMT from other types of malignant tumors, the appropriate method of diagnosing liver IMT is still *via* histopathologic examination.

Abstract

Jejunal diverticulosis is uncommon and often asymptomatic. It can produce significant complications, and some complications are potentially life threatening and require early surgical treatment, such as obstruction, hemorrhage and perforation. There is no consensus on the management of this disease. Only a few cases of jejunal diverticulosis with midgut volvulus have been reported. We herein report a case of 57-year-old woman with jejunal diverticulosis causing small bowel volvulus who complained of intermittent upper abdominal pin-prick for 5 years that eventually progressed to a complete obstruction. The computed tomography scans revealed a mesenteric vessel "whirlpool" and laparotomy showed midgut volvulus secondary to jejunal diverticula. This case highlights jejunal diverticulosis causing small bowel volvulus as an uncommon mechanism of small bowel obstruction, which should be included in the differential diagnosis of small bowel obstruction.

INTRODUCTION

Although jejunal diverticulosis is rare and often asymptomatic[1], it can produce severe complications, such as obstruction, diverticulitis, hemorrhage and perforation. Obstruction can be caused by inflammatory stenosis, jejuna stones of the small bowel or small bowel volvulus. Most of the patients with gastrointestinal obstruction may require surgical intervention. Here we describe a patient with midgut volvulus due to jejunal diverticula. The computed tomography (CT) scans revealed a mesenteric vessel "whirlpool" and laparotomy showed midgut volvulus secondary to jejunal diverticula.

CASE REPORT

A 57-year old woman presented to our department with a 5-year history of increasingly intermittent upper abdominal pin-prick pain, which would occur after meals and eased in the right lateral decubitus. She denied any change in bowel or bladder habits, or presence of other gastrointestinal symptoms. There was no other relevant past medical, family or surgical histories. Left upper quadrant tenderness was found on physical examination.

The initial contrast-enhanced CT scan of the abdomen showed mesentery and superior mesenteric artery with "whirlpool" signs (Figure 1). However, most whirl signs exhibited on CT suggest but not prove to be indicative of small bowel volvulus[2]. Therefore, the patient was referred for an angiography due to the suspicion of a vascular variation as a reason to explain her intermittent upper abdominal pain. On the angiography, the superior mesenteric artery appeared twisted. Subsequent contrast barium study was performed with the suspicion of intestinal volvulus. The upper gastrointestinal barium study showed a diverticulum of duodenum, multiple gi-

ant jejunal diverticula and certified midgut volvulus (Figures 2 and 3).

On the fourth day of hospitalization, the patient experienced a worsening of pain. Physical examination revealed tenderness in the whole abdomen, with tinkling bowel sounds. Abdominal X-ray showed dilated bowel loops and air-fluid levels. Surgery was indicated based on the clinical manifestations, the symptoms of obstruction and the examination results.

She underwent an emergency laparotomy which revealed diffuse giant jejunal diverticulosis and midgut volvulus. The diameters of these diverticula ranged between 3.5 cm and 8 cm. The whole jejuna and its mesentery were found twisted clockwise by 540-degree at the root of mesentery. The proximal half of the small bowel was dilated, congested, and oedematous (Figure 4). Excision of the small bowel containing multiple jejunal diverticula and an end-to-end anastomosis of the jejuna were performed. The patient had an uneventful postoperative recovery and was discharged on the 12th post-operative day.

DISCUSSION

Jejunal diverticulosis is a rare entity with an incidence rate ranging from 0.3%-1.3% in autopsy series to 2.3% in radiographic findings[1]. Etiology of jejunal diverticulosis is still uncertain. Increased intraluminal pressure may play an important role. The mean age of symptomatic patients is up to 60 years in all reported studies. It is reported that jejunal diverticulosis associated with visceral neuropathies can lead to an increased intraluminal pressure, and it is commonly seen in connective tissue diseases, such as systemic lupus erythematosus[3-6].

About 80% of the jejunal diverticulosis cases present with no symptoms, and chronic clinical manifestations may be misdiagnosed as dyspepsia and irritable bowel syndrome, which delayed the correct diagnosis in its early phase.

A few symptomatic patients may explain of chronic post-prandial abdominal pain, nausea and vomiting, borborygmi, alternating diarrhea and constipation, weight loss, anemia, steatorrhea, tenderness and fever[7]. We should pay attention to these symptoms which reflect inflammation, malabsorption, hemorrhage or mechanical obstruction.

Mechanical intestinal obstruction occurs in 2.3%-4.6% of cases of jejuno-ileal diverticulosis[8]. Obstruction can be caused by inflammatory stenosis, intussusceptions and voluminous jejuna stones. Besides, in jejuno-ileal

diverticulosis, volvulus of the diverticula-containing segment is a cause of intestinal obstruction. The involved segment, which is filled with fluid and is heavier than the non-involved part, might be responsible for initiating the volvulus[8]. It is reported that a large small-bowel diverticulum was much more frequently seen in patients with volvulus (35%) than in those with small bowel volvulus (1%) ($P < 0.001$)[9].

The diagnostic work-up in asymptomatic patients can start with plain abdominal X-ray or CT. But in some cases, these modalities fail to show typical jejunal diverticula. Since they are situated along the mesenteric border, it makes the diagnosis difficult. The specific diagnosis of small bowel diverticula is possible by radiologic contrast studies using various forms of barium[10,11]. The radiologic technique of enteroclysis is specific for the jejuna and the ileum, and the barium meal for the duodenum[12]. Similar to the diverticulitis of the large intestine, perforation is the most common complication in diverticulitis of the small intestine[13]. Perforation is associated with peritonitis in most cases. Thus, we should choose iodine contrast instead of barium if perforation is suspected, considering the high mortality of barium solution peritonitis. Enteroscopy may be another feasible method for diagnosing small bowel diverticulosis[10,14]. In recent years, endoscopy has replaced enteroclysis and has become the most widespread technique for the diagnosis of small bowel diverticula[15].

In case of acute abdomen pain due to small bowel volvulus, repeated physical examinations and X-ray films are recommended. Besides, CT examination and angiographic study are helpful in diagnosis. The "whirl sign" on abdominal CT refers to a whirling or spiral shape of the mesenteric vessels, which may accompany the intestinal loops and their feeding vessels[2,16]. Fisher first described it as a CT finding suggestive of midgut volvulus[17]. It is a sensitive marker of volvulus with a sensitivity of 60% and an odds ratio of 25.3 in predicting the presence of small bowel obstruction necessitating surgery[18]. Awareness of the CT whirl sign is important in the triage of patients who need emergency surgical intervention[19]. Although angiography is not feasible for all the suspected cases of intestinal volvulus due to its invasive nature and high cost, it is still a good method for preoperative evaluation of the "whirlpool" and "barber's pole"[16].

Usually uncomplicated jejunal diverticulosis does not require operative management. However, surgical intervention is mandatory in patients with complications of jejunal diverticulosis. Surgical therapy of jejunal diverticulosis with small bowel volvulus consists of untwisting or resecting the involved segment. A mortality rate of 25% was reported[8].

In our case, the main clinical symptom in the patient's history was increasingly intermittent upper abdominal pin-prick pain with vomiting. It was caused by hyperdistention of the voluminous diverticula. The thickened and enlarged small bowel found at laparotomy would suggest that partial obstruction was present for some time before the acute episode.

In summary, we present a case of a midgut volvulus which was induced by jejunal diverticula. Jejunal diverticulosis remains asymptomatic in about 80% of cases, making the diagnosis both delayed and difficult. Diagnosis is often initiated in cases with related complications, such as hemorrhage, perforation or obstruction. Intestinal obstruction can be caused by inflammatory stenosis, jejunal stones, intussusception or volvulus. It is suggested that a large small-bowel diverticulum might play a contributing role in the occurrence of small bowel volvulus in adults. Enteroclysis is probably the most reliable method for diagnosing small bowel diverticulosis. In case of acute abdomen pain due to small bowel volvulus, CT examination shows typical signs of this disorder. The whirl signs detected on CT have a high specificity for small bowel volvulus. Surgical excision of the affected jejuna segment with primary end-to-end anastomosis is the treatment of choice.

ACKNOWLEDGMENTS

The authors wish to thank Dr. Qing-Ping Cai from the Department of General Surgery, Changzheng Hospital, for providing the surgical information and photographs of the patient.

Abstract

Primary squamous cell carcinoma (SCC) of the liver is rare and reported sporadically. Up to date, only 24 such cases have been reported in the literature. It is associated with hepatic teratoma, congenital cysts, solitary benign non-parasitic hepatic cysts, hepatolithiasis/Caroli's disease or cirrhosis. We reported a case of primary SCC of the liver associated with multiple intrahepatic cholesterol gallstones. The patient underwent hepatectomy followed by radiotherapy, and has survived for over 19 mo without recurrence.

INTRODUCTION

Primary squamous cell carcinoma (SCC) of the liver is rare and reported sporadically. Only 24 such cases have been reported in the literature. It is found to be associated with hepatic teratoma[1], congenital cysts[2-14], solitary benign non-parasitic hepatic cysts (SBNHC)[2-6,8-11], hepatolithiasis/Caroli's disease[15,16] or cirrhosis[17]. The carcinogenesis seems to be related to the chronic inflammation of the biliary epithelium or the metaplastic and subsequent neoplastic transformation of cysts of the liver[15]. Although various therapeutic strategies, including systemic chemotherapy, radiotherapy, transarterial chemoembolization and hepatic resection, have been used, the prognosis of primary SCC of the liver is dismal with an overall survival less than one year.

We report a case of primary SCC of the liver occurring in association with hepatolithiasis. The patient underwent hepatectomy in January 2010 followed by radiotherapy, and has survived for over 19 mo without recurrence.

CASE REPORT

A 46-year-old woman presented with right upper quadrant pain and a 15-pound weight loss over the past five weeks before admission in January 2010. There was no radiating pain, vomiting, jaundice, fever, chill, cough or irregular vaginal bleeding. She had a history of hepatitis A, but without a history of alcohol drinking, smoking or surgery. On physical examination, the abdomen was soft, and no tenderness, rebound tenderness and palpable abdominal mass were found. The biochemical data were as follows: hemoglobin 110 g/L, white cell count 5.2 $\times 10^9$/L with neutrophil 82.5%, platelet 334 $\times 10^9$/L, alanine aminotransferase 28 μ/L, serum total protein 70 g/L, serum albumin 34.1 g/L, serum total bilirubin 15 μmol/L, serum direct bilirubin 9.5 μmol/L, alpha-fetal protein 7.33 ng/mL, and carcinoembryonic antigen (CEA) 8.5 ng/L, and serologic markers for the hepatitis-B virus were not detected. The plasma retention rate

Figure 1 Computed tomography scan showed a regular mass with inhomogeneous density, mild delayed enhancement in the peripheral zone, and necrosis in the central zone. R: Right.

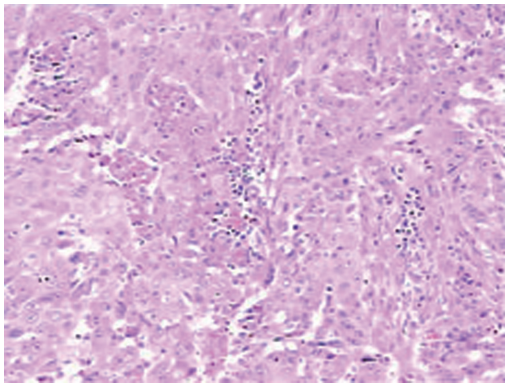

Figure 3 Histology of the tumor: Squamous cells with keratinization and areas of necrosis. Hematoxylin-eosin stain, × 10.

of indocyanine green at 15 min was 1.2%. Subsequent abdominal ultrasonography showed a mixed echoic mass measuring about 5.0 cm × 6.0 cm occupying the right lobe of the liver. The abdominal computed tomography (CT) showed a regular mass measuring about 5 cm × 6 cm at its greatest dimension with inhomogeneous density, mild delayed enhancement in the peripheral zone, necrosis in the central zone of the tumor and dilated secondary biliary ducts with intraductal lithiasis (Figures 1 and 2). Gastrointestinal endoscopy and colonoscopy showed negative findings. Chest CT revealed no mass over the lung.

The initial diagnosis before operation was intrahepatic cholangiocarcinoma (ICC) according to the CT findings (a regular mass, periductal dilatation and intraductal lithiasis). Surgery remains the exclusive choice of curative therapy for ICC. The patients underwent right hepatectomy and cholecystectomy in February 2011. A hard and yellowish white tumor mass was found, measuring about 5 cm × 6 cm at the greatest dimension with central necrosis occupying mainly S5 of a non-cirrhotic liver and numerous biliary calculi in the dilated intrahepatic bile duct adjacent to the tumor. The specimen appeared with a 1-cm negative margin without cysts on its cut surface.

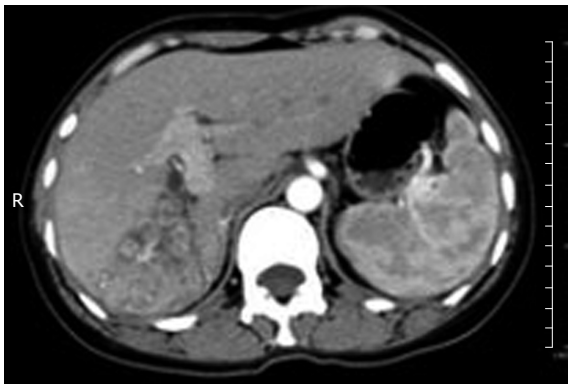

Figure 2 The bile ducts adjacent to the tumor were obviously dilated and full of biliary calculi. R: Right.

Histopathological examination showed a poorly-moderately differentiated SCC composed of squamous cells with keratinization and large areas of necrosis (Figure 3). The secondary bile ducts adjacent to the tumor were obviously dilated and full of biliary calculi. Chronic inflammatory lesions were found in the biliary epithelial and gallbladder mucosa without evidence of squamous metaplasia. Immunohistochemical tests were positive for cytokeratin (CK) 14, CK19 and CEA, but negative for CK 18 and thyroid transcription factor 1 (TTF-1). CK 14 positive indicated that basal cells of keratinized squamous epithelium were originated from the cancer cells. Metastatic lung or thyroid cancer to the liver could be ruled out, as TTF-1, an indicator of small cell carcinoma of the lung or thyroid, was negative. Subsequently a thorough search for a primary tumor showed a negative finding in the oral cavity and nasopharynx and a mild inflammatory change in cervical smear. Taken together, the final diagnosis of primary SCC of the liver was made.

The post-operative course was uneventful and the patient was discharged on the 14th day after operation. The patient was started on radiotherapy 2 mo after operation. Routine follow-up was continued in the hepatobiliary clinic. No tumor recurrence and distant metastasis were found during the 19-mo follow-up period.

DISCUSSION

Primary SCC of the liver is very rare, and only 25 cases have been reported from 1934 till now (including the present one) in the literature. Among 13 (52%) of these cases, SCC arose from congenital hepatic cysts[2-14] or SBNHC[2-6,8-11]. There were only two cases of SCC associated with hepatolithiasis/Caroli's disease[15,16]. The other cases were associated with cirrhosis and teratoma[1,17]. The precise steps leading to the carcinomas are unclear. Positive CK14 and negative CK18 indicate that basal cells of keratinized squamous epithelium are originated from the cancer. Positive CK19 indicates that the tumors are transformed from chronic inflammation of the biliary epithelium. Thus, chronic inflammation of the biliary epithelium might be the most reasonable mechanism

of carcinogenesis.

Clinically, patient presents with the abdominal pain and weight loss as initial symptoms. CT scan of the abdomen is helpful for evaluating the primary SCC, such as the number of lesions, location, extension, and whether the tumor invades surrounding structures. If the mass is suspected to be malignant, biopsy or even surgical resection should be conducted if patient's condition permits.

Although several management strategies have been proposed, ranging from hepatectomy, systemic chemotherapy and radiotherapy to hepatic arterial injection of low-dose anti-cancer drugs, the prognosis of primary SCC of the liver is dismal with an overall survival less than one year. Naik *et al*[18] described a patient with SCC who survived for over 6 year after preoperative radiotherapy and surgical resection. Boscolo *et al*[19] reported a case of complete remission of poorly differentiated SCC after systemic chemotherapy (cisplatin + 5-fluorouracil) and surgery. Spaggiari *et al*[16] reported a case with a 7-year survival after right hepatectomy. In our case, SCC occurred in association with hepatolithiasis. The patient was successfully treated by hepatectomy followed by radiotheraphy. The postoperative course was smooth, and she is still alive 19 mo after the operation without recurrence.

In conclusion, we described the first case of primary SCC of the liver associated with hepatolithiasis. The patient was successfully treated by surgery followed by radiotherapy. She has survived for 19 mo with no tumor recurrence and distant metastasis.

Acknowledgments to reviewers of *World Journal of Gastroenterology*

We acknowledge our sincere thanks to our reviewers. Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of our World Series Journals. Both the editors of the journals and authors of the manuscripts submitted to the journals are grateful to the following reviewers for reviewing the articles (either published or rejected) over the past period of time.

Giedrius Barauskas, Professor, Department of Surgery, Kaunas University of Medicine, Eiveniu str. 2, LT-50009 Kaunas, Lithuania

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/esps/. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision on acceptance is made only when at least two experts recommend publication of an article. All peer-reviewers are acknowledged on Express Submission and Peer-review System website.

Abstract

There are unstructured abstracts (no less than 200 words) and structured abstracts. The specific requirements for structured abstracts are as follows:

An informative, structured abstract should accompany each manuscript. Abstracts of original contributions should be structured into the following sections: AIM (no more than 20 words; Only the purpose of the study should be included. Please write the Aim in the form of "To investigate/study/…"), METHODS (no less than 140 words for Original Articles; and no less than 80 words for Brief Articles), RESULTS (no less than 150 words for Original Articles and no less than 120 words for Brief Articles; You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$), and CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc*. It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc*., and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of P values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of P values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*., in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Authors must revise their manuscript carefully according to the revision policies of Baishideng Publishing Group Co., Limited. The revised version, along with the signed copyright transfer agreement, responses to the reviewers, and English language Grade B certificate (for non-native speakers of English), should be submitted to the online system *via* the link contained in the e-mail sent by the editor. If you have any questions about the revision, please send e-mail to esps@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For papers supported by a foundation, authors should provide a copy of the approval document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted original articles are suggested to write science news to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for science news should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1365 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
