World Journal of Gastroenterology

Contents

Weekly Volume 23 Number 33 September 7, 2017

EDITORIAL

6009 Helminths as an alternative therapy for intestinal diseases

Sipahi AM, Baptista DM

REVIEW

6016 Dextran sodium sulfate colitis murine model: An indispensable tool for advancing our understanding of inflammatory bowel diseases pathogenesis

Eichele DD, Kharbanda KK

6030 Autoimmune hepatitis: Standard treatment and systematic review of alternative treatments

Terziroli Beretta-Piccoli B, Mieli-Vergani G, Vergani D

MINIREVIEWS

6049 Colorectal cancer, screening and primary care: A mini literature review

Hadjipetrou A, Anyfantakis D, Galanakis CG, Kastanakis M, Kastanakis S

6059 Behavioral gastroenterology: An emerging system and new frontier of action

Jia L, Jiang SM, Liu J

ORIGINAL ARTICLE

Basic Study

6065 Pharmacological evaluation of NSAID-induced gastropathy as a "Translatable" model of referred visceral hypersensitivity

Hummel M, Knappenberger T, Reilly M, Whiteside GT

6077 High yield reproducible rat model recapitulating human Barrett's carcinogenesis

Matsui D, Omstead AN, Kosovec JE, Komatsu Y, Lloyd EJ, Raphael H, Kelly RJ, Zaidi AH, Jobe BA

6088 Changes in expression of inhibitory substances in the intramural neurons of the stomach following streptozotocin- induced diabetes in the pig

Bulc M, Palus K, Zielonka L, Gajęcka M, Całka J

6100 HOX transcript antisense intergenic RNA represses E-cadherin expression by binding to EZH2 in gastric cancer

Chen WM, Chen WD, Jiang XM, Jia XF, Wang HM, Zhang QJ, Shu YQ, Zhao HB

6111 Ca^{2+}/calmodulin-dependent protein kinase Ⅱ regulates colon cancer proliferation and migration *via* ERK1/2 and p38 pathways
Chen W, An P, Quan XJ, Zhang J, Zhou ZY, Zou LP, Luo HS

6119 Aberrant DNA-PKcs and ERGIC1 expression may be involved in initiation of gastric cancer
Wang FR, Wei YC, Han ZJ, He WT, Guan XY, Chen H, Li YM

Retrospective Cohort Study

6128 Real world treatment patterns of gastrointestinal neuroendocrine tumors: A claims database analysis
Benson III AB, Broder MS, Cai B, Chang E, Neary MP, Papoyan E

Retrospective Study

6137 Patients with inflammatory bowel disease have increased risk of autoimmune and inflammatory diseases
Halling ML, Kjeldsen J, Knudsen T, Nielsen J, Koch-Hansen L

6147 Suspicious brush cytology is an indication for liver transplantation evaluation in primary sclerosing cholangitis
Boyd S, Vannas M, Jokelainen K, Isoniemi H, Mäkisalo H, Färkkilä MA, Arola J

6155 Management of gastric mucosa-associated lymphoid tissue lymphoma in patients with extra copies of the *MALT1* gene
Iwamuro M, Takenaka R, Nakagawa M, Moritou Y, Saito S, Hori S, Inaba T, Kawai Y, Toyokawa T, Tanaka T, Yoshino T, Okada H

6164 Ketogenic diet poses a significant effect on imbalanced gut microbiota in infants with refractory epilepsy
Xie G, Zhou Q, Qiu CZ, Dai WK, Wang HP, Li YH, Liao JX, Lu XG, Lin SF, Ye JH, Ma ZY, Wang WJ

Observational Study

6172 Definition of colorectal anastomotic leakage: A consensus survey among Dutch and Chinese colorectal surgeons
van Rooijen SJ, Jongen ACHM, Wu ZQ, Ji JF, Slooter GD, Roumen RMH, Bouvy ND

CASE REPORT

ABOUT COVER

Editorial Board Member of World Journal of Gastroenterology, Mostafa Sira, MD, Associate Professor of Pediatric Hepatology, Gastroenterology and Nutrition, National Liver Institute, Menofiya University, Menofiya 32511, Egypt

AIMS AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7th, 14th, 21st, and 28th each month. The *WJG* Editorial Board consists of 1375 experts in gastroenterology and hepatology from 68 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

INDEXING/ABSTRACTING

World Journal of Gastroenterology (*WJG*) is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central and Directory of Open Access Journals. The 2017 edition of Journal Citation Reports® cites the 2016 impact factor for *WJG* as 3.365 (5-year impact factor: 3.176), ranking *WJG* as 29th among 79 journals in gastroenterology and hepatology (quartile in category Q2).

Abstract

Animal models and clinical studies have shown that helminth infections exert immunomodulatory activity, altering intestinal permeability and providing a potential beneficial action on autoimmune and inflammatory disorders in human beings, such as inflammatory bowel disease (IBD) and celiac disease. This is consistent with the theory that intestinal microbiota is responsible for shaping human immunological responses. With the arrival of the immunobiologic era and the use of antibodies, we propose a distinctive pathway for treating patients with IBD and celiac disease. We have some evidence about the safety and tolerability of helminth use, but evidence about their impact on disease activity is lacking. Using worms to treat diseases could be a possible way to lower treatment costs, since the era of immunobiologic agents is responsible for a significant rise in expenses. Some questions remain to be investigated regarding the use of helminths in intestinal disease, such as the importance of the specific species of helminths used, appropriate dosing regimens, optimal timing of treatment, the role of host genetics, diet, environment, and the elucidation of the exact mechanisms of action. One promising approach is the use of helminth-derived anti-inflammatory molecules as drugs. Yet there are still many challenges with this method, especially with regard to safety. Studies on intestinal permeability point to *Strongyloides stercoralis* as a useful nematode for these purposes.

Key words: Helminths; Strongyloidiasis; Immunology; Inflammation; Inflammatory bowel diseases; Intestinal diseases; Intestinal permeability; Celiac disease

Core tip: Inflammatory bowel disease and celiac disease are immune-mediated pathologies that remain

a treatment challenge for gastroenterologists. Despite the recent introduction of novel therapies, notably biological agents and newer management strategies, there are still many patients who do not respond, or have a poor response to current treatments. Helminth therapy seems a promising pathway to newer drugs, because it has been proven to alter intestinal permeability, altering the host's immune response to a Type 2 cytokine-mediated response in animal models and pre-clinical studies. This editorial aims to stimulate further research in this field, hoping for better care for our patients.

Sipahi AM, Baptista DM. Helminths as an alternative therapy for intestinal diseases. *World J Gastroenterol* 2017; 23(33): 6009-6015 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6009.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6009

INTRODUCTION

The intestinal epithelium functions as an important part of the digestion and absorption of fluids and nutrients. It also plays an immunologic role because it protects the host from environmental pathogens and antigens[1]. When this barrier is altered, it leads to ease of antigen entry and subsequently to immune stimulation and inflammation[2].

Many intestinal diseases have immunogenic components that alter intestinal permeability. Some pathologic processes increase intestinal permeability, such as inflammatory bowel disease (IBD)[3-11], atopic eczema[12], celiac disease, dermatitis herpetiformis[13], cystic fibrosis[14,15], alcohol consumption[16], use of nonsteroidal anti-inflammatory drugs[17-20], and acute infectious diarrhea[12,21]. In contrast, some infections, such as those caused by *Blastocystis hominis*[22], can decrease intestinal permeability and alter the barrier function of the epithelium. These may thus provide an alternative pathway for treating patients by deviating the host's immunologic response.

Intestinal permeability can be measured in many ways. One is *via* measuring urinary clearance of radioactive chromium-51 labeled ethylenediaminetetraacetic acid (^{51}Cr-EDTA). When urinary clearance of ^{51}Cr-EDTA is decreased, this indicates decreased intestinal permeability. Werneck-Silva *et al*[23] demonstrated that infection with *Strongyloides stercoralis* can diminish intestinal permeability compared to healthy volunteers (P = 0.0001). Intestinal infection with *S. stercoralis* led to abnormalities in mucus secretion and intestinal motility, as well as possible loss of macromolecules. *S. stercoralis* is a soil-transmitted helminth and is one of the most common parasites that affects patients living in tropical areas[24]. It infects 100 to 200 million people worldwide[25]. It predominantly compromises the mucosa of the duodenum and upper jejunum, although the whole intestinal wall or more extensive segments of the intestine can be involved, especially in immunocompromised patients[26-28].

DISCUSSION

Hygiene hypothesis

The hygiene hypothesis was initially described in the 1970s. It suggests that the higher incidence of allergic diseases in predominantly urban white communities, compared to those rural and indigenous, is due to the less frequent viral, bacterial and helminth infections[29]. A decade later, Strachan proposed that reduced exposure to infections in early childhood, owing to a combination of diminished family size, improved living standards and higher levels of personal hygiene, might result in an increased risk of allergic disease later in life[30]. In addition to allergic disease[31-33], it is believed that the recent increase in other autoimmune and inflammatory disorders, especially in developed countries, could be explained by a similar hypothesis. Many factors may be involved, such as changes in intestinal microbiota during childhood[34].

Helminth infections, in specific intestinal worms, are a particular area of research interest, since they can modulate the host response, inducing immunologic tolerance. Aoyama *et al*[35] have demonstrated an inverse relationship between autoimmune liver diseases, such as primary biliary cirrhosis, autoimmune hepatitis, and primary sclerosing cholangitis, and *S. stercoralis* infection. Recent studies point to the negative effects of deworming, since the helminths are able to not only downregulate specific immune responses, but also to modulate autoimmune and allergic inflammatory responses, contributing to metabolic homeostasis[36]. The study on the use of helminths and their products as anti-inflammatory treatments is a growing field.

Helminth-induced immune responses

Parasitic helminths evolved with the mammalian immune system, promoting their own survival by altering host immune responses[37]. The immune response induced by these worms is dependent on a Type 2 cytokine response, involving the secretion of interleukin (IL)-4, IL-5, IL-9 and IL-13, accompanied by the activation of intestinal mast cells[38], eosinophils, goblet cells, enterocyte proliferation and intestinal contractility[39]. Granuloma formation then occurs, isolating the eggs and larvae, and inducing tissue repair[40]. Other accessory pathways are activated, including the upregulation of regulatory T cell and IL-10 and/or transforming growth factor beta levels, leading

to a predominantly anti-inflammatory response. It has been shown that IL-10- deficient-mice with helminth infections have higher mortality and/or morbidity[41].

The role of CD4+ T cells in expressing Th1, Th2 and Th17 cytokines in human infection with *S. stercoralis* is better explored by Anuradha *et al*[42], who demonstrated a decrease in functional Th1 and Th17 cells and an increase in functional Th2 cells, compared to uninfected individuals. The regulation of Th1, Th2 and Th17 cells was predominantly dependent on IL-10, while the regulation of Th2 but not Th1 or Th17 cells was also dependent on TGFβ. Anuradha *et al*[43] also examined the circulating levels of cytokines in infected individuals (n = 32) compared to those uninfected, discovering significantly lower circulating levels of pro-inflammatory cytokines (gamma interferon, tumor necrosis factor alpha and IL-1) and significantly higher levels of anti-inflammatory cytokines (IL-4, IL-5, IL-9, IL-10, IL-13, IL-27, IL-37, and TGF-β). In addition, treatment of infection led to an opposite immunological response in the two studies. The question is whether these anti-inflammatory properties could be used in intestinal disorders with a predominant Type 1 cytokine response.

Helminth therapy for intestinal inflammation

The ability of helminth infections to alter and/or to suppress immune responses and intestinal inflammation could be useful in IBD[37]. To date, only two species of helminths have been used as clinical treatment: *Trichuris suis*, the pig whipworm, and *Necator americanus*, the human hookworm.

The first is acquired by ingestion of ova and colonization of the caecum and proximal colon of the human gut by worms, which only lasts a few weeks. The second infection develops after percutaneous administration of larvae that migrate to the small intestine, where they survive by feeding on blood from the mucosa. *T. suis*, due to the species-specificity and the lack of chronic infection, requires repeated treatments, although it poses lesser health issues. In the case of *N. americanus*, the long lasting infection means greater risk of anemia and gastrointestinal symptoms, which could be deleterious side effects[37]. To date, there are no studies of *S. stercoralis* for treating intestinal inflammation.

Evidence of helminth therapy in inflammatory bowel disease

Approximately 15 years ago, the first clinical studies of helminth therapy for intestinal disease in humans utilized embryonated viable eggs of *T. suis* in the treatment of ulcerative colitis (UC) and Crohn's disease (CD). These studies showed safety, tolerance and a significant disease remission when oral administration of viable and embryonated eggs was performed repeatedly[44,45]. A placebo–controlled, double-blind, randomized trial in UC patients significantly improved the disease activity index and showed no side effects, although the remission rate was not different than placebo[46]. Another double-blind, placebo-controlled, randomized study (NCT01434693) reported that a single dose of *T. suis* ova (TSO) up to 7500 ova was well tolerated and did not result in short- or long-term treatment-related side effects in CD patients[47].

A brief review of Clinicaltrials.gov reveals three interventional studies of TSO in CD and two in UC. In CD, the studies were sponsored by Coronado Biosciences, which changed its name to Fortress Biotech, and by Dr. Falk Pharma GmbH. TRUST-1 (NCT01576471), a Phase 2 clinical trial evaluating 250 North American patients with moderate-to-severe disease did not improve the disease activity index or remission rates, although a nonsignificant improvement was noted in patients with a more severe disease score.

TRUST-2 (NCT01279577), a double-blind, placebo-controlled, randomized trial of 252 European adults with mildly-to-moderately active ileo-colonic, uncomplicated CD, documented that the administration of fortnightly doses of 250, 2500, or 7500 TSO/15 mL suspension/day over 12 wk, with a four-week follow-up, was safe, with no serious adverse drug reactions. There was a dose-dependent immunological response, but no TSO dose showed a clinically relevant effect over placebo for the induction of clinical remission (CD Activity Index < 150) or response[48].

In UC, the first study was sponsored by the New York University School of Medicine, and the second by the National Institute of Allergy and Infectious Diseases. Both were terminated due to a small sample size and because it was not possible to draw meaningful conclusions. MUCUS (NCT01433471), a randomized, double-blind, placebo-controlled crossover study, was conceived to examine mucosal immunity after therapy with 2500 eggs by mouth every 2 wk for 12 wk. Primary outcomes were designed to better understand the mechanism of action of TSO on the intestinal mucosa and secondary outcomes were to bring about changes in the Mayo Score and in the Simple Clinical Colitis Activity Index.

A second, more controversial approach, was the use of *N. americanus*. Croese *et al*[49] showed that 7 of 9 patients with CD infected with 25-50 larvae followed over 20 wk experienced an improved CD activity index, while the other 2 worsened. There were no search results for interventional studies regarding the use of *Strongyloides, Ascaris, Ancylostoma, Wuchereria, Onchocerca, Toxocara* or *Enterobius* in CD or UC on Clinicaltrials.gov.

Evidence of helminth therapy in celiac disease

There are few studies examining the use of helminths

in celiac disease, most of which with small samples. McSorley *et al*[50] and Daveson *et al*[51] examined 20 celiac patients followed by wheat challenge after 20 wk exposed to 5-10 larvae of *N. americanus*, compared to placebo, at Princess Alexandra Hospital, in Brisbane, Australia. The dose was well tolerated and analysis showed reduced gamma interferon and interleukin-17A in duodenal biopsies. No difference in symptoms was observed.

Another Australian clinical trial, NaCeD study (NCT016619330), evaluated the desensitization and gluten tolerance of 12 diet-managed celiac patients. They were previously infected with *N. americanus* and exposed to small incremental doses of gluten, in the form of pasta, over 12 wk. The mucosal histopathology before and after gluten challenge was examined. There were no significant differences in terms of duodenal villus height and crypt depth ratio and intraepithelial lymphocyte count.

Another clinical trial (NCT02754609) was registered in 2016 by James Cook University in Queensland, Australia, on Clinicaltrials.gov. This trial aims to be a phase 1b multicenter, multinational, randomized, double-blind, placebo-controlled clinical trial with a single-blind arm and an open label extension phase. The objective is to evaluate the safety and predictability of escalating gluten consumption to activate celiac disease. The cohort with diet-managed disease will be treated with placebo or with low- and medium-dose hookworm inocula. The primary outcome is to measure the difference in duodenal villus height and crypt depth ratio between baseline (week 2) and week 42.

There were no search results for interventional studies about *Trichuris, Strongyloides, Ascaris, Ancylostoma, Wuchereria, Onchocerca, Toxocara* or *Enterobius* use in the treatment of celiac disease on Clinicaltrials.gov.

Other uses for helminth therapy

There are other studies examining the role of helminth therapy in allergy, atopy and asthma, with conflicting results. The biggest problem seems to be that these studies proved that preventing allergic reactivity is possible, but only a handful have reported the ability to impact an already established process. In addition to allergy, a number of clinical trials are currently registered for the use of TSO in patients with multiple sclerosis[52], psoriasis, autism and rheumatoid arthritis[37], and for the use of *N. americanus* in patients with multiple sclerosis[35].

Helminth products as possible new drugs

Helminths are complex organisms that have a variety of immunomodulatory substances, such as lipids, carbohydrates and proteins, and jointly defined excretory-secretory products (ES). The identification of helminth products that can be used as biologicals in place of whole parasites is an engaging area of research. The ES-62 glycoprotein from the filarial nematode *Acanthocheilonema vitae* is one of the most studied compounds and is capable of promoting a Th2 response, inhibiting Th1 and Th17. Animal studies have demonstrated the ability of various ES products to inhibit intestinal inflammation in colitis models. These studies suggest a potential way for discovering new drugs for IBD. Concerns about antigenicity and safety need to be clarified prior to clinical testing[53].

Most published studies focus on the use of nematodes and their products in the treatment of intestinal disease. Unlike most studies, there is an ongoing multicenter phase 2 clinical trial, in the recruiting phase, sponsored by the University Hospital, Lille, France, named ACROHNEM (NCT02281916). It is designed to assess safety and tolerability of P28GST (protein 28 Kd glutathion S transferase), aiming to control inflammation in moderate CD, before or after intestinal resection surgery. P28GST is a parasite enzyme molecule from *Schistosoma* with potent immunogenic and anti-oxidant properties. Based on the experimental evidence of its anti-inflammatory properties, investigators hypothesized that the administration of P28GST could protect against recurrence after intestinal resection surgery in CD. To carry out this study, 24 moderate CD patients will be enrolled. Patients with moderate CD will be included after intestinal resection surgery. Drug therapy will consist of three injections of 100 μg of P28GST for 3 mo (one injection per month). The main objective of this study is to assess safety and tolerability in a 1-year follow-up. Secondary objectives are to control immunologic and inflammatory blood and tissue markers and evaluate clinical recurrence as assessed by CDAI (CD Activity Index).

CONCLUSION

The intestinal microbiota is responsible for shaping the human immune system, and the composition of the microbiome can alter and deviate specific host immune responses. Although much has been written about bacteria, we cannot forget that other organisms, such as the helminths, may possibly play an important role in maintaining a "healthy intestinal community"[54].

Mouse models[55] and human cross-sectional studies have shown that chronic helminth infections exert immunomodulatory activity and are able to regulate the host immune response, providing a potential beneficial action on autoimmune and inflammatory disorders in humans, such as IBD, celiac disease, asthma, atopy, allergy, multiple sclerosis, psoriasis, autism and rheumatoid arthritis[37].

We have some evidence about the safety and

tolerance of helminth use, but evidence about the impact on various intestinal diseases is lacking. We need more clinical studies with larger samples, longer follow-ups and standardized doses of helminths and helminth products. Some questions remain to be investigated regarding the use of helminths in intestinal disease, such as the importance of the particular species of helminths used; appropriate dosing regimens (low or high); optimal timing of treatment (before the onset of disease, in acute or chronic disease, or at younger ages); the role of host genetics, diet and environment, and elucidation of the exact mechanisms of protective effect.

In regard to the species of helminth, we believe that the majority of the studies had negative results because of the use of *T. suis*. This pig whipworm induces a less intense and persistent inflammatory response, although Williams *et al*[56] verified that *T. suis* can mature to adult size and reproduce in humans. That is why we see *S. stercoralis* as a more potentially useful nematode, as it has proven to significantly diminish the intestinal permeability in humans[23], altering the interleukin profile in a more systemic way[42]. The prolonged interaction between *S. stercoralis* and its host induces a greater immunomodulatory action. Regarding the appropriate dose and duration of treatment, we have little comprehension of how much and how long is required to exert a significant and beneficial effect; therefore, safety concerns limit the dose that can be applied.

One important challenge is the high polymorphism of the human species, which reacts in a spectral manner to helminth infection. The genetic profile of each individual alters this response. In this context, the identification of helminth-derived anti-inflammatory molecular mediators may be a better and promising approach, since it replicates the benefits without the detriments[57]. There are many challenges with this method, such as the selection of a substance with a good safety profile and low antigenicity that is easily produced and that has a significant impact on clinical trials.

Abstract

Inflammatory bowel diseases (IBD), including Crohn's disease and ulcerative colitis, are complex diseases that result from the chronic dysregulated immune response in the gastrointestinal tract. The exact etiology is not fully understood, but it is accepted that it occurs when an inappropriate aggressive inflammatory response in a genetically susceptible host due to inciting environmental factors occurs. To investigate the pathogenesis and etiology of human IBD, various animal models of IBD have been developed that provided indispensable insights into the histopathological and morphological changes as well as factors associated with the pathogenesis of IBD and evaluation of therapeutic options in the last few decades. The most widely used experimental model employs dextran sodium sulfate (DSS) to induce epithelial damage. The DSS colitis model in IBD research has advantages over other various chemically induced experimental models due to its rapidity, simplicity, reproducibility and controllability. In this manuscript, we review the newer publicized advances of research in murine colitis models that focus upon the disruption of the barrier function of the intestine, effects of mucin on the development of colitis, alterations found in microbial balance and resultant changes in the metabolome specifically in

the DSS colitis murine model and its relation to the pathogenesis of IBD.

Key words: Dextran sodium sulfate; Experimental colitis; Inflammatory bowel disease; Pathogenesis; Intestinal barrier

Core tip: In the last few decades the proliferation of research in experimental colitis models of inflammatory bowel diseases (IBD) has had profound effects in our understanding of human IBD pathophysiology as well as to exploit potential therapeutic avenues outside of immunologic therapy. The dextran sodium sulfate colitis model, through its rapidity, simplicity, reproducibility and controllability has been instrumental in our understanding of intestinal barrier function through the dysregulation of mucin, interaction with the intestinal microbiome and metabolome.

INTRODUCTION

Inflammatory bowel disease (IBD) is a group of inflammatory conditions of the colon and small intestine caused by a dysregulated immune response. Crohn's disease (CD) and ulcerative colitis (UC) are the principal types of IBD. Both usually involve severe diarrhea, pain, fatigue and weight loss. IBD can be debilitating and sometimes leads to life-threatening complications. A convenient and time honored approach to study the pathogenesis and complexity of human IBD has been the development of a variety of animal models. These animal models have provided meaningful and indispensable insights into the histopathological and morphological changes in the intestinal tract related to the pathogenesis of human IBD[1]. While no single model has proven to sufficiently represent the complexity of the clinical and histopathological characteristics of human disease, the collective data obtained from these various animal models have provided a more detailed understanding of the underlying principles of human IBD pathogenesis[2,3]. These models have become an indispensable tool to elucidate the histopathological, immunological and morphological changes in the intestinal tract and potential therapeutic targets. These various models can be grouped into categories broadly defined as spontaneous colitis, chemically inducible colitis, genetically modified and adoptive transfer models[1,4-7].

The most widely used mouse model of colitis employs dextran sodium sulfate (DSS), a chemical colitogen with anticoagulant properties, to induce epithelial damage. The DSS colitis model lends itself to IBD research due to its rapidity, simplicity, reproducibility and controllability. Acute, chronic and relapsing models of intestinal inflammation can be achieved by modifying the concentration of DSS and the frequency of administration[8]. There are excellent and exhaustive reviews focused on the immunological aspects of experimental animal models in inflammatory bowel disease and we would recommend the reader to refer to these articles for the specifics in immunology[2,9]. In this review, we aim to provide an updated and concise review of the less publicized aspects of research in murine colitis models that focus upon the barrier function of the intestine in one specific chemically induced experimental colitis model, the DSS colitis murine model.

HUMAN IBD PATHOPHYSIOLOGY: MECHANISTIC INSIGHTS

IBD is a disorder of chronic intestinal inflammation without an exact etiology. The leading hypothesis on IBD pathogenesis states that it is an inappropriate and overly aggressive inflammatory response to enteric microbes in a genetically susceptible host with environmental factors precipitating the onset or reactivation of disease[10,11]. Epidemiologic data suggest these environmental factors include antibiotic use, microbial exposure and possibly dietary components[12-15]. Host genetics, luminal microbiome and its associated antigens and immune response, all have been implicated in playing important roles in IBD pathogenesis (Figure 1).

Genetics

Advances in IBD genetics have indicated modifications in genes regulating mucosal barrier integrity and function, innate immune response and microbial homeostasis[11]. Thus far, four genes have been associated with increased susceptibility to CD and one gene mutation has been associated with ulcerative colitis[11]. The most widely known and studied gene implicated in IBD is the gene for *CARD15*, formerly known as *NOD2*, which is responsible for luminal bacterial recognition. The leucine-rich repeat region of *CARD15* binds muramyl dipeptide (MDP), which is the active moiety of peptidoglycan. This binding of bacterial peptidoglycan to MDP activates NFκB and mitogen-activated protein kinase signaling pathways, causing the production of various cytokines including TNF and IL-1β[10,16,17]. In normal circumstances, the pro-inflammatory cytokine secretion by intestinal APCs is minimal, yet bacterial killing occurs. This indicates that the intestinal immune

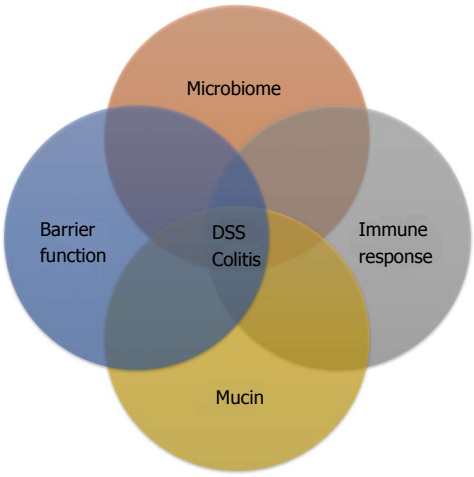

Figure 1 Factors that play important roles in the pathogenesis of inflammatory bowel diseases. DSS: Dextran sodium sulfate.

system can defend against luminal microbiota without appreciable tissue injury[10]. The importance of NFκB activation in the clearance of invasive bacteria is underscored by the observations that *CARD15* gene mutation fails to clear Salmonella from epithelial cells leading to increased bacterial interaction with the host's luminal defense mechanisms. Indeed, heterozygosity for a *NOD2* polymorphism confers a 1.75 to 4-fold increased risk whereas homozygosity confers even a much higher risk (11 to 27-fold) for development of IBD[10,18].

Microbiome and dysbiosis

A complex network of interactions exists between the host intestinal epithelial cells (IEC), host immune cells and the abundant intestinal microbiota. An altered balance of commensal pathogenic microbiota could lead to a pro-inflammatory milieu that exacerbates intestinal inflammation[11]. The dysbiosis theory suggests that intestinal microbiota of IBD patients change in diversity, composition and localization compared to that of healthy controls[19-24]. Fecal microbiota studies on IBD patients have revealed a decreased frequency in Bacteroidetes and Firmicutes and an increase of Proteobacteria and Actinobacteria phyla[21,23-26]. Advances in metagenomics sequencing of microbial RNA have confirmed decreases in bacterial composition and diversity in IBD patients compared to normal population[15]. Likewise, defects in the intestinal epithelial barrier integrity suggests increased uptake of luminal antigens that further leads to persistent immune activation[11]. Evidence suggests that reduced mucin production, through goblet cell depletion and epithelial cell tight junction dysfunction, by facilitating the access of gut luminal antigens to the intestinal mucosa, are also involved in the pathophysiology of IBD[15]. Additionally, *Faecalibacterium prausnitzii*, a member of the Firmicutes phylum and one of the most abundant species in the healthy human colon, is underrepresented in IBD patients and altered in terms of disease activity specifically in CD patients[19,20,24,27-30].

It is still uncertain as to whether the dysbiosis is the primary cause of inflammation or merely a secondary phenomenon of IBD. The uncertainty stems from the fact that intestinal microbiota analysis in IBD patients is performed after the development of the disease rather than prior to development[22]. However, the pathogenic role of the microbiome in IBD pathogenesis and therapy is indicated by studies showing an improvement in IBD by antibiotic treatment[31,32]. Indeed, treatment of UC patients with antibiotics improves mucosal inflammation[15]. Further, remission of inflammation and mucosal healing was observed in CD patient's that underwent diversion of feces with subsequent disease reactivation after infusion of feces[33]. Likewise, defects in the intestinal epithelial barrier integrity suggests increased uptake of luminal antigens that further leads to persistent immune activation[11]. Evidence suggests that reduced mucin production, through goblet cell depletion and epithelial cell tight junction dysfunction, by facilitating the access of gut luminal antigens to the intestinal mucosa, are also involved in the pathophysiology of IBD[15].Collectively, these observations attest to the role of microbial dysbiosis in the induction of IBD[34].

Immune response

The innate and adaptive immune system activation and dysfunction as well as a loss of tolerance to enteric commensal bacteria contribute to the abnormal inflammatory response in the intestinal tract in patients with IBD[11,35]. Characteristic histological findings in IBD is an influx of innate immune cells (neutrophils, macrophages, dendritic cells and NK cells) as well as adaptive immune cells (B cells and T cells) into the lamina propria. With activation of immune cells, there is an elevation in the TNF-α, IL-1β, IFN-γ and cytokines levels. Recent advances in genome-wide associated studies and immunological studies suggest aberration in the mucosal innate response, innate microbial sensing, autophagy and unfolded protein response are potential pathogenic pathways in IBD[35].

Microbial antigen sensing by the innate immune system is mediated by pattern recognition receptors (PRR), such as Toll-like receptors (TLR) that recognize pathogen associated molecular patterns. The stimulation of PRRs results in a signaling cascade in which NFκB activation produces pro-inflammatory mediators, thereby ensuring an effective and appropriate innate response to presented antigens. Specific TLR that have been implicated in CD include nucleotide-binding oligomerization domain (NOD)-like receptors, specifically *NOD2*, which encodes an intracellular sensor and is stimulated by specific components of bacterial peptidoglycan that results in NFκB activation as mentioned in the earlier section on genetics[35].

Adhesion molecules, such as intercellular cell adhesion molecule 1 (ICAM1) are necessary for the circulating cells to adhere to the activated endothelium, which leads to extravasation of mononuclear and polymorphonuclear cells into the inflammatory tissue[11]. In addition, adhesion molecules mediate migration of the extravasated immune cells through the stroma to the source of maximal chemokine production, as well as through the epithelium to the lumen, where they produce crypt abscesses[11]. Historically, the NFκB pathway was thought to elicit a pro-inflammatory response, but selective gene-deletion studies have shown that this pathway produces both beneficial and deleterious effects[11]. NFκB activation stimulates expression of numerous molecules that are involved in the inflammatory response such as IL-1β, TNF, IL-6, IL-8, ICAM1 and other adhesion molecules[11]. NFκB also stimulates the expression of protective molecules, *CARD15*, cyclo-oxygenase 2, B defensins, TNF-induced protein 3 that inhibit the inflammatory response[11].

IL-23 is a key cytokine in orchestrating the crosstalk between innate and adaptive immunity and has a central role in driving early responses to microbes[35]. Interestingly, IL23R polymorphisms have been associated with both CD and UC, suggesting that the IL-23 axis might represent a shared inflammatory pathway in chronic intestinal inflammation[35]. Recent studies have shown that, besides its activity on Th17 cells, IL-23 can also act on cells of the innate immune system. Unconventional, innate-like T cell populations, which are particularly represented at mucosal sites, have been found to respond to IL-23 stimulation and secrete Th17-related cytokines[35].

The adaptive immune system is highly specific and confers long lasting immunity and is adaptable with its antigen specificity and maturation[35]. The inhibitory cytokines IL-10 and TGF-β in Peyer's patches, mesenteric lymph nodes and lamina propria are involved in T-cell tolerance in the intestine[10]. Immunologically Th0 cells are activated and differentiate into Th1, Th2 or Th17 cells based upon the clearance of specific pathogens, but a dysregulated T cell response with abnormal development of activated T cells subsets may lead to the onset of inflammation by an excessive release of cytokines and chemokines with have multiple pathogenic effects[35]. Moreover, there is a genetic association between the inhibitory cytokine IL-10 and UC, in which IL-10 participates in the down-regulation of intestinal inflammation[10]. CD had been thought to be a Th1 mediated disease, secreting copious amounts of IFNγ, TNF-α, and IL-12; whereas UC was thought to be a Th2 mediated response, with signature cytokine secretion from IL-4, IL-5 and IL-13[15]. However, recent data has suggested this paradigm is not quite so straightforward[15]. Furthermore, data suggests that Th17 cell production of IL-17 and IL-23 play important roles in the pathogenesis of IBD, with DCs isolated from CD patients producing more IL-23 than UC patients[15].

Th17 cells are a subset of helper T-cells that are induced by IL-6 and TGF-β and expanded by IL-23[15]. Signaling is mediated through the engagement of heterodimeric IL-23 with its heterodimeric receptor that activates the JAK-STAT signaling pathway, which then regulates the transcription of several genes[10]. IL-23 secreted by macrophages and dendritic cells may contribute to Th17 proliferation, survival or both[10].

PATHOPHYSIOLOGY OF DSS-INDUCED COLITIS: AN INVALUABLE ANIMAL MODEL

Numerous animal experiment in the last 25 years have employed the DSS colitis model as a chemical induction of intestinal inflammation model that morphologically and symptomatically resembles epithelial damage seen in human ulcerative colitis[1,36,37]. The DSS model, initially reported by Okayasu *et al*[38], and has been used to investigate the role of leukocytes in the development of colitis in animal models and is now one of the most extensively employed experimental models abetted by its simplicity and reproducibility[38,39].

DSS is a water soluble, negatively charged sulfated polysaccharide with a highly variable molecular weight ranging from 5 to 1400 kDa. Murine colitis results from administration of 40-50 kDa DSS added to drinking water. In the DSS model, the sulfated polysaccharide does not directly induce intestinal inflammation, but rather acts as a direct chemical toxin to colonic epithelium resulting in epithelial cell injury. The proposed and most accepted mechanism by which DSS induces intestinal inflammation results in the disruption of the intestinal epithelial monolayer lining, leading to the entry of luminal bacteria and associated antigens into the mucosa and allowing the dissemination of proinflammatory intestinal contents into underlying tissue[2,4,6,38,40-42].

The effectiveness of the DSS-induced colitis depends on several factors, including DSS concentration (usually 1%-5%), duration and frequency of administration (acute or chronic), molecular weight of the manufactured DSS, strain of animals (C3H/HeJ, C57BL/6 and BALB/c mice strains are more susceptible), and microbial environment of animals (*i.e.* germ-free versus specific pathogen-free). Furthermore, depending upon these various factors, the animals may develop acute colitis, chronic colitis or even colitis induced dysplastic lesions (Table 1).

In various protocols, 40-50 kDa DSS is added to sterilized drinking water at various concentrations to produce the desired inflammatory effect. At this molecular weight the tissue distribution reveals that DSS penetrates the mucosal membrane of the intestine[4]. Acute colitis is induced by administering DSS to the chosen strain of mice, often C57BL/6 or BALB/c male mice, for a period of 6-10 d (average 7 d). Alternatively, chronic colitis is induced by

Table 1 Factors that influence effectiveness of dextran sodium sulfate to induce colitis

Factors	Variables	Description
DSS	Molecular weight	40-50 kDa for tissue penetration (larger molecule does not penetrate colonic tissue well and smaller molecule has poor distribution)
	Dosage concentration	Ranges from 1.5%-3% used most frequently (1% with mild symptoms and delayed onset)
	Duration of therapy	Acute: 5-10 d administration
	Manufacturer/batch	Chronic: 4-5 repeating cycles of DSS and sterile water
		Various manufacturers with differing potency
Host	Genetically susceptible strain of animal	Certain strains are more susceptible to DSS colitis than other strains. Susceptible strains: C3H/HeJ, C57BL/6, BALB/C
Environment	Housing Conditions	Group *vs* individual unit, frequency of cage changes alters coprophagy by host
	Microbial State	Germ-free *vs* specific pathogen free *vs* wild type

DSS: Dextran sodium sulfate.

administering 4-5 repeated cycles of DSS, each cycle involves administration of various DSS concentrations for 1 wk followed by sterile water for 7-14 d[1,38,43,44]. The severity of colitis can be augmented based upon the duration of DSS administration as well as the concentration of DSS[1]. During DSS administration, mice can exhibit pronounced weight loss (about 5%-10% reduction by day 5), altered stool consistency leading to diarrhea and hematochezia[41]. A significant physiological indicator of animal stress and imminent demise occurs if weight loss is greater than 20% of initial weight[41]. Following the desired protocol, the mice are then sacrificed and tissue samples are collected for histological analysis and other assays[8,41].

Observations of the chronological changes induced by DSS administration have revealed that the signs of disease appear as early as 1 d of treatment primarily identified by changes in the expression of tight junction proteins such as occludin, Zonula occludens-1 (ZO-1) and various claudins[4,8,40]. The altered expression of tight junction complexes and increased epithelial apoptosis has been identified in human IBD and is thought to contribute to leaks in the epithelial barrier[4]. These modest initial effects are followed by increasingly worsening symptoms, including increased intestinal permeability, severe bleeding and mortality[8]. The typical histological changes induced by acute DSS include mucin and goblet cell depletion, epithelial erosion, ulceration and infiltration of granulocytes into the lamina propria and submucosa resulting in immune responses[2,8]. In chronic DSS protocols, additional histological changes such as crypt architecture disarray and widening of the gap between the base of the crypt and muscularis with deep mucosal lymphocytosis tend to appear a few weeks after DSS induction[8]. Furthermore, transepithelial migration of neutrophils resulting in cryptitis and crypt abscess, a common histologic finding in human IBD, is reproduced in mice subjected to the chronic DSS administration[8]. With prolonged administration of DSS in rodents, squamous metaplasia of rectal mucosa, adenomatous changes and adenocarcinoma can also be seen histologically[45].

It has been identified that the molecular weight of DSS is critically important to the induction, severity and of DSS induced colitis[4]. Carcinogenic activity in the colon is achieved by DSS of 50 kDa while larger and smaller molecular weights (520 kDa and 10 kDa, respectively) failed to induce activity due to inadequate tissue penetration[4]. Additionally, the repeated pulses of DSS administration utilized in chronic phases of DSS colitis results in dysplasia that frequently resembles the clinical course in human UC[31].

The knowledge of the unique or exact mechanisms that result in carcinogenesis underlying colitis-associated cancer (CAC) in humans is lacking. The transition from inflammation, to dysplasia and hence cancer is not fully elucidated, but it has been proposed that a host of multiple factors are integral in the role of CAC including; immune response, activation of oncogenes, inhibition of tumor suppressors, as well as alterations in intestinal microbiota[46]. A variety of murine models of CAC have been developed. The most widely used and best studied is a chemically induced colitis-associated model that incorporates a combination of a potent carcinogen, azoxymethane (AOM) and DSS[47]. Long term administration or repeated cycles of DSS has been shown to induced chronic colitis and subsequent dysplasia in rodents[48]. In this murine model, as in human CAC, the degree of inflammation correlates with dysplasia and is associated with nuclear translocation and mutational activation of β-catenin which results in increased activity of the Wnt signaling pathway[46,48]. The change in Wnt signaling results in enhanced inflammatory immune response with release of pro-inflammatory cytokines (IL-6 and TNF-α), which results in elevated levels of c-myc, a known oncogene and activator of cell cycle progression[46]. Additionally, many important inflammatory components are increased and activated during CAC (NFκB, Janus Kinase, cyclooxygenase-2 and inducible nitric oxide synthase) leading to further infiltration of lymphocytes, plasma cells and macrophage to sites of chronic inflammation[46]. The limitation of the models is that Kras or p53 mutations, that are typical in human CAC, are not present in murine AOM/DSS-induced CAC models[46].

DSS colitis is associated with increased production of various cytokines and chemokines. Following

the induction of DSS colitis various tissue derived cytokines have been shown to be upregulated as early as the first day of DSS-induction[4]. The different inflammatory mediators assessed include TNF-α, the hallmark of DSS induced colitis, IL-6, IL-10, IL-17, IL-1β, TGF-β, mucin, TLR2/4 gene expression, MPO activity[1,4]. Differences in inflammatory profiles was expressed between acute and chronic DSS phases[4]. It was shown that in acute inflammation in DSS converts to a predominant Th-2 mediated response in the chronic state with noted decreased levels of TNF-α, IL-17 and elevated levels of IL-4,-6,-10 and IFNγ[4,49]. IL-6, IL-1β tissue levels correlate with IBD activity and IFNγ secretion has been linked to IL-17 section which tends to be expressed during chronic inflammation[31]. It has been shown that the cytokine profiles in DSS colitis phases correlates with barrier function, histological and clinical parameters lending the model as an integral tool in the study of cytokine role in induction and recovery from inflammation[4]. The bulk of research on IBD pathophysiology till date has focused on the immunological response and less attention has been paid to defects in barrier function that can potentially increase bacterial contact with the epithelium[50]. In animal studies assessing epithelial damage, DSS has been considered a toxicity model as induction of intestinal inflammation is not direct. Rather the chemical exerts an epithelial injury resulting in intestinal epithelial barrier disruption causing an influx of luminal bacteria and associated antigens into the mucosa and submucosa and thus triggering an inflammatory reaction[51]. An alternative mechanistic action for the induction of inflammation in the DSS model is through dysbiosis of murine gut microbiota leading to immunoregulation defects, mucin and goblet cell depletion and barrier dysfunction. Although the exact mechanism through which DSS induces colonic mucosal inflammation is not completely understood, recent results indicate that sulfate groups of the DSS molecules destabilize the mucus layers and make it more permeable to bacteria[52]. Hence, the DSS model is not simply a toxicity model, but also a barrier dysfunction model that encompasses mucus loss and the eventual bacterial penetration frequently found during intestinal trauma[53].

DSS DISRUPTS INTESTINAL BARRIER FUNCTION

The function of the intestinal epithelium is to simultaneously provide a barrier between the host and external environment while facilitating selective permeability that limits migration of harmful molecules but allows appropriate absorption of nutrients, ions and water[19]. This dynamic relationship of selective permeability is dependent upon specialized structures composed of tight junction complexes[40]. Tight junctions (TJ) are protein complexes consisting of Occludin, ZO, Claudins and junctional adhesion molecules (JAM) that are located at the apical ends of the lateral membranes of IEC and form a physiologically active barrier that can alter permeability based on the cellular environment[40,54-56] .

Dysfunctions of intestinal barrier lead to increased intestinal permeability that have been associated with the pathogenesis of IBD[2]. Barrier dysfunction in IBD has been identified as shifts in tight junction protein expression, and function with poorly adherent mucosa in the inflamed intestinal mucosa[2,40,43,54,57,58]. This change in composition and function corresponds to an increase in intestinal permeability with entry of commensal bacteria and decrease in transepithelial resistance[2,40,57]. The question remains whether the alteration in the intestinal barrier function is a primary necessity for the inflammatory response or a secondary development from the inflammatory response[40].

Several studies have shown that the appearance of intestinal inflammation is not the initial, inciting event, but rather the TJ complex changes and the subsequent increase in colonic permeability precede the development of intestinal inflammation[38,40,42,43,57,59]. In mice DSS colitis leads to a decrease in TJs expression that is followed by an increase in permeability and clinical manifestations of colonic inflammation[19]. Specifically, the protein pattern of TJ undergo rapid changes, as evident in the increased expression of claudin-2 and depletion of various claudins and zona occludens-1[19,40,54]. Therefore, the breach in the mucosa barrier is seen as a secondary event to the increase in colonic mucosal permeability resulting in the influx of inflammatory cells into the intestinal mucosa[40,57].

As noted earlier, the TJ are comprised of protein complexes that include occludin, ZO, claudins and junctional adhesion molecules. Importantly, claudin proteins are intrinsically involved in the formation of the IEC barrier function[60]. Claudins comprise a multigene family of 27 members and are expressed in a pattern that is both organ and segment-specific. A majority of these claudins (claudins 1, 3, 4, 5, 7, 8) confer barrier properties and are often found in tight epithelia of distal intestine. Claudins interact in a tissue-specific manner to form a charge-selective and size-selective barrier and predominantly contribute to epithelial barrier function and regulate paracellular permeability in intact epithelium[61]. Several mouse studies have assessed the expression of various claudins in conjunction to DSS administration. So far, the results have been varied. One study found enhanced expression of the claudin-1 protein, whereas other studies found decreased expression of claudin-1[54,60]. These contradictory findings could be related to species differences as claudin-1 was increased in rats while decreased in mice when exposed to DSS. Further studies conducted by independent laboratories reported similar findings demonstrating an up-regulation of the pore-forming claudin-2 and decreased expression

in claudin-3,-5,-7,-8[60]. Furthermore, alterations in claudin expression resulted in similar outcomes with pronounced barrier dysfunction with aggravated mucosal damage and increased colonic permeability in DSS-induced colitis[60] .

Claudin-2 has been shown to provide a critical role in regulating colonic epithelial homeostasis and barrier function; therefore, regulating mucosal immune response and mucosal inflammation. A frequent regulatory step in inflammation is the increased expression of claudin-2 and it insertion into TJ strands. Upregulation of claudin-2 expression is found to start in the lower crypt and progress toward the surface epithelium[56]. The functional role of this modified expression and the consequential increase in intestinal permeability is still uncertain[56]. Consequently, recent human studies have examined potential alterations in claudin family functions n IBD patients and demonstrated a robust increase in claudin-2 expression[62]. Similarly, claudin-2 was found to assist the uptake of mucosal antigens[62]. A corollary finding in DSS-treated Cl-2TG mice revealed significant suppression of pro-inflammatory molecules with overexpression of claudin-2 suggesting its pivotal role in immune adaptation[62]. The paradoxical finding of increased regulatory CD4+ cells of unchallenged mice and decreases in immune cell infiltration of DSS-challenged mice suggests that claudin-2 induced epithelial permeability facilitates the interaction of host immune molecules and luminal antigens to promote adaptive tolerance and protection from colitis rather than increased sensitization[62]. Additionally, the DSS-challenged mice showed decreased apoptosis and increased epithelial proliferation further supporting the role of claudin-2 in intestinal epithelial cell regulation[62]. Conversely, claudin-2 knockout mice subjected to DSS exhibited severe colitis[62].

In addition to changes seen in claudin expression, other studies assessing barrier dysfunction assessed changes in ZO-1. Merely one day of DSS administration caused a statistically significant reduction of ZO-1[40]. Thus, the loss of TJ integrity led to an increase in permeability which occurred before any significant clinical or histological evidence of colitis[40]. Another study supporting this premise reported a redistribution of occludin and ZO-1, from the junctions in colonic epithelium after 4 d of administration of DSS[42]. As seen in the claudin studies, the ZO-1 data presented suggests that TJ complex changes are a prerequisite for the development of intestinal inflammation[40,42].

Another adhesion molecule with essential roles in the development and homeostasis of several tissues is the large group of proteins E-cadherin, that represent the major component of adherens junctions[63]. Studies suggest that E-cadherin may factor into the pathogenesis of UC as mice with E-cadherin deficiency had more severe colitis in the DSS model[63]. Further, similar to redistribution of occludin, ZO-1, E-cadherin and B-catenin also translocate from the junctions in colonic epithelium after 4 d of DSS treatment[2,42].

DSS EFFECTS ON MUCIN

Observations in several human studies found patients with colonic inflammation had alterations in colonic mucus and decreased effectiveness in its barrier function[64]. The gastrointestinal tract is quite remarkable with respect to the protective mucus barrier organization. The secretory, gel-forming mucins form the outer loose layer of mucus and the inner dense membrane-bound mucins covers and protects the surface epithelial cells[64,65]. Biochemically, mucins are usually very large, filamentous molecules with a large region within their polypeptides, which comprise relatively short tandemly repeated peptide domains which are highly O-glycosylated[66]. In humans, fifteen different mucins have been described and are assembled in the MUC gene family, with only a few encoded for activity in the colon[64,66]. Of the mucins, only Muc2 has been shown to be the principle secretory gel-forming mucin in both large and small intestines providing the functional barrier between epithelium and microbiota[64,65]. Muc2 is the predominant mucin produced by intestinal goblet cells, and is thickest in the healthy colon[67]. Whereas, the other membrane bound mucins with transmembrane regions are involved in cell signaling, adhesion, growth and modulation of the immune system[64,66].

As mucus is in direct contact with many microorganisms within the intestinal tract, defects in gene coding or protein folding of the mucins could lead to poor membrane integrity and ultimately a breach in the epithelial barrier or alterations in the mucosal-bacterial interactions. Prior *in-vitro* studies on intestinal cell lines revealed that the mucin expression and structure is influenced by cytokines, bacteria and their associated components[66,67]. Likewise, in UC the alteration of immunological or bacterial factors can influence mucin production[67]. Goblet cell depletion is a frequent histopathology finding in UC patients implying that the synthesis of Muc2 is decreased in association with smaller goblet cells thecae and histologic appearance of goblet cell depletion[67]. This, in turn, leads to further adverse effects resulting in chronic inflammation that is characteristic of IBD[64,66]. With these considerations in mind, it is still uncertain whether mucin decrease and goblet cell depletion are the primary contribution to IBD or the consequences of inflammation[67].

Mice deficient in Muc2 are characterized by a loss of mucus layer with bacteria not only in direct contact with epithelial cells but found deeper in the crypts (Table 2). These observations are absent in healthy animals. Furthermore, mice deficient in Muc2 ultimately are more susceptible to spontaneous severe colitis and eventually cause an increased risk of colon cancer development[52,68-70]. Beyond DSS mouse models, other models with defective mucus

Table 2 Role of the different classes of mucins in dextran sodium sulfate induced colitis

Mucin gene	Mucin class	Expression site (GI tract)	Chromosome	Pathological findings with DSS treatment	Ref.
Muc1	Membrane bound	All epithelia	3	Muc1$^{-/-}$ protective when challenged with DSS Increased thickness with adherent mucus	[64,66]
Muc3	Membrane bound	Intestine, enterocytes	5	Increased up-regulation of *Muc3* gene	[65,66]
Muc4	Membrane bound	All epithelia	n.d.	Large type I transmembrane glycoprotein Muc4$^{-/-}$ more resistant to colitis due to up-regulation of Muc2 due to increase proliferation of cytokines	[65,66,73]
Muc2	Secretory	Intestine, goblet cells	7	Muc2$^{-/-}$ more susceptible to spontaneous colitis, increased risk of CAC DSS produces fulminant colitis *vs* wild type	[66-68]
Muc5ac	Secretory	Stomach	7		[66]
Muc5b	Secretory	Tongue, sublingual glands	7		[66]

CAC: Colitis-associated cancer; DSS: Dextran sodium sulfate.

function all develop colitis[50,71,72]. In order to fully comprehend the role of mucins, specifically Muc2, in epithelial barrier protection and colitis, studies were conducted on Muc2 deficient mice. DSS administration to these mice produced fulminant colitis within days compared to the treated wild-type mice[68]. Further, a single missense mutation in Muc2 lead to spontaneous colitis with increased intestinal permeability and increased cytokine production in the distal colon[67]. Additionally, during DSS induction the thickness of the mucus gel decreased at the same time as the mice developed increasing colitis symptoms[64]. Analysis of IL-10$^{-/-}$ mice revealed thicker mucus layers than wild type, but in further analysis specific mucin properties were altered and the usually impenetrable inner layer was found to be penetrable to intestinal bacteria[52]. Therefore, mucus thickness alone was not shown to be a meaningful predictor or indicator of mucus barrier function[52].

Post-translations modifications on mucin are key to their functionality. Along these lines, an increased levels of Muc2 seen following DSS administration fails to control inflammation because of decreased sulphation in Muc2[66,67]. Further studies have shown that alteration in glycosylation of mucins resulted in decrease Muc2 synthesis and a diminished mucus barrier, thereby increasing the susceptibility to DSS-induced colitis[67]. The IL-10$^{-/-}$ germ free mice given normal enteric bacteria, presenting with a loss of sulphation of newly synthesized Muc2 molecules, were more prone to develop colitis and produced severe and chronic colitis[66]. Collectively, these observations underscore the importance of post-translational modification on mucin in its functional role in regulating intestinal barrier integrity[67].

In conjunction with the secretory mucins, the various cell surface mucins are considered to serve a critical function in mucosal protection[65,67]. Muc4 is a large type-I transmembrane glycoprotein component normally expressed on the surface of colonic epithelial cells. Muc4$^{-/-}$ mice were more resistant to colitis and CAC induced by AOM/DSS because of the compensatory upregulation of Muc2 expression in these mice[65]. Although not statistically significant, an upregulation of Muc3 (orthologue of human Muc17) was also observed[65]. Additionally, Muc4$^{-/-}$ mice induced with DSS had increased expression of pro-inflammatory cytokines (TNF-α and IL-1β) which could also be responsible for the observed upregulation of Muc2 and Muc3[65]. Although both Muc4 and Muc13 belong to the transmembrane mucin subtype, deletion of either of the two mucin genes results in opposing phenotypic response to DSS treatment. Muc13$^{-/-}$ mice had increased macrophage expression in the inflamed mucosa accompanied by increased expression of intestinal IL-1β and TNF-α mRNA and significantly increased loss of body weight, diarrhea score, fecal blood score and severe histologic damage including intestinal epithelial cell apoptosis following DSS exposure. This suggests Muc13 confers protection to colonic epithelial cells from apoptotic stimuli, preventing damage-induced cell death[67]. In contrast, Muc4$^{-/-}$ mice exhibit a protective phenotype (decreased loss of body weight, diarrhea score, fecal blood score and less severe histologic damage) which is related to a compensatory upregulation of Muc2 and Muc3[65,73].

Muc1, a non-gel forming mucin transmembrane mucin, when deleted resulted in protection of colonic epithelial cells similar to findings in Muc4$^{-/-}$ mice when challenged with DSS[64]. Muc1$^{-/-}$ deficient mice had increased thickness of adherent mucus resulting in mild colitis[64]. Additionally, germ-free mice had a thin colonic mucus barrier, but luminal exposure to the bacterial products lipopolysaccharides (LPS) and peptidoglycan quickly restores the firmly adherent mucus layer thickness to levels observed in conventionally housed mice[64]. Muc1$^{-/-}$ mice developed a more severe inflammatory response after exposure to *H pylori* compared with wild-type mice, demonstrating that cell surface mucins can modulate the inflammatory response to chronic infection[67]. As opposed to observations in Muc2 deficient mice resulting in severe colitis, the Muc1$^{-/-}$ mice developed a very mild colitis which is thought to be due to an increased colonic mucus barrier and a decreased ability to recruit T cells to the affected region[64].

DSS ALTERS THE MICROBIAL BALANCE

The intestinal microbiome plays an integral role in host immune development, tolerance and intestinal physiological processes. This has spurred large collaborative efforts aimed at identifying and characterizing the microorganisms which are associated with the health and disease in humans[25,32,74,75]. However, the sheer presence of microbiota in the intestinal tract alone is not enough to exert these physiological effects, rather variant microbe compositions, temporal changes in populations and relative abundance of specific microbes are important in homeostasis and specific disease states, namely IBD[66,74-76].

Effects on mucosal inflammation

Studies involving DSS-induced colitis have revealed the critical role that gut microflora play in the pathogenesis of mucosal inflammation and the related role of barrier function as a bulwark against extensive stimulation of the mucosal immune system. However, the exact mechanism through which bacteria induce inflammation has been elusive[22,76]. Indeed, a number of recent studies have identified compositional changes at the bacterial phyla and species levels that can influence phenotypic expression of both pro- and anti-inflammatory responses in humans and in murine models relevant to IBD[22,25,74,76].

As indicated earlier, microbiome composition alterations can result in normally underrepresented members of the microbiome to become dominant, leading to perturbations in structure and function of the microbiome. Various DSS-induced colitis studies have noted that murine microbiota alterations occurred early (within 3 d) and are characterized by diversity reduction and changes occurred prior to the clinical or biochemical evidence of inflammation[31,75,77]. Composition changes in DSS-induced murine colitis indicated a significant proliferation in Bacteroidaceae and Clostridiaceae families[38]. Further studies have corroborated these initial findings to suggest dramatic reductions in the genera of Bacteroidetes, Prevotella, Clostridium and Lactobacillus with corresponding increases in pro-inflammatory gut microbiotic components Bacillaceae, Enterococcales and Enterobacteriaceae[31,78,79].

Effects on barrier functions

Beyond the simple changes in microbiome composition that may herald alterations in physiologic homeostasis, other recent studies have examined the role that bacteria influence barrier function alteration. Evidence suggests that epithelial integrity is compromised in DSS-induced colitis leading to penetrance of microbes and associated antigens into the mucosa and[69,75,80,81]. One such study examining the anti-inflammatory effect of *Faecalibacterium prausnitzii* suggested that its immunomodulatory effects are mediated *via* decreasing the paracellular permeability to effectively reduce the severity of colitis and prevent colitis progression. *Faecalibacterium prausnitzii* decrease NF-κB activation and IL-8 secretion *in vitro* and impairs the colonic synthesis of pro-inflammatory cytokines while inducing the secretion of anti-inflammatory cytokine *in vivo*[19]. Likewise, various strains of bifidobacteria have shown promising anti-inflammatory effects[82]. Specifically, strains of *Bifidobacterium bifidum* have been reported to inhibit LPS-dependent NF-κB activation in IECs and induce anti-inflammatory macrophage, dendritic, and T cell populations[82].

Effects on mucin

Metagenomics studies following the administration of DSS revealed an elevation in *Akkermansia muciniphila,* a Verrucomicrobia member*,* which have been found to metabolize sulfur and lead to mucin degradation and correlate with disease activity in mice administered DSS[31,75,78]. Additionally, DSS induced colitis obliterated the difference in abundance and structure of bacterial communities between the two mucus layers[52,69]. There were fewer bacterial in the firmly adherent mucus but the abundance of bacteria in the mucus layer of the DSS treated animals was 10-100 times greater compared to the control group, suggesting DSS treatment increased the total count of infectious bacteria[22]. Antibiotic administration improved DSS-induced colitis akin to observations showing reduced inflammation in germ-free murine colitis model[31,32].

Changes during the recovery phase

Interestingly, there is a rapid shift of the gut microbial community toward a healthy profile in the recovery phase following the DSS treatment regimen. Within two days of stopping DSS administration, the mice gut microbiota showed relative abundance in Bacteroidetes/Prevotella, Bacillaceae, to levels comparable to those observed in healthy controls[31]. These data demonstrated the high degree of resilience of the gut microbiota and a rapid recovery of its healthy mutualistic profile after DSS-induced dysbiosis[31].

Probiotic treatment against dextran sodium sulfate-induced colitis

Probiotic therapies with Lactobacilli and Bifidobacteria produced favorable outcomes in murine colitis models[82,83]. Probiotic bacteria have been shown to decrease intestinal permeability and restore gut barrier integrity by modulation of tight junction proteins[83]. Pretreatment with *Lactobacillus reuteri* strains prevented the onset of DSS-induced colitis by reducing bacterial translocation and suppressing adherence of lactobacilli on colonic mucosa and[22]. Further, probiotic treatment suppressed upregulation of P-selectin in the colonic endothelium, which decreased leukocyte-

endothelial cell interactions and concomitant leukocytes recruitment to tissue[22]. However, no significant changes in microbial composition were observed indicating that the protective effects are linked to strengthening of the epithelial barrier integrity to reduce bacterial translocation[22,69]. Other studies have also examined the effects of different bacterial species on epithelial TJ in the DSS-induced colitis model. Various strains of bifidobacteria have shown promising anti-inflammatory effects[83]. *Bifidobacterium bifidum* S17 has been found to adhere to cultured IEC and displays potent anti-inflammatory activity both *in vitro* and in two murine models of colitis[83]. *Bacillus subtilis* supplementation resulted in improved barrier function compared to the DSS group, as evident by upregulated expression of TJ proteins (claudin-1, occludin, JAM-A, and ZO-1) and downregulated cytokine expression (IL-6, IL-17, IL-23, and TNF-α)[84]. Additionally, only certain, limited strains of *Bifidobacterium longum* have indicated an increased expression of ZO-1 and occludin resulting in reduced severity of DSS-induced colitis[83].

DEXTRAN SODIUM SULFATE-INDUCED CHANGES IN METABOLOME

DSS colitis has been shown to produce disturbances in the metabolism of phospholipids depicted by decreased levels of phosphocholine and glycerophosphocholine in the colon of mice[1]. Phosphocholine and glycerophosphocholine are the most important metabolites of choline and the major cellular constituents required for the assembly of biological membranes and disturbance in the metabolism suggests the possibility of distorted membrane integrity in the presence of DSS[1].

The role of dietary fat intake in exacerbating intestinal inflammation and modulation of immune function has been investigated extensively[85]. There is supporting evidence to show that a high fat intake is associated with an increased risk of ulcerative colitis[85]. Of note, two factors determine the role of lipid nutrition in health and disease: (1) the composition and (2) the total amount of fat in the diet. Bile acids are produced in the liver and excreted into the duodenum as conjugated bile salts to facilitate homeostatic functions in the gastrointestinal tract. Once in the large intestine, various microbial species enable the transformation of the bile salts into secondary bile acids, such as deoxycholic acid and urosodeoxycholic acid (UDCA), which vary in hydrophobicity[86]. Increased luminal bile acid hydrophobicity reportedly leads to gut barrier dysfunction through the disruption of cell membranes causing cytotoxicity, production of reactive oxygen species, epithelial growth factor receptor activation and tight-junction redistribution[86]. Conversely, UDCA which is more hydrophilic leads to stabilization of lipid membranes[86]. Thus, changes in bile acid composition favoring increased hydrophobicity leads to increased gut permeability allowing for enhanced translocation of bacteria and associated antigens across the tight-junction barrier of the gut epithelium leading to intestinal inflammation. One such study identified animals with a lower concentration of fecal cholic acid had increased histologic damage[86,87]. Additionally, various types of dietary fats promote colitis *via* alterations in gallbladder bile and gut microbiota through changes in taurocholic acid levels in bile which facilitated the growth of the *Bilophila wadsworthia,* an inflammatory Gram-negative anaerobe[86,88]. Overall, fecal bile acid hydrophobicity found to be mediated through a higher proportion of deoxycholic acid positively correlates with the severity of DSS colitis[86].

A potential causal link between dietary fat, especially Omega-3 and Omega-6 fatty acids, and susceptibility to induced colitis has also been reported. A dose dependent effect of the changes in composition of omega fatty acids in exacerbating colitis in various models including the DSS colitis model has been reported[85,86]. Fat in the diet alone does not alter the susceptibility to DSS, rather the modifications to the fecal bile acid composition has been proven to be deleterious[85]. Omega-3 fatty causes decreased adiponectin mRNA expression acid leading to increased inflammation in colonic mucosa[85]. However, another study reported decreases adiponectin RNA expression with no changes in serum adiponectin levels by high fat diet[85]. There are also reports that suggest that the pro-inflammatory effect of adiponectin is mediated by increased IL-6 production[85].

In addition to studies examining primary effect of bile acids on inflammation, the effects that bile acids on cell surfaces have also been investigated[89]. A member of the G protein coupled receptor superfamily, GP-BAR1 is a cell surface bile acid-activated receptor that has been found to be highly expressed in the ileum and colon and activated by secondary bile acids, specifically lithocolic acid and tauro-LCA[89]. Cipriani *et al*[89] asserted that this receptor regulates intestinal barrier integrity since mice lacking the GP-BAR1 receptor developed alterations in colonic histopathology and mucous cell distribution and function[89]. GP-BAR1$^{-/-}$ mice challenged with DSS exhibited an exacerbation of colitis that was not correlated with major immunological abnormalities, but rather an increase in intestinal permeability[89]. Furthermore, they have discovered that oleanolic acid, a natural GP-BAR1 ligand, attenuated colon inflammation and these anti-inflammatory effects of ciprofloxacin were lost in GP-BAR1$^{-/-}$ mice[89].

The central argument that metabolome changes play a part in colitis development is highlighted by the critical role microbiome composition plays in bacterial-host immune response. Certain enzymes, such as 7α-dehydroxylase that are endemic to gut microbiota, can convert primary bile acids into their secondary forms and therefore result in pro-inflammatory versus anti-inflammatory conditions in the host gut lumen.

Additionally, shifts in the community composition and structure can reduce potentially immunomodulatory mucosal-associated species, such as *Faecalibacterium prausnitzii*, *Clostridium leptum* and *Clostridium coccoides*, that act to maintain epithelial health through the production of short-chain fatty acids and stimulation of mucin production, thereby effecting the host's inflammatory response[25,27,75,90].

CONCLUSION

The last several years have provided indispensable insights into the histopathological and morphological changes in intestinal barrier function that likely contribute to the development and progression of murine colitis and aids in the understanding to the pathogenesis of human IBD. As stated prior, no isolated model has proven to sufficiently represent the complex clinical and histopathological characteristics of human disease. But, the DSS-induced colitis model is the most commonly used model that provides an inexpensive, simple and reproducible model to study various aspects of the role of mucin in barrier integrity, alterations in microbial balance and changes in the metabolome that relate to the pathogenesis of IBD. It is our hope that our further understanding of the role of intestinal barrier function in activating the innate and adaptive immune system in the intestinal tract that may lead to new therapeutic targets for human IBD.

Abstract

Autoimmune hepatitis is a rare chronic inflammatory liver disease, affecting all ages, characterised by elevated transaminase and immunoglobulin G levels, positive autoantibodies, interface hepatitis at liver histology and good response to immunosuppressive treatment. If untreated, it has a poor prognosis. The aim of this review is to summarize the evidence for standard treatment and to provide a systematic review on alternative treatments for adults and children. Standard treatment is based on steroids and azathioprine, and leads to disease remission in 80%-90% of patients. Alternative first line treatment has been attempted with budesonide or cyclosporine, but their superiority compared to standard treatment remains to be demonstrated. Second-line treatments are needed for patients not responding or intolerant to standard treatment. No randomized controlled trials have been performed for second-line options. Mycophenolate mofetil is the most widely used second-line drug, and has good efficacy particularly for patients intolerant to azathioprine, but has the major disadvantage of being teratogenic. Only few and heterogeneous data on cyclosporine, tacrolimus, everolimus and sirolimus are available. More recently, experience with the anti-tumour necrosis factor-alpha infliximab and the anti-CD20 rituximab has been published, with ambivalent results; these agents may have severe side-effects and their use should be restricted to specialized centres. Clinical trials with new therapeutic options are ongoing.

Key words: Autoimmune hepatitis; Standard treatment; Second-line treatment; Adults; Children

© The Author(s) 2017. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: The first part of this review summarizes the standard therapeutic approach for autoimmune hepatitis (steroids and azathioprine) and the evidence on which it is based. The second part reviews systematically published data on first and second line alternative treatments. This information is summarized in two comprehensive tables, one for adult and one for paediatric patients.

INTRODUCTION

Autoimmune hepatitis (AIH) is a rare inflammatory liver disease of unknown origin characterised by high transaminase and immunoglobulin G (IgG) levels, positive autoantibodies, and, histologically, by interface hepatitis[1-4]. The condition affects all ages, and has a female preponderance[5]. There is no single diagnostic test[1,2]. The International Autoimmune Hepatitis Group (IAIHG) established comprehensive diagnostic criteria in 1993[6], based on expert opinion, intended to be used for research purposes. After their evaluation in a number of studies, the criteria were updated in 1999[7]. A simplified, clinical practice-friendly version was published in 2008[8]. These criteria are intended to help in guiding diagnosis and decision on therapy initiation in patients presenting with a clinical picture suggesting AIH, and have received extensive external validation since publication[9-11].

AIH is divided in type 1 and type 2, the latter being rare in adults and representing 30% of juvenile AIH. The distinction is made serologically: type 1 AIH is positive for anti-nuclear antibodies (ANA), and/or anti-smooth muscle antibodies (SMA), while type 2 AIH is positive for anti-liver kidney microsomal antibodies type 1 (anti-LKM1) and/or anti-liver cytosol type 1 (anti-LC1)[12].

AIH is the first liver disease for which pharmacologic treatment has been shown to improve survival. Indeed, it has an excellent response to steroid-based immunosuppressive therapy, with a reported response rate of 75%-90%[2]. Steroid-response is a crucial feature of AIH, and it is part of the IAIHG revised diagnostic criteria[7]. Lack of response to steroids should prompt a review of the diagnosis.

Treatment indications

If untreated, AIH has a severe prognosis. This knowledge derives from early clinical trials, when "HBsAg-negative hepatitis" (as AIH was called then) patients were treated with corticosteroids *vs* placebo. One placebo controlled study reported a 5-year survival rate of 32% in untreated patients *vs* 82% in patients treated with steroids[13]. According to the guidelines on the management of AIH by the American Association for the Study of Liver Diseases (AASLD)[2], the 6-mo survival rate in untreated patients is about 60%. Therefore, once diagnosed, AIH should be treated promptly. Elderly patients with mild pauci- or a-symptomatic disease, who have a high risk of developing steroid side effects, may be an exception, and in this clinical context treatment *vs* watchful waiting should be carefully evaluated case by case[14-16]. Untreated patients need a close follow-up. Treatment must be always initiated in the presence of clinical symptoms, severe biochemical and/or histological disease activity. Younger subjects, particularly children and adolescents, who have a more aggressive disease, should be treated without delay[17].

Treatment aims

The aim of treatment is disease remission, which is reached if the following criteria are met: (1) absence of clinical symptoms; (2) normal transaminase levels; and (3) normal IgG levels. In children/adolescents, negative or very low-titre autoantibodies (< 1:20 for ANA/SMA; < 1:10 for anti-LKM1) are an additional criterion of remission[3], which remains to be evaluated in adults by longitudinal studies.

In the past, transaminase levels below twice the upper limit of normal (ULN) have been considered proof of remission, but it is now clear that patients with abnormal transaminase levels have progressive disease[2,18]. Once remission is achieved, the lowest possible dose of immunosuppressive drugs should be used to maintain long-term remission with no or minimal side effects.

Disease relapse is defined as transaminase levels rising above the ULN after remission[12]. Relapse occurs mostly if the dose of the immunosuppressive drugs is reduced, or in case of non-adherence. Non-adherence is a frequent clinical problem, particularly in adolescents[19] and young adults, and is often due to real or perceived treatment side effects. It should always be suspected in case of relapse while on a stable dose of immunosuppressive drugs.

AIM AND METHODOLOGY OF THE SYSTEMATIC REVIEW

The aim of this review is, in its first part, to critically summarize the evidence on which standard AIH treatment (prednisone and azathioprine) is based, and, in its second part, to provide a systematic review of the published data on alternative treatments. For the purpose of the systematic review of the literature on alternative AIH treatment, publications cited in PubMed (http://www.ncbi.nlm.nih.gov/pubmed) were

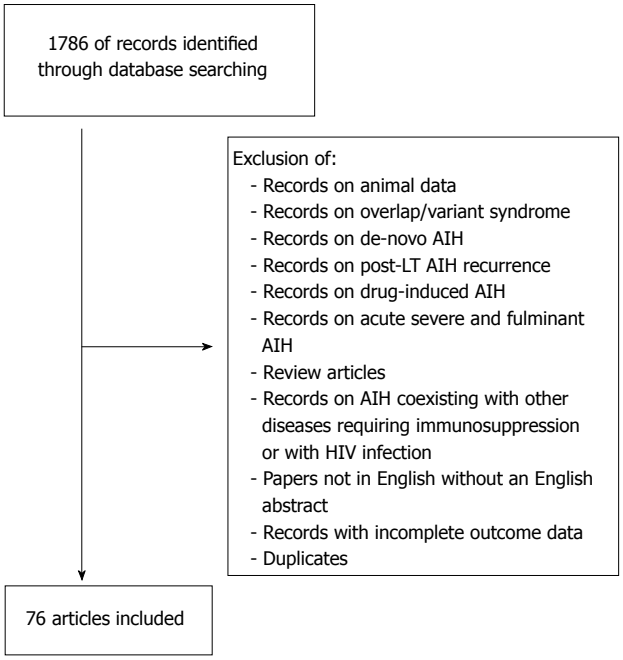

Figure 1 Selection of relevant articles for the systematic literature review on alternative AIH treatments. AIH: Autoimmune hepatitis; LT: Liver transplantation.

Table 1 Proposed schedule of prednisone tapering during remission-induction therapy in adults[25]

	Prednisone mg/d	Azathioprine
Week 1	60.0	Check transaminase levels every week before reducing the prednisone dose: if transaminase levels stop decreasing, add azathioprine 1-2 mg/kg per day, if jaundice is subsiding
Week 2	50.0	
Week 3	40.0	
Week 4	30.0	
Week 5	25.0	
Week 6	20.0	
Week 7	15.0	
Week 8-9	12.5	
Week 10-11	10.0	
If severe steroid side effects: consider reducing to 2.5 mg/d for 2 wk and then stopping prednisone		

Table 2 Proposed schedule of prednisone tapering during remission-induction therapy in children[2,12]

	Prednisone mg/kg/d	Azathioprine
Week 1	2.0	Check transaminase levels every week before reducing the prednisone dose: if transaminase levels stop decreasing, add azathioprine starting with 0.5 mg/kg per day, if jaundice is subsiding, at increasing doses up to 2-2.5 mg/kg/d until biochemical control
Week 2	1.75	
Week 3	1.50	
Week 4	1.25	
Week 5	1.00	
Week 6	0.75	
Week 7	0.50	
Week 8-9	0.25	
Week 10-11	0.10-0.20	
If severe steroid side effects: consider reducing to 2.5 mg/d for 2 wk and then stopping prednisone		

selected using the search words "autoimmune hepatitis" and "treatment". Citations were chosen on the basis of their relevance to the aim of this article (Figure 1). Fundamental characteristics of the abstracts judged pertinent to the review were noted, and full-length original articles were selected from the abstracts. Seventy-six articles were identified, 22 of them are not discussed in this review because of anedoctal reporting, the remaining 54 are included in Table 1 (adults) and Table 2 (children). Children/adolescents have a more aggressive disease, with a more frequent acute presentation[20] and therefore need a different management[17]. For this reason, the present review article discusses adult and pediatric treatment separately.

STANDARD TREATMENT

Why do we treat autoimmune hepatitis with steroids and azathioprine?

Standard treatment is based on steroids and azathioprine (Table 1). A systematic review of randomized controlled trials focused on these two drugs up to 2009 was published in 2010[21]. The exact azathioprine mechanism of action is unclear, but it is most probably linked to suppression of nucleic acid synthesis. The first evidence for steroid benefit in inducing remission and improving survival in treatment-naïve AIH stems from three trials performed in the 1970s, which demonstrated a significant better survival in patients with so called "HBsAg-negative chronic active liver disease" treated with steroids[22-24] in comparison to untreated patients. It should be noted that at that time the hepatitis C virus (HCV) had not been discovered and it is likely that some patients with HCV were included in the trials, although "HBsAg-negative chronic active hepatitis" was characterised by high globulin levels, female preponderance, and presence of autoantibodies, all features of AIH[13]. The benefit of steroid treatment would have probably been even greater if HCV-patients had been excluded[25]. In the Royal Free Hospital trial[22], 49 well characterised patients, including children, were randomised in a steroid-treated group (prednisolone 15 mg/d) and a placebo group. Mortality rate was 14% in the treated group, and 56% in the placebo group, with a follow-up ranging from 30 to 72 mo. The trial from the Mayo Clinic published one year later[23] included 63 patients, divided into four groups. Two groups were treated with protocols similar to current guidelines: the first group was treated with prednisone alone starting with 60 mg/d, tapered to a maintenance dose of 20 mg/d over 4 wk, the second group received prednisone 30 mg/d tapered to a maintenance dose of 10 mg/d combined with azathioprine at a fixed dose of 50 mg/d. The remaining groups were treated with azathioprine alone 100mg/d and placebo, respectively. The mortality rate in the first and second group was very low (6% and 7%), compared to a mortality rate of 36% and 41% in the groups treated with azathioprine

alone or placebo. The follow-up period ranged from 3 mo to 3.5 years. The side effect rate was lower in the azathioprine-prednisone group than in the prednisone alone group (10% *vs* 44%). A trial from King's College Hospital published in 1973[24] included 47 patients, divided into two groups, one treated with prednisone 15 mg/d, and the other with azathioprine alone, 75 mg/d, with a follow-up of two years. The mortality rate in the prednisone group was 5%, as compared to a mortality rate of 24% in the azathioprine group. From these early trials it is clear that prednisone is very effective in treating AIH, and that azathioprine alone is not able to obtain disease remission. Following these reports, strategies were sought to optimize the treatment schedule, *i.e.* to find the minimal doses of prednisone or prednisone/azathioprine able to control the disease with minimal side effects. A trial published in 1975[26] included 120 patients and compared four different schedules: (1) prednisone starting at 60 mg/d tapered to a maintenance dose of 20 mg/d; (2) prednisone starting at 30 mg/d tapered to 10 mg/d together with a 50 mg/d fixed dose of azathioprine; (3) prednisone at 60 mg/d tapered to a maintenance dose of 10 mg/d given on alternate days; and (4) placebo or azathioprine on a fixed dose of 100 mg/d without steroids, as control. Biochemical remission was achieved in 80% of patients in the first two groups, in 74% in the third group and in 34% in the control group. Histological remission was achieved in 57% and 60% of patients in the first two groups, but in only 19% and 24% in the third and in the control group. Side effects were less frequent in patients treated with prednisone/azathioprine from disease presentation, for which a lower dose of prednisone was used, leading to the conclusion that combined treatment is preferable. Of note, this trial enrolled "post-pubertal subjects", including patients from the age of 12 years. An additional trial published in 1982[27] compared a fixed low-dose prednisone alone (10 mg/d for body weight < 70 kg, 15 mg/d for body weight ⩾ 70 kg) in 37 patients with a fixed low-dose azathioprine alone (5 mg/kg per week for the first 2 wk, subsequently 10 mg/kg per week) in 47 patients. Mortality was very high in both groups at 1 year (27% and 28% respectively), indicating that a low prednisone dose and azathioprine alone are inadequate.

Despite the limitations of these early trials, prednisone ± azathioprine remains the mainstay of treatment for AIH, several reports showing high remission rates and favourable outcomes in both adult and juvenile AIH[20,28-38].

Of note, azathioprine monotherapy, though unsuccessful in the induction of remission, is effective in adults as maintenance therapy, at a dose of 2 mg/kg per day[39]. A 5-patient report suggests that it may be effective also in children[40]. In a recent retrospective series, 87% of 66 children with AIH were reported to maintain sustained biochemical remission (normal transaminase levels) in association with low 6-thioguanine nucleotides (TGN) levels (50-250 pmol 8 x 10 red blood cell cont) on an azathioprine dose of 1.2-1.6 mg/kg per day with or without associated steroids[41].

How to use prednisone and azathioprine

There is no treatment schedule applicable to all AIH patients. The suggested algorithms and treatment schedules must be tailored to the single patient, taking into account the severity of the disease, age and co-morbidities[1].

The AASLD guidelines published in 2010[2] recommend two alternative schedules: either prednisone alone at a dose of 60 mg/d or a combination of prednisone 30 mg/d and azathioprine 50 mg/d as initial treatment, favouring the latter because of fewer steroid side-effects[26]. However, as azathioprine can be hepatotoxic, particularly in cirrhotic and jaundiced patients[25], the more recent guidelines by the European Association for the Study of the Liver (EASL) recommend that it is added after two weeks of steroid monotherapy [predniso(lo)ne 1 mg/kg per day in adults], when partial disease control has been achieved[1]. In addition, this approach avoids the problem of distinguishing between azathioprine-induced hepatotoxicity and non-response, this distinction being an important issue in clinical practice. A retrospective series of 133 adult patients reports better results with a combination of steroids and another immunosuppressant (azathioprine in 96%, other unspecified drugs in 4%) from disease presentation compared to steroids alone or steroids followed by the addition of azathioprine/other immunosuppressants. Of note, only 2% of the patients included in this study were jaundiced at presentation[42], possibly explaining the high remission rate on azathioprine, without hepatotoxicity.

Prednisone should be rapidly tapered (Table 1) to minimise steroid side effects. This rapid decrease of the prednisone dose requires weekly checks of the transaminase levels to monitor response. Azathioprine should be added if the transaminase levels stop decreasing on steroid treatment alone (Table 1). Ultimately 85% of the patients will need azathioprine in addition to low-dose prednisone[12]. This protocol was originally used for children[25], but it is suitable to treat adult patients as well, because it allows to avoid azathioprine in a small proportion of patients and especially because it limits steroid side effects, which are often the reason for non-adherence. The initial recommended dose of azathioprine in adults is 50 mg/d or 1 mg/kg per day[2]. If steroid side effects are severe and require steroid discontinuation, the azathioprine dose is increased to 2 mg/kg per day.[39,43]

In children, the recommended treatment schedule is similar to that of adults, but a higher steroid dose is required due to the more aggressive disease course in this age group (Table 2). Children were included in early clinical trials[22,26], but a sub-analysis of paediatric patients was not performed, and the numbers were small. Current recommendations are based on series

from large centres, which report a remission rate of about 90% using predniso(lo)ne ± azathioprine[20,35,36]. Conventional treatment of juvenile AIH consists of prednisolone (or prednisone) 2 mg/kg per day (maximum 60 mg/d), decreased over a period of 4 to 8 wk in parallel to the decline of transaminase levels, to a maintenance dose of 2.5-5 mg/d (Table 2). Long-term low daily doses are not associated with impaired adult height[44]. The timing for the addition of azathioprine as a steroid-sparing agent varies according to the protocols used in different centres. In some, azathioprine is added only in the presence of steroid adverse effects, or if the transaminase levels stop decreasing on steroid treatment alone. In other centres azathioprine is added after a few weeks of steroid treatment in all patients, when the serum aminotransferase levels begin to decrease. Some centres use a combination of steroids and azathioprine from the beginning, but caution is recommended because of the azathioprine hepatotoxicity mentioned above[1,2,34]. The initial recommended azathioprine dose is 0.5 mg/kg per day[12], which can be increased to 1-2 mg/kg per day until normalization of the transaminase levels is reached. As in adults, azathioprine alone has been shown to be able to control the disease as long-term maintenance therapy, although only in retrospective series[40,41,45].

As AIH is very sensitive to prednisone, a maintenance dose of 5 mg/d is effective in controlling the disease, usually with, but sometimes without, azathioprine. Steroid reduction below 5 mg/d (or 2.5 mg/d in children) requires careful monitoring of transaminase levels, even if implemented after long-term disease remission. The dose should be reduced very slowly, *e.g.,* by 1 mg per month if 1 mg prednisone tablets are available, or, if not available, by reducing to 5-2.5 mg on alternate days for 1-2 mo, and then to 2.5 mg/d.

Side effects of steroids and azathioprine

Steroid side effects are dose and time dependent, and arise if a dose exceeding 7.5-10 mg/d is administered over several months[25]. The most common side effect is the development of cushingoid features. In a retrospective monocentric study of 103 adult AIH patients[46], mostly treated according to a standard protocol with a steroid starting dose of 1 mg/kg per day and a mean follow-up period of 95 mo, 15.5% developed cushingoid features. Although not severe, these changes are often a great concern for the patients, and may lead to non-adherence, with the dangerous consequence of poor disease control. Almost half of AIH patients discontinue steroids because of cosmetic changes (including acne) or obesity[47]. Severe, but less frequent steroid side effects include osteoporosis, brittle diabetes, cataract, psychosis and hypertension[2]. They are mainly related to the initial high dose, and are reversible[43,46]. Monitoring of these complications is advisable, including ophthalmologic controls and bone density scans on a regular basis.

Azathioprine side effects affect 10%-20% of patients and include hepatotoxicity, acute cholestatic hepatitis, pancreatitis, nausea and vomiting, rash, bone marrow suppression, veno-occlusive disease, opportunistic infections, and malignancy[2]. The most common side effect is bone marrow suppression, which is unpredictable, and can be aggravated by concomitant cytopaenia due to liver disease and hypersplenism. Haematological monitoring is necessary, particularly at the beginning of treatment. Measurement of erythrocyte concentrations of thiopurine methyltransferase (TPMT) activity may be advisable before institution of azathioprine therapy, but does not invariably predict response to the drug or toxicity[48,49]. TPMT genotyping predicts azathioprine haematological toxicity in those rare individuals with variant homozygosity, while heteroxygotes do not experience more toxicity than wild-type patients[50]. Five percent of patients develop early intolerance, most frequently with nausea and vomiting.

A possible complication of long-term treatment with azathioprine is the development of malignancies. In one study aiming at investigating disease control by azathioprine monotherapy at a dose of 2 mg/kg per day, 5 of 72 patients (7%) developed malignancies over a median follow up of 12 years[39]. Recently, two cases of T-cell lymphoma in adolescents treated with azathioprine for AIH were reported[51]. Thus, a lower azathioprine dose in association with low-dose steroids may be preferable for long-term maintenance therapy. Azathioprine is considered to be safe in pregnancy[52-54].

Measurement of the azathioprine metabolites 6-TGN and 6-methylmercaptopurine can be helpful in identifying drug toxicity and non-adherence, and in distinguishing azathioprine hepatotoxicity from disease non-response, as shown by a retrospective study in adults[55], and a small prospective study in children[56], but an ideal therapeutic level of the 6-thioguanine metabolites has not been established for AIH, unlike for inflammatory bowel diseases (IBD).

Treatment withdrawal

The AASLD[2] and the EASL guidelines[1] recommend a treatment duration of at least 2 and 3 years respectively, and both advise against a trial of treatment withdrawal before 2 years of complete biochemical remission. They recommend performing a liver biopsy before attempting treatment discontinuation, because histological inflammatory activity can still be present despite biochemical remission, predicting relapse. A recent report on 28 patients in whom treatment was withdrawn without histological evaluation, shows that the 54% of patients who did not relapse had transaminase levels less than half the ULN and IgG levels below 12 g/L on low-dose monotherapy (azathioprine/mercaptopurine or steroids) for at

least 2 years, suggesting that patients meeting these parameters may avoid pre-withdrawal liver biopsy[57]. This suggestion, however, requires confirmation by other centres.

Relapse after treatment withdrawal is frequent, having been reported in some 80% of patients[1,2,58]. Repeated relapses are associated with a poorer prognosis and a higher rate of drug side effects[2]. For this reason, patients experiencing a first relapse episode after appropriate evaluation of disease remission, should undergo life-long low-dose immunosuppressive therapy[1].

For AIH type 2, relapse is almost universal if treatment is completely withdrawn[20], and long-term low-dose maintenance therapy should be planned from the diagnosis. Since this condition mostly affects children, adolescents and young adults, life-long duration of the therapy should be discussed and carefully explained to the patients and their family.

ALTERNATIVE TREATMENTS

For patients who experience azathioprine side effects, ranging from the relatively frequent early gastrointestinal intolerance to the rarer and more serious bone marrow suppression, and for poor responders to standard treatment, alternative regimens are needed, primarily to avoid high-dose steroid side-effects. A systematic review of the published clinical data on pharmacological treatments different from prednisone and azathioprine is provided in this section. Treatments for whom there are only anecdotal data are not discussed cyclophosphamide[59], methotrexate[60-62], ursodeoxycholic acid[63-69], etanercept[70], plasma exchange[71], intravenous immunoglobulin[72], leukapheresis[73], chloroquine[74], thymostimulin[75], deflazacort[76,77], saireito[78], sympathomimetic amines[79], glycyrrhizin[80], fenofibrate[81].

Budesonide

Budesonide is a glucocorticosteroid with a potent topical effect and a high first-pass uptake (> 90%) in the healthy liver, thus appearing ideal for treating AIH. The first reports on its use included small numbers of patients at different stages of disease and gave controversial results[79-83] (Table 3). Subsequently, a large randomized controlled trial in 203 AIH patients (including 46 children/adolescents) was carried out, involving several European centres[82] (Table 3). Cirrhotic patients were excluded, because the first pass hepatic extraction of budesonide may be reduced in cirrhosis due to portosystemic shunting. In fact, severe complications have been reported in cirrhotic patients on budesonide[83,84], including portal vein thrombosis and Budd-Chiari syndrome, indicating that AIH patients with cirrhosis at diagnosis (at least one third) should not be treated with budesonide. The trial primary end-point was biochemical remission (defined as normalization of transaminase levels) in absence of steroid side effects. The overall results of the trial showed better response to budesonide/azathioprine than to prednisone/azathioprine treatment, the primary end-point being achieved in 60% of patients given budesonide *vs* 38.8% of those given prednisone[82]. These response rates, however, are below the remission rates achieved with standard treatment, and this has raised concerns. In the control arm, the prednisone dose was reduced as per-protocol, irrespective of the course of the clinical and biochemical response, an approach not recommended in AIH treatment[1], which should be tailored to individual patient response. The initial prednisone dose (40 mg/d) was low at least for children/adolescents[1,12], who should be treated with 2 mg/kg per day (up to 60 mg/d). All patients were prescribed azathioprine from the beginning, irrespective of the presence of jaundice, raising the possibility that the low response rate might be partly due to azathioprine hepatotoxicity[85]. The trial included treatment naïve patients and patients experiencing disease relapse, who are likely to represent a subgroup of poor responders[85]. Moreover, only transaminase levels were used to define biochemical remission, while the combination of normal transaminase and IgG/gammaglobulin levels best predicts absence of histological activity[46,86,87].

Though budesonide is still not recommended as first line therapy for AIH[1], it may be a valid alternative for the maintenance of remission long-time, particularly for patients experiencing steroid side effects. In a retrospective study 60 patients with either prednisolone side effects or dependence on a relative high dose of prednisolone were switched to budesonide[88]: the biochemical remission rate at 6 mo was 55%, and 25% of the patients needed to be switched back to prednisone due to budesonide side-effects or insufficient response. However, all patients who were in remission at the time of switching remained in remission. These findings indicate that budesonide is effective in maintaining remission in patients who have achieved it with prednisone, but also that it is not free of side effects, and that, not surprisingly, it is not effective in patients resistant to prednisone, as prednisone and budesonide share the same receptor.

A sub-analysis of the paediatric population (46 patients aged 9 to 17) enrolled in the budesonide trial[89] reported no significant difference in biochemical remission rate at 6 and 12 mo between the budesonide and the prednisone groups (32% and 33% at 6 mo and 50% and 42% at 12 mo, respectively) (Table 4). The frequency of steroid side effects was also not different, being 47% in the budesonide group and 63% in the prednisone group, apart from a lower mean weight gain in the budesonide group. The remission rate was well below that achieved with standard treatment, therefore, budesonide cannot be recommended for the treatment of children/

adolescents with AIH until a trial including strict diagnostic criteria and drug schedules appropriate for the juvenile disease is performed[85].

Mycophenolate mofetil

Mycophenolate mofetil (MMF) is the prodrug of mycophenolic acid. It is an inhibitor of inosine monophosphate dehydrogenase, the rate-limiting enzyme in de novo purine synthesis on which, in contrast to other cells, B and T lymphocyte proliferation relies. MMF is widely used as second line AIH treatment, mostly combined with prednisone, both for patients intolerant to azathioprine and for patients with unsatisfactory response to standard azathioprine/prednisone treatment. Its use in AIH is based on retrospective series[90-103] (Table 3) with a total number of 313 patients treated, suggesting that MMF is partially effective in patients intolerant to azathioprine, but may not be effective in case of azathioprine poor response. However, a recent paper from Australia including 96 patients[104] reported a similar remission rate both in patients intolerant and poor responders to azathioprine (Table 3). One single prospective uncontrolled trial from Greece tested the use of MMF as first-line treatment[102,105] (Table 3). MMF was reported to be safe and effective in inducing and maintaining remission in treatment-naïve patients (83/102 patients achieved biochemical remission at 3 mo) and to have a rapid steroid sparing effect. However, it is not clear whether it offers an advantage over azathioprine, as a head-to-head comparison with azathioprine was not performed. A trial comparing azathioprine to MMF is currently ongoing (NCT02900443). MMF has the major disadvantages of being about 15 times more expensive than azathioprine, and, most importantly, of being teratogenic, which is highly relevant, since AIH affects mainly young females. The most frequent side effects are gastro-intestinal symptoms.

In juvenile AIH patients in whom standard immunosuppression is unable to induce stable remission, or who are intolerant to azathioprine, MMF at a dose of 20 mg/kg twice daily, together with prednisolone, has been used successfully used[90,106–108] (Table 4). A recent meta-analysis, including data from several small studies of second line treatments in children refractory to standard therapy shows that MMF is efficacious with a low side effect profile (in contrast to calcineurin inhibitors), supporting the notion that MMF should be the primary choice for second-line therapy in juvenile AIH[109].

Calcineurin inhibitors

Cyclosporine A: Cyclosporine A is a calcineurin inhibitor extensively used in the setting of transplant medicine. Important side effects are renal toxicity and cosmetic changes, particularly in association to high doses. In small retrospective series[90,108,110–115], small prospective open and uncontrolled trials[115,116] and single case studies[91,107,117-121] cyclosporine A has been reported to be effective - using variable doses, duration of treatment and follow-up - either as first-line option or in patients not responding to azathioprine and prednisone, both in children and in adults (Tables 3 and 4). Though the results of these reports appear to be encouraging, the quality and quantity of the data are insufficient to recommend its use. In paediatrics, cyclosporine A has been used as first line treatment for type 1 AIH in an attempt to reduce steroid side effects in a prospective multicentre study in 84 treatment-naïve children[122,123] (Table 4). Cyclosporine alone was administered for 6 mo, and the patients were subsequently switched to azathioprine and prednisone. Transaminase levels normalization was obtained in 72% of the subjects after six months of cyclosporine monotherapy, but IgG levels were not included in the remission criteria. Cyclosporine side effects included hypertrichosis (55%), gingival hyperplasia (39%), elevation of creatinine (9%) and hypertension (3%). The main limitation of this study is lack of direct comparison with standard treatment.

Animal data suggest that cyclosporine A may promote autoimmunity[124-127], and the first reports of de novo autoimmune hepatitis arising after liver transplantation were in children treated with

cyclosporine[128]. These observations call for caution in the use of cyclosporine in AIH.

Tacrolimus: Tacrolimus is a more potent calcineurin inhibitor than cyclosporine, has less cosmetic side effects, but similar drug class toxicity. In AIH, it has been used both for refractory cases and for patients intolerant to other immunosuppressive regimens. A few retrospective small case series in adults have been published, with variable remission criteria, sometimes including only transaminase levels[91,93,129-135]. The reported efficacy was good in a total number of 80 patients (Table 3). Two prospective open-label trials from the '90s are available, both in naïve patients[133,136] (Table 3). The oldest one included 21 adult patients[133], with a follow up of 1 year, after which a liver biopsy was repeated, but histological results are not reported. Half of the patients were anti-LKM1 positive; tacrolimus was used as monotherapy. Of note, the serum target level of tacrolimus was low (0.6-1 ng/mL). The mean decrease of transaminase and bilirubin levels was satisfactory, but the remission rate is not reported. In terms of side effects, the mean creatinine value increased significantly after 1 year of treatment. The second prospective trial in naïve patients included seven adult subjects and used lower tacrolimus doses combined with 20 mg/d of prednisolone. Transaminase levels, albumin, bilirubin and prothrombin time significantly improved in 6/7 patients[136].

In children, one prospective, single centre, open label trial including 20 treatment naïve patients is available: none was anti-LKM1 positive, follow up was 1 year, after which a liver biopsy was repeated[137] (Table 4). Target tacrolimus blood levels were 2.5-5 ng/mL. 14/20 patients needed azathioprine and prednisone in addition to tacrolimus to achieve remission. Histological improvement of inflammation was seen in 12/14 cases. No effect on the renal function was observed. This trial suggests that tacrolimus as monotherapy is not effective in juvenile AIH, but could be considered as steroid/azathioprine sparing agent.

More high-quality data are needed, both in adults and children, to assess tacrolimus efficacy in AIH.

m-TOR inhibitors

Sirolimus: Sirolimus is a macrolide molecule acting by inhibiting the mammalian target of rapamycin (mTOR), a protein that modulates the proliferation and survival of activated lymphocytes. It is produced by the bacterium Streptomyces hygroscopicus and was isolated in 1972 on Easter Island (Rapa Nui). Sirolimus is used to prevent rejection in solid organ transplantion.

There is very limited experience in the use of this drug for poor responders to standard AIH treatment. Retrospective data on 5 adult patients with AIH refractory to prednisone, azathioprine and mycophenolate are available[138] (Table 3). Only transaminase levels were used to define remission, median follow up was 24 mo, the target serum level was low, 10-20 ng/dL. Complete remission was achieved in 2/5 patients. Side effects were limited to hyperlipidaemia occurring in 2/5 patients. In paediatrics, a small retrospective series reports the use of rapamycin in 5 cases refractory to standard treatment (3/4 also to MMF)[139], including 1 case of non-adherence (Table 4). Two of the four patients showed an improvement in transaminase levels; tolerability was good, though 2/4 had mouth ulcerations not requiring drug discontinuation. The target sirolimus blood levels reported in the paper are 4-8 ng/mL. A report of two additional adult cases of difficult-to-treat AIH patients managed with sirolimus is even less encouraging: in one case sirolimus was discontinued due to legs ulcers, and in the other it was ineffective[140]. No drug serum levels were reported.

In conclusion, data on sirolimus in difficult-to-treat AIH patients are scanty and rather disappointing.

In the transplant setting, sirolimus has been reported to be effective in difficult-to-treat de novo AIH or AIH recurrence[141] in a small series of 6 paediatric patients. Three of them experienced infections while on sirolimus, including one case of colitis and fever leading to drug discontinuation.

Everolimus: Everolimus has a mechanism of action similar to sirolimus, and is used to prevent solid organ rejection, or at higher doses, as an anti-cancer drug. Only one report is available on the use of everolimus for the treatment of AIH. It is a retrospective series of 7 adult patients with insufficient response to standard or alternative treatments (budesonide, MMF, calcineurin inhibitors), or with severe treatment side-effects[142] (Table 3). Everolimus target blood concentration was 3-6 ng/mL. Complete biochemical response was obtained in 3/7 patients after 5 mo, but all patients, except one who was non-adherent, had significant decrease in serum transaminase levels, allowing reduction of the steroid dose. Histology did not show disease progression in four patients treated for 3-5 years. No severe side effects were reported, but one patient died from cholangiocarcinoma diagnosed 6 mo after starting everolimus, though cancer was not considered to be associated with the drug. In conclusion, in view of the very few data available, the role of everolimus in the treatment of AIH remains to be explored.

Biologicals

Rituximab: Rituximab is a monoclonal chimaeric (murine/human) antibody that specifically binds the CD-20 antigen, a phosphoprotein expressed on the surface of B-lymphocytes, leading to B-cell depletion. It is approved for the treatment of non-Hodgkin lymphoma, rheumatoid arthritis and ANCA-

associated vasculitis. It has also been used recently as rescue treatment in refractory AIH. In a single-centre open-label pilot study in Canada, 6 AIH adult patients who had failed treatment with prednisone and/or azathioprine[143] for intolerable side-effects (3/6) or refractory disease (3/6) were treated with two doses of 1000 mg rituximab administered two weeks apart (Table 3). Tolerance was good, only one patient developing minor infections. In all patients, transaminase and IgG levels decreased; a liver biopsy performed after 1 year in 4 of the 6 patients showed improvement of the inflammatory activity. Though a recent survey shows that rituximab is used for difficult-to-treat AIH patients in several centres[144], this experience has not been published. A few case reports of patients with AIH coexisting with other autoimmune diseases have been published[145-149], all demonstrating a positive effect of rituximab also on AIH.

In children, two cases of refractory AIH have been successfully treated with rituximab[149] (Table 4). In addition, the recently published preliminary results of a real-world expert management of paediatric AIH also reported the use of rituximab as rescue therapy[150].

In summary, rituximab has shown good efficacy in a small number of difficult-to-treat AIH patients, but its safety profile needs to be evaluated carefully, as the drug may have severe long term side-effects, including B-cell depletion[151].

Infliximab: Infliximab is a recombinant humanized chimaeric antibody used for the treatment of ulcerative colitis, Crohn disease, rheumatoid arthritis, psoriatic arthritis/plaque psoriasis, and ankylosing spondylitis. It acts mainly by direct neutralization of soluble tumour necrosis factor-alpha, but it has also pro-apoptotic and anti-proliferative effects on lymphocytes[152].

One small retrospective series from Germany on the use of infliximab as salvage therapy in 11 adult AIH patients reports[153] (Table 3) normalisation of transaminase levels in 8 and of IgG levels in 6. However, 7 patients developed infectious complications, and treatment had to be stopped because of side effects in three cases. Recently, preliminary results of an extension of this cohort of difficult-to-treat AIH patients was published: the cohort now includes 18 cases, 15 reaching biochemical remission[154]. Two case reports have also been published: one describing a difficult-to-treat AIH patient who achieved normalization of transaminases levels after 3 mo of infliximab treatment[155], and one reporting good disease control on infliximab in a young patient with AIH and adult onset Still disease[156].

In children, a 10-year old girl with aggressive disease, unresponsive to standard treatment, MMF and tacrolimus, has been reported to have a good response to infliximab, though liver transplantation was deferred but not avoided[157] (Table 4).

As for rituximab, specialized centres have unreported experience[144,150]. It is important to note that anti-tumour necrosis factor-alpha can induce hepatotoxicity resembling AIH[158-162], as well as other immune-mediated disorders, such as lupus erythematosus[163]. This should raise caution in using this agent, which should be reserved for treatement–resistant AIH cases in specialised centres.

Thiopurines

6-mercaptopurine: Azathioprine is the prodrug of 6-mercaptopurine (6-MP), and is non-enzymatically converted into 6-MP, which represents the biologically active form of the drug. 6-MP is used for the treatment of IBD, where it has been shown that 6-MP is better tolerated than azathioprine[164,165], despite the close biochemical relationship and shared metabolic pathways (Figure 2). In AIH, 6-MP was used successfully in 3 patients intolerant or unresponsive to azathioprine, including one paediatric patient[166], representing the only published experience in children (Tables 3 and 4). The largest series of AIH patients intolerant or unresponsive to standard treatment switched to 6-MP is a retrospective study on 22 adult cases[167] (Table 3). The two patients with insufficient response to standard treatment did not respond to 6-MP, whereas 15/20 patients intolerant to azathioprine showed either partial (7/15) or complete (8/15) biochemical remission. Five patients discontinued 6-MP, four for gastrointestinal side effects, and one for leukopaenia. Recently, preliminary data from an additional multicentre retrospective series of 17 patients, all azathioprine-intolerant, reported complete biochemical response in 11 of the 12 patients followed-up for at least 12 mo[168]. These data suggest that 6-MP can be an alternative for patients intolerant to azathioprine, but the available data are insufficient to formulate recommendations.

Allopurinol: Azathioprine hepatotoxicity can be due to a skewed metabolism of the drug, leading to a preferential generation of the hepatotoxic metabolite 6-methylmercaptopurine (6-MMP) instead of the metabolic active 6-thioguanine nucleotides (6-TGN). Allopurinol co-administration redirects the thiopurine metabolism towards 6-TGN. This strategy is used in the treatment of IBD. A case report suggests that allopurinol can be helpful also in AIH[169] (Table 3). A retrospective case-series of 8 AIH adult patients intolerant or with insufficient response either to azathioprine/prednisone (4/8) or 6-MP/prednisone (4/8), one patient in each group being also on budesonide, reported complete biochemical remission in 3/3 intolerant patients and in 4/5 unresponsive patients[170] (Table 3). All patients had skewed thiopurine metabolism. In one further case report of a patient with insufficient response to prednisone/

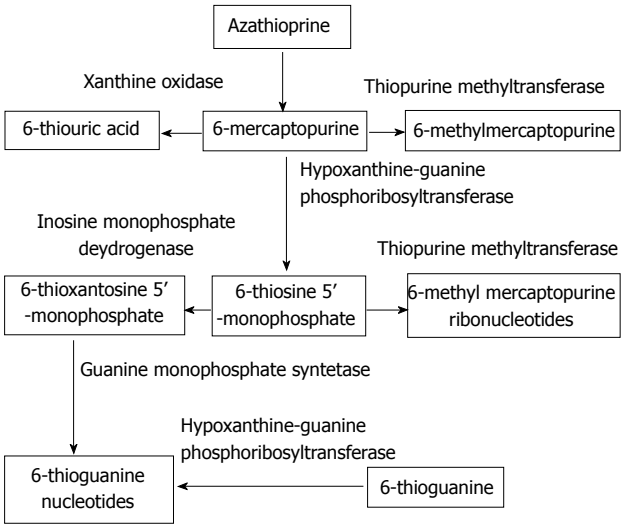

Figure 2 Simplified representation of the thiopurine metabolism. Azathioprine is non-enzymatically converted to 6-mercaptopurine, which is competitively converted into 6-methymercaptopurine, 6-thiouric acid and 6-thiosine 5'-monophosphate by different enzymes. The latter metabolite is further transformed into the metabolic active 6-thioguanine nucleotides.

azathioprine and shunted metabolism, allopurinol (100 mg/d) allowed rapid normalisation of transaminase levels and steroid reduction[171] (Table 3).

6-thioguanine: 6-thioguanine (6-TG) is enzymatically converted into 6-TGN, which are the active metabolites of azathioprine, bypassing the metabolic steps leading to the formation of the hepatotoxic metabolite 6-MMP (Figure 2). 6-TG is approved for the treatment of acute and chronic myeloid leukaemia, and chronic lymphatic leukaemia. It is used in IBD patients with insufficient response or intolerant to azathioprine or 6-MP[172]. Safety issues have been raised, particularly in respect to the development of nodular regenerative hyperplasia and sinusoidal obstruction syndrome[172]. In AIH, after an early preliminary report[173], a retrospective series of 12 adult patients switched from azathioprine or 6-MP to 6-TG for intolerance or insufficient response reported a median alanine aminotransferase levels drop from 81 IU/L to 30 IU/L (Table 3). Nodular regenerative hyperplasia developed in one case after 8 years of 6-TG treatment[174].

Due to the paucity of data and its potential hepatotoxicity, 6-TG cannot be recommended in AIH.

TREATMENTS UNDER INVESTIGATION

New compounds are currently under investigation in AIH. Preliminary results of a phase 1, first-in-human trial of preimplantation factor in AIH demonstrated good safety and tolerability, but a non-significant decrease in mean transaminase levels[175]. Other investigational drugs in AIH include VAY736, which leads to B-cell depletion and B-cell activating factor receptor blockade (NCT03217422), JKB-122, which is a toll-like receptor 4 antagonist (NCT02556372) and low dose interleukin 2 (NCT01988506).

CONCLUSION

The pharmacological treatment of AIH should be personalized, because of the heterogeneity of the disease. Treatment schedules in children differ, because of the more aggressive disease course in this age group. Standard treatment, based on steroids and azathioprine, is effective in the vast majority of patients, and side-effects can be minimised by rapid prednisone tapering. Budesonide was tried as first-line treatment in an attempt to reduce steroids side-effects, but the results of a randomized controlled trial do not allow to universally recommending it as first-line treatment instead of prednisone. A minority of patients prove difficult-to-treat, either because of severe side effects from standard treatment, or resistant disease. Mycophenolate mofetil is the most widely used second-line drug, and also the drug with the highest amount of available data. Calcineurin inhibitors are alternative options, but data on their efficacy are scanty. Infliximab and rituximab may represent an additional treatment option for selected difficult-to treat cases, but their use should be restricted to specialised centres because of potentially severe side effects. New pharmaceutical treatments are currently under investigation.

Abstract

Colorectal cancer (CRC) is a common health problem, representing the third most commonly diagnosed cancer worldwide and causing a significant burden in terms of morbidity and mortality, with annual deaths estimated at 700000. The western way of life, that is being rapidly adopted in many regions of the world, is a well discussed risk factor for CRC and could be targeted in terms of primary prevention. Furthermore, the relatively slow development of this cancer permits drastic reduction of incidence and mortality through secondary prevention. These facts underlie primary care physicians (PCPs) being assigned a key role in health strategies that enhance prevention and prompt diagnosis. Herein, we review the main topics of CRC in the current literature, in order to better understand its pathogenesis, risk and protective factors, as well as screening techniques. Furthermore, we discuss preventive and screening policies to combat CRC and the crucial role served by PCPs in their successful implementation. Relevant articles were identified through electronic searches of MEDLINE and through manual searches of reference lists.

Key words: Colorectal cancer; Prevention; Diagnosis; Screening; Primary care

Core tip: Colorectal cancer (CRC) is a common health problem, causing a significant burden in terms of morbidity and mortality. However, if detected early, the disease is highly curable. Primary care physicians are therefore in a unique position to enhance prevention and prompt diagnosis. The purpose of this paper was to

review the main topics of CRC in the current literature to provide a more comprehensive understanding of its pathogenesis, risk and protective factors, as well as screening techniques.

Hadjipetrou A, Anyfantakis D, Galanakis CG, Kastanakis M, Kastanakis S. Colorectal cancer, screening and primary care: A mini literature review. *World J Gastroenterol* 2017; 23(33): 6049-6058 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6049.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6049

INTRODUCTION

Colorectal cancer (CRC) is a global health burden, accounting for almost 700000 deaths per year worldwide[1]. CRC is the third most commonly diagnosed cancer worldwide and second in Europe[1]. According to the World Health Organization GLOBOCAN database, in 2012, almost 1.4 million new cases of CRC were diagnosed and almost 700000 deaths occurred worldwide[1].

CRC global incidence and mortality rates appear to be substantially higher for males than for females, with 21 new cases and 10.5 deaths per 100000 population compared to 17.6 new cases and 9.2 deaths respectively. In males, CRC ranks third in incidence, following lung and prostate cancers, and in females it ranks second, following breast cancer[1,2].

There is an over 10-fold geographical variation of CRC incidence throughout the world[3]. The highest incidence rates are observed in Australia and New Zealand, with the estimated age-standardized rates being 44.8 per 100000 population in men and 32.2 in women; Europe and North America follow close behind. The lowest incidence is observed in Africa, with the rates in Western Africa being only 3.5 per 100000 in men and 3.0 in women[1,3,4].

Incidence trends reported for the past few decades have revealed very interesting findings. In the United States, overall CRC incidence has been declining since the mid-80s, right about the time that CRC screening was introduced[5-7]. In Europe, incidence trend patterns show great diversity among countries, mainly due to differences in screening policies and prevalence lifestyle risk factors between countries. The largest increase in incidence was observed in Central-Eastern Europe over the past few decades[8-12].

CRC incidence increases with age, and cases are fairly uncommon before the 4th decade of life[1,3]. This is the reason why most screening programs are targeted to people over 50 years old. Nevertheless, recent studies have revealed an alarming increase in incidence between the ages 40 to 44, prompting consideration of lowering the recommended screening age[13,14].

Mortality rates have progressively declined in most economically developed countries, in contrast with poorer regions of the world, where mortality is either stable or increasing[1,11]. This reflects the diversity in screening services accessibility, specialized care and lifestyle risk factors[11]. The highest reported mortality rates are in Central-Eastern Europe, although the highest incidence to mortality ratio is observed in Middle-Western Africa[1,15].

In this paper, we aimed to perform a narrative literature review and compile all of the up-to-date knowledge on the current CRC medical literature. Our main objective was to summarize all the available information and provide gastroenterologists and primary care physicians (PCPs) with a comprehensive background for a better understanding of the current evidence.

SEARCH STRATEGY

We conducted a literature search in the PubMed database, with publication date limited to between January 1996 and August 2016, using the following Medical Subject Heading (commonly known as MeSH) terms: "colorectal neoplasms", "diagnosis", "early detection of cancer", "primary health care". The search was limited to English language. Editorials, Letters to the Editor and Case Reports were excluded. Inclusion criteria for papers were CRC topics in prevention, screening, detection and diagnostics, as well as follow-up in primary care. The titles and abstracts of all papers identified by the electronic search were manually assessed by two researchers working independently (AH, DA). Disagreements between the two reviewers were infrequent and resolved by consensus or arbitration of a third reviewer (MK).

Full texts of the articles that were considered eligible for inclusion were also scrutinized in order to offer a better approach on CRC issues related to pathogenesis, screening, diagnosis and management, as were articles related to early detection in the primary care setting.

A total of 159 studies were identified and assessed for eligibility. Among them, 7 overlapped and were excluded. Four articles were also excluded due to topical relevance to other types of cancer. Finally, 148 articles were assessed in detail for study inclusion. From these, 42 were excluded for not meeting the inclusion criteria. Figure 1 summarizes the process of identification and selection of studies.

PATHOGENESIS

The Adenoma-Carcinoma pathogenesis model is what gives endoscopic methods of screening the benefit of not only reducing mortality but also reducing incidence of CRC through early recognition and removal of adenomatous polyps from the colon[16]. The Adenoma-Carcinoma sequence applies to most CRCs and involves a sequential progression that takes, on average, a decade to occur. Many of the adenomas begin as small polyps that enlarge and become

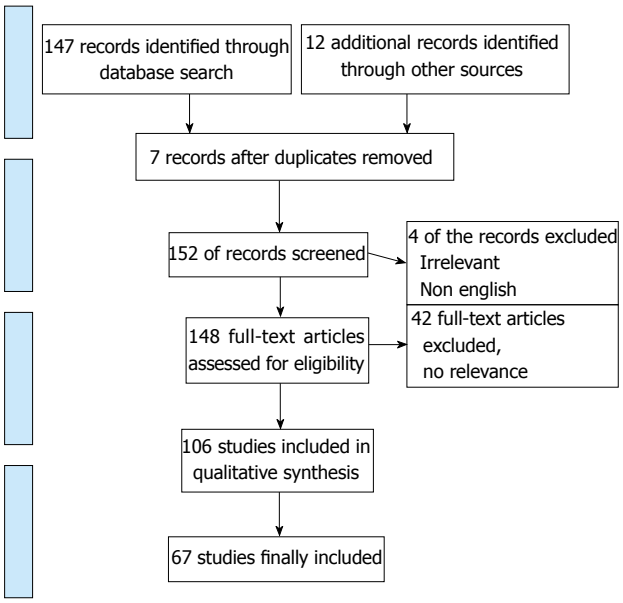

Figure 1 Study selection based on prisma diagram[112].

dysplastic and eventually cancerous[17-19]. Other CRCs may develop from non-polypoid adenomas, that are, by definition, more difficult to detect[20]. Nevertheless, there have been studies that suggest alternative developmental pathways to CRC, other than the traditional aforementioned model[21-23].

RISK FACTORS

The probability for developing CRC can be increased by both genetic and acquired/environmental factors. Although the impact of genetic susceptibility in an individual is much greater than the impact of acquired factors, the vast majority of CRC cases could be prevented through modifications in environmental factors[24-26]. A constructive way of classifying CRC risk factors is separating those that affect screening recommendations from those that do not. Hereditary syndromes, family history and inflammatory bowel diseases are the main risk factors that affect recommendations for screening[27]. In practice, risk factors that do not affect screening are the target of primary prevention strategies[24].

Hereditary colorectal syndromes comprise numerous specific genetic disorders that are associated with the development of CRC, altogether accounting for about 10% of CRC cases. The most common form is hereditary non-polyposis CRC, which reportedly accounts for only 2%-5% of CRC cases[28,29]. Family history, in addition to the genetic syndromes thus far known, constitutes a very significant risk factor for developing CRC, which appears to account for up to 25% of cases[28]. Although the mechanisms underlying this observation are not completely understood, studies have shown that individuals having first-degree family members diagnosed with CRC are at 2-3 times greater risk of developing CRC than the general population[28-31].

Although CRC, compared to other common cancers, includes a large percentage of hereditary cases, the vast majority of cases are sporadic, accounting for up to 70%[28]. The risk factors implicated in the mechanisms of sporadic disease are mainly environmental/acquired. Western lifestyle, cigarette smoking, alcohol intake, obesity and certain dietary habits are amongst the risk factors associated with increased risk for CRC[24,25,32-34].

PRIMARY PREVENTION

As expected, an important role in the etiology of CRC is attributed to lifestyle factors, since, as aforementioned, the majority of CRC cases are not associated with hereditary/familial factors[24,25,35]. Western lifestyle is a well-discussed risk factor for CRC, as it was readily observable by researchers that CRC incidence was consistently higher in industrialized countries[35]. This observation was further supported by the growing incidence in poorer regions as they adopted the western way of living[24,36].

Diet has been a popular subject of CRC research over the past few decades, both for its potential as a risk factor and as a protective factor. A number of researchers have argued the protective role of a diet high in fiber, with some studies showing a reduction in CRC incidence up to 50%[35,37-39]. Nevertheless, many recent reports have raised doubts about this argument, leaving the question of how protective dietary fibers really are, open for future prospective studies to answer[40,41]. Many authors have also asserted a protective role for calcium and vitamin D, as well as for other less verified dietary factors such as folate, vitamin B6, magnesium, garlic and omega 3 fatty acids[42-46]. On the other hand, frequent consumption of red meat and fat has been associated with increased risk for development of CRC[47-49].

Obesity has been consistently associated with increased risk for developing CRC, as well as with poorer outcomes following diagnosis[50-52]. In fact, a review of 29 studies reported that each 5 kg/m^2 incremental increase in body mass index is accompanied by CRC incidence increase of 24% in men and 9% in women[50]. In association with a healthy body weight, regular physical activity has been shown to reduce CRC incidence even more, with studies reporting up to 20%-30% lower risk[53,54].

Alcohol consumption as a risk factor for CRC has been a controversial subject, especially when referring to light and moderate consumption, but studies have consistently reported a higher risk for developing CRC among individuals with moderate to heavy consumption[55]. Tobacco smoking has been shown to double the risk of being diagnosed with a colon adenoma and to result to poorer outcomes following a cancer diagnosis, leading authors to recommend more intensive screening among smokers[24,56].

Although no accepted chemopreventive indications exist currently, many pharmaceutical agents have

shown preventive effects against CRC. Aspirin and COX-2 selective inhibitors are among the most investigated agents in regards to CRC prevention, and their regular use has shown ability to reduce incidence in individuals at both average and increased risk[57,58]. In the general population, the risks from their use seem to outweigh the benefits, but many advocate their use in certain individuals at increased risk for colorectal neoplasia[59].

SCREENING/SECONDARY PREVENTION

The fact that most CRCs take years to develop - following the Adenoma - Carcinoma sequence - permits the reduction of CRC mortality through screening, either by early detection and removal of the cancer or by detecting and removing the precancerous lesions[17-19].

There are roughly three categories of screening tests for CRC: stool-based, imaging, and endoscopic tests. Although stool-based tests can reduce mortality rates by early detection of asymptomatic cancerous lesions, imaging and endoscopic tests are capable of further reducing CRC incidence by detecting pre-cancerous lesions as well[16].

STOOL-BASED TESTS

Guaiac-based fecal occult blood test

Relying on the properties of alpha-guaiaconic acid, a phenolic compound extracted from Guaiacum trees, guaiac-based fecal occult blood test (gFOBT) can detect the presence of heme (of blood hemoglobin) in stool samples. Application of hydrogen peroxide onto guaiac paper causes alpha-guaiaconic acid to oxidize and turn blue. This reaction normally takes time, but heme (if present) catalyzes the reaction and within seconds a blue color change is visible[60-62]. This bioreactive method was proposed as a screening test for CRC almost half a century ago and has become the most frequently used screen for CRC worldwide[61].

While the gFOBT is cost affordable and non-invasive, it unfortunately bears many disadvantages. The interpretation of the result is subject to observer bias. Also, the reaction can be catalyzed by any peroxidase, such as heme found in meat, and false-positive results can lead to unnecessary colonoscopies; although, strict dietary restrictions that were proposed in the past seem to now be proven unnecessary[60,63]. False-negative results, on the other hand, can occur from ingestion of large doses of ascorbic acid (vitamin C)[64]. Aside from the dietary restrictions related to preparation for the gFOBT, the patient needs to provide three consecutive stool samples in order to achieve adequate sensitivity for occult blood[65]. The reported sensitivity and specificity vary between studies and different manufacturer brands, and efforts to introduce new, more sensitive guaiac-based tests resulted in lower specificity[66]. Finally, this test cannot detect polyps, since they do not bleed, and its sensitivity for advanced adenoma is relatively low[67].

Fecal immunochemical test

Fecal immunochemical test (FIT) detects blood in stool by using a specific antibody against human hemoglobin. As such, FIT is not affected by diet or observer bias, giving it a greater specificity than gFOBT. Besides specificity, however, its sensitivity for both cancer and adenomas has been shown to be superior to that of gFOBT[68,69]. According to a recent meta-analysis, the mean reported sensitivity and specificity for FIT detection of CRC is 79% and 94% respectively[70]. In addition, FIT requires fewer samples than gFOBT, making it more convenient for patients and thus increasing compliance[71]. Quantitative results can be provided with this method as well, facilitating the ability to determine positive cut-off points for different populations, patient characteristics, or system capabilities and resources[72].

In summary, stool-based tests are non-invasive and inexpensive methods capable of detecting occult bleeding. However, they are practically incapable of detecting polyps, since the latter do not usually bleed, and they have low sensitivity for detecting adenomas. Consequently, their role in reducing CRC incidence is close to none, but their implementation as a screening tool can reduce CRC mortality by providing early recognition of cancerous lesions. Comparing the two methods, FIT appears superior in terms of sensitivity and specificity (for both CRC and adenomas) and in terms of patient compliance. It is reasonable then to expect that, although more expensive, FIT could be more cost-effective than gFOBT since it could prompt less unnecessary colonoscopies.

IMAGING TESTS

Double-contrast barium enema

In double-contrast barium enema (DCBE), the colon is studied through X-rays obtained after coating the mucosa with barium and distending the colon with air, both of which are inserted transrectal. The DCBE is considered a safe method and has been used frequently in the past, but its use has been dramatically reduced as novel imaging methods become available. The reported sensitivity of DCBE for large polyps (> 10 mm) is only about 50%, and false positive results can occur due to inadequate bowel preparation[73,74].

Computed tomographic colonography

This method was first described more than 20 years ago, and provides 2- and 3-dimensional endoluminal images of the colon upon reconstructing of computed tomography or magnetic resonance images of the air-

distended colon[75,76]. The reported diagnostic value of computed tomographic colonography (CTC) has varied between studies, but as newer techniques of CTC are developed it is closing in on colonoscopy in terms of sensitivity and specificity for detecting CRC[77]. In a recent meta-analysis, the overall sensitivity and specificity of CTC was 66.8% and 80.3% respectively, both lower than the values for colonoscopy. For polyps > 10 mm though, the meta-analysis showed greater sensitivity and specificity (91.2% and 87.3% respectively)[78].

CTC appears to be more preferred by patients than colonoscopy; in addition, it has a very low risk of bowel perforation and requires no sedation[79,80]. On the other hand, CTC requires follow-up colonoscopy after positive results (to perform excision/biopsy), exposes the patient to radiation, and the lack of standardized methods leads to variable diagnostic performance[77,78]. The need for aggressive bowel preparation has been an issue, but newer techniques have been reported involving laxative-free CTC using "fecal tagging" with an ingested contrast agent[81]. Many authors include in CTC's advantages the potential of discovering extra-colonic pathology in asymptomatic patients, but this argument is controversial since these findings can sometimes lead to unnecessary patient anxiety, costly investigations and overdiagnosis[82-83].

Colon capsule endoscopy

The colon capsule endoscopy (CCE) method for CRC screening was initially introduced in 2006, and roughly consists of swallowing a pill-shaped device which is capable of photographing the gastrointestinal tract as it passes through it[84]. Initially, CCE did not gain significant acceptance as a screening tool for CRC, mainly because of its cost and relatively low diagnostic value compared to colonoscopy[85]. After introduction of the second-generation CCE (CCE-2) in 2009, the subject of CCE has become very popular in the medical literature[86]. The reported average sensitivity and specificity for the CCE-2 is 86% and 71% respectively, and since 2012 it has been prompted as an acceptable screening method for CRC by the European Society of Gastrointestinal Endoscopy[87]. Compared to colonoscopy, CCE might be a lot more preferable for the patient, but it is more expensive, lacks excision/biopsy ability and requires very aggressive bowel preparation[87,88].

ENDOSCOPIC TESTS

Flexible sigmoidoscopy

Flexible sigmoidoscopy (FS) enables the trained physician to visualize the distal gastrointestinal tract up to the splenic flexure, using a flexible, 60 cm long endoscope[89]. FS requires only minimal bowel preparation, no diet restrictions and no sedation, and can be performed by non-gastroenterologists (*e.g.,* PCPs) or even trained nurses[89-91]. Obviously, FS is unable to detect lesions in the proximal colon, which makes it lacking in sensitivity compared to colonoscopy[90]. In a meta-analysis, FS appeared to reduce CRC incidence and mortality among screened patients, by 32% and 50% respectively[92].

Colonoscopy

The traditional method of colonoscopy provides visualization of the entire large bowel and the distal part of the small bowel by using a flexible, 120-cm to 160-cm long endoscope[93]. It is considered by most the 'gold standard' in CRC screening, mainly because of its high sensitivity and specificity for detecting cancerous and precancerous lesions. It also provides the ability to excise or biopsy detected lesions during the same procedure[6,13,77,90]. Unfortunately, it is also an expensive method and not free of risk; it also requires sedation and extensive bowel preparation. The reported rate of major complications, such as bleeding or bowel perforation, is approximately 0.1%-0.2%, but could become significantly higher when excisions or biopsies are performed and in elderly or comorbid patients[93].

PREVENTION: SCREENING IMPLEMENTATION AND THE ROLE OF PCPS

It is beyond doubt that the burden of CRC can be significantly reduced through primary and secondary prevention. Scientific research over the past few decades has offered, as aforementioned, a variety of options for CRC screening and a better understanding of risk and protective factors for the development of CRC. Unfortunately, underutilization of screening and a lack in preventive policies are being reported[94-98].

Some European countries still have not implemented national mass screening programs, and others that did have reported low participation rates[97,98]. In the United States, there has been a significant decrease in incidence and mortality following widespread implementation of screening, but the overall use of screening is still below national standards[94]. Additionally, it has been reported that uninsured people in the United States and people of low socioeconomic or educational status show much lower participation rates[99].

Many researchers have attempted to identify the causes of CRC screening underutilization and ways to enhance it. While the barriers and sites of potential improvement have been identified at the levels of the health care system and the patient, most of the authors have advocated for the key role of PCPs.

Patients, in many studies, have shown low awareness concerning CRC screening and its importance. In one particularly insightful study, by Aubin-Auger *et al*[97], some patients showed low interest in CRC

screening, while others expressed the belief that CRC screening concerns only high-risk individuals or individuals that do not follow a healthy lifestyle. In a systematic review by Holden *et al*[100], the authors found that most patients not being screened state their reason as "not thinking about it". Strongly indicative of how important public awareness is for CRC screening participation was the "Presidential Effect", a term given to describe the increase in CRC screening participation of United States' citizens after the nation's President, Ronald Reagan, was diagnosed with colon cancer in 1985[101]. Similar reports of the impact of public figure announcements on cancer have been made, but data show that information given occasionally and in an unorganized manner often leads to short term results and mis- or overutilization of screening services[102,103].

At the level of health care systems, barriers and possibilities for enhancing CRC screening participation are more obvious. Several studies have revealed the efficacy of organized mass screening programs, especially when using patient reminders[100,104-107]. Participation rate has also appeared to be further enhanced when PCPs are involved in the invitation process[104,105]. Findings from studies have also led to authors advocating in favor of informational campaigns that increase public awareness of screening[108]. Another interesting finding in the literature is that patients with "usual source of care" are more likely to be screened for CRC[100]. This further highlights the importance of PCPs and family physicians in modern health care systems.

Research has also indicated barriers at the level of PCPs, with troubling findings in some cases. Screening recommendation rates by PCPs seem to remain low[100,109]. Several PCPs in surveys have reported a lack of knowledge and training, and some have even reported not finding screening to be effective[97,98,109,110]. The major role of PCPs in the effort to decrease CRC incidence and enhance screening participation has become more than obvious. PCPs constitute the first level of contact in a national health system for individual patients and their families. Their role in preventive medicine, through interventions in lifestyle habits, can effectively reduce CRC incidence, as well as that for other diseases. The unique patient-physician relationship in primary health care, in terms of trust and continuity of care, can effectively contribute to patient compliance, as clearly demonstrated throughout the literature.

Interventions through health care system organization, education of PCPs on CRC screening, prevention and counseling techniques, and in public awareness will, therefore, drastically decrease the burden of CRC[111].

CONCLUSION

Despite the significant improvements in screening techniques and our understanding of risk and protective factors, CRC remains a major global health burden. PCPs face a unique challenge in their capabilities and efforts to alter this phenomenon; their role in implementing screening and preventive policies is key to reducing the burden of CRC.

Abstract

Behavioral gastroenterology is a new interdisciplinary science that explores the influence of unhealthy lifestyles and psychological factors on the digestive system and addresses the prevention, diagnosis, treatment, and rehabilitation of digestive diseases. Moreover, the concept of whole-course intervention with a focus on disease prevention and a new model of integrated therapy based on alterations of lifestyle and psychology are being gradually established. This paradigm may substantively impact the prevention and treatment of digestive diseases.

Key words: Behavioral gastroenterology; Lifestyle; Psychological factors

Core tip: As a new interdisciplinary subject, behavioral gastroenterology shows a new concept of whole-course intervention with a focus on disease prevention and a new pattern of integrated therapy based on lifestyle and psychosocial adjustments. It will help both clinicians and patients to alter the old idea of focusing on traditional drugs or surgery, and this new paradigm is expected to become gastroenterology's new frontier of action.

INTRODUCTION

Behavioral medicine, a phrase first coined at the Yale meeting in 1977, has been developing rapidly. In 2003, the new discipline of behavioral cardiology took a broad view, concluding that heart disease is not inevitable but rather may develop largely from psychosocial stress and unhealthy lifestyles such as smoking, overeating, and physical inactivity[1]. Likewise, the effects of psychological-behavioral factors and unhealthy lifestyles on digestive diseases are no less impactful than those of traditional risk factors. Thus, by combining behavioral medicine and gastroenterology, a new pattern of psychological-behavioral treatment for gastroenterological patients has gradually emerged.

Based on the research that has integrated both traditional Chinese medicine and modern medicine, we established a behavioral gastroenterological group in the behavioral-psychosomatic medicine branch of the Guangdong Medical Association in 2012. The new concept of behavioral gastroenterology was first proposed in 2013. As an emerging field of clinical practice and an important part of behavioral medicine, behavioral gastroenterology comprehensively explores unhealthy lifestyles and behavioral-psychological factors that can affect the digestive system. This new discipline also addresses the prevention, diagnosis, and treatment of digestive diseases and rehabilitation of patients. Furthermore, a new concept of whole-course intervention with a focus on disease prevention and a new pattern of integrated therapy based on lifestyle/psychosocial adjustments have gradually been established. It is believed that both lifestyle and psychosocial factors can be improved by behavior modification, during which the patient and the practitioner work together.

BEHAVIORAL FACTORS AND DIGESTIVE DISEASES

Traditional Chinese medicine attaches great importance to lifestyle such as diet and daily routine, which are closely related to health and longevity. Similarly, modern medical research has also demonstrated that the onset of many digestive diseases is closely related to deviations in diet, sleep habits, work shifts, and poor lifestyle choices such as excessive alcohol consumption and tobacco use.

Dietary behavior

Certain types of foods are closely associated with symptoms of gastrointestinal diseases. For example, coffee, black pepper, chocolate, and onions often cause epigastric burning and heartburn, milk and dairy products, beans, bananas, and carbonated drinks often produce gas, and fresh meat, fried foods, wheat, manufactured goods, cakes, sweets, chocolate, citrus fruits, beans, and onions often can cause early satiety. Wheat (93.33%), milk and manufactured goods containing milk products (83.33%), turnip (71.67%), bacon (55%), banana (53.33%), and onion (46.67%) often lead to intestinal smooth-muscle dysfunction, which constitutes a type of functional dyspepsia (FD)[2]. Additionally, food consumption plays a key role in irritable bowel syndrome (IBS): more than 60% of IBS patients report the onset or worsening of symptoms after meals - within 15 min for 28% of patients, and within 3 h for 93% of patients[3]. Most IBS patients (84%) report meal-related symptoms as a reaction to at least one specific food, such as milk and dairy products, beans, or apples[4,5].

Eating behavior is also associated with digestive diseases. Gastroesophageal reflux disease (GERD) correlates with eating greasy or spicy food or drinking carbonated beverages[6]. Patients with nonalcoholic fatty liver disease often consume high-energy foods and carbohydrates but ingest fewer foods rich in polyunsaturated fatty acids, vitamins, and minerals[7]. Consumption of certain foods is closely correlated with digestive diseases. Long-term intake of hot foods and beverages positively correlates with the incidence of esophageal cancer[8]. Fast intake (12 min or less) has been reported by about 40% of FD patients but in only 17% of healthy people. Compared with nonspecific FD, significant differences in the frequency of meal skipping and fast intake have been reported by patients with dismotility-like FD and ulcer-like FD[2]. A large-sample multicenter study in China found that refractory FD patients often have unhealthy eating habits such as skipping meals, eating extra meals, or a preference for sweet food and gas-producing food[9].

Exercise behavior

A sedentary lifestyle is a risk factor for constipation and nonalcoholic fatty liver disease[10-11]. Tuteja *et al*[12] reported that exercise does not affect symptoms such as constipation but can improve patients' quality of life. A meta-analysis revealed that physical exercise can reduce the risk of the occurrence of esophageal cancer, especially adenocarcinoma[13].

Sleep behavior

GERD patients often report poor sleep quality[14]. Fass *et al*[15] reported that 50.2% of 505 IBS patients suffer sleep disorders such as easy wakening during nighttime sleep or fatigue in the morning. Their study also found that poor sleep quality decreases the threshold of visceral pain and that sleep disorders can induce and aggravate the symptoms of IBS. Sleep disorders have also been reported to be associated with the severity of symptoms and the comorbidity of anxiety for FD patients[16].

Work behavior

A study found that working a rotating shift can

significantly increase the risk of gastrointestinal disorders and peptic ulcers[17]. Nojkov *et al*[18] reported that the incidence of IBS is 48% for nurses with rotating shifts and 31% for nurses with strictly daytime work, and the probability of functional abdominal pain was 81% for nurses with rotating shifts, 54% for those with day shifts, and 61% for those with night shifts. Sleep quality is closely associated with IBS and the incidence of abdominal pain, which might be related to disruption of the circadian rhythm caused by rotating shifts.

Smoking and drinking habits

A large population-based study from developing countries indicated that smoking is not associated with GERD or epidemiologic FD; however, smoking is significantly associated with clinical FD, postprandial fullness, and epigastric pain[19]. Lunney PC *et al*[20] found that the condition of patients with Crohn's disease can be worsened by smoking, and those investigators recommended that such patients quit smoking. In addition, long-term consumption of alcoholic beverages can induce lesions of the liver or pancreas, and alcohol directly damages the mucosa of the esophagus and stomach, modifies the sphincter pressure, impairs gastrointestinal mobility, and alters gastric acid output[21].

PSYCHOLOGICAL FACTORS AND DIGESTIVE DISEASES

Psychological factors have received attention with respect to the occurrence and development of digestive diseases. A variety of psychological anomalies can be found in FD or IBS patients, especially those involving symptoms of anxiety and depression[22]. A series of refractory functional gastrointestinal disease studies by our groups in recent years revealed that the incidence of anxiety and depression are 61.5% and 63.3%, respectively, for refractory FD patients, and the severity of anxiety and depression is greater than for non-refractory FD patients[23]. Moreover, of 1057 patients, the incidence of anxiety and depression for FD patients with weight loss was 56.04% and 59.90%, respectively, and a higher incidence of anxiety and depression was found for patients of group A (lost $\geqslant$ 5% of initial body weight) than for those of group B (lost < 5% of initial body weight)[24]. Cruz Ruíz *et al*[25] reported that 58% of 100 IBS patients suffered anxiety, whereas 62% of those patients suffered depression, and female patients accounted for more than half. The incidence of symptoms of depression and anxiety was 66.2% and 65.5%, respectively, for the refractory IBS group, which was greater than that for the non-refractory IBS and control groups[26]. Similarly, a significantly higher percentage of refractory globus patients have anxiety and depression compared with non-refractory globus patients. And the prevalence of moderate-to-severe anxiety and depression was higher for the refractory globus group than for the non-refractory globus group[27].

A study from Zhou *et al*[28] revealed that functional constipation patients have higher scores for depression and anxiety, and the anorectal squeezing pressure is negatively correlated with these scores; these results indicate that depression and anxiety may contribute to functional constipation. GERD patients are more likely to have emotions such as anxiety, depression, and pessimism than the general population, and such psychological disorders may make people vulnerable to GERD[29].

BEHAVIORAL AND PSYCHOLOGICAL INTERVENTION

Behavioral gastroenterology advocates a new pattern of integrated therapy involving the adjustment of unhealthy lifestyles and psychological problems. This strategy is a shift from the former paradigm, which ascribed greater importance to the treatment of severe digestive diseases and complications. Furthermore, a series of effective behavioral and psychological interventions have been gradually established.

Dietary behavior intervention

Intermittent fasting is an internationally popular diet method that is effective for the control of body weight and the improvement of metabolic syndrome. Intermittent fasting generally entails normal intake for 5 d a week, but intake of a quarter of the normal calories for the other 2 d (usually 500 calories for females, 600 calories for males). A multicenter and large sample research demonstrated that patient body weight was reduced by 4.3 kg on average after 6 wk of intermittent fasting[30]. Halberg *et al*[31] found that healthy people who underwent 2 wk of intermittent fasting exhibited no obvious body weight loss, but they did show improved insulin sensitivity - that is, the capacity for glucose storage and fat decomposition was increased. This result may be the key to improving metabolic syndrome.

A diet low in fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAP) (Table 1) has been used recently for the management of functional gastrointestinal symptoms for IBS patients. Eswaran *et al*[32] showed that the low FODMAP diet led to a significant improvement in IBS symptoms, particularly pain and bloating. Staudacher *et al*[33] reported that more patients in the low FODMAP group expressed satisfaction with their symptom response (76%) compared with the standard-diet group (54%).

Intake control has received increasing attention, and intake reduction has been adopted by the majority of people. The strategy of "eating until you are 60% full", which was reported by the Healthy Aging Research Center of the University of London, was

Table 1 FODMAP food list

Food category	Low FODMAP food (things good to intake)	High FODMAP food (things to avoid/reduce)
Vegetables and Legumes	Alfalfa, Bean sprouts, Brussel sprouts, Butternut squash, Callaloo, Carrots, Celery, Chick peas, Chilli, Chives, Cho cho, Choy sum, Collard greens, Corn, Cucumber, Fennel, Green beans, Green pepper, Ginger, Leek leaves, Lentils	Garlic, Onions, Artichoke, Asparagus, Baked beans, Beetroot, Black beans, Cassava, Cauliflower, Falafel, Leek bulb, Mange Tout, Mixed vegetables, Mushrooms, Peas, sugar snap, Savoy Cabbage, Shallots, Taro
Fruit	Ackee, Bananas, Bilberries, Blueberries, Breadfruit, Cranberry, Clementine, Dragon fruit, Grapes, Kiwifruit, Lime, Mandarin, Orange, Passion fruit, Paw paw, Papaya, Pineapple, Plantain, peeled, Raspberry, Strawberry, Tamarind, Tangelo	Apples, Apricots, Avocado, Blackberries, Blackcurrants, Cherries, Currants, Dates, Goji berries, Grapefruit, Lychee, Mango, Peaches, Pears, Pineapple, Plums, Prunes, Sultanas, Tamarillo, Watermelon
Meats, Poultry, and Meat substitutes	Beef, Chicken, Kangaroo, Lamb, Pork, Prosciutto, Quorn, mince, Turkey, Cold cuts/deli meat/cold meats	Chorizo, Sausages, Processed meat - check ingredients
Fish and seafood	Canned tuna, Fresh fish (*e.g.*, Cod, Haddock, Plaice, Salmon, Trout, Tuna), Seafood (*e.g.*, Crab, Lobster, Mussels, Oysters, Prawns, Shrimp)	–
Cereals, Grains, Breads, Biscuits, Pasta, Nuts, and Cakes	Wheat free breads, Gluten free breads, Almonds, Biscuit, savoury, Biscuit, shortbread, Brazil nuts, Bulgur, Buckwheat, Brown rice, Chestnuts, Cornflour, Polenta, Popcorn, Potato flour, Pretzels, Quinoa, Rice, Sorghum, Walnuts	Wheat containing products, Almond meal, Amaranth flour, Barley including flour, Bran cereals, Bread, Cashews, Cous cous, Einkorn flour, Freekeh, Gnocchi, Muesli bar, Pistachios, Rye, Rye crispbread, Semolina, Spelt flour
Condiments, Dips, Sweets, Sweeteners, and Spreads	Aspartame, Acesulfame K, Barbecue sauce, Capers in vinegar, Capers, salted, Chocolate, Garlic infused oil, Golden syrup, Glucose, Marmalade, Marmite, Soy sauce, Stevia, Sweet and sour sauce, Sucralose, Sugar, Vegemite, Vinegars	Agave, Caviar dip, Fructose, Fruit bar, Hummus, Honey, Jam mixed berries/strawberry, Pesto sauce, Quince paste, Relish /vegetable pickle, Stock cubes, Sugar free sweets containing polyols, Sweeteners, Tahini paste, Tzatziki dip
Drinks and protein Powders	Drinking chocolate powder, Espresso, regular, black, Fruit juice (125 mL and safe fruits only), Malted chocolate powder, Tea (Chai tea weak, Green tea, Peppermint tea, White tea), Water	Beer, Coconut water, Cordial, Fruit juices made of apple, pear, mango and Orange, Rum, Sodas containing High Fructose Corn Syrup (HFCS), Soy milk, Sports drinks, Wine
Dairy foods	Butter, Dairy free chocolate pudding, Eggs, Margarine, Soy protein, Tempeh, Tofu, Whipped cream, Yoghurt with lactose free	Buttermilk, Cheese, Cream, Custard, Gelato, Ice cream, Kefir, Milk, Sour cream, Yoghurt

observed to extend the average lifespan of mice for five or six months - that is, it prolonged life by 30%. This would correspond to 20 years in humans.

Exercise behavior intervention

De Schryver *et al*[34] found that regular physical activity (including 30 min of brisk walking and 11 min a day family project) could significantly improve defecation problems (*e.g.,* overly frequent defecation, laborious defecation, and hard stools) caused by a lack of activity in middle-aged patients with chronic idiopathic constipation and significantly shorten the transit time in the sigmoid colon and rectum colon.

In addition, the results from Matsuzaki *et al*[35] revealed that the intensity of regular exercise is independently associated with gastric emptying in healthy individuals, and gastric emptying was significantly faster in the low-intensity exercise group than in the moderate-intensity exercise group. It is trusted to be an optimal exercise intervention for the treatment of FD.

Life behavior intervention

Nowak *et al*[36] implemented lifestyle adjustments for 23 patients with GERD during one month such as not leaning in during the 2 to 3 h after a meal, having more meals a day but less food at each meal, and a low-fat diet. The frequency and severity of GERD symptoms significantly decreased for 22 patients, and 11 patients reduced their use of GERD-specific drugs.

A report from Eherer *et al*[37] revealed that abdominal breathing training combined with proton pump inhibitors was more effective than proton pump inhibitors alone for the treatment of GERD. Thus, non-drug lifestyle intervention therapy can effectively improve symptoms and reduce the medication burden of patients.

Psychological intervention

Psychological factors are considered to be closely related to functional digestive diseases such as FD, IBS, GERD, and globus. Therefore, it is very important to quickly determine the causes of the psychological problems and help solve them. At the same time, appropriate drugs that can alleviate emotions should be used.

We performed a series of treatment research on the application of low-dose antidepressants in depressive patients with functional gastrointestinal diseases. Amitriptyline (25 mg/d) was used to treat globus patients. After 4 wk of treatment, the amitriptyline group showed significantly greater improvement in the Glasgow Edinburgh Throat Scale score and sleep quality than the group that received conventional treatment (pantoprazole, 40 mg/d)[38]. Paroxetine (20 mg/d) was also applied for globus treatment. After 6 wk of treatment, 71.7% of the subjects in the paroxetine group (33/46) exhibited a treatment response, which was significantly greater than those for the amitriptyline group (46.2%, 24/52) and the lansoprazole group (14.0%, 7/50). A more distinct improvement of emotional well-being, quality of life,

and quality of sleep was observed in the paroxetine group than in the lansoprazole or amitriptyline group[39]. Additionally, mirtazapine (30 mg/d) was utilized to treat the FD patients with weight loss. After 8 wk of treatment, mirtazapine not only alleviated symptoms associated with dyspepsia and depression linked to FD for patients with weight loss but also significantly increased body weight (mainly the visceral fat in body fat)[40].

The low-dose administration of antidepressants mentioned above may not only alleviate the symptoms of depression but also improve the patient's digestive symptoms. Because these satisfactory effects can be achieved at low medical cost, the treatments are worth promoting in the clinic.

CONCLUSION

Unhealthy lifestyle and psychological factors are closely related to the occurrence, development, curative effect, and prognosis of digestive diseases. Thus, the new concept of whole-course intervention with a focus on disease prevention, and the new model of integrated therapy for the adjustment of unhealthy lifestyles and psychological problems are being established. As a new interdisciplinary subject, behavioral gastroenterology will help both clinicians and patients to alter the old idea of focusing on traditional drugs or surgery while ignoring lifestyle adjustments, and this new paradigm is expected to become gastroenterology's new frontier of action.

Abstract

AIM

To evaluate whether non-steroidal anti-inflammatory drugs (NSAIDs)-induced gastropathy is a clinically predictive model of referred visceral hypersensitivity.

METHODS

Gastric ulcer pain was induced by the oral administration of indomethacin to male, CD1 mice (n = 10/group) and then assessed by measuring referred abdominal hypersensitivity to tactile application. A diverse range of pharmacological mechanisms contributing to the pain were subsequently investigated. These mechanisms included: transient receptor potential (TRP), sodium and acid-sensing ion channels (ASICs) as well as opioid receptors and guanylate cyclase C (GC-C).

RESULTS

Results showed that two opioids and a GC-C agonist, morphine, asimadoline and linaclotide, respectively, the TRP antagonists, AMG9810 and HC-030031 and the sodium channel blocker, carbamazepine, elicited a dose- and/or time-dependent attenuation of referred visceral hypersensitivity, while the ASIC blocker, amiloride, was ineffective at all doses tested.

CONCLUSION

Together, these findings implicate opioid receptors, GC-C, and sodium and TRP channel activation as

possible mechanisms associated with visceral hypersensitivity. More importantly, these findings also validate NSAID-induced gastropathy as a sensitive and clinically predictive mouse model suitable for assessing novel molecules with potential pain-attenuating properties.

Key words: Visceral hypersensitivity; Pain; Translation; Guanylate cyclase C; Non-steroidal anti-inflammatory drugs; Transient receptor potential channel

Core tip: Recently, standard animal models of pain have been vehemently challenged for their inability to successfully predict human clinical outcomes. Further, few animal models have been represented with reasonable translational value for conditions presenting with visceral pain. Non-steroidal anti-inflammatory drug -induced gastropathy represents a translatable model of visceral hypersensitivity in which several pain targets have demonstrated reliable sensitivity when assayed. Further, this model is robust enough that proper pharmacological evaluation can be conducted. Overall, this model has the potential to efficiently triage molecules with pain-attenuating properties for their utility in gastrointestinal disorders that include pain as a hallmark symptom.

INTRODUCTION

Stomach ulcers are common and afflict millions of individuals annually (www.mayoclinic.com)[1]. Like many gastrointestinal (GI) disorders, stomach ulcers cause significant pain, a hallmark feature of many ailments affecting visceral organs. Although stomach ulcers predicate a type of visceral hypersensitivity, surprisingly the mechanisms underlying the pain associated with gastric ulceration as with some other GI conditions [*i.e.*, irritable bowel syndrome (IBS), functional dyspepsia, pancreatitis] remain poorly understood[2-4]. Several preclinical models of gastric or duodenal ulceration have been established that highly resemble human ulcers in terms of pathological features including the indomethacin-induced gastropathy and acetic acid models[5-9]. While these and other models have been used to aid the development of novel disease ameliorating therapies (*i.e.*, proton pump inhibitors and histamine receptor antagonists) as well as elucidate the notable involvement of *Helicobacter pylori* infection in ulcer formation, a direct behavioral measure of the pain associated with ulceration in these models has not been reported[10]. Furthermore, despite the success of these drugs in healing ulcer lesions, sensory aberrations leading to such pain have not been clearly delineated and often remain a chief complaint for many patients[10,11]. This is especially true for those individuals who are actively treated for ulcers but who also require concomitant therapy with non-steroidal anti-inflammatory drugs (NSAIDs) or aspirin, analgesics commonly used for other chronic conditions such as osteoarthritis (OA) and cardiovascular disease[12,13]. In conditions like OA, these agents are used to treat musculoskeletal pain, but paradoxically cause or exacerbate stomach pain on their own[13,14]. NSAIDs and salicylates are ulcerogenic and therefore, chronic use can exacerbate existing gastric injury or lead to new ulcer formation[15]. For these and other patients, it has been hypothesized that persistent or unresolved visceral pain, despite the etiology, may be due to aberrations in primary afferent function or hypersensitivity, peripheral sensitization, and/or psychological/genetic abnormalities[16-20].

With this in mind, we characterized the pain associated with gastric ulceration. By combining a clinically relevant stomach ulcer model with a predictive behavioral endpoint, we investigated some potential mechanisms producing visceral hypersensitivity. To this end, we used the indomethacin-induced gastropathy model to model the mucosal injury and concomitant pain associated with NSAID use. This model recapitulates the human condition in that indomethacin is orally administered to mice to produce mucosal damage, inflammation and referred visceral hyperalgesia[21-23]. Like in other GI disorders, ulcer pain is diffuse. Moreover, it can be referred to somatic structures and may present itself atypically given the dichotomization of sensory fibers that innervate visceral tissues[24-27]. Therefore, since ulcer pain is reportedly present upon palpation or mechanical stimulation of the abdomen both in dogs[28] and humans[29], we extrapolated this to mice and quantified the referred abdominal hypersensitivity by measuring the number of behavioral responses evoked by von Frey fiber stimulation[23,30]. We then investigated the pharmacological role of guanylate cyclase C (GC-C) and opioid receptors as well as TRPs, ASICS and sodium channels in this regard since all have been implicated in visceral hypersensitivity and/or functional bowel disorders to some degree[31-35].

MATERIALS AND METHODS

Animals

Male CD-1 mice (Harlan Laboratories, Indianapolis, IN, United States) weighing 20-25 g were housed on cob bedding (five/cage) in a climate-controlled room and maintained on a 12-h light/dark cycle with free access

to food and water. Animals were acclimated to the Purdue Pharma L.P. animal facility for one week prior to testing.

Animal care and use statement

All studies were approved by the Purdue Institutional Animal Care and Use Committee in accordance with the NIH Guide for the Care and Use of Laboratory Animals and the Ethical Guidelines of the International Association for the Study of Pain (www.iasp-pain.org) and are reported in accordance with the ARRIVE guidelines (www.nc3rs.org.uk). All efforts were made to minimize the number of animals used and to avoid any undue pain.

Ulcer pain model

As previously described, mice were fasted overnight then dosed orally with 30 mg/kg indomethacin to develop the ulcer model[23,30]. Control animals received vehicle (10 mL/kg, p.o.). Morphine was administered 2 h post-indomethacin while the other compounds were administered 3 h post-indomethacin or 1 h before testing. Stomachs from a separate set of vehicle- and indomethacin-dosed mice were dissected and photographed to ensure ulcer model development.

Behavior

Referred abdominal hypersensitivity from indomethacin-induced gastric ulceration was quantified by measuring the threshold to withdrawal from the application of a tactile stimulus to the abdominal area[23]. Briefly, the abdominal area was shaved and the mice were subsequently placed inside Plexiglas boxes situated on elevated wire screen mesh flooring conducive to von Frey probing. Following a habituation period, baseline tactile sensitivity was assessed. Tactile hypersensitivity was then measured 4 and 24 h following indomethacin administration using von Frey filaments applied to the upper abdomen (bending force 0.005-3.58 g starting with the 0.407 g fiber). The upper abdominal region was stimulated with an incremental series of eight monofilaments of increasing logarithmic stiffness. The 50% withdrawal threshold was determined using the up-down method of Dixon, modified by Dixon[36] and Chaplan *et al*[37]. First, an intermediate von Frey monofilament (number 3.58) was applied to the abdomen causing a slight bending. If a positive response was noted (abdominal/whole body withdrawal or licking), a smaller filament was then tested. Conversely, if no response occurred, the next larger filament was tested. If an animal did not respond to monofilament application, a cut-off value of 3.58 was assigned to that mouse[23,30]. A separate set of naïve mice were also dosed with the highest doses of the compounds of interest. von Frey thresholds were determined 4 h and 24 h post-indomethacin administration, noting that at least four hours is needed before a pain response can be reliably measured.

Rotarod

To delineate efficacy and assess changes in motor performance following compound administration, naïve mice were tested on an automated accelerating rotarod (Ugo Basile, Italy). For training and testing, the rotarod speed was increased from 4 to 40 rpm over a 300 second period. The maximum time spent on the apparatus was set to 300 s. Mice received two training sessions separated by a minimum of 2 h on the first day then 24 h later they were administered compound or vehicle. The latency to fall was assessed 1 , 2 and 24 h post-compound administration. It is important to note that only the highest dose tested in the efficacy assessment was evaluated in the rotarod assay.

Blinding and randomization

All testing was conducted in a blinded manner with experimenters involved in the study being unaware of the group assignment of any animal they were testing. Dosing solutions were coded using A-E. Animals were dosed in a blinded fashion after pre-treatment baseline assessment such that animals were assigned to treatment groups based on baseline response thresholds so that group means were approximately equal (*i.e.*, randomization). Briefly, animals were ranked by response threshold from lowest to highest and treatments were assigned as follows (*e.g.*, A, B, C, D, E, B, C, D, E, A, C, D, E, A, B, D, E, A, B, C, *etc.*). The animals were then dosed in sequence based on animal number, so that the distribution of treatment across a given set of animals was not predictable.

Statistical analysis

All data are expressed as the mean ± SEM. Data were analyzed using a two-way repeated measures analysis of variance (ANOVA) using the factors of treatment and time. The Bonferonni multiple comparisons test was subsequently performed for post-hoc comparison using GraphPad Prism software (version 5.04; GraphPad Sofware, Inc., United States). Statistical significance was set to $P < 0.05$. The statistical methods of this study were reviewed by Salvatore Colucci, a biomedical statistician employed by Purdue Pharma L.P.

Compounds

Indomethacin, AMG 9810, HC-030031, carbamazepine, amiloride HCl and morphine were obtained from Sigma-Aldrich (St. Louis, MO, United States). Linaclotide, and asimadoline HCl were obtained from Toronto Research Chemicals (Toronto, ON, Canada). AMG 9810, HC-030031, asimadoline and linaclotide were administered p.o. as suspensions in 0.5% methyl-cellulose. Amiloride HCl was formulated in 25% hydroxypropyl-β-cyclodextran and administered intraperitoneally while morphine was dissolved in saline and given subcutaneously. Also, with the exception of morphine, all compounds were administered one hour prior to behavioral testing (three hours post-

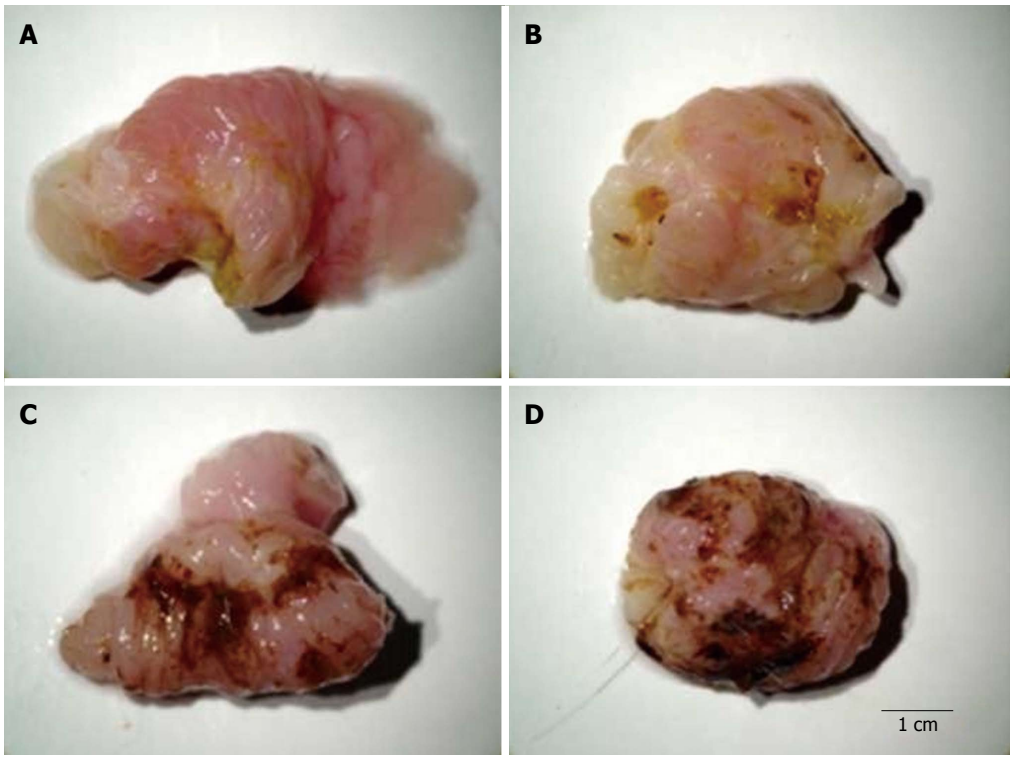

Figure 1 Representative digital photographs of stomachs dissected from mice orally dosed with vehicle (A) or 30 mg/kg indomethacin (B-D). Stomachs were scored as follows: A: score 0 = no lesion (normal mucosa = vehicle); B: score 1 = light petechial; C: score 2 = diffuse bleeding or aphtha; and: score 3 = multiple aphtha.

indomethacin dosing). Morphine was administered two hours before testing (or two hours after indomethacin). Route, vehicle and pre-treatment time for all compounds were chosen based on preliminary dosing experiments, pharmacokinetic (PK) data and/or previously published work. All doses are expressed as the free base and were administered in a dose volume of 10 mL/kg.

RESULTS

Ulcer model

Model development: We removed stomachs from vehicle- and indomethacin-dosed mice (4-h post-indomethacin administration). Mice were humanely euthanized. Their stomachs were grossly dissected, rinsed with saline and then photographed to demonstrate model development as shown in Figure 1. It is important to note that we found that visceral sensitivity is present in indomethacin-dosed animals irrespective of the degree of mucosal injury present. Behaviorally, severe mucosal damage does not always produce the most robust pain response.

Efficacy assessment

Opioid receptors: We examined the effect two distinct opioid receptor agonists had on visceral hypersensitivity. Firstly, we assessed the effect morphine (Figure 2A), the prototypical mu opioid receptor (MOR) agonist, had on the evoked visceral pain response. Results showed successful ulcer model development both 4 and 24-h post-indomethacin dosing ($P < 0.05$ *vs* vehicle), and that morphine attenuated the indomethacin-induced visceral hypersensitivity with a minimal effective dose (MED) equal to 10 mg/kg. Although there was a main effect of treatment [$F (4, 54) = 36$, $P < 0.05$ *vs* indomethacin] and a significant interaction with time [$F (8, 79) = 21$, $P < 0.05$ *vs* indomethacin], the effect morphine elicited on the pain behavior was only noted 2 h post-dosing (4 h post-indomethacin) for each of the higher doses tested, 10-30 mg/kg. Morphine was not efficacious in the assessment conducted 24-h post-indomethacin dosing. Nonetheless, the short-lived efficacy is consistent with the half-life of this drug. Subsequently, we next examined the effect asimadoline, a selective kappa opioid receptor (KOR) agonist, had in this pain model as well. Results showed consistent model development both 4 and 24-h post-indomethacin dosing ($P < 0.05$ *vs* vehicle). Asimadoline attenuated the indomethacin-induced visceral hypersensitivity with a MED= 10 mg/kg (Figure 2B). Like morphine, asimadoline was also efficacious in the model (10-30 mg/kg). There was a main effect of treatment [$F (4, 63) = 25$, $P < 0.05$ *vs* indomethacin] and a significant interaction with time [$F (2, 78) = 52$, $P < 0.05$]. However, unlike morphine, the kappa driven opioidergic effect was more prolonged such that the 30 mg/kg dose of asimadoline continued to attenuate the

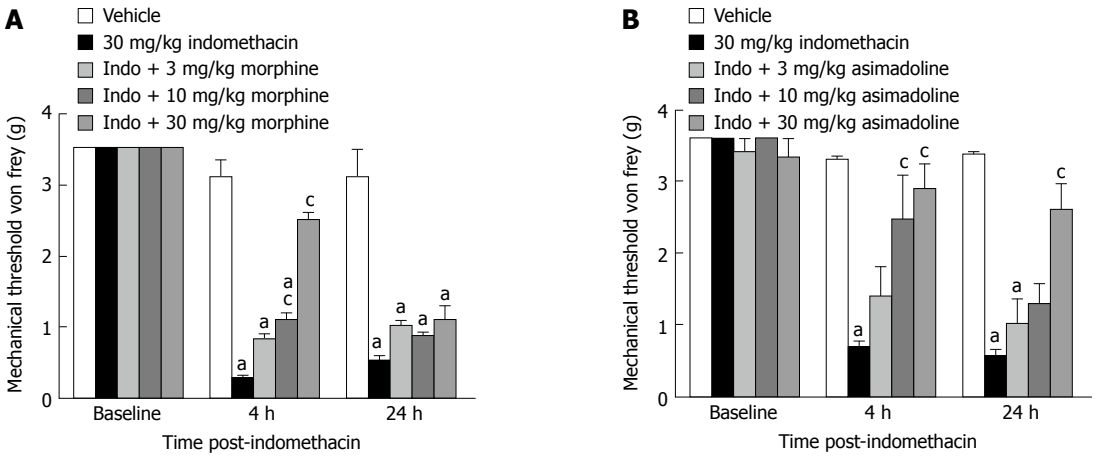

Figure 2 Effect of opioid receptor agonism on gastric ulcer pain. A: Dose-response and time course for the effect of a mu opioid receptor agonist on referred gastric ulcer pain. Morphine significantly attenuated referred gastric ulcer pain when dosed 10-30 mg/kg; B: Dose-response and time course for the effect of a selective kappa opioid receptor agonist on referred gastric ulcer pain. Asimadoline significantly attenuated referred gastric ulcer pain when dosed 10-30 mg/kg. All data are expressed as the mean ± SEM, where n = 8-10 mice/group. $^{a}P < 0.05$ *vs* vehicle, $^{c}P < 0.05$ *vs* indomethacin.

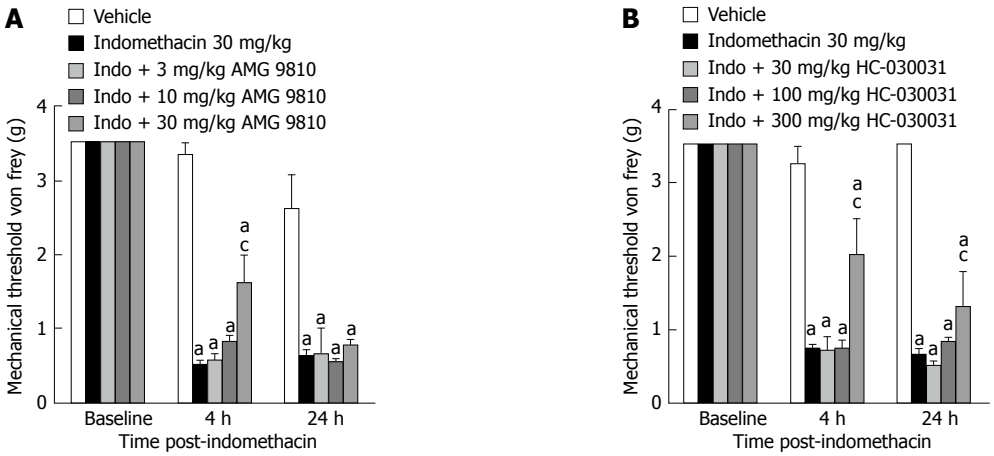

Figure 3 Effect of transient receptor potential channel blockade on gastric ulcer pain. A: Dose-response and time course efficacy for selective TRPV1 channel blockade on referred gastric ulcer pain. AMG 9810 significantly attenuated referred gastric ulcer pain when dosed at 30 mg/kg; B: Dose-response and time course for the effect of selective TRPA1 channel blockade on referred gastric ulcer pain. HC-030031 significantly attenuated referred gastric ulcer pain when dosed at 300 mg/kg. All data are expressed as the mean SEM where n = 10 mice/group. $^{a}P < 0.05$ *vs* vehicle, $^{c}P < 0.05$ *vs* indomethacin.

evoked pain response even at the 24-h assessment.

TRP channels

Next, we assessed the effect two distinct TRP channel receptor antagonists had on the visceral hypersensitivity. Firstly, we assessed the effect that AMG 9810, the most studied TRPV1 receptor compound, had on the evoked visceral pain response. In the ulcer pain model, indomethacin-dosed mice demonstrated reduced mechanical thresholds to von Frey fiber application compared to vehicle-treated animals as previously shown both 4 and 24-h post-dosing (Figure 3A, $P < 0.05$ *vs* vehicle). Systemic treatment with the TRPV1 antagonist AMG 9810 attenuated the referred ulcer pain by increasing the mechanical threshold at which a behavioral response was elicited. Although there was a main effect of treatment [F (4, 44) = 43.2, $P < 0.05$ *vs* indomethacin alone] and a significant interaction with time [F (8, 75)= 15, $P < 0.05$], only the 30 mg/kg dose significantly attenuated the visceral hypersensitivity present 4 h post-dosing as revealed by post hoc comparison. Efficacy was not observed at the 24-h assessment.

We then examined the effect HC-030031, a selective transient receptor potential ankyrin 1 receptor (TRPA1) antagonist, had in this pain model as well. Indomethacin-dosed mice demonstrated reduced mechanical thresholds to von Frey fiber application compared to vehicle-treated animals as previously shown both 4 and 24-h post-dosing (Figure 3B, $P < 0.05$ *vs* vehicle). Similar to TRPV1 blockade, the systemic treatment with the TRPA1 antagonist HC-030031 also significantly attenuated the referred ulcer pain in indomethacin dosed mice (Figure 3B). Although there was a main effect of treatment [F (4, 46) = 38, $P < 0.05$ *vs* indomethacin alone]and a significant interaction with time [F (8, 71)= 15.4, $P < 0.05$], only the 300 mg/kg dose attenuated the visceral hypersensitivity as noted

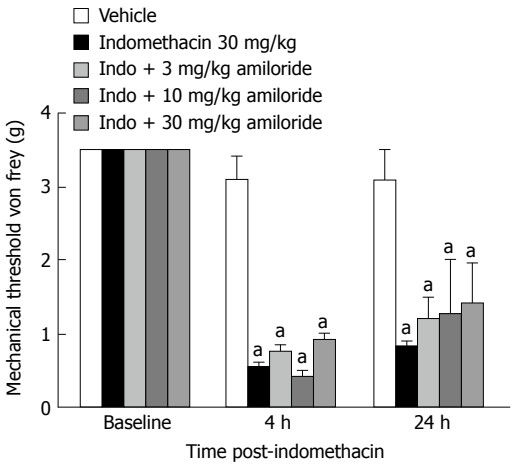

Figure 4 Effect of acid-sensing ion channels channel blockade on gastric ulcer pain. Dose-response and time course for the effect of non-selective ASIC channel blockade on referred gastric ulcer pain. Amiloride did not attenuate referred gastric ulcer pain at any of the doses tested. Data are expressed as the mean SEM where n = 10 mice/group. $^{a}P < 0.05$ *vs* vehicle.

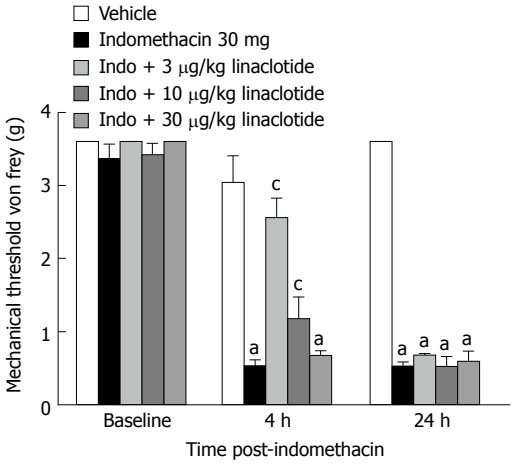

Figure 5 Effect of guanylate cyclase C agonism on gastric ulcer pain. A: Dose-response and time course for the effect of linaclotide on referred gastric ulcer pain. Linaclotide significantly attenuated referred gastric ulcer pain when dosed 3-10 μg/kg. Data are expressed as the mean SEM where n = 9-10 mice/group. $^{a}P < 0.05$ *vs* vehicle, $^{c}P < 0.05$ *vs* indomethacin.

by post-hoc comparison. Unlike the TRPV1 antagonist AMG9810, the effect of 300 mg/kg HC-030031 persisted at the 24-h assessment.

ASICs: We also investigated the sensory role of ASICs in ulcer pain. In the ulcer pain model, indomethacin-dosed mice demonstrated reduced mechanical thresholds to von Frey fiber application compared to vehicle-treated animals as previously shown both 4 and 24-h post-dosing (Figure 4; $P < 0.05$). Surprisingly, however, the non-selective ASIC blocker amiloride did not significantly reduce the referred ulcer pain at any doses tested when evaluated by post-hoc comparison. Referred abdominal hypersensitivity was present in all dose groups 4 and 24-h post-dosing.

Guanylate cyclase-C: We determined if the newly developed GC-C agonist, linaclotide, was efficacious at attenuating ulcer pain. Indomethacin dosed mice demonstrated reduced mechanical thresholds compared to vehicle-dosed animals both 4 and 24-h post-dosing (Figure 5; $P < 0.05$). There was a main effect of indomethacin treatment [F (4, 62) = 486, $P < 0.05$] and a significant interaction with time, [F (2, 128) = 64; $P < 0.05$] 4 h post-dosing. 3-10 μg/kg linaclotide (MED = 3 μg/kg) significantly attenuated the indomethacin-induced mechanical hypersensitivity ($P < 0.05$). Surprisingly, the 3 μg/kg dose produced the most efficacious response while the 30 μg/kg dose was without effect. Visceral hypersensitivity was still notably present in mice that received 30 μg/kg linaclotide. That is, their tactile response was consistent with vehicle-dosed controls. The three doses of linaclotide tested were not efficacious in the ulcer pain model during the 24-h assessment.

Sodium channels: Lastly, we determined if the non-selective sodium channel blocker, carbamazepine, was efficacious in the ulcer model. Indomethacin dosed mice demonstrated reduced mechanical thresholds compared to vehicle-treated animals both 4 and 24-h post-dosing (Figure 6, $P < 0.05$). There was a main effect of indomethacin treatment (F (4, 58)= 14, $P < 0.05$) and a significant interaction with time (F (2, 71) = 65, $P < 0.05$). The 100 mg/kg dose of carbamazepine significantly reversed the referred tactile hypersensitivity noted during the 4-h assessment ($P < 0.05$). Those animals that received the 100 mg/kg dose of carbamazepine also demonstrated significantly less visceral hypersensitivity during the 24-h assessment as well ($P < 0.05$ *vs* indomethacin).

Side effect assessment

von Frey Threshold: To determine whether the compounds used in these experiments had any activity in the absence of visceral hypersensitivity, we assessed whether the highest doses tested in the efficacy model affected the von Frey thresholds of naïve animals. Post hoc analysis revealed that amiloride (Figure 7A; $P < 0.05$ *vs* vehicle), linaclotide, asimadoline and carbamazepine (Figure 7B; $P < 0.05$ *vs* vehicle) altered the von Frey thresholds of naïve mice when dosed at the highest dose examined in the ulcer model. Tactile sensitivity was enhanced 4-h after the dosing of linaclotide, asimadoline and carbamazepine, and 4 and 24-h after the administration of amiloride.

Rotarod performance: To place the efficacy of the compounds assessed into context with any inherent side effect liability, the highest dose of each compound examined in the ulcer model was subsequently evaluated in naïve mice using the rotarod assay. Morphine produced a slight but non-significant decrease

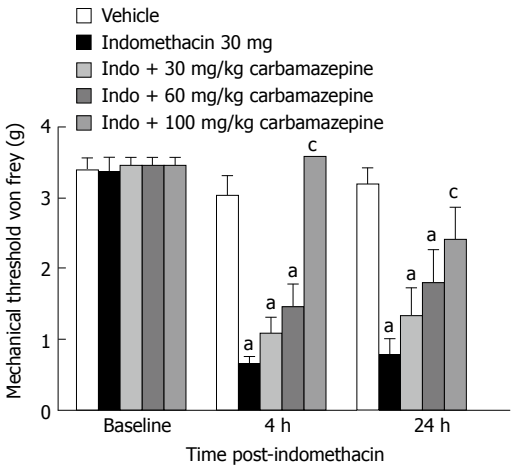

Figure 6 Effect of sodium channel blockade on gastric ulcer pain. Dose-response and time course for the effect of carbamazepine on referred gastric ulcer pain. Carbamazepine significantly attenuate referred gastric ulcer pain when dosed at 100 mg/kg. Data are expressed as the mean ± SEM with 9-10 mice/group. $^{a}P < 0.05$ *vs* vehicle, $^{c}P < 0.05$ *vs* indomethacin.

in rotorad performance one hour after administration (Figure 8A), while carbamazepine produced significant deficits in rotarod performance both 1 and 2 h following dosing (Figure 8B; $P < 0.05$ *vs* vehicle). Conversely, AMG 9810, HC-030031, linaclotide, asimadoline and amilioride did not produce any deficits in motor performance as show.

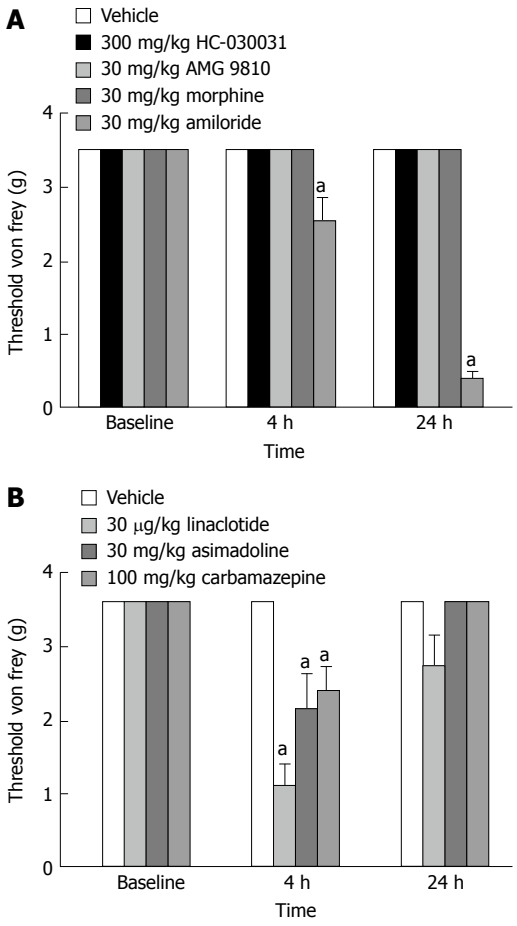

Figure 7 Effect of compound administration on von Frey threshold in naïve mice. A: The non-selective ASIC blocker amiloride significantly decreased abdominal threshold in mice 4 and 24-h post-administration when dosed at 30 mg/kg. B: Linaclotide, asimadoline and carbamazepine significantly decreased abdominal threshold in mice 4-h post-administration. Data are expressed as the mean ± SEM, where *n* = 9-10 mice/group. $^{a}P < 0.05$ *vs*

DISCUSSION

Pain is a characteristic feature of many chronic disorders affecting the GI tract. In this study we measured the pain associated with NSAID-induced gastropathy[13,14] and then investigated relevant pharmacological mechanisms underlying its development and maintenance.

Firstly, our findings show that the NSAID-induced gastropathy model in mice consistently produces stomach ulceration and referred abdominal hypersensitivity that can be reliably measured. Importantly, the model is robust enough that proper pharmacological evaluation can be conducted. Since gastric ulcers are a source of visceral pain which can be referred to somatic dermatomes upon palpation of the abdomen[28,29], this study was able to measure the threshold at which mice responded to abdominal application of von Frey filaments. Although this response was used as an index of the pain, it was no surprise that the mice demonstrated such robust behavior given the macroscopic changes depicted in Figure 1.

In characterizing the mechanisms associated with this pain model, we first assessed the effects of two distinct opioid analgesics. We determined that the MOR agonist, morphine, attenuated the ulcer pain in a dose- and time-dependent manner. This was not unexpected given the robust presence of MORs on enteric neurons of the GI tract, as well as this compound's well-published *in vitro* and *in vivo* pharmacological profile[38]. Interestingly and unknowing to us at the time of dosing was that the effect morphine had on ulcer pain may extend beyond its historical pain-ameliorating actions at the receptor level. That is, morphine may also provide gastric defense. An early study reported that morphine is protective to the stomach because it increases mucous production and decreases acid secretion[39]. However, contrary to this effect, it is also noteworthy to mention that morphine may be pro-ulcerogenic in certain circumstances as well. Esplugues and Whittle[40] had suggested that morphine can potentiate acid- and ethanol-induced gastric injury, although the experimental conditions employed herein did not support this result. Nonetheless, in this investigation, we demonstrated that morphine attenuated referred visceral pain at doses that did not alter von Frey thresholds or produce ataxia in naïve mice. However, it is important to note that the utility of MOR agonists for the treatment of visceral pain needs to be judiciously scrutinized given their effect on GI

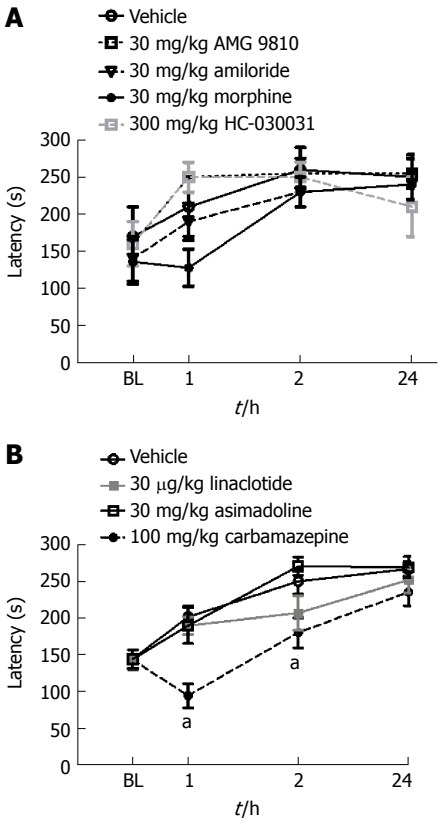

Figure 8 Effect of compound administration on rotarod performance. A: AMG 9810, amiloride, morphine and HC-030031 did not produce any significant deficits in rotarod performance 1-24 h post-administration; B: Linaclotide and asimadoline were without effect while carbamazepine significantly altered rotarod performance 1 and 2-h post-administration, $^{a}P < 0.05$. motility.

We next examined the efficacy of asimadoline, a potent KOR agonist. Asimadoline has 500-fold selectivity for kappa versus MORs and it is purported to produce its analgesic actions peripherally rather than centrally[41,42]. Previous work in animals has suggested that KOR agonists may represent a more viable approach to treating painful visceral conditions due to the nature of KOR expression and function[43,44]. In this regard, we hypothesized that asimadoline may be beneficial in attenuating visceral hypersensitivity. Interestingly, on a dose-per-dose basis, asimadoline was more efficacious than morphine in the model. Like morphine, it did not produce any deficits in rotarod performance at the highest dose tested; however, the 30 mg/kg dose did enhance tactile sensitivity in naïve animals. While Delgado-Aros *et al*[45] found that asimadoline produced hyperalgesia in patients dosed with high doses of the compound, there is a disconnect between human and rodent. In the human condition, these results may suggest that the KOR system becomes engaged during pathological conditions of persistent hypersensitivity[41,46] and that it does not significantly alter noxious sensation in healthy states[44]; however, these findings/assumptions are not consistent with ours since the mice tested were naïve and not subjected to ulcer induction. Although continued research is necessary to further our understanding on how KOR agonists modulate visceral pain, there is clinical evidence to support such an indication. Most notably, Cara Therapeutics have recently developed a peripherally restricted compound, CR665, which has demonstrated efficacy in human visceral pain[47-48].

TRP channels have received a significant amount of attention for their alleged role in pain including visceral hypersensitivity[35,49]. Since TRP channels transduce noxious stimuli at the peripheral terminals of nociceptors, these channels are well-poised anatomically to function as the first integrators of the pain response[50]. In support of this Akbar and colleagues[51] demonstrated a 3.5-fold increase in the density of TRPV1 immuno-reactive fibres in the colonic biopsies of patients with IBS compared to healthy controls. Transient receptor potential vanilloid-1 (TRPV1) is a ligand-gated nonselective polymodal cation channel that integrates a variety of pain stimuli[49]. Since noxious GI events are conveyed to the CNS by vagal and spinal afferents, and TRPV1 is expressed within both dorsal root and nodose ganglia innervating the GI tract[52,53], we examined whether selective blockade of the TRPV1 receptor would attenuate ulcer pain. Our results showing the ability of AMG 9810 to attenuate pain in the ulcer model suggests that the irritating effects of indomethacin on the gastric mucosa may engage the TRPV1 receptor either directly or indirectly such that these afferent neurons become hypersensitive to the hydrochloric acid that is normally innocuous to the stomach. Overall, the net effect may be analogous to proton activation of the channel. Alternately, it also becomes noteworthy to consider early reports supporting the protective effects of capsaicin-sensitive afferent neurons on the gastric mucosa[16,54]. While activation is believed to be protective, ablation of capsaicin-sensitive neurons impairs mucosal defense. With regard to our findings, one may have expected antagonism of TRPV1 to be detrimental. However, unlike nerve ablation which removes the entire nerve terminal and its functionality, an antagonist would leave the protective effects of these neurons intact.

Like TRPV1, TRPA1 is a non-selective cation channel that is a propagator of painful signaling that is activated by a variety of stimuli as well[55]. TRPA1 is mainly expressed in small diameter peptidergic nociceptors of the DRG, nodose and trigeminal ganglia along with TRPV1. TRPA1 has also been shown to be extensively expressed in enterochromaffin cells of colonic myenteric neurons as well as within non-neuronal tissue such as the small intestine and pancreas[55-57]. Therefore, together with its profile, co-expression pattern and connectivity to afferents that potentially impact the stomach, we hypothesized that TRPA1 would be a potential mediator of ulcer pain.

We found that the TRPA1 antagonist, HC-030031, attenuated abdominal hypersensitivity in the ulcer model. This result is in agreement with a study by Kondo *et al*[57] who demonstrated the efficacy of this compound in the context of a noxious gastric distention model. However, these findings are in direct contrast to a recent study by Kojima *et al*[58] who examined the effect of the TRPA1 agonist, ASP7663, in a similar model. Surprisingly, they maintained that TRPA1 agonism, not antagonism, represents a rational approach to treating visceral pain and that the analgesic effect of ASP7663 on colorectal distension-induced abdominal pain is mediated by direct desensitization of the TRPA1 channel.

Another potential transducer of noxious signals in the GI tract are ASICs (ASIC 1-3), a family of proton-gated sodium channels expressed within primary afferent neurons. Since a positive correlation between pain and local acidity has been reported and protons trigger inward currents through sodium channels in visceral sensory neurons causing hyper-excitability[21,59,60], we were surprised that amiloride did not attenuate the referred ulcer pain at any of the doses tested. Another study by Jones *et al*[61] examining the effect of amiloride on afferent fiber sensitivity to circumferential stretch of the colon also failed to see efficacy. The authors suggested that different ASIC subunits may exert opposing effects on mechanosensation. Likewise, different subunits may be involved in mechanical hypersensitivity of the colon as shown in a study using ASIC3 knockout mice[62] and this too may be reflective of the enhanced tactile sensitivity observed following dosing of the non-selective blocker amiloride to naïve animals and its lack of efficacy in the ulcer model.

Voltage-gated sodium channels have also received a significant amount of attention in recent years for their diverse role in pain. Given this, we investigated the role of the non-selective sodium channel blocker, carbamazepine, in the ulcer model. Unlike a prior efficacy report[63], we found carbamazepine produced a positive signal when administered at a high dose, 100 mg/kg. However, it is difficult to conclude if this was an efficacious response or a mixed result driven by the sedative properties of this molecule. As expected, carbamazepine also affected other measures of neurological function, such as rotarod performance and innate tactile threshold, thereby complicating interpretation of the reflexive endpoint used. Nonetheless, sodium channels appear to be important in pain as they have been causally linked to human conditions like IBS[64]. Notably, a number of selective sodium channel blockers targeting Nav 1.7 and Nav 1.8 in the periphery have entered clinical development[65]. Given the expression pattern of these targets as well as their selectivity profiles, one would expect that the not so distant future will provide novel sodium channel blockers that may alleviate conditions associated with visceral hypersensitivity although the discovery and developmental path for these compounds thus far has been very challenging.

Lastly, we examined whether linaclotide (Linzess™), a first-in-class, orally administered synthetic peptide of the guanylin peptide family, would produce an efficacious response in the ulcer model[33]. Linaclotide, a GC-C agonist, and its active metabolite are purported to bind to GC-C to act locally within the GI lumen to elevate cGMP. Mechanistically, Silos-Santiago *et al*[66] suggest that the cGMP significantly decreases the firing rates of sensitized afferent neurons in response to mechanical stimuli to lessen the pain response. In agreement with this study, we found that linaclotide was efficacious in attenuating ulcer pain when dosed 3-10 μg/kg. Surprisingly, however, the maximum effect was observed when linaclotide was administered at the lowest dose, 3 μg/kg. Although we would not have predicted this result, this finding did align with findings published previously by Eutamene *et al*[67] using the colorectal distension model. Similarly, this study showed that higher doses of linaclotide, 30 μg/kg, did not affect colorectal hypersensitivity, while lower doses did attenuate it. Interestingly, IBS clinical trial results examining the efficacy of linaclotide in patients confirmed these preclinical findings as well such that the FDA approved package insert for this compound states that continued abdominal pain (7% *vs* 5% placebo) is a possible side effect of therapy (www.linzesshcp.com). Although the mechanism for this paradoxical effect is unclear, it could be related to the physiochemical-pharmacokinetic properties of the molecule. Linaclotide has no oral bioavailability when given at efficacious doses; it is purported to act locally within the GI tract. However, with increasing dosage, the PK of linaclotide is documented to be non-linear. So, it is conceivable that such reduced anti-hyperalgesic effects at higher doses may be attributable to a corresponding loss of pharmacological specificity[67].

Visceral hypersensitivity underlies the pain experienced by patients presenting with various GI-related disorders. Although there is an unmet need to model visceral pain pre-clinically, this can be very challenging given the unique sensory innervation of visceral organs as well as our incomplete understanding of disease etiology[68]. Nonetheless, given the characteristics of visceral pain, both favorable (*i.e.*, not produced by noxious stimuli) and unfavorable (*i.e.*, pain is referred, diffuse, poorly localized)[27], we have demonstrated that the ulcer model is uniquely sensitive for assessing the effects of compounds directed against several well-known pain mechanisms. Furthermore, while we think this model is well-suited for drug discovery namely because of its ease and its reliability in performing stringent pharmacological evaluation (*i.e.*, dose-response data), it does have its limitations. For one, it is an acute model of visceral pain. While acute visceral pain is burdensome, the unmet need lies with the undulating hypersensitivity that persists from chronicity like in IBS. Also, most

discovery groups perform their pain studies in rats, so consistency with regard to species selection does differ as this model was validated in mice. Lastly, functional GI disorders represent a heterogeneous group of disorders that include genetic and environmental contributors. Notably, these factors are difficult to recapitulate in animals. While these limitations are well-recognized, together with its clinical relevance, we believe that the NSAID-induced gastropathy model may help uncover additional targets contributing to persistent GI pain of ill-defined etiology and further advance future drug discovery efforts for this unmet need.

ACKNOWLEDGMENTS

The authors would like to thank Brian Strassle for his expertise in helping prepare some figures for this manuscript and Salvatore Colucci for advising on the statistical evaluation.

COMMENTS

Background

Non-steroidal anti-inflammatory drugs (NSAIDs) and salicylates are ulcerogenic and therefore, chronic use can exacerbate existing gastric injury or lead to new ulcer formation. For these and other patients, it has been hypothesized that persistent or unresolved visceral pain, despite the etiology, may be due to aberrations in primary afferent function or hypersensitivity, peripheral sensitization, and/or psychological/genetic abnormalities.

Research frontiers

With this in mind, the authors characterized the pain associated with gastric ulceration. By combining a clinically relevant stomach ulcer model with a predictive behavioral endpoint, the authors investigated some potential mechanisms producing visceral hypersensitivity.

Innovations and breakthroughs

Pain is a characteristic feature of many chronic disorders affecting the gastrointestinal (GI) tract. In this study the authors measured the pain associated with NSAID-induced gastropathy and then investigated relevant pharmacological mechanisms underlying its development and maintenance.

Applications

The authors believe that the NSAID-induced gastropathy model may help uncover additional targets contributing to persistent GI pain of ill-defined etiology and further advance future drug discovery efforts for this unmet need.

Peer-review

In this paper, the authors used the indomethacin to create NSAID- induced Gastropathy mouse model, and then investigated the pharmacological role of opioid and guanylate cyclase C receptors as well as TRPs, ASICS and sodium channels on this translatable model of visceral hypersensitivity. In summary, this study has demonstrated that the NSAID-gastropathy model has the potential to efficiently triage molecules with pain-attenuating properties for their utility in GI disorders that include pain as a hallmark symptom, and may help uncover additional targets contributing to persistent GI pain of ill-defined etiology and further advance future drug discovery efforts. The overall structure of the manuscript is complete, and all figures are necessary and appropriate. The study has a certain significance and it may possibly help researchers to develop further studies.

Abstract

AIM

To efficiently replicate the biology and pathogenesis of human esophageal adenocarcinoma (EAC) using the modified Levrat model of end-to-side esophagojejunostomy.

METHODS

End-to-side esophagojejunostomy was performed on rats to induce gastroduodenoesophageal reflux to develop EAC. Animals were randomly selected and serially euthanized at 10 (n = 6), 17 (n = 8), 24 (n = 9), 31 (n = 6), 38 (n = 6), and 40 (n = 6) wk postoperatively. The esophagi were harvested for downstream histopathology and gene expression. Histological evaluation was

completed to determine respective rates of carcinogenic development. Quantitative reverse transcription-polymerase chain reaction was performed to determine gene expression levels of *MUC2, CK19,* and *CK20,* and results were compared to determine significant differences throughout disease progression stages.

RESULTS

The overall study mortality was 15%. Causes of mortality included anastomotic leak, gastrointestinal hemorrhage, stomach ulcer perforation, respiratory infection secondary to aspiration, and obstruction due to tumor or late anastomotic stricture. 10 wk following surgery, 100% of animals presented with esophagitis. Barrett's esophagus (BE) was first observed at 10 wk, and was present in 100% of animals by 17 wk. Dysplasia was confirmed in 87.5% of animals at 17 wk, and increased to 100% by 31 wk. EAC was first observed in 44.4% of animals at 24 wk and increased to 100% by 40 wk. In addition, two animals at 38-40 wk post-surgery had confirmed macro-metastases in the lung/liver and small intestine, respectively. *MUC2* gene expression was progressively down-regulated from BE to dysplasia to EAC. Both *CK19* and *CK20* gene expression significantly increased in a stepwise manner from esophagitis to EAC.

CONCLUSION

Esophagojejunostomy was successfully replicated in rats with low mortality and a high tumor burden, which may facilitate broader adoption to study EAC development, progression, and therapeutics.

Key words: Esophageal adenocarcinoma; Gastroesophageal reflux disease; Levrat; Esophagojejunostomy; Experimental rat model; Mucin genes; Cytokeratins

Core tip: The current study reportsrefined surgical techniques with improved tumor burdens for the modified Levrat model of end-to-side esophagojejunostomy in a rat for future *in vivo* studies of esophageal adenocarcinoma (EAC). For the first time, the model was established with significantly reduced mortality and morbidity and further validated through evaluation of conserved EAC disease progression markers, such as mucin and cytokeratins. The reported approach will allow for broader adoption of the model to allow for greater understanding of the complete disease progression spectrum from Barrett's esophagus to metastatic EAC and aid in the development of novel therapeutics.

INTRODUCTION

Esophageal adenocarcinoma (EAC) incidence has increased dramatically in the western world in recent decades, with a 600% increase seen in the United States since the mid-1970s[1]. Despite recent advances in the development of multimodality patient-centered care plans, EAC still carries a poor prognosis with an overall 5-year survival rate of less than 15%[2]. Due to the increasing incidence and lethality of EAC, a better understanding of the underlying cancer biology and improved methods for prevention and treatment are urgently needed.

Barrett's esophagus (BE) is induced by chronic gastroesophageal reflux disease (GERD) and is a premalignant precursor to the progression of dysplasia and EAC[3,4]. GERD stimulates the replacement of squamous epithelium of the distal esophagus by intestinal-type metaplastic columnar epithelium, pathologically characterized by goblet cells and the expression of intestinal and differentiation markers, such as mucin genes (*MUC2*, *MUC5AC*), cytokeratins (CK7, CK20) and villin[5-9]. Furthermore, several studies have shown that transcription factors involved in the establishment of tissue differentiation, such as CDX2 and SOX2, play a key role in the development of BE and precede morphological changes[10,11]. Although there is great interest the underlying biology of BE carcinogenesis, the exact molecular mechanisms involved in the longitudinal progression to EAC have not been fully elucidated. Therefore, molecular biomarkers that are dysregulated across the progression spectrum would have significant clinical utility for early detection, risk identification, prognosis and therapeutic intervention.

Well-established small animal models efficiently recapitulate human de novo disease progression at the histological and molecular levels, providing clinical utility for development of effective treatment strategies. In 1962, Levrat *et al*[12] reported a surgical model of esophagoduodenostomy (ED) in rats to induce chronic gastroduodenal reflux. This model was further refined to demonstrate that ED with or without gastrectomy, esophagojejunostomy (EJ) with or without gastrectomy, and pancreatico-esophageal anastomosis could recreate disease progression to EAC without the administration of exogenous carcinogens[13-18]. Additionally, the study of gene expression profiles from BE to EAC confirmed significant homology between human and rat disease[19]. The modified Levrat model of end-to-side EJ with vagal nerve preservation to induce EAC through chronic gastroduodenoesophageal reflux (GDER) currently represents the gold standard of the model and has been extensively utilized to evaluate EAC disease progression and novel therapeutics. Therefore, this surgical approach provides a representative and translatable model for the study of reflux-induced carcinogenesis and downstream genetic alterations associated with EAC.

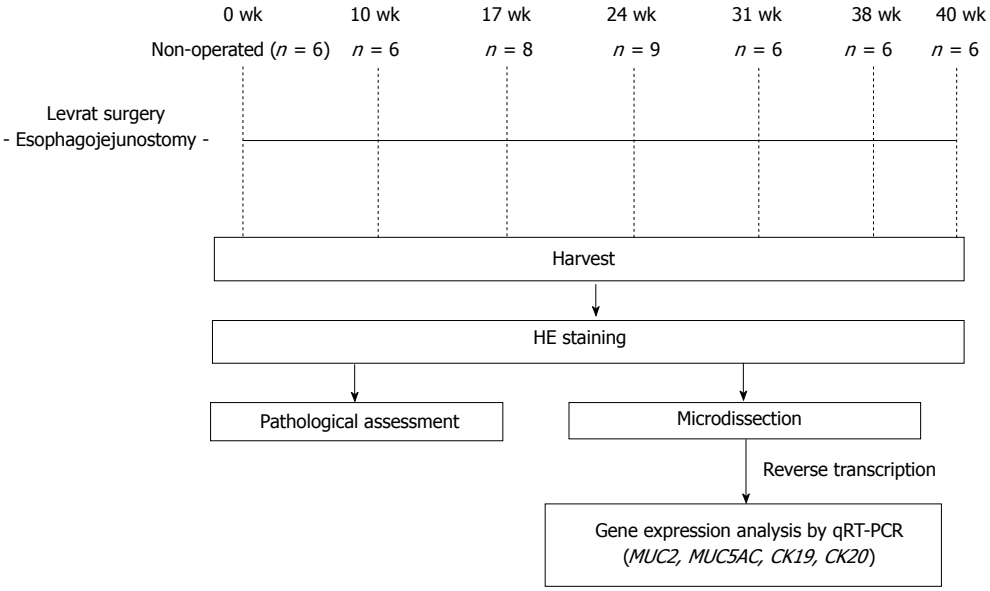

Figure 1 Study schema representing the major steps in the experimental design. qRT-PCR: Quantitative reverse transcription-polymerase chain reaction.

Through our extensive use of the modified Levrat model over recent years to study EAC, we have successfully optimized our protocols to maximize tumor burden and minimize mortality. The aim of the present study was to describe efficient use of the modified Levrat model through improved surgical techniques, perioperative care, management of complications, and analysis of molecular profiles. We feel the successful broader implementation of a reliable and replicable model that mimics human disease will enable other laboratories to reproduce it effortlessly and advance further research into the pathophysiology and biology of EAC.

MATERIALS AND METHODS

Ethics statement

This study was conducted with approval from the Institutional Animal Care and Use Committee of Allegheny General Hospital in Pittsburgh, Pennsylvania under Protocol #992. All animals received humane care in compliance with the standards set forth in "The Guide for the Care and Use of Laboratory Animals." All animals were weighed weekly and euthanized if acute decompensation occurred prior to study endpoint.

Experimental design

The cohort for this study was randomly preassigned from a larger protocol of 225 animals. Mortality and morbidity were calculated from the larger sample set to proportionally reflect the range and incidence rates of causes across sub-studies. The modified Levrat surgery of end-to-side EJ was performed on 200 to 250 g 6-wk to 8-wk-old male Sprague-Dawley rats (Harlan Laboratories, Indianapolis, IN) to induce chronic GDER and the subsequent spectrum of *de novo* premalignant lesions leading to EAC formation. Animals were randomly selected for serial euthanasia at 10 (n = 6), 17 (n = 8), 24 (n = 9), 31 (n = 6), 38 (n = 6), and 40 (n = 6) wk postoperatively. Additionally, six animals served as controls and were harvested with no surgical intervention. The higher effective n at 17 and 24 wk is reflective of animals that were prematurely sacrificed from the original designated time point due to health considerations. Pathological assessment was performed on all harvested esophageal specimens stained with hematoxylin and eosin (HE). Tissue samples were further evaluated for *MUC2*, *MUC5AC*, *CK19*, and *CK20* gene expression using quantitative reverse transcription-polymerase chain reaction (qRT-PCR) to compare each level of disease progression. These markers were selected based on known roles in human esophageal carcinogenesis. Study schema of experimental design is represented in Figure 1.

Modified levrat surgical model

Preoperative management: Prior to intervention, animals were acclimatized for at least one week and housed on a 12-h alternating light-dark cycle. Standard feed included a solid pellet diet and free access to tap water. One day prior to surgery, rats were provided with a gel-based diet (BioServ, Flemington, NJ; # S5769) to encourage stomach clearing to reduce the risk of anastomotic leak. Animals were nil per os (NPO) for 2-4 h before surgery. For sedation, animals were placed in an acrylic anesthetizing chamber for induction with 5% isoflurane and transferred to a nose cone mask for maintenance with 2% isoflurane in 1 mL/L of oxygen. The anesthetized rats were then placed on a circulating water heating bed to maintain adequate body temperature during surgery and were given prophylactic ketoprofen (3 mg/kg) and

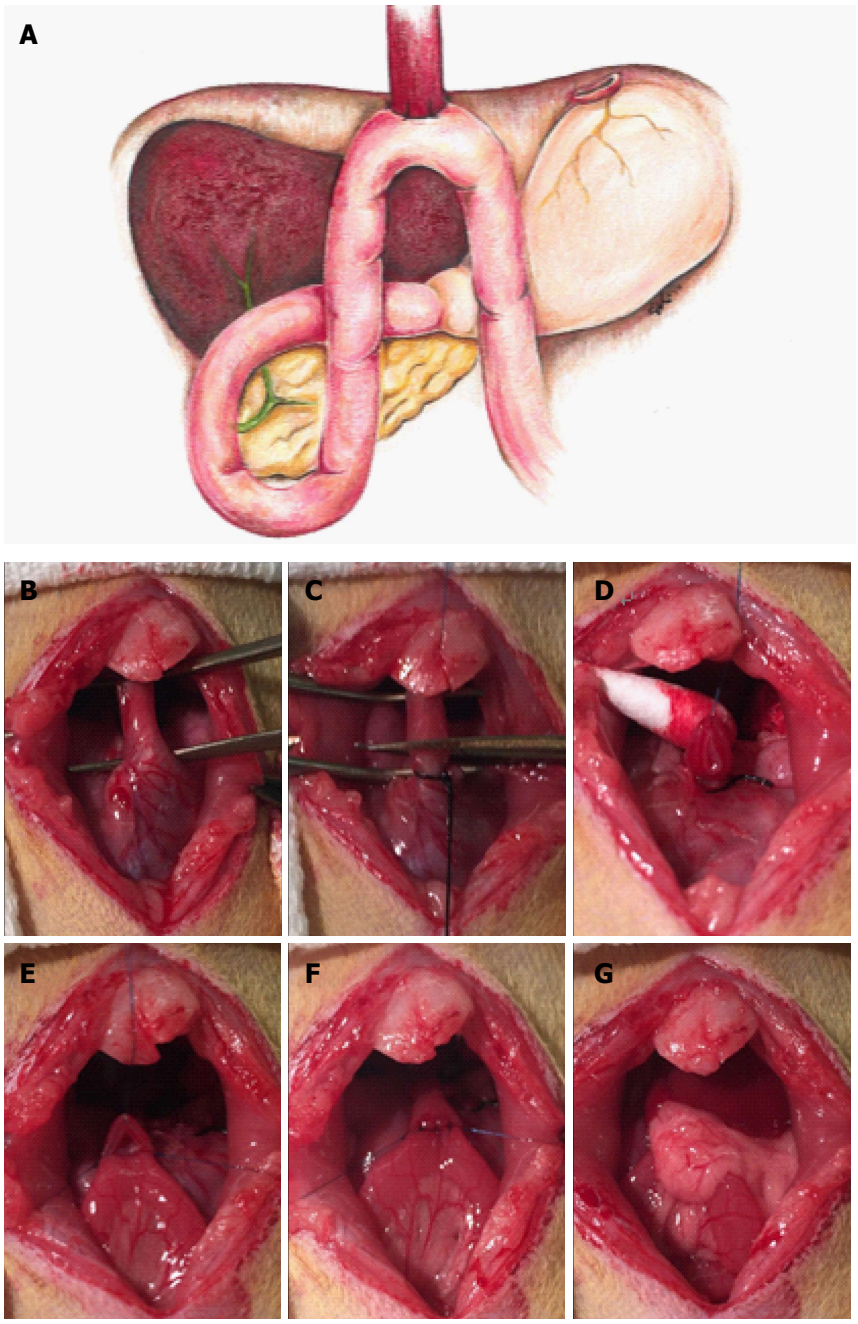

Figure 2 Diagram of modified Levrat model and images of the main steps of the surgical procedure. enfloxacin (5 mg/kg) immediately prior to surgery.

Surgical techniques: All animals underwent an end-to-side EJ with gastric preservation through upper midline abdominal incision. The esophagus was mobilized, preserving the left and right vagus nerves (Figure 2B), and the gastroesophageal junction was ligated using 3-0 silk. A temporary 7-0 prolene suture (Ethicon, Somerville, NJ, United States) was delicately threaded through muscle layer only of the distal esophagus 1 cm above the silk knot to prevent retraction of the esophagus through the diaphragm. Care was taken to minimize tension on the esophagus to prevent recoiling of the mucosal layer into the lumen, and the esophagus was cut just above the gastroesophageal junction (Figure 2C). A loop of jejunum was identified 4 cm distal to the ligaments of Treitz and 3 mm jejunostomy was made using a #11 surgical blade. Residual intestinal fluid in the immediate area was drained using a sterile swab to

minimize risk of postoperative abscess formation and infection. An end-to-side anastomosis was constructed between the distal esophagus and jejunum in an antecolic manner with eight interrupted full-thickness 7-0 prolene sutures. Special care was taken to include the esophageal mucosa to ensure adequate mucosal-to-mucosal apposition (Figure 2D-F). The first 5 sutures were placed on the anterior wall, and the entire anastomosis was carefully flipped 180° to expose the posterior wall. Before placing the posterior sutures, patency of the proximal and distal lumen was confirmed. The final 3 sutures were placed, and the anastomosis was returned to anatomical position. This delicate flip allowed all suture knots to remain external to the lumen and minimized anastomotic failure due to postoperative obstruction. The omentum was wrapped around the completed anastomosis to prevent anastomotic leakage (Figure 2G), and the celiotomy was closed using 4-0 vicryl (Ethicon, Somerville, NJ, United States). All rats received a 25-30 mg/kg bolus of Lactated Ringer's Solution (LRS), were placed on 100% oxygen until awake, and placed in a cage with a raised wire mesh grate to eliminate direct exposure to obstructive bedding. Rats remained NPO for at least 1 h postoperatively to prevent aspiration.

Postoperative management: For the duration of the study, postoperative animals were housed in cages with raised grates to eliminate access to bedding. Any ingestion of foreign material post-surgery results in anastomotic failure and leak or obstruction. Durable plastic huts were provided as enrichment, and rubber stoppers on water bottles were continuously monitored for integrity. Animals continued to receive daily injections of LRS, ketoprofen (3 mg/kg), and enfloxacin (5 mg/kg) until postoperative day 3. Additionally, all rats were placed on a 10-d diet modification plan designed to gradually shift from liquid diet to full solid diet, in an effort to facilitate proper healing of the anastomosis, minimize aspiration-related complication, and encourage feeding after surgery. On postoperative days 0 to 3, rats received a nutritional diluted liquid supplement diet (Ensure; Abbot, Columbus, OH, United States) with acetaminophen (Tylenol®) for pain control. Animals were then transitioned to a gel diet (BioServ, Flemington, NJ; # S5769) (days 4-6), followed by a mushed pellet diet (days 7-9), and then regular solid pellet diet on postoperative day 10. The days on a specific modified diet were extended by 1-2 d if the animal seemed slow to recover from surgery. During the postoperative window, all rats were individually housed to closely monitor health, consumption, and stool production and to reduce chances of wound damage. On day 14, all rats were ear-tagged and pair-housed. At 12 wk, all rats were treated with iron dextran (50 mg/kg, i.m.) every two weeks prophylactically for anemia. All animals received a weight check at least once a week, and during periods of weight loss, rats were weighed more frequently, and modified diets were provided in a supplemental fashion. Animals having more than 45% weight loss or acute decompensation in the postoperative period were sacrificed, and all remaining rats were euthanized at their respective time points for histological evaluation.

Gross and histological evaluation

Tissue preparation and pathological assessment: Upon necropsy, the entire esophagus and jejunum, to a length approximately 1 cm distal to the anastomosis was harvested. After the specimen was cut open longitudinally, samples were rinsed in ice-cold phosphate buffered saline to remove debris, oriented to maximize exposure of suspicious areas, and flash frozen in Tissue-Tek Optimal Cutting Temperature (OCT) compound (Sakura Finetek, Torrance, CA; #4583). Next, frozen esophagi in OCT blocks were cut into 5 micron sections using a cryostat (Fisher Scientific, Waltham MA; Microm HM 550) and stained with HE for pathological assessment and gene expression analysis. Two experienced pathology experts independently performed the histological analysis to identify areas of disease. Histological changes were defined on the basis of the following established classification criteria: (1) esophagitis: intraepithelial inflammation, thick basal cell layer, elongated lamina propria papillae, and spongiosis; (2) proliferative hyperplasia: Increased thickness of the squamous epithelium (sometimes hyperkeratotic) with no cellular atypia; (3) BE: Replacement of normal esophageal squamous epithelium with columnar-lined epithelium containing goblet cells; (4) dysplasia: dysplastic squamous cell epithelium with enlarged, atypical nuclei and an increased number of mitotic figures, which may invade lamina propria of the epithelium but does not invade the submucosal layer; and (5) EAC: Mucinous, dysplastic glandular cell growth with both atypia and invasion through the basement membrane.

Gene expression analysis by PCR

In order to evaluate the expression of a subset of four biomarkers at each esophageal disease level, qRT-PCR was performed on macrodissected esophageal tissues, including 3 normal esophageal epithelium (controls), 5 esophagitis, 5 BE, 11 dysplasia, 19 EAC and 2 EAC (primary profiled) with metastasis. Briefly, two experienced pathology experts independently confirmed areas of the highest disease for each sample and marked HE slides for macrodissection. Based on the marked areas, 200 μmol/L of tissue was macrodissected using a cryostat, and special care was taken to ensure all collections were highly representative of the disease states. RNA was isolated from the tissue using a miRNeasy kit (Qiagen, Valencia, CA; #217004), and a reverse transcription reaction was performed using a RT^2 first strand kit (Qiagen,

Valencia, CA, United States; #330401), according to the manufacturer's protocol. qRT-PCR was performed with the RT^2 SYBR Green ROX qPCR MasterMix (Qiagen, Valencia, CA, United States; #330523) in a total volume of 25 μL using the following RT^2 Primer Assays: MUC2 (Qiagen, Valencia, CA, United States; #PPR69984A), MUC5AC (Qiagen, Valencia, CA, United States; #PPR59660B), CK19 (Qiagen, Valencia, CA, United States; #PPR44322A) and CK20 (Qiagen, Valencia, CA, United States; #PPR44539A). Real-time PCR reactions were conducted at 95 ℃ for 15 min, followed by 40 cycles of 94 ℃ for 15 s, 55 ℃ for 30 s, and 70 ℃ for 30 s, using a StepOnePlus real-time quantitative system (Applied Biosystems; Carlsbad, CA, United States). Raw data was exported from the real-time instrument software and relative gene expression was calculated using the ΔΔ-Ct method. B-Actin (Qiagen, Valencia, CA, United States; #PPR0650C-200) and RPLP1 (Qiagen, Valencia, CA, United States; #PPR42363C-200) were selected as endogenous controls. All samples were normalized against pathologically confirmed normal squamous esophagus and run in technical triplicates.

Statistical analysis

Statistical analysis was conducted by a biomedical statistician using SPSS software (IBM, Armonk, NY, United States; Version 23). The gene expression levels in normal squamous esophagus, esophagitis, BE, dysplasia, and EAC tissues were compared by an independent 2-tailed *t* test to identify significant differences in expressions. A $P < 0.05$ was considered to be statistically significant.

RESULTS

Surgical model and outcomes

Fifteen percent of the operated animals died before the intended endpoint of the experiment, and necropsies were performed on all euthanized and found dead animals to identify the cause of death. Of these, 23.5% animals died within 2 wk post-surgery due to surgical and procedure-related complications, such as anastomotic leaks and continuous gastrointestinal hemorrhage. An additional 26.5% of the animal deaths were between 2-10 wk following surgery, with the major cause of death being stomach ulcer perforation. The remaining 50% of animal deaths were 10 wk after surgery, and the major causes of mortality were attributed to respiratory infection secondary to aspiration, stomach ulcer perforation, and obstruction due to tumor or late anastomotic stricture. Overall, the anastomotic leak rate for the study was 2.2%. A randomized cohort of 47 animals was preselected and utilized for histopathology and gene expression. The effective numbers of rats examined for study endpoints were as follows: non-operated (n = 6), 10 wk (n = 6), 17 wk (n = 8), 24 wk (n = 9), 31 wk (n = 6), 38 wk (n = 6), and 40 wk (n = 6) after surgery.

Histological findings

The results of histological findings for each disease level at each time point are shown in Table 1. All animals that underwent EJ showed histological features of esophagitis and proliferative hyperplasia from 10 wk following surgery (Figure 3B). BE was observed as early as 10 wk (16.7%; 1/6 animals) following surgery, and 100% of animals at 17, 31, and 38 wk showed the presence of BE (Figure 3C). Dysplasia was first recognized at 17 wk post-surgery (87.5%; 7/8 animals), and the incidence increased over time to 100% at 31-40 wk (Figure 3D). EAC was first observed at 24 wk (44.4%; 4/9 animals) post-surgery and sequentially increased to 100% at 40 wk. All of the neoplastic cases were localized to the esophagus just above the esophagojejunal anastomosis. Five of 6 (83.3%) EAC cases at 40 wk were well-differentiated mucinous carcinomas (Figure 3E). In addition, two animals at 38-40 wk post-surgery had confirmed macro-metastases in the lung/liver and small intestine, respectively (Figure 4).

Gene expression analysis

The relative *MUC2* gene expression was highest in BE, and it was progressively down-regulation across the BE-dysplasia-adenocarcinoma spectrum. When compared to normal squamous esophagus, BE, dysplasia, and EAC had significantly higher expression levels of MUC2 (P = 0.017, 0.005 and < 0.001, respectively). Additionally, there was significant difference in *MUC2* gene expression between esophagitis and BE (P = 0.028) (Figure 5A). The relative *MUC5AC* gene expression was highest in EAC and lowest in BE among esophageal disease types. Esophagitis, dysplasia,

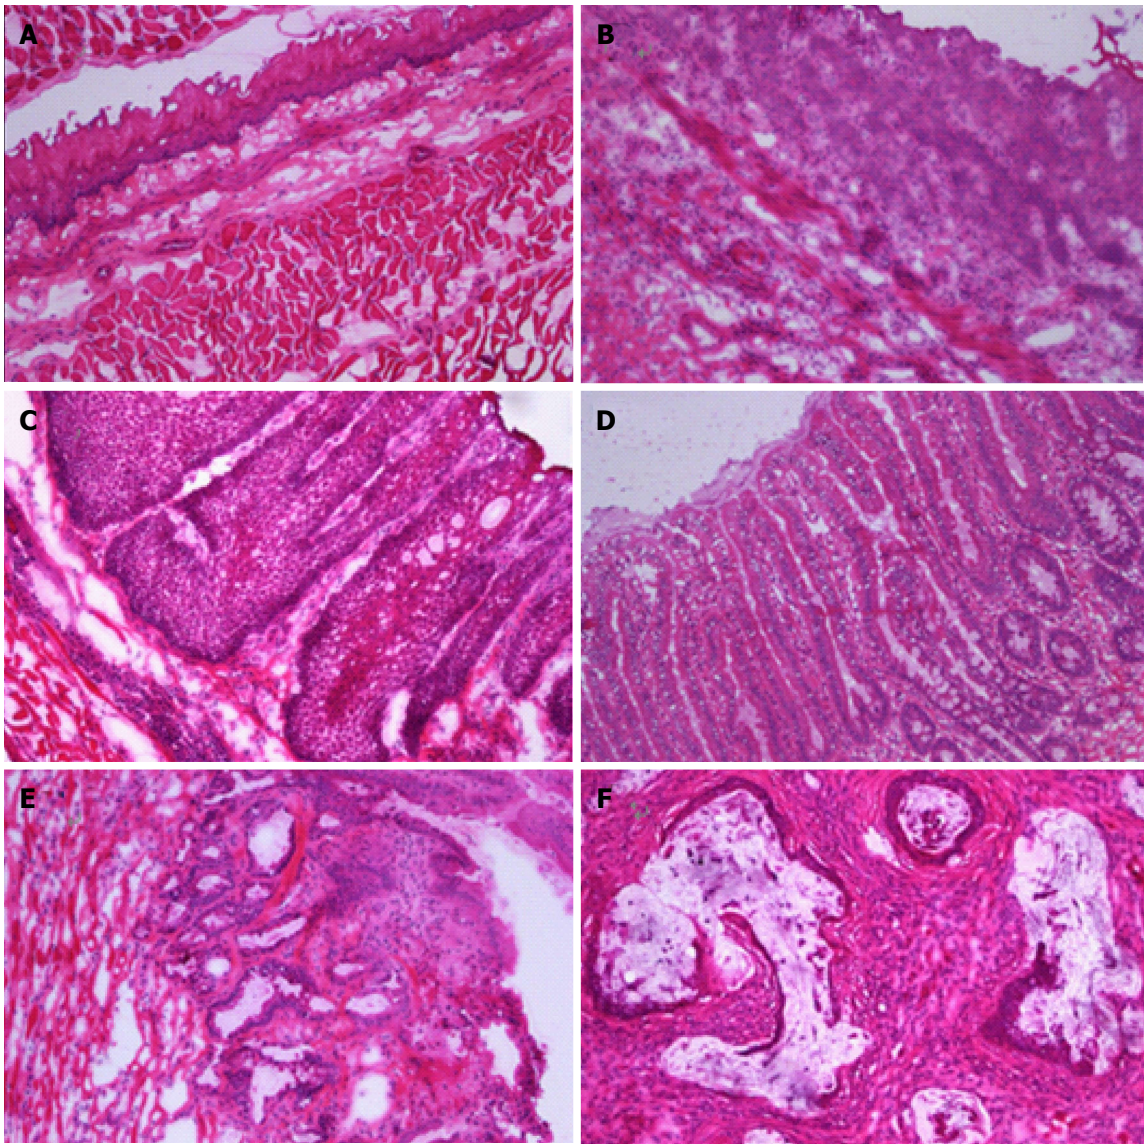

Figure 3 HE staining of esophageal disease progression (× 10). A: Normal rat esophagus; B: Esophagitis; C: BE with goblet cells; D: Dysplasia; E: EAC. EAC: Esophageal adenocarcinoma; BE: Barrett's esophagus.

and EAC had significantly higher expression levels of MUC5AC, compared to normal squamous esophagus (P = 0.03, 0.021, and 0.029, respectively) (Figure 5B). Both *CK19* and *CK20* gene expression increased in a stepwise manner from esophagitis to EAC. All four histological stages (esophagitis, BE, dysplasia, and EAC) had significantly higher *CK19* and *CK20* expression levels than normal squamous esophagus (*CK19*: P = 0.019, 0.015, < 0.001 and < 0.001, respectively; *CK20*: P = 0.047, 0.018, 0.001 and < 0.001, respectively) (Figure 5C and D).

DISCUSSION

The present study describes a detailed surgical technique and efficient perioperative management for the modified Levrat surgery of end-to-side esophagojejunostomy with gastric preservation. Implementation of the outlined standards provided maximal utilization of the model to produce a high tumor burden balanced with minimal mortality. Additionally, successful management of perioperative complications allowed us to extend the postoperative window to 40 wk to evaluate well-differentiated EAC and metastasis.

The overall mortality rate in this study was 15%, with 23.5% of the total mortality within the first 2 wk post-surgery, resulting in an overall procedure-related mortality of only 3.5%. This rate was lower than that reported by other investigators for the modified Levrat model[20,21]. Improved and aseptic surgical techniques and perioperative managements may have also contributed to the reduction of operative mortality. Of note, taking special care to include the esophageal mucosa when constructing the anastomosis was essential to obtain adequate mucosal-to-mucosal apposition. Additionally, covering the anastomotic site with omentum minimized the risk of anastomotic leakage post-surgery. A postoperative progressive

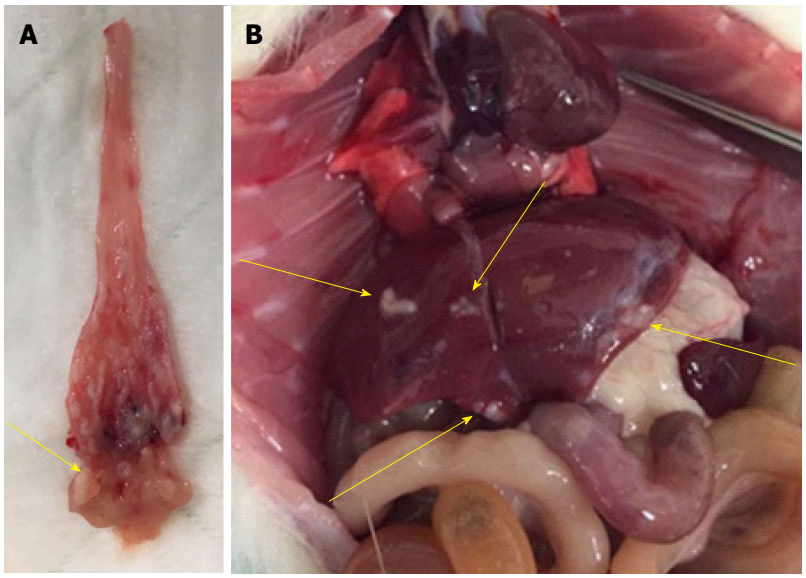

Figure 4 Primary esophageal adenocarcinoma tumor (A) and respective liver metastasis (B), as grossly observed in a 40-wk post-surgical rat.

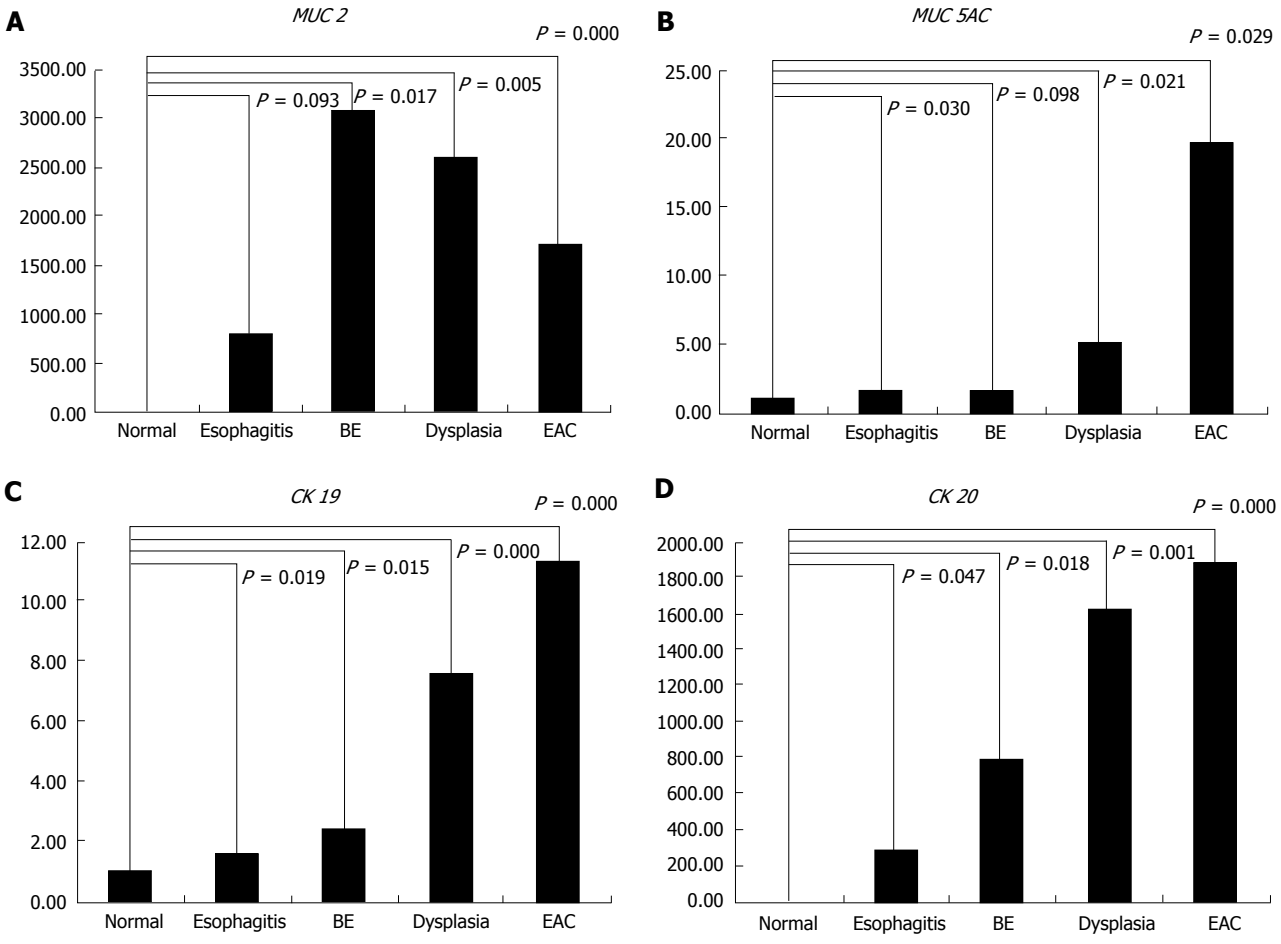

Figure 5 Panel A to D represents the relative gene expression level of *MUC2*, *MUC5AC*, *CK19*, and *CK20* for each esophageal disease level, respectively. BE: Barrett's esophagus; EAC: esophageal adenocarcinoma.

modified diet plan greatly contributed to the protection of the surgical site for the first 10 d after surgery to minimize leak rate. Additionally, supplemental diets provided during periods of weight loss or illness minimized acute morbidity, as anastomotic stricture or tumor growth presented a significant risk factor for obstruction.

As shown in the present study, the rat reflux model induced by EJ displayed sequential changes in the esophageal epithelium at the site of anastomosis and distal esophagus, similar to those seen in human esophagus. Dysplastic changes were first recognized

near the anastomosis in 87.5% rats at 17 wk post-surgery. Additionally, 83.3% (5/6 animals) and 100% (6/6 animals) of the animals evaluated at 38 wk and 40 wk post-surgery showed histological evidence of EAC at the site of anastomosis with an adjacent area of dysplastic BE, respectively. The overall incidence of EAC reported in this study was higher compared to other previously reported rates of only 17.4% at 30 wk and 74% at 40 wk for the rat surgical reflux model[22,23]. This difference is likely a direct result of improved surgical techniques and successful management of health complications that allowed for the extension of the perioperative window to 40 wk. Additionally, frequent iron injections may enhance esophageal carcinogenesis by increasing oxidative stress[24]. In other words, oxidase damage could be a contributing factor in the formation of EAC in the rat reflux model, and may similarly occur in human patients with GERD and iron overload. Moreover, the high incidence of EAC and the presence of distant metastasis at 38-40 wk post-surgery may indicate that the 38-40 wk time point is ideal for the study of EAC progression and metastasis in the modified Levrat model.

Since Levrat and colleagues first described the surgically induced reflux model of esophagitis by performing ED in rats, it has been extensively used to study esophageal carcinogenesis and to evaluate novel preventive and treatment strategies[25-27]. In our previous studies, we have utilized the modified Levrat' s surgical model for studying both chemoprevention and targeted therapy and have demonstrated potent efficacy for multiple cancer mechanistic inhibitors against EAC progression[20,28,29]. For the first time, we demonstrated macro-metastatic lesions originating from the primary tumors in the model[30]. Additionally, we further enhanced the utility of the model through combined magnetic resonance imaging (MRI) and small animal endoscopic biopsy to simultaneously track *in vivo* tumor volumes and molecular correlates longitudinally[31]. With these advancements, the animal model has been highly efficient, not only to develop preventative and treatment strategies, but also to provide a platform to better understand the molecular mechanisms that affect disease progression from inflammation to EAC.

The identification and validation of molecular biomarkers that modulate expression across the progression spectrum may serve as powerful tools for early detection, risk stratification, prognosis, and the development of treatment strategies for EAC. The present study assessed the expression levels of *MUC2, MUC5AC, CK19,* and *CK20* at each esophageal disease level harvested from surgically induced rat reflux model. Interestingly, compared to normal squamous esophagus and esophagitis, statistically significant *MUC2* expression was highest in BE and then progressively down-regulated through the neoplastic sequence.

Mucin genes are expressed in a site specific manner in the human gastrointestinal tract, and all MUC subtypes are aberrantly expressed in Barrett's metaplasia[32,33]. Although BE had a low *MUC5AC* expression level in this study, the expression pattern of *MUC2* was consistent with reported human esophageal literature[6,7,34]. Furthermore, this study demonstrated a relative stepwise increase in expression of *CK19* and *CK20* across the EAC progression. This result may support the possible role of these markers for early detection and risk stratification.

Limitations of the study included small sample size and precision of histological macrodissection. Although the sample set utilized for molecular analysis was small, a quantitative RT-PCR approach was utilized to determine gene expression. Additionally, an inherent limitation of macrodissection included possible inadvertent inclusion of heterogenous tissue that could conceal a specific cell-type signature. Therefore, further investigation with a larger sample size, or applying a microdissection technique to isolate a highly-enriched pure cell population may be beneficial.

In summary, the present study displays improved surgical technique and successful perioperative management of the modified Levrat model to enhance the value in context of a low mortality rate and consistently higher disease burden. This will enable broader adoption of the model to facilitate further research into the pathophysiology and biology of EAC. We further demonstrated a unique expression pattern of *MUC2*, *CK19*, and *CK20* that was relevant to human EAC progression, reinforcing the possible utility as conserved diagnostic molecular markers of BE and EAC.

COMMENTS

Background

Esophageal adenocarcinoma (EAC) is an extremely lethal disease with an overall survival rate of less than 20%. Small animal models are required to efficiently replicate and study the biology and pathogenesis of human EAC.

Research frontiers

Currently, the treatment options for EAC are outdated, reflected by lack of improvement in patient outcomes over the last three decades, thereby establishing the need for the development of new and improved therapeutic paradigms. The modified Levrat surgery in a rat model has been previously utilized successfully to accelerate development of such agents for chemoprevention, but significant improvements are required to expand the applicability for treatment of established-disease.

Innovations and breakthroughs

These findings report a validated highly replicable protocol to study EAC carcinogenesis and subsequent utilization for treatment efficacy studies. For the first time, the authors demonstrate a significantly reduced mortality rate and increased tumor burden. Additionally, they further validate the translatable nature of the model through gene expression analysis of conserved markers of human Barrett's carcinogenesis, such as mucin and cytokeratin.

Applications

The reported methodology will allow for more efficient utilization of the model to study EAC disease progression and treatment options, which in turn will be translated to clinical settings to improve patient prognosis.

Peer-review

This is a well-designed basic study. Authors in this study generated modified End-to-side esophagojejunostomy (EJ) rat model. Using this model, authors determine respective rates of carcinogenic development and gene expression levels of *MUC2*, *CK19*, and *CK20*. In order to better understand the underlying biology and prevent and treat EAC, the modified EJ model generated in the present study and the data obtained are important for understand disease progression spectrum from Barrett's esophagus to metastatic EAC.

Abstract

AIM

Influence of chronic hyperglycemia on chemical coding of enteric neurons in stomach using pig as a model for human diabetic complications.

METHODS

Ten pigs were divided into two groups: diabetic (D group, n = 5) and control (C group, n = 5). Pigs constituting the experimental group were given streptozotocin (150 mg/kg). Animals were euthanized

six weeks after the induction of diabetes. The samples of stomach were collected from animals of both groups. The cryostat sections were processed for double immunofluorescence staining using primary antisera directed towards pan-neuronal marker (Hu C/D) proteins and/or neuronal isoform of nitric oxide synthase (nNOS), vasoactive intestinal peptide (VIP) and galanin (GAL).

RESULTS

In the control group in the myenteric ganglia (MG) of the corpus we have noted 22.28% ± 1.19% of nNOS positive neurons, while in diabetic group we have found 40.74% ± 2.22% of nNOS immunoreactive perikarya (increase by 82.85 %). In turn in the pylorus we have observed 15.91% ± 0.58% nNOS containing neurons in control animals and 35.38% ± 1.54% in the diabetes group (increase by 122.37%). In the MG of the antrum and submucosal ganglion (SG) in the corpus hyperglycemia did not cause statistically significant changes. With regard to VIP-positive cell bodies in the antrum MG in the control animals we have noted 18.38 ± 1.39% and 40.74% ± 1.77% in the experimental group (increase by 121.65%). While in the corpus we have observed 23.20% ± 0.23% in the control and 30.93% ± 0.86% in the diabetes group (increase by 33.31%). In turn in the pylorus VIP positive cells bodies constituted 23.64% ± 1.56% in the control group and 31.20% ± 1.10% in the experimental group (increase by 31.97%). In the submucosal ganglion in the corpus we have noted 43.61% ± 1.06% in the control animals and 37.00% ± 1.77% in the experimental group (decrease by 15.15%). Expression of GAL-positive perikarya showed statistically significant changes only in the MG of the antrum and pylorus. In the antrum GAL positive perykarya constituted 26.53% ± 1.52% in the control and 36.67% ± 1.02% in the experimental animals (increase by 38.22%). While in the pylorus GAL positive neurons in the control group constituted 16.32% ± 0.92% and 17.99% ± 0.38% in the experimental animals (increase by 10.23%).

CONCLUSION

Our results support the hypothesis that in the course of diabetes, long term episodes of high glucose serum level may influence the chemical phenotyping of enteric neurons.

Key words: Immunohistochemistry; Inhibitory neurons; Streptozotocin; Hyperglycemia; Pig

© The Author(s) 2017. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: Our results revealed the neuronal plasticity of enteric neurons within porcine stomach in response to chronic hyperglycemia. We used the pig as a model for human gastrointestinal disorders occurring in people with diabetes. Our study highlights the important role of the enteric nervous system in response to high glucose serum level. We observed a substantial increase in the expression of nitric oxide, galanin and vasoactive intestinal peptide inside the enteric neurons. Since all of the investigated molecules have inhibitory properties, they may be involved in the impairment of the motor function of the stomach occurring in people with long-term diabetes.

INTRODUCTION

Diabetes is one of the most frequently diagnosed endocrinopathies worldwide[1,2]. Long-term episodes of hyperglycemia often occur during course of diabetes. As a consequence of poorly-controlled glucose serum level, numerous tissue and organ dysfunctions can occur[3]. The central, peripheral and autonomic neurons are particularly vulnerable to carboxylic stress, which is a consequence of hyperglycemia[4]. One of the many consequences of autonomic system damage are numerous disorders in the gastrointestinal tract[5-7]. They can involve any organ in the digestive system, such as the esophagus, stomach, gallbladder tract, pancreas, small and large intestines. Generally, they are referred to as diabetic gastrointestinal autonomic neuropathy[5,8]. These disorders are not directly life-threatening, but often lead to a significant impairment in the quality of life[9]. Up to 75% of patients with long-term diabetes experience gastric motor dysfunction, leading to the following symptoms: constipation, nausea, heartburn, post-prandial fullness, abdominal pain as well as diarrhea[10,11].

In physiological conditions, the enteric nervous system (ENS) regulates the function of the gastrointestinal tract. ENS (called the "enteric brain") is independent of the central nervous system control[12]. This unique arrangement of neurons is organized in the muscular and submucosal plexuses and can control secretion processes, absorption and gastrointestinal motility[13]. The functioning of enteric neurons is based on the secretion of a broad spectrum of neurotransmitters, which are structurally and chemically differentiated[14]. The most useful division of bioactive substances of enteric neurons include two classes of neurons: inhibitory and excitatory[12,13]. The nitric oxide (NO) produced by enteric neurons is a major non-adrenergic, non-cholinergic (NANC) inhibitory neurotransmitter which mediates smooth muscle relaxation in the gastrointestinal tract and is, therefore, an important factor in the stomach and gut contractility[14]. Vasoactive intestinal peptide (VIP),

together with NO comprise the primary inhibitory NANC neurotransmitters[15]. The biological activity of VIP leads to hyperpolarization of the smooth muscle fibers. Moreover, the relaxation function of VIP involves increased production of NO in smooth muscle cells[14,15]. Consequently, VIP acts as an inhibition factor of gastric emptying and reduced gastric acid secretion. Simultaneously, VIP is involved in the regulation of blood flow in the submucosal layer[16]. It is also essential that this substance has an effective neuroprotective function. This has been confirmed by the increasing survival of neurons previously damaged by lipopolysaccharide, as well as in the case of axotomy[17,18]. Galanin (GAL) can play both inhibitory and excitatory functions, depending on the digestive tract region, as well as the animal species. For example, in the dog ileum galanin is an excitatory factor while in the guinea pig it exhibits an opposite action[19].

Notably, in the field of metabolic disorders, the pig has gained appreciable interest as its metabolic, biochemical and pathophysiological response to diabetes partly mimics that observed in humans[20-22]. It has been shown that the blood supply of the porcine pancreas is similar to the human pancreas and the number of insulin-producing cells is within a similar range as observed in humans, making it a valuable model for the study of diabetes[23]. The most suitable and generally accepted pig model of hyperglycemia is streptozotocine-induced type 1 diabetes, where carbohydrate metabolism and pancreatic insulin secretion remain at a very similar level to humans with long-term diabetes[20]. Thus, taking advantage of its close similarity to humans, we raised the question of how the porcine gastric enteric neurons adapt to hyperglycemia. Therefore, the aim of this study was to provide data on the adaptive changes in chemical phenotyping, including inhibitory substances [vasoactive intestinal polypeptide, galanin and neuronal isoform of nitric oxide synthase (nNOS)] in the gastric enteric neurons of streptozotocin-induced hyperglycemic pigs.

MATERIALS AND METHODS

Animals

Ten juvenile both sex pigs of the White Large Polish breed, weighing from 17.0 kg to 20 kg, were used in this study. The pigs were randomly divided into two groups: diabetic (D group, n = 5) and control (C group, n = 5) and were housed in cages suitable for pigs. Prior to the experiment initiation, the animals were given one week of acclimatization to observe their general health, to minimize physiological stress and to ensure the proper conduct of the study. All treatment of animals was conducted in compliance with the instructions of the Local Ethical Committee in Olsztyn (Poland) (decision number 13/2015/DTN) with special attention paid to minimizing any stress reaction.

Chemical induction of diabetes

After acclimatization, hyperglycemia in the diabetic group was induced by use of streptozotocin (STZ) (Sigma-Aldrich, St Louis, MO, United States, S0130) 150 mg/kg of body weight, dissolved in a freshly-prepared disodium citrate buffer solution (pH = 4.23, 1 g streptozotocin/10 mL solution). For this purpose, pigs were anesthetized and the solution was administrated *via* intravenous needle inserted into an ear with continuous infusion for approximately 5 min. To avoid nausea and vomiting after streptozotocin injection, animals were fasted for 18 h before the experiment and the control pigs were injected with equal amounts of vehicle (citrate buffer).

General health condition evaluation

The pigs were continuously observed for 24 h after streptozotocin injection. In order to avoid temporary hypoglycemia, 250 mL of a 50% glucose solution per animal was administered intravenously. The pigs received a normal diet throughout the whole time of the experiment twice a day and tap water ad libitum. The blood glucose level was measured to confirm diabetes. The blood glucose concentration was estimated using an Aceent-200 (Cormay) biochemical analyzer, with the colorimetric measurement at a wavelength of 510 nm/670 nm. For this purpose, capillary blood from the ear was collected. The plasma glucose level was measured prior to the experiment initiation in both control and experimental groups. The next measurement was made 48 h after the induction of diabetes. Subsequent measurements of glucose levels were monitored weekly until the end of the experiment.

Tissue collection

Six weeks after streptozotocin injection, animals were deeply anesthetized *via* intravenous administration of pentobarbital (Vetbutal, Biowet, Poland) and perfused transcardially *via* the ascending aorta with 4% paraformaldehyde in a 0.1 mol/L phosphate buffer (PB, pH 7.4). The samples were post-fixed by immersion in the same fixative for 1 h, rinsed several times with phosphatase buffer (PB) and then transferred into 30% sucrose solution and stored at 4 ℃ until sectioning. The tissue blocks were cut in frontal or sagittal planes using a Microm HM 560 cryostat (Carl Zeiss, Germany) at a thickness of 12 μm and mounted on gelatinized glass slides.

Immunofluorescence procedure

The sections were processed for a double immunofluorescence staining. Briefly, after air-drying at room temperature for 45 min and rinsing in 0.1 mol/L phosphate-buffered saline (PBS; pH 7.4; 3 ×

Table 1 Serum glucose levels

Date	Control group (mmol/L)	SE	Experimental group (mmol/L)	SE
Before streptozotocin injection	5.01	0.10	5.030	0.10
1 wk after streptozotocin injection	5.08	0.10	17.36	0.38
2 wk after streptozotocin injection	4.91	0.18	20.72	0.24
3 wk after streptozotocin injection	5.19	0.06	21.58	0.27
4 wk after streptozotocin injection	5.31	0.12	20.08	0.09
5 wk after streptozotocin injection	4.84	0.32	22.26	1.21
6 wk after streptozotocin injection	5.20	0.10	21.45	1.11

Serum glucose levels in controls and after induction of diabetes by streptozotocin administration (up 1 to 6 wk).

10 min), the sections were incubated in a blocking buffer containing: 10% of normal goat serum (MP Biomedicals, United States), in 0.1 mol/L PBS, 0.1% donkey serum (Abcam, United Kingdom), 1% Triton X-100 (Sigma-Aldrich, United States), 0.05% Thimerosal (Sigma-Aldrich, United States) and 0.01% NaN_3 for 1 h at room temperature to reduce non-specific background staining. Subsequently, after another wash in PBS (3 × 10 min) the sections were incubated overnight at 4 ℃ with primary antibodies raised in different species and directed towards general neuronal marker Hu C/D proteins (mouse polyclonal: Invitrogene United States; code A-212711:1000 working diluted 1:1000), anti-nNOS antibodies (rabbit polyclonal: Chemicon, Billerica, MA, United States, cat. No. AB 5380; working dilution 1:4000), VIP (rabbit polyclonal; Biomol, Hamburg, Germany, cat. No. VA1285; working dilution 1:6000) and GAL (rabbit polyclonal: Millipore, Billerica, MA, United States, cat. No. AB 2233; working dilution 1:1000). All antibodies were diluted in PBS containing 0.3% Triton X-100 and 1% BSA. On the following day, the sections were rinsed (PBS, 3 × 15 min) and incubated with secondary antibodies (donkey anti-mouse Alexa Fluor 488, 1:1000 Invitrogen United States; code A21202, and donkey anti-rabbit Alexa Fluor 546 1:1000 Invitrogen, United States; code A10040) diluted in PBS containing 0.25% BSA and 0.1% Triton X-100) for 4 h. The sections were then rinsed three times (PBS, 3 × 5 min) and mounted in fluorescent mounting medium (DAKO, Carpinteria, CA, United States). The prepared specimens were viewed and photographed using an Olympus BX51 microscope equipped with epi-fluorescence and appropriate filter sets, coupled with a digital monochromatic camera (Olympus XM 10) connected to a PC and analyzed with Cell Dimension software (Olympus, Tokyo, Japan). Standard controls, *i.e.*, pre-absorption of the neuropeptide antisera with appropriate antigen, omission, and replacement of the primary antisera by non-immune sera, were performed to test the antibodies and specificity of the method. The test was performed as follows: sections of the stomach were incubated with "working" dilution of the primary immunoserum, which had been previously pre-absorbed for 18 h at 37 ℃ with 20 μg of appropriate purified protein VIP (064-24, Phoenix Pharmaceutical), GAL (026-06, Phoenix Pharmaceutical) and nNOS (N3033, Sigma, St Louis, MO, United States). Additional negative controls, such as omission and replacement of all primary antisera with non-immune sera, were also performed. This procedure completely eliminated specific staining.

Counting of the nerve structures and statistical evaluation

The number of nNOS, VIP and GAL-like immuno-reactive (LI) enteric neurons was expressed as a percentage of the total number of Hu C/D positive perikarya. At least 700 Hu C/D labeled cell bodies of intramural ganglia and each part of the stomach were examined. Only neurons with well-visible nucleus were counted. To prevent the double-counting of Hu C/D immunoreactive neurons, the sections were located at least 100 μm apart. Data pooled from all animals groups were statistically analyzed using Statistica 10 software (StatSoft Inc., Tulsa, OK, United States) and were expressed as a mean ± SE. Significant differences were evaluated using Student's *t*-test for independent samples ($^aP < 0.05$, $^bP < 0.01$, and $^cP < 0.001$).

RESULTS

Plasma glucose level and physiological status

The baseline plasma glucose level measured in animals before STZ treatment and the development of hyperglycemia were both within standard reference values for the pig (5.01 mmol/L ± 0.10 mmol/L). During the weeks following STZ implementation, a consistent increase in plasma glucose concentration was observed. A significant 3.4 -fold (17.36 mmol/L ± 0.38 mmol/L) increase in glucose level was observed on the 7th day after STZ injection and 4-5 wk after the injection the highest increase (4.4 fold) level of glucose was observed (22.26 mmol/L ± 1.21 mmol/L). In the last week of experiment, the baseline serum glucose level decreased slightly, reaching 21.24 mmol/L ± 1.11 mmol/L. The mean glucose concentration during the experimental period is presented in Table 1.

Despite significant hyperglycemia, none of the diabetic animals showed any abnormalities throughout the entire period of the experiment. Moreover, none of the animals required exogenous insulin injection.

Immunofluorescence

All biologically active substances studied were presented in the investigated area of the stomach (Table 2). In the control group, the nNOS distribution varied and clearly depended on the analyzed area of the stomach (Figure 1A-S and Figure 2A-F). In the myenteric ganglia (MG) of the antrum, the total number of nNOS neurons was 37.12% ± 2.81% (Figure 1A-C), while in the corpus,

Table 2 The average percentage of neurons immunoreactive to bioactive substances used in this study

Stomach part	Control group			Experimental group		
	Antrum	Corpus	Pylorus	Antrum	Corpus	Pylorus
		nNOS[1]			nNOS[1]

[1]Relative frequency of particular neuronal subclasses is presented as percent (mean ± SE) of all neurons counted within the ganglia stained for Hu C/D proteins. nNOS, VIP and GAL immunoreactive perikarya in various parts of the porcine stomach under physiological conditions (Control group) and during experimentally induced hyperglicemia (Experimental group). Statistically significant data ([a]$P < 0.05$, [b]$P < 0.01$, and [c]$P < 0.001$) in particular animal group are marked by superscripted alphabetical lettering. nNOS: Neuronal isoform of nitric oxide synthase; VIP: Vasoactive intestinal peptide; GAL: Galanin; Hu C/D: Pan-neuronal marker.

the quantity of nNOS positive cells bodies inside the MG was relatively lower 22.28% ± 1.19% (Figure 1G-I). Additionally, in submucosal ganglion (SG) in the corpus, nNOS-LI neurons were estimated at 18.62% ± 1.66% (Figure 2A-C). In the pylorus, in MG about 15.91% ± 0.58% nNOS-LI were observed (Figure 1M-O).

Although experimentally-induced hyperglycemia contributed to the expression of nNOS in enteric neurons, the changes were differentiated. Statistically significant changes were observed in the MG in the corpus from 22.28% ± 1.19% to 40.74% ± 2.22% (increase by 82.85%) (Figure 1J-L) increased of 18.46% and in the pylorus from 15.91%±0.58% to 35.38% ± 1.54% (increase by 122.37%) (Figure 1P-S) increased of 19.47%. In contrast, in the MG in the antrum and SG in the corpus, hyperglycemia did not cause statistically significant changes (Figures 1D-F and 2D-F).

The other investigated substance was VIP. As in the case of nNOS, VIP-positive cells were presented in all studied areas, but clear differences were noted between the various regions of the stomach (Figures 2G-L and 3A-S). In the control group the largest number of VIP-positive cells bodies were noted within the SG in the corpus 43.61% ± 1.06% (Figure 2G-I). Definitely fewer VIP-positive perikarya were observed within the MG in the antrum 18.38% ± 1.39% (Figure 3A-C), pylorus 23.64% ± 1.56% (Figure 3M-O) and MG of the corpus 23.20% ± 0.23% (Figure 3G-I).

In the diabetic group, statistically significant changes were observed in all investigated areas. The highest increase in VIP-immunopositive perikarya was noted in the MG inside the corpus from 18.38% ± 1.39% to 40.74% ± 1.77% (increase by 121.65%) (Figure 3J-L). With regard to MG in the antrum and pylorus, the changes in chemical coding were relativity smaller from 23.20% ± 0.23% to 30.93% ± 0.86% (increase by 33.31%) inside to antrum (Figure 3D-F) and from 23.64 ± 1.56% to 30.47% ± 1.10% inside to pylorus, respectively (increase by 31.97%) (Figure 3P-S). However, in the SG of the corpus, a decrease in the number of VIP-LI neurons was noted from 43.61% ± 1.06% to 37.00% ± 1.77% (decrease by 15.15%) (Figure 2J-L).

As in the case of previously studied substances, the distribution of GAL varied and clearly depended on the area of the stomach (Figure 2M-S and 4A-S). In the control group, the largest population of cells were observed in the MG of antrum 26.53% ± 1.52% (Figure 4A-C). In the MG in the area of corpus and pylorus, a comparable number of GAL-positive neurons were observed 17.73% ± 1.12% in the corpus (Figure 4G-I) and 16.32% ± 0.43% in the pylorus (Figure 4M-O). The highest population of GAL-positive perikarya was noted in the SG in the corpus 41.42% ± 0.88% (Figure 2M-O).

In the diabetic group, statistically significant changes were noted only in the MG in the antrum and pylorus, whereas increased expression of GAL-LI in enteric neurons was observed from 26.53% ± 1.52% to 36.67% ± 1.02% in the antrum (increase by 38.22%) (Figure 4D-F) and from 17.73% ± 1.12% to 17.99% ± 0.38% in the pylorus (increase by 10.23%) (Figure 4P-S). However, in the corpus in both the MG and SG, the population of GAL-LI neurons changed in a statistically insignificant manner compared to the control group (Figures 4J-L and 2P-S).

DISCUSSION

Autonomic neuropathy is a commonly occurring complication in poorly-controlled blood glucose level patients. Studies of the development mechanisms of this pathology have been conducted in many research center[4,5,8,23]. Moreover, different animal models have been used to determinate the exact mechanism of diabetes complications[24]. Thus, there are doubts as to whether the pig is a suitable model for the study of diabetic autonomic neuropathy occurring in patients with long-term diabetes. Unfortunately,

since spontaneous diabetes in large domestic animals such as the pig are extremely rare[25], it is important to select an appropriate method leading to the induction of diabetes and, thus, the development of hyperglycemia. Total pancreatectomy is a technique involving a considerable mortality rate of animals and is

not presently used[25]. Therefore, in the present study we used streptozotocin administered intravenously in order to induce diabetes. This method is widely-accepted and used in many studies to determine the side-effects of elevated blood glucose[26]. In our study, the choice of streptozotocin as a diabetogenic substance also turned out to be the opposite, because all animals developed hypoglycemia during the first week of experiment and we did not note mortality falling during the study. Moreover, it is worth underlining that the type 1 STZ-induced hyperglycemic/diabetic pig model has been predominately validated in studies of the cardiovascular complications as well as in peripheral neuropathy[27,28]. On the other hand, diabetic gastroenteropathy, especially concerning the chemical phenotyping of enteric neurons in this model is unclear. The available data describing neurochemical changes in the ENS of hyperglycemic/diabetic animals are limited to the studies on small animal models, mainly rat and mice[29-34].

Our results demonstrated that the porcine ENS, exhibits alterations in the chemical coding of the inhibitory neurons after six weeks of sustained hyperglycemia. It is generally recognized that NO, together with a VIP, acts as inhibitory neurotransmitter in muscle and submucosal layer of gastrointestinal tract[14,15]. As shown in our results, a visible increase in nNOS expression was presented in the myenteric ganglion of the corpus and pylorus. Contrary to these results, in the MG of the antrum and in the SG of the corpus, changes in the synthesis of nNOS have not been noted. As mentioned above, the previous studies, of the chemical coding of enteric neurons were conducted mainly on rodents. The obtained results indicate a differential response of enteric neurons, depending on the duration time of hyperglycemia and the gastrointestinal tract region studied. Belai *et al*[29,30] described a decrease in nNOS expression in the antrum, while in the small intestine and colon the same authors did not find statistically important changes compared to the control group. Meanwhile, another study revealed an increased level of nNOS in the antrum during streptozotocin-induced diabetes in rats[32]. In turn, hyperglycemia evoked a visible increase in the number of myenteric neurons in all investigated areas and a slight decrease in VIP-LI immunoreactivity in the submucosal ganglia in the corpus. As previously reported in diabetic rats, chronic hyperglycemia caused a marked increase in the immunoreactivity of VIP, in both the submucosal and myenteric ganglion. However, in the myenteric plexus, the increase was preceded by a slight decrease in the intensity of VIP immunoreactivity[31,34]. It is worth underlining that since these results focused on the ileum, we cannot directly relate them to the stomach.

Galanin is a neurotransmitter which can play an inhibitory or excitatory role depending on the investigated area of gastrointestinal tract as well as animal species. Galanin is also a modulator regulating the activity of other neurotransmitters, including VIP and NO. In this study, although we have shown an essential increase of galanin expression in myenteric ganglion neurons in the antrum and pylorus, in the corpus of the stomach we did not observe statistically significant changes compared to the control group. To date, an increase in galanin immunoreactivity has only been observed in the colon of non-obese diabetic mice (NOD) and the ileum of 12-wk-old diabetic rats[31,35]. Only in obese mice with coexisting diabetes has a decrease of galanin in the colon been noted[35]. Taking into account our results and the available data on the expression of neuroactive substances in enteric neurons (especially on inhibitory properties) the common pattern of changes is generally acceptable, i.e. inhibitory neurotransmitters such as nNOS, VIP and GAL appear to decrease in the early stage of diabetes with an increase in later stages, possibly secondary to regeneration[7]. Our results clearly indicate that the neurotoxic effect of chronic hyperglycemia in pigs leads to neuronal regeneration, which is reflected by an up-regulation of the synthesis of NO, VIP and GAL. It is well-known that NO and VIP have strong neuroprotective activity[36-40]. Therefore, the ENS adapts to changes in environmental conditions, increasing the synthesis of biologically active substances which may play a protective role against cellular oxidative stress as a consequence of high glucose serum levels. Moreover, we have noted down-regulation of VIP expression in the corpus of the submucosal ganglion. The different reaction of submucosal neurons probably results from another function played by neurons which leads to regulation of secretory activity[16]. It is worth noting that since other investigated substances within the submucosal ganglion in the corpus of the stomach did not show statistically significant changes, we can conclude that these neurons have a different sensitivity to high glucose level.

Our results may partly explain the reason of gastrointestinal motility disorders observed in people with long-term diabetes. Increase of the expression of inhibitory substances may impair the function of the pyloric sphincter relaxation and the antrum contraction. Which, in turn, contributes to gastric emptying which has been observed in humans[11].

In conclusion, this is the first report describing changes in the expression of inhibitory substances in the intramural neurons of the stomach in hyperglycemic STZ-induced diabetic pigs. Our results indicate that after six weeks of high glucose serum level expression of inhibitory substances (such as NO), vasoactive intestinal polypeptide and galanin undergo significant changes (described as chemical phenotyping), which suggests that STZ-injected pigs might serve as a good model in early studies of autonomic nerve changes under hyperglycemic conditions. Furthermore, our data provide a background for more detailed studies on the contribution of enteric neurons to the pathogenesis

of gastrointestinal disturbances as well as reference data for further, pre-clinical studies on hyperglycemia-related autonomic neuronal changes in a species more closely related to humans.

COMMENTS

Background

Diabetes mellitus is associated with several changes in gastrointestinal (GI) tract motility that lead to nausea, bloating, abdominal pain, diarrhoea and constipation. Up to 75% of patients with diabetes can experience these symptoms. The pathogenesis of altered GI functions in diabetes is multifactorial and the role of the enteric nervous system (ENS) in this respect has gained significant attention. The neuronal remodelling affects the ratio of inhibitory neurons, which in turn leads to impaired of nerve mediated muscle responses and can contribute to the motility dysfunction seen in diabetes patients.

Research frontiers

Streptozotocin is widely used to induce experimental diabetes in animals. Its application leads to blood insulin levels decrease and result in development of hyperglycaemia. Long term elevated glucose level cause diabetic neuropathy.

Innovations and breakthroughs

This is the first study utilizing pig as a model species for human diabetes induced gastrointestinal complications. The results suggest that swine due to close physiological similarity to human especially concerning gastrointestinal tract function seems to be better model for biomedical research than rodents.

Applications

The results provide evidence that acute hyperglycaemia changes properties of neuromodulators/neurotransmitters in GI. Pharmacological modulation of selected biologically active substances can be potentially new approach for treatment of the diabetes evoked gastrointestinal complications.

Terminology

Streptozotocin treatment supplies a substrate for xanthine oxidase resulting in the formation of superoxide radicals. Consequently, hydrogen peroxide and hydroxyl radicals are also generated. Furthermore, streptozotocin liberates toxic amounts of nitric oxide that inhibits aconitase activity and participates in DNA damage. As a result of the streptozotocin action B cells undergo the destruction by necrosis.

Peer-review

The authors have provided evidence that long term episodes of artificially initiated hyperglycaemia induced changes of expression of neuronal isoform of nitric oxide synthase, vasoactive intestinal peptide and galanin in inhibitory neurons inside the stomach ENS. Those changes might be responsible for broad spectrum of gastrointestinal disturbances.

Abstract

AIM

To clarify the mechanisms of HOX transcript antisense intergenic RNA (HOTAIR) in gastric cancer (GC) migration and invasion.

METHODS

Quantitative real-time polymerase chain reaction (qPCR) was used to detect the expression level of HOTAIR in GC tissues. The correlation of its expression with clinicopathological features was analyzed. Area under receiver operating characteristic curve (AUC_{ROC}) was constructed to evaluate the diagnostic value of HOTAIR. Wound-healing assay and Transwell assay were performed to detect the biological effects of HOTAIR in GC cells. qPCR, western blot and

immunohistochemistry were used to evaluate the mRNA and protein expression of E-cadherin. RNA-binding protein immunoprecipitation was used for the analysis of EZH2 interactions with HOTAIR. Chromatin immunoprecipitation assay was performed to investigate direct interactions between EZH2 and E-cadherin.

RESULTS

The expression of HOTAIR was up-regulated in GC tumorous tissues compared with the para-tumorous tissues ($P < 0.001$). Its over-expression was correlated with tumor-node-metastasis (TNM) stage ($P = 0.024$), tumor invasion ($P = 0.018$), lymph node metastasis (P = 0.023), and poor prognosis ($P < 0.001$). Multivariate Cox regression analysis confirmed expression of HOTAIR as an independent predictor of overall survival ($P = 0.033$), together with TNM stage ($P = 0.002$) and lymph node metastasis ($P = 0.002$). The AUC_{ROC} was up to 0.709 (95%CI: 0.623-0.785, $P < 0.001$). Knockdown of HOTAIR by siRNA in GC cells suppressed the migration and invasion of GC cells. Significantly negative correlation between HOTAIR and E-cadherin was found in GC tissues and cell lines, and HOTAIR contributed to the regulation of E-cadherin through binding to EZH2 with the E-cadherin promoter.

CONCLUSION

HOTAIR may play a pivotal role in tumor cell migration and invasion. It can be used as a potential diagnostic and prognostic biomarker for GC.

Key words: Long noncoding RNA; HOX transcript antisense intergenic RNA; Gastric cancer; Migration and invasion; E-cadherin

Core tip: In this study, we found that HOX transcript antisense intergenic RNA (HOTAIR) expression was up-regulated in gastric cancer (GC) tissues. High expression of HOTAIR was associated with clinicopathological characteristics and poor prognosis in GC patients. Additional experiments revealed that HOTAIR knockdown significantly inhibited the invasion and migration of GC cells. We also tested whether HOTAIR recruited EZH2 to promote tumor cell migration and invasion by repressing E-cadherin in GC. The findings from our study will help clarify the role of HOTAIR in GC progression and its potential as a therapeutic target.

HOX transcript antisense intergenic RNA represses E-cadherin expression by binding to EZH2 in gastric cancer. *World J Gastroenterol* 2017; 23(33): 6100-6110 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6100.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6100

INTRODUCTION

Gastric cancer (GC) is one of the most common malignancies worldwide, having high rates of both incidence and mortality[1]. Even though remarkable progress has been made in surgical resection and chemotherapy, which are the main therapeutic approaches for GC, the prognosis continues to be dismal[2]. The main cause of treatment failure is cancer recurrence and metastasis[3,4].

Tumor metastasis is a complex process, in which cancer cells leave the primary tumor site and migrate to distant secondary organs. Metastatic cancer cells fractionally retain their epithelial properties and obtain mesenchymal characteristics that give them the ability to invade or distract[5]. This process is called epithelial-to-mesenchymal transition (EMT). EMT is characterized by E-cadherin expression loss and N-cadherin and vimentin up-regulation[6]. It is regulated by many signaling pathways, transcriptional factors and post-transcriptional factors[7]. Post-transcriptional regulatory networks include the miRNA and long noncoding (lnc)RNA families[8]. Emerging evidence shows that lncRNAs have an important role in regulating EMT and cancer metastasis[5,9]. Several important lncRNAs are reported to induce EMT, including highly upregulated in liver cancer (HULC)[10], metastasis-associated lung adenocarcinoma transcript (MALAT)-1[11], H19[12], and HOX transcript antisense intergenic RNA (HOTAIR)[13].

HOTAIR is identified as an oncogene involved in many kinds of cancers, including breast cancer[14], esophageal squamous cell carcinoma[15], colorectal cancer[16], and GC[13]. HOTAIR acts mainly through the polycomb repressive complex (PRC)2 (EZH2, RbAp46, RbAp48 and SUZ12)[17], which trimethylates histone H3 lysine-27 (H3K27) of the HOXD locus and repress HOXD gene expression[14]. EZH2 which is the core catalytic component of the PRC2, can affect cancer progression by altering H3K27 trimethylation and silencing transcription[17].

A previous study showed that silencing of HOTAIR inhibits GC cell migration, invasion and metastasis, and reverses the EMT in GC cells[13]. HOTAIR in combination with PRC2 could epigenetically inhibit miR34a, and control C-Met (HGF/C-Met/Snail pathway) and Snail, thus promoting the EMT process of GC cells and tumor metastasis[13]. However, the overall clinical role of HOTAIR in GC and the molecular mechanisms of HOTAIR involved in GC cell metastasis have not yet been fully investigated.

Up-regulation of HOTAIR expression in GC tissues was found in the present study. We also found that over-expression of HOTAIR was related to the clinicopathological characteristics of and poor prognosis in GC patients. Additional experiments revealed that HOTAIR knockdown significantly repressed migration and invasion. Finally, we tested whether HOTAIR recruited EZH2 to promote tumor cell migration and invasion by repressing E-cadherin in GC. These studies

will help clarify the role of HOTAIR in GC progression and its potential as a therapeutic target.

MATERIALS AND METHODS

Tissue collection and ethics statement

A cohort of 65 primary GC patients was enrolled in this study, each of who underwent surgery at the First Affiliated Hospital of Nanjing Medical University and Jining NO.1 People's Hospital between 2008 and 2009. None received chemotherapy or radiotherapy prior to surgery. This study was approved by the University Ethics Committee. All patients participated after providing informed consent. Tumor stage was evaluated in accordance with the tumor-node-metastasis (TNM) classification system (UICC/AJCC 2002). Clinical characteristics are shown in Table 1. Patients discharged from hospital were followed up routinely and according to a scheduled program, at least once a year.

Cell lines and culture conditions

Human GC cell lines SGC-7901and BGC-823 were obtained from the Chinese Academy of Sciences Committee on Type Culture Collection Cell Bank. Cells were cultured in RPMI 1640 or Dulbecco's modified Eagle's medium (Gibco-BRL, Shanghai, China) supplemented with 10% fetal bovine serum (FBS) (Invitrogen, Shanghai, China), 100 U/mL penicillin, and 100 mg/mL streptomycin (Invitrogen) in an incubator at 37 ℃ with 5% CO_2.

RNA extraction and quantitative polymerase chain reaction (qPCR)

Total RNA was extracted from the frozen tissues using TRIzol reagent (Invitrogen). RNA concentrations were estimated by spectrophotometer absorbance readings of 260 nm. One microgram of total RNA was used for reverse transcription to cDNA with a Reverse Transcription Kit (TaKaRa, Shiga, Japan). An ABI 7500 real-time PCR system (Applied Biosystems, Foster City, CA, United States) was used to quantify HOTAIR. Ten microliters of SYBR Premix Ex*Taq* (TaKaRa) was mixed. Primer sequences are listed in Supplementary Table 1. The relative expression was calculated using the equation: ΔCt = Ct (target gene) − Ct (GAPDH); Fold change = $2^{-[\Delta Ct(tumour) - \Delta Ct(nomal)][18]}$.

Cell transfection

HOTAIR small interfering (si)RNAs and negative control siRNA (si-NC) were purchased from Invitrogen. The siRNA sequences are listed in Supplementary Table 1. BGC-823 or SGC-7901 cells were grown in 6-well plates until confluent, then transfected with Lipofectamine 2000 (Invitrogen). At 48 h after transfection, cells were harvested for qPCR or western blot analysis.

Wound-healing assay

Cells were seeded in 6-well plates in normal cell growth medium and incubated to confluence. A 20-μL tip was used to make a straight scratch, simulating a wound. The medium was changed to medium containing 1% FBS. At different time points, images of the plates were acquired using a microscope.

Cell migration and invasion assays

For the migration assays, at 48 h after transfection, 5×10^4 cells in serum-free medium were placed into the upper chamber of an insert (8-μm pore size; Millipore, Bedford, MA, United States). For the invasion assays, 10^5 cells in serum-free medium were placed into the upper chamber of an insert coated with Matrigel (Sigma-Aldrich, St. Louis, MO, United States). Medium containing 10% FBS was added to the lower chamber. After incubation for 24 h, the cells remaining on the upper membrane were removed with cotton wool. Cells that had migrated or invaded through the membrane were stained with methanol and 0.1% crystal violet, imaged and counted in five random fields per well using an IX71 inverted microscope (Olympus, Tokyo, Japan). Experiments were repeated independently three times.

Western blot assay and antibodies

Cell protein lysates were separated by 15% SDS-PAGE, transferred to 0.22-μm nitrocellulose membranes

(Sigma-Aldrich) and incubated with specific antibodies. GAPDH antibody was used as a control. Autoradiograms were quantified by densitometry (Quantity One software; Bio-Rad, Hercules, CA, United States). Anti-E-cadherin was purchased from Abcam (Cambridge, United Kingdom). Anti-GAPDH was purchased from Cell Signaling Technology (Danvers, MA, United States).

RNA-binding protein immunoprecipitation assay

Binding protein immunoprecipitation assay (RIP) experiments were performed using a Magna RIP RNA-Binding Protein Immunoprecipitation Kit (Millipore). Antibody for EZH2 RIP assays was from Abcam.

Chromatin immunoprecipitation assay

Chromatin immunoprecipitation assay (ChIP) assays were performed using an EZ-CHIP KIT (Millipore). EZH2 antibody was obtained from Abcam. H3 trimethyl Lys 27 antibody was from Millipore. The ChIP primer sequences are listed in Supplementary Table 1. Quantification of immunoprecipitated DNA was performed using qPCR with SYBR Green Mix (TaKaRa). ChIP data were calculated as a percentage relative to the input DNA by the equation of $2^{(\text{Input Ct - Target Ct})} \times 0.1 \times 100$.

Immunohistochemistry

The immunohistochemical analysis of E-cadherin was performed as described previously[19]. To quantify E-cadherin protein expression, both the intensity and extent of immunoreactivity were evaluated and scored. In the present study, staining intensity was scored as follows: 0, negative staining; 1, weak staining; 2, moderate staining; and 3, strong staining. The scores of the extent of immunoreactivity ranged from 0 to 3, and were determined according to the percentage of cells that showed positive staining in each microscopic field of view (0, < 25%; 1, 25%-50%; 2, 50%-75%; 3, 75%-100%). A final score ranging from 0 to 9 was achieved by multiplying the scores for intensity and extent.

Statistical analysis

SPSS version 21.0 software was used for all statistical analysis. Significance of the differences between groups was estimated by Student's *t*-test, χ^2 test, or Mann-Whitney test. Survival curves were estimated by the Kaplan-Meier method. The log-rank test was used to estimate the statistical difference between survival curves. Cox proportional hazards analysis was performed to calculate the hazard ratio (HR) and the 95% confidence interval (CI) to evaluate the association between HOTAIR expression and overall survival (OS) time. Multivariate Cox regression was performed to adjust for other covariates. Spearman correlation analysis was performed to investigate the correlation between HOTAIR and E-cadherin mRNA expression. Receiver operating characteristic (ROC) curve was produced to evaluate the diagnostic value for differentiating between GC and adjacent non-tumor tissues. A two-tailed *P* value of $\leqslant 0.05$ was considered statistically significant. All the graphs were plotted using GraphPad Prism 6.0 (GraphPad Software, La Jolla, CA, United States).

RESULTS

HOTAIR was up-regulated in GC tissues

HOTAIR showed markedly higher expression in GC tissues as compared with matched adjacent non-tumor tissues ($P < 0.001$; Figure 1A).

Diagnostic value of using HOTAIR as a marker

An ROC curve was generated by comparing HOTAIR expression in GC tissues to expression in matched adjacent non-tumor tissues. With a cut-off value of 9.31, the area under the ROC curve (AUC_{ROC}) reached 0.709 (95%CI: 0.623-0.785, $P < 0.001$; Figure 1B). The sensitivity was 64.62%, the specificity was 75.38%, and Youden's index was 0.4.

HOTAIR expression and clinicopathological factors in GC

Patients with GC were divided into two groups based on the cut-off ratio of HOTAIR expression (2.35-fold) in tumor tissues: high-expression group ($n = 33$) and low-expression group ($n = 32$) (Figure 1C). Table 1 showed that HOTAIR over-expression was significantly correlated with tumor invasion ($P = 0.018$), lymph node metastasis ($P = 0.023$) and higher TNM stage ($P = 0.024$). However, there was no correlation between HOTAIR expression and age, sex and histological grade ($P > 0.05$).

Up-regulation of HOTAIR associated with poor survival of GC

To assess the impact of HOTAIR expression on OS of GC patients, Kaplan-Meier analysis and log rank test were used. The results revealed that patients in the high-expression group had a shorter OS (median OS: 25.9 mo) than those in the low-expression group (median OS: 42.5 mo, $P < 0.001$; Figure 1D). Univariate analyses of clinical variables considered as potential predictors of survival are shown in Table 2. Further analysis in a multivariate Cox proportional hazards model showed that HOTAIR expression ($P = 0.033$), along with TNM stage ($P = 0.002$) and lymph node metastasis ($P = 0.002$), were strongly associated with OS. These results revealed that HOTAIR expression was an independent prognostic indicator of OS.

Knockdown of HOTAIR suppressed migration and invasion of GC cells

The wound-healing assay showed that HOTAIR knockdown cells were significantly slower than control

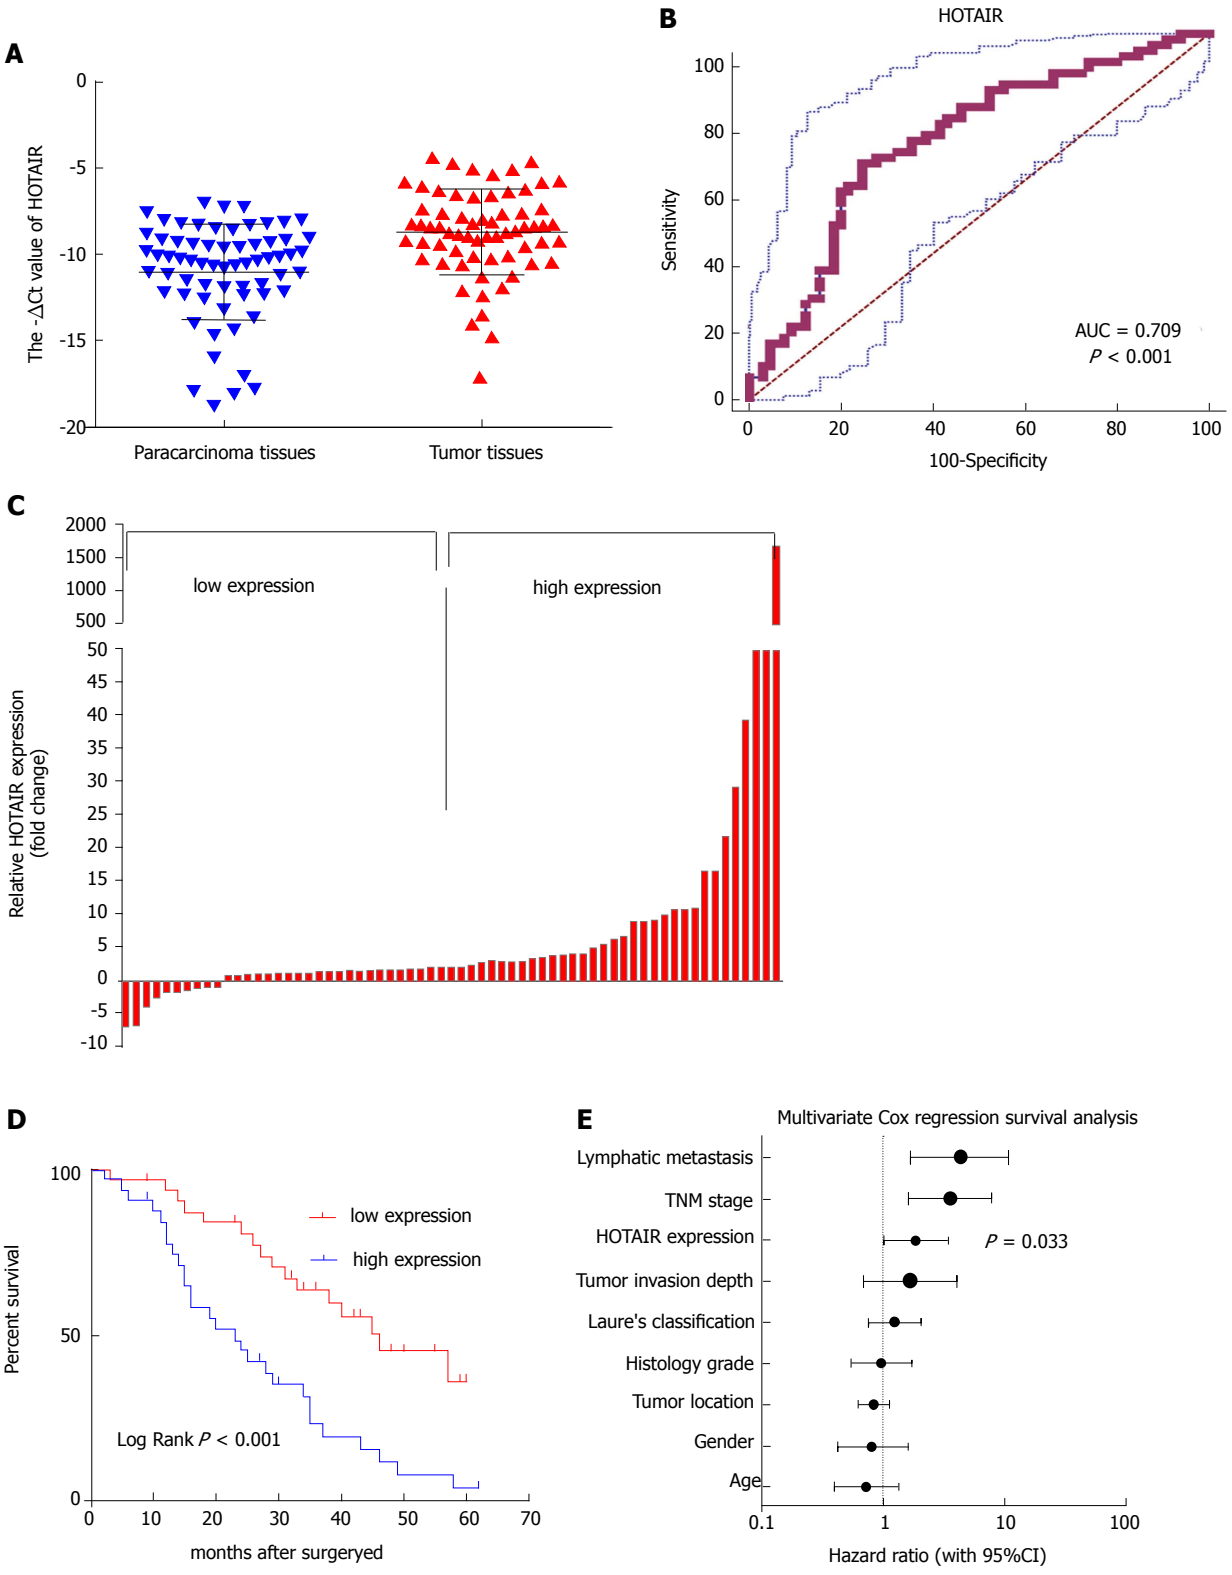

Figure 1 HOTAIR up-regulation correlates with poor survival in patients with GC. A: HOTAIR expression was significantly up-regulated in tumor tissues compared with their corresponding para-carcinoma tissues (shown as -ΔCt); B: ROC curves for observing the diagnostic value of HOTAIR; C: HOTAIR expression was classified into two groups according to HOTAIR expression levels (median split); D: Kaplan-Meier analysis of OS was analyzed according to HOTAIR expression levels; E: Different factors (including HOTAIR, tumor invasion depth, lymph node metastasis, TNM stage, histological grade, gender, tumor location, Lauren's classification and age) were analyzed for their association with patient survival using Cox regression model. The hazard ratio and 95%CI are plotted for each factor. CI: Confidence interval; GC: Gastric cancer; HOTAIR: HOX transcript antisense intergenic RNA; OS: Overall survival; ROC: Receiver operating characteristic; TNM: Tumor-node-metastasis.

cells (Figure 2A-D). Transwell assay and invasion assay demonstrated knockdown of HOTAIR notably reduced the number of BGC-823 or SGC-7901 cells migrating across the membrane (Figure 2E-H). These results

Table 2 Univariate and multivariate analysis of clinical pathological characteristics and overall survival of 65 patients with gastric cancer

Factor	Univariate analysis			Multivariate analysis		
	HR	95%CI	*P* value	HR	95%CI	*P* value
HOTAIR expression	2.943	1.580-5.483	0.001	1.998	1.058-3.772	0.033

confirmed that knockdown of HOTAIR inhibited the migration and invasion of GC cells.

HOTAIR was inversely correlated with E-cadherin in GC tissue and cell lines

The HOTAIR and E-cadherin expression levels in GC tissues were detected by qPCR and immunohistochemistry. E-cadherin expression was significantly down-regulated in tumor tissues (P = 0.001), as compared with the para-tumorous tissues (Figure 3A and B). E-cadherin mRNA levels were negatively associated with HOTAIR expression in GC tissues (r^2 = -0.298, P = 0.016) (Figure 3C). HOTAIR silencing strikingly enhanced the expression of E-cadherin at transcript (Figure 3D and E) and protein (Figure 3F and G) levels in BGC-823 and SGC-7901 cells. These results demonstrated that HOTAIR promoted EMT in GC tissues and cell lines, and that HOTAIR over-expression was significantly associated with migration and invasion.

HOTAIR recruited EZH2 to inhibit the expression of E-cadherin

HOTAIR plays its role in the epigenetic regulation of gene expression mainly by binding to PRC2 complex. We firstly used RIP assay to investigate whether HOTAIR could bind to EZH2, which is the core catalytic component of the PRC2. The results showed that endogenous HOTAIR was abundant in the anti-EZH2 RIP fraction (Figure 4A), validating that HOTAIR can bind to EZH2 in GC cells. Then we conducted ChIP assay to determine whether HOTAIR regulates E-adherin *via* recruiting EZH2 in GC cell lines. ChIP assay demonstrated that knockdown of HOTAIR significantly reduced the binding of EZH2 and H3K27me3 with the E-cadherin promoter in GC cells (Figure 4B). The rescue experiments showed that up-regulation of HOTAIR increased the binding of EZH2 and H3K27me3 with the E-cadherin promoter in GC cells (Figure 4C). These results indicated that HOTAIR inhibits E-cadherin expression partly through combining with EZH2.

DISCUSSION

LncRNAs are non-protein-coding transcripts > 200 nucleotides. Dysregulation of lncRNAs has been found in GC cells and their aberrant expression is correlated with tumorigenesis, metastasis, prognosis or diagnosis[20,21].

We found that HOTAIR was markedly up-regulated in GC tissues, which was correlated with the invasion of primary tumor, lymph node metastasis, and TNM stage. The ROC curve used for distinguishing between GC tissues and normal tissues showed that HOTAIR is a promising cancer biomarker. Univariate and multivariate Cox regression analyses demonstrated that HOTAIR is a valuable prognostic factor independent of major clinicopathological features. We also found that decreased HOTAIR expression inhibited migration and invasion of tumor cells.

To clarify the molecular mechanism of HOTAIR action contributing to GC metastasis, we also investigated potential target genes involved in cell migration and invasion. Previous studies have revealed that the expression of epithelial markers (such as E-cadherin) are increased following HOTAIR knockdown in GC cells[13,22,23]. Further mechanistic studies have shown that by recruiting and binding to PRC2, HOTAIR could epigenetically silence miR34a expression to promote GC cell EMT and metastasis[13]. However, there are still some issues that need to be clarified. For one thing, E-cadherin is a target gene of EZH2. Because EZH2 can mediate transcriptional silencing of E-cadherin through trimethylation of H3 lysine 27[24,25], and HOTAIR binds to EZH2[14]. Furthermore, a significantly negative correlation was found between HOTAIR and E-cadherin in GC tissues in the present study, and knockdown of EZH2 also up-regulated E-cadherin expression in GC cells as shown by another study[26]. So, why does HOTAIR not regulate expression of E-cadherin directly by binding to EZH2? We speculate that HOTAIR promotes tumor cell migration and invasion by repressing E-cadherin *via* EZH2 directly. To confirm this, we performed ChIP analysis in HOTAIR-silenced GC cell lines. Not unexpectedly, HOTAIR contributed to the regulation of E-cadherin *via* recruiting EZH2 and H3K27me3 to the E-cadherin promoter. Our findings provide additional insight into the mechanisms by which HOTAIR promotes GC migration and invasion.

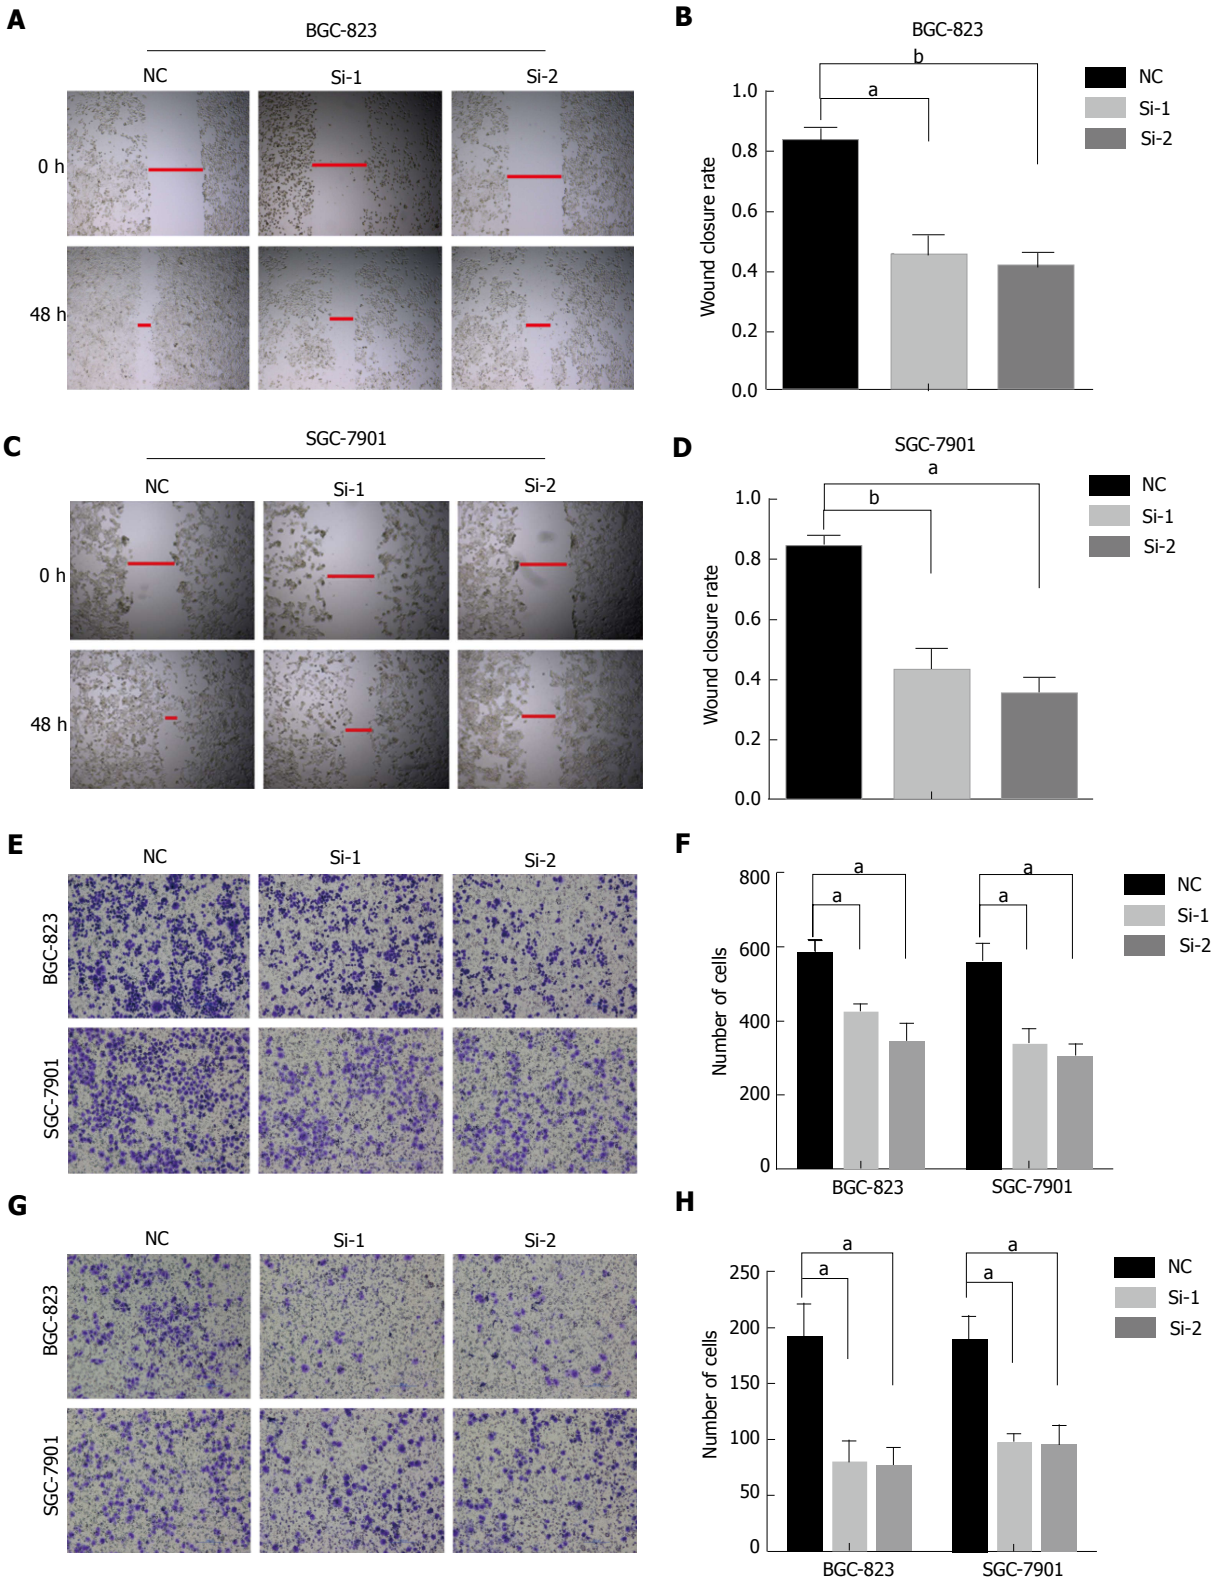

Figure 2 HOTAIR knockdown decreases migration and invasion of gastric cancerGC cells. A and B: HOTAIR knockdown samples exhibited slower scratch closure rate by the wound-healing detection in BGC-823 cells; C and B: Wound-healing assay in SGC-7901 cells with HOTAIR silencing; E and F: Representative pictures of cell migration across the membrane in BGC-823 and SGC-7901 cells with HOTAIR reduction; G and H: Representative pictures of Transwell invasion assay in BGC-823 and SGC-7901 cells with HOTAIR depletion. ($^{a}P < 0.05$, $^{b}P < 0.01$). GC: Gastric cancer; HOTAIR: HOX transcript antisense intergenic RNA.

In conclusion, we demonstrated that HOTAIR was significantly up-regulated in GC tissues, and its overexpression was correlated with tumor progression and poor prognosis. We can distinguish between

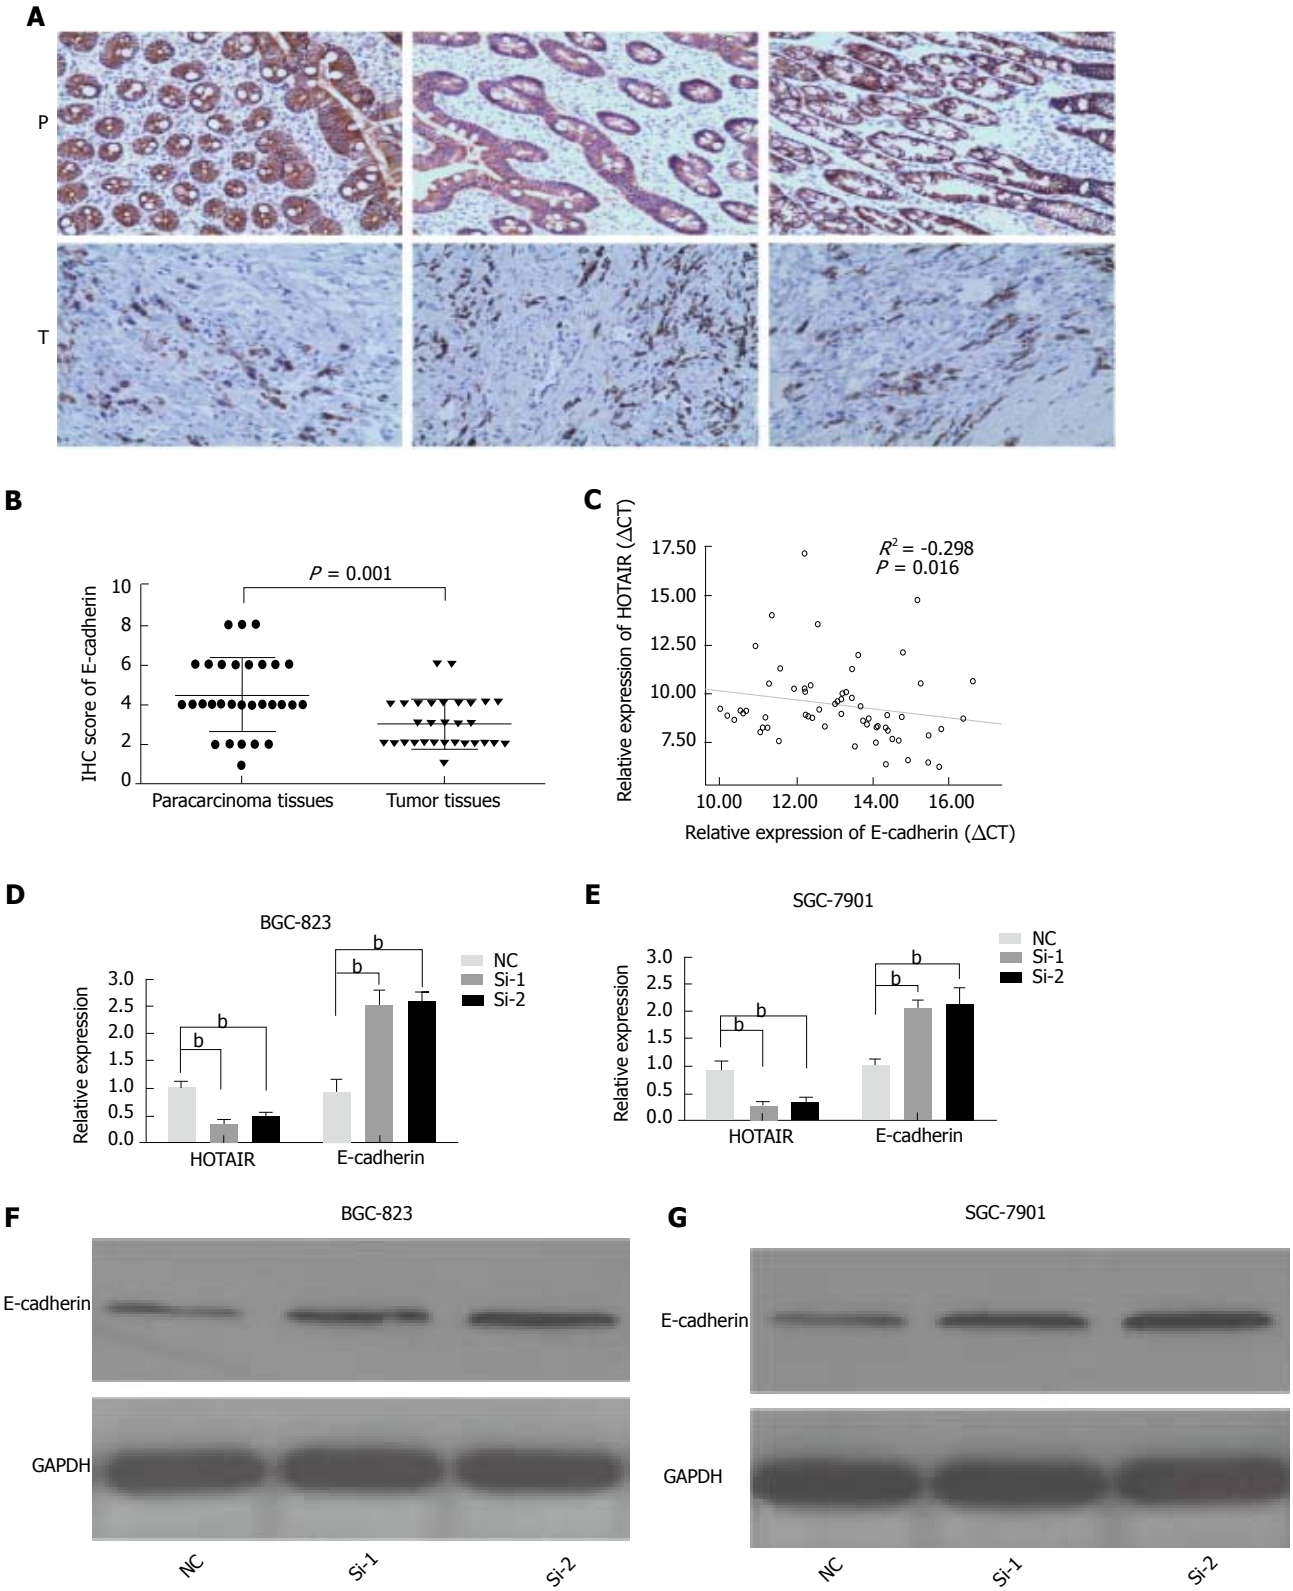

Figure 3 HOTAIR negatively correlates to E-cadherin expression in GC tissues and cell lines. A: E-cadherin immunostaining in para-carcinoma tissues (denoted as '*P*') and GC tissues (denoted as 'T'); B: Representative E-cadherin protein levels and scores in GC tissues and para-carcinoma tissues was analyzed by immunohistochemistry (n = 30); C: Negative correlation between E-cadherin mRNA levels and HOTAIR levels in 65 GC samples; D, E: Relative expression of HOTAIR and E-cadherin in BGC-823 and SGC-7901 cells treated with siRNA for 48 h; F, G: Western blot analysis of E-cadherin after HOTAIR-siRNA (Si1 and Si2) treatment for 48 h in BGC-823 and SGC-7901 cells. $^{a}P < 0.05$, $^{b}P < 0.01$. GC: Gastric cancer; HOTAIR: HOX transcript antisense intergenic RNA; si: Small interfering.

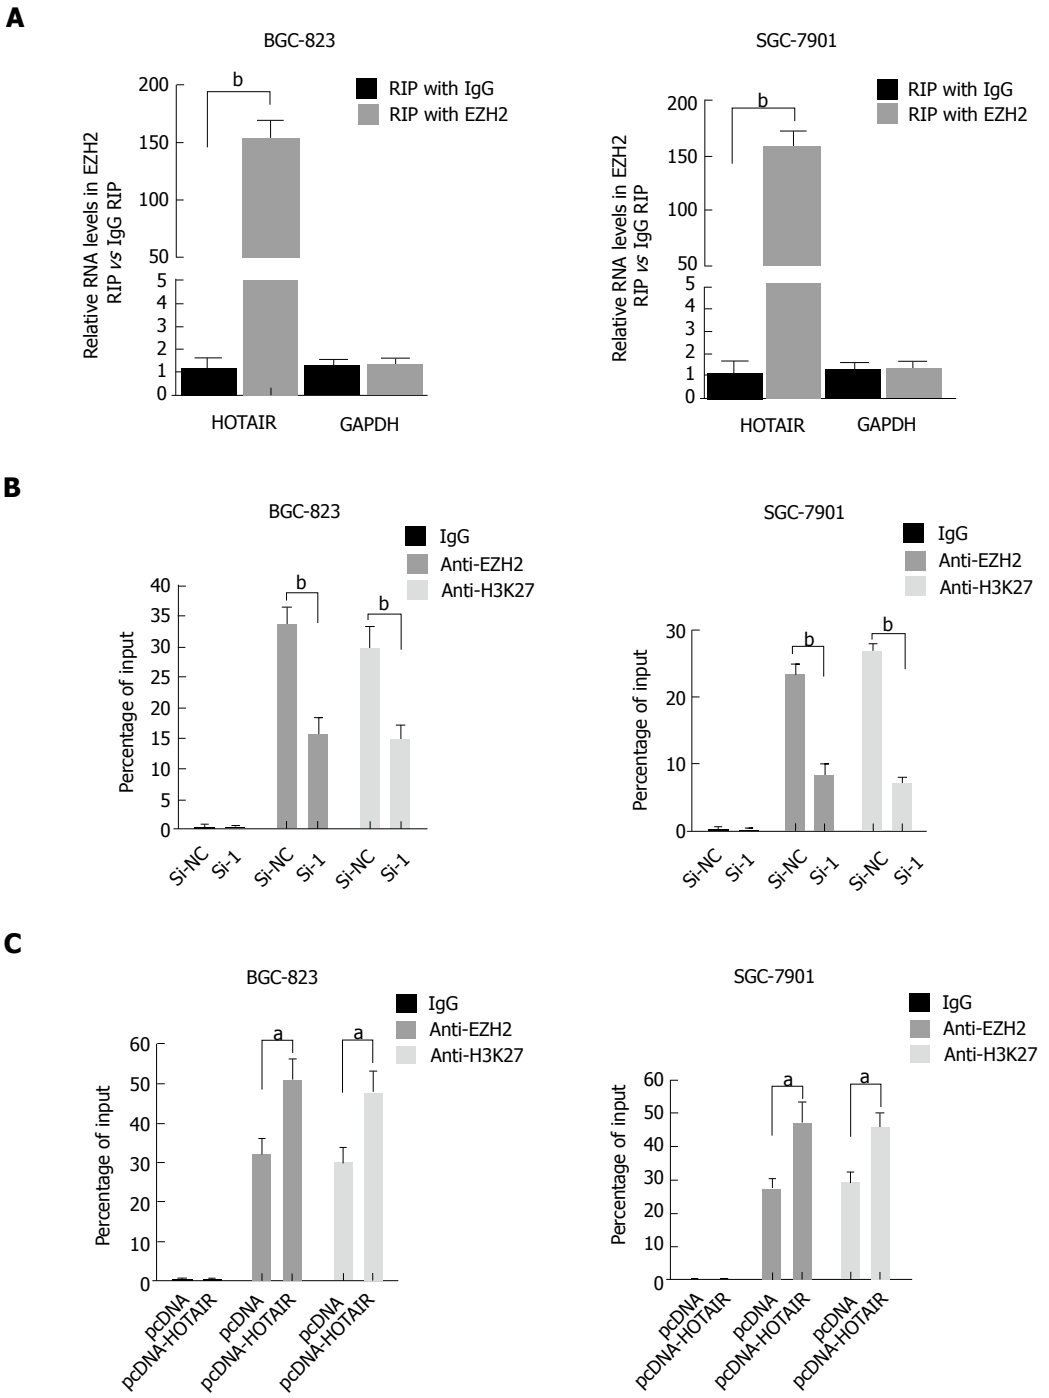

Figure 4 HOTAIR represses E-cadherin expression by associating with EZH2. A: RIP experiments were performed in BGC-823 and SGC-7901 cells, and HOTAIR levels were analyzed in co-precipitated RNA using qPCR. The fold-enrichment of HOTAIR in EZH2 RIP is relative to its matching IgG control RIP ($^{a}P < 0.05$, $^{b}P < 0.01$); B: ChIP of EZH2 and H3K27me3 in the E-cadherin promoter regions after siRNA treatment targeting si-NC or HOTAIR-siRNA-1 in BGC-823 and SGC-7901 cells. qPCR was performed to quantify ChIP assay results. Enrichment was quantified relative to input controls. Antibody directed against IgG was used as a negative control. Results are represented as the average ± SD based on three independent experiments. $^{a}P < 0.05$, $^{b}P < 0.01$; C: ChIP of EZH2 and H3K27me3 in the E-cadherin promoter regions after transfected with empty vector (denoted as 'pcDNA') or pcDNA-HOTAIR in BGC-823 and SGC-7901 cells. qPCR was performed to quantify ChIP assay results. Enrichment was quantified relative to input controls. Results are represented as the average ± SD based on three independent experiments ($^{a}P < 0.05$, $^{b}P < 0.01$). ChIP: Chromatin immunoprecipitation; GC: Gastric cancer; HOTAIR: HOX transcript antisense intergenic RNA; qPCR: Quantitative polymerase chain reaction; RIP: RNA-binding protein immunoprecipitation; SD: Standard deviation; si: Small interfering.

cancerous and non-cancerous lesions based on the expression of HOTAIR. HOTAIR may regulate the invasive ability of GC cells, partially *via* EMT regulation. Our findings have provided new insight into the GC pathogenesis, which benefits diagnosis and therapy in cancer.

COMMENTS

Background

Gastric cancer (GC) is one of the most aggressive malignancies with high morbidity and mortality worldwide. Treatment options are limited due to the lack of knowledge of the molecular and genetic bases of gastric carcinogenesis. A deeper understanding of the molecular mechanisms of GC will shed light on its

pathogenesis, and identification of new biomarkers for diagnosis and prognosis may improve individualized treatment strategies in the future.

Research frontiers

Emerging evidence suggest that long non-coding (lnc)RNA may play a role in gastric carcinogenesis. HOX transcript antisense intergenic RNA (HOTAIR) is one of the well-documented lncRNAs, which is aberrantly expressed in several tumors and plays a crucial role in cancer development. However, the overall clinical role of HOTAIR in GC and the molecular mechanisms of HOTAIR involved in GC cell metastasis has not yet been well investigated.

Innovations and breakthrough

The authors demonstrated that HOTAIR promotes tumor cell migration and invasion by repressing E-cadherin *via* EZH2 directly. Their findings have provided additional insight into the mechanisms of gastric carcinogenesis.

Applications

The results from this study provide novel clues for further investigation of HOTAIR as a potential biomarker and therapeutic target for GC.

Terminology

RNA-binding protein immunoprecipitation assay was used for the analysis of EZH2 interactions with HOTAIR. ChIP assay was performed to investigate direct interactions between EZH2 and E-cadherin.

Peer-review

The study aimed to investigate the clinical significance and the mechanism behind lncRNA HOTAIR in GC. The overall study is solid and well designed. The results are consistent with the proposed hypothesis.

Abstract

AIM

To investigate the role of calmodulin-dependent protein kinase Ⅱ (CaMKⅡ) in colon cancer growth, migration and invasion.

METHODS

CaMKⅡ expression in colon cancer and paracancerous tissues was evaluated *via* immunochemistry. Transcriptional and posttranscriptional levels of CaMKⅡin tissue samples and MMP2, MMP9 and TIMP-1 expression in the human colon cancer cell line HCT116 were assessed by qRT-PCR and western blot. Cell proliferation was detected with the MTT assay. Cancer cell migration and invasion were investigated with the Transwell culture system and wound-healing assay.

RESULTS

We first demonstrated that CaMKⅡ was over-expressed in human colon cancers and was associated with cancer differentiation. In the human colon cancer cell line HCT116, the CaMKII-specific inhibitor KN93, but not its inactive analogue KN92, decreased cancer cell proliferation. Furthermore, KN93 also significantly

prohibited HCT116 cell migration and invasion. The specific inhibition of ERK1/2 or p38 decreased the proliferation and migration of colon cancer cells.

CONCLUSION
Our findings highlight CaMKⅡ as a potential critical mediator in human colon tumor development and metastasis.

Key words: Ca^{2+}/calmodulin-dependent protein kinase II; Colon cancer; Proliferation; Migration

Core tip: In the present study, we demonstrated that calmodulin-dependent protein kinase Ⅱ (CaMKⅡ) was over-expressed in human colon cancers and was associated with cancer differentiation. We investigated the role of CaMKII in human colon cancer proliferation and migration. The results revealed that in the human colon cancer cell line HCT116, the CaMKⅡ-specific inhibitor KN93, but not its inactive analogue KN92, decreased cancer cell proliferation. KN93 also significantly prohibited colon cancer cell migration and invasion. Additionally, we found that ERK1/2 and p38 were the targets of CaMKⅡ regulation. These findings highlight CaMKⅡ as a potential critical mediator in human colon tumor development and metastasis.

INTRODUCTION

Colorectal cancer (CRC) is the third most common cancer and the fourth leading cause of cancer death globally. Researchers estimate that roughly 1.4 million new cases of CRC will be diagnosed and 694000 deaths will result from CRC per year[1]. Despite improvements in multimodal anticancer strategies, the prognosis of advanced CRC is still poor, with 5-year survival rates for stage III and stage IV colon cancer at 65.4% and 12.8%, respectively[2]. A detailed understanding of the biological processes that modulate the progression and metastasis of CRC may provide new molecular pathogenesis targets for CRC diagnosis and benefit anti-tumor therapy.

The calcium ion (Ca^{2+}) is a ubiquitous intracellular signal responsible for a broad range of cellular events, such as cell growth, cytoskeletal organization, regulation of synaptic transmission, and Ca^{2+} homeostasis[3]. The Ca^{2+}/calmodulin (CaM)-dependent protein kinases (CaMKⅠ, CaMKⅡ and CaMKⅣ) are multifunctional serine/threonine kinases whose activity is activated upon Ca^{2+}/CaM binding[4]. The upstream CaMK kinases (CaMKKs) phosphorylate a critical Thr 200 in the activation-loop to activate CaMKIV, whereas CaMKII is fully activated by the autophosphorylation of its own Thr 286[5]. Studies have revealed that the calcium signal is involved in cancer cell proliferation, invasion, tumor growth and metastasis[6-9]. However, fewer studies have focused on CaMKII, one of the most important sensors and regulators of the Ca^{2+} signal, in digestive cancers, especially in CRC.

In the present study, we first demonstrated that CaMKII was over-expressed in human colon cancers and was associated with cancer differentiation. We further sought to investigate the role of CaMKII in human colon cancer proliferation and migration. The results revealed that in the human colon cancer cell line HCT116, the CaMKII-specific inhibitor KN93, but not its inactive analogue KN92, decreased cancer cell proliferation. KN93 also significantly prohibits HCT116 cell migration and invasion. Additionally, we determined that CaMKII inhibition decreased the phosphorylation of ERK1/2 and p38. The specific inhibition of ERK1/2 or p38 decreased the proliferation and migration of colon cancer cells. These findings highlight CaMKII as a potential critical mediator in human colon tumor development and metastasis.

MATERIALS AND METHODS

Reagents

Antibodies against CaMKIIα, ERK1/2, phospho (p)-ERK1/2, p38, p-p38, MMP2, MMP9, TIMP-1 and GAPDH were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, United States). KN-93 (2-[N-(2-Hydroxyethyl)]-N-(4-methoxybenzene-sulfonyl)] amino-N-(4- chlorocinnamyl)-N-methylbenzylamine), KN-92 (2-[N-(4-Methoxybenzenesulfonyl)] amino-N-(4-chlorocinnamyl)-N-methylbenzylamine), PD98059 and SB203580 were obtained from Calbiochem (La Jolla, CA, United States). Other chemicals of the highest purity were purchased from Sigma (St. Louis, MO, United States).

Tissue samples

Colon tissue samples were obtained from the Department of Gastrointestinal Surgery at Renmin Hospital of Wuhan University in accordance with local ethics committees. All samples were obtained from the primary colon sites of pretreatment cases of paracancerous lesions (n = 5), well-differentiated colon cancer tissues (n = 6) and poorly differentiated colon cancer tissues (n = 6). All samples were analyzed and assessed by two histological specialists working blindly.

Cell culture and treatment

The human colon cancer cell line HCT116 was obtained from the Type Culture Collection of the Chinese Academy of Sciences (Shanghai, China) and cultured

in Dulbecco's modified Eagle's medium (DMEM) (Gibco, Rockville, MD, United States) containing 10% heat-inactivated fetal bovine serum (FBS) (Gibco) and 1% penicillin/streptomycin (Life Technologies, Rockville, MD, United States) at 37 ℃ in a humidified atmosphere with 5% CO_2. For conditioned media, 3 × 10^5 HCT116 cells were seeded in 6-well plates and then stimulated for the indicated amount of time.

Immunostaining

Immunohistochemistry (IHC) for CaMKII was performed on paraffin-embedded tissues from paracancerous tissues, well-differentiated colon cancers and poorly differentiated colon cancers. Specimens were fixed in a 4% formaldehyde solution for 12-48 h and embedded in paraffin. IHC was performed on 3.5 μm tissue sections on slides. Heat-induced epitope retrieval was carried out. For immunofluorescent staining for CaMKII, all slides were blocked with serum solution and incubated with the primary antibody overnight at 4 ℃. After rinsing again, the slides were incubated for 45 min at room temperature with secondary antibodies. Visualization was achieved with the DAB (3,3'-diaminobenzidine) detection kit, and the cell nuclei were counterstained using hematoxylin. After staining, five fields (at a magnification of × 100) were randomly selected in each slide. Staining was quantified with Image J software and evaluated by two investigators following the "blinded" principle.

MTT assay

Cell proliferation was measured with the MTT assay (ATCC, Manassas, VA, United States). A total of 5 × 10^3 cells were seeded at the well bottoms of 96-well culture plates and treated with TGFβ1 or conditioned medium from fibroblasts or colon cancer cells in triplicate. After treatment, MTT solution [3-(4,5-dimethylthiazol-2-yl)- 2,5-diphenyltetrazoliumbromide] was added to the culture medium (0.5 mmol/L), and plates were incubated for 2 h at 37 ℃ with 5% CO_2. Detergent solution was then added to solubilize formazan crystals. Finally, the optical density was determined at 540 nm with a Benchmark Plus microplate reader (Bio-Rad, Hercules, CA, United States).

Western blot analysis

Protein from unstained paraffin-embedded samples was deparaffinized and rehydrated *via* successive washes in xylene/ethanol and water. After incubation in extraction buffer at 100 ℃ for 20 min followed by a 2 h incubation at 80 ℃, proteins were obtained by centrifugation. Whole cell lysates were prepared with RIPA lysis buffer containing protease and phosphatase inhibitor cocktail. Protein concentrations of cell lysates were determined with the bicinchoninic acid protein assay. A total of 30-40 μg of lysate were loaded onto a 10% SDS-PAGE gel and subjected to gel electrophoresis. Resolved proteins were transferred to a polyvinylidine fluoride membrane. Membranes were then blocked in 5% non-fat dry milk in Tris-buffered saline with Tween (TBS-T) for 1 h and then incubated with antibodies to GAPDH, CaMKIIα (Cell Signaling Technology), ERK1/2, phospho-ERK1/2, p38, p-p38, MMP2, MMP9 and TIMP-1 at 4 ℃ overnight. Membranes were washed with TBS-T and then incubated with horseradish peroxidase-conjugated secondary antibody for 1 h at room temperature. The blotting bands were visualized with enhanced chemiluminescence. GAPDH was used as a loading control.

Quantitative real-time PCR

Cells were seeded at 10^6 cells per 10 cm dish and were allowed to grow to 80% confluency in complete media. Cells were removed with 0.025% ethylene-diaminetetraacetic acid and centrifuged for 5 min at 1100 rpm. Cell pellets were resuspended in 1 mL of TRIzol (Life Technologies, Carlsbad, CA, United States), and RNA was extracted according to the manufacturer's protocol. Total RNA in unstained paraffin-embedded samples was extracted with the RNeasy FFPE Kit (Qiagen, Hilden, Germany). The SuperScript First-Strand Kit (Life Technologies) was used to synthesize cDNA from 5 μg of total RNA. Quantitative PCR was established with the RT2 SYBR Green Flour FAST Mastermix (Qiagen, Venlo, the Netherlands) and run on a Bio-Rad CFX96 Real-Time PCR Detection System (Bio-Rad). Data were analyzed with Bio-Rad CFX Manager 3.0 software and are shown as relative fold-changes.

For all PCR reactions, GAPDH was used as an endogenous control, and CT values were normalized to levels of GAPDH expression. Primers were designed with Integrated DNA Technologies PrimerQuest software (Coralville, IA, United States). Sequences used to analyze RNA expression include the following: CaMKII, Forward: 5'-GAG AGC ACC AAC ACC ACC ATC G-3' and Reverse: 5'-AGG CTG ACT CGT CGC CCA TCA GG-3'; MMP2, Forward: 5'-TCT CCT GAC ATT GAC CTT GGC-3' and Reverse: 5'-CAA GGT GCT GGC TGA GTA GAT C-3'; MMP9, Forward: 5'-TTG ACA GCG ACA AGA AGT GG-3' and Reverse: 5'-GCC ATT CAC GTC GTC CTT AT-3'; TIMP-1, Forward: 5'-CTT CTG GCA TCC TGT TGT TG-3' and Reverse: 5'-GGT ATA AGG TGG TCT GGT TG-3'; GAPDH, Forward: 5'-ACA GTC CAT GCC ATC ACT GCC-3' and Reverse: 5'-GCC TGC TTC ACC ACC TTC TTG-3'. The results are averaged from three independent experiments.

Migration and invasion assay

A 24-well Transwell plate (Fisher Scientific, Hampton, NH, United States) was used to measure migratory and invasive ability *in vitro*. A total of 2 × 10^5 HCT-116 cells were plated on the bottom of each well. For the migration assay, 1 × 10^5 colon cancer cells were plated in the top chamber with a non-coated membrane. For the invasion assay, 2 × 10^5 HCT-116 cells were seeded in the top chamber coated with Matrigel (BD Biosciences, San Jose, CA, United States). In both

Scale bar, 100 μm; B: qRT-PCR of CaMKII mRNA in paraffin-embedded paracancerous tissue, well-differentiated colon cancer and poorly differentiated colon cancer samples; C: Western blot of CaMKII protein in paraffin-embedded paracancerous tissue, well-differentiated colon cancer and poorly differentiated colon cancer samples. All data are presented as the mean ± standard error of at least three independent experiments. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* paracancerous tissue.

assays, cells were cultured in DMEM containing 10% FBS with the indicated treatment. After incubation at 37 °C for 24 h, migrated cells were fixed and stained with the Diff-Quik stain and counted in four random fields. The experiments were performed in triplicate wells, and each experiment was performed at least two or three times as indicated.

Wound-healing assay

A wound-healing assay was performed with 6-well plates. HCT116 cells were seeded at confluency 24 h before the experiment. The cell layers were carefully scratched with 200-mL sterile pipette tips and washed twice with fresh medium. The cells were photographed under a light microscope at × 200 magnification 24 h later.

Statistical analysis

All experiments were performed in triplicate. Data are expressed as the mean ± SD. Differences between groups were calculated *via* one-way analysis of variance. Differences were considered significant at $P < 0.05$.

RESULTS

CaMKII is over-expressed in colon cancers

The expression of CaMKⅡ was evaluated by IHC with a monoclonal CaMKⅡ antibody on sections obtained from formalin-fixed, paraffin-embedded samples of paracancerous tissue, well-differentiated colon cancer samples and poorly differentiated colon cancer samples. As expected, CaMKⅡ was significantly overexpressed in the poorly differentiated colon cancer samples and well-differentiated cancer samples compared to the paracancerous tissues (Figure 1A). A quantification assay suggested that the expression of CaMKⅡ was highest in poorly differentiated colon cancer tissues. We further evaluated CaMKII protein and mRNA levels in cancer and paracancerous

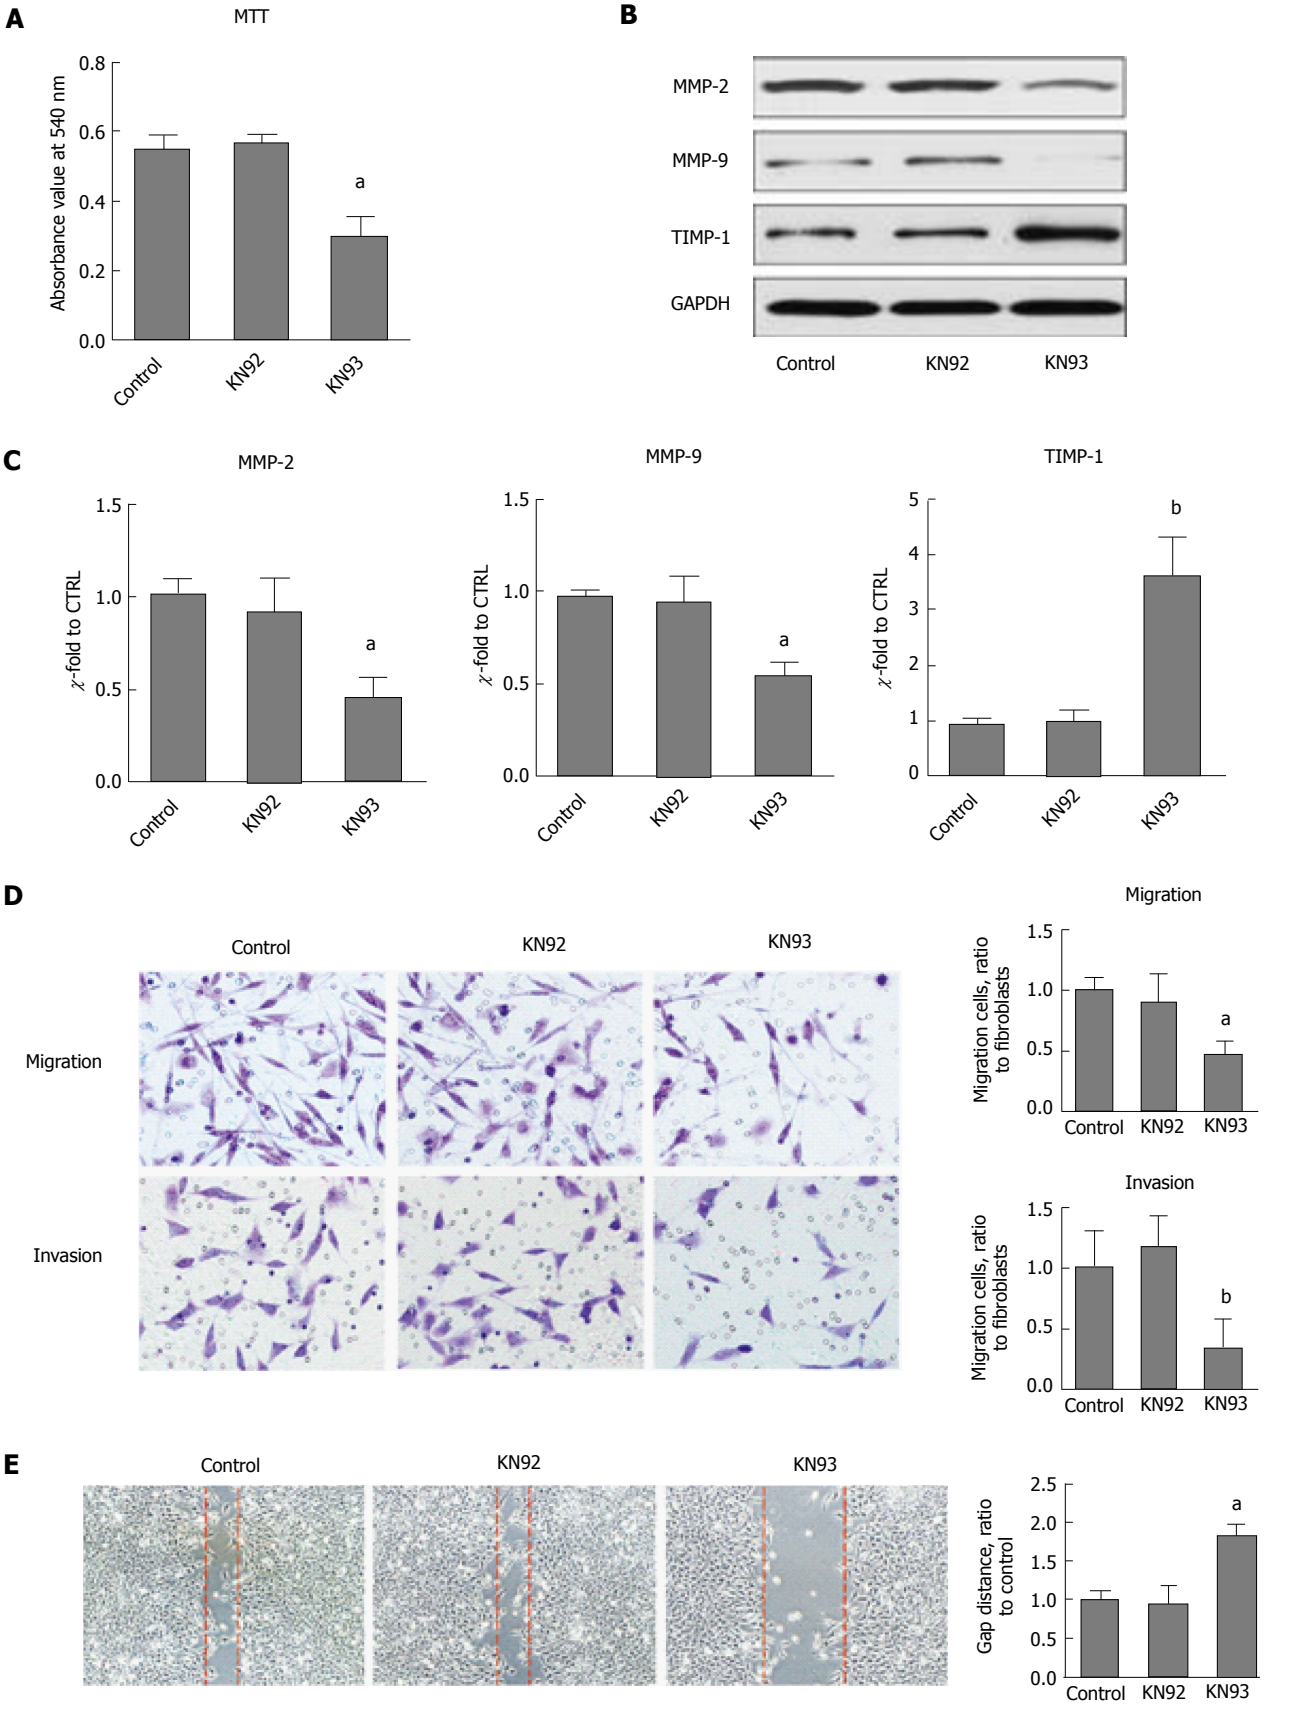

Figure 2 CaMKII is required for colon cancer proliferation and migration. Human colon cancer cells HCT116 were treated with or without KN93 or KN92 at 10 μmol/L for 24 h. A: MTT analysis for cell proliferation; B: Western blot of MMP2, MMP9 and TIMP-1; C: qRT-PCR assay of MMP2, MMP9 and TIMP-1; D: Immigration and invasion analysis by T transwell assay; E: Wound-healing test. All data are presented as the mean ± standard error SE of at least three independent experiments. [a]$P < 0.05$, [b]$P < 0.01$ *vs* control group.

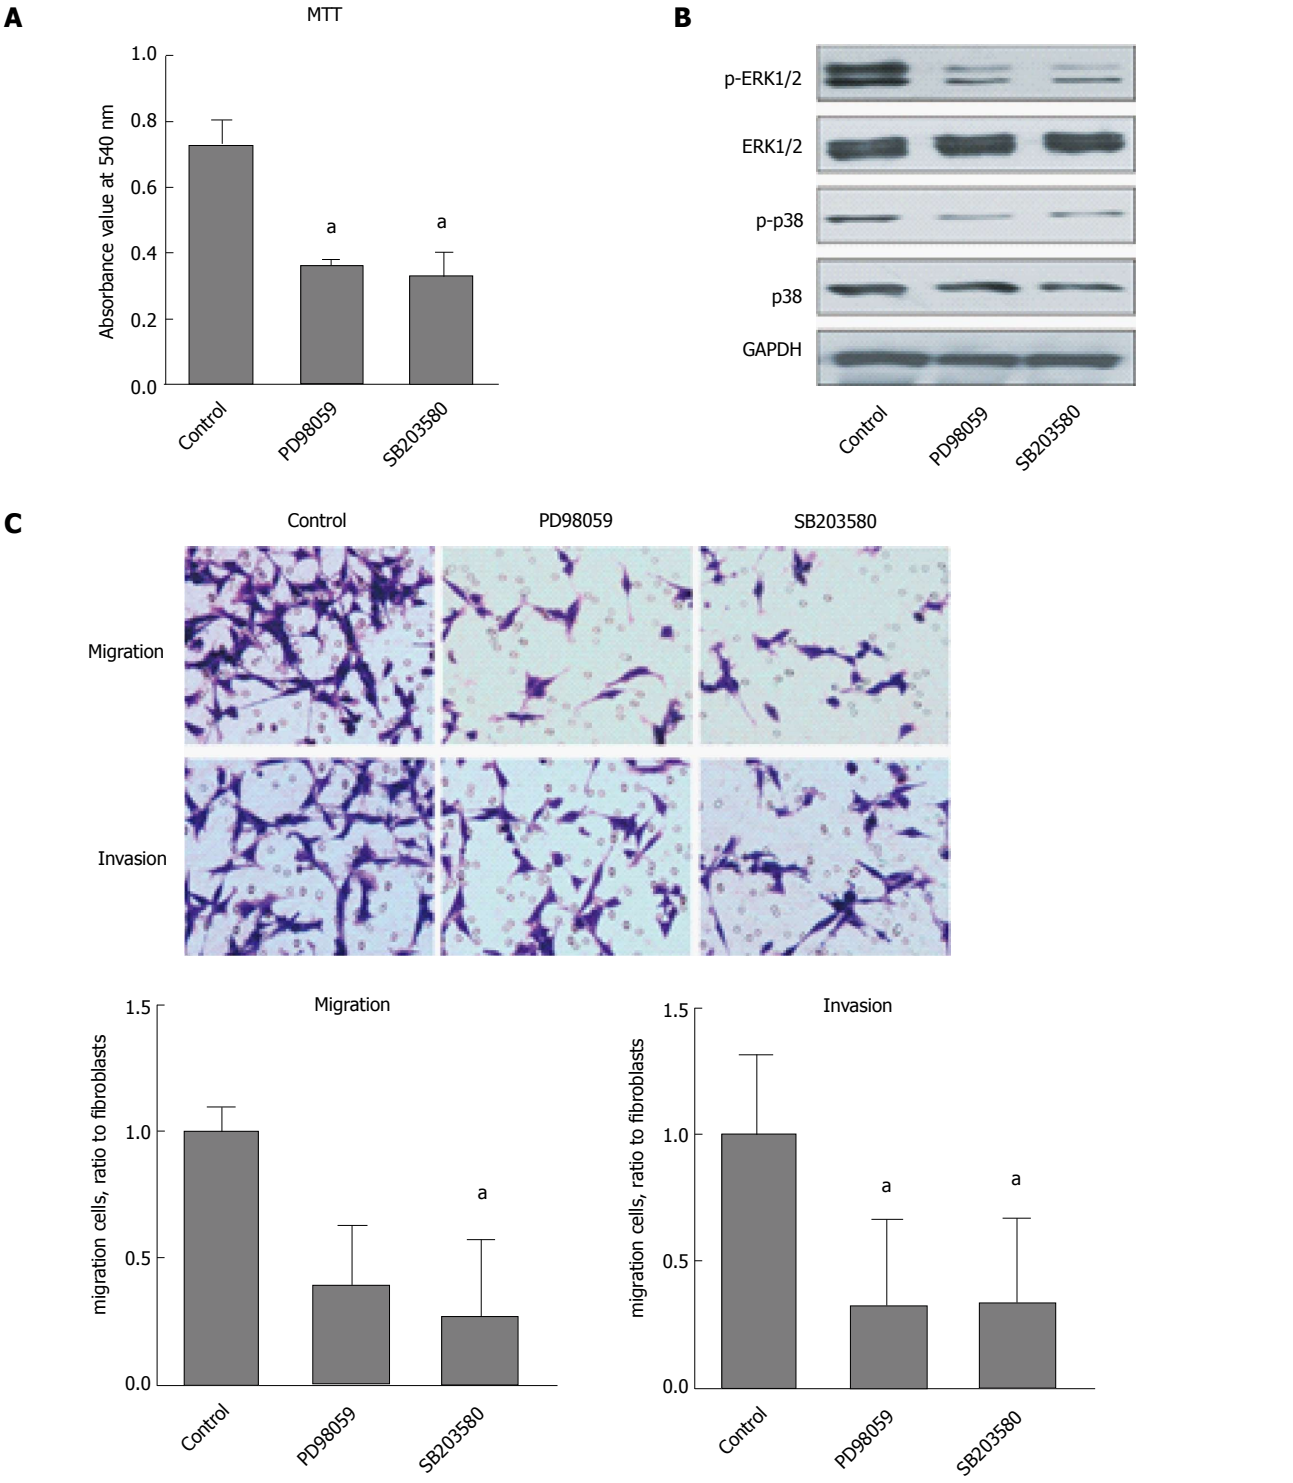

Figure 3 CaMKII regulates colon cancer cells proliferation and migration *via* ERK1/2- and p38-dependent pathways. Human colon cancer cells HCT116 were treated with or without PD98059 (50 μmol/L) or SB203580 (10 μmol/L) for 24 h. A: MTT assay for cell proliferation; B: Western blot analysis of ERK1/2, phosphor-ERK1/2, p38 and phosphor-p38; C: Immigration and invasion analysis by T transwell assay. tissues. The results were similar to the findings of the above studies (Figure 1B and C). We deduced that CaMKII may be a potential regulator in colon cancer development.

CaMKII is required for colon cancer proliferation and migration

CaMKII has been shown to drive cancer growth and metastasis. To ascertain whether CaMKII regulates

colon cancer proliferation and migration, the CaMKII specific inhibitor KN93 was selected. Human colon cancer HCT116 cells were treated with KN93, and its inactive analogue, KN92, was used as an additional control. We found that KN93 inhibited colon cancer cell proliferation (Figure 2A). Importantly, in migration and invasion experiments, the motility of HCT116 cells was significantly attenuated (Figure 2B and C). Furthermore, CaMKII inhibition decreased MMP2 and MMP9 expression at both transcriptional and posttranscriptional levels. The opposite results were detected for TIMP-1 expression (Figure 2D and E). Thus, we concluded that CaMKII is required for colon cancer cell proliferation and migration.

CaMKII regulates colon cancer cell proliferation and migration via ERK1/2 and p38-dependent pathways

We further investigated the molecular mechanism of CaMKII regulation in human colon cancer cells. As shown in Figure 3, KN93, but not KN92, decreased the phosphorylation of ERK1/2 and p38, which are involved in colon cancer development. Pretreatment with specific inhibitors of ERK1/2 or p38 (PD98059, SB203580) decreased HCT116 cell proliferation, migration and invasion. These data demonstrated that the effects of CaMKII on human colon cancer are ERK1/2- and p38-dependent.

Taken together, these results indicate that CaMKII is an important regulator of human colon cancer growth and migration.

DISCUSSION

It is widely accepted that intracellular Ca^{2+} signaling pathways regulate various biological events, including cell proliferation, motility, activation and differentiation, during cancer development[10,11]. In the present study, we demonstrated that CaMKII is over-expressed in colon cancers and highly expressed in poorly differentiated colon tumors. We highlight the role of CaMKII in colon cancer growth and metastasis.

CaMKII inhibitors can inhibit CaMKII activity by interacting with the Ca^{2+}/CaM-binding site or interfering with its catalytic activities. Previous studies revealed that CaMKII-specific inhibitors such as KN-62, KN-93, and autocamtide 2-related inhibitory peptide inhibit CaMKII-dependent processes in tumor and normal cells, causing cell cycle arrest, cellular apoptosis, or the inhibition of cell proliferation[12-14].

Some studies have implicated CaMKII as an important player in cancer cell proliferation. CaMKII inhibition decreased ovarian cancer cell motility and decreased tumor growth and metastasis[15]. The *in vivo* administration of KN-93 to mice xenografted with human osteosarcoma cells significantly decreased intratibial and subcutaneous tumor growth[16]. In CRC, we demonstrated that CaMKII inhibition strongly inhibited human colon cancer cell proliferation (Figure 2A).

Recent studies support the important role of CaMKII in cancer invasion and metastasis. The up-regulation of CaMKIIα was found in primary osteosarcoma tissues from patients and in aggressive osteosarcoma cell lines[17]. CaMKIIα depletion decreased motility and invasion, whereas CaMKIIα over-expression increased the tumorigenic properties of osteosarcoma cells *in vitro*. Our current results revealed the important role of CaMKII in colon cancer migration and invasion. KN93 dramatically decreased the expression of MMP2 and MMP9, increased TIMP-1 levels and prohibited the invasive motility of colon cancer cells (Figure 2). CaMKII is a critical regulator of colon cancer progression.

The MAPK pathway is one of the important downstream targets in CaMKII regulation[4]. CaMKII directly or indirectly up-regulated multiple signaling pathways, such as ERK1/2, AKT1 and β-catenin, and is involved in regulating the survival and proliferation of non-small cell lung cancer cells[6]. We further investigated whether ERK1/2 and p38 were involved in CaMKII pathways. Our data showed that the inhibition of CaMKII by KN93 significantly decreased ERK1/2 and p38 phosphorylation (Figure 3). The specific inhibition of ERK1/2 or p38 decreased the proliferation, migration and invasion of HCT116 cells. Therefore, CaMKII mediates colon cancer growth and migration *via* ERK1/2- and p38-dependent pathways.

Taken together, the current study provided evidence for CaMKII as a pivotal regulator of colon cancer cell proliferation and migration. CaMKII is a potentially important target in CRC treatment.

COMMENTS

Background

Ca^{2+}/calmodulin (CaM)-dependent protein kinase II (CaMKII) is one of the most important sensors and regulators of the Ca^{2+} signal which is involved in cancer cell proliferation, invasion, tumor growth and metastasis. Despite the critical role of CaMKII, fewer studies focus on it in digestive cancers, especially in colorectal cancer.

Research frontiers

Recently, studies have revealed CaMKII is an effective controller in ovarian cancer and osteosarcoma cell motility, cell growth and metastasis.

Innovations and breakthroughs

In the present study, the authors demonstrated that CaMKII was over-expressed in human colon cancers and was associated with cancer differentiation. Meanwhile, in the human colon cancer cell line HCT116, the CaMKII-specific inhibitor KN93, but not its inactive analogue KN92, decreased cancer cell proliferation. CaMKII inhibition also significantly prohibited colon cancer cell migration and invasion. Additionally, ERK1/2 and p38 were the targets of CaMKII regulation.

Applications

These findings highlight CaMKII as a potential critical mediator in human colon tumor development and metastasis. Its relationship to colon cancer

differentiation indicates CaMKII a potential target for clinical diagnosis and prognosis.

Terminology

CaMKII is a ubiquitous serine/threonine protein kinase. Autophosphorylation of CaMKII at threonine 286 switches the kinase from Ca^{2+}-dependent to Ca^{2+}-independent activity and leads to sustained CaMKII auto-activation. More importantly, this activation is thought to phosphorylate numerous different proteins and regulate diverse signaling pathways.

Peer-review

This is a brief study concerning the role of Ca^{2+}/calmodulin-dependent protein kinase II involved in invasion and migration of the colon cancer. The study is interesting and topical. The experiments were well designed. The manuscript is clear and structured very well.

Abstract

AIM

To investigate the molecular mechanisms of gastric carcinogenesis.

METHODS

We used label-free quantification technology integrated with liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis to identify differentially expressed proteins in 160 specimens of normal gastric mucosa, gastric mucosa with mild dysplasia, moderate dysplasia, severe dysplasia, and early mucosal gastric cancer (GC) collected at the Second Hospital of Lanzhou University from 2010 to 2015. Immunohistochemistry was used to verify the differentially expressed proteins detected by LC-MS/MS.

RESULTS

With a threshold of a 1.2-fold change and a *P*-value

< 0.05 between mild dysplasia, moderate dysplasia, severe dysplasia or early mucosal GC and matched normal gastric mucosa tissues, proteomic analysis identified 365 significantly differentially expressed proteins. ERGIC1 expression decreased, while DNA-PKcs expression increased gradually along with different stages of GC initiation based on the tendency of fold change. The expression patterns of ERGIC1 and DNA-PKcs revealed by immunohistochemistry were consistent with the LC-MS/MS results.

CONCLUSION

The results suggest that aberrant ERGIC1 and DNA-PKcs expression may be involved in GC initiation.

Key words: DNA-PKcs; ERGIC1; Dysplasia; Proteomics; Gastric cancer

© The Author(s) 2017. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: Using label-free combined with liquid chromatography-tandem mass spectrometry (LC-MS/MS), the expression of 365 proteins based on the tendency of fold change was revealed to be statistically different between the various stages of gastric cancer (GC) initiation. Furthermore, we observed that ERGIC1 expression decreased, while DNA-PKcs expression increased gradually along with different stages of GC initiation based on the tendency of fold change. The expression patterns of ERGIC1 and DNA-PKcs revealed by immunohistochemistry were consistent with the LC-MS/MS results. These data indicate that abnormal ERGIC1 and DNA-PKcs expression may play an important role in GC initiation.

INTRODUCTION

Gastric cancer (GC) accounts for a large quantity of cancer-related deaths[1]. Over the decades, the prognosis of GC patients has improved, while overall survival rate of patients with GC has not been improved significantly yet, especially for advanced GC patients[2-4], which might be attributed to the poor understanding of mechanisms underlying the initiation and progression of GC. It is widely accepted that GC is a complex, heterogeneous, and multistep disease caused by various factors encompassing *Helicobacter pylori* infection, heredity, living habits, *etc*., which trigger series of molecular alterations, such as inactivation of tumor suppressor genes, activation of oncogenes, telomerase activation, DNA damage and even genome instability[5-8]. DNA-PKcs is the catalytic subunit of the DNA-dependent protein kinase and can combine with the Ku 70/Ku 80 heterodimer (Ku 70/80) into the DNA-dependent protein kinase (DNA-PK), which plays a crucial role in the activation of the non-homologous end joining (NHEJ) pathway[9,10]. Moreover, ERGIC1 has been identified as a cycling protein and participates in membrane trafficking and selective transport of cargo between the endoplasmic reticulum (ER), the intermediate compartment (ERGIC), and the Golgi apparatus in HepG2 cells, suggesting a possible role in protein secretion out of the ER[11].

Currently, high-throughput sequencing technologies, such as microarray assay and next-generation sequencing, have helped researchers obtain much more insight into molecular alterations[12]. These new tools have given a huge impetus to the discovery of novel intracellular molecular pathways and molecular subtypes of GC. For instance, some researchers have recommended that GC should be classified into Epstein-Barr virus-positive subtype, microsatellite instability subtype, genomically stable subtype, and chromosomally unstable subtype on the basis of the spectra of genetic alterations related with relevant clinical features, which is a totally new classification method[7,12].

However, it has been reported that GC is characterized by subtype heterogeneity and a lack of consistent genomic alterations across different individuals[13]. Furthermore, due to different translation regulation, posttranslational modifications and stability of proteins, genetic conditions cannot always provide reliable protein expression patterns, suggesting that it may be not sufficient to take advantage of the gene sequence-targeted tools to explore the molecular mechanisms underlying the GC initiation and progression[14]. Thus, proteomics has been thrust into the spotlight for its accurate and direct presentation of protein expression patterns that can provide much more information about the cellular function or dysfunction compared with genetic analysis[15]. It has been widely accepted that GC initiation can be divided into five stages including normal gastric mucosa, atrophic gastritis with mild dysplasia, atrophic gastritis with moderate dysplasia, atrophic gastritis with severe dysplasia, and mucosal GC. To date, abnormal expression of many proteins has been reported to be involved in GC carcinogenesis in several GC proteomic studies[12]. However, all of the previous studies only focused on identifying the differences between normal gastric epithelial tissues and GC rather than investigating the differences of protein among mild dysplasia, moderate dysplasia, severe dysplasia, and mucosal GC, which may contribute to more accurate insight into the molecular mechanisms underlying GC initiation. Thus, in this study we collected specimens of normal gastric mucosa, gastric mucosa with mild

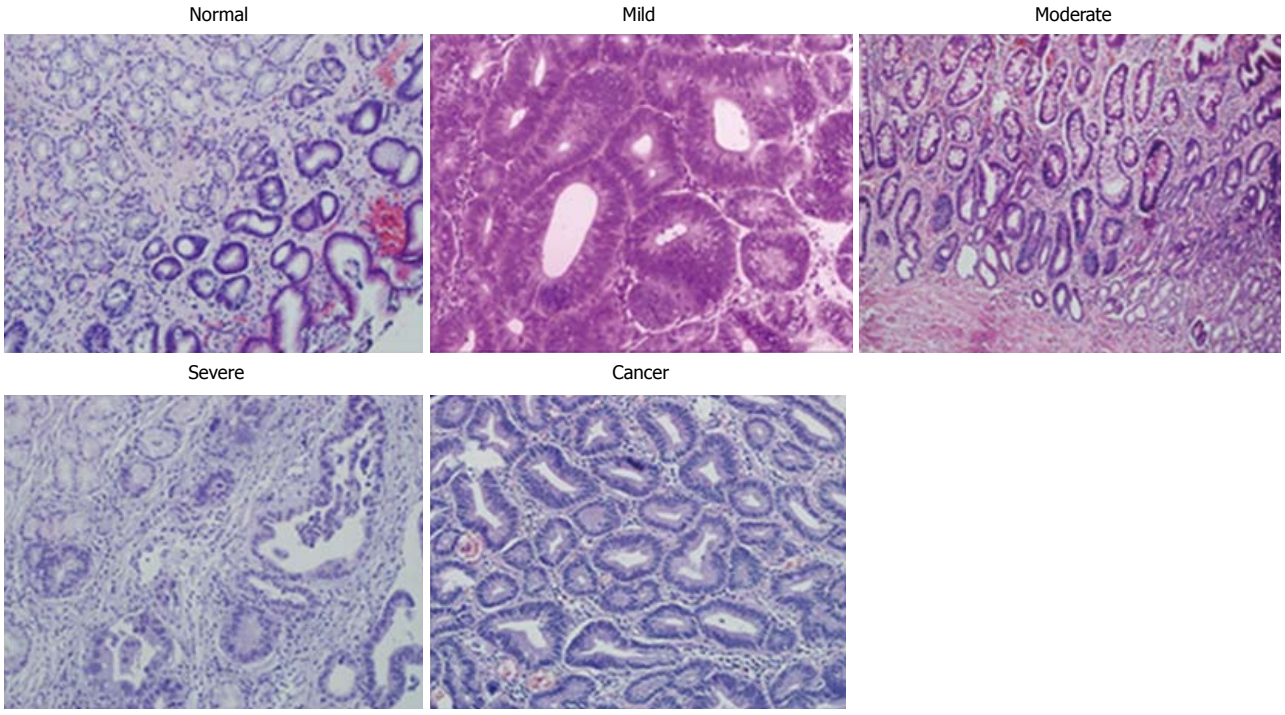

Figure 1 Representative graphs of HE staining (20 ×) of various gastric tissues including dysplasia.

Table 1 Basic demographic data of the study subjects

Group	*n*	Age (range) (yr)	Male/female
Healthy	30	43 (38-51)	16/14
Mild dysplasia	30	54 (42-67)	22/18
Moderate dysplasia	30	58 (40-65)	14/16
Severe dysplasia	30	63 (43-76)	19/11
Gastric cancer	40	61 (39-68)	23/17

dysplasia, moderate dysplasia, severe dysplasia, and early mucosal GC, and utilized label-free quantification technology integrated with liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis to identify differentially expressed proteins in the five kinds of specimens in order to determine the molecular mechanisms underlying GC initiation, which may promote potential preventive and therapeutic strategies for GC. We also focused on ERGIC1 and DNA-PKcs proteins for their inverse expression patterns identified in the proteomic analysis.

MATERIALS AND METHODS

Clinical specimens

Clinical specimens were collected at the Second Hospital of Lanzhou University from 2010 to 2015. A total of 160 patients were enrolled in this study, including 30 patients with a normal gastric mucosa, 30 patients with atrophic gastritis accompanied by mild dysplasia, 30 patients with atrophic gastritis accompanied by moderate dysplasia, 30 patients with atrophic gastritis accompanied by severe dysplasia, and 40 patients with early intestinal-type GC (Table 1 and Figure 1). All patients underwent upper gastroduodenoscopy or gastrectomy and were pathologically reviewed and examined. This study was approved ethically by the Second Hospital of Lanzhou University. All of the patients provided written informed consent to participate in the study.

Proteomic analysis of gastric samples

Sample preparation: The five kinds of formalin-fixed, paraffin-embedded (FFPE) specimens were divided into three groups, respectively. Each FFPE specimen was cut into six pieces at a thickness of at least 4 μm, in order to ensure that the protein quantity to detect was no less than 40 μg. Fifteen groups of FFPE specimens were deposited in liquid nitrogen after conventional dewaxing, gradient alcohol, and hydration for proteomic analysis.

After 2 μL of SDT buffer was added, the sample was ground with a pestle and a mortar. The homogenate was sonicated and then boiled for 15 min. After centrifugation at 14000 *g* for 40 min, the supernatant was filtered with 0.22 μm filters. The protein content of the filtrate was quantified with the BCA Protein Assay Kit (Bio-Rad, the United States), and the sample was then stored at -80 ℃.

SDS-PAGE separation: Samples (40 μg proteins) were mixed with 5 × loading buffer and boiled for 5 min. The proteins were separated on a 12.5% SDS-PAGE gel at a constant current of 14 mA for 90 min. Protein bands were visualized by Coomassie Brilliant Blue R-250 staining.

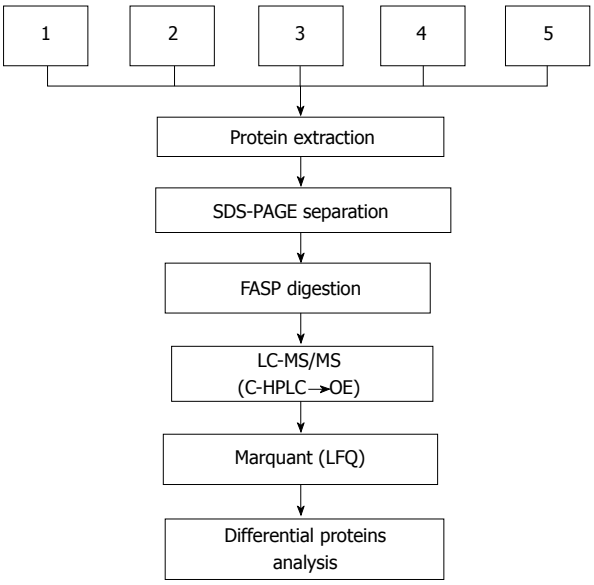

Figure 2 Outline of proteomic experimental workflow. SDS-PAGE: Sodium dodecyl sulfate polyacrylamide gel electrophoresis; C-HPLC: Capillary-high performance liquid chromatography; QE: Q-exactive; LFQ: Label free quantitative.

Filter-aided sample preparation (FASP digestion): A total of 100 μg proteins for each sample were added into 30 μL SDT buffer (4% SDS, 100 mmol/L DTT, 150 mmol/L Tris-HCl, pH 8.0). The detergent, DTT and other low-molecular-weight components were removed using UA buffer (8 mol/L urea, 150 mmol/L Tris-HCl pH 8.0) by repeated ultrafiltration (Microcon units, 10 kDa). Then, 100 μL of iodoacetamide (100 mmol/L IAA in UA buffer) was added to block reduced cysteine residues and the samples were incubated for 30 min in darkness. The filters were washed with 100 μL of UA buffer three times and then 100 μL of 25 mmol/L NH_4HCO_3 buffer twice. Finally, the protein suspensions were digested with 4 μg of trypsin (Promega) in 40 μL of 25 mmol/L NH_4HCO_3 buffer overnight at 37 ℃, and the resulting peptides were collected as a filtrate. The peptides of each sample were desalted on C18 Cartridges (Empore SPE Cartridges C18 (standard density), bed I.D. 7 mm, volume 3 mL, Sigma), concentrated by vacuum centrifugation, and reconstituted in 40 μL of 0.1% (v/v) formic acid. The peptide content was estimated by UV light spectral density at 280 nm using an extinction coefficient of 1.1 of 0.1% (g/L) solution that was calculated on the basis of the frequency of tryptophan and tyrosine in vertebrate proteins.

Mass spectrometry: Each fraction was injected for nanoLC-MS/MS analysis. The peptide mixture was loaded onto a reverse phase trap column (Thermo Scientific Acclaim PepMap100, 100 μm × 2 cm, nanoViper C18) connected to a C18-reversed phase analytical column (Thermo Scientific Easy Column, 10 cm long, 75 μm inner diameter, 3 μm resin) in buffer A (0.1% formic acid) and separated with a linear gradient of buffer B (84% acetonitrile and 0.1% Formic acid) at a flow rate of 300 NL/min controlled by IntelliFlow technology (one hour gradient: 0%-35% buffer B for 50 min, 35%-100% buffer B for 5 min, and held in 100% buffer B for 5 min).

LC-MS/MS analysis was performed on a Q Exactive mass spectrometer (Thermo Scientific) that was coupled to Easy nLC (Proxeon Biosystems, now Thermo Fisher Scientific) for 120 min. The mass spectrometer was operated in positive ion mode. MS data were acquired using a data-dependent top10 method that dynamically chooses the most abundant precursor ions from the survey scan (300-1800 m/z) for high energy collision dissociation (HCD) fragmentation. Automatic gain control target was set at 3×10^6, and maximum inject time set at 10 ms. Dynamic exclusion duration was 40.0 s. Survey scans were acquired at a resolution of 70000 at m/z 200. The resolution for HCD spectra was set at 17500 at m/z 200, and isolation width was 2 m/z. Normalized collision energy was 30 eV and the underfill ratio, which specifies the minimum percentage of the target value likely to be reached at maximum fill time, was defined as 0.1%. The instrument was run with peptide recognition mode enabled (Figure 2).

Data analysis: The MS data were analyzed using MaxQuant software version 1.3.0.5 (Max Planck Institute of Biochemistry in Martinsried, Germany).

Immunohistochemistry

Primary antibodies were used in this study as follows: mouse monoclonal anti-human DNA-PKcs (GR190339-3; Abcam, Cambridge, United Kingdom) and anti-human ERGIC1 (GR104221-6; Anbobio, San Francisco, CA, the United States). The anti-human DNA-PKcs antibody was diluted 1:400, and the anti-human ERGIC1 antibody diluted 1:3500. The paraffin sections were mounted on slides, dewaxed in xylene, and sequentially dehydrated in 100%, 95% and 85% ethanol. The sections were stained using the PV-6000 Polymer Detection System (Zhongshan Goldenbridge, Beijing, China). Initially, endogenous peroxidase was blocked using 3% H_2O_2. After the sections were incubated with the primary antibody overnight at 4 ℃, they were washed with PBS and then incubated with polymer helper for 30 min and poly peroxidase-anti-mouse/rabbit IgG for 30 min. After that, the sections were washed with PBS, and then incubated with 3,3-diaminobenzidine (DAB, Zhongshan Goldenbridge). The sections incubated with PBS without primary antibodies were used as negative controls. Finally, the sections were counterstained with hematoxylin and examined under a light microscope. The cells that were stained a yellow or brown color in the nucleus and/or cytoplasm were defined as positive. Five randomly selected fields per section were analyzed. In a ran-

Table 2 Results of DNA-PKcs and ERGIC1 from proteomic analysis

Protein ID	Gene	Protein	Fold change			
			Mild/normal	Moderate/normal	Severe/normal	Cancer/normal
P78527	*PRKDC*	DNA-dependent protein kinase catalytic subunit	1.12	1.54	1.60	2.30

Table 3 Results of DNA-PKcs and ERGIC1 from immunohistochemistry

Group	*n*	DNA-PKcs				*n*	ERGIC1			
		-	+	+ +	+ + +		-	+	+ +	+ + +
Normal	30	12	18	0	0	30	2	2	2	24
Mild	30	14	16	0	0	30	2	3	3	22
Moderate	30	5	3	23	0	30	2	3	25	0
Severe	30	3	2	25	0	30	5	5	20	0
Cancer	30	0	2	6	22	40	9	27	4	0

domly selected field from representative areas, the immunoreactive cells among 100 cells were assessed and quantified by percentage. Then, the average percentage of the five fields was used to assess the area of immunostaining (0 = 0%-5%; 1 = 6%-25%; 2 = 26%-50%; 3 =51%-75%; 4 = 76%-100%). In addition, the intensity of immunostaining was also semi-quantitatively assessed (0 = negative, 1 = weak, 2 = moderate, 3 = intense). Then, the scores from the "area × intensity" were calculated and used to describe the overall staining intensity that semi-quantitatively reflects the overall expression levels of proteins. The overall staining intensity was scored as follows: negative (-): 0-2; mild (+): 3-5; moderate (++): 6-8; and strong (+++): 9-12. All the sections were assessed and scored by two pathologists who were blinded to the clinical data of the patients.

Statistical analysis

All the data are expressed as mean ± SD or percentage. The χ^2 test (SPSS v.16.0 for Windows; SPSS, Inc, Chicago, IL, United States) was used to evaluate the difference between categorical variables. A *P*-value less than 0.05 was considered statistically significant.

RESULTS

Differentially expressed proteins detected by LC-MS/MS

To identify differentially expressed proteins in normal gastric mucosa, atrophic gastritis with mild dysplasia, atrophic gastritis with moderate dysplasia, atrophic gastritis with severe dysplasia, and early mucosal GC, we performed a study with label-free quantification technology integrated with LC-MS/MS. A total of 17443 peptides matching 2807 proteins were identified from tissue analysis. The expression of a total of 365 proteins, with a threshold of a 1.2-fold change and a *P*-value less than 0.05 between mild dysplasia, moderate dysplasia, severe dysplasia or early mucosal GC and matched normal gastric mucosa tissues, were considered to be statistically significantly different.

Aberrant expression of DNA-PKcs and ERGIC1 revealed by proteomic analysis

The fold changes in mild dysplasia, moderate dysplasia, severe dysplasia, and early mucosal GC compared to matched normal gastric mucosa tissues were 1.12, 1.54, 1.6, and 2.3 for DNA-PKcs, and 1.18, 0.84, 0.73, and 0.46 for ERGIC1, respectively (Table 2).

Aberrant expression of DNA-PKcs and ERGIC1 revealed by immunohistochemistry

In order to confirm the results of DNA-PKcs and ERGC1 from proteomic analysis, we further examined the expression of DNA-PKcs and ERGC1 by immunohistochemistry. The strongly positive (+++) rates in normal gastric mucosa, mild dysplasia, moderate dysplasia, severe dysplasia, and early mucosal GC were 80% (24/30), 73% (22/30), 0% (0/30), 0% (0/30), and 0% (0/40), respectively, for ERGC1, and for DNA-PKcs the strongly positive (+++) staining was observed only in the sections of early mucosal GC. The moderately positive (++) rates in normal gastric mucosa, mild dysplasia, moderate dysplasia, severe dysplasia, and early mucosal GC were 6.6% (2/30), 6.6% (3/30), 83% (25/30), 67% (20/30), and 10% (4/40), respectively, for ERGC1, and 0% (0/30), 0% (0/30), 76%(23/30), 83% (25/30), and 20% (6/30), respectively, for DNA-PKcs (Figures 3 and 4). The details on the rates of different-grade overall staining intensity are presented in Table 3.

In general, the average immunohistochemistry scores of the DNA-PKcs protein significantly increased, while those of ERGC1 protein significantly decreased along the sequence of normal gastric mucosa, mild dysplasia, moderate dysplasia, severe dysplasia, and early mucosal GC.

DISCUSSION

Using label-free quantification technology combined with LC-MC/MC, the expression of 365 proteins based on the tendency of fold change was revealed to be

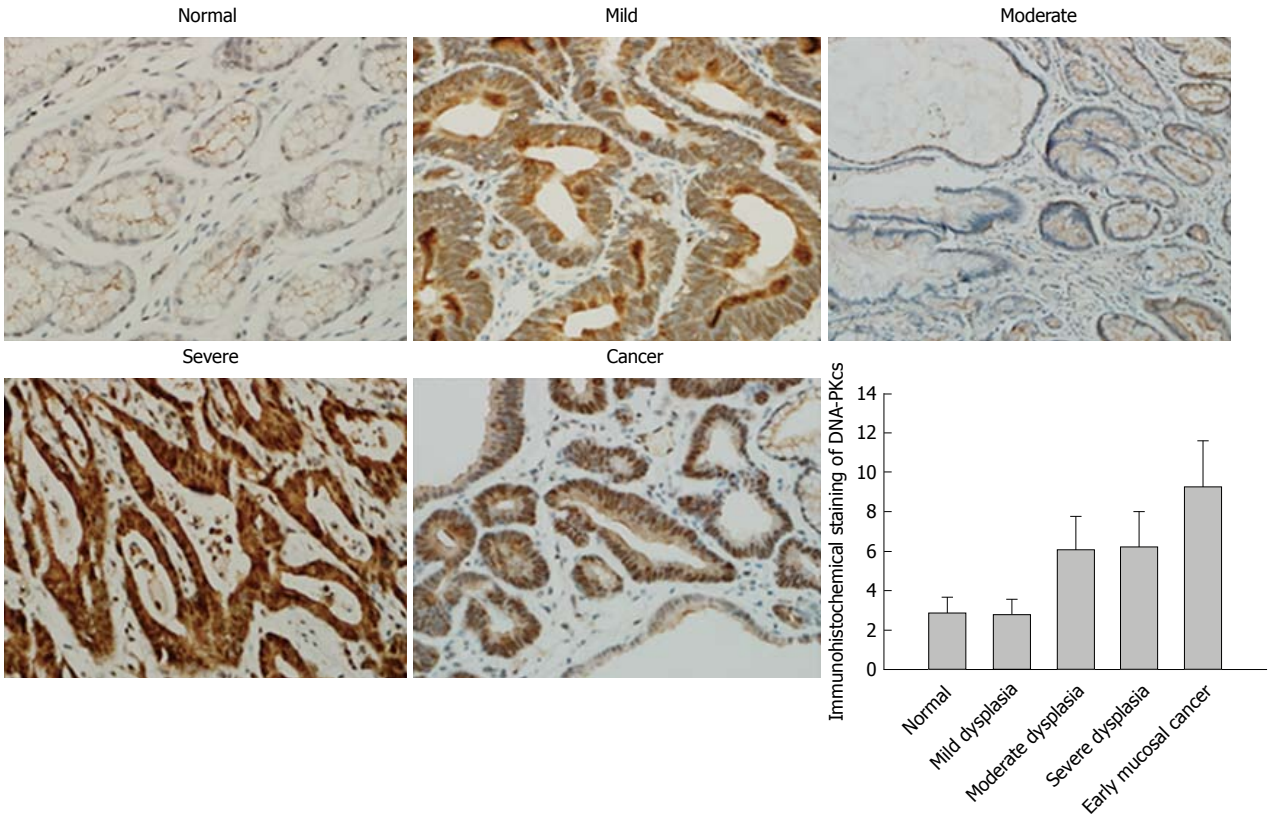

Figure 3 Immunohistochemical staining of DNA-PKcs (40 ×). A: Normal; B: Mild dysplasia; C: Moderate dysplasia; D: Severe dysplasia; E: Early mucosal cancer.

statistically different between various stages of GC initiation. Furthermore, we observed that ERGIC1 expression decreased, while DNA-PKcs expression increased gradually along with different stages of GC initiation based on the tendency of fold change, suggesting that abnormal ERGIC1 and DNA-PKcs expression may play an important role in GC initiation.

It has been reported that DNA-PKcs plays an important role in the activation of the NHEJ pathway[9,10]. When a DNA damage signal in cells is sent out, DNA-PKcs will recognize it and initiate a damage response in the first place, followed by the event that Ku 70/80 binds to the damaged DNA ends and induces DNA-PKcs to form DNA-PK that triggers NHEJ repair activities[16]. NHEJ is an error-prone and non-specific DNA repair mechanism and can be induced before homologous recombination, whose excessive activation has the capability of regulating cell cycle arrest, cell apoptosis, chromosome re-combination, and genome instability, all of which are closely related with carcinogenesis[17,18]. Dysregulation of DNA-PKcs has been reported to be associated with pathological processes in various cancers[19]. Consistent with the previous study indicating that DNA-PKcs expression in GC was up-regulated compared with normal gastric mucosa, and associated with GC progression[20], up-regulation of DNA-PKcs expression was also found in our study. Furthermore, our study showed more information that DNA-PKcs expression increased along with different stages of GC initiation. Hence, it is possible to hypothesize that enhanced NHEJ resulting from the overexpression of DNA-PKcs may contribute to GC initiation and progression.

ERGIC1, a cycling protein, plays a part in protein secretion out of the ER by participating in membrane trafficking and selective transport of cargo between the ER, the intermediate compartment, and the Golgi apparatus[11]. ER stress is defined as a disequilibrium between protein folding ability of the ER and protein load, causing the accumulation of misfolded and unfolded proteins[21]. Many factors, including hypoxia, starvation, infections, changes in secretary needs and so on, throw a challenge to the folding capacity of the cell and subsequently trigger ER stress[22]. ER stress has been speculated to be involved in many cancers including GC[23]. ER stress is capable of activating NF-κB, ROS, and JNK signal pathways[24-27], resulting in chronic inflammatory response that contributes to carcinogenesis. Besides, accumulating evidence indicated that ER stress response could facilitate cancer progression probably by promoting tumor angiogenesis and malignant cell autophagy, and mitigating apoptosis[28-31]. In this study, we observed that ERGIC1 expression decreased gradually along with different stages of GC initiation. Down-regulation of ERGIC1 expression may affect the protein secretion function of the ER and then disturb ER homeostasis,

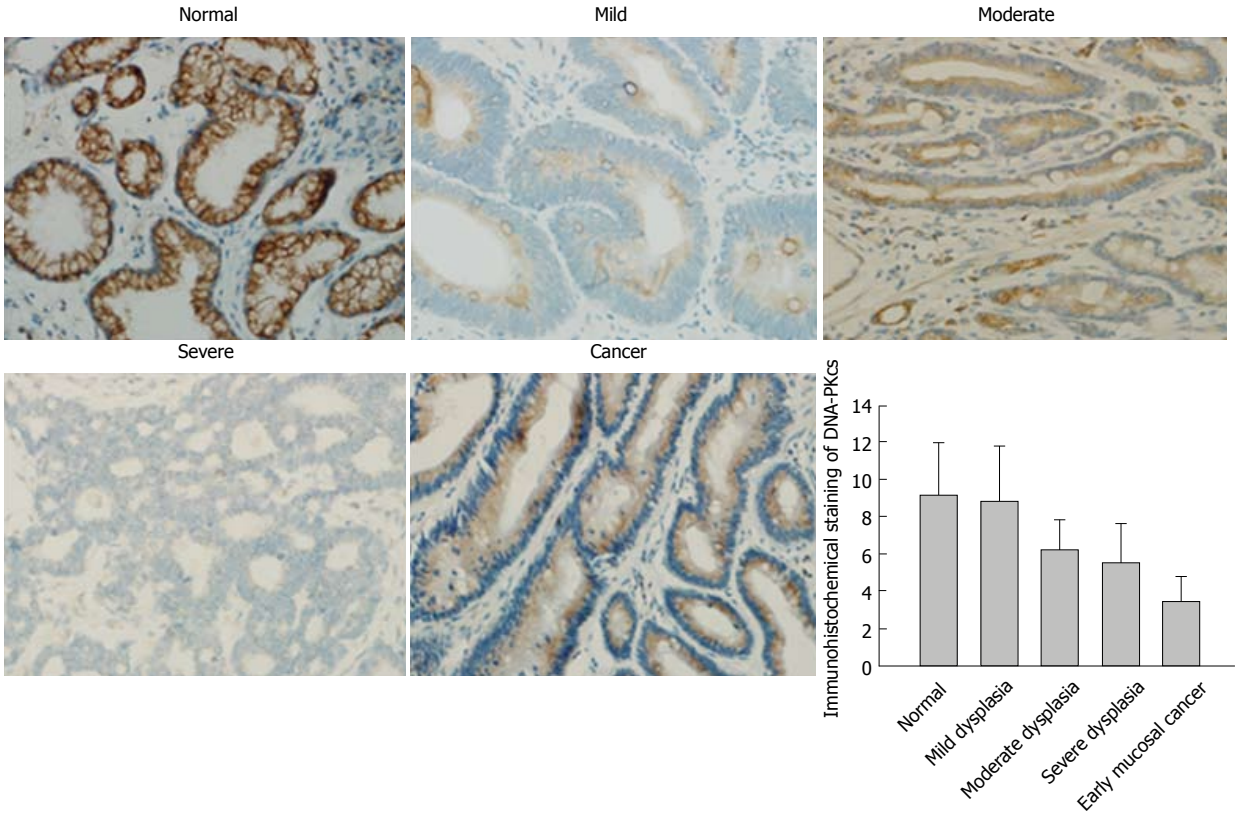

Figure 4 Immunohistochemical staining of ERGIC1 (40 ×). A: Normal; B: Mild dysplasia; C: Moderate dysplasia; D: Severe dysplasia; E: Early mucosal cancer.

which may cause the accumulation of unfolded and misfolded proteins, finally resulting in ERS. Thus, it is possibly reasonable to speculate that down-regulation of ERGIC1 expression may contribute to GC initiation by promoting ERS in gastric mucosal epithelial cells. Besides, some studies suggested that ER stress response can also induce the apoptosis of malignant cells[32-34], indicating that ER stress response may play a dual role in cancers. Furthermore, a study by Vainio *et al*[35] indicated that ERGIC1 expression was up-regulated in prostate cancer samples and knockdown of ERGIC1 could inhibit the ERG oncogene expression in prostate cancer cells *in vitro*, which suggested that the change tendency of ERGIC1 expression in cancers may be different, depending on the genomic or biological function of cancer cells. Therefore, another possible molecular mechanism responsible for the role of down-regulation of ERGIC1 in the GC initiation is that down-regulation of ERGIC1 perhaps disturbs the expression of some oncogenes or anti-oncogenes. Additionally, despite that there are some specific relationships between ERGIC1 and DNA-PKcs based on the inverse expression patterns observed in the current study, we did not provide adequate evidence to confirm that. Thus, further studies are required to elucidate the mechanisms by which down-regulation of ERGIC1 contributes to the initiation and progression of GCs and the internal link between ERGIC1 and DNA-PKcs.

In conclusion, our study conducted a systematic proteomic analysis of normal gastric mucosa, gastric mucosa with mild dysplasia, gastric mucosa with moderate dysplasia, gastric mucosa with severe dysplasia and early mucosal GC, which covered the whole sequential process of GC initiation, and suggested that the aberrant DNA-PKcs and ERGIC1 expression may be involved in the initiation of GC.

COMMENTS

Background

Gastric cancer (GC) is a global malignant disease with high incidence and mortality. The carcinogenesis of GC has been defined as a biological process involving polygene-driven, multi-step, and multi-stage events. However, the molecular mechanisms underlying the carcinogenesis of GC remain unknown.

Research frontiers

Using proteomics analysis, the current study aimed to investigate the molecular mechanisms of GC carcinogenesis.

Innovations and breakthroughs

The authors first report that aberrant ERGIC1 and DNA-PKcs expression may be involved in GC initiation.

Applications

Using label-free quantification technology combined with liquid chromatography-tandem mass spectrometry (LC-MS/MS), the authors observed that ERGIC1 expression decreased, while DNA-PKcs expression increased gradually along with different stages of GC initiation based on the tendency of fold change. The expression patterns of ERGIC1 and DNA-PKcs revealed by

immunohistochemistry were consistent with the LC-MS/MS results.

Peer-review

The authors demonstrated that that ERGIC1 expression decreased, while DNA-PKcs expression increased gradually along with different stages of GC initiation. A total of 160 specimens were enrolled in this study to identify differentially expressed proteins in normal gastric mucosa, gastric mucosa with mild dysplasia, moderate dysplasia, severe dysplasia, and early mucosal GC. These results are interesting and very valuable to verify the molecular mechanisms of GC carcinogenesis.

Author contributions: All authors were equally involved in the design of the study; Chang E conducted the statistical analyses and all authors contributed equally in the interpretation of results and writing of the manuscript.

Supported by Novartis Pharmaceuticals, One Health Plaza, East Hanover, No. NJ 07936-1080, United State.

Institutional review board statement: We conducted a retrospective cohort study using the Truven Health Analytics MarketScan Database and the IMS Health Pharmetrics Database, both commercial health insurance claims database for employer-insured beneficiaries in the United States. The databases are fully compliant with the Health Insurance Portability and Accountability Act and meets the criteria for a limited-use dataset. Since the patient and provider data included in this analysis were fully de-identified, this study was exempt from the Institutional Review Board review.

Conflict-of-interest statement: Cai B and Neary MP are employees of Novartis Pharmaceuticals Corporation; Benson III AB was paid as a research consultant for the study as a subject matter expert by Novartis and is an employee of Northwestern University; Broder MS, Chang E and Papoyan E are employees of Partnership for Health Analytic Research, LLC (PHAR, LLC), a health services research company paid by Novartis to conduct this research.

Data sharing statement: The study statistician, Eunice Chang, conducted all statistical analysis for this study using Health Insurance Portability and Accountability Act-compliant commercial-insurance secondary databases MarketScan and PharMetrics.

Abstract

AIM

To describe real-world treatment patterns of gastrointestinal neuroendocrine tumors (GI NET).

METHODS

In this retrospective cohort study, we used 2009-2014 data from 2 United States commercial claims databases to examine newly pharmacologically treated patients using tabular and graphical techniques. Treatments included somatostatin analogues (SSA), cytotoxic chemotherapy (CC), targeted therapy (TT), interferon

(IF) and combinations. We identified patients at least 18 years of age, with ⩾ 1 inpatient or ⩾ 2 outpatient claims for GI NET who initiated pharmacologic treatment from 7/1/09-6/30/14. A 6 mo clean period prior to first treatment ensured patients were newly treated. Patients were followed until end of enrollment or the study end date, whichever was first.

RESULTS

We identified 2258 newly treated GI NET patients: mean (SD) age was 55.6 years (SD = 9.7), 47.2% of the patients were between 55 and 64 years, and 48.8% were female. All regions of the United States were represented. 59.6% started first-line therapy with SSA monotherapy (964 with octreotide LAR, 380 with octreotide SA, and 1 with lanreotide), 33.3% CC, 3.6% TT, and 0.5% IF. The remainder received combinations. Mean follow up was 576 d. Overall mean first-line therapy duration was 361 d (449 d for SSA, 215 for CC, 267 for TT). 58.9% of patients had no pharmacological treatment beyond first line. The most common second-line was combination therapy with SSA. In graphical pattern analysis, there was no clear pattern visible after first line therapy.

CONCLUSION

In this study, 60% of patients initiated treatment with SSA alone or in combination. The relatively long time to discontinuation suggests possible sustained effectiveness and tolerability.

Core tip: In this retrospective study of real-world treatment patterns, somatostatin analogues were the most common initial pharmacologic treatment in patients with gastrointestinal neuroendocrine tumors, and most of the remaining patients began treatment with chemotherapy. However, despite the many treatment options, over half of the patients discontinued treatments after first line and only less than 10% of patients received any second-line pharmacotherapy. Given limitations of claims data to elucidate reasons for this lack of continued treatment, a study using more detailed clinical information such as medical charts or physician surveys is warranted.

Benson III AB, Broder MS, Cai B, Chang E, Neary MP, Papoyan E. Real-world treatment patterns of gastrointestinal neuroendocrine tumors: A claims database analysis. *World J Gastroenterol* 2017; 23(33): 6128-6136 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6128.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6128

INTRODUCTION

Neuroendocrine tumors (NET) comprise a broad family of rare and often slow growing malignancies. NET can develop anywhere in the body and arise from neuroendocrine cells throughout the endocrine system[1,2]. Approximately two-thirds of NET tumors occur in the gastrointestinal (GI) tract. These sites include the stomach, small intestine, appendix, colon, and rectum[3]. NET secrete peptides and neuroamines that cause distinct syndromes (*e.g.*, carcinoid syndrome), in which case they are referred to as "functional" tumors. Clinical presentation depends on the site of the primary tumor and whether they are functional. Surgery may be curative in the early stages, but delayed diagnosis is typical.

While rare, the incidence and prevalence of NET appear to be increasing worldwide[4-8]. The incidence of NET in the United States increased from 10.9 cases per million person-years (PMPY) in 1973 to 52.5 PMPY in 2004, and to 69.8 PMPY in 2012 as reported using the United States Surveillance Epidemiology and End Results database[4,9]. Prevalence also increased and was reported as 216 per million per year for GI NET in the United States.

The management of GI NET is based on a variety of factors including stage, anatomic location, and the presence and type of symptoms. The most recent NCCN guidelines for unresectable and metastatic GI NET recommend somatostatin analogues (SSA) as first-line treatment, but do not recommend a particular treatment sequence for the remaining therapies[10]. Considering the heterogeneity of GI NET tumors and the resultant lack of specificity in guidelines, we aimed to describe the current real-world treatment patterns of GI NET in a large sample of patients.

MATERIALS AND METHODS

Data source

We conducted a longitudinal, retrospective cohort analysis of newly pharmacologically treated GI NET patients using two large United States commercial claims databases. Data from the Truven Health Analytics MarketScan database and the IMS Pharmetrics database (both using dates from January 1, 2009 to December 31, 2014) were combined to increase sample size. To prevent duplicate records, patients with the same age, gender, region, and date of first GI NET diagnosis in a calendar year found in both databases were randomly removed from one of the databases. Both databases are Health Insurance Portability and Accountability Act compliant administrative claims databases that contain de-identified adjudicated medical claims (*e.g.*, inpatient and outpatient services) and pharmacy claims (*e.g.*, outpatient prescriptions) submitted for payment by

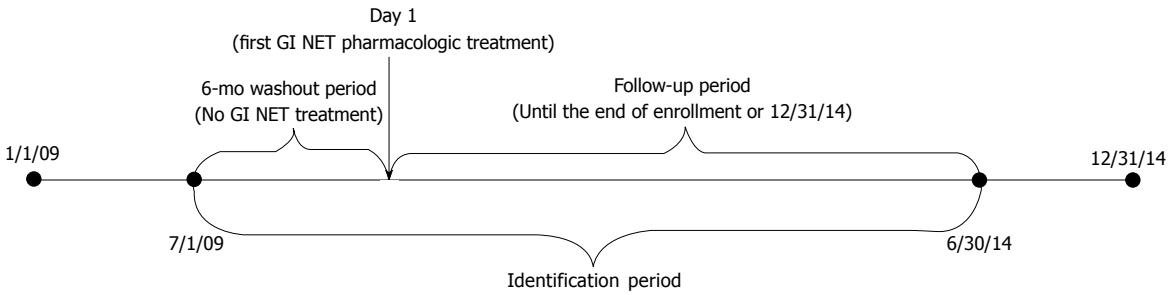

Figure 1 Study timeline. The first gastrointestinal neuroendocrine tumors (GI NET) pharmacologic treatment claim on or after the appearance of the GI NET diagnosis code and within the ID period (7/1/2009 to 6/30/2014) was considered to be the index date. Patients were required to be enrolled for a baseline period of at least six months before the index date. Patient follow-up was variable and continued until the end of enrollment or the study end date (12/31/14), whichever was first.

providers, healthcare facilities, and pharmacies. For both data sources, claims include information on each physician visit, medical procedure, hospitalization, drug dispensed, date of service, number of days of medication supplied, test performed, and complete payment information. Each medical claim has a principal diagnosis and secondary diagnoses codes associated with it. Available patient demographic information includes age, gender, and geographic region. Dates of enrollment and disenrollment are also recorded. As the data were fully de-identified, this study was considered exempt from approval by the Institutional Review Board.

Cohort selection

Patients at least 18 years of age were identified from each dataset if they had at least 1 inpatient or 2 outpatient claims with an International Statistical Classification of Disease-9-Clinical Modification (ICD-9-CM) for GI NET (209.00-209.03, 209.10-209.17, 209.23, 209.24-209.27, 209.40-209.43, 209.50-209.57, 209.62, 209.65-209.67) during the study period (1/1/2009-12/31/2014). The first GI NET pharmacologic treatment claim on or after the appearance of the GI NET diagnosis code and within the ID period (7/1/2009 to 6/30/2014) was considered to be the index date. Patients were required to be enrolled for a baseline period of at least six months before the index date. To ensure new treatment, patients with any evidence of pharmacologic treatment during this baseline period were excluded. In order not to include the same patient twice, we searched for any patients with the same age, gender, region, and date of GI NET diagnosis who could be found in both databases, but we found none. Patient follow-up was variable and continued until the end of enrollment or the study end date (12/31/2014), whichever was first (Figure 1).

Study variables and measures

The primary outcome measure was the use of pharmacologic or liver directed therapy. Pharmacotherapy was divided into four groups: SSA, TT, CC and IF. SSA included octreotide and lanreotide, TT included everolimus and sunitinib, and CC included temozolomide, streptozotocin, doxorubicin, liposomal doxorubicin, fluorouracil, capecitabine, dacarbazine, oxaliplatin and thalidomide. Pharmacologic therapy was identified in claims using both the Healthcare Common Procedure Coding System (HCPCS) and National Drug Codes (NDC). Liver directed therapies comprised liver resection, transplant, lesion ablation (using radiotherapy, cryotherapy, microwave and thermal energy, and including laparoscopic, open and percutaneous routes), embolization (including bland, radioisotope, and chemotherapy), and radiation therapy. Liver directed therapies were identified in claims using HCPCS, ICD-9-CM, and Current Procedural Terminology (CPT) codes. Chemotherapy observed only once and on the same date as embolization was considered chemoembolization and not part of a pharmacologic regimen.

First-line therapy was defined as the pharmacologic treatment regimen observed on, or within three months of, the index date. Therapy included monotherapy or combination therapies. A three-month period after the index date was used to identify pharmacologic therapy intended as first-line but not administered on the index date. This would include, for example, combination chemotherapy where the second agent is given after some delay. Second-line therapy was defined as beginning when treatment was switched from one category of pharmacotherapy to another (*e.g.*, from SSA alone to CC alone), or when a new category of treatment was added (*e.g.*, from SSA alone to SSA plus CC). Changes from one cytotoxic agent to another, or one SSA to another, were not considered a switch. The first day of treatment switch or addition was defined as the initiation date of second-line therapy.

Statistical analysis

Means and proportions were presented in tabular analyses. An inverse Kaplan-Meier curve was used to show duration of first-line therapy. All data transformations and statistical analyses were performed using SAS® version 9.4 (SAS Institute, Cary, NC). Graphical analyses were conducted using GRAPHx™, a proprietary graphics-based algorithm. The GRAPHx method uses multi-colored line segments to represent

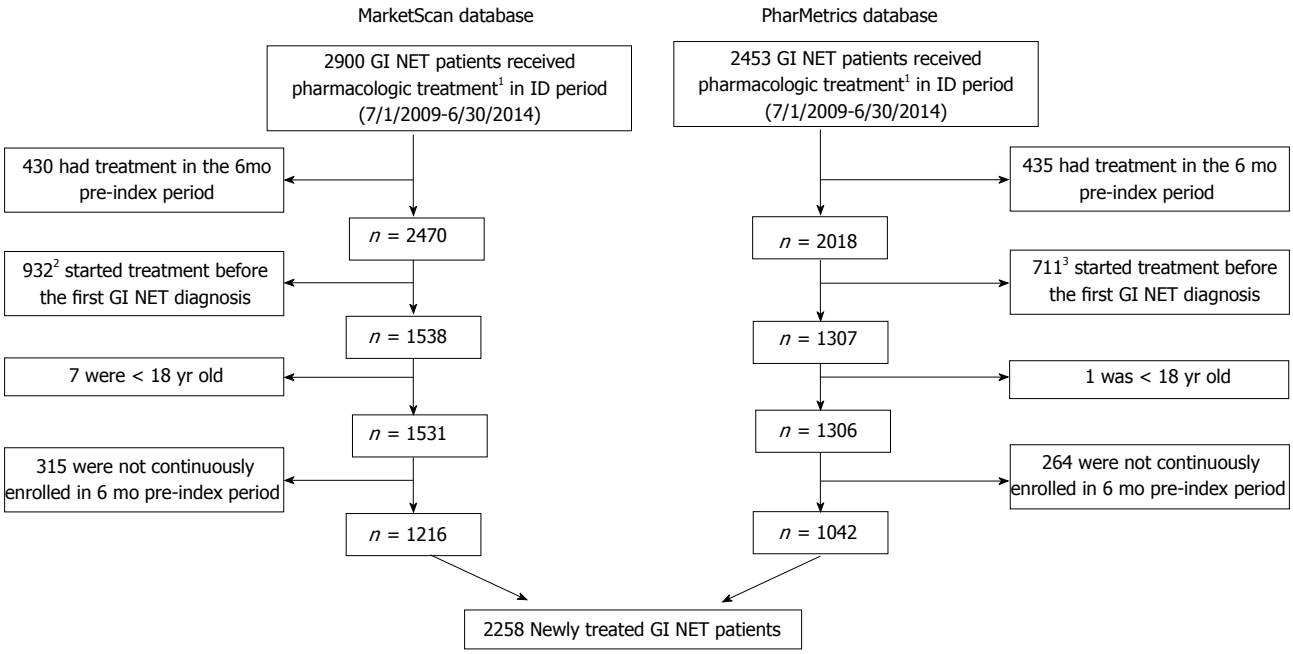

Figure 2 Patient identification. There were 2900 and 2453 gastrointestinal neuroendocrine tumors (GI NET) patients who also had a claim for pharmacologic treatment between 7/1/2009 and 6/30/2014 in the MarketScan and PharMetrics databases, respectively. After excluding patients who had treatment during a 6-mo pre-index period (and therefore were considered to be continuing, rather than initiating, treatment); received treatment before receiving a diagnosis of GI NET; were < 18 yr old; or were not continuously enrolled in the 6-mo pre-index period, there remained 2258 newly treated GI NET patients who were included in the study. [1]Somatostatin analogues (SSAs), targeted therapy, cytotoxic chemotherapy, or interferon; [2]324 (34.8%) within 3 mo, and 516 (55.4%) within 6 mo; [3]249 (35.0%) within 3 mo, and 380 (53.4%) within 6 mo.

various treatments, plotting them over time. The images are reviewed visually for the presence and length of segments and change in colors and patterns over time.

RESULTS

There were 2900 and 2453 patients meeting the definition of GI NET who also had a claim for pharmacologic treatment between 7/1/2009 and 6/30/2014 in the MarketScan and PharMetrics databases, respectively. After excluding patients who had treatment during a 6-mo pre-index period (and therefore were considered to be continuing, rather than initiating, treatment); received treatment before receiving a diagnosis of GI NET; were < 18 years old; or were not continuously enrolled in the 6-mo pre-index period, there remained 2258 newly treated GI NET patients who were included in the study (Figure 2).

Gender was evenly split with *n* = 1103 (48.8%) female patients and *n* = 1155 (51.2%) male. The average age was 55.6 years (SD = 9.7) and 47.2% of the patients were between 55 and 64 years. All regions of the United States were represented. More than half of patients, *n* = 1345 (59.6%), were treated with SSA as first-line monotherapy, 964 with octreotide LAR, 380 with octreotide SA, and 1 with lanreotide. An additional 75 patients (3.3%) received SSA in combination with other either CC, TT or IF. The second largest group, *n* = 752 (33.3%), was treated with CC monotherapy, and *n* = 81 (3.6%) received TT monotherapy (Table 1). Mean duration of first-line therapy was 361 d (SD = 385) for all newly treated patients. The mean observed duration of treatment for first-line SSA monotherapy users was 449 d (SD = 434.2). It was 215 d (SD = 228.8) for first-line CC monotherapy and 267 d (SD = 325.7) for first-line TT monotherapy (Table 2). By 588 d of treatment (1.61 years), half of SSA initiators had discontinued treatment, compared to 182 d (0.498 years) for half of CC users and 171 d (0.47 years) for half of TT users to discontinue treatment (Figure 3). Liver directed therapy was used by 12.5% during first-line pharmacologic therapy; another 3.7% received it sometime after the first-line (Table 2).

By the end of the study follow-up period [mean (SD, median) of 576 d (447.1, 454)] 58.9% (*n* = 1331) patients had stopped pharmacologic therapy completely. These patients continued to be enrolled in one of the databases but no longer had claims for pharmacologic treatment. In Figure 4, these patients can be identified as colored line segments that terminate in gray segments of variable length, with the gray representing the period of no treatment. An additional 32.7% (*n* = 738) continued their initial therapy until the end of their enrollment; these patients were still receiving their first-line therapy at the time they left a covered plan or reached the end of study. This pattern is shown in Figure 4 as a colored segment terminating in white. The remaining 8.4% (*n* = 189) were observed to change pharmacologic treatment during the follow-up period (a colored segment terminating in different colored segment)

[1]964 with octreotide LAR, 380 with octreotide SA, and 1 with lanreotide. SSA: Somatostatin analogues; CC: Cytotoxic chemotherapy; TT: Targeted therapy; IF: Interferon.

(Figure 4 and Table 2). Among these 189 patients who were observed to begin second-line therapy, 128 (67.7%) had initially been treated with SSA. Among these 128 first-line SSA users, 89 (69.5%) added additional therapy (*e.g.*, CC or TT) as their second-line treatment. In patients who did not begin therapy with SSA, most received SSA monotherapy or combination therapy as second-line (Table 3). Liver directed therapy (short, red segments) appears dispersed throughout periods of both pharmacologic treatment (colored segments) and periods of no pharmacologic treatment (gray segments) (Figure 4). Among 1331 patients who stopped pharmacologic treatment and did not begin a second-line treatment, 5.5% were treated with liver-directed therapy within 30 d before or after they stopped.

DISCUSSION

This study used two very large, nationally representative claims databases, which together represent up to 100 million covered lives, to describe real-world treatment of GI NET. Three findings were of particular interest. First, the most common initial pharmacologic treatment was with SSA, with average duration of use of just over 18 mo. Second, although 60% of patients initiated treatment with SSA alone or in combination, most of the remainder began treatment with CC, therapy recommended

	Point estimate (95%CI)

[1]Among patients who stopped.

by NCCN only if no other options (SSA, TT, or liver directed treatment) are feasible. Third, despite the many available treatment options, less than one in 10 patients was observed to receive treatment with second-line pharmacotherapy of any type.

Each of these findings must be considered in light of what is known about the disease as well as the inherent limitations of the data source. Treating NET patients is a complex process. Treatments are individualized based on tumor size, location, and pathology, as well as whether the tumor is functional, type and extent of symptoms, and speed of progression. Our data did not include this level of detail. Insurance companies aggregate information on inpatient and outpatient services (generally reported as ICD-9-CM or ICD-10), procedures (ICD-9 procedure codes and CPT codes) and pharmacy claims (NDC) as claims are submitted for payment by providers, healthcare facilities, and pharmacies. So for example, while GI NET can be identified by using a list of ICD-9-CM codes, presence of advanced disease must be inferred by observing the use of pharmacologic treatment. Another limitation of the date source is that the available length of time for analysis is relatively brief, so conclusions regarding average duration of use may not be representative of long-term treatment patterns.

Our primary finding that 60% of patients initiated pharmacologic therapy with SSA is consistent with the NCCN recommendation of these drugs for initial treatment of clinically significant and progressive NET. Consistent with the clinical observation that SSA tend to be well tolerated, patients initiating treatment with SSA remained on first-line therapy longer than the patients who began treatment with CC and TT. The second finding noted above, that 1/3 of GI NET patients began treatment with CC, is more surprising. CC is relatively ineffective in these patients, and as a result is recommended only if other options are not feasible.

There are several possible explanations for the frequent use of CC. Patients observed to initiate cytotoxic treatment may have been treated in the past with other agents and either progressed or were intolerant to those agents. We reviewed data for 6 mo before the first pharmacologic treatment, but treatments more than 6 mo in the past would have been missed. It may also be that some of the patients had a pathology finding suggesting chemotherapy would be beneficial, or a different type of GI tumor that was incorrectly coded as NET. Our data were de-identified, meaning we could not confirm the diagnosis in medical records, physician or patient surveys, or by other means. Finally, some clinicians may have been unfamiliar with either best practice recommendations or the available, albeit limited, data on GI NET treatment. Our findings are consistent with a recent large case series from a tertiary referral center that found SSA and CC were the two most common treatment strategies used for gastroenteropancreatic NET[11].

Previous studies have found significant divergence between clinical guidelines and treatment in other, more common, cancers. Chagpar and colleagues found that while Stage I colon cancer patients were treated according to guidelines by 95%, higher stage patients were less likely to be treated according to guidelines. Stage II

Table 3 Second-line treatment, stratified by first-line treatment *n* (%)

high-risk patients showed the lowest concordance with only 36% being treated per recommendation[12]. In a prospective study of women with breast cancer, Giorano and colleagues found that 83% of patients 55-64 years old received care concordant with chemotherapy guidelines compared with 29% of patients 75 or older[13].

The finding that only a small proportion of patients are observed to receive second-line treatment is also surprising. The 5-year survival of patients with advanced GI NET is more than 70%. Most surviving patients would be expected to receive continued treatment, whether in the form of liver-directed treatment or pharmacotherapy. We considered multiple explanations for this finding. First, although median follow-up was over 15 mo, many patients were eventually lost to follow-up when they disenrolled from a plan included in our databases. One third of patients were continuing to use their index treatment when they were lost to follow-up. Whether (or when) these individuals progressed to second-line treatment cannot be determined using these databases. If these patients were systematically different from the ones who remained under observation, our results would be biased.

Despite this significant loss to follow-up, nearly 60% of patients were observed to continue enrollment but stop therapy. That is, they survived and remained in the data set, but no second-line pharmacotherapy use could be identified. We considered the possibility that these patients received some liver-directed treatment that alleviated their symptoms or controlled their disease, obviating the need for second-line treatment. However, we found no evidence of this: liver-directed treatment was observed in only 5.5% of patients around the time they stopped first-line treatment. We also considered whether some patients may have had a secondary source of payment, such that their claims for pharmacotherapy did not appear in our databases. Just over 11% of patients were 65 and older and would have been eligible for Medicare. Payment rules regarding patients with both commercial coverage and Medicare are complex[14] but generally require the commercial payer (for which we did have data) to be primarily responsible for payment. In cases where Medicare had primary responsibility, we would have missed claims for pharmacologic or liver-directed therapy and thus underestimated treatment. The magnitude of this problem is impossible to know using our current data source. A study using Medicare data and examining patients over 65 only might be less likely to suffer from this bias. Finally, it may indeed be the case that some patients stop therapy completely. Such patients may be terminal and choose not to undergo further treatment, or they may be relatively asymptomatic and decline to be treated on that basis. Further research with detailed clinical data would be needed to confirm which, if any, of these explanations is the most accurate.

In this large, claims-based, retrospective study of real-world pharmacologic treatment patterns, we found that 60% of GI NET patients began therapy with SSA and about one-third with CC. The relatively long time to discontinuation of SSA, as well as their use in combination with other agents, suggests they may be well tolerated and potentially have sustained effectiveness. We also found that over half of the patients discontinued treatment after first-line and only less than 10% of the patients received second-line treatment despite the availability of a number of different options. To address the limitations of this study and expand knowledge of real-world treatment patterns, a study using more detailed clinical information such as medical charts or physician surveys is warranted. In addition, future studies should consider using databases that would allow for greater longitudinal follow-up, such as registries, to assist in the further understanding of treatment patterns and length of therapy.

COMMENTS

Background

Neuroendocrine tumors (NET) comprise a broad set of rare tumors. Almost 2/3 arise in the gastrointestinal (GI) tract. The management of GI NET is based on a variety of factors including stage, anatomic location, and the presence and type of symptoms. The most recent NCCN guidelines for unresectable and metastatic GI NET recommend somatostatin analogues (SSA) as first-line treatment, but do not recommend a particular treatment sequence for the remaining therapies.

Research frontiers

This study's results add to the limited knowledge about real-world treatment patterns for GI NET, which is especially significant in light of the lack of treatment guidelines regarding treatment sequences beyond first-line therapy.

Innovations and breakthroughs

This study used two very large, nationally representative claims databases to describe real-world treatment of GI NET. The three key findings were: first, the most common initial pharmacologic treatment was with SSA, with average duration of use of just over 18 mo; second, although 60% of patients initiated treatment with SSA alone or in combination, most of the remainder began treatment with cytotoxic chemotherapy, therapy recommended by NCCN only if no other options (SSA, targeted therapy, or liver directed treatment) are feasible; and third, despite the many available treatment options, less than one in 10 patients was observed to receive treatment with second-line pharmacotherapy of any type. The authors findings are consistent with a recent large case series from a tertiary referral center that found SSA and CC were the two most common treatment strategies used for gastroenteropancreatic NET. Previous studies have also found significant divergence between clinical guidelines and treatment in other, more common, cancers.

Applications

This study suggests that there is frequent use of CC in GI NET treatment, although CC is relatively ineffective in these patients and recommended only if other options are not feasible. This may be a result of clinicians unfamiliarity with either best practice recommendations or the available, albeit limited, data on GI NET treatment. To address the limitations of this study and expand knowledge of real-world treatment patterns, a study using more detailed clinical information such as medical charts or physician surveys is warranted. In addition, future studies should consider using databases that would allow for greater longitudinal follow-up, such as registries, to assist in the further understanding of treatment patterns and length of therapy.

Terminology

NET arise from cells that release hormones in response to nerve stimulation. Insurance claims databases compile coded information related to charges for medical care for large populations, but they do not contain clinically detailed records.

Peer-review

The article aims to describe real-world treatment patterns of GI NET.

Abstract

AIM

To investigate whether immune mediated diseases (IMD) are more frequent in patients with inflammatory bowel disease (IBD).

METHODS

In this population based registry study, a total of 47325 patients with IBD were alive and registered in the Danish National Patient Registry on December 16, 2013. Controls were randomly selected from the Danish Civil Registration System (CRS) and matched for sex, age, and municipality. We used ICD 10 codes to identify the diagnoses of the included patients. The IBD population was divided into three subgroups: Ulcerative colitis (UC), Crohn's disease (CD) and Both the latter referring to those registered with both diagnoses. Subsequently, odds-ratios (OR) and 95%CI were obtained separately for each group and their respective controls. The use of Bonferoni post-test correction adjusted the significance level to $P < 0.00125$. *P*-values were estimated using Fisher's exact test.

RESULTS

There were significantly more women than men in the registry, and a greater percentage of comorbidity in the IBD groups ($P < 0.05$). Twenty different IMDs were all significantly more frequent in the IBD group. Sixteen

were associated with UC versus twelve with CD. In both UC and CD ORs were significantly increased (P < 0.00125) for primary sclerosing cholangitis (PSC), celiac disease, type 1 diabetes (T1D), sarcoidosis, asthma, iridocyclitis, psoriasis, pyoderma gangrenosum, rheumatoid arthritis, and ankylosing spondylitis. Restricted to UC (P < 0.00125) were autoimmune hepatitis, primary biliary cholangitis, Grave's disease, polymyalgia rheumatica, temporal arteritis , and atrophic gastritis. Restricted to CD (P < 0.00125) were psoriatic arthritis and episcleritis. Restricted to women with UC (P < 0.00125) were atrophic gastritis, rheumatoid arthritis, temporal arteritis, and polymyalgia rheumatica. Restricted to women with CD were episcleritis, rheumatoid arthritis, and psoriatic arthritis. The only disease restricted to men (P < 0.00125) was sarcoidosis.

CONCLUSION

Immune mediated diseases were significantly more frequent in patients with IBD. Our results strengthen the hypothesis that some IMDs and IBD may have overlapping pathogenic pathways.

Core tip: Essential to inflammatory bowel disease (IBD) pathogenesis are environmental factors, altered gut microbiota and genetic susceptibility. The latter causing impairment of barrier function, autophagy, and Th1, 2 and 17 cell responses. Interestingly, these mechanisms are also thought important in other immune mediated diseases, as is the overlap of susceptibility genes. Besides the classic extraintestinal manifestations, we found a variety of immune mediated diseases to be more frequent in individuals with IBD. Physicians should be aware of this when treating these patients. Furthermore, these findings support the hypothesis that immune mediated diseases may have overlapping pathogeneses. Thus, understanding IBD might help us understand other immune mediated diseases and vice versa.

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC) are two distinct types of chronic inflammatory bowel diseases. The insight into etiology factors and the complex pathogenetic process is not yet fully understood. The diseases are often diagnosed in young individuals and recent studies report increasing incidences of both UC and CD, not only in Denmark but globally[1]. It has been suggested that inflammatory bowel disease (IBD) may be due to an inappropriate inflammatory response to the intestinal flora in genetically susceptible individuals. So far, several susceptibility genes have been identified[2]. Many of these are also found in other immune mediated diseases (IMDs), indicating overlaps between pathogenic pathways. The identified risk genes in IBD are involved in maintaining normal microbial gut homeostasis and adequate immune response[3,4]. Mutations in these may impair mechanisms essential to innate and adaptive immune response, *i.e.* weakened mucosal barrier, a decrease of antibacterial agents, impaired autophagy and antigen recognition. Mutations may also cause an imbalance of pro- and anti-inflammatory cytokines related to the regulation of Th1, 2 and 17 in particular[5]. CD is considered Th1 mediated thus characterized by interferon gamma, tumor necrosis factor alpha, and IL 12. UC is associated with a Th2 response where IL 4, 5, 10 and 13 are dominant. The Th17 response is present in both CD and UC but most pronounced in CD. It is characterized by IL 17 and 23 production. Th17 can also produce interferon gamma like Th1[5-8]. It is suggested that disturbances in these mechanisms may cause a loss of self-tolerance leading towards chronic inflammation or autoimmunity[9-12].

The gut microbiota of patients with IBD has been shown to contain less diversity, a reduced number of bacteria, and an altered microbial metabolite profile compared to healthy individuals[13]. Environmental factors, *i.e*. medication (antibiotics, non-steroid anti-inflammatory drugs and hormones), diet, geography, and previous infections might influence this[4]. A similar etiology is believed to exist in other IMDs, *i.e.* rheumatoid arthritis, ankylosing spondylitis, multiple sclerosis, type 1 diabetes (T1D), and celiac disease[14,15].

It has become clear, that patients with an existing IMD are more likely to develop other IMDs, this is more evident in females than in males[16]. Apart from the extraintestinal manifestations of IBD, little is known about the association between IBD and other IMDs.

Only a few large population based studies on the subject exist. The results of these suggest that IBD is associated with asthma, rheumatoid arthritis, psoriasis, multiple sclerosis, autoimmune thyroiditis, T1D, and vasculitis[17-22]. Different study designs, varying validity of diagnoses, population sizes and confounders, *i.e.* ethnicity, economic and social status, all make the findings of these studies difficult to interpret.

In Denmark healthcare is free and all contacts to hospitals are registered on an individual basis based on a civil registration number together with diagnosis

and procedural codes. This allows a unique access to information not confounded by economic and social status.

The aim of this study was to examine if IMDs are more frequent among patients with CD and UC compared to the background population.

MATERIALS AND METHODS

This was a cross-sectional study including all living patients with IBD who were matched with a control group to compare the point-prevalence of specific IMDs.

Identification of patients and controls

The Danish National Patient Registry include all contacts within the healthcare system both in-hospital, since 1977, and in outpatient settings since 1994. Data were retrieved on December 16, 2013 and included all patients alive registered with a diagnosis compatible with CD and UC. Patients were identified using the ICD 10 codes: CD K50.0-K50.9; UC, K51.0-K51.9). ICD 10 codes including "other" or "unspecified" were excluded to avoid inclusion of non-specific diseases and incorrect diagnosis codes.

The Danish Civil Registration System (CRS) includes all Danish inhabitants and each person has a unique 10-digit identification number. The CRS includes demographic data *e.g.* name, sex, date of birth, and death[23]. All IBD patients were paired (2:1) with random controls identified in the CRS and matched by sex, age (± 1 year) and municipality. Demographic data presented are based on data from the CRS.

The selected forty IMDs are all considered to be of either autoimmune or inflammatory origin. The same criteria were used for the IMDs. ICD 10 codes for the IMDs are listed in the Supplementary Table 1.

To assess comorbidity we used the Charlson comorbidity index which has been developed to estimate 1-year mortality in cancer patients. It is also useful in research to identify possible confounding diseases. It includes a number of systemic diseases associated with increased mortality, *i.e.* organ failure, AIDS, and cancer[24].

Ethics

This study was approved by the Danish Data Protection Agency (approval # 2013-41-1596). Approval from the Ethics Committee was not needed as this is a registry study.

Statistical analysis

The occurrence of IMDs was obtained separately for each group. Then OR and 95%CI were calculated. Fisher's exact test was used to calculate *P*-values.

We used the Bonferroni post-test correction to reduce the likelihood of false positives. We did 40 comparisons (the 40 IMDs investigated) and adjusted the significance level accordingly to $P < 0.00125$. Calculations was made using STATA version 13.0 (StataCorp LP, TX, United States).

RESULTS

A total of 47325 patients were alive and registered with IBD on December 16, 2013. A total of 92839 controls were identified.

CD was registered in 13343 patients, UC in 31066, and 2916 were registered with both diagnoses. A total of 92839 controls were found for the IBD group, 26172 for CD, 60951 for UC and 5716 for those with both diagnoses. Due to the matching criteria, five IBD patients had only one or no controls.

There was an excess of women in all IBD groups, most pronounced in CD ($P < 0.05$). The mean age at onset of disease was significantly higher in UC. Comorbidity was most frequent in those with either UC or CD ($P < 0.05$). See Table 1.

Twenty out of forty IMDs had significantly increased ORs in the IBD groups compared to their controls ($P < 0.00125$). Sixteen IMDs were associated with UC and twelve with CD. See Tables 2 and 3.

Seven of the IMDs were considered rheumatologic diseases, included ankylosing spondylitis, rheumatoid arthritis, psoriatic arthritis, polymyalgia rheumatic, temporal arteritis, polyarteritis nodosa, and Churg

[a]$P < 0.00125$; [b]$P = 0.00125$-0.05; [c]$P > 0.05$; [1]Patients registered with both CD and UC; [2]No. of cases in IBD cohort/No. of cases in control cohort. CD: Crohn's disease; UC: Ulcerative colitis; IBD: Inflammatory bowel disease.

Strauss Syndrome.

Five IMDs were gastrointestinal including celiac disease, atrophic gastritis, primary sclerosing cholangitis, primary biliary cholangitis, and autoimmune hepatitis.

The remaining IMDs were T1D, Grave's disease, pyoderma gangrenosum, psoriasis, iridocyclitis, episcleritis, sarcoidosis, and asthma.

There was a trend towards significance (P = 0.00125-0.05) for Wegener's granulomatosis, chorioretinitis, vitiligo, lichen ruber planus, scleroderma, and multiple sclerosis.

Seven IMDs were only significant in women. While only one was restricted to men. See Table 4.

In general, the same pattern is seen in those registered with both CD and UC.

We did not observe any OR below one, neither did we record any cases of Sjögren's syndrome, inclusion body myositis, eosinophilic esophagitis, or autoimmune adrenalitis.

DISCUSSION

In this study, we documented an increased frequency

Table 4 Odds-ratios for immune mediated diseases restricted to either gender

Disease	Females	95%CI	Males	95%CI
IBD				
Episcleritis	3.6[a]	2.1-6.1	2.9[b]	1.4-6.1
Atrophic gastritis	3.5[a]	2.1-5.9	-[c]	
Polyarteritis nodosa	2.6[a]	1.5-4.5	-[c]	
Rheumatoid arthritis	1.9[a]	1.6-2.2	1.4[b]	1.1-1.9
Giant cell arteritis	1.7[a]	1.3-2.2	-[c]	
Psoriatic arthritis	1.6[a]	1.3-2.0	1.4[b]	1.1-1.9
Polymyalgia rheumatica	1.5[a]	1.3-1.8	-[c]	
Sarcoidosis	1.5[b]	1.1-2.2	1.9[a]	1.3-2.6
UC				
Atrophic gastritis	3.1[a]	1.7-5.8	-[c]	
Rheumatoid arthritis	1.7[a]	1.4-2.1

Both[1]				
Iridocyklitis	3.6[a]	1.9-6.8	2.7	1.2-6.2
Celiac disease	6.0[a]	1.9-18.6	3/0[b,2]	
Autoimmune hepatitis	17.9[a]	2.3-141.5	7.8[b]	0.9-69.8

[a]$P < 0.00125$; [b]$P = 0.0125$-0.05; [c]$P > 0.05$; [1]Patients registered with both CD and UC; [2]No. of cases in IBD cohort/No. of cases in control cohort. CD: Crohn's disease; UC: Ulcerative colitis; IBD: Inflammatory bowel disease.

of twenty IMDs in patients with IBD compared to matched cohorts.

Although most of the IMDs are considered to be Th1 mediated, UC was associated with more IMDs than CD. The presence of Th17 cells in UC and their ability to induce a Th1 response might explain this. Another explanation might be that certain susceptibility genes can act differently depending on the setting[25]. A gene might increase the risk of one disease while reducing the risk of others[25-27].

Extraintestinal manifestations

Ankylosing spondylitis, pyoderma gangrenosum, psoriasis, iridocyclitis, episcleritis, and primary sclerosing cholangitis (PSC) are all well described in IBD[28]. Thus the significant associations were expected. Except from PSC, these will not be discussed further.

Primary sclerosing cholangitis and gastrointestinal immune mediated diseases

PSC is predominant in men and most frequent in UC[29]. We found PSC to be associated with both types of IBD and both genders. Most striking is the association with CD which is less often described. Studies suggest that PSC is more frequent when colon is affected and a distinct subtype, PSC-IBD has been suggested[30-33]. This study does not include data on localization, severity or extension. Several PSC risk genes are shared with IBD and other IMDs[33,34]. Gene mutations influencing IL 10 signaling are identified in CD, UC and PSC. The absence of IL 10 can cause severe CD due to lack of Th1 and macrophage inhibition[33-35]. Interestingly, hepatobiliary inflammation is thought to be induced by microbial metabolites and changes in the microbiota and this inflammation is linked to the *FUT2* gene, which is also found in CD[33,34,36].

In contrast to most other studies[18,36,37], we found celiac disease to be more frequent in those with IBD regardless of type, as did another Danish study[16]. Other studies found IBD to be more common in patients with celiac disease but not vice versa[38-40]. Similarities and differences in pathogeneses might explain these conflicting results. Celiac disease is like IBD an inflammatory disorder of the intestine, often diagnosed in young individuals, more common in women, and Th1 mediated. Changes in microbiota and dysfunctional IL 18 receptor are also noted in both conditions[27,41]. Risk genes of celiac disease shared with CD relates to adaptive immunity while those shared with UC primarily relates to barrier function. Different from IBD is the absence of Th17 response, impaired autophagy and while important in celiac disease, IL 15 is not that important in IBD[41].

We found autoimmune hepatitis, primary biliary cholangitis, and atrophic gastritis to be more common in UC only. Again, results from previous studies conflict[16,18,21,42-45]. Little is known about the association with atrophic gastritis, which to our knowledge is unique to this study. Th1, 2 and 17 responses are important in IBD, PSC and primary biliary cholangitis pathogenesis. Primary biliary cholangitis and IBD have overlapping susceptibility genes, which is not the case with autoimmune hepatitis[46,47]. The pathogenesis of primary biliary cholangitis resembles those of autoimmune hepatitis and CD, dysfunctionalities in IL 12 signaling promotes a Th1 and possibly also a Th17 response, causing a granulomatous inflammation[47,48].

Endocrine diseases

UC is reported to occur more frequently in family members of patients with T1D[18,19,49]. However, three studies did not find any association[16,20,21]. This study found T1D associated with both UC and CD. Confounding due to treatment with corticosteroids is unlikely, as the mechanisms in steroid induced diabetes resemble those in type 2 diabetes[50,51]. Levels of IL 18 are elevated in CD and T1D, but not in UC. IL 18 causes a Th1 response and is likely to affect mucosal barrier function too[27,52]. PTPN2 is one of many shared risk genes[2,53]. It promotes beta cell apoptosis in T1D while causing intestinal barrier dysfunction, impaired autophagocytosis, and inhibition of Th17 in IBD[25,54]. Changes in the gut microbiota are also suggested to trigger T1D[27].

Data on autoimmune thyroiditis and IBD is sparse, similarities to IBD limited and only few risk genes overlap[55-57]. Restricted to UC only, we found OR significantly increased for Grave's disease. None was

detected for Hashimoto's thyroiditis. Similar results are reported in two other studies[18,58]. One study reports hypothyroidism more common in CD[19]. In addition, three other studies did not find any association at all[16,17,21].

Rheumatic diseases

Rheumatoid arthritis was associated with both UC and CD while psoriatic arthritis was restricted to CD. Previously published data support this[18,20,21,59]. The microbiome of the gut and skin are possible triggers in rheumatoid arthritis and psoriatic arthritis[60]. Both types of arthritis share characteristics with CD in particular. Th1 and 17 are essential in all three pathogeneses[2,61-64].

ORs for polymyalgia rheumatica and temporal arteritis were significantly increased in the IBD and UC group, not in CD. This is supported by one study while refuted by another[16,18]. Overlapping susceptibility genes suggest that Th1, Th17 and regulatory T cells are of importance to the pathogeneses[65].

ORs for Churg Strauss Syndrome and polyarteritis nodosa were significantly increased in the overall IBD group but not in the subgroups. The low number of cases calls for careful interpretation and future studies.

Other disorders

In this study, asthma was more common in both UC and CD. Both UC and allergic asthma are considered Th2 mediated. Also, a Th17 response is described in severe asthma[66]. Risk genes are associated with IL 13 and 17 production, dysfunctional regulatory T cells and regulation of Th1, 2 and 17 responses[26,66]. Studies have not found that asthma reduces the risk of IBD[67,68], rather the opposite seems more likely[17,18,20,21].

The association of sarcoidosis and IBD were restricted to UC and males with CD. Another study confirms the linkage to UC[18]. There is not much documentation for this association. The inflammation in sarcoidosis is similar to CD; granulomatous; Th1 and 17 driven; and mutations in NOD2 and IL 23 receptor gene are identified[2,69-71].

There were no cases of Sjögren's syndrome, inclusion body myositis, eosinophilic esophagitis, or autoimmune adrenalitis. This is unexpected. Some case reports have described the coexistence of Sjögren and primary adrenocortical insufficiency in IBD patients[16,72-74]. One case report describes eosinophilic esophagitis and CD[75]. While to our knowledge, no association between inclusion myositis and IBD has been reported. Although specific ICD 10 codes were used misclassification is still possible *e.g.* autoimmune adrenalitis might be registered as Addison's disease.

Strengths and limitations

The strength of this study is that it includes all patients alive with CD or UC in Denmark. The Danish population is homogenous regarding ethnicity and religion. Health care is free to all residents; thus, NPR is not biased by inclusion of specific hospitals, age groups, insurance policies, social, or financial status. As the general practitioners do not provide data, diseases not requiring hospital treatment could be underrepresented *i.e.* asthma, Grave's disease, Hashimoto's thyroiditis, and atrophic gastritis[76].

A limitation of the study is possible bias caused by varying validity of the ICD 10 codes. Only few Danish studies have addressed this issue. The average positive predictive value (PPV) of an ICD 10 diagnosis for any medical condition in the NPR varies from 65.5 % to 81%[76].

However, the completeness is 94% for both UC and CD while the PPV of UC and CD is 90% and 97% respectively[77].

The validity of T1D is like that of IBD, very high[24,78]. The PPV of asthma among hospitalized children is 85% while 65% among adults. However, a sensitivity analysis did not find the PPV in adults, low enough to nullify the hypothesis[79,80]. As a collective group the PPV of connective tissue diseases is reported as high[24]. The PPV of rheumatoid arthritis is low[81].

Despite varying validity of ICD 10 codes, most of our findings are in alignment with those of the studies using algorithms to increase the validity. Important to this study, is the occurrence of the classic extraintestinal manifestations which indicates that our results are not too biased.

Detection bias is another concern. Patients seen on regular basis by a physician such as those with IBD are more likely to be diagnosed.

To eliminate confounders like sex, age and geography in the IBD group, we used these as matching criteria. Information regarding smoking status was not available to us, thus no correction was made.

Another confounder is drug induced autoimmunity. A wide variety of drugs are suggested to induce autoimmunity. Among these are antibiotics, statins, methotrexate, thiopurines, and biological agents (anti-TNF-α agents)[82-88]. Biological agents, which are often used to treat IBD, ankylosing spondylitis, psoriasis, and rheumatoid arthritis, are paradoxically suggested to induce IMDs. No correction was made since we do not have data regarding patients' use of prescribed drugs.

While Bonferroni post-test correction reduced the risk of false positives, the risk of false negatives simultaneously increased. Knowing this, a low number of false positives were still preferred in this study.

In conclusion, our study emphasizes that immune mediated diseases are more frequent among patients with CD or UC. Our results strengthen the thesis of partially overlapping pathogeneses among some immune mediated diseases including IBD and emphasized the complexity of IBD pathogenesis. Our most important findings are the increased risk of

celiac disease and T1D in both UC and CD, but also the increased risk of primary sclerosing cholangitis in CD although not being limited to CD. Finally, when treating patients with UC or CD one should be aware of the strong association with other immune mediated diseases.

COMMENTS

Background

Extraintestinal manifestations in Crohn's disease (CD) and ulcerative colitis (UC) are well described. The authors aimed to investigate whether other immune mediated diseases were associated with inflammatory bowel disease (IBD).

Research frontiers

Most studies on the subject are small or case reports. Only few larger studies have been conducted. The authors aimed to estimate odds-ratios of developing an immune mediated diseases (IMD) in patients with IBD compared individuals without IBD.

Innovations and breakthroughs

This is one of few larger studies on the subject. It includes all patients alive with CD or UC in Denmark. Due to free health care to all residents the study is unbiased by inclusion of specific hospitals, age groups, insurance policies, social or financial status. The authors found several IMDs not considered classic extraintestinal manifestations to be significantly associated with IBD.

Applications

Physicians treating patients with IBD should obe aware of the increased risk of developing other IMDs than the classic extraintestinal manifestations. The findings support the hypothesis that shared pathogenic pathways among IMDs could exist.

Peer-review

It's a well-written and interesting manuscript.

Abstract

AIM

To investigate markers for high-grade dysplasia for the optimal timing of liver transplantation in patients with primary sclerosing cholangitis (PSC).

METHODS

Earlier data support a dysplasia-carcinoma sequence, even low- to high-grade dysplasia, in PSC-associated cholangiocarcinoma (CCA). Surveillance using endoscopic retrograde cholangiography (ERC) and brush cytology aims to detect cases of biliary dysplasia, and liver transplantation is an option in cases with suspicion of malignancy in brushing. This study investigated markers to identify patients with high-grade biliary dysplasia for optimal timing in early liver transplantation. Patients undergoing surveillance using ERC and brush cytology during 2008-2014 and who were diagnosed with biliary dysplasia in explanted liver or CCA until February 2016 were included in the study. Demographic data, cholangiography findings, laboratory values, cytological morphology and DNA ploidy were

analysed.

RESULTS

Thirty PSC patients had biliary neoplasia in the explanted liver during the study period. Sixteen of these patients had low-grade dysplasia, 10 patients had high-grade dysplasia, and 4 patients had CCA. Fifteen PSC patients diagnosed with CCA were not transplanted. Patients with low-grade dysplasia were younger. Alkaline phosphatase or carcinoembryonic antigen values did not differ between groups during surveillance, but carbohydrate antigen 19-9 was higher in CCA patients. No difference in PSC duration, ERC scores, suspicious cytology, or ploidy analysis was found between groups. No difference was observed between fibrosis stage in explanted livers. Low- and high-grade dysplasia could not be differentiated before liver transplantation based on liver enzymes, tumour markers, ERC scores, brush cytology or DNA ploidy.

CONCLUSION

Repeated suspicion of neoplasia in brush cytology should be an indication for evaluations of liver transplantation prior to the development of CCA.

Key words: Endoscopic retrograde cholangiography; Brush cytology; Cholangiocarcinoma; Biliary dysplasia

© The Author(s) 2017. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: We investigated markers of high-grade dysplasia for the optimal timing of early liver transplantation (LT) in patients with primary sclerosing cholangitis (PSC). PSC patients in our unit undergo surveillance with endoscopic retrograde cholangiography (ERC) and brush cytology (BC) to identify evidence of dysplasia before progression to cholangiocarcinoma. Carbohydrate antigen 19-9 was higher in patients with cholangiocarcinoma, but no other differences between laboratory values, ERC scores, BC or ploidy analysis between the low-grade, high-grade or CCA groups were observed. Repeated suspicion of neoplasia in BC should be an indication for the evaluation for LT prior to the development of cholangiocarcinoma.

INTRODUCTION

Primary sclerosing cholangitis (PSC) is a chronic cholestatic disease that often presents in conjunction with inflammatory bowel disease (IBD). PSC leads to bile duct strictures and liver fibrosis. PSC also markedly increases the risk for cholangiocarcinoma (CCA), with a lifetime risk of 5%-10%[1,2]. Bile duct dysplasia is a precursor for CCA[3] in PSC. Brush cytology (BC) and imaging are used for the detection of malignancy in PSC.

The incidence of PSC is high in Nordic countries. The primary diagnosis of PSC in our hospital uses endoscopic retrograde cholangiography (ERC) with BC in all patients for individual risk stratification to estimate disease progression and risk for dysplasia[4]. PSC patients also undergo a regular surveillance programme using ERC and BC according to a previously described protocol[5], which demonstrated that the frequency of ERCs depends on disease severity in ERC and earlier results in BC and ploidy analysis. The indications for liver transplantation (LT) in PSC patients include end-stage liver disease or symptoms of the disease (*e.g.*, recurrent cholangitis). CCA is also an indication for LT in combination with chemoradiation in select centres[6]. CCA is generally a contraindication for LT in our centre. However, LT may be considered to prevent progression to CCA[4,7] in cases with biliary dysplasia.

This study evaluated risk factors in PSC patients with histologically confirmed biliary dysplasia or CCA.

MATERIALS AND METHODS

Patients

This study included PSC patients with verified biliary dysplasia or CCA. There were 588 PSC patients under surveillance at the Helsinki University Hospital during 2008-2014. PSC patients in the study population who were diagnosed with CCA or biliary dysplasia until February 2016 were included in this study. All explanted PSC livers were re-evaluated, and cases with biliary dysplasia or CCA (n = 30) were included. All PSC patients who were diagnosed with CCA during the aforementioned period who did not undergo liver transplantation were included (n = 15). At least one ERC was performed for each patient during the study period. Low-grade dysplasia (LGD) of the bile ducts was observed in 16 transplanted patients, and high-grade dysplasia (HGD), including carcinoma in situ, was observed in 10 patients with LT. CCA was observed in four patients with LT and 15 patients without LT. Suspicion of biliary dysplasia was considered an important decision criterion for evaluation for liver transplantation in 7/10 patients with HGD, 12/16 patients with LGD, and 4/4 patients with CCA. Thirty-two patients (71%) were male, and 13 patients were female.

Laboratory results

Laboratory parameters [carbohydrate antigen 19-9 (CA19-9), carcinoembryonic antigen (CEA), alkaline

phosphatase (ALP), aspartate aminotransferase (AST), alanine aminotransferase (ALT), creatinine, bilirubin, and international normalised ratio (INR)] were collected one day before the latest ERC.

Imaging studies

Images from the latest ERC were scored according to a modified Amsterdam score[4]. An MRI and/or CT were performed prior to LT.

Brush cytology and ploidy analysis

All brush samples and DNA flow cytometry specimens until LT or detection of CCA were included. Brush samples were re-evaluated and graded as benign (including atypical due to inflammation or regeneration), suspicious for neoplasia, or malignant (Figure 1).

Table 1 Histological findings in 30 explanted livers of primary sclerosing cholangitis patients with biliary low-grade dysplasia or high-grade dysplasia/cholangiocarcinoma

	LGD	HGD + CCA[2]	*P* value
n	16	14	
Early LT[1], *n*	12	11	1.000
Histology intrahepatic

Ulceration	11	6	0.224
Intestinal metaplasia	2	1	0.822
Squamous metaplasia	1	0	0.790

[1]In early LTs, suspicion of biliary neoplasia was an important decision criterion for LT; [2]CCA four patients; HGD ten patients. Values are median values unless otherwise indicated (IQR). *P* values: Mann-Whitney *U*-test for continuous variables, Fisher's exact test for dichotomous variables. CCA: Cholangiocarcinoma; HGD: High-grade dysplasia; IQR: Interquartile range; LGD: Low-grade dysplasia; LT: Liver transplantation.

Cytocentrifuge slides and slides from cellblocks were evaluated when cellblocks were available. Ploidy analyses were performed as previously described[7]. Briefly, a separate sample for DNA flow cytometry was obtained before the BC sample and added to RPMI 1640 medium (Gibco/Thermo Scientific, MA, United States) supplemented with 1% L-glutamine, 1% penicillin-streptomycin, 0.5% heparin and 0.5% human serum albumin. Cells were centrifuged, washed, treated with RNAse (Sigma Chemical Company, MO, USA) and stained with ethidium bromide (Sigma Chemical Company, MO, United States) in Tris-EDTA buffer. HL-60 cells were used as a normal control, and goose and salmon trout red blood cells were used as internal controls. DNA flow cytometry was performed using a FACSCalibur flow cytometer (BD Biosciences, Oxford, United Kingdom). The results were analysed using ModFit LT software (Becton Dickinson Immunocytometry Systems, Becton, Dickinson and Company, Franklin Lakes, NJ, United States), and a DNA index over 1.1 was considered aneuploidy.

Histology

Two pathologists, who were blinded to the BC or original interpretation, re-evaluated explanted livers and bile ducts or other histological samples (Table 1, Figure 2). Biliary dysplasia was graded as high-grade or low-grade. Patients were divided into groups (LGD, HGD, CCA) using the worst histological finding.

Statistical analysis

Statistical analyses were performed using the IBM SPSS statistical software package version 24 (IBM, New York, NY, United States). The Jonckheere-Terpstra and Mann-Whitney *U*-tests were used to evaluate

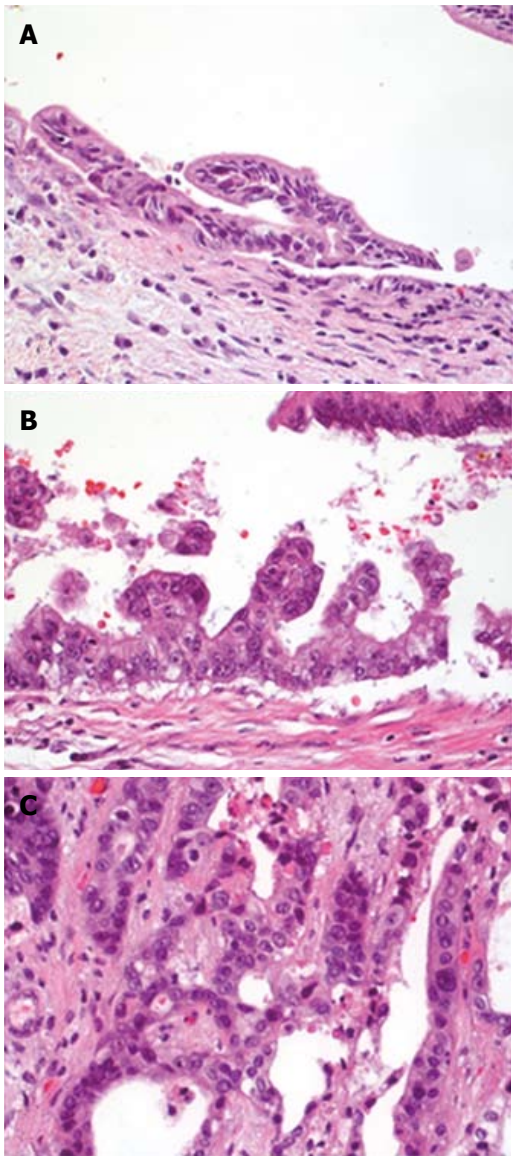

Figure 2 Histology from explanted livers diagnosed with biliary neoplasia. A: Bile duct from explanted liver with low-grade dysplasia; B: Bile duct from explanted liver with high-grade dysplasia; C: Cholangiocarcinoma from explanted liver.

differences in continuous variables between groups. Fisher's exact test was used for dichotomous variables. Bonferroni correction was used in pairwise tests, and adjusted values are presented.

Ethics
The local ethics committee approved the study protocol.

RESULTS

Demographics
There was no statistically significant gender difference between groups (Table 2), but all groups included a majority of male patients (32 males and 13 females in total). Patients with LGD were significantly younger than other patients (P = 0.003). There was no difference in PSC duration before dysplasia or CCA diagnosis. Thirty (67%) patients had IBD. Twenty-two of these 30 patients had ulcerative colitis, seven patients had Crohn's disease, and one patient had indeterminate colitis. The presence of IBD was not significantly different between groups.

Laboratory values
ALP, bilirubin, AST and ALT values were not significantly different between the three groups at the latest ERC before LT or detection of CCA. CA19-9 was higher in CCA patients (P = 0.002). CEA values did not significantly differ between groups (P = 0.081).

ERC findings
There were no significant differences in ERC scores between patient groups (Table 2). Intrahepatic disease without extrahepatic changes was observed in ERC in only two patients, and both of these patients exhibited LGD. Only mild extrahepatic ERC changes (modified Amsterdam ERC score 1-2) were observed in 11 patients, and five of these patients exhibited CCA. Abundant extrahepatic ERC changes (score $\geqslant$ 3, corresponding to dominant stricture) were observed in 32 patients. Fourteen (14/32) of these patients were diagnosed with CCA.

Brush cytology
All patients underwent ERC with BC (1-9 BC/patient, median 3 BCs). The number of available BCs did not significantly differ between groups (Table 3). Suspicious BC was observed in 11/16 patients with LGD, 8/10 patients with HGD and 4/4 patients with CCA in liver transplanted patients. Eleven of 15 patients without LT had suspicious or malignant BC (malignant 2 patients, suspicious 9 patients). Suspicious or malignant BC was observed in 34/45 patients (76%), with no difference between the neoplastic groups.

Ploidy analyses
Ploidy analysis of a brush sample was available for all patients (1-7/patient, median 3 DNA flow cytometry analyses). Aneuploidy was observed in 18/45 patients (40%), and there were no significant differences between groups. DNA indices were between 1 and 2.41 and did not significantly vary between the three groups. The median DNA index in HGD was 1.2.

Symptoms
Eighty percent of patients were symptomatic, with no difference between groups (Table 2). However, CCA patients were more often icteric than patients with LGD (P = 0.014).

Explanted livers
The median weight of explanted livers was 1399 g (range, 768-2195 g, IQR 1244-1526 g). The median

fibrosis stage was 3 (range 1-4[8]), with no difference between the groups. Only mild fibrosis (stage 1-2) was observed in 3/16 of the patients with LGD, and 4/14 patients with HGD or CCA. The remaining patients exhibited a fibrosis stage of 3-4. Histologically typical PSC morphology was observed in all liver samples, including onion-skin fibrosis around the bile ducts and cholangitis. No dysplasia in peripheric bile ducts was observed. All patients with HGD also exhibited LGD of the bile ducts. All CCA patients also exhibited HGD of the bile ducts. Hepatocellular carcinoma was observed in two patients, who also exhibited LGD.

Cholangiocarcinoma

Nineteen patients exhibited CCA. Four CCAs were diagnosed in explanted livers after LT. Two CCAs were diagnosed at laparotomy during a planned LT. Two CCAs were detected at autopsy. A histological sample from the main tumour or metastasis was obtained during surgery or core-needle biopsy in eight patients. Two CCAs were verified with imaging and (malignant) BC, and one CCA was verified using imaging only. CCAs were diagnosed a median of 4.0 years after PSC diagnosis (range, 0-19 years). Six CCAs were detected less than one year after PSC diagnosis, two of these CCAs were detected at a diagnostic ERC. The localisation of CCA was perihilar or extrahepatic in 14 cases and intrahepatic in four cases. The origin of the tumour could not be determined in one patient with peritoneal carcinosis. The median time from the latest BC until CCA diagnosis was 53 d. BC was malignant in two CCA patients, and it remained suspicious in 13 patients. BCs were benign in four CCA patients. BC was suspicious in two of the patients with intrahepatic CCA and benign in two of these patients.

DISCUSSION

Forty-two patients with histologically confirmed biliary neoplasia were found during ERC surveillance: 16 patients with LGD, 10 patients with HGD and 16 patients with CCA. An additional 3 CCAs were

detected without histological confirmation. Patients with LGD were younger. AST, ALT or CEA values did not differ between the groups. CA19-9 was significantly elevated only in patients with CCA. No difference in PSC duration, ERC changes, suspicious BC, ploidy analysis, presence of IBD or histological fibrosis was found between the three groups. It was impossible to differentiate LGD from HGD based on liver enzymes, tumour markers, or BC. Evaluations for LT should already be performed when BC is repeatedly suspicious.

The number of cytological samples suspicious for neoplasia was equal in all three neoplastic groups. The sensitivity of BC to detect biliary neoplasia was quite low (43%) in earlier studies[9]. The sensitivity to detect CCA with BC (neoplasia suspicion or malignant BC) in our previous study was up to 71% in a large, unselected patient population[5]. This high accuracy was thought to be a result of the sampling method[4] and the protocol used in our hospital. Two experienced gastroenterologists perform the ERCs, and the cellular yield is generally very high. A dedicated team of cytopathologists also perform the cytological interpretation. However, biliary neoplasia is not always found in the explanted liver, even with suspicious BC. Twenty-one patients exhibited benign biliary histology in the explanted liver in our earlier study, and four of these patients had suspicious BC[5]. It would be clinically relevant to differentiate the HGD group from the other two neoplastic groups before LT because the timing of an early LT would likely exhibit the most benefit. However, we report that cytology alone did not separate three groups with neoplastic biliary changes. Neoplastic biliary changes were also not detected in liver biopsy because biliary dysplasia was not observed in the peripheral bile ducts. However, HGD may be diagnosed with BC in select cases[10].

We also used DNA flow cytometry in addition to BC in selected cases (*e.g*., advanced ERC changes or previously suspicious BC). Based on earlier studies[7,11], aneuploidy was not more commonly observed in CCAs. This result may reflect the fact that cancer cells in CCA may not be reachable for brushing because of their growth pattern or desmoplasia. The median DNA index was higher in patients with HGD, but this difference was likely the result of the low number of cases, and statistical significance was not observed. The demand for more cases to reach significance is also based on the fact that only a portion of the dysplasias, or even CCAs, presented with aneuploid DNA. Better markers for HGD than aneuploidy are needed. The combination of genetic abnormalities with BC may help distinguish benign and malignant bile duct strictures[12,13]. However, there are no specific markers to detect HGD without histology.

CA19-9 levels often rise with CCA, but it is not specific for CCA[14,15]. CA19-9 may be markedly elevated in up to 32% of PSC patients in the absence of CCA[15]. CA19-9 was elevated mostly in CCA patients in the present study, which supports the use of CA19-9 as a tumour marker for CCA. However, it is not suitable for biliary dysplasia screening. Several surveillance algorithms of PSC recommend the use of CA19-9[2,16,17]. Elevated CEA values were also commonly observed in CCA patients but only immediately prior to the CCA diagnosis (data not shown). These findings suggest that CA19-9 and CEA are late markers, and they cannot be used for the detection of premalignant lesions. The elevation of CA19-9 generally indicates that the dysplasia surveillance programme has actually failed to find cases with dysplasia. CA19-9 is not expressed in 5%-10% of the population who have the Lewis a- b-genotype[18], and the fucosyltransferase genotype influences CEA levels[19].

ALP is generally elevated at PSC diagnosis, and normalisation of ALP is associated with a better prognosis[20-24]. ALP levels are not helpful in differentiating HGD from LGD, which was observed in this study. CCA patients were not younger than other patients, and there was up to 19 years of time between PSC and CCA diagnosis. One-third (6/19) of CCAs were detected within one year of PSC diagnosis in the present study. Ten of the 19 CCA patients in this study were diagnosed with PSC prior to the beginning of this study period (2008). Therefore, the effect of this surveillance programme could not be evaluated for the entire PSC population. Patients with LGD were significantly younger than patients with CCA or HGD. Retrospectively, some of these patients could have waited for the LT if there were no symptoms, but this study demonstrated that it is generally impossible to diagnose HGD prior to LT.

ERC findings were similar in all patient groups, which is likely due to several end-stage PSCs with cirrhosis in the LGD group. ERC with BC is routinely performed for the screening and detecting of biliary dysplasia before LT in our hospital, even LT due to end-stage cirrhosis or symptoms. Our results demonstrate that the ERC score is not helpful for the differentiation of these three groups. Our strategy significantly differs from the practice in many US transplantation centres, where pre-liver transplant screening for CCA in patients with PSC is routinely performed in only 30% of centres[25].

LGD was observed in conjunction with HGD in all cases, and HGD of the bile ducts was observed in all four CCA patients who received LT. These CCAs were discovered after LT in the explanted liver. These findings support the dysplasia-CCA sequence as described by Lewis *et al*[3]. This theory of a dysplasia-cancer sequence, which was indirectly demonstrated in this study, justifies the dysplasia surveillance programme of PSC. However, further tools are needed to differentiate premalignant cases.

All HGDs and 14/19 CCAs were located in perihilar or extrahepatic bile ducts, which supports earlier studies that demonstrated that most CCAs were located in perihilar or distal bile ducts[26]. CCA or dysplasia in

these locations is generally reachable using BC, and surveillance with BC may be justified. However, we observed 19 CCAs in these patients compared to 26 with premalignant lesions. One CCA was diagnosed in a patient who was dropped from the surveillance due to advanced age. Two CCAs were detected during the planned LT, and the LT was cancelled. Four CCAs were detected after LT, CCA was diagnosed in the explanted liver, and two of these patients had clean perioperative pathology samples. Two CCA patients were not under surveillance for years, but they returned with symptoms. The surveillance protocol was not optimal for all patients, and they entered the surveillance programme gradually. If HGD is considered the highest risk for CCA and patients diagnosed with CCA during the first year after PSC diagnosis are excluded, then at least 43% of CCAs were possibly prevented using early LT.

Early CCA is an indication for LT combined with chemo- and radiotherapy in select centres[6]. Surveillance of biliary dysplasia using BC provides another option, with LT being performed at an earlier phase to avoid oncological treatment. The indications of LT in PSC patients in most centres include end-stage liver disease or symptomatic disease (*e.g.*, recurrent cholangitis). CCA is generally a contraindication for LT in our centre. LTs due to PSC have been performed since 1984 in our unit, and dysplasia in ERC has been considered a partial indication for LT in PSC patients since 2001[27].

The limitation of this study is the small number of patients, which restrains the findings of this study, and some significant differences may be missed. Some patients who subsequently developed CCA did not follow the surveillance protocol until they became symptomatic. Our hospital is the only hospital in our country that performs organ transplantations. Therefore, no liver transplantations were missed during surveillance.

In conclusion, there is currently no reliable method to differentiate LGD from HGD prior to LT. CA19-9 rises with CCA but not in biliary dysplasia. Repeated suspicious BC, which suggests dysplasia and a high risk for future CCA, may be an indication for LT.

COMMENTS

Background

Primary sclerosing cholangitis (PSC) patients exhibit an elevated risk for cholangiocarcinoma (CCA), with a lifetime risk of 5%-10%. Biliary dysplasia is a precursor of CCA, and liver transplantation (LT) may be considered to prevent progression to CCA in cases with biliary dysplasia. A more common indication for LT is end-stage liver disease or disease symptoms. CCA develops via a low-grade dysplasia (LGD) to high-grade dysplasia (HGD) to CCA sequence. PSC patients in our centre undergo regular surveillance with endoscopic retrograde cholangiography (ERC) and brush cytology (BC) to detect biliary dysplasia, and patients with repeated suspicious findings are referred for evaluation of LT. The diagnosis of HGD prior to consideration for LT would be beneficial because of the high risk of progression to CCA. This study compared ERC, BC, ploidy analysis, and laboratory values between patients diagnosed with CCA, HGD or LGD.

Research frontiers

Biliary dysplasia is an established indication for LT in few transplantation centres. BC is used to detect biliary neoplasia, but HGD may be verified from brushing only in selected cases.

Innovations and breakthroughs

This study found that differentiating HGD and LGD prior to histological verification in the explanted liver is not practically possible. BC, laboratory values and ERC scores did not differ between patients with LGD, HGD and CCA, with the exception of CA19-9, which was elevated in CCA patients.

Applications

This study suggests that the patient should be referred for evaluation of LT when biliary neoplasia is repeatedly suspected in BC of a PSC patient to prevent progression to CCA.

Terminology

ERC - an endoscopic procedure that enables an evaluation of bile ducts by injecting contrast medium to the bile ducts for radiographic visualisation.

Peer-review

The paper is novel, and an interesting study evaluating clinical and laboratory characteristics of PSC patients in order to identify subjects with biliary dysplasia that could benefit from early liver transplantation. The figures are good and eye-catching.

Abstract

AIM

To identify the clinical features of gastric mucosa-associated lymphoid tissue (MALT) lymphoma with extra copies of *MALT1*.

METHODS

This is a multi-centered, retrospective study. We reviewed 146 patients with MALT lymphoma in the stomach who underwent fluorescence *in situ* hybridization analysis for t(11;18) translocation. Patients were subdivided into patients without t(11;18) translocation or extra copies of *MALT1* (Group A, *n* = 88), patients with t(11;18) translocation (Group B, *n* = 27), and patients with extra copies of *MALT1* (Group C, *n* = 31). The clinical background, treatment, and outcomes of each group were investigated.

RESULTS

Groups A and C showed slight female predominance, whereas Group B showed slight male predominance. Mean ages and clinical stages at lymphoma diagnosis were not different between groups. Complete response was obtained in 61 patients in Group A (69.3%), 22 in Group B (81.5%), and 21 in Group C (67.7%). *Helicobacter pylori (H. pylori)* eradication alone resulted in complete remission in 44 patients in Group A and 13 in Group C. In Group B, 14 patients underwent radiotherapy alone, which resulted in lymphoma disappearance. Although the difference was not statistically significant, event-free survival in Group C tended to be inferior to that in Group A (*P* = 0.10).

CONCLUSION

Patients with t(11;18) translocation should be treated differently from others. Patients with extra copies of *MALT1* could be initially treated with *H. pylori* eradication, similar to patients without t(11;18) translocation or extra copies of *MALT1*.

Key words: Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue; Gastric neoplasms; Esophagogastroduodenoscopy; t(11;18) translocation; Trisomy 18

Core tip: We subdivided and retrospectively reviewed 146 patients with gastric MALT lymphoma into patients without t(11;18) translocation or extra copies of *MALT1* (Group A, *n* = 88, 60.3%), patients with t(11;18) translocation (Group B, *n* = 27, 18.5%), and patients with extra copies of *MALT1* (Group C, *n* = 31, 21.2%). Groups A and C exhibited similar clinical characteristics. *Helicobacter pylori* eradication alone resulted in complete remission in approximately half the patients in Group A and Group C. Consequently, patients with extra copies of *MALT1* could be treated similar to patients without t(11;18) translocation or extra copies of *MALT1*.

INTRODUCTION

Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma) is one of the non-Hodgkin lymphomas, originating in tissues or organs outside of the lymph nodes. Typically, this neoplasm involves the gastrointestinal tract, thyroid, ocular adnexa, lungs, salivary glands, liver, and skin[1,2]. Of these organs, the stomach is the most frequently identified primary site. Approximately two-thirds of patients with gastric MALT lymphoma have chronic *Helicobacter pylori* (*H. pylori*) infection in the stomach, which is believed to be the causative organism. Clinically, eradication of *H. pylori* is the first-line management of choice, resulting in regression of lymphoma in 75% to 80% of patients[3]. Meanwhile, cases with chromosomal abnormalities of t(11;18)(q21;q21)/*API2-MALT1* translocation have been shown to be resistant to *H. pylori* eradication. Consequently, evaluation of t(11;18)(q21;q21) translocation at the initial workup is valuable to forecast the response to antibiotic therapy against *H. pylori*[4].

Previously, we reported a case of gastric MALT lymphoma with trisomy 18[5]. In that case, although there were no fusion genes of *API2-MALT1*, trisomy 18 was identified as extra copies of *MALT1*, using a fluorescence *in situ* hybridization (FISH) analysis for t(11;18)(q21;q21)/*API2-MALT1* translocation, since *MALT1* is located on chromosome 18q21. The patient required radiation therapy to treat the gastric lymphoma lesions, because the gastric lesions only partially improved after eradication therapy for *H. pylori*. Though radiation therapy resulted in complete remission, MALT lymphoma recurred in the stomach 16 mo later. Previous studies investigating chromosome aneuploidy in MALT lymphomas also reported that trisomy 18 might be indicative of progression or relapse in patients with gastric MALT

lymphoma[6-8]. Based on our experience and previous reports, we hypothesized that gastric MALT lymphoma with extra copies of the *MALT1* gene may be resistant to *H. pylori* eradication and may show more frequent progression or relapse than those without chromosomal aberrations. However, no studies have described the initial treatment and response in such patients. The purpose of this study is to reveal the clinical characteristics and outcomes of gastric MALT lymphoma in patients with t(11;18)(q21;q21)/*API2-MALT1* translocation or extra copies of *MALT1*, in order to determine initial treatment strategies for cases presenting with chromosomal aneuploidy.

MATERIALS AND METHODS

Letters of inquiry regarding patients with gastric MALT lymphoma were sent from the Department of Gastroenterology and Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, to ten collaborating institutions. The inclusion criteria were: (1) patients with pathologically diagnosed MALT lymphoma in the stomach, and (2) patients who underwent fluorescence *in situ* hybridization analysis for t(11;18)(q21;q21)/*API2-MALT1* translocation on biopsy samples from the gastric MALT lymphoma lesions. FISH analysis was performed for all patients on fresh biopsy samples using dual-color, dual-fusion translocation probes for *API2*/*MALT1*. MALT lymphoma with a large-cell component was excluded from this study. Finally, a total of 146 patients diagnosed with gastric MALT lymphoma between October 1997 and November 2015 were identified. Thus, these patients were retrospectively registered in this study.

According to the FISH result for t(11;18) translocation, patients were subdivided into three groups as follows: (1) Group A: patients without t(11;18)(q21;q21)/*API2-MALT1* translocation or extra copies of *MALT1* (Figure 1A), (2) Group B: patients with t(11;18) translocation (Figure 1B), and (3) Group C: patients with extra copies of *MALT1* (Figure 1C). To determine the patient characteristics of gastric MALT lymphoma with or without chromosomal aberrations, we retrospectively examined the gender, age at diagnosis, endoscopic features, clinical stages according to Lugano classification[9], *H. pylori* infection status, treatments, response to treatments, and outcomes. *H. pylori* infection status was examined by urea breath tests, rapid urease tests, microscopic observations or culture tests on endoscopically biopsied specimens, stool antigen tests, serum or urine antibody tests, or a combination of these methods. Success of *H. pylori* eradication was confirmed by urea breath tests, rapid urease tests, microscopic observations or culture tests on endoscopically biopsied specimens, or stool antigen tests. The follow-up period was defined as the period from the lymphoma diagnosis to death from any cause or to the patient's last hospital visit.

Macroscopic features of gastric lymphoma lesions observed during esophagogastroduodenoscopy were classified into the following six subtypes[10]: (1) erosions/ulcers; (2) early gastric cancer-like lesion that formed a slightly depressed area; (3) whitish mucosa; (4) cobblestone appearance; (5) submucosal tumor-like lesion; and (6) mixed (a combination of these five subtypes). All cases were reviewed and their subtypes were classified by board certified endoscopists.

Event-free survival was measured from diagnosis until documented progression/relapse, death from primary disease, or commencement of the second treatment for any reason. For the comparisons of the two groups, statistical analyses including *t*-tests, χ^2 tests, and *F*-tests were performed using JMP 8.0.1 software (SAS Institute, Cary, NC, United States). Cumulative event-free probabilities were calculated by Kaplan-Meier analysis and log-rank tests were performed using the JMP 8.0.1 software. $P < 0.05$ was considered to indicate a statistically significant difference. The present study was approved by the Ethical Committee of the Okayama University Hospital and adhered to the Declaration of Helsinki.

RESULTS

In this study, clinical data of 146 patients (76 women and 70 men) were collected from nine institutions (Table 1). FISH analysis for t(11;18)(q21;q21)/*API2-MALT1* revealed that t(11;18) translocation and extra copies of *MALT1* were not identified in 88 patients (Figure 1A). Fusion genes of *API2-MALT1* indicating t(11;18)(q21;q21)/*API2-MALT1* translocation were detected in 27 patients (10 women and 17 men) (Figure 1B). Extra copies of *MALT1* were found in 31 patients; the ratio of *MALT1* signals to *API2* signals was 3:2 in 28 patients, suggesting trisomy 18 (Figure 1C), and 4:2 in one patient, suggesting tetrasomy 18, (Figure 1D). The remaining two patients had a combination of lymphoma cells with either trisomy 18 or tetrasomy 18. In one patient with extra copies of *MALT1*, several lymphoma cells had six *MALT1* signals with four *API2* signals, which is considered as trisomy 18 with tetraploidy (Figure 1E).

Patients without t(11;18) translocation or extra copies of *MALT1* (Group A) showed slight female predominance (48 women and 40 men), while patients with t(11;18)(q21;q21) translocation (Group B) showed slight male predominance (10 women and 17 men). However, there was no statistically significant difference between Groups A and B regarding sex ratio ($P = 0.11$). Patients with extra copies of *MALT1* (Group C) showed slight female predominance (18 females and 13 males) compared to Group A ($P = 0.73$). The mean ages at lymphoma diagnosis was 65.9 ± 12.3 years in Group A, 64.2 ± 11.2 years in Group B, and 65.0 ± 14.9 years in Group C and was not different between groups. Lymphoma lesions were localized in the stomach without lymph node or other organ

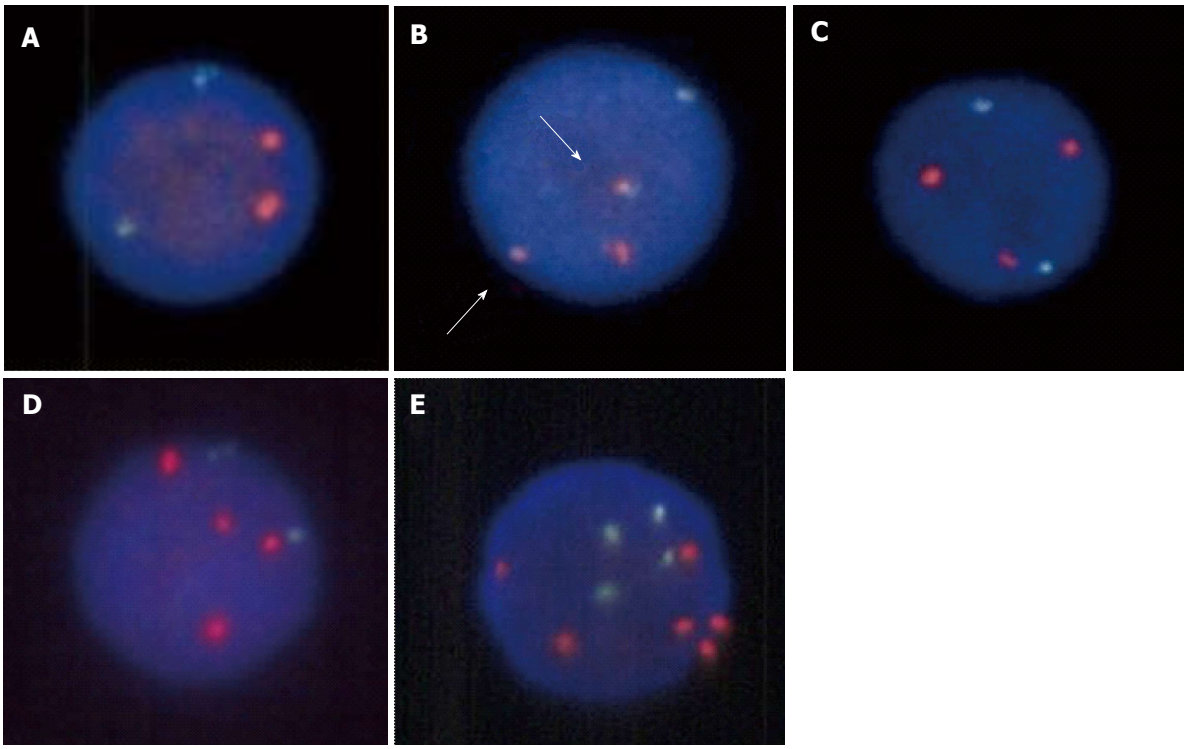

Figure 1 FISH images of the lymphoma cells. In the FISH analysis for t(11;18)(q21; q21) translocation, *API2* is visualized as a green signal and *MALT1* as a red signal. A: Two green signals and two red signals are seen in cases without t(11;18) translocation or extra copies of *MALT1*. B: Fusion genes of API2-*MALT1* are detected as yellow signals, indicating t(11;18) translocation (B, arrows). C: Although no fusion genes are visible, an extra copy of *MALT1* is noted, indicating trisomy 18. D: Two extra copies of *MALT1* are visible, indicating tetrasomy 18. E: In one patient, several lymphoma cells have six *MALT1* signals with four API2 signals, which is considered as trisomy 18 with tetraploidy.

involvement in most of the patients (131/146, 89.7%), thus they were classified as stage I according to the Lugano system of staging[10]. *H. pylori* infection status was examined in all patients. In Group A, 75.0% of the patients were positive for *H. pylori*. Group C had similar positivity for *H. pylori* (67.7%). In contrast, only 7.4% of the patients in Group B had *H. pylori* infection ($P < 0.01$, *vs* Group A). Endoscopic features are summarized in Table 2. Overall, gross findings of the gastric lymphoma lesions were as follows: erosions/ulcers in 44 patients (30.1%), whitish mucosa in 42 patients (28.8%), submucosal tumor-like lesions in 29 patients (19.9%), cobblestone appearance in 17 patients (11.6%), early gastric cancer-like lesions in 10 patients (6.8%), and mixed lesions in four patients (2.7%). The ratio of each macroscopic morphology was similar between Groups A and C. Moreover, no patients in Group B presented with submucosal tumor-like lesions.

Treatments and outcomes are shown in Table 3. Follow-up periods were 3.9 ± 3.1 years in Group A, 5.1 ± 4.5 years in Group B, and 2.9 ± 2.2 years in

Group C. Only four patients died during the follow-up period: One patient in Group A died 2.4 years after lymphoma diagnosis because of concomitant advanced lung cancer, although complete response was obtained for gastric MALT lymphoma after *H. pylori* eradication. Two patients in Group C died of pneumonia 1.1 years and 2.0 years after lymphoma diagnosis, respectively. The other patient in Group A had stage IV lymphoma involving the stomach, ileum, colon, rectum, and lymphadenopathies of the neck, supraclavicular, subphrenic, and retroperitoneum. The patient underwent chemotherapy with cyclophosphamide, vincristine sulfate, and prednisone, followed by rituximab monotherapy and yttrium-90 ibritumomab tiuxetan monotherapy. However, the patient died of refractory lymphoma 1.4 years after the initial diagnosis due to intestinal perforation. Since pathological analysis was waived because of the patient's deteriorated condition, it was unknown whether histologic transformation occurred in the terminal stage. All patients, except for the four mortality cases, were alive at the patient's last visit to each institution. Five patients in Group A and one in Group B did not undergo esophagogastroduodenoscopy during the follow-up period, thus their lymphoma status, whether remitted or unchanged, was unknown. Complete response was obtained in 61 patients in Group A (69.3%), 22 in Group B (81.5%), and 21 in Group C (67.7%). On the other hand, lymphoma lesions were partially remitted or unchanged in 20 patients in Group A (22.7%), four in Group B (14.8%), and eight in Group C (25.8%).

Table 4 Treatment regimens resulted in complete remission

	Total	Group A: No chromosome aberration[1]	Group B: t(11;18) positive	Group C: Extra copies of *MALT1*
n	103	61	21	21
Treatment				
Eradication alone	58	44	1	13
RT alone	20	6	14	0
Chemotherapy alone	4	1	1	2
RT and chemotherapy	2	1	0	1
Eradication and RT	13	5	4	4
Eradication and chemotherapy	3	2	0	1
Eradication, RT and chemotherapy	1	0	1	0
None	2	2	0	0

[1]Patients without t(11;18) translocation or extra copies of *MALT1*. RT: Radiotherapy; MALT: Mucosa-associated lymphoid tissue.

With regard to treatment regimens, most of the patients without t(11;18) translocation or extra copies of *MALT1* (Group A) were treated with *H. pylori* eradication alone (*n* = 62, 70.5%). More than half of the patients with t(11;18)(q21;q21) translocation (Group B) were treated with radiotherapy alone (*n* = 15, 55.6%). Approximately two-thirds of the patients with extra copies of *MALT1* (Group C) were treated with *H. pylori* eradication alone (*n* = 20, 64.5%).

Table 4 shows treatment regimens that resulted in complete remission of MALT lymphoma lesions. Complete remission of lymphoma was observed in

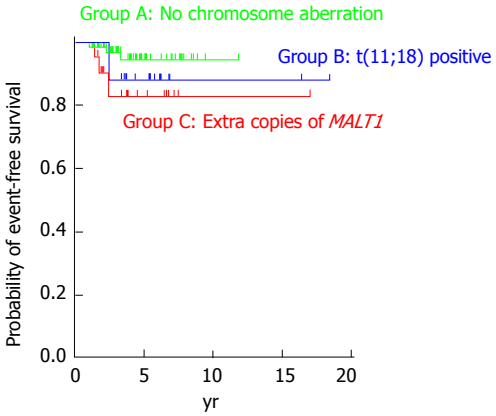

Figure 2 Cumulative event-free probabilities for the three groups. Although event-free survival of Group C patients appears to be inferior to that of the patients of the other two Groups, log-rank test revealed that the difference between Groups A and C was not statistically significant (P = 0.10).

44 (72.1%) and 13 (61.9%) patients in Groups A and C, respectively, by *H. pylori* eradication alone. In contrast, only one (4.5%) patient achieved complete remission after *H. pylori* eradication alone, whereas 14 (63.6%) patients achieved complete remission after radiotherapy alone in Group B. Figure 2 shows cumulative event-free probabilities between the three groups. Although event-free survival of Group C patients seems to be inferior than that of the Group A and Group B patients, log-rank test revealed that the difference between Groups A and C was not statistically significant (P = 0.10).

DISCUSSION

To our knowledge, the present report is the largest retrospective study investigating chromosome aberrations in gastric MALT lymphoma. Our review of 146 patients revealed that 31 patients (21.2%) had extra copies of *MALT1*. Prevalence of trisomy 18 in MALT lymphomas has been reported to range from 5% to 39%[11-17]. Other chromosomal abnormalities involved in MALT lymphomas are trisomies 3, 7 and 12. The incidence varies between reports in the literature: trisomy 3 can be detected in 6% to 24%, trisomy 7 in 3% to 15%, and trisomy 12 in 3% to 38%[17].

The clinical significance of these chromosomal numerical changes has been investigated in several studies[6-8,18-20]. Tanimoto *et al*[19] investigated 34 patients with primary ocular adnexal MALT lymphoma and found that disease recurrence was documented in five cases, all of which had trisomy 18. Statistical analysis revealed that the time to recurrence was significantly shorter in patients with trisomy 18 than in those without trisomy 18 (P = 0.05). We also reported a patient with gastric MALT lymphoma with trisomy 18 in whom only partial improvement was documented after eradication therapy for *H. pylori*, and lymphoma recurred in the stomach 16 months after radiotherapy[5]. On the other hand, Taji *et al*[17] retrospectively reviewed 13 patients with localized MALT lymphoma in the stomach, and reported that all patients with unresponsive or progressive disease had t(11;18) translocation or trisomy 3. Conversely, one patient with complete response had trisomy 18, and another patient with complete response had both trisomies 12 and 18. Based on these findings, the authors speculate that trisomy 3 is related to resistance to *H. pylori* eradication therapy and disease recurrence in gastric MALT lymphoma, whereas trisomies 12 and 18 are not. Nakamura and colleagues reviewed 90 cases of gastric MALT lymphoma and reported that extra copies of *MALT1* were found in 18 of 71 (25%) cases[6]. Although overall survival was not associated with the presence of extra copies of *MALT1*, disease progression or relapse of lymphoma was more frequently observed in patients with extra copies of *MALT1*. Possible correlations between extra copies of *MALT1* and progression or relapse of lymphoma have been described in other studies as well[7,8]. In the present study, although the difference was not statistically significant, log-rank test revealed similar tendencies (Figure 2). Consequently, patients with additional copies of *MALT1* may require more frequent clinical follow-up.

In the present study, the sex ratio of the patients with extra copies of *MALT1* (Group C) was similar to that of the patients without t(11;18) translocation or extra copies of *MALT1* (Group A), with the number of females being greater than males. On the contrary, although the difference was not statistically significant, patients with t(11;18) translocation (Group B) included more males than females. It was also noteworthy that Group C patients had similar prevalence of *H. pylori* infection to Group A. Other patient characteristics, such as the age at lymphoma diagnosis, clinical stages, and macroscopic morphology were not different between Groups A and C. The majority of Group A and Group C patients were treated with *H. pylori* eradication alone. Moreover, *H. pylori* eradication alone resulted in complete remission of lymphoma in 44 patients in Group A and 13 in Group C. Overall, the results observed in this study suggest that patients with trisomy and tetrasomy 18 require no distinct treatment from patients without aberrations. To our knowledge, the present study is the first to reveal clinical responsiveness to *H. pylori* eradication in gastric MALT lymphoma patients with extra copies of *MALT1*. In addition, in the present study, FISH analysis was performed by using fresh biopsy samples, whereas previous reports primarily involved analyses of archival pathologic specimens with the aim of clarifying the etiology of chromosomal aberrations. We believe that our results would be more readily interpreted in actual clinical settings for physicians responsible for gastric MALT lymphoma patient therapy.

The present study included 27 patients (18.5%)

with t(11;18)(q21;q21)/*API2-MALT1* translocation. t(11;18)(q21;q21)/*API2-MALT1* is the most frequent translocation among gastric, pulmonary, intestinal, and cutaneous MALT lymphomas, accounting for 13% to 35% of cases[3,21,22]. Other chromosomal aberrations detected in MALT lymphomas include t(1;14)(p22;q32), t(14;18)(q32;q21), t(3;14)(q27;q32), and t(3;14)(p14.1;q32)[3]. Several of such karyotypic alterations have been known to activate the nuclear pathway, which is considered to lead to lymphomagenesis. Thus, these translocation-positive MALT lymphomas arise independent of *H. pylori* infection and are unresponsive to antibiotic treatment[3]. Moreover, these patients often show a late response and lymphoma relapse during follow-up[18,23]. Regardless of the adverse clinical features, t(11;18) translocation is infrequently identified in transformed MALT lymphoma or diffuse large B-cell lymphoma, indicating that high-grade transformation is less likely to occur in translocation-positive MALT lymphomas than in those without chromosome aberration[3,8,18,24]. In this context, polymerase chain reaction or FISH analysis for t(11;18) translocation is essential during the initial workup to determine the appropriate treatment strategy[25]. Of additional clinical interest is that trisomy and tetrasomy 18 can be detected as extra copies of *MALT1* by FISH analysis, since *MALT1* is located on chromosome 18[18,20].

In our study, all patients with t(11;18) translocation (Group B), except two, were negative for *H. pylori* infection. With regard to the macroscopic morphology of the gastric lesions, no patients in Group B presented with submucosal tumor-like lesions (Table 2). We speculate that this result reflects the lower proliferative potential of MALT lymphoma cells with t(11;18) translocation, compared to that of cells without t(11;18) translocation or extra copies of *MALT1*. Since almost no patients in Group B had *H. pylori* infection, most of the patients were treated with radiotherapy and/or chemotherapy. These clinical features were concordant with previously reported characteristics of MALT lymphoma with t(11;18) (q21;q21)/*API2-MALT1* translocation[8,22-24].

There were several limitations associated with this study. First, the presence of extra copies of *MALT1* is often suggestive of partial or complete trisomy/tetrasomy 18; both are different. Trisomy/tetrasomy 18 should be determined only when extra copies are identified by FISH using centromere-specific probes for chromosome 18, or when gains of chromosome 18 are confirmed by array comparative genomic hybridization or by cytogenetic analysis (G-banding). However, these assays could not be performed because of the retrospective nature of this study. Second, not all chromosome alterations were investigated. As described above, trisomies 3, 7 and 12 and t(14;18) and t(3;14) translocations can be involved in MALT lymphomas[26,27]. Therefore, Group A may have been heterogeneous and included patients with chromosomal aberrations other than t(11;18) translocation and trisomy 18. Third, only patients who underwent FISH analysis for t(11;18) translocation were enrolled in this study. FISH analysis may be waived for patients in which *H. pylori* was eradicated immediately following the diagnosis of MALT lymphoma and lymphoma regression was achieved. Thus, selection bias is a possibility in this study. Fourth, because this is a retrospective, multi-centered study, treatment strategies of each patient may have varied according to the attending physician's preference and the availability of chemotherapy and/or radiotherapy at each institution. Fifth, methods to examine *H. pylori* infection status varied among the different institutions participating in this study. Prospective studies utilizing uniform protocols are required to definitively compare treatment responses and prognosis in each group.

In conclusion, we reviewed 146 patients, including 31 (21.2%) with extra copies of *MALT1* and 27 (18.5%) with t(11;18)(q21;q21)/*API2-MALT1* translocation. Patients with t(11;18) translocation should be treated differently from others. However, patients with extra copies of *MALT1* have similar clinical characteristics to cases without t(11;18) translocation or extra copies of *MALT1*. We propose that these patients can be initially managed in the same way as cases without chromosomal aberrations. However, since progression or relapse tended to be more frequently seen in patients with extra copies of *MALT1*, these patients may require closer clinical follow-up.

COMMENTS

Background

Previous studies investigating chromosome aneuploidy in extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma) reported that trisomy 18 might be indicative of progression or relapse in patients with gastric MALT lymphoma.

Research frontiers

No studies have described the initial treatment and response in patients with extra copies of *MALT1*.

Innovations and breakthroughs

Patients with extra copies of *MALT1* have similar clinical characteristics to cases without t(11;18) translocation or extra copies of *MALT1*. The present study is the first to reveal clinical responsiveness to *Helicobacter pylori* eradication in gastric MALT lymphoma patients with extra copies of *MALT1*.

Applications

Patients with extra copies of *MALT1* can be initially managed in the same way as cases without chromosomal aberrations.

Terminology

MALT lymphoma is one of the non-Hodgkin lymphomas, originating in tissues or organs outside of the lymph nodes. Typically, this neoplasm involves the gastrointestinal tract, thyroid, ocular adnexa, lungs, salivary glands, liver, and skin. Of these organs, the stomach is the most frequently identified primary site.

Peer-review

This is a well-designed multicenter study on the role of extra copies of *MALT1*

in gastric MALT lymphoma. The conclusion can be supported by the results. It can add something interest to current knowledge.

Abstract

AIM

To investigate whether patients with refractory epilepsy and healthy infants differ in gut microbiota (GM), and how ketogenic diet (KD) alters GM.

METHODS

A total of 14 epileptic and 30 healthy infants were recruited and seizure frequencies were recorded. Stool samples were collected for 16S rDNA sequencing using the Illumina Miseq platform. The composition of GM in each sample was analyzed with MOTHUR, and inter-group comparison was conducted by R software.

RESULTS

After being on KD treatment for a week, 64% of epileptic infants showed an obvious improvement, with a 50% decrease in seizure frequency. GM structure in epileptic

infants (P1 group) differed dramatically from that in healthy infants (Health group). Proteobacteria, which had accumulated significantly in the P1 group, decreased dramatically after KD treatment (P2 group). *Cronobacter* predominated in the P1 group and remained at a low level both in the Health and P2 groups. *Bacteroides* increased significantly in the P2 group, in which *Prevotella* and *Bifidobacterium* also grew in numbers and kept increasing.

CONCLUSION

GM pattern in healthy infants differed dramatically from that of the epileptic group. KD could significantly modify symptoms of epilepsy and reshape the GM of epileptic infants.

Key words: Ketogenic diet; Cronobacter; Seizures; Gut microbiota; Epilepsy

Core tip: Many infants with epilepsy are refractory to current antiepileptic drugs, and ketogenic diet (KD) could help to moderate seizure frequency as an alternative treatment. A large number of reports have demonstrated that gut microbiota (GM) can affect children's neurodevelopment. Concurrently, GM could be dramatically affected by diet. KD could rapidly alter GM and alleviate seizure frequency in infants with refractory epilepsy. The GM structure of epileptic infants - comprising large numbers of pathogens, such as *Streptococcus* - differed from that of healthy controls. After KD therapy, GM of epileptic patients changed significantly, with fewer pathogens and more beneficial bacteria.

Ketogenic diet poses a significant effect on imbalanced gut microbiota in infants with refractory epilepsy. *World J Gastroenterol* 2017; 23(33): 6164-6171 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6164.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6164

INTRODUCTION

Pediatric epilepsy is widespread, with complications including cognitive impairment, delayed neurodevelopment and loss of bodily control[1,2]. Disequilibrium between excitation and depression of the central nervous system is acknowledged as the main factor in epilepsy incidence[3]. Prior reports have identified increased inflammatory reactions and pro-inflammatory cytokines, such as interleukin (IL)-6, IL-17 and interferon, in the cerebrospinal fluid (CSF)[4]. Anti-epileptic drugs (AEDs) and surgery are the main conventional treatments for infants with epilepsy[5]. However, there are still 30% of epileptic infants who suffered from therapeutic futility and recurrent attacks.

A growing number of reports indicated that KD is a promising therapeutic alternative for infants with refractory epilepsy, as it has been shown to ameliorate their clinical symptoms, including the frequency of seizures[6-10]. It remains unclear exactly how this occurs. Several reports implicated changed neurotransmitters after KD therapy, including γ-aminobutyric acid (GABA), monoamines and glutamate[7,11]. Dahin *et al*[12] and Freeman *et al*[13] also identified increased ketone bodies (KBs) and decreased dopamine and serotonin[12,13]. However, Sariego-Jamardo *et al*[14] found little change of neurotransmitters, pterins and amino acids in the CSF of KD responders as opposed to non-responders. These discrepant findings suggested a need for the further elucidation of the mechanisms of KD therapy.

Several studies showed that diet posed a significant effect on GM[8,15]. A high-fat diet induced selective enrichment of bile-metabolizing microbiota, such as *Bacteroides*[16], whilst high-fiber foods promoted the accumulation of plant-polysaccharide fermenting microbial organisms, including *Prevotella* and *Clostridium*[16]. A number of reports implicated involvement of GM in enteric nervous system, blood-brain barrier and glial cell development, all of which were pivotal to behavioral control and cognitive progression[17,18]. GM could produce neurotransmitters and gut hormones directly[19] or indirectly by producing signaling molecules to regulate host cells[20]. GM-derived short-chain fatty acids (SCFAs) could stimulate enterochromaffin cells to produce serotonin[21]. Wikoff *et al*[22] also documented decreased serotonin in peripheral serum in the absence of GM. Moreover, *Clostridium sporogenes* and *Ruminococcus gnavus* promoted decarboxylation of tryptophan to tryptamine, which modulated mood and appetite through amine-associated receptors[23]. Based on the involvement of GM in the gut-brain axis, increasing reports demonstrated imbalanced GM in neurogenic diseases (NDs), including autism-spectrum disorder, Parkinson's disease, and depression[24]. However, GM dysbiosis in childhood epilepsy remains unexplored.

Previous studies declared that short-term dietary intake could rapidly alter human GM[8,15]. In this study, we performed a comparison between diseased infants (before and after KD treatment) and healthy controls, to explore if and how GM of infants with refractory epilepsy differed with that of age-matched healthy subjects. We also evaluated the therapeutic effect of KD on refractory epilepsy and the changes in GM after treatment. It is hoped that this research will help to bridge some gaps in the current understanding of refractory childhood epilepsy.

MATERIALS AND METHODS

Sample collection

We enrolled 14 pediatric patients with refractory

epilepsy (aged 1.95 ± 3.10 years, 11 male and 3 female) in Shenzhen Children's Hospital, according to the following inclusion criteria: Convulsion more than four times per week after treatment with ⩾ 3 AEDs; no antibiotic exposure for at least 1 mo; no known genetic metabolic disorders or severe systemic illnesses; and successive KD therapy for at least 1 wk. KD was provided by Zeneca (Shenzhen, China), including Qitong ketogenic liquid milk (3.4 g protein, 8.0 g lipid and 0.6 g carbohydrate per 100 g milk), Qitong ketogenic cookies and Qitong ketogenic set-meal packages[25].

Healthy subjects (aged up to 3 years, 15 male and 15 female) were also recruited based on the following criteria: No antibiotic exposure for at least 1 mo before this study, no disease symptoms for at least 1 mo following recruitment, and no history of seizures (Supplementary Table 1). Fisher's exact test was used to evaluate the effect of gender and age on GM composition.

DNA extraction, library construction and sequencing

The genomic DNA of microbiota was extracted from stool samples using the Power Soil DNA Isolation Kit (Mo Bio Laboratories, Carlsbad) following the manufacture's protocol. The hypervariable V3-V4 region of the 16S rRNA gene was amplified using PCR kit (TransGenAP221-02, Peking), and DNA products were quantified by gel electrophoresis and Qubit (Thermo Fisher, Singapore). After library construction, the qualified libraries were sequenced using the Illumina MiSeq Sequencing platform (Illumina, San Diego).

Taxonomy classification and diversity detection

After filtration, overlapped paired reads were assembled as tags with FLASH (v1.2.11), and clustered to operational taxonomic units (OTUs) through USEARCH (v7.0.1090)[26]. Representative OTUs were mapped against the Greengenes database (v201305)[27] and classified with RDP classifier (v2.2)[28]. The diversity of microbiota was calculated with MOTHUR (v1.31.2)[29].

Principal component analysis and statistical analysis

PCA was performed with R software (v3.2.5). Wilcoxon rank-sum test was used to compare GM in diseased infants and healthy controls (Health group). Comparative analysis between the epileptic infants before (P1 group) and after treatment (P2 group) was conducted by Wilcoxon signed-rank test. Linear discriminant analysis Effect Size (LEfSe) analysis was used to identify microbial species which were apparently enriched in a specific group.

RESULTS

Data output and patients' characteristics

The average number of high-quality sequencing reads produced for each sample was 117196 (range, 31900 to 305190). The number of assembled tags averaged 22800, with a range from 12655 to 27337. Both gender and age had no significant effect on GM (P = 0.069 and 0.234, respectively).

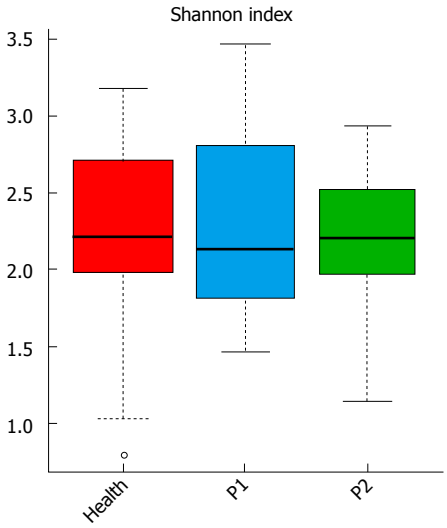

Figure 1 Gut microbial diversity of the three groups. Distribution of Shannon index (evenness) is shown. Red, blue, and green represent the Health, P1 and P2 groups, respectively. The gut microbiota (GM) of the healthy infants was more stable than that of the other two groups.

GM of healthy individuals differs dramatically with that of diseased infants

Shannon index analysis indicated higher GM diversity in healthy infants, in comparison with infants with refractory epilepsy (Figure 1, Supplementary Table 2). PCA of GM profile also identified that healthy infants could be clearly distinguished from patients (Figure 2, Supplementary Table 3). The phylum Firmicutes predominated in patients (45.82%) and was unchanged after KD therapy (47.00%) (Supplementary Table 4). Bacteroidetes accounted for 53.01% of GM in healthy infants, followed by Firmicutes (34.38%). After KD treatment, Bacteroidetes increased from 26.75% to 38.71%. Actinobacteria was enriched in healthy infants (8.49%) and occupied a lower percent in patients (2.38% before treatment and 2.92% after treatment). Proteobacteria was highly accumulated in infants with refractory epilepsy (24.34%) and decreased dramatically after KD therapy (10.77%). At the genus level, *Cronobacter* was dominant in the patients (23.30% *vs* 0.00% in the healthy group). By contrast, healthy subjects harbored more than twice *Bacteroides* (42.68%) than infants with refractory epilepsy (17.93%). *Prevotella* and *Bifidobacterium* also accumulated in the healthy group (7.25% and 7.84%, respectively) (Supplementary Table 5).

KD therapy ameliorates epilepsy and GM of patients started to improve

After a week of KD therapy, 3 (21%) patients were seizure-free and 6 (43%) had a 50% to 90% decrease of seizure frequency (Supplementary Table 1). The

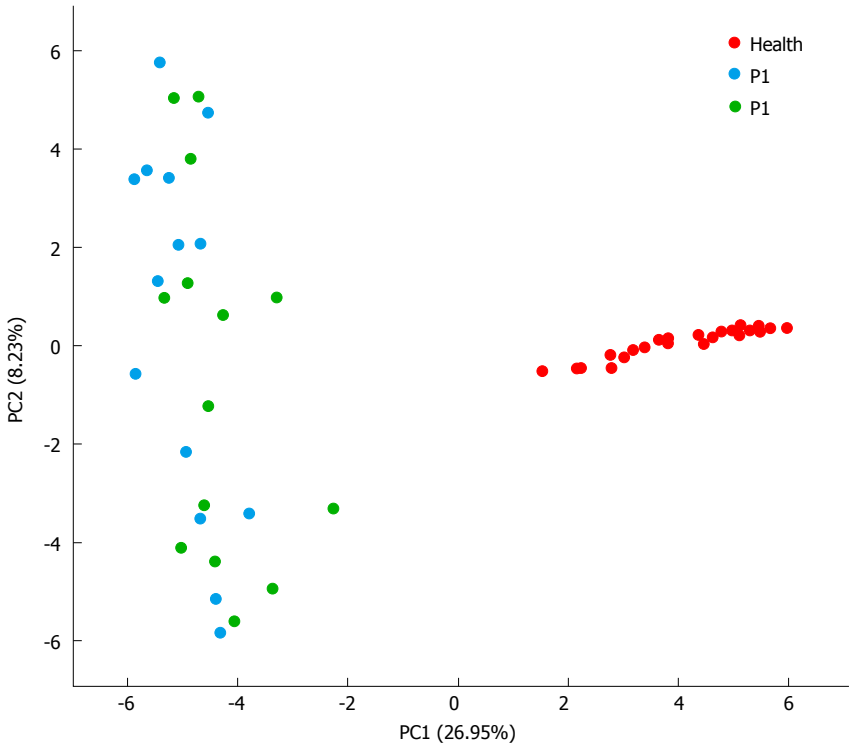

Figure 2 Principal component analysis. Each plot in the principal component analysis (PCA) graph stands for a sample. Red, blue and green colors represent the Health, P1 and P2 groups, respectively.

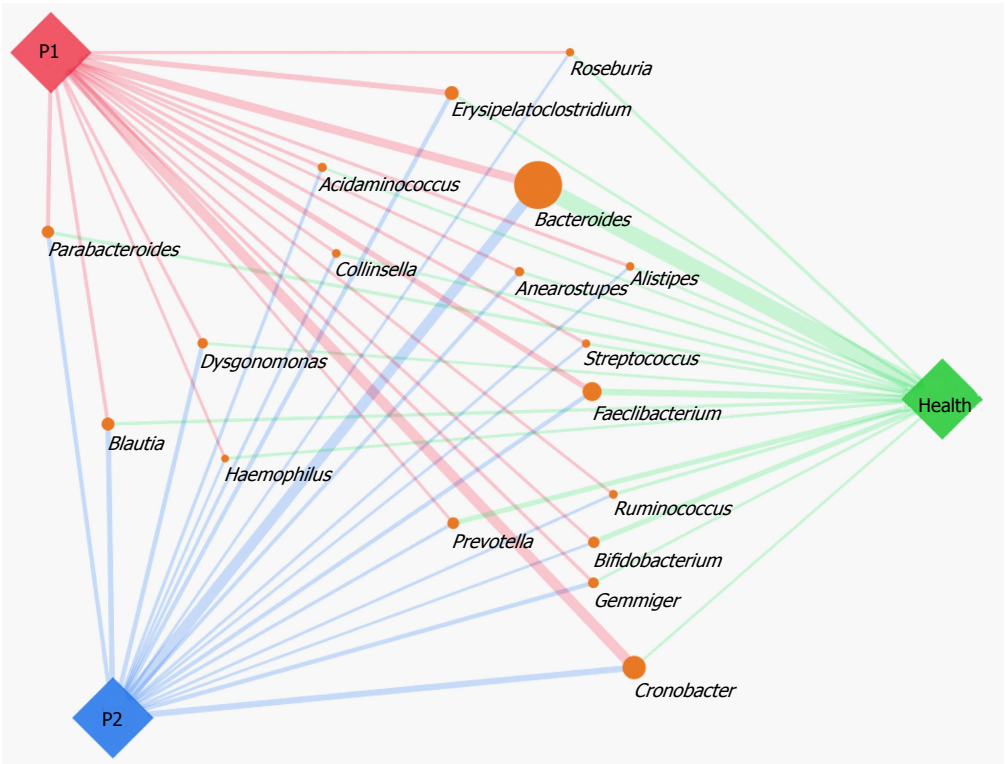

Figure 3 Gut microbiota structures in the Health, P1 and P2 groups at the genus level. SVG package (version 1.1) was used to produce the paragraph. The size of the circle representing each genus was determined by the relative abundance of the three groups, and the width of line linking the P1, P2 and Health groups indicates the relative abundance of each group.

remaining 5 (36%) infants experienced no significant improvement in seizure control (Supplementary Table 1). GM of the P2 group was more similar to that of the Health group, by comparison with P1 group (Figures 3 and 4). After KD treatment, *Bacteroides* increased significantly, by 24.42%. *Prevotella* also

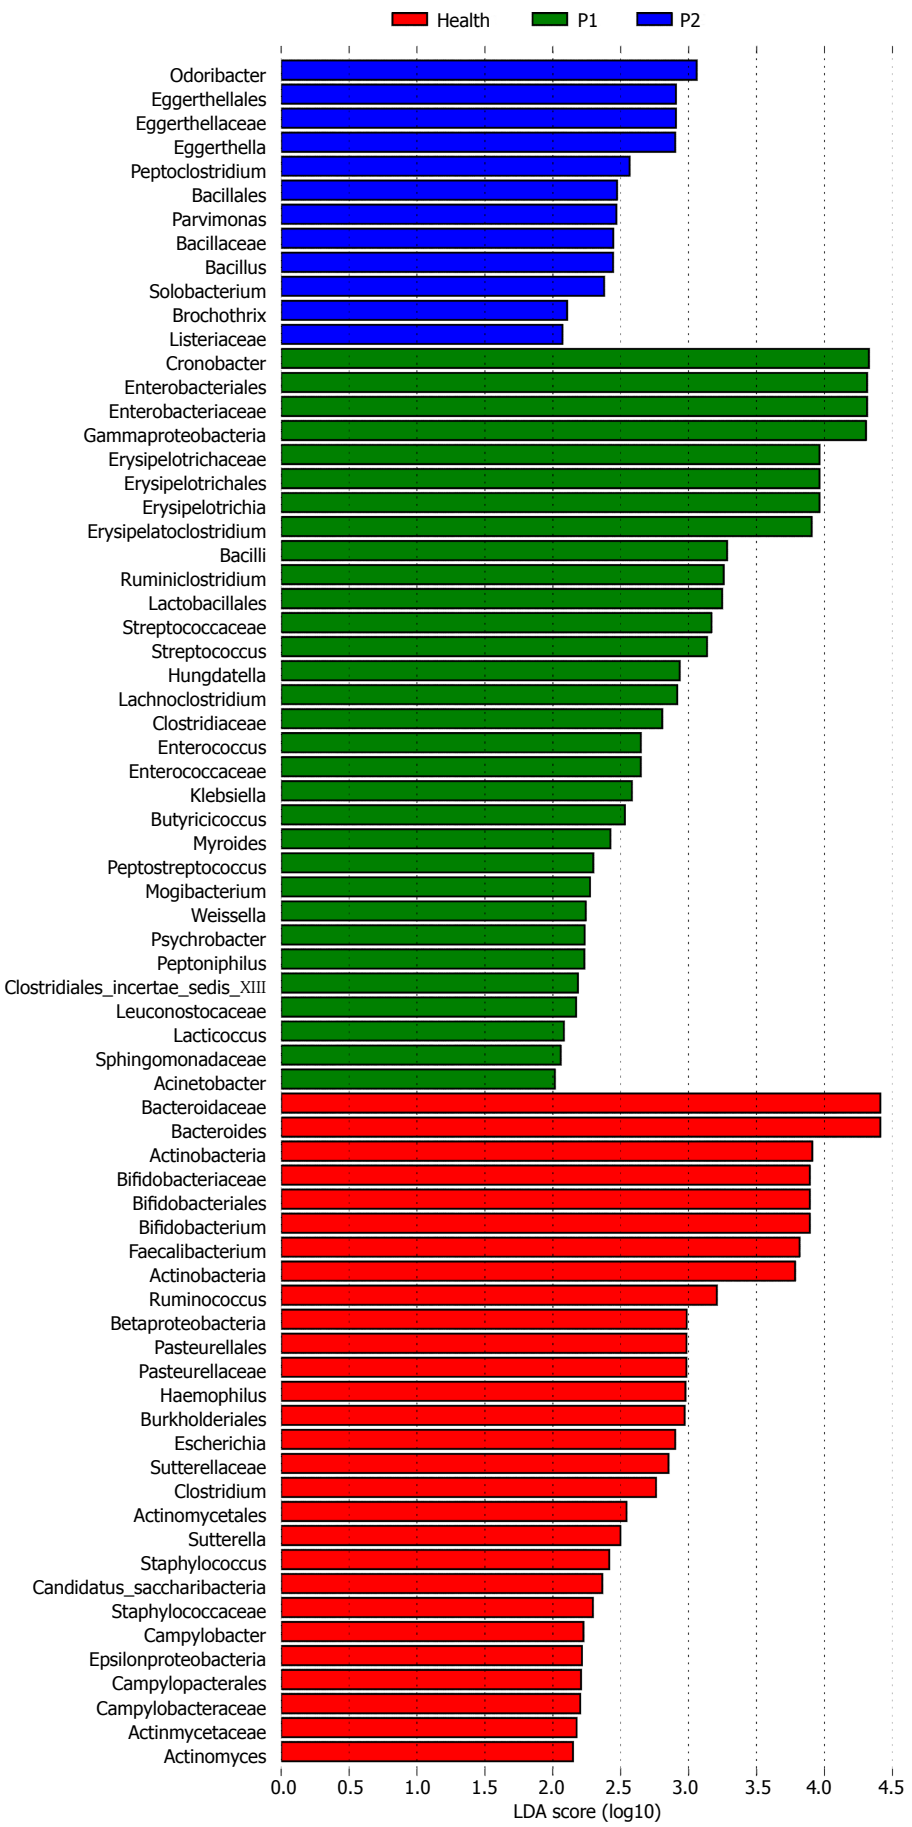

Figure 4 Significantly enriched gut microbiota components in the Health, P1 and P2 groups. LEfSe analysis was applied to detect the gut microbiota (GM) components in the three groups. Red, green, and blue represent the Health, P1 and P2 groups, respectively. The LDA score was set as ≤ 2. The enrichment degree is proportional to the LDA score.

increased in the P1 group from 0.37% to 1.85% after KD treatment (Figure 3 and Supplementary Table 5). *Cronobacter* decreased sharply in after-treatment patients, from 23.3% to 10.44 % (Figures 3 and 4 and Supplementary Table 5). KD exposure also induced a decrease in *Erysipelatoclostridium* (by 8.67% in the P1 group and 4.89% in the P2 group); it represented just 0.64% in healthy infants (Figures 3 and 4 and Supplementary Table 5). *Streptococcus*, *Alistipes*, *Ruminiclostridium*, *Barnesiella* and *Enterococcus* also decreased after KD therapy (Figures 3 and 4 and Supplementary Table 5).

DISCUSSION

KD is increasingly used for the treatment of refractory epilepsy in childhood, but the mechanism remains unclear. Previous reports indicated that GM played an important role in the gut-brain axis[24], and was affected significantly by intake of high-fat food[16]. This study focused on differed GM structures between healthy and epileptic infants, as well as altered GM in patients after one week of KD treatment. The results pointed to an imbalanced GM in patients and a significant improvement after KD therapy.

Proteobacteria comprises a variety of notorious pathogens, such as *Escherichia*, *Salmonella* and *Vibrio*. It accounted for 24.34% in pediatric patients and decreased dramatically after KD treatment. Bacteroidetes was dominant in healthy infants and increased largely in after-treatment patients.

We identified accumulated *Bacteroides* in healthy subjects as well as in patients after treatment. *Bacteroides* was reported to digest and metabolize high-fat food and to regulate the secretion of IL-6 and IL-17 in dendritic cells (DCs), a process strongly associated with seizure severity of epileptic patients[4,16]. However, patients-enriched *Cronobacter* decreased dramatically after KD therapy. Prior reports demonstrated that there were multiple virulence determinants of *Cronobacter*, including *Cronobacter* plasminogen activator and ferric ion transporter protein, which paly a detrimental role in human health[30-32]. *Prevotella* is a robust producer of SCFAs[33], which could protect the intestinal mucosa and function as neurotransmitters. Previous reports also indicated that SCFAs mediated nervous impulse and mitigated Parkinson's disease[33,34]. Similarly, we identified increased *Prevotella* in the Health and P2 group, when compared with the P1 group. Some other genera also offer clues to epilepsy recovery, such as *Erysipelatoclostridium*, *Blautia, Bifidobacterium* and *Streptococcus*. *Bifidobacterium* was well known to be beneficial to health[35], and *Streptococcus,* a common pathogen, played a role especially in respiratory diseases[36]. Although GM imbalance in diseased infants was identified and GM improved after KD treatment, more exploration was needed to elucidate the contribution of a healthy GM to epilepsy onset/recovery.

This study revealed that KD can mitigate the symptoms of epilepsy and correct an imbalanced GM in epileptic infants. However, further analysis is needed to unravel how GM may be involved in epilepsy onset/recovery.

There are some limitations that need to be clarified. First, 16S rDNA analysis identified microbes at the genus level, which makes it difficult to unravel different microbes at the species or function level. Second, it would be more useful to evaluate the efficacy of KD treatment and its effect on the GM if this could be done with a longer period of follow-up. Third, an animal model might be applied to demonstrate whether GM imbalance could induce epilepsy associated symptoms. Considering these limitations, we are planning to perform metagenomic analysis on GM of healthy and epileptic infants. This will provide more insights into distinct metabolic networks in imbalanced GM.

In conclusion, we found that GM of infants with refractory epilepsy differed dramatically from that of healthy infants. Epileptic patients harbored significantly enriched pathogens and decreased beneficial bacteria. Although this study provides new insight into the involvement of GM in pediatric refractory epilepsy, the gap between KD and epilepsy recovery is still huge. To uncover the mechanism and pathogens involved in refractory infantile epilepsy, further research should underscore functional gene networks in GM.

COMMENTS

Background

Infants with refractory epilepsy could not be cured by several anti-epileptic drugs (AEDs) and ketogenic diet (KD) was increasingly used as an alternative therapy to refractory epilepsy. High-fat diet was reported to pose a significant impact on gut microbiota (GM), which could regulate neural systems.

Research frontiers

Previous reports demonstrated that GM could affect neural systems by secreting metabolites as neurotransmitters. In parallel, the gut-brain axis is a research hot spot in biomedicine, including the study of autism, Parkinson's disease, and depression.

Innovations and breakthroughs

This study showed that the GM pattern of diseased infants differs significantly from that of healthy controls. The decreased number of dominant pathogens and significantly increased number of beneficial bacteria after KD treatment offer new insight into KD therapy for epilepsy.

Applications

This study found several types of bacteria altered in the GM, suggesting that these bacteria could be monitored as biomarkers to provide an important reference for epilepsy treatment.

Terminology

GM, which consists of many kinds of bacteria including pathogens, commensals,

and probiotics, plays an important role in the human body.

Peer-review

The authors have performed important research in pediatric epilepsy. They discovered that the composition of the GM in healthy and diseased infants was significantly different, specifically in healthy infants as opposed to those with refractory epilepsy. Bacterial patterns were dramatically changed after KD therapy, and this was associated with a reduction in the frequency of seizures. These findings should enhance our knowledge of the relationship between epilepsy and GM and provide new insight into the clinical treatment of epilepsy.

Abstract

AIM

To determine the level of consensus on the definition of colorectal anastomotic leakage (CAL) among Dutch and Chinese colorectal surgeons.

METHODS

Dutch and Chinese colorectal surgeons were asked to partake in an online questionnaire. Consensus in the online questionnaire was defined as > 80% agreement between respondents on various statements regarding a general definition of CAL, and regarding clinical and radiological diagnosis of the complication.

RESULTS

Fifty-nine Dutch and 202 Chinese dedicated colorectal

surgeons participated in the online survey. Consensus was found on only one of the proposed elements of a general definition of CAL in both countries: 'extravasation of contrast medium after rectal enema on a CT scan'. Another two were found relevant according to Dutch surgeons: 'necrosis of the anastomosis found during reoperation', and 'a radiological collection treated with percutaneous drainage'. No consensus was found for all other proposed elements that may be included in a general definition.

CONCLUSION

There is no universally accepted definition of CAL in the Netherlands and China. Diagnosis of CAL based on clinical manifestations remains a point of discussion in both countries. Dutch surgeons are more likely to report 'subclinical' leaks as CAL, which partly explains the higher reported Dutch CAL rates.

Key words: Colorectal anastomotic leakage; Colorectal surgery; Definition; Complication

Core tip: The present international online survey proves the inconsistent views as to what is considered colorectal anastomotic leakage among surgeons in the Netherlands and China, and shows large differences between the countries. This is in line with the current literature, since there is no uniformly accepted definition worldwide. We therefore propose to perform a systematic literature review to identify the available definitions. The final stage would be to perform a Delphi analysis within a representative panel of colorectal surgeons to develop a widely accepted definition of colorectal anastomotic leakage.

Definition of colorectal anastomotic leakage: A consensus survey among Dutch and Chinese colorectal surgeons. *World J Gastroenterol* 2017; 23(33): 6172-6180 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6172.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6172

INTRODUCTION

Colorectal anastomotic leakage (CAL) remains gastrointestinal surgeons' most feared complication, despite important improvements in perioperative care and the development of novel surgical techniques. It is associated with high rates of morbidity and mortality[1,2], poor quality of life[3], and increased healthcare costs[4,5]. Since CAL influences the direct postoperative course and has recently been proven to impact oncological outcome as well[6-8], it is frequently used as an outcome measure in clinical studies. However, the CAL rates vary considerably in the international literature from 1.5% to 23%[9,10]. Large variations in leakage rates have been reported between studies published by Western and Asian research groups, in which the reported incidence of CAL in Asian publications is substantially lower[5,11-14]. Such differences can be partly explained by the variations of operation technique, tumor location, and patient characteristics[15,16]. However, little attention has been paid to potential differences in the CAL definition and the available methods of diagnosis.

Although CAL is sometimes defined as "a defect in the bowel wall at the anastomotic site, leading to communication of intra- and extraluminal compartments"[17], this definition translates rather difficult to the clinical situation. Therefore, many authors formulate new definitions or diagnostic criteria in their studies, which usually include clinical and radiological features[18], and the impact of a leak on the treatment plan. However, since the pathophysiology of anastomotic leakage is multifactorial, the manifestation of a clinical leak can be rather variable[15]. Furthermore, due to the increased use of (routine) diagnostics such as CT or contrast enema, "radiological" leaks that do not eventually influence patient management are diagnosed more often. These factors complicate comparison of study results, and weaken the reliability of further analyses. This in turn hampers the construction of evidence-based guidelines on patient management and surgical technique.

Clearly, there is a need for a generally accepted and practical definition for CAL and its diagnostic criteria to serve as a template for future research on CAL and the clinical decision-making process[19]. Several surveys have been performed to reach consensus regarding the definition of CAL, however, most of them were restricted to a single country[19]. We hypothesized that the aforementioned reported differences in incidence rates between Asian and Western countries can partly be explained by differences in the definitions and diagnostic methods used. The aim of this study was therefore to determine the level of consensus regarding different aspects of a general definition of CAL within and between populations of Chinese and Dutch colorectal surgeons, that can be considered good representatives of the East and West, respectively.

MATERIALS AND METHODS

An online survey was performed among colorectal surgeons from the Netherlands and China. In the Netherlands, the survey was constructed and run through an online database using SurveyMonkey TM (Palo Alto, CA, United States). Colorectal surgeons in the Netherlands were identified from the contacts section of the colorectal subdivision of the Dutch Society of Gastro Intestinal Surgery (NVGIC): the Taskforce Coloproctology (WCP). Within this subdivision, 141 senior and junior colorectal surgeons were identified. Respondents were invited to partake in the online

Table 1 English questionnaire on definition of colorectal anastomotic leakage

		Yes	No
General definition			
Do we have to consider the following findings as anastomotic leakage?			
1	Extravasation of contrast after rectal enema on a CT scan		
2	Radiological collection around the anastomosis and no treatment		
3	Radiological collection around the anastomosis treated with antibiotics		
4	Radiological collection around the anastomosis treated with percutaneous drainage		
5	Abdominal sepsis and reoperation needed		
6	Necrosis of the anastomosis seen at reoperation		
7	Necrosis of the blind loop seen at reoperation		
8	Signs of peritonitis during reoperation		
9	Air bubbles around the anastomosis seen on a CT scan		
10	Free intra-abdominal air seen on a CT scan		
Clinical diagnosis			
In what extent do the following clinical parameters contribute to the suspicion of colorectal anastomotic leakage? Please note the relevance on a numeric scale of 0-10:			
1	Increased C-reactive protein		
2	Increased leukocytes		
3	Tachycardia		
4	Increased respiratory rate		
5	(Sub-) febrile temperature		
6	Postoperative ileus (> 4 d)		
7	Deterioration in clinical condition		
8	Abdominal pain, other than wound pain		
Radiological diagnosis			
Answer the following questions using percentages (0% = never, 100% = always)			
1	In how many percent of patients with clinical suspicion of anastomotic leakage do you perform radiodiagnostics?		
2	In how many percent of patients with clinical suspicion of anastomotic leakage do radiodiagnostics change your treatment policy?		
3	In how many cases did the CT scan report no anastomotic leakage while there finally was an anastomotic leakage.		
4	In how many percent of cases do you consider a reoperation without previous radiodiagnostics?		
Early anastomotic leakage			
In your opinion, is 'very early (< 3 d) anastomotic leakage the result of technical failure?			
1	Yes		
2	No		

survey by email. Dutch surgeons completed the questionnaire between May and June 2015.

In China, the survey was conducted on the platform provided by DXY (www.dxy.cn), which is the largest medical website in China with more than one million registered medical users. An invitation was sent to all the registered colorectal surgeons to invite them to participate in a five-minute survey. Due to a relatively large number of registered users, the survey was designed to be terminated when 200 replies were received. Surgeons from Hong Kong, Macao, and Taiwan were not invited in this survey, because of the application of different medical systems in those areas. A demographic chart of the regions represented by the respondents can be observed in Figure 1.

The survey was divided into three major categories with questions addressing the general definition, and the clinical and radiological diagnosis of CAL. It was partly adapted from a previous study of Adams *et al*[20] and was initially constructed in English, and then translated to Dutch and Chinese by surgeons fluent in both English and Dutch and English and Chinese for the Dutch and Chinese versions, respectively, and checked for interpretation bias. Details of the English questionnaire are shown in Table 1 (See supplementary data for Dutch and Chinese versions).

Category Ⅰ mainly focused on the agreement of general definitions used in the international literature[20]. Surgeons were asked to state whether ten different clinical situations should or should not be included in a general definition. Category Ⅱ focused on clinical manifestations and their predictive value for CAL. A 10-point grading scale ranging from 1 (not predictive at all) to 10 (very predictive) was used to assess the agreement of the respondents' views on the clinical parameters. The parameters used were partially adapted from the Dutch Leakage Score (DULK)[11]. Category Ⅲ consisted of four questions regarding the use of radiological examination and the influence of this diagnostic method on patient care. This third category was also partially adapted from Adams *et al*[20]. The last general question focused on surgeons' views regarding the cause of very early anastomotic leakage.

Definitions

Very early anastomotic leakage was defined as leakage occurring within the first three days post-surgery.

Postoperative ileus was defined as an interval of more than 4 d from surgery until passage of flatus or stool and the tolerance of an oral diet[21].

Blind loop was defined as a bypassed loop of bowel after the construction of an end-to-end or end-to-side bowel anastomosis.

Statistical analysis

Basic descriptive statistics were used to summarize data for the online survey. Consensus was defined as > 80% agreement between respondents on various statements, as described by Duncan *et al*[22]. If less than 80% of respondents deemed the statements important, it was stated that no consensus was reached. Graphical depictions of information were used where appropriate to facilitate data interpretation. Chi square test or Mann-Whitney test were applied with proper indications. A *P*-value smaller than 0.05 was considered to indicate statistical significance.

RESULTS

Of the 141 colorectal Dutch surgeons who were invited to partake in the online survey, 62 respondents accepted the invitation, and 59 completed the survey, resulting in a 42% response rate and 95% survey completion. In total, 100% of 201 questionnaires

Figure 1 Demographic chart of the Chinese regions this survey covers. The gray scale reflects the number of participants in each region, varying from 21 from Zhejiang to 1 from Hainan. Correlating with the number of colorectal surgeons in each region, more surgeons from the east regions participated in this survey. Tibet and Ningxia had no participants, which also corresponds to the fact that the number of surgeons is very limited compared to the east provinces. Due to the application of different medical systems in these regions, Hong Kong, Macao, and Taiwan were not included in this survey.

received from Chinese surgeons were completed. A demographic chart of the regions represented by the respondents can be observed in Figure 1, as it shows that this survey covers 96.8% (30/31, Hong Kong, Macao, Taiwan not included) of provinces and areas of China.

Consensus was found on only one clinical situation proposed as an element of a general definition in both countries: 'extravasation of contrast on enema' (Figure 2), and in the Netherlands on two additional elements: radiological collection for which percutaneous drainage was needed (50/59 respondents, 85%) and necrosis of the anastomosis visible upon reintervention (51/59 respondents, 86%). For all other items on the available general definitions, clinical and radiological diagnosis of CAL, no consensus was found. Scores were significantly different between China and the Netherlands for the following elements: radiological collection treated conservatively (21% *vs* 39%, respectively, $P = 0.010$), necrosis of the blind loop on reintervention (41% *vs* 69%, respectively, $P \leqslant 0.001$), and air surrounding the anastomosis on a CT scan (65% *vs* 44%, respectively, $P = 0.004$).

Grades given for the clinical parameters are shown in Figure 3 for both China and the Netherlands. Clinical deterioration, increased C-reactive protein (CRP), tachypnea, and tachycardia were seen as being most contributory for the clinical suspicion of CAL in the Netherlands, and were given a weighed score of 7.83, 7.45 7.13 and 7.13, respectively (Table 2). In China, clinical deterioration and abdominal pain other than wound pain were deemed most attributable for the suspicion of anastomotic leakage in the direct postoperative period, with scores of 6.67 and 6.61, respectively. Increased plasma concentration of CRP received the lowest score of all parameters in China (4.35), while in the Netherlands this was deemed

Table 2 Sensitivity scores of clinical parameters for the suspicion of anastomotic leakage in the direct postoperative period in China and The Netherlands

Clinical parameter	China	The Netherlands	*P*-value
	Score ± SD	Score ± SD	
Increased CRP	4.35 ± 2.466	7.45 ± 1.871	< 0.001
Leukocytosis	5.96 ± 2.596	6.53 ± 1.824	0.095
Tachycardia	4.55 ± 2.411	7.13 ± 1.937	< 0.001
Tachypnea	4.46 ± 2.244	7.13 ± 1.937	< 0.001
Febrile temperature	6.23 ± 2.281	5.86 ± 1.963	0.207
Postoperative ileus	4.47 ± 2.363	5.76 ± 1.679	< 0.001
Clinical deterioration	6.67 ± 2.033	7.83 ± 1.205	< 0.001
Abdominal pain	6.61 ± 2.247	6.74 ± 1.835	0.659

CRP: C-reactive protein.

more sensitive (7.45, $P < 0.001$). Upon categorization of the grades for the value of clinical parameters into different categories of the numeric scale: disagree (0-3), neutral (4-6) and agree (7-10), most surgeons from both countries (45%-59% of surgeons for each parameter) remained neutral towards the added value of specific clinical parameters during the postoperative course.

The data on radiodiagnostics are shown in Table 3. The majority of Chinese and Dutch surgeons perform radiodiagnostics upon clinical suspicion of a leak. The distribution of the answers over the different classifications, however, was significantly different between the two nationalities (Chi square test, $P = 0.020$). Expected false-negative rates for CT scans were equal for surgeons in both countries. A significantly larger portion of the Chinese colorectal surgeons (25.4% *vs* 13.6%, $P \leqslant 0.001$) would consider performing a reoperation for the suspicion of CAL without performing radiological diagnostics. The distribution of the scores differed significantly between countries as to in how many cases a reoperation is considered without previous radiodiagnostics (Chi square test, $P = 0.002$).

Concerning the question about early CAL, 90.6% of the Chinese surgeons agreed that the cause of such should be considered a technical failure, whilst only 70.4% of the Dutch colorectal surgeons agreed to this statement ($P \leqslant 0.001$).

DISCUSSION

Despite extensive research in the field of CAL, no international consensus regarding a practical definition exists, which limits the transparency and comparison of study outcomes. Several definitions of CAL have been proposed during the last decade[18,23], but review of the literature shows that newly published papers fail to adopt these definitions[24]. Instead, authors seem to prefer to use their own definitions or no definition at all[24]. It could be postulated that these previously proposed definitions were not yet implemented in clinical practice and (retrospective) research because of limited awareness of the existence of such a

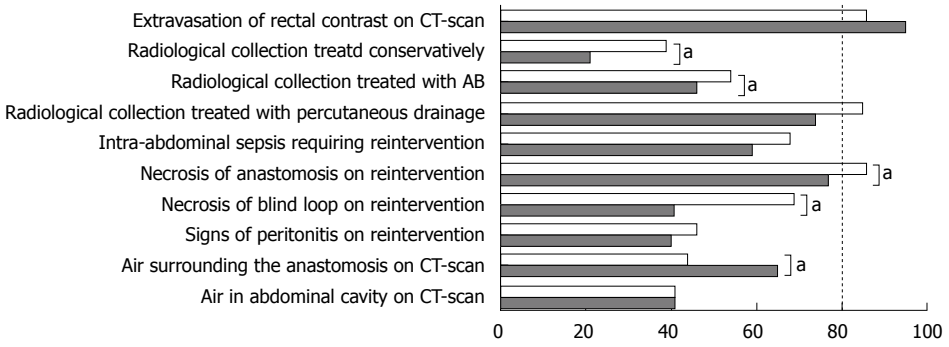

Figure 2 Percentage of respondents in agreement to general definitions of colorectal anastomotic leakage in the Netherlands (white bars) and China (dark grey bars). The dotted line indicates the 80% consensus threshold for the different statements. An a indicates a significant ($^aP < 0.05$) difference between percentages of agreement of Dutch and Chinese surgeons.

definition and/or lack of support from a large expert group.

Reports from Asian studies show CAL rates that are substantially lower than those reported by Western research groups[25]. This could partially be explained by demographic differences that exist in patient population, availability and use of diagnostic tools, or how perioperative care is structured. Another explanation could be that Chinese surgeons only report a leak as such when reintervention is required.

On the other hand, despite the lower prevalence of obesity in Asian countries, rates of type Ⅱ diabetes mellitus and metabolic syndrome are relatively high due to ethnic and genetic factors. Indeed, Asians account for 60% of diabetes mellitus cases worldwide[26], which is considered an important risk factor for CAL[27,28]. Furthermore, the most common location of colorectal tumors in the Asian population is the left hemicolon[16,29], compared to the Western population, in which the predominant side is the right[29,30]. The literature shows a significantly higher CAL risk for surgeries on colorectal tumors located in the left hemicolon[31]. These regional differences therefore fail to completely explain the variation in reported CAL rates. It is very likely that important regional differences exist as to what is considered an anastomotic leak, *i.e.*, Asian surgeons may report a leak mostly when a reintervention is required, while the Western surgeons may report latent leaks. In order to gain more insight into these differences in views, the present survey was conducted both in China and in the Netherlands, countries that are considered to be representative for their continent.

In the first part of the survey, surgeons were asked whether different statements including clinical and radiological signs and interventions regarding CAL should be considered anastomotic leakage. Of ten statements, only one was deemed as CAL by more than 80% of respondents in both countries: 'Extravasation of contrast after rectal enema visible on a CT scan'. This is generally considered a radiological hallmark sign for anastomotic leakage after left-sided colorectal surgery and should naturally be included in a general definition. Moreover, other important and evident CAL signs including "Radiological collection around the anastomosis treated with percutaneous drainage" and "Necrosis of the anastomosis seen at reoperation" received more than 80% positive responses in the Netherlands, however, not in China, and thus were not considered as consent according to the predetermined criteria. Despite this, the majority of the Chinese surgeons also agreed on these items and their answers did not differ significantly from those of their Dutch colleagues. In conclusion, it seems that for the evident signs of CAL, the majority of surgeons from both countries have quite similar views.

"Radiological collection treated conservatively" was only considered to be CAL in 21% of the Chinese surgeons (versus 39% in the Netherlands), which is almost a consensus of NOT including this statement in a general definition of CAL. On the contrary, it is at

Table 3 Surgeons' opinion regarding the value of radiodiagnostics in the diagnosis of colorectal anastomotic leakage

Responders, *n* (%)	China (%)	The Netherlands (%)	*P*-value
In how many percent of patients with clinical suspicion of anastomotic leakage do you perform radiodiagnostics?			
	202 (100)	55 (93)

least remarkable that in current grading systems, a radiological collection can be considered anastomotic leakage. As such this is reported as a grade A CAL according to the International Study group of Rectal Cancer (ISREC)[18] and grade Ⅰ-Ⅱ CAL according the Clavien-Dindo Scale.

Despite the fact that only a minority of Dutch surgeons consider conservatively treated radiological collections as CAL, these numbers are higher than those among the Chinese. These differences in views regarding the subclinical signs of CAL may eventually lead to a significantly higher reported CAL rate in the Dutch studies than the Chinese ones. However, considering the fact that more than 30%[32] of the CAL do not require invasive intervention, the treatment provided by surgeons from both countries may eventually be similar, *i.e.*, leading to a similar intervention rate for the complication. To rule out the reporting difference in this regard, one solution is to report complications with a Clavien-Dindo score higher than Ⅲa, which actually is also commonly accepted and applied in recent studies.

The second part of the survey focused mainly on clinical markers and parameters for CAL. Early clinical diagnosis of CAL remains a challenge for surgeons worldwide. Many clinical symptoms and biomarkers have been suggested as early signs of CAL[33-36]. However, previous studies of these parameters have shown that almost none of these parameters yield sufficient diagnostic accuracy to allow for a confirmative diagnosis[37]. This explains our findings that most surgeons do not base their diagnosis of CAL on these parameters, which results in a relatively low score of their contribution to the suspicion of CAL. Surgeons from both countries deemed "deterioration of clinical condition" as an important symptom of CAL, which further accentuates the complexity of CAL diagnosis based on its clinical manifestations. We believe the surgeons' opinions indeed reflect the unsatisfactory status of CAL diagnosis, which stresses the need for further research in this field[38]. However, important differences exist between the two countries. Although surgeons from both countries agreed about the predictive value of higher temperature, abdominal pain other than wound pain, and increased leukocyte count, more than half of the clinical parameters scored significantly lower in China than in the Netherlands. Although these abnormal clinical manifestations are indeed very common after gastrointestinal surgery[39], it seems that they are considered less suggestive by the Chinese surgeons.

The third part of the survey focused on radiological tools used in the diagnosis of CAL. Based on the present data, the majority of the surgeons in both countries would perform radiological examination on patients in whom CAL was suspected (these numbers are slightly higher in the Netherlands), and more than half of the treatment plans would be changed after the imaging. In this regard, although differences have been found in the views of Chinese and Dutch surgeons regarding the definition of CAL, the treatment they provide is similar. However, our data also show that surgeons from both countries do not blindly rely on the results from radiodiagnostics. Instead, they state that in approximately 30% of the cases in which CAL is suspected, CAL is eventually diagnosed in spite of a negative radiological report. This correlates with previously reported false negative rates of CT scans[40]. Experience with inaccurate CT scan reports may be a reason for surgeons to consider reoperation without affirmative CT results, which according to the data, occurs in about 25% of cases.

Further research and education may facilitate the achievement of international consensus. However, definition without considerations of the practical issues in different regions is unlikely to gain sufficient popularity. In 2010, the ISREC proposed a graded system for the diagnosis and treatment of CAL[18]. Grade A CAL refers to anastomotic leakage for which no active therapeutic intervention is required. It seems that this grade correlates with the second statement "Radiological collection surrounding the anastomosis

treated conservatively" that is not classified as CAL according to the majority of both Dutch and Chinese surgeons. This discrepancy between an established definition and the views of colorectal surgeons could partly explain why the ISREC definition has not been adopted in practice and science. In accordance with that, our survey clearly demonstrates how different practices may influence surgeons' opinion.

For example, in the Netherlands the Enhanced Recovery After Surgery (ERAS) program has been widely adopted for years, and recommends no abdominal drainage after surgery. In China, on the contrary, ERAS is less commonly implemented, and an intra-abdominal drain is often left *in situ* for longer periods after surgery. Moreover, CT imaging is less commonly used as radiodiagnostic for CAL, and laboratory analysis by means of CRP is not yet implemented in routine practice in many rural areas. This could explain why increased CRP was deemed least contributory in the diagnostic process in the present survey. These points, though small, significantly influenced the results, and would certainly impact the applicability of a proposed CAL definition.

To successfully embed a definition in clinical practice, research on CAL would greatly benefit from establishing a uniform definition and recording in national databases. We will therefore continue to perform an extensive and systematic literature review. The results from that review and the consensus assessment described in this paper will lead to an international Delphi analysis that will allow us to reach consensus on a new definition proposal that will be supported by a large panel of experts. We sincerely welcome others to participate in this further research, in order to formulate a new definition based on joint experience and opinions.

The most important limitations of the study are the following. The content of questionnaires is always susceptible to researcher imposition and there may be a level of subjectivity in the answers given. Furthermore, the relatively low numbers of respondents from both countries would have a negative influence of the generalizability of study results. Finally, the original questionnaire was constructed in English and translated into Dutch and Chinese, which could introduce bias and weaken the validity of comparisons between the countries. Finally, as some of the clinical parameters used in the questionnaire were derived from the DULK-score, which was constructed and validated in the Netherlands, it is plausible that the Dutch participants scored similarly on these items because they were familiar with the content of the DULK-score, because they have been (in)directly involved in the construction of the scoring system. However, the use of the DULK-score has not remained limited to the Netherlands, and it is unknown whether the subset of Dutch surgeons familiar with the DULK-score is higher than the number of Chinese surgeons who use this score routinely, and whether this difference is large enough to alter the data significantly.

In conclusion, no international consensus of a practical definition of CAL is yet available, which limits the transparency and comparison of published results. The present international online survey proves the inconsistent views as to what is considered CAL among surgeons in the Netherlands and China, and shows large differences between countries. Dutch surgeons are more likely to report 'subclinical' leaks as CAL, which partly explains the higher reported Dutch CAL rates. Surgeons from both countries rely on radiological diagnostics and laboratory parameters in the decision-making process, but are well aware of the limitations of these diagnostic aids. A Delphi analysis within a representative panel of colorectal surgeons is desired to develop a widely accepted definition of CAL.

ACKNOWLEDGMENTS

The authors thank the Dutch Society of Gastro Intestinal Surgery and their subdivision, the Taskforce Coloproctology, and Taskforce Anastomotic Leakage, for their support during the survey.

COMMENTS

Background

Colorectal anastomotic leakage (CAL) is the most feared complication after colorectal surgery. No international consensus exists regarding a general definition of CAL.

Research frontiers

Over the past decades, thousands of articles on CAL have been published. Unfortunately, a uniform and accepted worldwide definition of CAL is not available. This limits the transparency and comparison of study results and usefulness in clinical practice.

Innovations and breakthroughs

An international survey has been performed to identify the differences in reported definitions of CAL and to evaluate the opinions of expert leaders in both a Western and Eastern country.

Applications

The present international online survey proves the inconsistent views as to what is considered CAL among surgeons in the Netherlands and China, and shows large differences between the countries. This is in line with the current literature, since there is no uniform accepted definition worldwide. We therefore propose to perform a systematic literature review to identify the available definitions. The final stage is to perform a Delphi analysis within a representative panel of colorectal surgeons to develop a widely accepted definition of CAL.

Terminology

CAL is the major complication after colorectal surgery with a stable incidence (1.5%-23%). It is associated with high rates of morbidity and mortality, poor quality of life, and increased health expenditure. Since CAL influences the direct postoperative course and has recently been proven to impact oncological outcome as well, it is frequently used as an outcome measure in clinical studies.

Peer-review

In this study, the authors have presented a thorough and critical analysis of the availability of a definition of CAL and the opinions of both Dutch and Chinese surgeons regarding this definition.

Abstract

The prognosis of pancreatic cancer remains poor, even after initial surgical therapy. Local recurrence after Whipple's pancreatico-duodenectomy may lead to intestinal obstruction at the level of the afferent limb or the alimentary limb. Endoscopic insertion of a self-expandable metal stent (SEMS) into the intestinal malignant stricture is the preferred method of choice for palliation. We describe two new endoscopic techniques to treat a malignant intestinal obstruction with the insertion of a SEMS into the afferent limb and the alimentary limb. A case of malignant gastric outlet obstruction after a Whipple's resection was treated by the creation of an endoscopic gastrojejunostomy by the insertion of a lumen apposing HotAxios stent in between the stomach and the alimentary limb under fluoroscopic and endoscopic ultrasound control. Biliary obstruction and jaundice caused by a malignant stricture of the afferent limb after a Roux-en-Y Whipple's resection was treated by the insertion of a SEMS by means of the single-balloon overtube-assisted technique under fluoroscopic control. Feasibility and advantages of both techniques are discussed.

Key words: Intestinal obstruction; Self-expandable metal stent; Whipple's pancreatico-duodenectomy

Core tip: Malignant recurrence after Whipple's pancreatico-duodenectomy is frequent and may lead to intestinal obstruction. Endoscopic palliation of the intestinal obstruction is challenging. We present 2 endoscopic techniques: Endoscopic ultrasound-guided creation of a gastrojejunostomy using a fully covered lumen apposing metal stent, and insertion of a self-expandable metal stent by means of the single-balloon overtube-assisted technique under fluoroscopic control.

How to treat intestinal obstruction due to malignant recurrence after Whipple's resection for pancreatic head cancer : Description of 2 new endoscopic techniques. *World J Gastroenterol* 2017; 23(33): 6181-6186 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6181.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6181

INTRODUCTION

Whipple's pancreatico-duodenectomy was named after Alan Oldfather Whipple who described the technique in 1935[1]. It still is the surgical treatment of choice to cure pancreatic head cancer[2]. Modifications of the technique have emerged, including pylorus-preserving Whipple's resection and Roux-en-Y intestinal reconstruction[3]. After resection of the pancreatic head, both the remnant bile duct and pancreatic duct have to be anastomosed to the afferent limb (hepaticojejunostomy/pancreaticojejunostomy) and food passes through the alimentary limb. Despite the different surgical Whipple's variations, the risk of local tumor recurrence after Whipple's resection for pancreatic head cancer remains more than 50%[4]. Few cases present with malignant intestinal obstruction at the level of the afferent or the alimentary limb. Endoscopic palliative therapy by means of insertion of self-expandable metal stents (SEMS) is the preferred method of choice to treat malignant intestinal obstruction in case of pancreatic cancer[2]. However, endoscopic SEMS placement in the afferent or the alimentary limb remains a challenging procedure[5]. We report on the endoscopic treatment modalities of two cases of malignant intestinal obstruction due to tumor recurrence after Whipple's pancreatico-duodenectomy.

CASE REPORT

Case 1

A 71 year-old woman was referred with symptoms of upper gastrointestinal obstruction because of local tumor recurrence at the level of the gastrojejunal anastomosis with peritoneal carcinomatosis. She underwent Whipple's resection for pancreatic head cancer two years earlier. Initially, an uncovered enteral SEMS (Wallflex 60 x 22 mm, Boston Scientific) was inserted and ended up in the afferent limb, eventually obstructing the alimentary limb worsening the gastric outlet syndrome. CT scan confirmed the dilated afferent limb towards the hepaticojejunostomy, with food remnants and the empty alimentary limb underneath the stomach (Figure 1). Since the uncovered SEMS could not be removed from the afferent limb because of tumor ingrowth obstructing the entrance to the alimentary limb, we decided to create an endoscopic gastrojejunostomy, using the HotAxios device (XLumina Axios 10 mm x 15 mm, Boston Scientific), under endoscopic ultrasound (EUS) guidance (linear-array echoendoscope GF-UCT 180, Olympus) and fluoroscopy. The HotAxios device is a cystotome catheter with a preloaded covered lumen apposing metal stent. It is developed to drain pancreatic pseudocysts with an all-in-one device[6]. Here we used it to create an endoscopic gastrojejunostomy. The empty alimentary limb was identified by transgastric EUS, accessed with a 19 gauche needle (Figure 2), and confirmed fluoroscopically by intraluminal contrast dye injection.

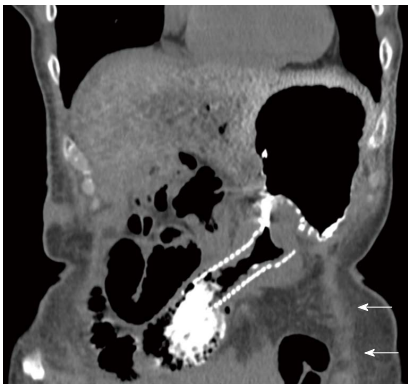

Figure 1 Coronal computed tomography image of a non-covered metallic stent with peroral contrast in the dilated afferent limb in a patient with classical Whipple's duodenopancreatectomy. Note the obstructed empty alimentary limb underneath the stomach (arrows).

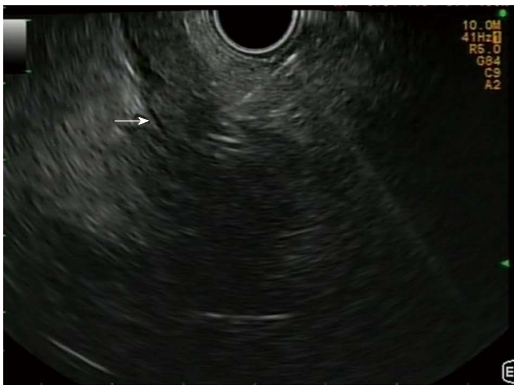

Figure 2 Linear endoscopic ultrasound image of the transgastric puncture of the obstructed alimentary limb (arrow) with a 19 gauche needle.

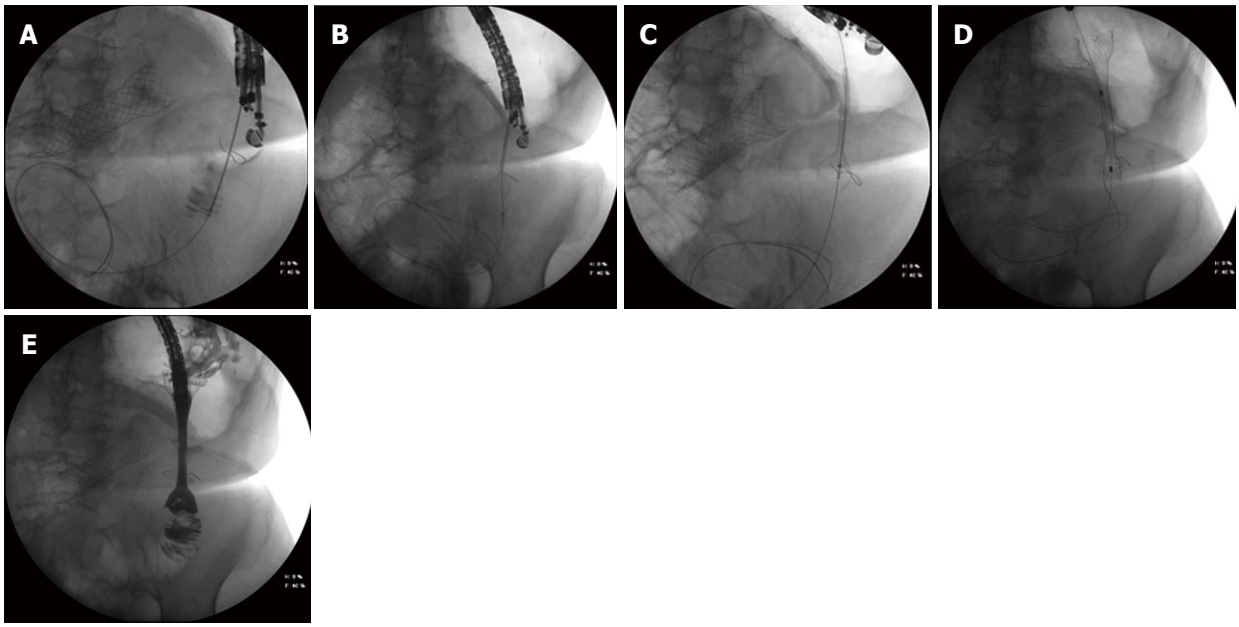

Figure 3 Fluoroscopic image. A: The transgastric access of the alimentary limb using a 19 gauche needle. Correct access of the limb was confirmed after injection of contrast dye. A: 0.035 inch guidewire is introduced into the alimentary limb. Note the SEMS in the afferent limb; B: The HotAxios lumen apposing stent deployment between the alimentary limb and the gastric lumen; C: The HotAxios lumen apposing stent migrating outside to stomach. The distal flange is well positioned inside the lumen of the alimentary limb; D: The fully covered oesophageal stent inside the HotAxios lumen apposing stent, creating a gastrojejunostomy; E: Fluoroscopic image confirming the creation of a gastrojejunostomy between the stomach and the alimentary limb using the combination of a HotAxios lumen opposing stent and a fully covered oesophageal stent. Water soluble contrast dye is injected through the oesophageal stent into the alimentary limb. Note the non-covered SEMS in the afferent limb.

Next, a 0.035 inch guidewire was placed (Figure 3A), allowing smooth introduction of the HotAxios stent deployment system into the alimentary limb using electrocautery. The fully covered 10 mm HotAxios lumen apposing stent was deployed under fluoroscopic and endoscopic guidance, with the distal flange in the intestinal lumen, and the proximal flange in the stomach (Figure 3B). However, upon release, it immediately migrated outside the stomach because of the distance between the alimentary limb and the stomach (Figure 3C). A fully covered metal esophageal stent (Taewoong Medical Niti, 80 mm x 22 mm) was introduced over the guidewire and deployed inside the HotAxios stent, with the proximal part protruding into the gastric lumen (Figures 3D and E). After the procedure, the patient quickly resumed oral feeding.

Three months later, she was readmitted for vomiting due to intragastric migration of the esophageal stent. The HotAxios stent was still in place. A fully covered Nagi stent (Taewoong Medical, 20 mm x 16 mm) was placed inside the HotAxios stent, and the patient resumed oral feeding. Seven months after the initial presentation, she died due to malignant progression of the disease.

This case illustrates the feasibility of the HotAxios system in creating an EUS-guided gastrojejunostomy to treat malignant gastric outlet syndrome. This technique has recently emerged as an alternative to surgical gastrojejunostomy treating benign and malignant gastric outlet syndrome, with technical success rate of 92% and 85% clinical success[7-9]. Serious adverse events of this endoscopic ultrasound technique were reported in 11.5%, and encompass gastrointestinal perforation, peritonitis and bleeding[9]. We encountered another complication. After deployment of the HotAxios lumen apposing stent to create the gastrojejunostomy, the gastric flange migrated outside the stomach without the possibility to reposition it into the stomach. Since the guidewire was still in place, we were able to save the gastrojejunostomy by inserting a second fully covered oesophageal SEMS inside the HotAxios stent.

Case 2

A 76-year-old woman who underwent Roux-en-Y Whipple's resection two years earlier for pancreatic head cancer, was referred because of obstructive jaundice and dilated intrahepatic bile ducts. Percutaneous transhepatic cholangiography and biliary drainage excluded an obstruction at the level of the bilioenteric anastomosis. However, afferent limb syndrome was diagnosed based on the obstruction of the afferent limb 20 cm distally from the hepaticojejunostomy with a dilated intestinal segment between the hepaticojejunostomy and the enteral stricture of the afferent limb (Figure 4A). Next, we performed a single-balloon enteroscopy (SBE) through the Roux-en-Y anastomosis into the afferent limb under fluoroscopic guidance, and reached the jejunal stenosis, with endoscopic characteristics of a malignant stricture (Figure 5). The length of the

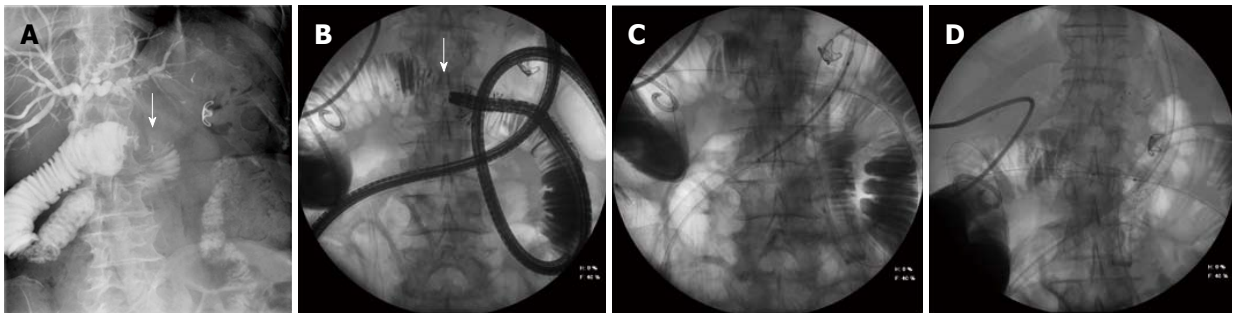

Figure 4 Fluoroscopic image. A: A percutaneous transhepatic cholangiography confirming patency of the biliary anastomosis. The malignant stricture (arrow) is located at the level of the afferent limb (afferent limb syndrome), leading to dilated intrahepatic bile ducts and a dilatation of the afferent limb. Note the presence of an old Ovesco clip in the stomach. B: The single-balloon enteroscopy up to the level of the malignant stricture in the afferent limb. Contrast injection through the working channel of the enteroscope clearly delineates the length and the malignant aspect of the stricture (arrow). C: The peroral insertion technique of the self-expandable metal stent over a stiff guidewire through the overtube with the balloon inflated to protect the intestinal mucosa and to guide the catheter up to the malignant stricture of the afferent limb. D: The self-expandable metal stent in place in the malignant stricture of the afferent limb. Both the stiff guidewire and the overtube of the single-balloon enteroscope were used to insert the SEMS. SEMS: Self-expandable metal stent.

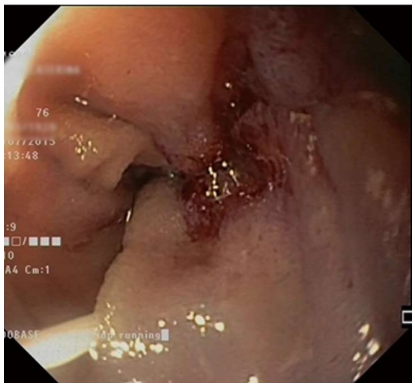

Figure 5 Endoscopic image of the malignant stricture of the afferent limb. Note the guidewire inserted into the stricture.

stricture was estimated by means of the injection of water soluble contrast. A 0.035 inch guidewire was inserted into the stricture under endoscopic and fluoroscopic control, and a CRE dilation balloon (8-10 mm) was inserted over the guide wire to dilate the stricture. Biopsies confirmed the intestinal recurrence of a pancreas adenocarcinoma. After a multidisciplinary oncology discussion, a non-surgical endoscopic approach was suggested. One week later, a second SBE was performed in order to place a SEMS into the malignant stricture. Again, the length of the stricture was estimated by contrast injection under fluoroscopic control (Figure 4B). A 0.035 inch stiff guidewire (VisiGlide 450 cm, Olympus) was inserted into the dilated jejunal segment proximal of the stricture. The overtube of the SBE was anchored as close as possible near the malignant stricture with the balloon inflated. Next, the enteroscope was removed under fluoroscopic guidance, leaving the guidewire and the overtube in place. An uncovered SEMS (Wallflex 60 mm x 22 mm, Boston Scientific) was inserted over the guidewire through the overtube into the stricture, located by means of the previously injected contrast (Figure 4C). The stent was deployed under fluoroscopic guidance (Figure 4D). Afterwards, the enteroscope was reintroduced through the overtube to control for the correct positioning of the SEMS. The percutaneous biliary drain was removed and the patient was discharged two days later with normal oral food intake. Gemcitabine-based chemotherapy was started.

Three months later, she presented again with obstructive jaundice and afferent limb syndrome suggestive of tumor invasion of the uncovered SEMS. A third SBE procedure was performed, confirming the diagnosis of SEMS obstruction. We used the same single-balloon overtube-assisted technique to insert a new partially covered SEMS (ComVi Enteral Colonic Stent 100 mm x 22 mm, Taewoong) inside the uncovered SEMS. No complications were encountered. Ten months after the second SEMS insertion, she died due to malignant progression of the disease.

This case emphasizes the usefulness, feasibility and reproducibility of the single-balloon overtube-assisted technique for SEMS insertion in malignant strictures of the small intestine, especially in patients with altered anatomy such as Roux-en-Y anastomosis where conventional endoscopes cannot reach. Since the currently available enteral SEMS deployment catheters cannot be used through the working channel (2.8 or 3.2 mm) of the 200 cm long enteroscope, the SEMS is introduced over a long stiff guidewire through the balloon-anchored overtube under fluoroscopic control. This balloon-assisted overtube technique enables to relieve intestinal obstruction without surgical intervention by a combined endoscopic and fluoroscopic approach [10,11].

DISCUSSION

Malignant recurrence after (modified) Whipple's pancreatico-duodenectomy for pancreatic head adenocarcinoma remains high[4]. Sometimes, local

recurrence may lead to the afferent limb syndrome (stricture of the afferent limb) or a gastric outlet-like syndrome (stricture of the alimentary limb) because of intestinal tumor infiltration. In the case of malignant intestinal obstruction following Whipple's resection, palliative surgery is generally indicated to obtain symptom relief (resection of an intestinal segment, enterostomy or intestinal bypass)[12]. Case reports have shown that endoscopic enteral SEMS placement has become feasible, either by the creation of an EUS-guided gastrojejunostomy or by insertion of a SEMS by means of the balloon-assisted overtube technique[7-11]. We illustrated both procedures in two cases of malignant intestinal obstruction (afferent and alimentary limb obstruction) after Whipple's resection.

COMMENTS

Case characteristics

Both patients underwent Whipple's pancreatico-duodenectomy as a curative treatment of pancreatic head cancer. However, local tumor recurrence in the alimentary limb resulted in the gastric outlet syndrome (case 1) and local tumor recurrence in the afferent limb resulted in obstructive jaundice (case 2).

Clinical diagnosis

The patient with the gastric outlet syndrome presented with recurrent vomiting and weight loss (case 1). The patient with the afferent limb syndrome presented with fever, abdominal pain and jaundice.

Differential diagnosis

Vomiting may be a side-effect of chemotherapy (gemcitabine) or may be caused by peptic ulcer disease (case 1). Obstructive jaundice may be the clinical sign of a postoperative stricture at the level of the hepaticojejunostomy (case 2).

Laboratory diagnosis

The patient with the gastric outlet syndrome presented a slight increase in CA19.9 tumor marker (case 1). The patient with the afferent limb syndrome presented with elevated CRP and liver function tests (case 2).

Imaging diagnosis

Abdominal CT scan of the patient with the gastric outlet syndrome suspected peritoneal carcinomatosis (case 1). MRI-MRPC of the patient with the afferent limb syndrome suspected a postoperative stenosis at the level of the hepaticojejunostomy (case 2).

Pathological diagnosis

No histological biopsies were taken during the endoscopic ultrasound (EUS)-guided gastrojejunostomy procedure to confirm local tumor recurrence (case 1). During the first single-balloon enteroscopy biopsies were taken at the level of the afferent limb stricture, confirming the presence of a well-differentiated pancreatic adenocarcinoma (case 2).

Treatment

Both patients were treated endoscopically in a palliative setting. The first patient underwent EUS-guided gastrojejunostomy followed by chemotherapy (Oxaliplatine) (case 1). The second patient underwent self-expandable metal stent (SEMS) insertion into the afferent limb followed by chemotherapy (Gemcitabine) (case 2).

Related reports

The two endoscopic techniques presented here have been described previously under the form a case reports.

Term explanation

Whipple's resection is the surgical curative treatment for pancreatic head cancer, with resection of the pancreatic head and the duodenum and the creation of a hepaticojejunostomy and a pancreaticojejunostomy on to the afferent jejunal limb. The afferent limb syndrome is caused by an obstruction at the level of the afferent limb after Whipple's resection. The gastric outlet syndrome is caused by an obstruction at the level of the alimentary limb after Whipple's resection.

Experiences and lessons

Local tumor recurrence remains high after initial curative Whipple's pancreatico-duodenectomy for pancreatic head cancer. The clinical presentation as the gastric outlet syndrome or the afferent limb syndrome is rare. New endoscopic techniques may allow to overcome these clinical syndromes by creating an EUS-guided gastrojejunostomy or by SEMS insertion into the afferent limb.

Peer-review

This is a well-written and illustrated overview of two endoscopic techniques for the palliation of intestinal obstruction due to local tumor recurrence after Whipple's pancreatico-duodenectomy for pancreatic head cancer.

Abstract

Arterioportal shunt (APS) is an organic communication between the hepatic arterial system and the portal venous system. The APS is one of the major causes of transient hepatic attenuation differences on dynamic computed tomography (CT) or magnetic resonance imaging (MRI). This condition is usually associated with trauma, liver cirrhosis, and malignancies of the liver. However, there has been no report about oxaliplatin-induced APS. A 41-year-old male was diagnosed with Stage ⅢB gastric cancer. The patient initially underwent neoadjuvant chemotherapy with capecitabine and oxaliplatin After 3 cycles of therapy, the mass had markedly decreased, and a total gastrectomy with splenectomy was performed. Since the malignancy was locally invasive, the patient was continued on the same regimen of the adjuvant chemotherapy. After 3 more cycles, a computed tomography revealed a 1 cm sized arterial-enhancing nodule in the right lobe of the liver. An MRI revealed an arterial enhancing lesion, and a positron emission tomography CT scan showed a hypermetabolic lesion in the same portion of the liver. We tried to perform a liver biopsy; however, an ultrasonography could not detect any mass. A presumptive diagnosis of an APS due to a recurred cancer was made. We found a similar but slightly different case report of an oxaliplatin-induced liver injury, mimicking a metastatic tumor on an MRI. Based on a prior report, the patient was continued

on treatment with adjuvant chemotherapy following discontinuation of oxaliplatin. After 2 cycles, the arterial enhancing liver mass resolved, supporting the final diagnosis of an APS, related to oxaliplatin-induced sinusoidal injury. The patient has not experienced any a relapse after two years of additional follow up recurrent gastric cancer upon interpretation of multiple imaging modalities.

Core tip: Although there have been several recent reports about oxaliplatin-induced sinusoidal injury, this is first case report of a non-tumorous incidental arterioportal shunt following oxaliplatin chemotherapy. We made a presumptive diagnosis of an AP shunt mimicking a recurred gastric cancer, due to an oxaliplatin-induced transsinusoidal injury. This case is the first report of an oxaliplatin-induced incidental arterioportal shunt mimicking recurred gastric cancer on various images.

Kim HB, Park SG. Arterioportal shunt incidental to treatment with oxaliplatin that mimics recurrent gastric cancer. *World J Gastroenterol* 2017; 23(33): 6187-6193 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6187.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6187

INTRODUCTION

Transient hepatic attenuation differences (THAD) lesions indicate areas of parenchymal enhancement, visible during the hepatic artery phase on a dynamic computed tomography (CT) or magnetic resonance imaging (MRI), and are thought to be a physiological phenomenon due to the dual hepatic blood supply. The arterioportal shunt (APS) is one of the most important THAD[1,2].

APS is an organic communication between the hepatic arterial system and the portal venous system, and is caused by the redistribution of arterial flow into a focal region of the portal venous flow. This condition is associated with hepatic tumors, trauma, intervention, liver cirrhosis and metastatic tumors[2-5].

CASE REPORT

A 41-year-old Korean man was admitted with a chief complaint of epigastric pain. The patient initially underwent an endoscopy, which revealed a 4 cm sized ulcerofungating mass in the gastric cardia and CLO test (Campylobacter-like organism test; Rapid urease test) was negative. Pathologic findings revealed poorly differentiated adenocarcinoma without intestinal metaplasia and a CT scan showed a bulky ulcerative mass with direct invasion of the pancreas, and the left diaphragm. Furthermore, there were multiple perigastric and upper aortic lymph node enlargements. Based on these findings, the patient was diagnosed with Stage ⅢB gastric cancer (T4N2M0) (Figure 1A and B). He had a far advanced stage of gastric cancer; therefore, the patient underwent firstly a neoadjuvant chemotherapy with capecitabine and oxaliplatin. After 3 cycles of this therapy (#1-#3), the mass had markedly decreased and a total gastrectomy with splenectomy was performed (Figure 1C and D). Since this was a stage ⅢB gastric cancer [T4bN0 (0/48) M0], the patient was continued on the same regimen as adjuvant chemotherapy

After another 3 cycles of therapy (#4-#6), a follow-up CT demonstrated an arterial enhancing mass like lesion in the peripheral portion of the right lobe of the liver (Figure 2).

We presumed initially a new hepatocellular carcinoma or recurred gastric cancer, and we evaluated the arterial enhancing mass like lesion. He had a no history of hepatitis (hepatitis B and C) and he was social alcohol drinking. There was no proof of liver cirrhosis in CT, too. The test results showed HBsAg (-), HBsAb (+), and HCVAb (−) and tumor marker of hepatocellular carcinoma was under the normal range such as Alpha-fetoprotein (α-FP) of 2.2 ng/mL (normal; < 5 ng/mL) and protein induced by vitamin K absence-Ⅱ of 23 mAU (0–39 mAU). CEA (Carcinoembryonic antigen) and CA 19-9 (carbohydrate antigen) were under the normal range, too. Various other image studies were done. An MRI showed the arterial enhancing lesion, and a PET CT scan showed a hypermetabolic lesion in that same portion of the liver (Figures 3 and 4). We tried to perform a pathological confirmation of the lesion through a liver biopsy. However, we could not obtain the tissue because no typical mass was detected on ultrasonography.

In summary, he had a no risk of hepatocellular carcinoma and normal range of tumor markers, and there was no mass in liver. He was initially far advanced stage of gastric cancer, and he was high risk subtype of recurrence. Base on the data, we assumed it might be an arterial-portal shunt in the liver. However, this phenomenon strongly indicated a recurred mass in the liver despite of no obvious proof of recurrence such as typical mass or elevated tumor marker (CEA, CA 19-9). After reviewing literature, we found a few case report of an oxaliplatin-induced liver injury, mimicking a metastatic tumor on an image, although it was a slightly different case (mainly colon cancer and different enhance pattern)[6-10].

Therefore, we continued with the adjuvant che-

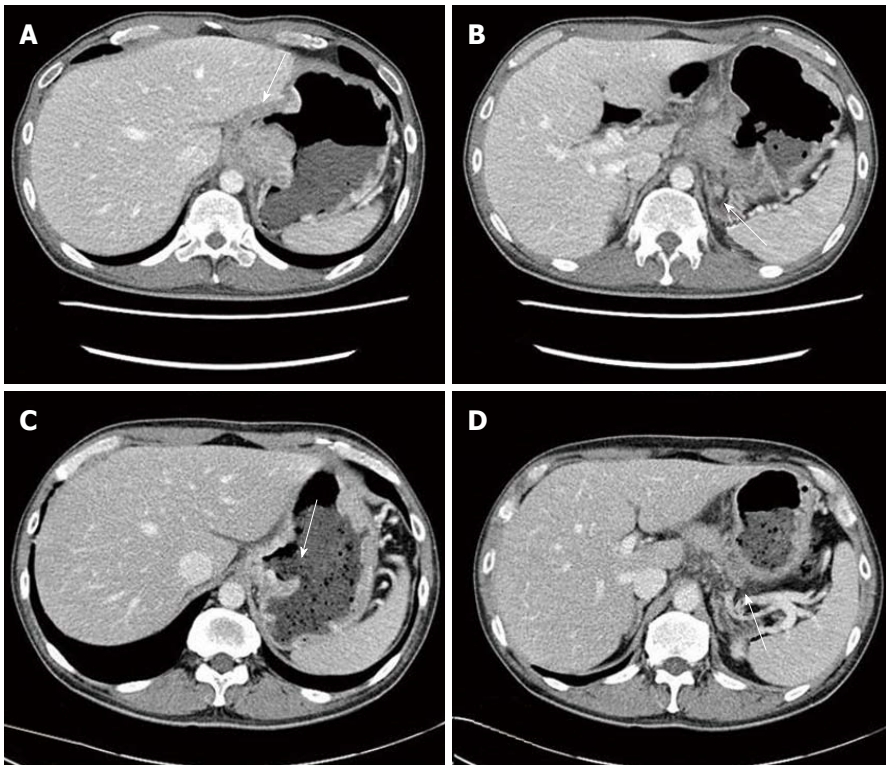

Figure 1 On admission, computed tomography revealed a bulky ulcerative mass with direct invasion of pancreas and left diaphragm (A and B). After 3 cycle of neoadjuvant chemotherapy (capecitabine and oxaliplatin), the mass had markedly decrease (C and D).

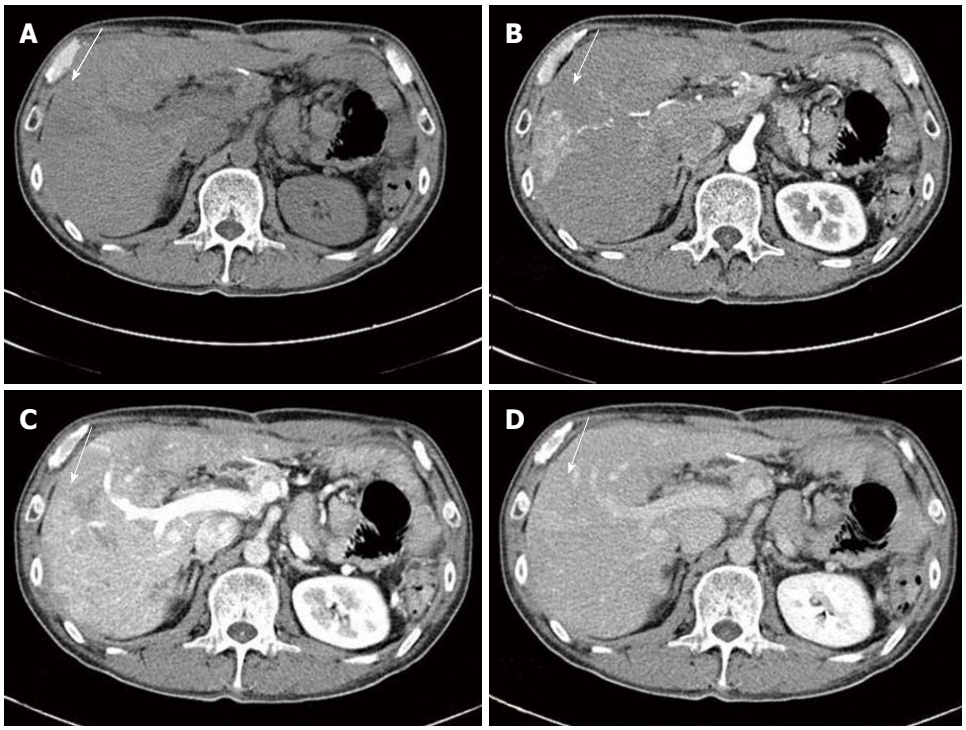

Figure 2 After total six cycle of chemotherapy (capecitabine and oxaliplatin), dynamic computed tomography showed an arterial enhanced mass like lesion. A: Pre-enhanced image; B: Arterial phase image; C: Portal phase image; D: Delayed phase image.

motherapy, this time, eliminating oxaliplatin. After 2 cycles of capecitabine monotherapy, the arterial enhancing mass in the liver disappeared (Figure 5). We were able to confirm the diagnosis of an AV shunt due to oxaliplatin-induced sinusoidal injury, the patient has not relapsed in 2 years.

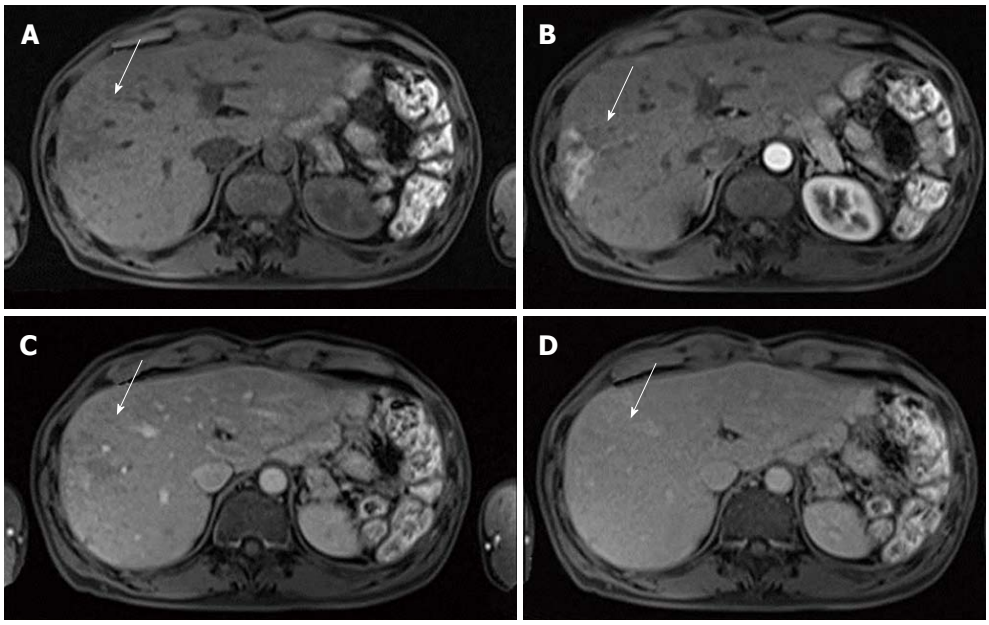

Figure 3 Dynamic magnetic resonance imaging demonstrated an arterial enhance mass like lesion as same as computed tomography scan. A: Pre-enhanced image; B: Arterial phase image; C: Portal phase image; D: delayed phase image.

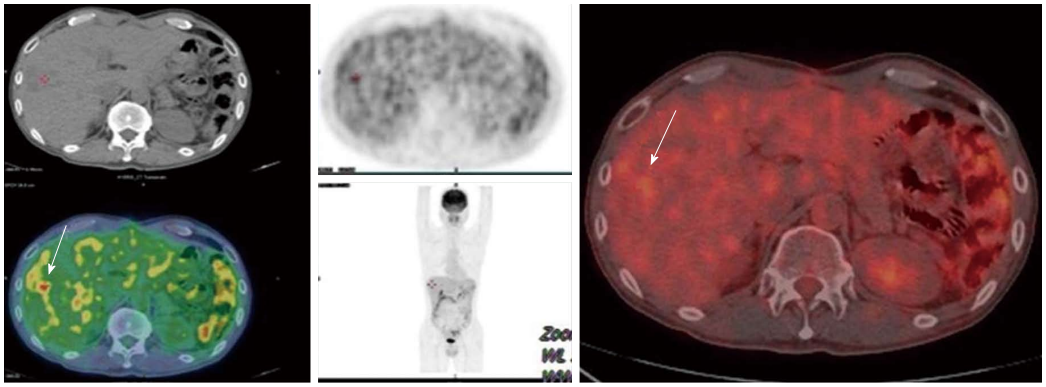

Figure 4 This arterial enhances mass like lesion had a hypermetabolism in positron emission tomography computed tomography.

DISCUSSION

A unique feature of the liver's blood supply system is its dual blood supply, which comes from the hepatic artery (25%) and the portal vein (75%). A perfusion gradient between the artery and portal vein under various conditions such as diminished blood flow through the portal vein can result in an increased attenuation or signal intensity difference during the early phases of a contrast-enhanced dynamic imaging of the liver. In most cases, this finding reflects an increased arterial blood flow, related to an APS. APSs tend to show an amorphous or nodular appearance in the peripheral portion of the liver. There are various causes of APS: hepatic neoplasms, hepatic trauma including interventional procedure, liver cirrhosis, inflammatory diseases, obstruction of the portal or hepatic vein due to various causes, external compression such as hepatic tumor (hepatocellullar carcinoma and cholangiocarcinoma, metastatic tumor, hematoma), or an internal obstruction (tumor thrombus, invasion of cancer). There are various routes, depending on each cause. These routes are transtumoral (through the tumor itself), transversal (due to portal vein tumor thrombosis), transplexal (peribiliary vascular plexus) and transsinusoidal (between microscopic hepatic arterioles and portal venules, distal to portal vein compression or thrombosis), each of which can occur alone or in combination with each other[2-5].

However, our case was an incidental arterioportal shunt, mimicking a recurred gastric cancer, on various images (dynamic CT, MRI and PET). Actually, we are uncertain about why the arterial enhancing nodule (suspected APS) spontaneously disappeared. However, our patient had no history of liver cirrhosis, intervention of liver, or liver trauma (including trauma

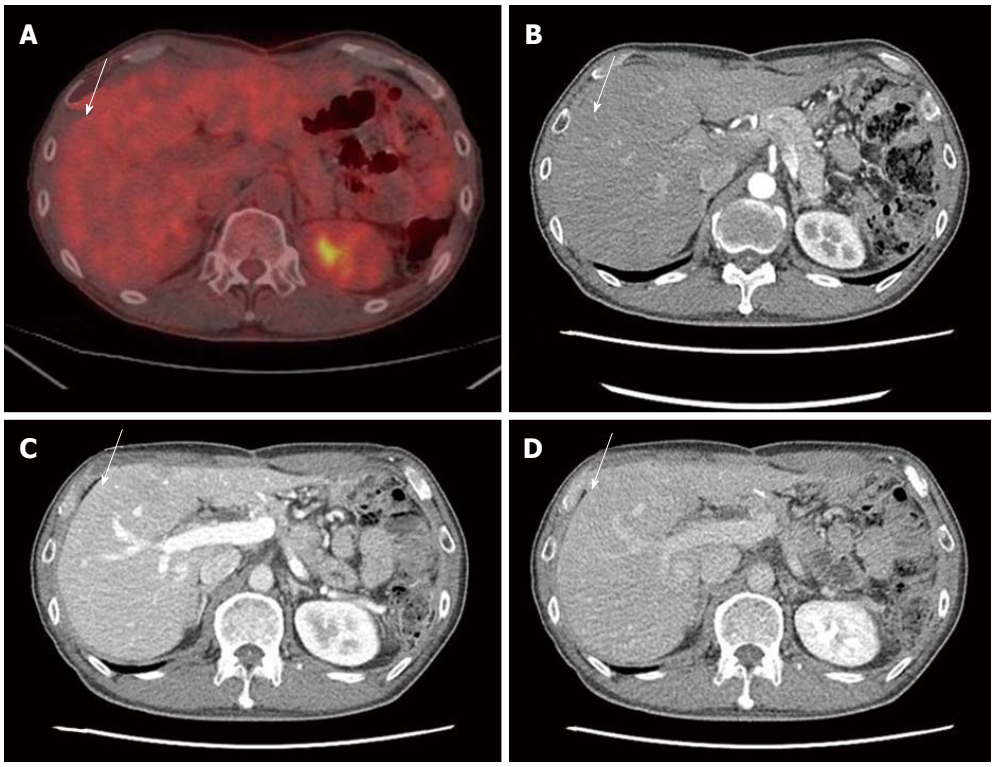

Figure 5 After adjuvant chemotherapy without oxaliplatin, the arterial enhance lesion disappeared. A: PET CT; B: Arterial phase image; C: Portal phase image; D: Delayed phase image.

from surgery of the liver). Moreover, no typical mass was picked up by the sonography.

Oxaliplatin is platinum-based, and a third generation chemotherapeutic agent, administered to patients with gastric cancer, and colorectal cancer. It has comparably less toxic side effects than that of cisplatin. However, there are increasing numbers of reports indicating that oxaliplatin-based chemotherapy could cause damage to a non-tumor-bearing liver. Several reports have confirmed the association between hepatic sinusoidal injury and oxaliplatin. Oxaliplatin-induced hepatic sinusoidal injury can range from a mild sinusoidal dilatation to a hepatic sinusoidal obstruction syndrome. Clinical manifestations vary from asymptomatic to hepatomegaly, jaundice, and ascites. The oxaliplatin sinusoidal injury lesions appeared after the administration of oxaliplatin; however, most lesions disappeared after the cessation of oxaliplatin treatment[6-10].

The incidence of hepatic sinusoidal injury ranges between 19% and 54%. A retrospective study demonstrated that approximately half the patients who received preoperative chemotherapy with oxaliplatin developed some degree of hepatic sinusoidal dilation and microscopic hemorrhage related to damage to the hepatic sinusoidal endothelial cell barrier[11,12].

Oxaliplatin-induced liver damage is characterized histologically by sinusoidal dilatation and congestion outlined by atrophic hepatocyte and/or fibrosis and venular obstruction. An immunohistochemical study of cluster of differentiation 34 revealed a decrease in sinusoidal endothelial cells in this lesion. Such an injury often increases the porosity of the sinusoidal endothelium, and increases cellular fenestrations. This led to the obstruction of the sinusoids and interruption of the portal circulation, resulting in hepatic congestion and eventually elevated portal pressures. Finally, some advanced cases of oxaliplatin-induced sinusoidal injury, have induced veno-occlusive disease, sinusoidal obstruction and portal hypertension[13-15]. Among the pathogenesis of oxaliplatin-induced sinusoidal injury, hepatic congestion due to an obstruction of the sinusoids and an interruption of portal circulation is similar to APS, through a transsinusoidal route. It is thought that oxaliplatin-induced sinusoidal obliteration of peripheral hepatic venules could lead to a retrograde filling of small portal vein branches, by way of a transsinusoidal route[2-5].

Our patient underwent splenectomy, and there might be a question that it may affect to oxaliplatin induced sinusoidal injury. However, we couldn't find the relationship between splenectomy and oxaliplatin-induced sinusoidal injury or APS, and splenectomy was rather as option of treatment of hypersplenism from oxaliplatin-induced sinusoidal injury[16].

In conclusion, although we had no established

evidence of a relationship between oxaliplatin and incidental APS, we concluded on the diagnosis because of the following reasons: Firstly, there was no reason lead to be APS such as trauma, intervention and liver cirrhosis. Secondly, the arterial enhancing lesion appeared after the administration of oxaliplatin and disappeared after the cessation of oxaliplatin. Thirdly, although no definitive mechanism exists for our case, oxaliplatin-induced sinusoidal injury has been identified, and this is enough evidence from literature, to support our case. To the best of our knowledge, this is the first case report of arterioportal shunt incidental to treatment with oxaliplatin that mimics recurrent gastric cancer upon interpretation of multiple imaging modalities.

COMMENTS

Case characteristics

After adjuvant chemotherapy with capecitabine and oxaliplatin in stage IIIb gastric cancer, a computed tomography revealed a 1 cm sized arterial-enhancing nodule in the liver.

Clinical diagnosis

The authors presumed initially a new hepatocellular carcinoma or recurred gastric cancer.

Differential diagnosis

Hepatocellular carcinoma, recurred gastric cancer, arterioportal shunt.

Laboratory diagnosis

Various tumor marker were under the normal range.

Imaging diagnosis

Various imaging including dynamic computed tomography (CT), magnetic resonance imaging, and Positron emission tomography-CT showed an arterioportal shunt.

Pathological diagnosis

The authors could not obtain the tissue because no typical mass was detected on ultrasonography.

Treatment

The patient was continued on treatment with adjuvant chemotherapy following discontinuation of oxaliplatin.

Related reports

There was no report of non-tumorous incidental Arterioportal shunt (APS) related to treatment with oxaliplatin.

Term explanation

APS is an organic communication between the hepatic arterial system and the portal venous system.

Experiences and lessons

The authors want to share this case as rare condition of arterioportal shunt due to oxaliplatin induced sinusoidal injury.

Peer-review

This is the first case report of arterioportal shunt incidental to treatment with oxaliplatin that mimics recurrent gastric cancer upon interpretation of multiple imaging modalities

Abstract

Attaran *et al*[1] have recently shown that decreased susceptibility of established *Helicobacter pylori (H. pylori)* biofilms to specific antibiotics, was associated with the overtly enhanced transcription of two efflux pump genes, *hp1165* and *hefA*, involved in specific resistance to tetracycline and multiple antibiotics, respectively. Apart from antibiotic exposure, secretion of multiple antimicrobial peptides, such as human β-defensins (hβDs), by the gastric epithelium upon *Hp* challenge, may act as early triggering events that positively impact biofilm formation and thus, antibiotic resistance. In this regard, we undertook genomic transcriptional studies using *Hp* 26695 strain following exposure to sublethal, similar to those present in the gastric niche, concentrations of hβDs in an attempt to provide preliminary data regarding possible mechanisms of immune evasion and selective sensitivity of *Hp*. Our preliminary results indicate that hβD exposure ignites a rapid response that is largely due to the activation of several, possibly interconnected transcriptional regulatory networks – origons - that ultimately coordinate cellular processes needed to maintain homeostasis and successful adaptation of the bacterium in the gastric environment. In addition, we have shown that both antibiotic and hβD resistance are mediated by dedicated periplasmic transporters, including the aforementioned efflux pump genes *hp1165* and *hefA*, involved in active export of antibiotics from the cell membrane and/or, as recently suggested, substrate sensing and signalling. Furthermore, it

appears that sublethal doses of hβDs may enhance biofilm formation by the sustained expression of, mainly, quorum sensing-related genes. In conclusion, we provide additional data regarding the role of specific innate immune molecules in antibiotic cross-resistance mechanisms that may deepen our understanding in the context of the development of novel eradication regimens.

Key words: *Helicobacter pylori*; Human β-defensins; Biofilm; Antimicrobial resistance

Core tip: In the course of *Helicobacter pylori* infection, epithelium-derived human β-defensins may act as early triggering signals that induce biofilm formation and enhanced expression of antibiotic resistance genes, regardless of prior antibiotic exposure.

Kazakos EI, Dorrell N, Polyzos SA, Deretzi G, Kountouras J. Comment on "Effect of biofilm formation by clinical isolates of *Helicobacter pylori* on the efflux-mediated resistance to commonly used antibiotics". *World J Gastroenterol* 2017; 23(33): 6194-6196 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i33/6194.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i33.6194

TO THE EDITOR

Attaran *et al*[1] concluded that, in biofilm-forming populations, overexpression of two efflux pump genes, *hp1165* and *hefA,* conferring resistance to tetracycline and multiple antibiotics respectively, may favor reduced antibiotic susceptibility of *Helicobacter pylori* (*H. pylori) in vivo*.

Further to antibiotic exposure, additional, epithelial-derived molecules may function as triggering signals during the dynamic *H. pylori* interaction with the gastric mucosa, provoking overexpression of efflux pumps that in turn, regulate the bacterium's biofilm-producing capacity and promote its virulence. Several studies have unraveled the role of constitutive and/or induced expression of human β-defensins (hβDs)1 - 4 in the bacterium's adaptation in the human stomach and *H. pylori* -related pathologies [2,3].

In this respect, we performed whole genome transcriptome analyses (competitive genomic RNA/RNA hybridisations) using *H. pylori* -specific microarrays based on the *Hp* 26695 and J99 genome sequences and annotation available at the time. Briefly, *H. pylori* 26695 strain was exposed to sublethal, similar to those encountered at the gastric epithelium concentrations of hβDs, in an attempt to identify possible mechanisms of *H. pylori* immune escape and clarify their role in biofilm development *in vitro*. Our preliminary results have identified profound changes in the transcriptional profile

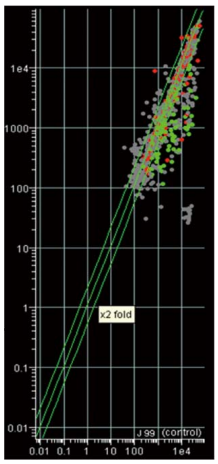

Figure 1 Representative scatter analysis of the general patterns of *H. pylori* genomic response to human β-defensin 3 (hβD3) revealed by transcriptional profiling. Scatter plots (log2 ratio) of average normalized intensities representing Cy5-red channel versus Cy3-green channel are shown for experiments in the presence of sublethal concentrations of hβD3 compared with "control" conditions (no hβD3). Differential expression of a given gene is reflected by deviation from the central diagonal line. The upper diagonal defines ⩾ 2-fold up-regulation and the lower one defines ⩾ 2-fold down-regulation.

of *H. pylori* 26695 demonstrated by the induction or suppression of multiple gene components of distinct regulatory and signaling cascades activated as a result of environmental stress (Figure 1, unpublished data). Overall, the vast majority of genes affected, encoded components of the cell wall stimulon, possibly as means to prevent hβD-specific binding and proper immune recognition, or could be further assigned to certain origons, essential for colonisation of the gastric niche and long-term adaptation, intracellular metal homeostasis and urease activation that largely determine *H. pylori* pathogenicity. Apart from the marked induction of *hp1165* and *hefA*, also reported by the authors[1], several other genes coding for transmembrane ABC transporters (*glnP, dppF, hp1458, hp1486*), efflux proteins (*hp0656, hp0946*), multidrug and toxic extrusion proteins were found to be significantly up-regulated, thereby indicating their prominent role in the cellular response to hβDs challenge, membrane detoxification and maintenance of osmotic balance.

Interestingly, enhanced biofilm production by *Hp* 26695, observed in our studies upon exposure to sublethal concentrations of hβD1 and hβD3, was primarily attributed to the down-regulation of *metK* and *luxS* genes, involved in synthesis of quorum-sensing autoinducer-2, in accordance to previously published data[4,5].

Collectively, our results indicate that sublethal doses of epithelial-secreted antimicrobial peptides such as hβDs, may select co-resistance to antibiotics commonly used in *Hp* eradication therapies and *vice versa*, considering that they provoke the activation of shared, contact-dependent signaling networks, including efflux pumps. Furthermore, it appears that hβDs may independently act as triggering stimuli

promoting biofilm formation *in vivo* which in turn, accounts, at least partly, for the observed failure of eradication regimens and the establishment of *H. pylori* -related chronic inflammation.

Given the complexity of *H. pylori* -host epithelial crosstalk aforementioned data warrant further investigation to achieve the development of successful anti-biofilm strategies that will ultimately re-enforce our therapeutic options mainly towards eradication of *H. pylori* -related resistance. Furthermore, future research focus on the polymorphic variability of the human genome that directly affects epithelial dynamics of hβDs expression may reveal important correlation patterns between *H. pylori* pathogenesis, including biofilm formation, and individual disease susceptibility.

ABOUT COVER

Editorial board member of *World Journal of Gastroenterology*, Gabriele Grassi, MD, PhD, Associate Professor, Department of Life Sciences, University Hospital of Cattinara, 34149 Trieste, Italy

AIMS AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7th, 14th, 21st, and 28th each month. The *WJG* Editorial Board consists of 1375 experts in gastroenterology and hepatology from 68 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

INDEXING/ABSTRACTING

World Journal of Gastroenterology (*WJG*) is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central and Directory of Open Access Journals. The 2017 edition of Journal Citation Reports® cites the 2016 impact factor for *WJG* as 3.365 (5-year impact factor: 3.176), ranking *WJG* as 29th among 79 journals in gastroenterology and hepatology (quartile in category Q2).

Abstract

Perianal fistulas can occur to up to one-third of patients with Crohn's disease (CD) leading to significant disabling disease and morbidity. Fistulising perianal CD treatment often necessitates a combined pharmacological and surgical approach. Anti-tumor necrosis factor (anti-TNF) therapy, particularly infliximab, has been shown to be very effective for both perianal and internal fistulising CD. Nevertheless, current data suggest that sustained remission and long-term complete fistula healing can be achieved in only 30% to 50% of patients. Moreover, these percentages refer mostly to clinical rather than deep remission, defined as endoscopic and radiologic remission, which is quickly emerging as the preferred goal of therapy. Unfortunately, the therapeutic options for perianal fistulising CD are still limited. As such, it would be of great value to be able to predict, and more importantly, prevent treatment failure in these patients by early and continued optimization of anti-TNF therapy. Similar to ulcerative colitis and luminal CD, recent data demonstrate that higher infliximab concentrations are associated with better clinical outcomes in patients with perianal fistulising CD. This suggests that therapeutic drug monitoring and a treat-to-trough therapeutic approach may emerge as the new standard of care for optimizing anti-TNF therapy in patients with perianal fistulising CD.

Key words: Inflammatory bowel disease; Infliximab; Adalimumab; Magnetic resonance imaging; Drug monitoring; Fistula healing

Core tip: Defining and predicting deep remission is important to guide the management of patients with perianal fistulizing Crohn's disease (CD). Deep remission, defined as complete fistula healing based on objective endoscopic and radiologic findings, should be the goal of care in the treatment of patients with perianal CD. Currently, anti-tumor necrosis factor (anti-TNF) are the standard of care for perianal CD, but long-term outcomes are disappointing. Data suggests that higher infliximab concentrations are associated with better clinical outcomes in patients with perianal fistulising CD and thus therapeutic drug monitoring may be a valid therapeutic strategy for optimizing anti-TNF therapy towards improved objective outcomes and deep remission.

Papamichael K, Cheifetz AS. Defining and predicting deep remission in patients with perianal fistulizing Crohn's disease on anti-tumor necrosis factor therapy. *World J Gastroenterol* 2017; 23(34): 6197-6200 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6197.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6197

INTRODUCTION

Perianal fistulas can develop to up to one-third of patients with Crohn's disease (CD) leading to disabling disease, morbidity, and a significant impairment in quality of life[1]. The treatment of fistulising perianal CD is not simple and often requires a multidisciplinary approach of both pharmacological and surgical therapy especially for complex perianal fistulae[2]. Anti-tumor necrosis factor (anti-TNF) therapy has revolutionized the treatment of both perianal and internal fistulising CD[3-18]. Nevertheless, therapeutic outcomes from randomised controlled trials (RCTs), post-hoc analyses of RCTs and real-life prospective or retrospective studies show that long-term remission can be achieved in only 30%-50% of patients (Table 1). Moreover, these percentages refer mostly to clinical remission, based on symptoms and physician global assessment (PGA), and not to objective endoscopic and/or radiological healing. At this time, the preferred goal of treatment should be deep remission, or the combination of clinical and the more objective measures, including radiologic and endoscopic healing. As therapeutic options for perianal fistulising CD are still limited it is very important to attempt to predict and subsequently prevent treatment failure in these patients. Preliminary data demonstrate that higher infliximab concentrations are associated with improved clinical outcomes in patients with perianal fistulising CD, suggesting that therapeutic drug monitoring (TDM) and a treat-to-trough approach is likely a valid therapeutic strategy for optimizing anti-TNF therapy in these patients[19,20].

Defining deep remission

Most studies typically use clinical remission, defined as absence of any draining fistulas based on PGA and patients' reports, as a therapeutic endpoint for perianal fistulising CD[3-18]. Nevertheless, deep remission, defined as mucosal and/or radiological healing of fistulas, is likely a more appropriate goal of therapy for perianal fistulising CD. T2-weighted magnetic resonance imaging (MRI) with fat-suppression is considered the gold-standard for fistula imaging and an MRI-based score is currently available for defining disease activity, although it is still not widely used in clinical practice[1]. Thomassin *et al*[11] have recently showed that deep remission, defined as a composite clinical (absence of any draining fistulas and self-reported drainage episodes by the patient at two successive evaluations), endoscopic (absence of ulcers in the anal canal) and radiological (absence of T2 hyperintensity and contrast enhancement on MRI) remission, was achieved in approximately one-third of patients with perianal fistulizing CD[11].

Predicting deep remission

As new drugs for the treatment of perianal fistulising CD are still awaited, it is important to be able to predict who will achieve deep remission and who will not respond adequately to typical anti-TNF dosing and will require early (and continued) optimization[1,2]. Although several variables have been associated with improved outcomes (Table 2), prediction of deep remission remains a challenge. Thomassin *et al*[11] have recently identified absence of rectal involvement on MRI (OR = 4.6; 95%CI: 1.03-20.5) as the only variable associated with deep remission in patients with perianal fistulizing CD[11]. Similar to ulcerative colitis and luminal CD[19-25], recent data demonstrate that higher infliximab concentrations are associated with better clinical outcomes in patients with perianal fistulising CD[26,27]. Regarding maintenance therapy Yarur *et al*[26] recently showed that infliximab trough concentrations $\geqslant$ 10.1 μg/mL are associated with fistula healing and based on quartile analyses proposed that physicians should aim for even higher concentrations (> 20.2 μg/mL) before giving up and moving on to alternative therapies with a different mechanism of action.

CONCLUSION

Deep remission defined as a composite clinical, endoscopic and radiological remission should really be considered the goal of therapy in patients with perianal fistulizing CD. TDM may be a valid therapeutic strategy for optimising anti-TNF therapy, improving therapeutic outcomes, and moving towards more personalized medical care.

Table 1 Long-term outcomes of patients with perianal fistulizing Crohn's disease on anti-tumor necrosis factor maintenance therapy

Type of anti-TNF therapy	*n*	Complex fistulas, %	Follow up, wk	Therapeutic outcome of interest	Therapeutic outcome, %	Ref.

[1]Median; [2]Mean. CDAI: Crohn's disease activity index; TNF: Tumor necrosis factor; ADM: Adalimumab; IFX: Infliximab; CZP: Certolizumab pegol; RCT: Randomized controlled trial; PGA: Physician global assessment; ND: Not defined; FDAI: Fistula drainage assessment index; MRI: Magnetic resonance imaging.

Table 2 Variables associated with improved therapeutic outcomes of anti-tumor necrosis factor maintenance therapy in patients with perianal fistulizing Crohn's disease

Variables	Ref.
Clinical or phenotypic	
Ileocolonic disease	[6]
Concomitant immunosuppressants	[6]
Duration of seton drainage (< 34 wk)	[6]
Duration of infliximab treatment (> 118 wk)	[6]
Number of infliximab infusions (> 19)	[6]
Absence of complex fistulas	[14]
Male gender	[26]
Absence of switch of anti-TNF therapy	[11]
Imaging	
Absence of persisting fistulas on MRI	[5]
Absence of collections at baseline on MRI	[5]
Absence of rectal wall involvement on MRI	[5]
Absence of single-branched fistulas on MRI	[5]
Absence of rectal involvement on MRI	[11]
Serologic	
Infliximab (maintenance) trough concentrations ⩾ 10.1 μg/mL	[26]
Endoscopic	
Absence of active proctitis	[11]

TNF: Tumor necrosis factor; MRI: Magnetic resonance imaging.

Abstract

Double balloon enteroscopy (DBE) is an endoscopic technique broadly used to diagnose and treat small bowel diseases. Among the associated complications of the oral DBE, post-procedure pancreatitis has taken the most attention due to its gravity and the thought that it might be associated to the technique itself and anatomical features of the pancreas. However, as the etiology has not been clarified yet, this paper aims to review the published literature and adds new results from a porcine animal model. Biochemical markers, histological sections and the vascular perfusion of the pancreas were monitored in the pig during DBE practice. A reduced perfusion of the pancreas and bowel, the presence of defined hypoxic areas and disseminated necrotic zones were found in the pancreatic tissue of pigs. All these evidences contribute to support a vascular distress as the most likely etiology of the post-DBE pancreatitis.

INTRODUCTION

Double balloon enteroscopy (DBE) is an endoscopic technique for diagnosis and treatment of small bowel diseases[1]. This variety of deep enteroscopy allows a complete exploration of the small bowel by alternatively combining the inflation and deflation of two balloons placed at the tip of the tube and the overtube following a precise sequence of push and pull manoeuvres, which allow the endoscope to progress deep into the small bowel[2]. DBE is not only exploratory but also a therapeutic technique which after more than fifteen years has even been considered as the "gold standard" technique for the endoscopic exploration of the small bowel. Furthermore, the combination of the endoscopic capsule and DBE has been highlighted as the most effective tool for diagnosis and treatment of diseases affecting the small bowel[3]. This was openly stated in the "guideline" published by the ESGE in 2008[4,5] and has also been largely reported in the scientific literature. However, as in any other endoscopic technique complications can appear, and among them post-procedure pancreatitis (post-DBE) is within the most severe.

There is a large series of studies describing direct and indirect complications associated to DBE[6]. In a multicentric study involving 10 endoscopy units from four different continents[7], a total of 40 complications from a total of 2362 DBE were reported (1.7%). This number is within the range of complication currently associated to the therapeutic conventional endoscopy techniques. Concerning the post-DBE pancreatitis several case-series published in Europe[8,9], Asia[7,10,11] and United States[12] refer figures as low as 0.3%, and in the opposite, as high as 3%[13-15] or even 12.5%[16]. Overall, in a recent paper, Kopacova reported a historic accumulation of more than 100 post-DBE pancreatitis already published[17].

According to the international consensus of classification of acute pancreatitis[18,19], the diagnosis requires two of the following three items: (1) abdominal pain consistent with acute pancreatitis; (2) serum lipase activity or amylase activity at least three times greater than the upper limit of normal; and (3) characteristic findings of acute pancreatitis on contrast-enhanced computed tomography (CT) and less commonly magnetic resonance imaging (MRI) or transabdominal ultrasonography. In clinical practice suspicion of post-DBE pancreatitis must always be ruled out before patients are delivered home. Severe pancreatitis is not difficult to recognize, however the mild form may be a problem. Mild acute pancreatitis is characterized by the absence of organ failure and the absence of local or systemic complications. Patients with subclinical mild acute pancreatitis are usually discharged during the early phase and usually do not require pancreatic imaging, and mortality is very rare. Besides many of mild pancreatitis could be missed in patients with DBE performed on an outpatient basis[17]. It is unknown how many patients with self-controlled abdominal pain have been able to have mild acute pancreatitis post-DBE[17]. This circumstance of lack of patient follow-up suggests to some authors a generalized underestimation of the number of post-DBE pancreatitis[13].

Increased levels of one or more of the pancreatic serum markers is very common after oral DBE[16,20,21]. Thus, amylase concentration below the double of the basal levels has been found in 39%[15], 46%[21] or even 58%[20] of oral DBE at 24 h of procedure. Hyperlipasemia has been described from as soon as 4 h[16,17,20,22], to up 12 h[16] or 24 h[16,17,20] after DBE. Also, in patients where pancreatic disease was diagnosed lipase levels remained increased even after amylase returned to normal figures[23]. The C-reactive protein (CRP) can also be related to either non-specific inflammation of the bowel mucosa or pancreatic inflammation, thus its diagnostic significance very much depends on the concomitant appearance of increased levels of amylase and/or lipase[14,16]. Regarding the evolution of these three serum markers, in a recent study, we determined pre- and post-procedure (4 h) levels of amylase, lipase and CRP in a series of 55 randomly selected patients for oral DBE (non-published data). Results in demonstrate a significant increase of the three markers after 4h of DBE. Contrastingly, neither the age, sex, geographical origin, insertion depth and duration of the procedure, nor the type of procedure (diagnostic *vs* therapeutic) showed any significant correlation with the levels of the pancreatic markers.

Up to here, the most common evidences for suspicion and diagnosis of the oral post-DBE pancreatitis have been summarized. However, despite more than 15 years of worldwide DBE practice the ethiopathogenesis of the post-DBE pancreatitis is not yet completely clarified. A shared belief in the literature is that the cause of this grave complication is associated to the technique itself[14,20,21,24,25]. Thus, a combination of different circumstances such as mechanical stress by the instruments (balloons, mainly) or the push

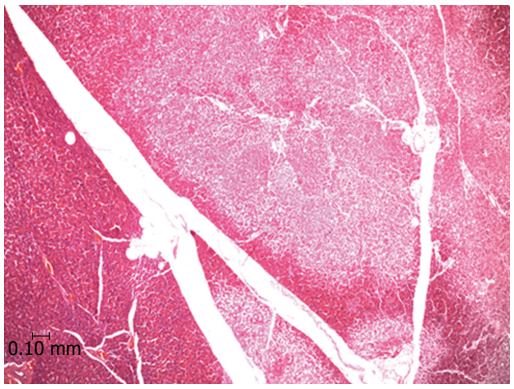

Figure 1 Light microscopy image of the porcine pancreas after double-balloon enteroscopy showing located ischemic necrosis in pancreatic interlobular tissue.

and pull manoeuvres, anatomical features of the pancreas and its vascularization, and undetermined conditions of the patient could be implicated in each case[2,10,20,24-26]. Nevertheless, up to three different hypotheses have been formulated. One refers to a reduced blood perfusion of the pancreas and the bowel (vascular etiology)[14,24,27], another to obstruction of the duodenal papilla by mechanical pressure or damage (papilla injury etiology)[13,15,16,21,25,28-30], and the third one to potential pancreatic reflux due to increased intraluminal pressure within the small bowel (reflux etiology)[24,31]. To better understanding the problem in the last decade we have carried out several of experiments in porcine model[32-39] where oral DBE were systematically monitored. Although the porcine model was previously used both *ex vivo* and *in vivo* for DBE training and to increase the security conditions in translational studies[2,35,36], no previous *in vivo* studies were directly aimed at finding out the etiology of the post-DBE pancreatitis. In the present work, we are summarizing our findings[33,34,39], with addition of some unpublished results, and reviewing the related literature in order to gather substantial evidences supporting the vascular etiology as the most likely explanation for the potential appearance of pancreatitis after oral DBE.

VASCULAR ETIOLOGY: REDUCED PANCREATIC AND INTESTINAL PERFUSION DURING DBE BY ORAL APPROACH

A broad number of scientific studies have suggested this cause[14,24,27]. This hypothesis establishes that during DBE the continuous repetition of push and pull manoeuvres progressively recoils the root of the mesentery such that the vascularization supplying the pancreas and the first portion of the small bowel is significantly reduced[14,24,27]. The increasing ischemia causes different degrees of cellular damage and a reactive condition leading to subclinical or occasionally clinical pancreatitis after the procedure. Also, the potential compression of the pancreas and its vascularization against the vertebral spine during the exploration may intensify the damage to this organ and increase the risk of inflammation[26]. The tail and body of the pancreas are the portions less mobile and more susceptible to such an ischemic and mechanical stress, which may explain why these portions are the most frequently affected in many cases of clinically diagnosed post-DBE pancreatitis[20,21,25,40].

Evidences of structural disorders and hypoxia in the pancreas

In an experiment set up already published oral DBE were performed in Large White pigs[33]. Serum levels of pancreatic markers (amylase, lipase and CRP) were monitored before, during and after (24 h and 7 d) the procedure, which lasted for either 90 (n = 10) or 140 min (n = 10). In order to avoid any pressure over the duodenal papilla the balloons were never inflated until the Treitz ligament was reached. Amylase, lipase and CRP levels at 24 h post-DBE were significantly increased, however none of the pigs showed any clinical symptom of pancreatitis after the procedure. Besides, no association between the serum markers and the duration of the procedure or the total explored distance was found. Seven days post-DBE the pigs were euthanized and the pancreases removed and processed for histopathological study. A remarkable result was that 47.4% of the animals showed pancreatic lesions which consisted in disseminated focal areas of ischemic type tissue necrosis with inflammatory cell infiltration around the necrotic foci. There was a lack of dilation of the pancreatic ducts. The lesions mainly affected the exocrine component and always affected the tail of the pancreas (Figure 1). The pancreatic tail (left lobe in pigs) was preferentially damaged because it is the portion with the most limited blood supply. In pigs, it is supplied by a single artery, which is a branch of the splenic artery, and a similar situation is found in humans where the main artery of the tail of the pancreas is the major pancreatic artery[41]. Such anatomical particularity predisposes the left pancreatic lobe to suffer from hypoxia or even ischemia if blood supply is mechanically restricted. It is interesting to highlight that CT has revealed that human pancreatitis is predominantly located in the tail of pancreas[14,40,42]. This preferential location of the histopathological lesions and the lack of clinical symptoms in spite of substantial elevations of serological markers is a clue to assume a similar etiopathogeny for the appearance of the lesions in the pigs and humans[15,26].

To further investigate whether a pancreatic ischemia during DBE was in the origin of the histopathological findings immunohistochemistry of hypoxia markers was carried out. The vascular endothelial growth factor

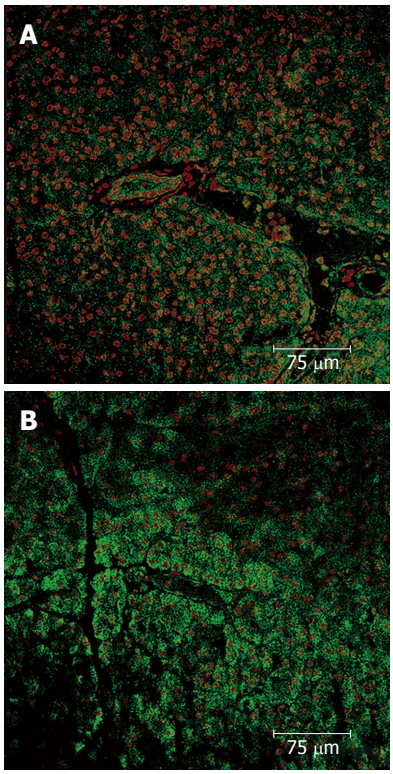

Figure 2 Pancreas immunohistochemistry. A: Expression of the VEGF in a normal parenchyma; B: Pancreatic acini with normal structure and nuclei, which express VEGF. In upper right corner a ischemic zone where less VEGF expression is shown, the pancreatic acini structure has been lost and nuclei are pyknotic. VEGF: Vascular endothelial growth factor.

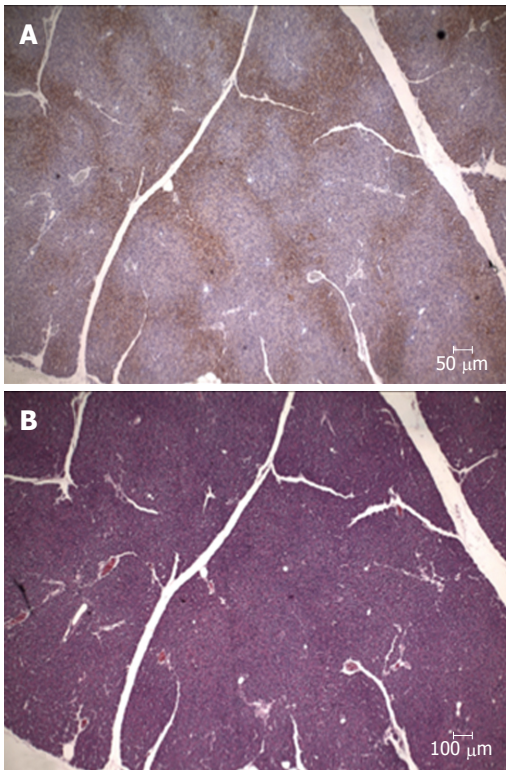

Figure 3 Pancreas immunohistochemistry. A: Expression of the pimonidazole hydrochloride (Hypoxyprobe®) presence of focal areas positively stained; B: Serial section stained with hematoxyline-eosine.

(VEGF) is an endogenous factor involved in vascular permeation and angiogenesis which may be over expressed when blood supply is reduced[43]. In the endocrine component of the pancreas an increased expression of VEGF has been observed in experimental situations reproducing a hypoxic scenario[44-46]. Likewise, in the pancreases of our pigs (same animals of the previous experiment) a positive immunostaining for VEGF was observed in both the endocrine and exocrine components. No VEGF expression was found in the control group while in the experimental group there were areas where VEGF was not expressed alongside others where it was highly expressed. In the necrotic areas low or nule VEGF expression was observed, as corresponds to areas with damaged cells. Around these necrotic areas however high VEGF expression was found, which correspond to a reactive expression due to ischemia. Overall the highest expression of VEGF was in the tail and body of the pancreas (Figure 2).

Complementarily, the exogenous marker pimonidazole hydrochloride (Hypoxyprobe®) was used in another set of pigs (non-published results). This compound is a derivative of the 2-nitroimidazole, which forms irreversible adducts with thiol groups in proteins, peptides and amino acids in tissues with oxygen tension of below 10 mmHg[47]. This exogenous marker has been largely tested in animal models and humans for immunodetection of hypoxic tissues harvested from both normal organs and malignant tumors[48,49]. In our experiment Hypoxyprobe® was administered endovenously to 5 anaesthetized Large White pigs (70-90 kg). Then, an oral DBE was performed for 60 min, and after euthanasia, the presence of hypoxic areas in the pancreas assessed by immunostaining. Results demonstrated the presence of focal areas positively stained for pimonidazole adducts (Figure 3), which was an unequivocal demonstration of pancreatic hypoxia (proof of concept). Like in the previous experiment the hypoxic areas were preferentially located (more abundant and wider) in the tail of the pancreas, and affected the exocrine and endocrine components. Although pancreatic hypoxia associated to oral DBE was conceptually demonstrated in this study, it could not be concluded that the direct cause of the hypoxia suffered by the pancreas was DBE. In theory, the presence of pimonidazole adducts could either be a consequence of reduced blood flow or increased oxygen demands by the pancreatic tissue[49], thus further studies were needed to directly assess if a reduced perfusion of the pancreas do really exist during oral DBE.

Evidences for reduced perfusion of the pancreas in the oral DBE

Blood flow to the human and porcine pancreas is primarily supplied by the celiac and superior mesenteric

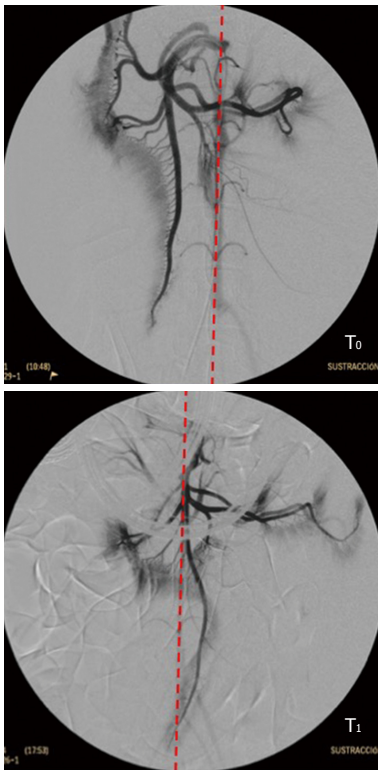

Figure 4 Selective angiogram of the cranial mesenteric artery. T_0: Before the DBE; T_1: With the endoscope inserted at maximum during DBE. Red line shows the aorta topography. DBE: Double balloon enteroscopy.

arteries. These two main vessels supply the head and body of the pancreas by a vascular arcade resulting from anastomosis of the cranial and caudal pancreaticoduodenal arteries. The left pancreatic lobe, as mentioned above, is supplied by a single, terminal, and constant major pancreatic artery which arises from the first portion of the splenic artery, a branch of the celiac artery[41,50-52].

To assess whether a reduced perfusion of the pancreas is associated with the oral DBE two experiments were designed in porcine model. In a former study[39] an endovascular approach under fluoroscopic guidance was carried out in 10 Large White pigs of 45-50 kg. The femoral artery was approached and after selective catheterization angiographies of the superior mesenteric and celiac arteries obtained (time T_0). Then, conventional oral DBE was performed for 90 min, and at the end of procedure, with the endoscope inserted at maximum depth the angiographic study was repeated (time T_1). During the procedure continuous estimation of the explored distance was done[35], but to avoid potential interference of the vascular catheterization neither serum markers of pancreatitis nor histopathological study were done. At T_0, the cranial mesenteric vascular axis was located mainly to the right of the spine, in its usual anatomical position, but at T_1 it was completely to the left (Figure 4), which was related with the intestinal folding and the pull-and-push manoeuvres. Besides, at T_1 a lack of vascular repletion was seen in the caudal pancreaticoduodenal artery. There was a reduction in the level of opacification of the branches of the cranial mesenteric artery addressed to the pancreas and bowel. As revealed by the injected contrast the perfusion of the jejunal arteries, the network of straight arteries, and the capillary network in the antimesenteric border of the small intestine was significantly reduced. With regards to the selective angiography of the celiac trunk, differences between T_0 and T_1 were also relevant. As it was common in all the experiments, none of the animals presented signs of post-DBE pancreatitis. The study described was most surely the only angiographic evaluation of the pancreas and small bowel carried out simultaneously to DBE. The results give radiological evidences of a reduced perfusion to these organs and agree with the recommendation of handling the overtube gently during the push-and-pull manoeuvres to avoid excessive restrain of the mesentery and the traction force on the pancreas[27].

A step further in the evaluation of the vascularization of the pancreas during DBE was achieved in a second experiment (non-published results). The similar and genuine vascular pattern of the tail of the pancreas in pigs and humans supplied by a major pancreatic artery from the splenic artery, lead us to design an endovascular super-selective approach to this vessel at the end of an oral DBE. 5 pigs (40-50 kg) were anaesthetised and, first of all, a CT angiogram (Philips Brillance CT-6) with vascular 3D reconstruction obtained from each animal so as to monitor his individual vascular anatomy before angiographic procedure (Figure 5). The images displayed the whole pattern of ramifications of the celiac artery, the pancreatic branch for the tail of pancreas included. Then, an oral DBE was currently done for 60 min, and by the end of procedure, when the endoscope was inserted at the maximum depth, a super-selective angiography of the major pancreatic artery achieved. In brief, this was the followed protocol. Under fluoroscopic guidance (BV-300; Philips, Best, the Nertherlands), a 0.035- inch hydrophilic guide wire (Radifocus guidewire, Terumo, Tokyo, Japan) and a 5-French cobra catheter (Radiofocus Cobra Small; Terumo, Tokyo, Japan) were selectively addressed towards the celiac artery. Celiac arteriograms clearly depicted the vascular anatomy of the hepatic and splenic arteries and their branches. By road-map guidance, the cobra catheter was selectively positioned and wedged into the major pancreatic artery. The super-selective angiography of this artery was conducted by manual injection of 3-5 mL contrast medium to ensure that the tip of the catheter was at the desired site[53]. The nuclear dye Hoechst (Bizbenzimida H 33258 fluorochrome) was injected through that vessel to allow its contact with the cells in the tail of the pancreas (Figure 5). Hoechst is a membrane-permeable, adenine-thymine specific fluorescent dye useful for *in vivo* staining of DNA. It

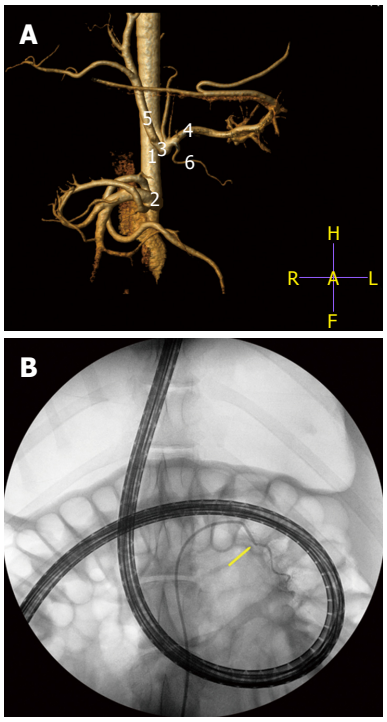

Figure 5 Computed tomography angiogram (A) with vascular 3D reconstruction to monitor his individual vascular anatomy (1) abdominal aorta; (2) cranial mesenteric artery; (3) celiac artery; (4) splenic artery; (5) hepatic artery; and (6) major pancreatic artery. B: Super-selective angiography of the major pancreatic artery (arrow) with the endoscope inserted at maximum during DBE. The nuclear dye Hoechst (Bizbenzimida H 33258 fluorochrome) is injected through that vessel to allow its contact with the cells in the tail of the pancreas. DBE: Double balloon enteroscopy.

has been proved very useful as a marker of tumour cells and to assess the vascular supply to tumours[54-56] as well as vascular perfusion[57] and hypoxia[58]. After euthanasia the pancreases were collected, the tail trimmed in 1 cm × 1 cm × 1 cm blocks, which were identified by zone and frozen in liquid nitrogen. Criosections (10 μm thick) were obtained and stained with the nuclear marker TO-PRO®3 iodide (Molecular Probes) at a dilution of 1:100 in PBS. To-Pro3 was used as a control dye of the whole cellular population in the tissue sections. Fluorescence microscopy was used to evaluate the nuclear DNA staining with the two dyes.

The quantification of staining for both dyes in a digital analyser allowed to directly asses potential changes in the perfusion of the tail of pancreas during DBE (Figure 6). In average, from the total number of nuclei (To-Pro staining) only 35% of them were Hoechst positive. Moreover, the sequenced study in proximo-distal and latero-medial direction of the tail of the pancreas allowed to identify the proximo-lateral portion as the one with the lowest level of Hoechst staining (25%) and the disto-medial portion the one with the highest level (42%). The other two portions, proximo-medial and disto-lateral, showed a 35% and 38% of positive Hoechst cells, respectively. According to these results, a positive gradient in proximo-distal direction was observed in terms of potential blood supply to the tail of the pancreas during oral DBE.

These conclusive results, which directly associated the oral DBE with a reduced vascular supply to the tail of the pancreas, together with all the previous evidences give consistent clues to support the vascular etiology as a likely cause of post-DBE pancreatic inflammation in the porcine model. The anatomical similarities between the human and porcine pancreas supports a translation of results which may help to better understand the pathogeny and clinics of post-DBE pancreatic disorders.

OCCLUSIVE ETIOLOGY: MANIPULATION AND OCCLUSION OF THE DUODENAL PAPILLA

The potential occlusion of the duodenal papilla by the balloons during oral DBE is a risk largely mentioned in the literature[13,15,16,21,25,28-30]. Evidences of pancreatic disorders during Endoscopic Retrograde Cholangio-pancreatography (ERCP) practice are conclusive. For this reason, there is a recommendation of avoiding the inflation of the balloons in the pancreato-biliar area until the Treitz ligament has been reached[16,31,36]. However, awareness of this anatomical landmark by the endoscopist is not always guaranteed[14], especially during the learning curve of DBE. Some studies have related the increase of amylase and lipase levels after DBE with the distance of the first balloon inflation from the Treitz ligament[14,16,59,60]. The longer the distance the lower the figures of the serum markers. Nevertheless, a correspondence between this trend and the incidence of persistent hyperamylasemia or pancreatitis has not been concluded[9].

In the experimental field, we used a porcine model to demonstrate if the direct contact of the inflated balloons with the duodenal papilla was responsible for significant and persistent changes in the serum markers as well as the appearance of structural disorders in the pancreatic tissue[34]. The results were conclusive. The longer the contact of the inflated overtube's balloon with the papilla the higher the levels of amylase (up to 22.7% increase), lipase (up to 7.5 times higher) and CRP (up to 6.3 times higher). Contrastingly, in the DBE control group, where the balloons were inflated after the ligament of Treitz, the serum markers did not increase more than two times the baseline.

Moreover, in those pigs where the overtube's balloon was inflated and kept around the duodenal papilla the histopathological study showed moderate to severe acinar vacuolization, oedema and even necrosis. The histopathological pattern resembled the structural disorders currently found in experimental studies of pancreatitis caused by forced obstruction of the pancreatic duct[61,62]. On the other hand, it has been described that slight vacuolization and/or oedema are reversible if the cause of obstruction disappears, which is compatible with a complete functional and

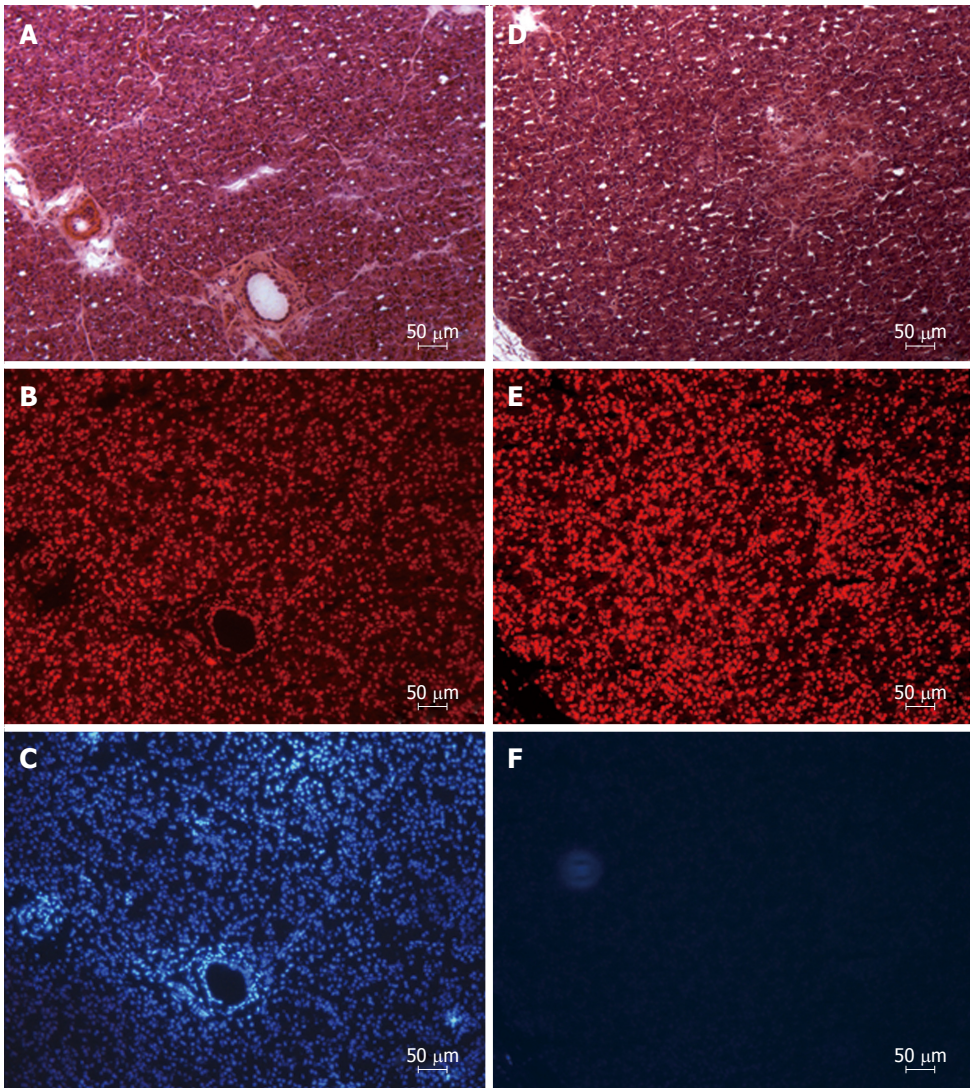

Figure 6 Fluorescence microscopy image of cryosections from left lobe of the pancreas showing distribution of endocrine and exocrine cells with nuclei stained in disto-medial (A-C) and proximo-lateral (D-F) portions. A and D: Serial sections stained with hematoxyline-eosine; B-E: Serial sections stained with the nuclear marker TO-PRO®3 iodide; C and F: Serial sections showing the location the nuclear dye Hoechst (Bizbenzimida H 33258 fluorochrome).

structural recovery of the pancreas[63]. This could explain the absence of symptoms of pancreatitis in any of the pigs despite the persistent contact of the balloon with the duodenal papilla.

These results in animal model clearly support the theory that avoiding contact with the duodenal papilla during DBE insertion decreases the risk of iatrogenic lesions in the pancreas[14,16,59,60]. However, even when the pancreato-biliar area is avoided hyperamylasemia and symptoms of pancreatitis can still appear after DBE. Therefore, avoiding the obstructive picture does not seems to be the only solution, although it reduces the risk of post-DBE pancreatitis[2,33].

THE REFLUX ETIOLOGY

This hypothesis is based on the fact that the endoluminal pressure within the small bowel and particularly, around the pancreato-biliar area rises while DBE progresses. The increased pressure within the duodenal lumen leads to reduced drainage, retrograde circulation or even reflux of the pancreatic secretion[25,31], which cause a severe pancreatic lesion[24]. Accordingly, the pancreatic structural disorders and correspondent inflammation are expected to affect the whole organ in a diffuse pattern. However, that is not the case of the post-DBE pancreatitis, as revealed by imaging diagnosis and histopathology, where the pancreatic affection is preferentially located in the tail of the pancreas in both human[7,13,14,40,42] and porcine models[33]. In addition, no significant dilatation of pancreatic ducts is currently found. Thus, rather than a primary cause of post-DBE pancreatitis this etiology should be considered as secondary or occasional. So, it seems difficult that the etiopathogeny of post-EDB pancreatitis is mainly due to a duodenal reflux mechanism[2].

ADDITIONAL RISK FACTORS FOR POST-DBE PANCREATITIS

In addition to reviewing the etiologies of the post-DBE pancreatitis, a discussion about potential risks involved in this complication is pertinent. The time length of the procedure, the final depth of endoscope insertion and the purpose of the DBE (diagnostic *vs* therapeutic) have been mentioned[14,16,17,20,31,40]. Again, the use of a validated animal model for DBE allows a more accurate approach to this topic[32-35].

The question about how long can DBE take to avoid complications such as pancreatitis has not received yet a unanimous answer. A large variety of figures are found in the literature. Explorations as short as 30 min or as long as 240 min[64] have been referred. Between those limits, DBE of 148 min[14,20], 115 min[16] and 95 min[25] are mentioned. Some authors agree a time window between 70 and 100 min as the criteria to avoid DBE complications such as perforation[2,65,66], while in relation with the learning curve other authors highlight the important reduction in time after approximately 10 DBEs, which in average was quantified from 109 min to 92 min[67]. From another perspective, some works define the maximum effective time of exploration as the period from the beginning of procedure till the moment when no more than 1-2 cm are progressed after several push-and-pull cycles. Such a time of effective exploration, which in humans and pigs takes around 60 min, has been referred as "the gold hour" of DBE practice. However, the relevance of this reference is uncertain. While it is noticeable that oral DBE longer than one hour have been associated with increases of pancreatic lesion or pancreatitis[14,16,17,20,31,40], other studies do not find any consistent reason to consider the time as a direct risk factor[14,21]. This was also the overall conclusion of an experimental study in porcine model[33]. The time and length of each push-and-pull manoeuvre was carefully monitored and no significant association between DBE duration (90 min *vs* 140 min) and the risk of pancreatitis (amylase and lipase levels) or the grade of histopathological disorders was found.

The final insertion depth of the endoscope is another controversial risk associated to DBE, especially because the estimation of the explored distance is always subjective. Several methods to assess insertion depth have been proposed[2,68], but the most frequently used was presented by May in 2005[2]. This method was later validated for experimental purposes in a porcine model[35]. On the other hand, evaluating how insertion depth may be a risk of pancreatitis is neither easy nor accurate in DBE practice. The influence of this variable cannot be isolated from other factors associated to the patient and/or the pathology, which strongly condition how deep the endoscope is addressed. Even under experimental conditions the total insertion depth of the endoscope was not correlated with the level of pancreatic markers or the appearance of structural disorders in the pancreas[33]. Nevertheless, when both the time length DBE interval and the depth of insertion are combined potential complications are more likely.

Several other risks for post-DBE pancreatitis have been suggested[17]. The indication (purpose) of DBE, whether diagnostic or therapeutic is one of them. Diagnostic DBE are less invasive and have a lower risk of major complications (around 1%), such as pancreatitis, haemorrhage or perforation, than therapeutic (up to 5%)[17,69]. The learning curve has also been suggested as a risk for major complications[14]. Up to a minimum of 50 DBE are needed to finish the learning curve[69] but this was never related with higher amylase or lipase levels, or post-DBE pancreatitis[20,59,70]. On the other hand, the use of CO_2 insufflation during DBE is highly recommended as it prevents over-inflation of the small bowel. CO_2 is helpful for an easier and deeper insertion of the endoscope, and has a possible preventive effect to post-DBE pancreatitis[14,17].

CONCLUSION

Based on a growing number of indirect clinical evidences and supported by experimental studies in porcine model, a vascular distress is suggested as the most likely etiology of post-DBE pancreatitis. During oral DBE the push-and-pull manoeuvres cause mechanical strength on the small bowel, pancreas and mesentery, which reduce the normal blood supply. The resulting situation of pancreatic ischemia commonly determines transient cellular hypoxia, with a lack of clinical signs of pancreatitis, however it may occasionally drive severe hypoxia, necrosis and clinical pancreatitis.

Abstract

AIM

To investigate association of circulating inflammatory factors at the time of colorectal cancer (CRC) surgery with survival.

METHODS

Plasma levels from 174 CRC patients (69 females and 105 men), with median age 70 years (range 29-90), localized in the colon (n = 105) or rectum (n = 69), with stage Ⅰ (n = 24), stage Ⅱ (n = 54), stage Ⅲ (n = 67) and stage Ⅳ (n = 29) were measured using commercially available Bio-Plex Pro™ Human Chemokine

Panel 40-Plex, including 40 different chemokines, cytokines and interleukins. The prognostic association of each inflammatory factor was analysed as CRC-specific and total mortality.

RESULTS

Out of 174 patients, 66 died during the follow-up, 40 because of CRC specific mortality. High tertile levels of 8 factors were significantly associated with increased CRC-specific mortality, of which CCL1, CCL20, CCL24, CX3CL1, IL-4 and TNF-α remained significant in a multivariate Cox regression analysis. High tertile levels of 14 factors were associated with increased total mortality, of which CCL1, CCL15, CCL20, CX3CL1, CXCL13, IFN-γ, IL-2, IL-4 and IL-10 remained significant after adjustment for clinical covariates. For most of the inflammatory factors the association between higher tertile levels and an increased mortality in general appeared two years after surgery. High tertile levels of TNF-α and CCL24 were exclusively associated with CRC-specific mortality. The distribution of these factors were not associated with TNM stage with exception for CCL20.

CONCLUSION

High plasma levels of inflammatory factors are associated with increased risk of mortality among CRC patients and could be potential biomarkers for revealing prognosis.

Key words: Colorectal cancer; Inflammation; Cytokines; Plasma; Prognosis; Mortality

Core tip: Plasma levels of 40 different cytokines, chemokines and interleukins were analyzed in colorectal cancer (CRC) patients of which high tertile levels of nine factors were associated with total mortality and six factors with CRC-specific mortality. For most of the inflammatory factors the association between higher tertile levels and an increased mortality in general appeared two years after surgery.

INTRODUCTION

Inflammation is of importance in cancer development, and many tumours develop due to prolonged or chronic inflammation throughout their progression[1]. Carcinogenesis in colorectal cancer (CRC) is a multistep process maintained by accumulation of genetic and epigenetic aberrations in several pathways[2,3]. Also, local immunoregulation mediated by inflammatory cells, such as white blood cells, of the tumour microenvironment are involved in the release of inflammatory factors that are able to activate local immune networks to promote both the development and growth of malignant CRC cells by increasing their proliferation, survival and angiogenesis[1,4]. Inflammatory factors such as cytokines together with angiogenic factors are able to trigger the development of invasive abilities as they increase the migration and motility of tumour cells, resulting in the occurrence of metastasis[1]. Cytokines, which include chemokines and interleukins, are a broad and loose category of small proteins produced by white blood cells, stromal cells and cancer cells[1,5]. They are able to regulate the intensity and duration of the immune response by either stimulating or inhibiting the activation, proliferation and/or differentiation of various cells and are also able to regulate the secretion of antibodies and other cytokines[5]. By targeting selected cytokine networks or pathways one may be able to restrain CRC tumorigenesis or even improve the response rate in CRC tumours to chemotherapies, and there are several clinical trials that have focused on evaluating the blockage of different cytokines[6-8].

Increased levels of inflammatory factors have been associated with increased mortality in CRC patients, also in stage I which has a good oncological prognosis, but also in asymptomatic assumed healthy individuals[9-12].

The aim of this paper was to study the association of plasma levels of cytokines, chemokines and interleukins in CRC patients at the time of surgery with survival. The hypothesis is that strong inflammation at the time of surgery is associated with worse prognosis.

MATERIALS AND METHODS

Study population

This study involved analysis of plasma samples from 174 CRC patients from southeastern Sweden who had undergone surgical resections for primary colorectal adenocarcinoma between 2006-2013 at the Department of Surgery, County Hospital Ryhov, Region of Jönköping County, Jönköping, Sweden. The clinicopathological characteristics of the patients were obtained from surgical and pathological records. Follow-up was performed by consulting the medical records from all hospital departments and the primary care up to January 31, 2016. The date of an eventual cancer recurrence and the date and cause of death as related to CRC-specific mortality or not were determined from a review of the patient's files. The study was approved by the Regional Ethical Review Board in Linköping, Linköping, Sweden, and written informed consent was obtained from each patient.

Plasma samples

Venous blood samples were collected at the time of surgery and centrifuged to separate plasma and blood cells. Plasma was stored at -80 ℃ until analysis. Plasma samples were available from 174 patients (69 females and 105 men), and their median age was 70 years (range 29-90). The patients' tumours were localized in the colon (n = 105) or rectum (n = 69) and were classified as stage Ⅰ (n = 24), stage Ⅱ (n = 54), stage Ⅲ (n = 67) and stage Ⅳ (n = 29).

Human cytokine assay

Diluted plasma (1:4) from 174 CRC patients and an eight-point standard curve were analysed for each of the 40 factors using a commercial Bio-Plex Pro™ Human Chemokine Panel 40-Plex (Bio-Rad Laboratories, Inc., CA, United States) including chemokines, cytokines and interleukins according to the manufacturer's recommendations. Magnetic separation was performed using the Bio-Plex Pro Wash Station (Bio-Rad Laboratories). Bead fluorescence readings were taken using the Bio-Plex Manager version 6.1.0.727 (Bio-Rad Laboratories) with Low PMT (Low RP1) setting on the Bio-Plex 200 System (Bio-Rad Laboratories). The results are presented as pg/mL and grouped into tertiles defined as low, middle or high tertile.

Statistical analysis

A Shapiro-Wilk test was used to determine the normal distribution. The Pearson χ^2 test was used to determine differences in distribution of covariates; age, gender, localization, cancer recurrence, radical surgery, TNM stage, preoperative treatment, and adjuvant treatment between patients with CRC-specific mortality compared to survivors or deceased by other causes. An association of the inflammatory variables with TNM stage was analysed by comparing the distribution of inflammatory factors using Jonkheere Terpstra test. The association of age, sex, tumour localization, TNM stage, local radical resection, pre- and postoperative adjuvant treatment and tertiles of the examined inflammatory variables with CRC specific and total mortality were performed with Kaplan-Meier curves, log-rank test and Cox's regression analysis. Both univariate and multivariate Cox regression analysis were performed. The proportional hazard assumption was verified by visual inspection of log-log plots. The statistical analyses were performed using the SPSS for Windows computer package (IBM® SPSS® Statistics, 2012, version 21, SPSS Inc., Chicago, IL, United States).

RESULTS

Clinical baseline characteristics

The clinical baseline characteristics of the total study population are presented in Table 1. Out of 174 patients, 40 died because of CRC. Thirty five of these were stage Ⅲ and Ⅳ patients. Twenty-six of the 174 patients died from other causes and 108 were still alive at the end of follow-up. Frequency of radical surgery, TNM stage and adjuvant treatment differed significantly between patients with CRC-specific mortality compared with survivors or deceased by other causes. On the other hand, age, gender, localization of the cancer and preoperative treatment did not differ between the groups. A threshold of $P < 0.20$ was set for the covariates used in the adjustment of statistical analyses. Age was included in the adjusted model since mortality is highly associated with increased age in general.

Associations between TNM stage and levels of inflammatory factors

Each of the inflammatory factors were tested for any eventual association with TNM stage by the Jonkheere Terpstra test.Only CCL20, CCL27, IL-8 and MIF were associated with TNM stage (Table 2).

Total mortality in relation to high tertile levels of inflammatory factors

In a univariate Cox regression analysis, the highest tertile levels of 14 factors, CCL1, CCL3, CCL15, CCL20, CX3CL1, CXCL1, CXCL10, CXCL13, IFN-γ, IL-1β, IL-2, IL-4, IL-8/CXCL8 and IL-10, were significantly associated with total mortality (Table 3). CX3CL1 had the highest hazard ratio (HR) of 3.3 with a 95%CI of 1.8-6.1, $P < 0.001$, for the highest tertile. Nine of the factors in the univariate analysis, CCL1, CCL15, CCL20, CX3CL1, CXCL13, IFN-γ, IL-2, IL-4 and IL-10, remained significant after adjustment of clinical covariates with $P < 0.20$, such as TNM stage, radical surgery, preoperative- and adjuvant treatment and age. Figure 1 shows an example of a Kaplan-Meier analysis of plasma levels of IFN-γ and an increased risk of total mortality. The Kaplan-Meier curves illustrate mortality as a function of follow-up time in relation to tertile levels.

CRC-specific mortality in relation to high levels of inflammatory factors

When investigating the CRC specific mortality among the inflammatory factors, the univariate Cox regression analysis revealed that the highest tertile levels of 8 factors, CCL1, CCL3, CCL15, CCL20, CX3CL1, CXCL16, IL-4 and IL-8/CXCL8, were significantly associated with CRC specific mortality (Table 4). CCL20 showed the highest HR of 4, CI of 1.6-10.1, $P < 0.01$. After adjustment for clinical covariates with $P < 0.20$, only 4 factors remained significant, CCL1, CCL20, CX3CL1 and IL-4. In addition, TNF-α and CCL24 became significant after this adjustment. Kaplan-Meier analysis of CRC specific mortality and tertile levels of CCL1 is shown in Figure 2.

In summary, higher tertile levels of the inflammatory factors CCL1, CCL20, CX3CL1 and IL-4 were all associated with increased risk of both total and CRC-

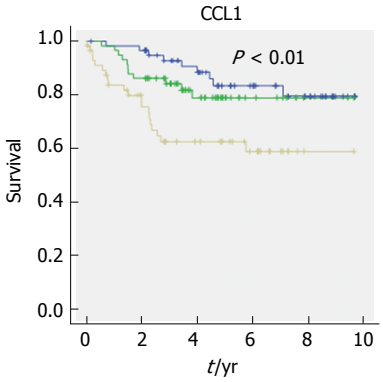

Figure 2 Kaplan-Meier curve of CCL1 as an example of an inflammatory factor significant for colorectal cancer-specific mortality in a multivariate analysis. Upper blue line: lowest tertile levels in pg/mL; middle green line: middle tertile levels in pg/mL; lower yellow line: highest tertile levels in pg/mL.

specific mortality after Cox regression analysis when adjusted for clinical covariates. Higher tertile levels of TNF-α and CCL24 were exclusively associated with CRC-specific mortality. For most of the inflammatory factors the association between higher tertile levels and an increased mortality in general appeared two years after surgery. Twenty three inflammatory factors did not have any association with CRC-specific or total mortality when studying the follow-up time in relation to the tertile levels of these factors (Table 5).

DISCUSSION

In this study, we screened plasma samples from 174 CRC patients for 40 different inflammatory factors using a commercial multiplex kit, which allow simultaneous quantification of several factors of interest, to determine whether the plasma levels of these factors were associated with CRC prognosis.

We found that high tertile levels of CCL1, CCL20, CX3CL1 and IL-4 were associated with increased CRC-specific mortality in a multivariate Cox regression analysis. We also found an increased total mortality in association of high tertile levels of CCL1, CCL15, CCL20, CX3CL1, CXCL13, IFN-γ, IL-2, IL-4 and IL-10.

Several studies have focused on higher or lower levels of some of the inflammatory factors included in our study such as CCL15, CCL20, CX3CL1, CXCL13, CXCL16, IL-4, IL-8/CXCL8, IL-10 and TNF-α by either comparing expression levels in tissue, in serum or

[1]When adjusted for age, TNM stage, radical surgery, preoperative- and adjuvant treatment. CRC: Colorectal cancer.

in plasma from CRC patients and controls or among patients only[13-22]. Also, expression levels of some of these factors have been studied in relation to survival[13-15,17,18,20-22].

More recent studies have found an association of increased levels of inflammatory markers and increased mortality in CRC patients, but also in CRC patients stage Ⅰ and in asymptomatic healthy individuals[9-12]. Our findings of a worse prognosis in association with increased level of inflammation may therefore be a more general phenomenon and not directly related to the cancer disease. As mentioned, the local immunoregulation mediated by inflammatory cells, such as white blood cells, of the tumour microenvironment are important for the release of inflammatory factors such as cytokines, which are able to activate local immune networks to promote both the development and growth of malignant CRC cells[1,4]. White blood cells

Table 5 Inflammatory factors not associated with colorectal cancer specific or total mortality

CCL26	

play an important part in immunoregulation but play dual roles. They are supposed to defeat the cancer development by producing cytokines and activating inflammatory signalling pathways enabling necrosis or apoptosis of cancer cells. But the cancer itself may also induce an immunomodulation of the white blood cells, making them unable to produce cytokines and other inflammatory factors. In this way, the cancer cells avoid inflammatory recognition and are then able to continue their development[1,4].

The CX3CL1 chemokine is expressed by epithelial cells in both CRC and normal colorectal mucosa. Higher levels of this chemokine have been associated with better prognosis and higher survival rate in CRC patients, depending on anti-tumour immunity through a higher number of attracted lymphocytes[16]. This is contradictory to our findings in the univariate analysis, which show an association between higher tertile levels of CX3CL1 and a > 3.5-fold increased risk for CRC-specific mortality among our CRC patients.

The CCL15 chemokine has a strong chemotactic activity for myeloid cells such as dendritic cells, monocytes, neutrophils and some T-lymphocytes[23]. In a study by Inamoto *et al*[13] a trend between higher levels of CCL15 and poor survival among CRC patients was observed. In this study we confirm that a higher inflammatory tertile level of CCL15 is related to CRC-specific mortality when we do not include age as a covariate in the statistical analysis.

Expression of the CCL20 chemokine has been demonstrated in dendritic cells, macrophages, eosinophilic granulocytes and in B- and T-cell lymphocytes, as reviewed by Schutyser *et al*[24]. In CRC, higher serum levels of CCL20 may serve as a potential biomarker for prognosis. It may also be useful for identification of patients with increased risk of disease recurrence in stage Ⅱ CRC[14]. In the present investigation, higher tertile levels of CCL20 in plasma is associated with a 4-fold increased risk for CRC-specific mortality in the univariate analysis, which could be explained by a relation to TNM stage.

IL-4 is produced by basophils, activated T-lymphocytes and mast cells and seems to be upregulated in CRC[25,26]. It has been suggested that IL-4 might be involved in the process of supporting the tumour-initiating cells, enabling them to escape immune surveillance and in turn promote CRC progression[19]. Our data show that the highest tertile level of IL-4 is associated with an increased risk of CRC specific mortality as a result of ongoing CRC progression over time.

The CCL1 chemokine is secreted from fibroblasts[27] and Th2 cells[28]. CCL1 has been implicated in other types of cancer but little is known about its effects on CRC[27]. The Th2-cells express the CCR8 receptor[29,30], which is activated by CCL1[31], and it mediates Th2 cell recruitment to sites of inflammation[32,33]. In cancer, the CCL1-CCR8 autocrine loop has been shown to have a protective function by enabling lymphoma and T cell leukaemia cells to avoid apoptosis *in vitro*[34,35] and to play a role in T cell transformation[36]. In this study, higher tertile levels of this chemokine were associated with a 2.8 fold increased risk for CRC-specific mortality and one might speculate that the CCL1-CCR8 autocrine loop may help CRC cells to progress their development and spread. Due to our results CCL1 might be a new important factor to consider in further studies regarding its implications on CRC.

There are several limitations identified in our study that need to be taken into consideration. First, a control group was not included in the present work since our focus was on survival among CRC patients, making us unable to study differences and/or associations in levels of the inflammatory factors among patients and healthy individuals. However, there are already several studies that have investigated differences in levels of cytokines among both patients and healthy control subjects[37,38]. Second, our cohort was relatively small influencing the statistical evaluation and especially associations with stage, which was weak due to low power. This also makes it difficult to stratify the patients into respect to more variables such as type of surgery, with inflammatory complicated CRC such as peritumorous abscess, perforation or peritonitis, or inflammatory bowel disease. Third, it is also important to realize that the level of inflammatory factors in the circulation might reflect the release of factors during cancer carcinogenesis, due to other underlying diseases or by systemic inflammation in general. In this study we did not have the possibility to investigate this.

Future aspects should focus on studying these inflammatory factors in a larger CRC patient cohort to see if they might have the potential as biomarkers that can be measured through a rapid, simple, non-invasive and less costly plasma analysis enabling the identification of CRC patients with worse prognosis. Functional studies are needed to elucidate weather these are causative factors for tumour progression or a biomarker for CRC prognosis or a marker for a general fragility.

In summary, high tertile levels of a range of chemokines, cytokines and interleukins are associated with a worse prognosis in patients operated for CRC, both as expressed as cancer specific mortality (CCL1, CCL20, CCL24, CX3CL1, IL-4 and TNF-α) and total mortality (CCL1, CCL15, CCL20, CX3CL1, CXCL13, IFN-γ, IL-2, IL-4 and IL-10). This suggests that the observed association of a worse prognosis in CRC patients with an increased level of inflammation may not only be associated to the cancer disease but expression of a fragile host.

COMMENTS

Background

Inflammation is of importance in cancer development, and many tumours develop due to prolonged or chronic inflammation throughout their progression.

Research frontiers

Several studies have previously investigated expression of some inflammatory factors in circulation of patients with colorectal cancer (CRC).

Innovations and breakthroughs

This study analyzed 40 different inflammatory factors at the same time in plasma from CRC patients which was investigated in multivariate Cox regression analysis taken into account clinical co-variates.

Applications

The identification of high levels of several factors associated with CRC specific mortality makes them interesting targets for further studies and as potential targets for immune therapy. The results further support that CRC progression is an inflammatory active condition.

Terminology

Chemokines are a family of small cytokines that are secreted by a variety of cells and can attract cells expressing the corresponding receptor, normally leukocytes.

Peer-review

The authors in this study investigated whether the circulating inflammatory factors were associated with worse long-term prognosis in CRC. The results showed that high plasma levels of inflammatory factors were associated with an increased risk of total and CRC specific mortality among CRC patients. The whole manuscript is well designed and used a fluency style.

Abstract

AIM

To investigate the effects of herb-partitioned moxibustion (HPM) on phosphorylation of mitogen-activated extracellular signal-regulated kinase (MEK)1, extracellular signal-regulated kinase (ERK)1/2 and cAMP response element binding protein (CREB) in spinal cord of rats with chronic inflammatory visceral pain (CIVP), and to explore the central mechanism of HPM in treating CIVP.

METHODS

Male Sprague-Dawley rats were randomized into normal, model, HPM, sham-HPM, MEK-inhibitor and dimethyl sulfoxide (DMSO) groups. The CIVP model was established using an enema mixture of trinitrobenzene sulfonic acid and ethanol. HPM was applied at bilateral Tianshu (ST25) and Qihai (CV6) acupoints in the HPM group, while in the sham-HPM group, moxa cones and herb cakes were only placed on the same points but not ignited. The MEK-inhibitor and DMSO groups received L5-L6 intrathecal injection of U0126 and 30% DMSO, respectively. Abdominal withdrawal reflex (AWR), mechanical withdrawal threshold (MWT) and thermal withdrawal latency (TWL) were applied for the assessment of pain behavior. The colonic tissue was observed under an optical microscope after hematoxylin-eosin staining. Expression of phosphor (p)MEK1, pERK1/2 and pCREB in rat spinal cord was detected using Western blotting. The levels of MEK, ERK and CREB mRNA in rat spinal cord were detected using real-time polymerase chain reaction.

RESULTS

Compared with the normal group, the AWR scores were increased significantly ($P < 0.01$) and the MWT and TWL scores were decreased significantly ($P < 0.05$) in the model, sham-HPM and DMSO groups. Compared with the model group, the AWR scores were decreased significantly ($P < 0.01$) and the MWT and TWL scores were increased significantly in the HPM and MEK-inhibitor groups ($P < 0.05$). Compared with the sham-HPM and DMSO groups, the AWR scores were decreased significantly ($P < 0.01$) and the MWT and TWL scores were increased significantly ($P < 0.05$) in the HPM and MEK-inhibitor groups. Compared with the normal group, the expression of pMEK1, pERK1/2 and pCREB proteins and the levels of MEK, ERK and CREB mRNA in rat spinal cord were increased significantly in the model, sham-HPM and DMSO groups ($P < 0.01$ or < 0.05). Compared with the model group, the expression of pMEK1, pERK1/2 and pCREB proteins and the levels of MEK, ERK and CREB mRNA in rat spinal cord were reduced significantly in the HPM and MEK-inhibitor groups ($P < 0.01$ or < 0.05). Compared with the sham-HPM and DMSO groups, expression of pMEK1, pERK1/2 and pCREB proteins and the levels of MEK, ERK and CREB mRNA in rat spinal cord were reduced significantly in the HPM and MEK-inhibitor groups ($P < 0.01$ or < 0.05).

CONCLUSION

HPM down-regulates protein phosphorylation of MEK1, ERK1/2 and CREB, and mRNA expression of MEK, ERK and CREB, inhibiting activation of the MEK/ERK/CREB signaling pathway in the spinal cord of CIVP rats, which is possibly a critical central mechanism of the analgesic effect of HPM.

Core tip: Chronic inflammatory visceral pain (CIVP) (abdominal pain) is one of the major symptoms of inflammatory bowel disease. Herb-partitioned moxibustion (HPM) at bilateral Tianshu (ST25) and Qihai (CV6) acupoints was effective in enhancing the pain threshold and easing pain in CIVP rats. Levels of phosphorylated protein and mRNA expression of mitogen-activated extracellular signal-regulated kinase 1, extracellular signal-regulated kinase and cAMP response element binding protein were abnormally increased in the spinal cord of CIVP rats. HPM effectively down-regulated the abnormally increased expression, which is possibly one of the analgesic mechanisms of HPM.

Moxibustion eases chronic inflammatory visceral pain through regulating MEK, ERK and CREB in rats. *World J Gastroenterol* 2017; 23(34): 6220-6230 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6220.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6220

INTRODUCTION

Chronic inflammatory visceral pain (CIVP) is a complex process involving a variety of neurotransmitters, cytokines, and signaling pathways. The extracellular signal-regulated kinase (ERK) signaling pathway is a major branch of the mitogen-activated protein kinase (MAPK) pathway and has been thoroughly explored. The ERK pathway is responsible for the regulation of pain and inflammation[1]. It has been shown that electroacupuncture (EA) can enhance the pain threshold of rats with inflammatory pain in the hind paw and that this effect is mediated *via* regulation of the ERK signaling pathway[2].

Mitogen-activated extracellular signal-regulated kinase (MEK)/ERK/CREB is part of the ERK pathway. MEK resides in the upstream region of the ERK pathway, and induces ERK1/2 through phosphorylating its threonine and tyrosine. Activated ERK1/2 regulates phosphorylation of various proteins such as cAMP-response element binding protein (CREB) and transcription factors (TFs), subsequently influencing multiple biological functions[3]. The MEK/ERK/CREB signaling pathway plays an important role in modulating the transmission and maintenance of pain signals[4,5].

Our previous studies have demonstrated that herb-partitioned moxibustion (HPM) reduces chronic inflammatory pain in rat models of trinitrobenzene sulfonic (TNBS)/ethanol-induced ulcerative colitis (UC)[6,7]. However, the questions remain whether

the MEK/ERK/CREB signaling pathway is involved in CIVP and whether HPM exerts its analgesic effect *via* regulation of this pathway. We used Western blotting and real-time polymerase chain reaction (PCR) to observe the effects of HPM on protein phosphorylation and mRNA expression of MEK, ERK and CREB in the spinal cord of rats with TNBS/ethanol-induced CIVP, to discover the analgesic mechanism of HPM from the perspective of the MEK/ERK/CREB signaling pathway.

MATERIALS AND METHODS

Animals

Fifty-four healthy adult male Sprague-Dawley rats, weighing 150 ± 20 g, were provided by Shanghai Sippr-BK Laboratory Animal Co. Ltd. [license no: SCXK(Hu)2013-0016]. The rats were housed in a room with a 12/12-h light/dark cycle (08:00-20:00 light; 20:00-08:00 dark). The feeding room and behavior detection room were both at 20 ± 1 ℃ with a relative humidity of 50%. After 1 wk of adaptive feeding, the rats all presented with normal behavior for ingestion and drinking and were included in the investigation. The experiment was conducted following the Guide for the Care and Use of Laboratory Animals, and the protocol was approved by the Committee on Use of Human and Animal Subjects in Teaching and Research, Shanghai University of Traditional Chinese Medicine.

Using a completely randomized design, the 54 rats were randomized into normal, model, HPM, sham-HPM, MEK-inhibitor and DMSO groups, with 9 rats each. A TNBS/ethanol-induced CIVP rat model was replicated in the six groups, except for the normal group[8,9]. Prior to modeling, the rats were fasted for 24 h but allowed free access to water. CIVP was induced with 5% (w/v) TNBS and 50% ethanol in a 2:1 ratio. The rats were weighed and then anesthetized with 2% pentobarbital sodium intraperitoneally at 30 mg/kg. The TNBS enema solution was administered at 3 mL/kg with the needle inserted into anus by 6-8 cm. After enema administration, the tails of the rats were lifted to keep the rats upside down for 1 min. The enema was performed once every 7 d, for four times in total.

After modeling, the rats were subjected to pain behavior tests and one rat from each group was killed to collect colon tissue for hematoxylin-eosin (HE) staining to verify successful induction of the model; after which, the intervention began.

Main reagents and instruments

The following reagents and instruments were used: 5% TNBS (Sigma, St Louis, MO, United States); phospho (p)MEK antibody (Cell Signaling Technology, Danvers, MA, United States); pERK antibody (Cell Signaling Technology); pCREB antibody (Cell Signaling Technology); MEK inhibitor U0126 (Calbiochem, Darmstadt, Germany); DMSO (Santa Cruz Biotechnology, Dallas, TX, United States); horseradish peroxidase goat anti-rabbit IgG (Beyotime, Shanghai, China); Von Frey filaments (Stoelting Co, Wood Dale, IL, United States); BME2410A thermal stimulator (Institute of Medical Biology, Chinese Academy of Medical Sciences, Beijing, China); electrophoresis system: Mini-PROTEAN 3 cell (Bio-Rad, Hercules, CA, United States); imaging system: ChemiDoc™ (Bio-Rad, Hercules, CA, United States); PCR primers ABI 7300 (Thermo Fisher Scientific, Waltham, MA, United States).

Pain behavior tests

Abdominal withdrawal reflex (AWR) was measured based on Al-Chaer's method[10] by offering a series of colorectal distending (CRD) stimuli: 20, 40, 60 and 80 mmHg. Each rat was measured three times; each stimulus lasted 20 s, with an interval of 5 min, and the average value of the three measurements was considered as the final record.

Mechanical withdrawal threshold (MWT) was measured using a Von Frey filament (gradient folding force: 2.0, 4.0, 6.0, 8.0 and 15.0 g) to poke perpendicularly the center of the hind paw, lasting ≤ 4 s[11]. It was considered positive when the rat lifted or licked the hind paw. The test started with 2 g; each force was applied five times, with an interval of 30 s between measurements. The maximum force was 15 g, as was the maximum MWT value. The 50% positive response threshold was calculated using an up-down method.

According to Hargreaves' method[12], we examined the thermal withdrawal latency (TWL) by radiating the hind paw with a thermal stimulator. The duration from the beginning of radiation to the withdrawal reaction was designated the TWL. The stimulation was controlled at the same intensity and automatically cut off at 20.1 s to prevent burns. Each rat was examined five times, with an interval of 3 min. The maximum and minimum values were excluded and the mean of the middle three values was taken as the final record.

Intervention

Rats in the normal and model groups were only taken out and fixed at the same time as those in the HPM group but did not receive any treatment. Rats in the HPM group received HPM treatment at bilateral Tianshu (ST25) and Qihai (CV6) points[13-15], with two moxa cones for each point at each session (about 10 min); one session was performed every day, for a total of seven sessions. The herb cakes were mainly made of *Aconiti praeparata* powder and yellow wine. The moxa cones were made using a specific mold, and each moxa cone weighed 90 mg. HPM treatment was performed as shown in Figure 1.

In the sham-HPM group[16,17], when the rats were fixed in position, the moxa cones were placed on the same acupoints for 10 min but not ignited. The control procedure was also conducted once every day, for

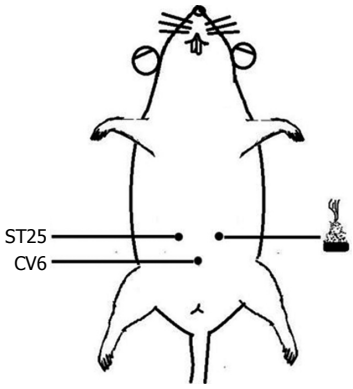

Figure 1 Herb-partitioned moxibustion treatment.

seven times in total. Rats in the MEK-inhibitor group received intrathecal injection at L5-L6 of U0126 which was dissolved in 30% DMSO solution[18] (1 μg/μL), 10 μL each time, once every day, for 7 consecutive days. Rats in the DMSO group received intrathecal injection of 30% DMSO at the same location, 10 μL each time, once per day, for 7 consecutive days.

Sample collection and processing

Pain behavior was retested on the second day of the last intervention session. The rats were killed for collection of colon and spinal cord tissue. After weighing and anesthetic overdose, the abdomen was dissected along the median line and 5 cm of colon was rapidly removed. After cutting longitudinally and rinsing, the colonic tissues were fixed in 4% formaldehyde solution. The samples were then dehydrated in an alcohol series, made transparent, and embedded for subsequent use. The spinal cord from L6 to S2 was collected and kept at -80 ℃.

Pathological observation of colonic tissue

The colonic samples were stained with HE to observe the pathological alterations under an optical microscope.

Western blotting of pMEK1, pERK1/2 and pCREB proteins in spinal cord

The spinal cord tissues were removed from the -80 ℃ freezer, weighed and mixed with lysate solution in a proportion of 100 mg:1 mL. The sample was centrifuged at 4 ℃ and 12000 r/min for 15 min, and the supernatant obtained contained total protein. The bicinchoninic acid method was used for the determination of total protein content. Electrophoresis was performed with each well containing 50 μg total protein.

The resolved protein sample was transferred to a nitrocellulose membrane using a wet transfer printing method. Primary antibody (1:1000) was incubated overnight at 4 ℃, followed by secondary antibody (1:1000) for 2 h at room temperature. After 2-min incubation with electrochemiluminescence, the samples were analyzed using a Bio-Rad imaging system. The gray values of target protein and internal reference protein bands were read, and the ratio between the gray value of the target protein band and that of the internal reference protein band was taken as the relative expression level.

Detection of MEK, ERK and CREB mRNAs by real-time PCR

TRIzol reagent (Invitrogen, Carlsbad, CA, United States) was used to acquire total RNA from the tissues. A total RNA equivalent was used to reverse transcribe cDNA using a Thermo Scientific PCR kit (United States). ABI Prism7300 SDS software was used to analyze the mRNA expression level of the target gene. The relative mRNA expression of a target gene was calculated as $2^{-\Delta\Delta CT} \times 100\%$; ΔCT = CT value of the target gene - CT value of the internal reference (GAPDH). The sequences of primers were as follows: GAPDH forward 5′-GGAGAAACCTGCCAAGTATG-3′, reverse 5′-GACAACCTGGTCCTCAGTGT-3′; MEK forward 5′-AGAGCGTGCAGACCTCAAGCT-3′, reverse 5′-AGCCGCAGGGTTCTGCATA-3′; ERK forward 5′-ATCAACACCACCTGCGACCTT-3′, reverse 5′-TGGCCA CATACTCGGTCAGAA-3′; CREB forward 5′-CCACTC AGCCGGGTCTACCAT-3′, reverse 5′-CCAGAGGCAGCTT GAACAACA-3′.

Statistical analysis

SPSS version 19.0 software was used for data analysis. Measurement data in normal distribution were expressed as mean ± SD; measurement data in non-normal distribution were expressed as median (P25, P75). One-way analysis of variance was used to analyze the inter-group differences if the data followed a normal distribution, least significant difference (LSD) for those with homogeneous variances, and Games-Howell for those with heterogeneous variances. A rank-sum test was adopted if the data did not follow a normal distribution. $P < 0.05$ indicated statistical significance.

RESULTS

Comparison of AWR scores

Compared with the normal group, the AWR scores were increased significantly in the model, sham-HPM and DMSO groups under 20, 40, 60 and 80 mmHg distension ($P < 0.01$). Compared with the model group, the AWR scores were decreased significantly in the HPM and MEK-inhibitor groups after intervention under the four levels of distension ($P < 0.01$). Compared with the sham-HPM group, the AWR scores were decreased significantly in the HPM and MEK-inhibitor groups after intervention under the four levels of distension ($P < 0.01$). Compared with the DMSO group, the AWR scores decreased significantly in the HPM and MEK-inhibitor groups after intervention ($P < 0.01$). The results indicated that HPM and U0126

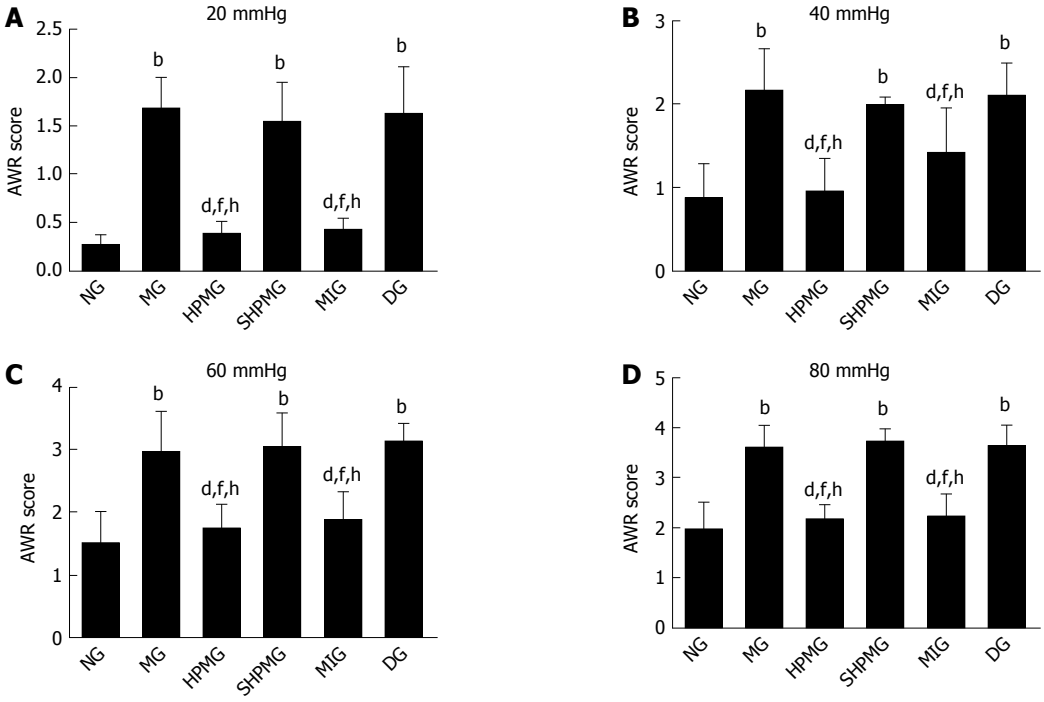

Figure 2 Comparison of the abdominal withdrawal reflex scores after treatment. A: AWR scores under 20 mmHg CRD stimulation; B: AWR scores under 40 mmHg CRD stimulation; C: AWR scores under 60 mmHg CRD stimulation; D: AWR scores under 80 mmHg CRD stimulation. $^{b}P < 0.01$ *vs* normal group; $^{d}P < 0.01$ *vs* model group; $^{f}P < 0.01$ *vs* sham-HPM group; $^{h}P < 0.01$ *vs* DMSO group. AWR: Abdominal withdrawal reflex; CRD: Colorectal distending; NG: Normal group; MG: Model group; SHPMG: Sham-HPM group; MIG: MEK-inhibitor group; DG: Dimethyl sulfoxide group; HPM: Herb-partitioned moxibustion.

reduced the AWR scores and enhanced the pain threshold in the CIVP rats (Figure 2).

Comparison of MWT and TWL scores

Compared with the normal group, the MWT and TWL scores were decreased significantly in the model, sham-HPM and DMSO groups ($P < 0.05$). Compared with the model group, the MWT and TWL scores were increased significantly in the HPM and MEK-inhibitor after intervention ($P < 0.05$). Compared with the sham-HPM group, the MWT and TWL scores were increased significantly in the HPM and MEK-inhibitor groups after intervention ($P < 0.05$). Compared with the DMSO group, the MWT and TWL scores were increased significantly in the HPM and MEK-inhibitor groups after intervention ($P < 0.05$). This indicated that HPM and MEK inhibitor enhanced the MWT and TWL scores, and the pain threshold of the CIVP rats (Figure 3).

Histomorphological observation of colonic tissue

In the normal group, colonic epithelium had the following: a clear structure; mucosa that was complete; arrangement of glands that was regular; and an occasional minor infiltration of inflammatory cells in the lamina propria, without hyperemia, edema or ulceration. In the model group, colonic tissue had an indistinct structure, substantially impaired mucosa, ulcerations, a large amount of inflammatory cell infiltration in the mucosa and submucosa and proliferation of lymph cells, accompanied by hyperemia, edema, damaged glands and indistinct muscular layer. In the HPM group, the mucosal epithelium was generally complete; the arrangement of glands was substantially regular; there was also a large amount of inflammatory cell infiltration in the mucosa and submucosa, accompanied by edema. In the sham-HPM group, the colonic tissue had an indistinct structure, impaired mucosa, a large amount of inflammatory cell infiltration and deficient glands, accompanied by severe hyperemia and edema, but the muscular layer was generally complete. In the MEK-inhibitor group, the colonic tissue had generally complete mucosal epithelium, regular arrangement of glands, obvious infiltration of inflammatory cells (mainly eosinophils and lymph cells) and mild edema. In the DMSO group, the colonic tissue had an indistinct structure, partially impaired mucosal epithelium, ulcerations, obvious hyperemia, edema, inflammatory cell infiltration in the submucosa, damaged glands and indistinct muscular layer (Figure 4).

Comparison of pMEK1, pERK1/2 and pCREB expression in rat spinal cord

Compared with the normal group, expression of pMEK1, pERK1/2 and pCREB was increased significantly in the model, sham-HPM and DMSO groups ($P < 0.01$ or < 0.05). Compared with the model group, expression of pMEK1, pERK1/2 and pCREB was reduced significantly after intervention in HPM and MEK-inhibitor groups ($P < 0.01$ or < 0.05). Compared with the sham-HPM group, expression of pMEK1, pERK1/2 and pCREB was decreased significantly after intervention in the HPM and

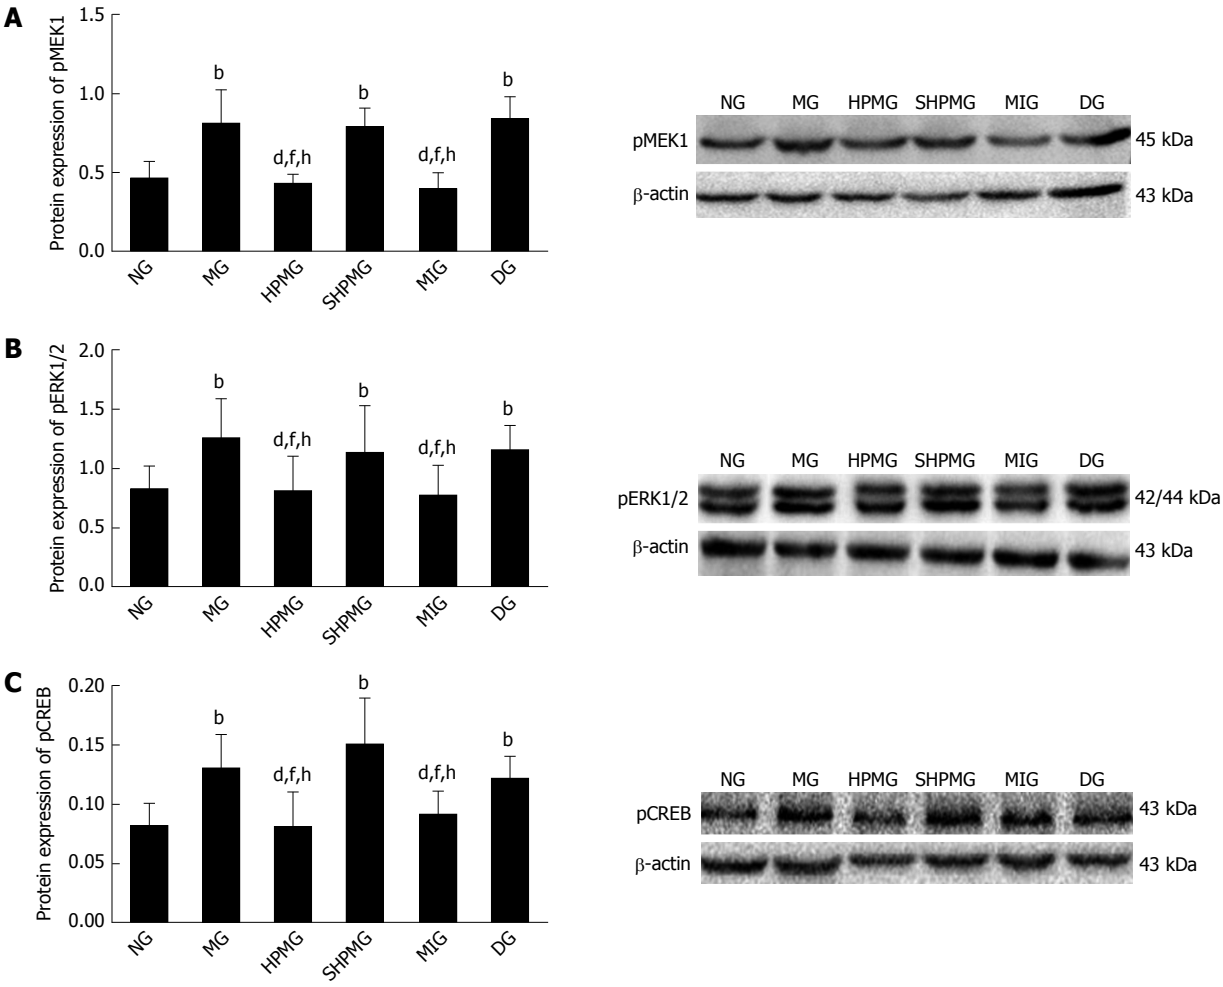

Figure 5 Comparison of expression of phospo-mitogen-activated extracellular signal-regulated kinase 1, phosphor-extracellular signal-regulated kinase 1/2 and cAMP response element binding protein in rat spinal cord. A: Protein expression of pMEK1; B: Protein expression of pERK1/2; C: Protein expression of pCREB. $^{b}P < 0.01$ *vs* normal group; $^{d}P < 0.01$ *vs* model group; $^{f}P < 0.01$ *vs* sham-HPM group; $^{h}P < 0.01$ *vs* DMSO group. pCREB: cAMP response element binding protein; DMSO: Dimethyl sulfoxide; pERK: Phosphor-extracellular signal-regulated kinase; HPM: Herb-partitioned moxibustion; pMEK1: Phospo-mitogen-activated extracellular signal-regulated kinase 1; NG: Normal group; MG: Model group; SHPMG: Sham-HPM group; MIG: MEK-inhibitor group; DG: Dimethyl sulfoxide group.

MEK-inhibitor groups ($P < 0.01$ or < 0.05). Compared with the DMSO group, expression of pMEK1, pERK1/2 and pCREB was reduced significantly after intervention in the HPM and MEK-inhibitor groups ($P < 0.01$ or < 0.05) (Figure 5). The results suggested that HPM and U0126 down-regulated expression of pMEK1, pERK1/2 and pCREB, and inhibited activation of the MEK/ERK/CREB signaling pathway.

Comparison of mRNA expression of MEK, ERK and CREB in rat spinal cord

Compared with the normal group, expression of MEK, ERK and CREB mRNA was increased significantly in the model, sham-HPM and DMSO groups ($P < 0.01$). Compared with the model group, expression of MEK, ERK and CREB mRNA was decreased significantly in the HPM and MEK-inhibitor groups after intervention ($P < 0.01$). Compared with the sham-HPM group, expression of MEK, ERK and CREB mRNA was decreased significantly in the HPM and MEK-inhibitor groups after intervention ($P < 0.01$). Compared with the DMSO group, expression of MEK, ERK and CREB mRNA was reduced significantly in the HPM and MEK-inhibitor groups after intervention ($P < 0.01$) (Figure 6). This indicated that HPM and U0126 down-regulated expression of MEK, ERK and CREB mRNA, and inhibited activation of the MEK/ERK/CREB signaling pathway.

DISCUSSION

CIVP is a common manifestation of inflammatory bowel diseases. Its chronic expansion, unpredictable location and unclear pathogenesis all make it harder to evaluate compared to somatic pain. So far, the measurement of CIVP is generally based on behavioral response, such as visceral pain index, AWR, abdominal contraction record and application of analgesics[19], which may only partially reflect the situation of CIVP. It has been shown by clinical and experimental studies that CIVP involves both somatic (mainly mechanical and thermal hyperalgesia, as shown by

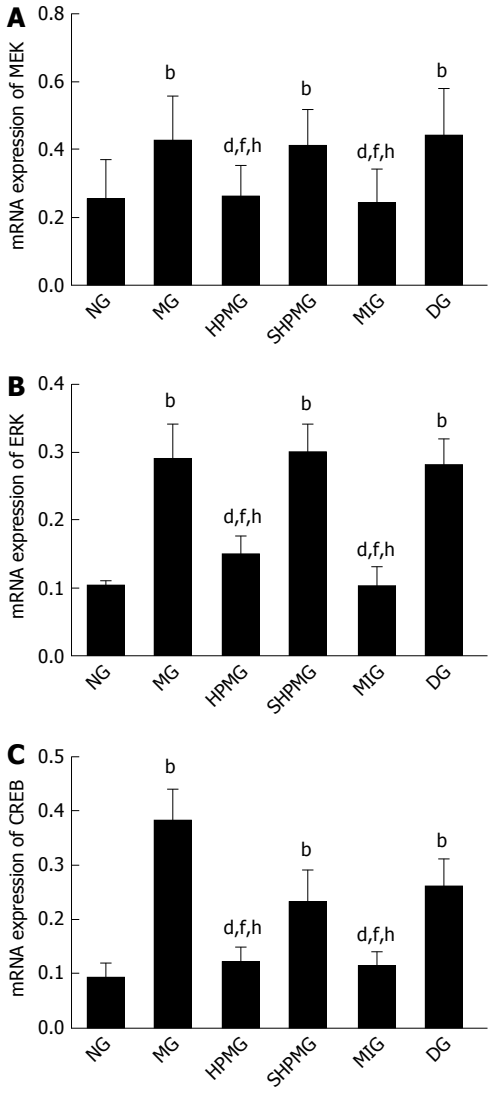

Figure 6 Comparison of expression of mitogen-activated extracellular signal-regulated kinase, extracellular signal-regulated kinase and cAMP response element binding protein mRNAs in rat spinal cord. animal experiments)[6,20] and visceral pain. This is possibly caused by central sensitization triggered by transmission of peripheral nociceptive stimulation into the spinal cord, or by joint action of visceral afferent and limb efferent fibers in the center[8]. Our previous experiment on a rat model of UC showed that HPM at Tianshu (ST25) and Qihai (CV6) was effective in easing CIVP[6], which has made it a significant project to reveal the analgesic mechanism of HPM.

Currently, neural plasticity is considered one of the key factors in the development of CIVP[21]. Peripheral injury or inflammation induces secretion of large amounts of inflammatory mediators, leading to sensitization of peripheral receptors, central nervous system plasticity, and reorganization and reconstruction of the central neurons involved in pain transmission. This long-term neural plasticity can occur simultaneously in the spinal cord and brain, presenting as allodynia (decreased pain threshold, pain induced by painless stimulators) and hyperalgesia (enlarged pain receptive field, enhanced response to nociceptive stimulations, and prolonged pain duration). The MAPK signaling pathway is widely distributed in various types of cells and transmits extracellular signals from the cell surface to the nucleus through cascade activation and activation of numerous proteinases, nucleoproteins and TFs. This produces a critical regulatory effect on pain, inflammation and tumors that is associated with cell proliferation and differentiation[22].

The ERK signaling pathway is a classic MAPK signaling pathway[23]. By following Ras-Raf-MEK-ERK, ERK plays a key role in signal transduction from cell membrane receptors to the nucleus. This shows that activation of ERK in the spinal cord dorsal horn neurons is significant in producing and maintaining central sensitization[24]. This indicates that the ERK pathway is involved in regulation of nociceptive signals in the spinal cord, and early intervention at the spinal cord level should be effective in blocking pain transmission[25]. The application of specific ERK inhibitor further highlights the signal transduction mechanism in chronic visceral pain.

U0126 effectively and exclusively blocks activation of the ERK pathway and enhances the pain threshold[26]. When the ERK pathway is blocked by U0126, the inflammatory mediators produced are also inhibited[27], which means that U0126 has an anti-inflammatory function. Hence, we selected U0126 for injection into the UC CIVP rat model as a positive control for the HPM group, to observe how HPM intervenes in the ERK pathway in CIVP, by detecting the critical proteins upstream and downstream of the ERK pathway.

When receiving MEK upstream signals, pERK migrates to the nucleus, inducing activation of a series of TFs such as CREB, Elk, activator protein-1, c-myc and c-fos[28]. Therefore, activation of MEK and precise transmission of signals to the ERK pathway are critical to the biological function of cells. When receiving nociceptive stimulation, the phosphorylation of ME34921R and ERK in spinal cord dorsal horn neurons is increased[29], suggesting that nociceptive stimulation can provoke the central ERK signaling pathway. U0126 inhibits activation of MEK and ERK, as well as the downstream functional factors, and thus can regulate inflammation and pain[30].

The downstream factors of the ERK pathway include multiple protein kinases and TFs, and CREB is one of the most important. As a type of endonuclear TF, when phosphorylated, CREB can modulate various pain-related target genes, for example, c-fos, neurokinin-1 and brain-derived neurotrophic factor, through which,

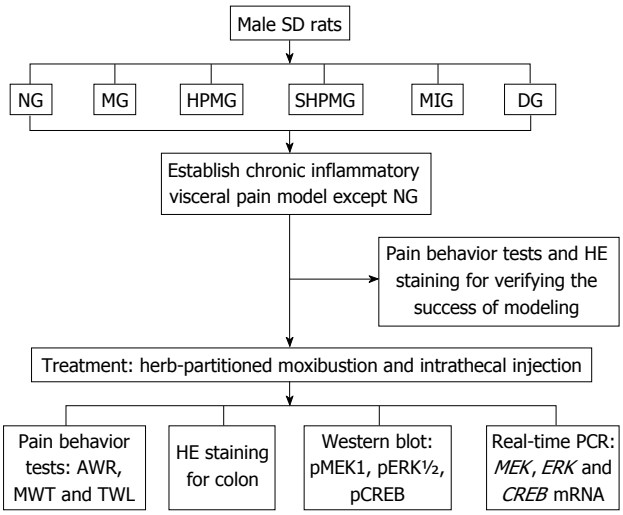

Figure 7 Flow chart of the study design and treatment. AWR: Abdominal withdrawal reflex: CREB: cAMP response element binding protein; ERK: Extracellular signal-regulated kinase; DG: DMSO group; HE: Hematoxylin-eosin; HPM: Herb-partitioned moxibustion; MEK: Mitogen-activated extracellular signal-regulated kinase; MIG: MEK-inhibitor group; MG: Model group; MWT: Mechanical withdrawal threshold; NG: Normal group; SD: Sprague-Dawley; SHPMG: Sham-HPM group; TWL: Thermal withdrawal latency.

it can influence the integration and regulation of pain signals. The whole process is of major significance in adjusting pain signal transduction and central sensitization[31]. ERK and CREB are also closely related in the chronic pain depression model[4,32]. Since CREB is a downstream factor of the ERK pathway, inhibition of pERK leads to decreased expression of pCREB, suggesting that pain can be controlled by inhibiting ERK and expression of its downstream functional factor CREB.

Phosphorylation is the basis of the transcription function of CREB, and pERK can migrate from the cytoplasm to the nucleus and phosphorylate CREB to play its role in modulating the target genes. Peripheral nociception triggers the expression of pCREB in the spinal cord dorsal horn of rat models of chronic pain, while intrathecal injection of CREB inhibitor significantly inhibits pain induced by nociception[33]. This indicates that CREB plays an important role in central sensitization and long-term neural plasticity, which is a potential mechanism by which activated ERK participates in central sensitization and development of chronic pain[34].

By adopting the rat model of Crohn's disease CIVP induced by TNBS/ethanol enema, we observed the effect of HPM on the phosphorylated protein and mRNA expression of MEK1, ERK1/2 and CREB in the spinal cord. CIVP rats had both visceral and somatic pain, manifested by increased AWR, decreased pain threshold, and reduced MWT and TWL. The expression of phosphorylated protein and mRNA of MEK, ERK and CREB was increased significantly in the models, showing that the MEK/ERK/CREB signaling pathway in the spinal cord is activated in CIVP rat models. After application of MEK inhibitor, expression of phosphorylated protein and mRNA of MEK1, ERK1/2 and CREB was decreased significantly, and the pain behavior also showed significant improvement, suggesting a close relationship between the MEK/ERK/CREB pathway in the spinal cord and CIVP. After HPM at Tianshu (ST25) and Qihai (CV6), expression of phosphorylated protein and mRNA of MEK1, ERK1/2 and CREB was also decreased significantly, indicating that HPM can inhibit activation of the MEK/ERK/CREB pathway in the spinal cord of CIVP rats and improve pain behavior. In summary, the MEK/ERK/CREB signaling pathway is closely associated with the development of CIVP. HPM can alleviate the pain in CIVP rats, and this action is related to inhibition of the MEK/ERK/CREB pathway in the spinal cord (Figure 7).

We suppose that HPM exerts its analgesic effect through down-regulating phosphorylation and mRNA expression of MEK1, ERK1/2 and CREB in the spinal cord of CIVP rats, and subsequently inhibiting activation of the MEK/ERK/CREB signaling pathway. However, this study only focused on the MEK/ERK/CREB pathway in the spinal cord to discover the analgesic mechanism of HPM, and it is unclear whether other MAPK pathways, such as p38 MAPK and C-Jun N-terminal kinase, are involved in the signal transmission in CIVP. Pain has a complex pathogenesis, and a variety of non-neural cells, for example, glial cells and stem cells, also play an important role in the development of inflammation and pain[35]. The relationship between these cells and the MEK/ERK/CREB signaling pathway, and the questions in which cells this signaling pathway is activated, and how they bind, require further studies.

COMMENTS

Background

Recent studies suggest that central sensitization is one of the critical factors causing chronic inflammatory visceral pain (CIVP), and the extracellular signal-regulated kinase (ERK) signaling pathway is involved in transduction of pain signals. Moxibustion can effectively mitigate CIVP, but its potential mechanism is still unknown.

Research frontiers

The pathogenesis of CIVP is complicated, involving multiple neurotransmitters, cytokines and signaling pathways. ERK signaling pathway is closely related to the development of pain and inflammation. Moxibustion can successfully mitigate CIVP, and studies on the ERK signaling pathway will help reveal its mechanism of action.

Innovations and breakthroughs

This study discovered that the spinal cord MEK/ERK/CREB signaling pathway was activated in CIVP rats. Herb-partitioned moxibustion (HPM) exerted its analgesic effect by down-regulating protein phosphorylation and mRNA expression of mitogen-activated extracellular signal-regulated kinase MEK, ERK1/2 and cAMP response element binding protein (CREB), and inhibiting activation of the MEK/ERK/CREB signaling pathway in the spinal cord of CIVP rats.

Applications

To provide experimental evidence for HPM in treating CIVP, and the results may

reveal one of the mechanisms of the analgesic effects of HPM in treating CIVP.

Terminology

HPM is an external therapy in traditional Chinese medicine that reduces chronic inflammatory pain.

Peer-review

The authors aimed to investigate the effect of HPM on the phosphorylation of MEK1, ERK1/2 and CREB in spinal cord of rats with CIVP, and to explore the central mechanism of HPM in treating CIVP. This is a great, exciting and very tough study relying on establishing a rat model.

Abstract

AIM

To examine the changes of the ghrelin/ghrelin O-acyltransferase (GOAT) axis and the mammalian target of rapamycin (mTOR) pathway in the hypothalamus after sleeve gastrectomy.

METHODS

A total of 30 obese type-2 diabetes Sprague-Dawley (SD) rats, 6 wk of age, fed with high-sugar and high-fat fodder for 2 mo plus intraperitoneal injection of streptozotocin were randomly divided into three groups: non-operation group (S0 group, n = 10), sham operation group (Sh group, n = 10) and sleeve gastrectomy group (SG group, n = 10). Data of body mass, food intake, oral glucose tolerance test (OGTT), acylated ghrelin (AG) and total ghrelin (TG) were collected and measured at the first day (when the rats were 6 wk old), preoperative day 3 and postoperative

week 8. The mRNA expression of preproghrelin, GOAT and neuropeptide Y (NPY), and protein expression of ghrelin, GOAT, GHSR and the mTOR pathway (p-Akt, p-mTOR and p-S6) were measured in the hypothalamus.

RESULTS

SG can significantly improve metabolic symptoms by reducing body mass and food intake. The obese rats showed lower serum TG levels and no change in AG, but the ratio of AG/TG was increased. When compared with the S0 and Sh groups, the SG group showed decreased TG (1482.03 ± 26.55, 1481.49 ± 23.30 and 1206.63 ± 52.02 ng/L, respectively, $P < 0.05$), but unchanged AG (153.06 ± 13.74, 155.37 ± 19.30 and 144.44 ± 16.689 ng/L, respectively, $P > 0.05$). As a result, the ratio of AG/TG further increased in the SG group (0.103 ± 0.009, 0.105 ± 0.013 and 0.12 ± 0.016, respectively, $P < 0.05$). When compared with the S0 group, SG suppressed mRNA and protein levels of preproghrelin (0.63 ± 0.12 *vs* 0.5 ± 0.11, $P < 0.05$) and GOAT (0.96 ± 0.09 *vs* 0.87 ± 0.08, $P < 0.05$), but did not change NPY mRNA expression (0.61 ± 0.04 *vs* 0.65 ± 0.07, $P > 0.05$) in the hypothalamus. The protein levels of p-Akt, p-mTOR and p-S6 were higher in the SG group, which indicated that the hypothalamic mTOR pathway was activated after SG at the postoperative week 8.

CONCLUSION

The reduction of ghrelin expression and activation of the mTOR pathway might have opposite effects on food intake, as SG improves obesity and T2DM.

Core tip: Recent studies have demonstrated a complex relationship between ghrelin, ghrelin O-acyltransferase (GOAT) and the mammalian target of rapamycin (mTOR) pathway. In our study, we examined the changes of the ghrelin/GOAT axis and the mTOR pathway in the hypothalamus after sleeve gastrectomy (SG). The mRNA and protein levels of ghrelin and GOAT decreased after SG, while NPY mRNA expression did not change. We also found that SG increased the protein levels of p-Akt, p-mTOR and p-S6. The reduction of ghrelin expression and activation of the mTOR pathway might have opposite effects on food intake. These findings might explain the weight, glucose and food intake regain after SG.

Changes of Ghrelin/GOAT axis and mTOR pathway in the hypothalamus after sleeve gastrectomy in obese type-2 diabetes rats. *World J Gastroenterol* 2017; 23(34): 6231-6241 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6231.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6231

INTRODUCTION

Obesity and type-2 diabetes mellitus (T2DM) are closely related epidemic diseases with increasing incidence rates worldwide. Lifestyle factors such as high-fat diet, lack of physical activity, genetic and environmental factors are important causes of diabetes. As one of the most commonly used bariatric surgeries, sleeve gastrectomy (SG) can effectively reduce obesity and improve metabolic symptoms by weight loss and hormonal change. Recent studies have found that weight loss and T2DM remission may be related to ghrelin, bile acids and microbiota changes after SG[1].

Ghrelin, mainly found in the stomach, is an endogenous ligand for the growth hormone secretagogue receptor type 1a (GHS-R1a) and has two major molecular forms, acylated ghrelin (AG) and unacylated ghrelin (UAG)[2-4]. As the activated form of ghrelin, AG is best known for its effect on growth hormone-releasing neurons. For instance, AG was shown to increase neuropeptide Y (NPY) mRNA expression levels by the mammalian target of rapamycin (mTOR) in the hypothalamus[5,6]. The enzyme responsible for transforming UAG to AG was identified in 2008 and named ghrelin O-acyltransferase (GOAT)[7]. A recent study found that AG could regulate GOAT expression in the stomach[8] and that the widespread expression of GOAT corresponded to the widespread distribution of ghrelin expression, *e.g.*, in the pancreas, stomach and hypothalamus[8,9]. Multiple studies have demonstrated that both ghrelin and GOAT play important roles in the regulation of obesity, blood glucose and insulin[5,10,11]. However, it is not clear whether the ghrelin/GOAT axis in the hypothalamus (*via* autocrine/paracrine signaling) is involved in the maintenance of blood glucose concentrations and energy homeostasis by restricting food intake after SG.

Recent studies suggested that the mTOR pathway may play an important role and have complex impact on several cellular functions, such as cell growth, weight loss, food intake and even insulin resistance[12-16]. It was also demonstrated that both energy deprivation and AG can activate the mTOR pathway to affect food intake[6,17]. Meanwhile, insulin inhibits GOAT expression *via* the mTOR pathway in islet cells[3] and SG can suppress the mRNA levels of preproghrelin and GOAT in a remnant stomach[18]. However, changes of the Ghrelin/GOAT axis and the mTOR pathway in the hypothalamus after SG have not yet been investigated. The aim of this study was to evaluate these changes to explain the mechanism of SG from a central point of view.

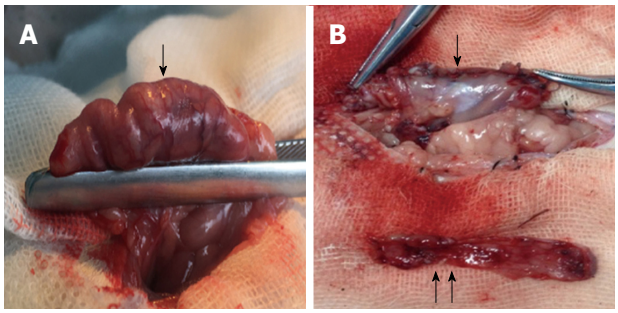

Figure 1 An intact stomach before SG (A) and the remnant stomach (↓) and resected gastric fundus (↑↑) after SG (B). The ↓ appearing in the figure A means that the gastric fundus and a large portion of the gastric body should be resected.

MATERIALS AND METHODS

Animals and experimental protocol

Seventy-seven male Sprague-Dawley rats (6 wk of age, weight: 150-180 g) were obtained from the Laboratory Animal Center of the Second Military Medical University. Equipment and reagents were obtained from the following sources: electronic analytical balance (Libror AEL-200 type, Japan); Roche glucometer (ACCU-CHEK® Performa, Roche Diagnostics); streptozotocin (Sigma-Aldrich, China); rat total ghrelin, AG and Insulin ELISA assay kit (R&D system, United States); ghrelin, GHSR, GOAT, p-AKT(s473), mTOR, p-mTOR(s2448), P70s6k, GAPDH antibody (Abcam, United States); and p-S6 (s235/236) antibody (Sigma-Aldrich, United States). All procedures conformed to the institutional standards of The Second Military Medical University Animal Care and Use Committee (approval no. SCXK(H) 2013-0016).

Establishment of the animal model

Rats had a mean body mass of 173.82 ± 14.32 g and were randomly divided into NF (fed normal fodder, n = 20) or HF groups (fed high-sugar and high-fat fodder, n = 57). During the 2-mo experiment, all rats were housed at 20-25 ℃ and 40%-60% relative humidity. Rats with a 20% higher body mass than the average weight of the NF group[19] were defined as obese rats. Noninsulin-dependent diabetes mellitus was induced in overnight-fasted rats by a single intraperitoneal injection of 45 mg/kg streptozotocin. Blood glucose was measured from the tail vein once daily within 3 d after injecting streptozotocin. Only the rats with an average blood glucose concentration > 16.7 mmol/L were included as successful T2DM models. Of all rats, 32 models were successfully established, with a success rate of 56.14%.

Animal grouping

Of the 32 T2DM model rats, two rats died after SG. The remaining 30 rats were randomly divided into three groups: non-operation (S0 group, n = 10), sham operation (Sh group, n = 10) or sleeve gastrectomy group (SG group, n = 10).

Surgical operation and intervention study

All rats of the operation groups (both Sh and SG) were food- and water-deprived for 12 h before surgery. The rats were anesthetized by an i.p. injection of 0.3% sodium pentobarbital (50 mg/kg) and observed until corneal and pain reflexes were absent. A hypodermic injection of 0.9% sodium chloride solution (20 mL) and an intramuscular injection of penicillin sodium (800000 IU) were given to prevent dehydration and infection before the surgery began.

A 3-cm incision was made 1 cm below the xiphoid process. After opening the abdominal cavity and exposing the stomach, the ligaments surrounding the stomach and gastroepiploic tissues were broken. A 3-5-mm transverse incision was made along the greater curvature to empty the stomach contents. This step could avoid the contents outflowing quickly to prevent abdominal infection. After empting the stomach, the gastric fundus and a large portion of the gastric body (70% of the total stomach) were resected (Figure 1A). The residual stomach was then closed by a single-layer continuous suture using 6-0 absorbable lines (Figure 1B). Before closure of the skin, the abdominal cavity was rinsed with a warm 0.9% sodium chloride solution (20-30 mL).

Sham-operated rats underwent a similar procedure as the SG group, including anesthesia, a 3-5-mm transverse incision was made along the greater curvature near the pylorus to empty stomach contents. After empting the stomach, the incision was extended to 2 cm, with a waiting time that corresponded to the resection time in SG rats, followed by stomach closure. Rats that were operated on were allowed access to water 2 h after surgery, but were fasted for 24 h after operation. After 2-3 d, they were fed a non-residue diet; and after recovery, they consumed their preoperative diet.

Body mass, food intake, oral glucose tolerance test, ghrelin measurements

Body mass was measured once every 5 d preoperatively and once a day postoperatively for 8 wk. Food intake was measured by recording the total amount of fodder consumed per week. To perform the oral glucose tolerance test (OGTT), all rats were fasted overnight and received a 50% glucose solution (1 g/kg) by oral gavage[20]. Blood was collected from the orbital vein to measure the glucose and insulin concentrations at 0, 15, 30, 60, 90 and 120 min after glucose infusion at the first day (rats were 6 wk old), preoperative day 3 and postoperative week 8. The area under the glucose curve (AUC-glucose), AUC-insulin and HOMA-IR (fasting insulin × fasting glucose/22.5) were calculated. The blood collected from the OGTT at 0 min was also used to measure AG and TG.

Hypothalamic tissue was collected for Western

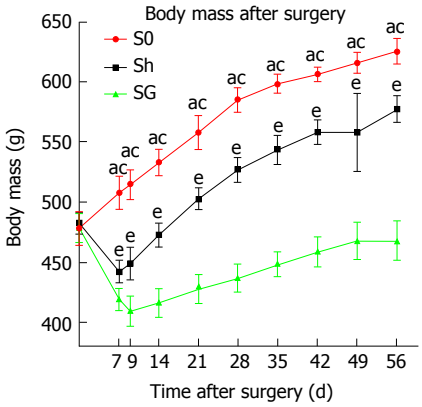

Figure 2 Body mass before and after surgery. Statistical differences were analyzed by one-way ANOVA followed by the LSD-*t* test. $^{a}P < 0.05$, S0 *vs* SG; $^{c}P < 0.05$, S0 *vs* Sh; $^{e}P < 0.05$, Sh *vs* SG. LSD: Least significant difference; Sh: Sham operation group; SG: Sleeve gastrectomy.

blotting and real-time polymerase chain reaction (PCR). All rats were sacrificed by an overdose of anesthesia. Sections containing the hypothalamus were cut according to the rat brain atlas of Paxinos and Watson and immediately frozen in liquid nitrogen[21].

Western blot analysis

The hypothalamus was crushed in PMSF lysate (50 mmol/L Tris-HCl, pH 8.0, 150 mmol/L NaCl, 1% Triton X-100, 100 μg/mL PMSF) for 30 min and then centrifuged at 12000 rpm for 5 min. Protein concentration was measured by the BCA protein assay reagent. A total of 40 μg protein was separated by a 10% SDS-PAGE and transferred to polyvinylidene fluoride membranes. All membranes were incubated overnight at 4 ℃ with primary antibodies. They were then incubated with secondary antibodies at room temperature for 1 h and visualized using the GChemiDoc MP imaging system and image lab software (Bio-Rad, United States). All results were expressed as target protein/GAPDH ratio.

Real-time PCR analysis

Total RNA was extracted with Trizol Reagent (Invitrogen, United States). Then, 2 μg total RNA was reversely transcribed with Oligo (dT) primer and M-MLV Reverse Transcriptase (Promega, United States), according to the manufacturer's instructions. The complementary DNA was used for real-time PCR, and a final volume of 20 μL was made as follows: 10 μL 2 × SYBR premix exTaq (TaKaRa, China), 0.8 μL forward and reverse primers (2.5 μmol/L, 5 μL cDNA, 4.2 μL ddH_2O). PCR and data collection were performed on a CFX Connect™ Real-Time PCR Detection System (Takara), and data analysis was operated with the $2^{-\Delta\Delta Ct}$ method normalized to the endogenous control β-actin. Primers used in real-time PCR were as follows: Rat preproghrelin: 5′-AAGCCCAGCAGAGAAAGGAATC-3′ (forward); 5′-CAACATCGAAGGGAGCATTGAAC-3′ (reverse). Rat GOAT: 5′-ATTTGTGAAGGGAAGGTGGAG-3′ (forward); 5′-CAGGAGAGCAGGGAAAAAGAG-3′ (reverse). Rat NPY: 5′-GGCCAGATACTACTCCGCTC-3′ (forward); 5′-GTCTTCAAGCCTTGTTCTGGG-3′ (reverse). Rat β-actin: 5′-GAGACCTTCAACACCCCAGCC-3′ (forward); 5′-TCGGGGCATCGGAACCGCTCA-3′ (reverse).

Statistical analysis

Data are presented as the mean ± SD. SPSS 20.0 (IBM, New York, United States) was used for statistical analyses, and GraphPad Prism 6.0c (GraphPad Software, San Diego, CA, United States) was used to edit images. Statistical indicators between the three groups (S0, Sh and SG) were determined by one-way ANOVA, followed by least significance difference (LSD) *post hoc* comparison. The statistical indicator between two time points in one group was determined by a paired *t* test, whereas Student's *t* test was used to compare the means of two independent groups at the same time point.

RESULTS

Body mass and food intake

Baseline body mass before surgery did not differ between groups ($P > 0.05$). Rats in the Sh group and SG group weighed significantly less in the first postoperative week, which gradually normalized and increased in the second week after surgery when rats continued with their preoperative diet. The minimum weight was 442.17 ± 9.57 g in Sh rats at postoperative day 7 and 409.25 ± 12.7 g in SG rats at postoperative day 9. The weight in the sham group was restored to preoperative levels at postoperative day 17. The weight of SG rats remained low and did not reach baseline levels (Figure 2).

Food intake was significantly decreased in the Sh group and the SG group but was consistently higher in the Sh group compared to the SG group (Figure 3).

OGTT

Fasting blood glucose: Fasting blood glucose did not differ between treatment groups at the first day ($P > 0.05$) and significantly increased in obese model rats ($P < 0.05$). Eight weeks after surgery, the fasting blood glucose levels in the SG group were significantly lower than in the S0 and Sh groups ($P < 0.05$; Table 1)

Blood glucose and AUC-glucose: Blood glucose levels of the S0, Sh and SG groups did not differ among all the time points at the first day but significantly increased as rats became obese. Blood glucose levels and AUC-glucose in the SG group significantly decreased after surgery and were significantly lower than in the S0 and Sh groups (Figure 4 and Table 2).

Blood insulin and AUC-insulin: Fasting insulin and

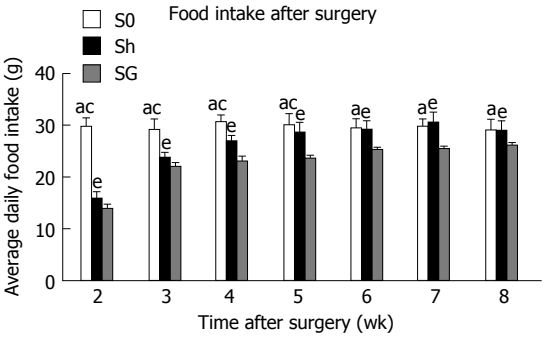

Figure 3 Food intake after surgery. Statistical differences were analyzed by one-way ANOVA followed by the least significant difference-*t* test. $^{a}P < 0.05$, S0 *vs* SG; $^{c}P < 0.05$, S0 *vs* Sh; $^{e}P < 0.05$, Sh *vs* SG. LSD: Least significant difference; Sh: Sham operation group; SG: Sleeve gastrectomy.

Table 1 Changes in fasting blood glucose

Time points	Fasting blood glucose (mmol/L)		
	S0	Sh	SG
First day	6.18 ± 1.19	5.89 ± 1.12	6.19 ± 0.94
Preoperative	15.03 ± 2.4[a]	15.9 ± 1.2[a]	15.88 ± 2.32[a]
Postoperative wk 8	14.55 ± 1.29	14.29 ± 1.69	9.00 ± 1.17[c,e]

Statistical differences among the three groups were analyzed by one-way ANOVA followed by LSD-*t* and between two time points in one group using a paired *t* test. $^{a}P < 0.05$, preoperative *vs* first day levels in the same group; $^{c}P < 0.05$, postoperative *vs* preoperative levels in the SG group; $^{e}P < 0.05$, SG *vs* S0 and Sh postoperatively. LSD: Least significant difference; Sh: Sham operation group; SG: Sleeve gastrectomy.

maximal insulin were significantly increased, and the maximal insulin excretion time was at the 90th min in all groups after glucose loading at preoperative day 3, while the maximal insulin excretion time was at the 60th min after glucose loading on the first day. Compared with the S0 and Sh groups, the SG group had lower fasting insulin and maximal insulin concentrations. The maximal insulin excretion time in SG rats was at the 60th min again. AUC-glucose and AUC-insulin were increased in all obese model groups and were significantly reduced in the SG group at 8 weeks after surgery. HOMA-IR, which reflects insulin resistance, was also significantly reduced in the SG group (Table 3, Figures 5 and 6).

TG and AG

The obese rats showed a lower serum TG level and no change in AG, but the ratio of AG/TG was increased. When compared with the S0 and Sh groups, the SG group showed decreased TG (1482.03 ± 26.55, 1481.49 ± 23.30 and 1206.63 ± 52.02 ng/L, respectively, $P < 0.05$) but unchanged AG (153.06 ± 13.74, 155.37 ± 19.30 and 144.44 ± 16.689 ng/L, respectively, $P > 0.05$). As a result, the ratio of AG/TG was further increased in the SG group (0.103 ± 0.009, 0.105 ± 0.013 and 0.12 ± 0.016, respectively, $P < 0.05$) (Figure 7).

mRNA expression levels of preproghrelin, GOAT and NPY in the hypothalamus

The mRNA expression levels of preproghrelin and GOAT were lower in the SG group than in the S0 group, while NPY mRNA expression did not differ between groups (Table 4).

Ghrelin, GHSR and GOAT protein in the hypothalamus

Ghrelin and GOAT protein expression was significantly reduced in SG rats, while the level of GHSR protein expression was increased (Figure 8).

Protein expression of the mTOR pathway in the hypothalamus

The levels of p-Akt, p-mTOR and p-S6 protein expression were higher in the SG group, while the protein expression levels of mTOR and P70S6K did not differ between the Sh and SG groups (Figure 9).

DISCUSSION

As a bariatric surgery, SG can not only significantly reduce body weight but also effectively improve T2DM and obesity-induced metabolic complications[1]. More and more surgeons worldwide choose SG, especially in Asia, because of the less difficulty and complications of SG when compared with other bariatric surgeries. As the number of SGs is increasing, the surgeons' viewpoint of SG changes from bariatric surgery to metabolic surgery. However, when compared with Roux-en-Y gastric bypass (RYGB), which is regarded as the "gold standard" in metabolic surgery, the effect of SG on improving metabolic symptoms and weight loss is seemingly imperfect[22-24]. Weight and blood glucose regain is still the most disputed problem after SG. Our data showed that body mass, food intake, fasting blood glucose, postprandial blood glucose, AUC-glucose, AUC-insulin and HOMA-IR were significantly reduced after SG. However, the body mass levels at postoperative week 8 were comparable to the preoperative level. Remarkably, hyperglycemia and insulin resistance were significantly improved. The mechanism of SG is still unclear; the most important mechanisms are believed to be the restriction of calories and the complex hormonal changes. One of these hormonal changes include the markedly reduced ghrelin levels after removal of the gastric fundus.

Previous studies demonstrated that low plasma ghrelin levels are beneficial in elevating fasting insulin levels and improving hyperglycemia, insulin resistance and obesity, while higher levels of ghrelin inhibit insulin release in the pancreas and enhance the food intake signals in the hypothalamus[25,26]. Furthermore, ghrelin gene knock-out mice had lower blood glucose and higher blood insulin levels[5]. As one of the two existing forms of ghrelin in the body, AG is commonly considered the active form due to its "negative" effect

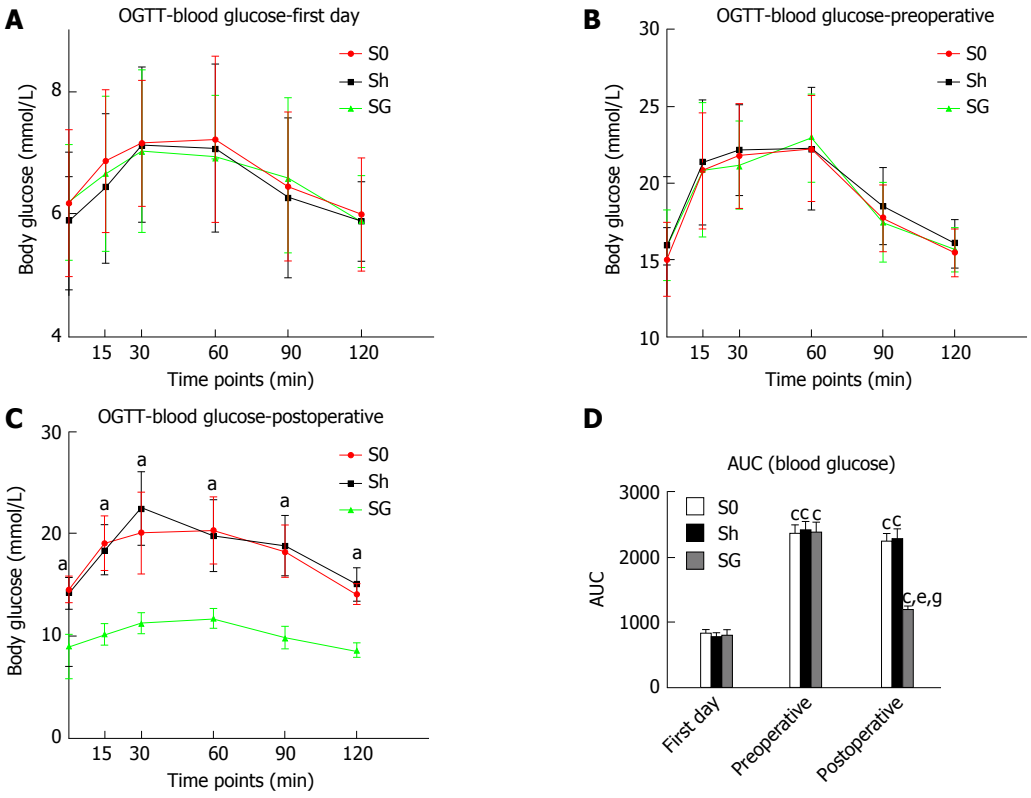

Figure 4 Oral glucose tolerance test curve of blood glucose at the first day (A), preoperatively (B) and postoperatively (C) and AUC-blood glucose (D). on blood glucose metabolism and positive effect on food intake signals in the hypothalamus[27,28], whereas UAG can antagonize AG's effects[29-31]. Recent studies found that obese individuals have lower blood ghrelin levels but no change in serum AG levels or the ratio of AG/UAG. SG can further reduce serum UAG but not AG levels and increase the ratio of AG/UAG[32]. Our data demonstrated that the level of TG was significantly decreased in obese rats; however, AG levels were unchanged and the ratio of AG/TG was increased. As shown in Figure 7, SG can further reduce the serum TG levels after SG-induced resection of the gastric fundus. However, AG was still not changed, but the ratio of AG/TG was further increased. Since SG can only reduce the levels of serum TG or UAG, it is unclear how SG can improve obesity and T2DM with increasing ratios of AG/TG or AG/UAG. Previous studies mentioned that ghrelin secretion depends on a specific secretion cue related to fasting and feeding[33], which should be abolished by SG. However, ours and other studies did not confirm whether SG really abolished ghrelin's special cyclic secretion. We propose that altered ghrelin secretion cues might be more important than plasma TG, AG or UAG in SG-induced improvement of obesity and metabolic symptoms.

AS is required for active ghrelin to bind with and activate its receptor; GOAT is essential for octanoylation of ghrelin[34]. A number of studies demonstrated that GOAT mainly exists in tissues that play an important role in the regulation of food intake, blood glucose metabolism and energy homeostasis, such

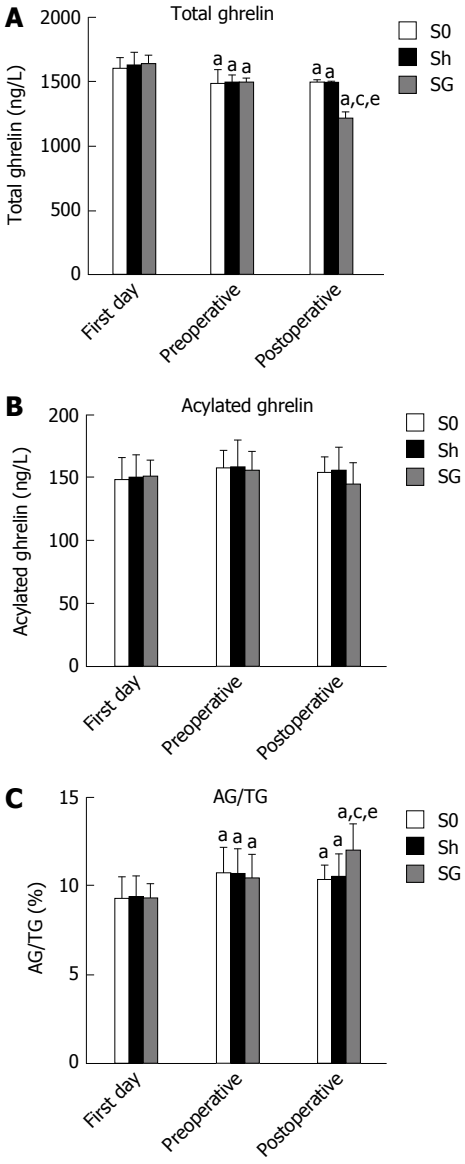

Figure 7 Changes of total ghrelin (A), acylated ghrelin (B) and acylated ghrelin/total ghrelin (C) at the first day, preoperatively and postoperatively. Statistical differences among the three groups at the same time point were analyzed by one-way ANOVA followed by the LSD-*t* test and between two time points in the same group using paired *t* test. $^{a}P < 0.05$, preoperative or postoperative *vs* first day levels in the same group; $^{c}P < 0.05$, postoperative *vs* preoperative levels in the SG group; $^{e}P < 0.05$, SG *vs* S0 and Sh postoperatively. as the stomach, hypothalamus and pancreas[8]. However, the relationship between GOAT expression and energy homeostasis is inconsistent. Gonzalez[35] found that a 30% food reduction for 21 d increased GOAT expression in the gastric mucosa, while a 48-h fasting period had no effect on GOAT expression in rats. On the contrary, other studies reported that GOAT expression was decreased after food restriction[36,37]. Body energy level is not the only factor determining GOAT expression. Gahete *et al*[8] found that AG could increase GOAT expression in the stomach, whereas insulin inhibited the expression of GOAT mRNA *via*

Table 4 Hypothalamic mRNA expression of preproghrelin, ghrelin O-acyltransferase and neuropeptide Y

X-mRNA/β-acting-mRNA	S0	SG
Preproghrelin	0.63 ± 0.12	0.50 ± 0.11[a]
GOAT	0.96 ± 0.09	0.87 ± 0.08[a]
NPY	0.61 ± 0.04	0.65 ± 0.07

Hypothalamic mRNA expression of preproghrelin, GOAT and NPY was quantified using PCR and expressed as the ratio to the β-actin mRNA. Statistical differences between the two groups were analyzed using Student's *t* test. $^{a}P < 0.05$, S0 *vs* SG. GOAT: Ghrelin O-acyltransferase; SG: Sleeve gastrectomy; NPY: Neuropeptide Y.

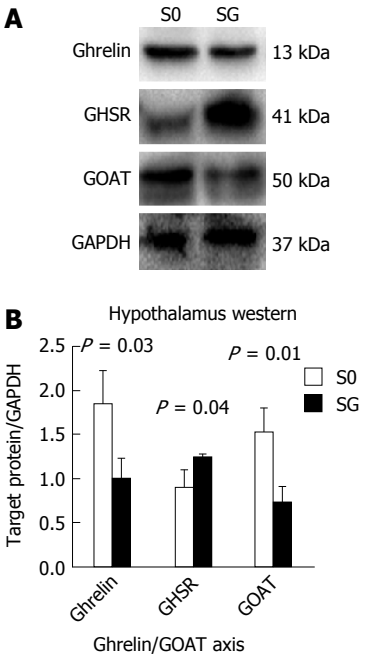

Figure 8 Ghrelin/ghrelin O-acyltransferase axis in hypothalamus. A: Expression of ghrelin, GOAT and GHSR protein in the hypothalamus. GAPDH was used as an internal control; B: Ratio of target protein gray value to GAPDH gray value. Statistical differences between the two groups were analyzed by Student's *t* test. GOAT: Ghrelin O-acyltransferase; SG: Sleeve gastrectomy.

the mTOR pathway[3]. In our study, both mRNA and protein expression levels of ghrelin and GOAT significantly decreased after SG, while GHSR protein expression significantly increased. As mentioned above, this phenomenon may be related to the abolishment of ghrelin's special cyclic secretion. The "override inhibition" theory[38] describes a phenomenon in which hormones, normally secreted in response to an episodic stimulus, are paradoxically inhibited when that stimulus occurs continuously. Therefore, SG may eliminate the periodic effect of cyclic ghrelin on the hypothalamus, resulting in a reduced expression level of preproghrelin mRNA and ghrelin protein, as well as a GHSR compensatory increase. The reduction of GOAT mRNA and protein may be due to a local ghrelin decrease and energy deprivation after SG. Although ghrelin was significantly decreased, the level of NPY mRNA expression in SG rats did not change, which

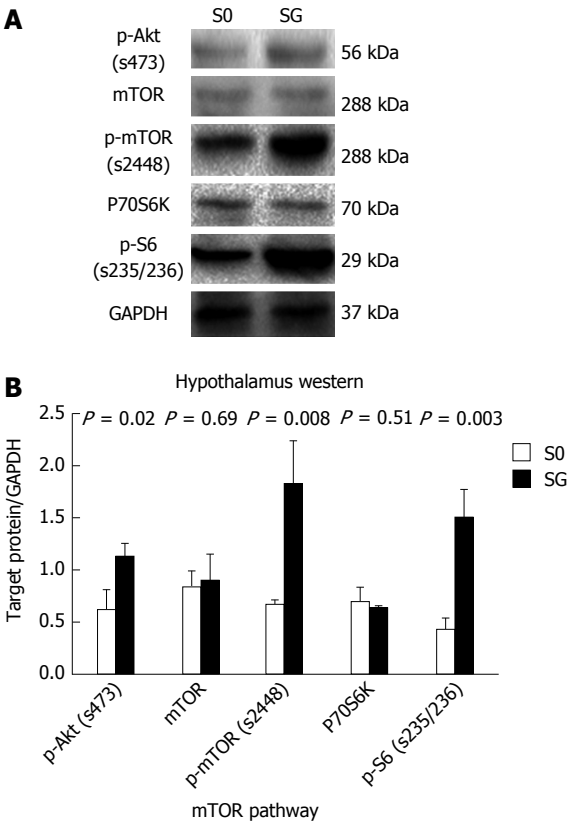

Figure 9 The mammalian target of rapamycin pathway in hypothalamus. A: Protein expression of the mTOR pathway in the hypothalamus. GAPDH was used as an internal control; B: Ratio of target protein gray value to GAPDH gray value. Statistical differences between the two groups were analyzed by Student's *t* test. SG: Sleeve gastrectomy; mTOR: Mammalian target of rapamycin.

may be related to the activation of the mTOR pathway in the negative energy balance of the hypothalamus after SG.

Several studies have shown that the hypothalamic mTOR pathway plays a major role in the regulation of energy homeostasis and food intake[6]. A recent study demonstrated that energy deprivation and administration of ghrelin into the 4th ventricle led to increased levels of p-mTOR and increased NPY mRNA expression and promoted feeding through the activation of the hypothalamic mTOR pathway. Moreover, rapamycin could significantly inhibit mTOR activity and reduce food intake[6,17]. Our data suggest that SG can significantly increase the protein levels of p-Akt, p-mTOR and p-S6 in the hypothalamus. As a classic restrictive metabolic surgery, it is possible that SG first reduces the calorie intake, which then activates the mTOR pathway. Therefore, the activation of the mTOR pathway may be the reason for the increased NPY level after SG.

One of the limitations of our study is that we did not compare SG with other restrictive metabolic surgeries. Kawasaki *et al*[21] found no difference in hypothalamic mRNA expression of NPY between normally fed rats and SG rats. However, when compared with gastric banding rats, the NPY mRNA expression in SG rats was significantly lower. The reduction of ghrelin expression and activation of the mTOR pathway might have an opposite effect on food intake after SG.

Overall, altered glucose metabolism and food intake changes following SG should be divided into peripheral and central changes. In the periphery, SG can significantly reduce food intake by decreasing gastric volume and changing blood ghrelin levels. Further studies should focus on how SG changes ghrelin's special cyclic secretion, especially AG's. In the center, as mentioned above, we found two opposite factors for the regulation of food intake. A recent study has shown that a residual stomach expansion occurred in more than 50% of the SG patients over a short-term period[39,40]. Increased food intake may be the most important factor for the residual stomach expansion. The results of our study provide a clue for further studies on SG and its regulation of food intake from a central point of view.

COMMENTS

Background

Sleeve gastrectomy (SG), which is a classic restrictive metabolic surgery, becomes more and more popular worldwide because of its less difficulty and complications. However, weight and blood glucose regain is still the most disputed problems after SG. Increasing food intake might be the most important reason for these problems.

Research frontiers

This study aimed to examine the changes of the ghrelin/ghrelin O-acyltransferase (GOAT) axis and the mammalian target of rapamycin (mTOR) pathway in the hypothalamus after SG. These changes provide a clue for further studies on SG and its regulation of food intake from a central point of view.

Innovations and breakthroughs

The authors compared between SG rats and non-operation rats in ghrelin/GOAT axis and the mTOR pathway in the hypothalamus, and found that SG could suppress mRNA and protein levels of preproghrelin and GOAT but did not change neuropeptide Y mRNA expression. The protein levels of p-Akt, p-mTOR and p-S6 were higher in the SG group, which indicates that the hypothalamic mTOR pathway was activated after SG on the postoperative week 8.

Applications

The findings in this study suggest that patients who underwent SG still need to control food intake for better improvement of obesity and glucose metabolism.

Terminology

SG is a novel procedure of metabolic surgery to remove at least 70% of stomach from the greater curvature. Ghrelin, mainly found in the stomach, could increase food intake and should be inhibited after SG. GOAT is essential for transforming unacylated ghrelin to acylated ghrelin. The mTOR pathway has an important and complex impact on several cellular functions, such as cell growth, weight loss, food intake and even insulin resistance.

Peer-review

The authors examined changes of the ghrelin/GOAT axis and the mTor pathway in the hypothalamus after SG. This is a carefully done study and the findings are of considerable interest.

Abstract

AIM

To investigate whether Dihydromyricetin (DHM) inhibits cell proliferation and promotes apoptosis by downregulating Notch1 expression.

METHODS

The correlation between Notch1 and Hes1 (a Notch1

target molecule) expression in hepatoma samples was confirmed by qRT-PCR. In addition, MTT assays, flow cytometry and TUNEL analysis showed that DHM possessed strong anti-tumor properties, evidenced not only by reduced cell proliferation but also by enhanced apoptosis in QGY7701 and HepG2 hepatocellular carcinoma (HCC) cells. The expressions of Notch1, Hes1, Bcl-2 and Bax were determined by Western blot.

RESULTS

Among the tested samples (n = 64), the expression levels of Notch1 (75% of patients) and Hes1 (79.7% of patients) mRNA in tumor tissues were higher than in the normal liver tissues. There was a negative correlation between the expression of Notch1 and the degree of differentiation and positively correlated with the Alpha Fetal Protein concentration. The viability of HCC cells treated with DHM was significantly inhibited in a dose and time-dependent manner. Apoptosis was induced in HepG2 and QGY7701 cell lines following 24 h of DHM treatment. After treatment with DHM, the protein expression of Notch1 was downregulated, the apoptosis-related protein Bax was upregulated and Bcl2 was downregulated. Notch1 siRNA further enhanced the anti-tumor properties of DHM.

CONCLUSION

Notch1 is involved in the development of HCC and DHM inhibits cell proliferation and promotes apoptosis by down-regulating the expression of Notch1.

Key words: Dihydromyricetin; Apoptosis; Hepatocellular carcinoma; Notch1

© The Author(s) 2017. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: The novel findings of this study are that Notch1 is highly expressed in tumor cells with higher degrees of malignancy and proliferative activity, Notch1 is involved in the development of hepatocellular carcinoma (HCC) and may serve as a potential diagnostic marker for HCC. Dihydromyricetin can strongly induce apoptosis of the hepatic cancer cell lines QGY7701 and HepG2 by downregulating the expression of Notch1.

INTRODUCTION

Hepatocellular carcinoma (HCC) ranks sixth and third worldwide in tumor incidence and mortality, respectively[1]. Despite dramatic improvements in surgical treatment and chemotherapy, the one-year survival rate of patients diagnosed with HCC is not high[2,3]. In addition, traditional chemotherapy drugs have obvious side effects. Therefore, seeking an effective drug treatment that reduces the mortality of patients with HCC is of great significance.

Dihydromyricetin (DHM, $C_{15}H_{12}O_8$, PubChem CID: 161557) is a component of wild woody vines of the genus *Vitis*, which is a flavonoid compound[4]. DHM was reported to have antioxidant[5,6], anti-inflammatory[7], anti-hypertensive[8], hypoglycemic[9], hepatoprotective[10,11], and anti-carcinogenic effects[12]. Previous studies have reported that DHM can inhibit the invasion and metastasis of HCC cells[13]. Combined application of DHM and nedaplatin induced apoptosis of HCC cells through the p53/Bcl-2 pathway, and enhanced sensitivity to nedaplatin chemotherapy[14]. DHM has great potential as a treatment option for liver cancer.

The Notch signaling pathway plays an important role in the fate of many cells and is crucial for the biological development of embryos. The Notch pathway is composed of a transmembrane family of receptors (Notch 1-4), their ligands (Jagged 1-2, Delta-like 1-3), and downstream target genes in the HES and HEY protein families[15]. Notch receptors bind to ligands in the membranes of adjacent cells, causing the intracellular segment of the Notch receptor to release, and the receptor then travels to the nucleus, resulting in activation of Notch target genes, thus successfully mediating cell growth and development[16].

Studies of Notch and liver diseases have been conducted in recent years. Notch3 is highly expressed in HCC, can promote the self-renewal of HCC cells and plays a significant role in maintaining stem cells by downregulating β-catenin and upregulating the expression of Nanog[17]. High expression of Notch1 and Notch4 is closely associated with poor prognosis of patients with HCC[18]. Suppression of the Notch signaling pathway averts cholestatic liver fibrosis by lessening the differentiation of hepatic progenitor cells into cholangiocytes[19]. Inhibition of Notch1 expression promoted pancreatic cancer and prostate cancer cell apoptosis[20,21], but whether downregulation of Notch1 induces apoptosis in hepatoma cells has rarely been reported. Moreover, the anti-tumor activity of DHM and its regulation of the Notch pathway are still unclear.

In the present study, we demonstrated that aberrant Notch1 expression was involved in tumor progression. DHM could downregulate the expression of Notch1 to induce apoptosis in HepG2 and QGY7701 HCC cells and restrain their proliferation. Inhibition of Notch1 signaling may serve as a novel target for HCC treatment.

MATERIALS AND METHODS

Reagents and chemicals

DHM (Sigma, United States) was solubilized in 100% dimethyl sulfoxide to prepare a primary solution of 50 mmol/L and stored at -20 ℃. Rabbit anti-human

primary antibodies against Notch1, Hes1, Bcl-2 and Bax were obtained from Cell Signaling Technology (Beverly, MA, the United States of America). Notch1 siRNA was obtained from Santa Cruz Biotechnology (the United States of America). FITC Annexin V staining Kit was brought from BD Biosciences (the United States of America). MTT [3-(4,5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide] was obtained from Sigma-Aldrich Biotechnology (United States).

Clinical specimens

All patients were diagnosed with pathological primary HCC. Tissue samples were obtained from these patients during hepatectomy surgery. HCC was confirmed by pathology. All tissue samples were frozen in liquid nitrogen. This study was approved by the Medical Ethics Committee of the Affiliated Hospital of Guangdong Medical University.

Cell lines and cell culture

The cells (SK-Hep-1, QGY7703, MHCC97L, HepG2, QGY7701 and HL7702) were maintained in DMEM supplemented with 10% fetal bovine serum and antibiotics (penicillin and streptomycin) in a humidified 5% CO_2 incubator. Upon reaching 80% confluence, the cells were treated with various concentrations of DHM (0, 5, 25, 50, 100 or 150 μmol/L) for 12 h, 24 h and 36 h and DMSO treatment served as a control.

Cell inhibition and cytotoxicity assay

The cells were placed into 96-well plates and treated with different concentrations of DHM. DMSO treatment served as a control. Twenty μL of MTT (5 mg/mL) solution was transferred to each well, and then the plate was incubated at 37 ℃ for 4 h. Next, the cell supernatants were removed, and 150 μL of DMSO was added to each well to solubilize the formed crystals. The optical density values were measured at 570 nm with a spectrophotometer (PerkinElmer, the United States of America).

Apoptosis assay

The HepG2 and QGY7701 cells were seeded in the 6-well plates. Following overnight growth, the cells were pretreated with 50, 100, or 150 μmol/L DHM and incubated for 24 h. Following careful collection and suspension in binding buffer, the HepG2 and QGY7701 cells were incubated with 5 mL of annexin V-FITC and 5 mL of PI for 15 min in darkness prior to flow cytometric analysis.

Western blot

The tissues protein samples were prepared with Fastprep-24 Sample Preparation equipment (MP, United States). The cells treated with DHM were harvested and lysed in lysis buffer to assess the expression of Notch1, Hes1, Bcl-2 and Bax. Equal amounts of protein samples were loaded per well. Membranes containing protein blots were incubated in blocking buffer (5% non-fat milk) for 1 h at room temperature, and then the membranes were incubated with the primary antibodies (1:1000 dilution) at 4 ℃ overnight. Following a wash with TBST, membranes were incubated with goat anti-rabbit secondary antibodies for 1 h. Detection was performed using an Odyssey Infrared Imaging System (LI-COR Biosciences Inc., Lincoln, NE, the United States of America).

qRT-PCR analysis

Frozen tissues were used to isolate messenger RNA (mRNA) using TRIzol reagent (Invitrogen, Guangzhou, China), according to the manufacturer's protocol. Reverse transcription was performed with 1 μg of RNA using the PrimeScript RT Reagent kit with a gDNA Eraser kit (Takara Bio, Inc, Otsu, Japan). The primer sequences used were as follows: Notch1 forward, 5'-CACCCATGACCACTACCCAGTT-3' and reverse, 5'-CCTCGGACCAATCAGAGATGTT-3'; Hes1 forward, 5'-AGATCTATGCCAGCTGATAAT-3'and reverse, 5'-AAGCTTCACTTAATACAGCT-3', and 18s forward, 5'-CGGCGACGACCCATTCGAAC-3' and reverse, 5'-GAATCGAACCCTGATTCCCCGTC-3'. Data were evaluated using the comparative count method and normalized to the corresponding 18S value.

TUNEL assay

In situ cell death detection kit-POD (Roche, Switzerland) was used to detect the late-stage apoptosis. Cells were seeded in 96-well plates and treated with various concentrations of DHM. Cells were fixed with 4% paraformaldehyde, and then counterstained with 4',6-diamidino-2-phenylindole for 5 min at room temperature in the dark and observed under a fluorescence microscope (Olympus IX70, Japan) to detect the apoptotic cells.

siRNA transfection

QGY7701 and HepG2 cells were plated into 6-well plates and transfection procedures were performed according to the manufacturer's protocol. Three different Notch1 siRNA sequences were tested in both QGY7701 and HepG2 cell lines for screening the efficacy of Notch1 knockdown and selecting the best performing siRNA transcript. Notch1 siRNA-2 showed the best degree of knockdown and was used in subsequent experiments. Before each experiment, we transiently transfected cells using an Notch1 siRNA gene knockdown kit (JIMA Biotechnology Company, Shanghai, China) and the negative control siRNA.

Colony formation assay

Cells in each logarithmic growth phase were detached from culture flasks using 0.25% trypsin. Then, the cells were percussed into a single cell suspension, and 1000 cells were cultured in each well of a 6-well plate, and humidity was saturated for 1 wk. The cells were stained with crystal violet. Clones were directly counted by the naked eye or counted using a microscope, and

data were analyzed using ImageJ software.

Statistical analysis

The data were obtained from at least three independent experiments, and all results are presented as the mean ± SD. The results were evaluated using Student's *t* test, Pearson correlation analyses were used to examine the correlation of two parameters. The significance levels were defined as $P < 0.05$.

RESULTS

Notch1 expression is activated in HCC tissues and reflects differentiation properties

The expression of Notch1 protein by Western blots and found that Notch1 accumulated predominantly in HCC tissues (Figure 1A). In addition, the expression of Notch1 and Hes1 genes in HCC and normal liver tissue samples was analyzed by qRT-PCR (Figure 1B and C). Among the tested samples ($n = 64$), the expression levels of Notch1 (75% of patients) and Hes1 (79.7% of patients) mRNA in tumor tissues were higher than in the normal liver tissues (Figure 1D). A positive correlation between Notch1 and Hes1 expression suggests that high expression of Notch1 in tumors may result in an upregulation of the target gene Hes1 (Figure 1E). To clarify the role of Notch1 in tumorigenesis and tumor differentiation, we analyzed the association among Notch1 expression, AFP concentration, and the degree of tumor differentiation. There was a negative correlation between the expression of Notch1 and the degree of differentiation and a positive correlation with the AFP concentration (Figure 1F and G). The results showed that Notch1 was highly expressed in tumor cells with higher degrees of malignancy and proliferative activity. Based on the results above, Notch1 was involved in the development and progression of HCC.

DHM inhibits the proliferation of HCC cells

We also screened the Notch1 protein expression profiles in several hepatoma cell lines. Notch1 exhibited higher expression levels in hepatoma cells compared with the immortalized normal liver cell line HL7702 (Figure 2B). Among the hepatoma cell lines, we found that QGY7701 and HepG2 cells highly express Notch1. Therefore, we chose these two lines for the next experiment. MTT assays showed that the proliferation of DHM-treated QGY7701 and HepG2 cells was inhibited. After 12 h, 24 h and 36 h, the viability of HCC cells treated with DHM was significantly inhibited in a dose- and time-dependent manner (Figure 2C and D). As shown in Figure 2, the proliferation of cells was significantly inhibited after treatment with 150 μmol/L and 50 μmol/L DHM for 12 h ($P < 0.01$), and the cell viability of both QGY7701 and HepG2 cells treated with 50 μmol/L DHM for 48 h and 25 μmol/L DHM for 24 h was significantly inhibited ($P < 0.001$). The microscopy suggested that the proliferation of the two cell lines was inhibited and partial apoptosis occurred compared with the control group (Figure 2E). A colony formation assay was utilized to further determine the proliferative ability of cells treated with various concentrations of DHM, and similarly, DHM suppressed colony-forming capability in a dose-dependent manner (Figure 2F-H).

DHM induces apoptosis in HCC cells

Flow cytometry revealed that apoptosis was induced in HepG2 and QGY7701 cell lines following 24 h of DHM treatment (Figure 3A-C). A TUNEL assay was utilized to detect late-stage apoptosis of the cell lines treated with various concentrations of DHM for 24 h. In the fluorescence images, there were cells in late-stage apoptosis in both the HepG2 and QGY7701 cell lines (Figure 3D-F).

Effects of DHM treatment on proteins in the Notch1 pathway and on apoptosis-related proteins in HCC cells

In this study, Notch1, Hes1 and apoptosis-related proteins were detected by Western blotting. The results demonstrated that DHM downregulated the expression of Notch1 and Hes1 in QGY7701 and HepG2 cells. Meanwhile, Bax was upregulated, and Bcl-2 was downregulated. The results suggested that down-regulation of Notch1 activated the mitochondrial apoptotic pathway (Figure 4A and C). It is known that a lower ratio of Bcl-2/Bax leads to apoptosis, and our data showed that the ratio of Bcl-2/Bax was reduced (Figure 4B and D).

DHM induces apoptosis in HCC cells by downregulating the Notch1 pathway

To further elucidate whether the inhibition of proliferation and the promotion of apoptosis of QGY7701 and HepG2 cells were caused by the down-regulation of Notch1 following DHM treatment, siRNA was used to silence Notch1 expression, and Notch1-silenced cells were treated with DHM. The knockout efficiency of the three different Notch1 siRNA sequences is shown in Figure 5A. The expression levels of Notch1, Hes1 and the apoptotic proteins Bcl-2 and Bax were analyzed by Western blot. Compared with the control group, Bax was upregulated, and Hes1 and Bcl-2 were downregulated after the depletion of Notch1 *via* siRNA. The results were consistent with the DHM 100 μmol/L treatment group. However, the effect of the Notch1-siRNA and DHM 100 μmol/L combination on protein expression was more obvious (Figure 5B and D). As expected, the ratio of Bcl2/Bax decreased the most in the Notch1-siRNA + DHM 100 μmol/L group (Figure 5C and E). In summary, DHM exerted anti-tumor activity by downregulating the expression of Notch1.

DISCUSSION

As a multifunctional protein, Notch1 plays a role in regulating cell differentiation, development, proliferation and survival in various contexts[15,16]. Abnormal expression of Notch1 often leads to tumors. For example,

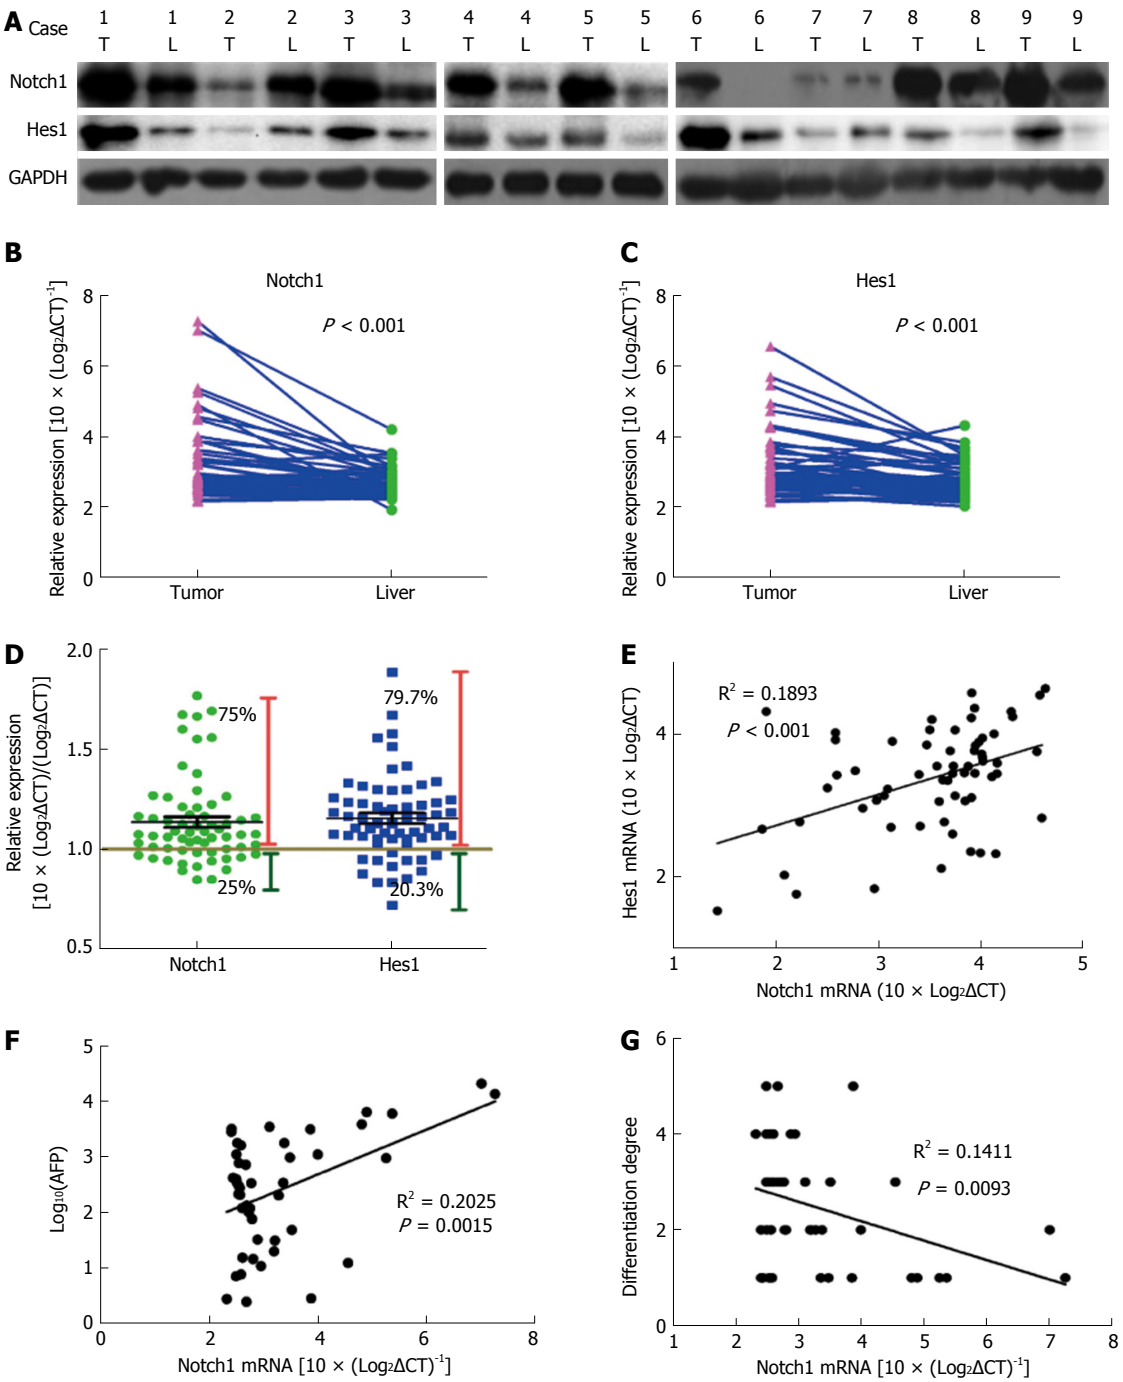

Figure 1 Notch1 expression is activated in hepatocellular carcinoma tissues and reflects differentiation properties. Protein levels were detected by Western blot analysis. A: Notch1 and Hes1 proteins were obviously abundant in most of the tumor tissues; B and C: Gene expression levels were measured with qRT-PCR. *Notch1* and *Hes1* genes were expressed at higher levels in tumor tissues compared with normal liver tissues; D: *Notch1* and *Hes1* gene expression levels were higher in 75% and 79.7% of the hepatocellular carcinoma patients, respectively; E: A Pearson correlation analysis revealed a correlation between Notch1 and Hes1 expression (r^2 = 0.1893, P < 0.001); E and G: Notch1 is positively correlated with the AFP level (r^2 = 0.2025, P = 0.0015) and negatively correlated with the degree of differentiation (r^2 = 0.1411, P = 0.0093).

in pancreatic cancer, colon cancer, non-small cell lung cancer, cervical cancer and other tumors, Notch1 expression is increased, and Notch1 participates in the promotion of cell proliferation, inhibition of apoptosis and cellular differentiation[22-24]. Overexpression of Hes1 has also been reported in the development of HCC[17]. Western blotting and qRT-PCR analysis of clinical HCC samples indicated that Notch1 and Hes1 were highly expressed in tumor samples, and the expression rates of Notch1 and Hes1 accounted for 75% and 79.7% of the total data, respectively. The above results show that Notch1-mediated activation of Notch signaling is a hallmark of HCC. This further explains the correlation among Notch1 expression, AFP (a clinical diagnostic marker of HCC) expression, and the degree of differentiation. The expression of Notch1

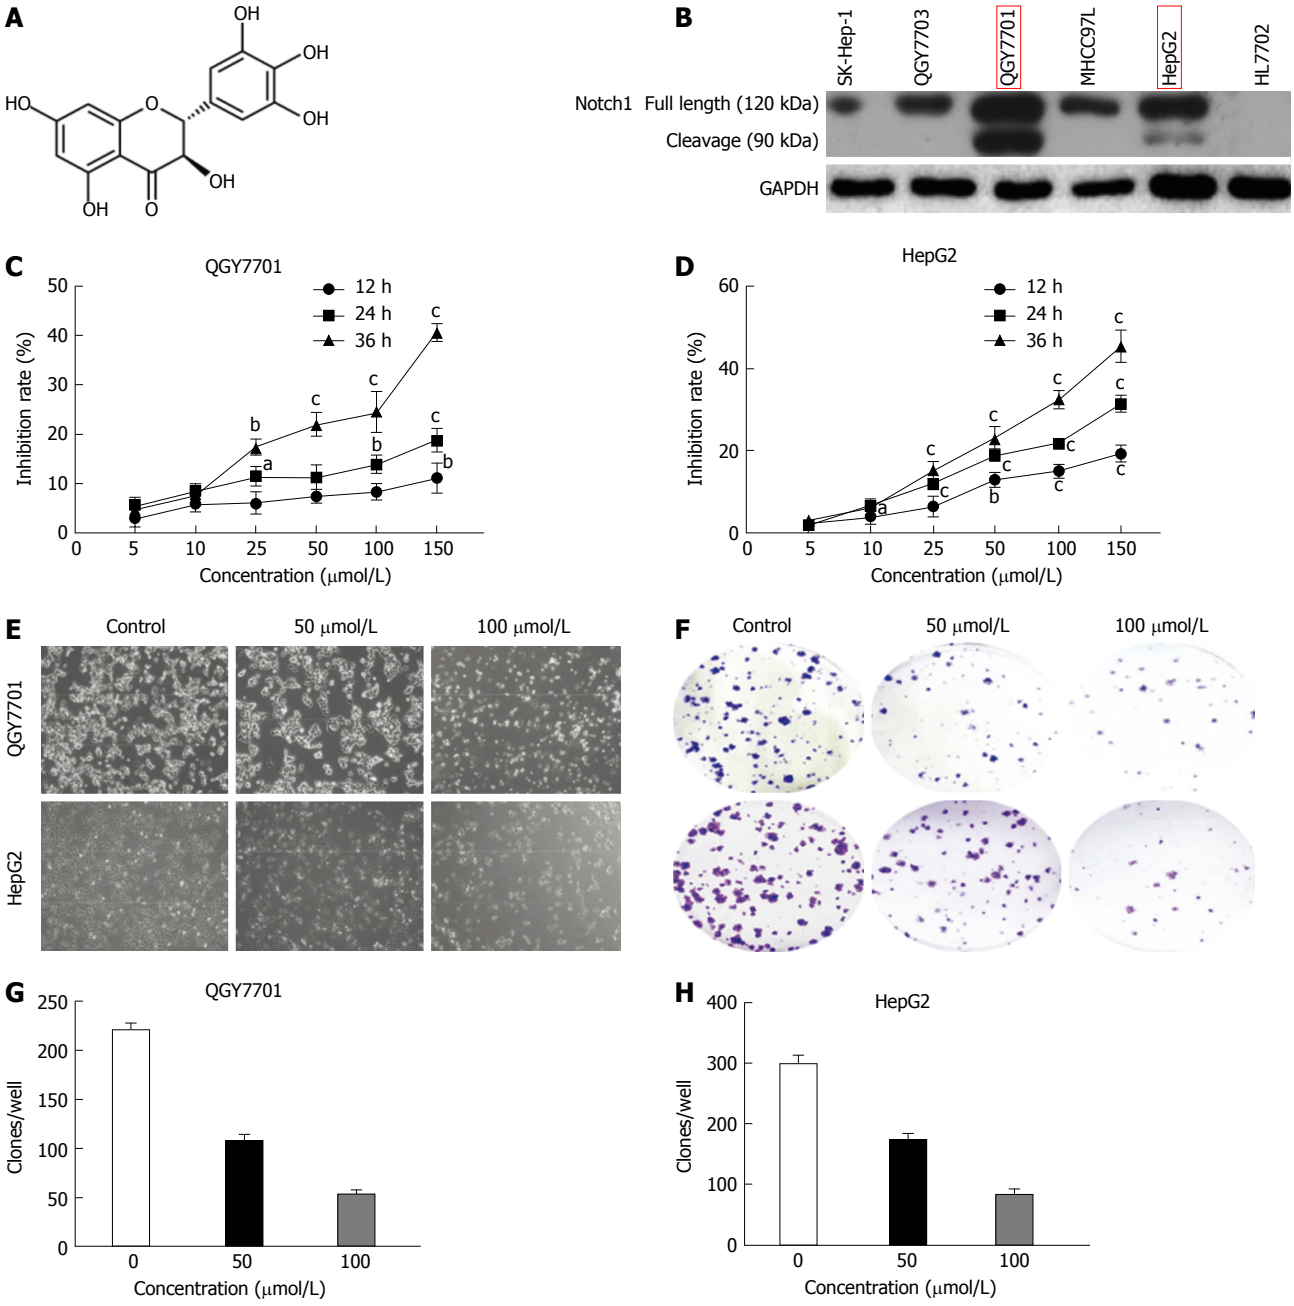

Figure 2 Dihydromyricetin inhibits the proliferation of QGY7701 and HepG2 hepatocellular carcinoma cells. A: Chemical structure of DHM; B: The Notch1 expression profiles of several hepatocellular carcinoma (HCC) cell lines were screened by Western blotting; C and D: MTT assays were used to analyze the rate of cell inhibition (means ± SD) of QGY7701 and HepG2 cells treated with dihydromyricetin (DHM) at different concentrations (5, 10, 25, 50, 100 and 150 μmol/L) at 12 h, 24 h and 36 h; E: The proliferation of QGY7701 and HepG2 cells treated with different concentrations of DHM (0, 50, or 100 μmol/L) for 24 h was observed under microscope (× 200 magnification); F: Colony formation capability assay with different concentrations of DHM in HCC QGY7701 and HepG2 cells; G and H: The clones were quantified, and the data are presented as a statistical figure; Each experiment was repeated at least three times. $^{a}P < 0.05$, $^{b}P < 0.01$ and $^{c}P < 0.001$, *vs* 0 μmol/L (control) group.

was positively correlated with AFP expression and negatively correlated with the degree of differentiation. This indicated that Notch1 is highly expressed in tumor cells with higher degrees of malignancy and proliferative activity. Experienced clinicians frequently find that tumors with higher growth activity seem to be more susceptible to chemotherapeutic treatment. These facts suggest that Notch1 is involved in the development of HCC and Notch1 may be a potential diagnostic indicator of HCC and target for chemotherapeutic treatment.

The inhibition of cell proliferation and promotion of apoptosis are common targets by many chemotherapeutic agents[25]. DHM inhibits the proliferation of diverse types of cells, including osteosarcoma, melanoma, leukemia and gastric cancer cells[26-29]. Many molecules and signaling pathways are involved in the anti-tumor effect of DHM, including the Chk1/Chk2/Cdc25C pathway[29], the NF-κB and MAPK signaling pathways[7], and the transforming growth factor-β pathway[30]. Nevertheless, the effect of DHM

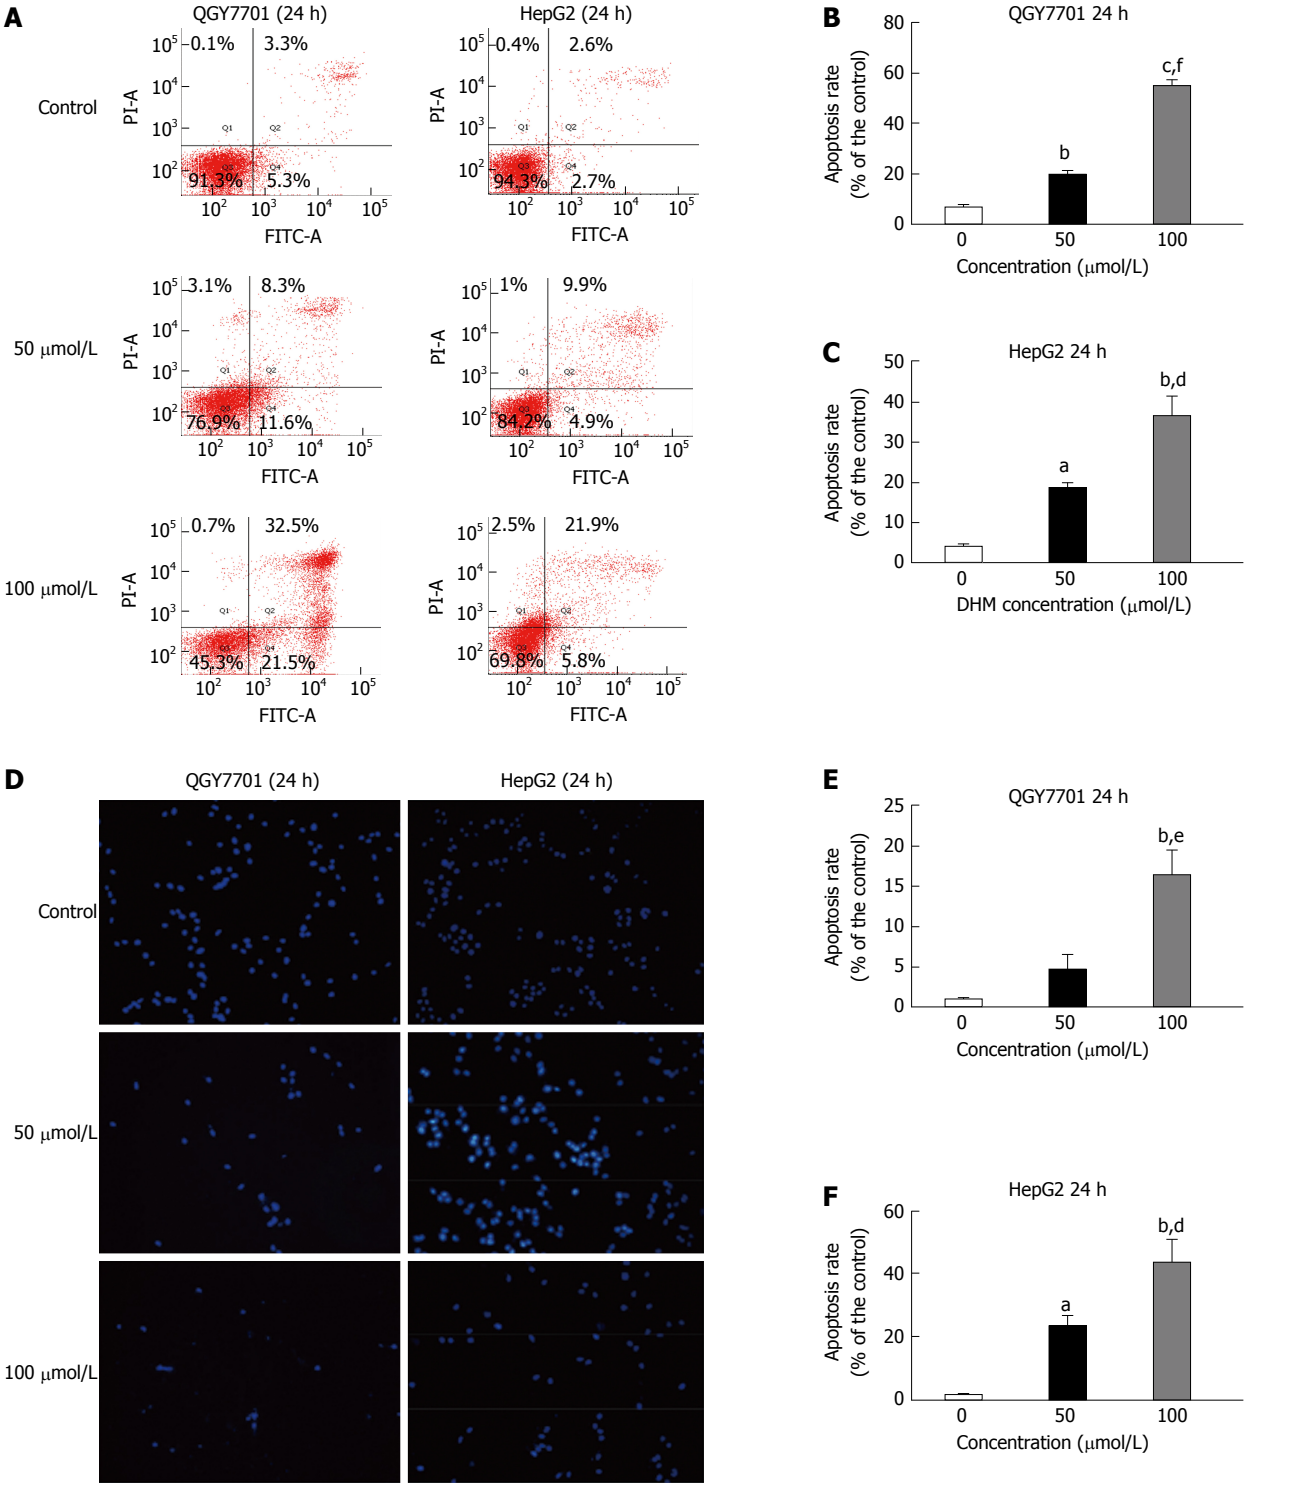

Figure 3 Dihydromyricetin induces apoptosis in QGY7701 and HepG2 hepatocellular carcinoma cells. A: Apoptosis of QGY7701 and HepG2 cells treated with DHM at different concentrations (0, 50, or 100 μmol/L) for 24 h was analyzed by flow cytometry; B and C: Apoptosis was quantified and presented as a statistical figure; D: A TUNEL assay was utilized to examine the apoptosis of QGY7701 and HepG2 cells treated with different concentrations (0, 50, or 100 μmol/L) of DHM for 24 h; E and F: Apoptosis was quantified and presented as a statistical figure; Each experiment was repeated more than three times; $^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$ *vs* 0 μmol/L (control) group; $^{e}P < 0.05$, $^{d}P < 0.01$, $^{f}P < 0.001$ *vs* 50 μmol/L group.

on liver cancer and the specific underlying mechanism remain unclear. We found that DHM treatment of the QGY7701 and HepG2 hepatoma cell lines led to cell proliferation inhibition in a time- and dose-dependent manner. The colony-forming capability of QGY7701 and HepG2 cells treated with different concentrations of DHM was inhibited. Cell images demonstrated the inhibition of cell proliferation and induction of apoptosis in cells treated with high concentrations of DHM. Flow cytometry and TUNEL assays further verified the occurrence of significant apoptosis in QGY7701 and HepG2 cells treated with DHM. In view of the high

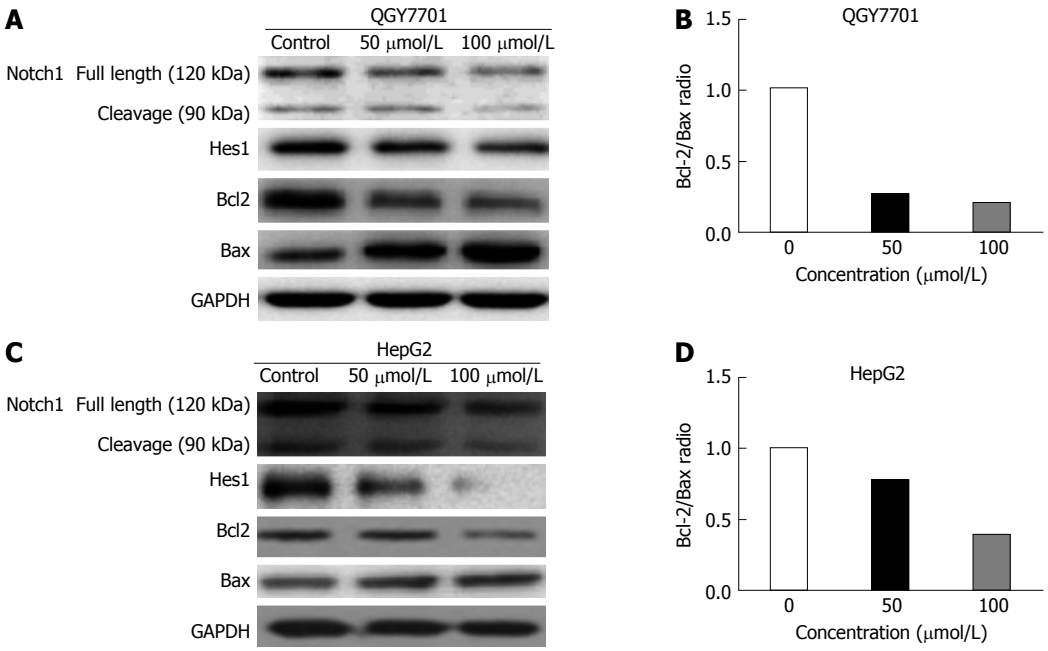

Figure 4 Effects of dihydromyricetin treatment on proteins in the Notch1 pathway and on apoptosis-related proteins in hepatocellular carcinoma cells. A and C: The levels of the Notch1, Hes1, Bcl-2, and Bax proteins in QGY7701 and HepG2 cells treated with DHM at different concentrations (0, 50, or 100 μmol/L) were analyzed by western blot; B and D: The Bcl-2/Bax protein ratios were measured by optical density analysis with ImageJ software.

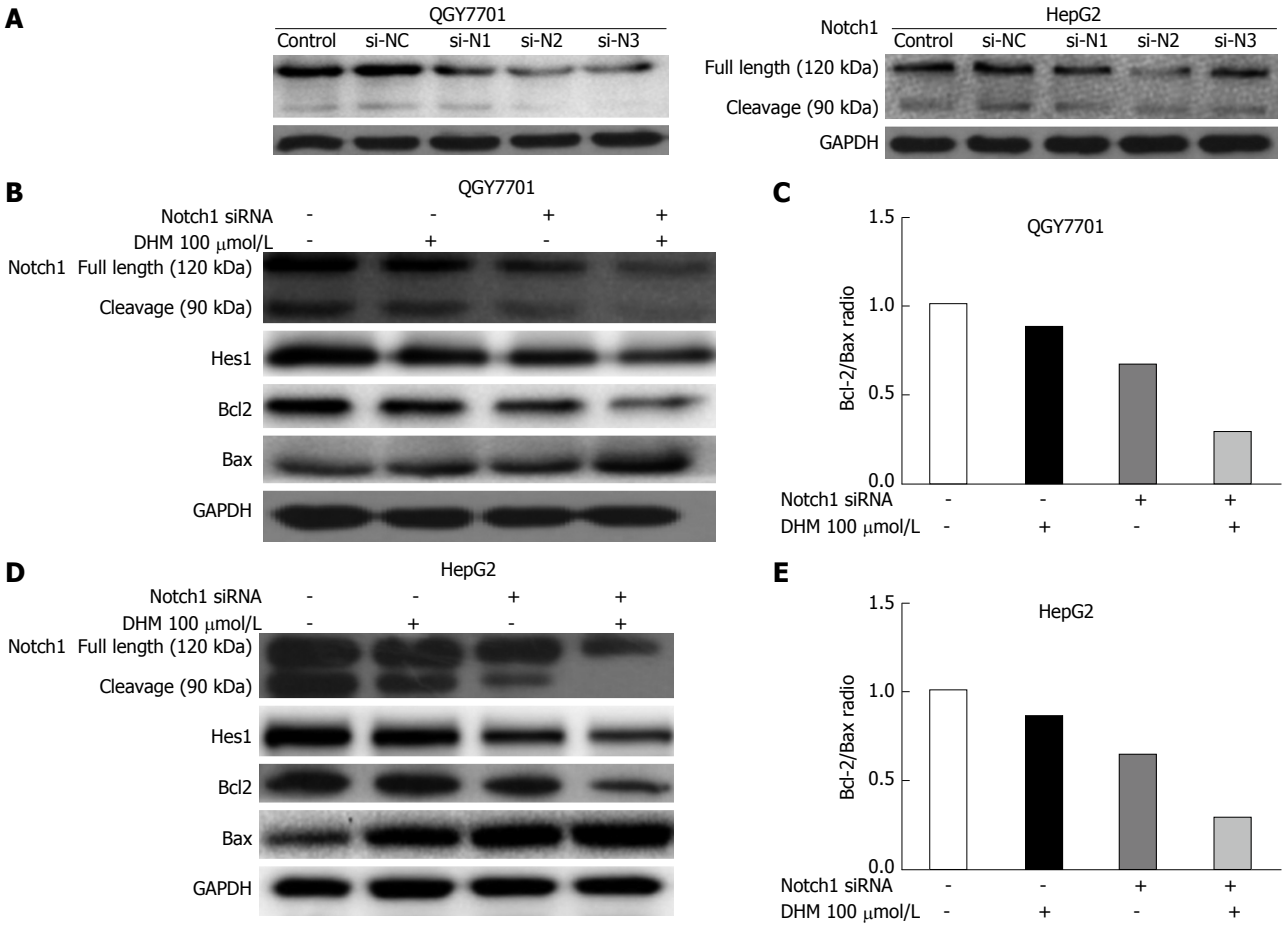

Figure 5 Dihydromyricetin induced apoptosis in hepatocarcinoma cells by downregulating the Notch1 pathway. A: Knockdown efficiency of 3 different Notch1 siRNA sequences was tested in both QGY7701 and HepG2 cell lines by Western blot; B and D: The effects of different treatment methods (Notch1-siRNA, dihydromyricetin 100 μmol/L, and combined treatment) on Notch1, Hes1, Bcl-2, and Bax protein levels as determined by Western blot; C and E: The Bcl-2/Bax protein ratios were measured by optical density analysis with ImageJ software. si-NC: si-negative control; si-N1: si-Notch1-1; si-N2: si-Notch1-2; si-N3: si-Notch1-3.

expression of Notch1 in HCC samples, we examined the effect of various concentrations of DHM on the expression of Notch1, and found that Notch1 and Hes1 were downregulated. Bcl-2 and Bax proteins play major roles in the regulation of mitochondria-mediated apoptosis, which is a common apoptosis pathway. The Bcl-2 (pro-apoptotic protein) and Bax (anti-apoptotic protein) ratio can further reflect the anti-apoptotic tendencies. The ratio of anti-apoptotic to pro-apoptotic molecules, such as the Bcl-2/Bax ratio, indicates the threshold sensitivity of cells to the induction of apoptosis *via* the intrinsic (mitochondria-mediated) pathway[31,32]. The data showed that Bcl-2 and Bax were downregulated in DHM-treated QGY7701 and HepG2 cells, and the Bcl-2/Bax ratio was also decreased. Additionally, we knocked out the expression of Notch1 and treated these Notch1-deficient cells with DHM. The results showed that the effects of Notch1 silencing and DHM treatment were not different. However, when used in combination, Bcl-2 was downregulated, Bax was upregulated, and the reduction in the ratio of Bcl-2/Bax was more significant. These results show that the anti-tumor capacity of DHM in the QGY7701 and HepG2 hepatocarcinoma cell lines is partially exerted through inhibition of the Notch1 pathway.

In summary, our experiments confirmed that Notch1 is involved in the development of HCC and may serve as a potential diagnostic marker for HCC and an indicator of malignancy. DHM inhibits cell proliferation and promotes apoptosis by down-regulating the expression of Notch1, indicating that it can be used as a candidate drug for the treatment of HCC.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is a highly malignant type of solid tumor which is a serious threat to human health. It is urgent to develop novel chemotherapeutic drugs and therapeutic targets for the treatment of HCC.

Research frontiers

Notch-1 was detected to be overexpressed in HCC; Notch1 is involved in the development and progression of HCC. Dihydromyricetin (DHM) has numerous pharmacological activities, such as antiinflammatory, antioxidation and anticarcinogenic effects. However, whether DHM can induce hepatoma cell apoptosis by Notch1 is not yet known.

Innovations and breakthroughs

This is the first study to demonstrate that DHM inhibits cell proliferation and promotes apoptosis by down-regulating the expression of Notch1.

Applications

DHM may be used a potential effective candidate agent for the treatment of HCC.

Peer-review

This article is well written. The authors investigate whether DHM inhibits cell proliferation and promotes apoptosis by downregulating Notch1 expression. These results show that the anti-tumor activity of DHM in the QGY7701 and HepG2 HCC cell lines is partially exerted through inhibition of the Notch1 pathway.

Abstract

AIM

To investigate the potential effect of curcumin on

hepatitis B virus (HBV) covalently closed circular DNA (cccDNA) and the underlying mechanism.

METHODS

A HepG2.2.15 cell line stably transfected with HBV was treated with curcumin, and HBV surface antigen (HBsAg) and e antigen (HBeAg) expression levels were assessed by ELISA. Intracellular HBV DNA replication intermediates and cccDNA were detected by Southern blot and real-time PCR, respectively. The acetylation levels of histones H3 and H4 were measured by Western blot. H3/H4-bound cccDNA was detected by chromatin immunoprecipitation (ChIP) assays. The deacetylase inhibitors trichostatin A and sodium butyrate were used to study the mechanism of action for curcumin. Additionally, short interfering RNAs (siRNAs) targeting HBV were tested along with curcumin.

RESULTS

Curcumin treatment led to time- and dose-dependent reductions in HBsAg and HBeAg expression and significant reductions in intracellular HBV DNA replication intermediates and HBV cccDNA. After treatment with 20 μmol/L curcumin for 2 d, HBsAg and cccDNA levels in HepG2.2.15 cells were reduced by up to 57.7% ($P < 0.01$) and 75.5% ($P < 0.01$), respectively, compared with levels in non-treated cells. Meanwhile, time- and dose-dependent reductions in the histone H3 acetylation levels were also detected upon treatment with curcumin, accompanied by reductions in H3- and H4-bound cccDNA. Furthermore, the deacetylase inhibitors trichostatin A and sodium butyrate could block the effects of curcumin. Additionally, transfection of siRNAs targeting HBV enhanced the inhibitory effects of curcumin.

CONCLUSION

Curcumin inhibits HBV gene replication *via* down-regulation of cccDNA-bound histone acetylation and has the potential to be developed as a cccDNA-targeting antiviral agent for hepatitis B.

Key words: Curcumin; Hepatitis B virus; Covalently closed circular DNA; Histone deacetylation

Curcumin inhibits hepatitis B virus infection by down-regulating cccDNA-bound histone acetylation. *World J Gastroenterol* 2017; 23(34): 6252-6260 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6252.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6252

INTRODUCTION

Hepatitis B virus (HBV) is a species of the genus *Orthohepadnavirus*. HBV infection leads to severe diseases, including hepatitis, liver cirrhosis and hepatocellular carcinoma[1]. HBV has also been suggested to be involved in the development of pancreatic cancer[2]. Approximately 350 million individuals are infected with HBV, and more than 0.6 million people with HBV infection die every year as a result of end-stage liver disease and hepatocellular carcinoma worldwide[1,3]. The HBV genome is made of partially double-stranded relaxed circular DNA (rcDNA), 3020-3320 bp in size[4]. After the virus infects hepatocytes, rcDNA is released into the nucleus and converted to covalently closed circular DNA (cccDNA), which, along with histone binding, constitutes a minichromosome. The mean copies of cccDNA per HBV-infected hepatocyte range from 5 to 50[5,6]. Moreover, cccDNA serves as the critical template for viral replication and mRNA synthesis, which is the source of persistent and recurrent HBV infection. Nucleos(t)ide analogues (NAs) can efficiently inhibit HBV replication; however, they do not promote clearance of residual cccDNA[7].

Several treatment strategies are available to target cccDNA by inhibiting cccDNA minichromosome formation or inducing cccDNA degradation. Disubstituted sulfonamide (DSS) compounds have been reported to be specific inhibitors that prevent rcDNA conversion into cccDNA; however, DSS cannot promote cccDNA decay[8]. Lucifora *et al*[9] showed that inducing apolipoprotein B mRNA-editing enzyme catalytic polypeptide-like 3A (APOBEC3A) and 3B (APOBEC3B) cytidine deaminase by interferon-α and lymphotoxin-β receptor activation induces cccDNA degradation *via* cytidine deamination and apurinic/apyrimidinic site formation. However, the absence of specificity of these cytidine deaminases results in genomic damage and cell-cycle arrest[10]. Recently, with the aid of DNA-cleaving enzymes, including zinc-finger nucleases (ZFN), TAL effector nucleases (TALENs), and CRISPR-associated system 9 (Cas9) proteins, specific targeting of HBV cccDNA was shown to cleave cccDNA[11-15]. Nevertheless, chronic expression of enzymes leads to off-target cleavage at homologous sequences in the human genome and represents a major limitation.

Furthermore, cccDNA-bound acetylated histones can modulate HBV replication and expression[16,17]. Hepatitis B virus X (HBx) protein can be recruited onto a cccDNA minichromosome to accelerate acetylation. Using a cccDNA chromatin immunoprecipitation (ChIP)-Seq assay, Tropberger *et al*[18] reported that low levels of histone posttranslational modifications (PTMs)

were associated with transcriptional repression and promoter silencing.

Curcumin [1,7-bis(4-hydroxy-3-methoxyphenyl)-1,6-heptadiene-3,5-dione] was isolated from the rhizome of *Curcuma longa* L. (Zingiberaceae family), which exhibits antimicrobial activities against various bacteria, viruses, fungi, and parasites[19-23]. Curcumin can inhibit HBV *via* down-regulation of the gluconeogenesis gene coactivator PGC-1α[24] or transactivation of transcription and increased stability of p53[25].

Based on findings that curcumin can inhibit p300 histone acetyltransferase activity[26,27], we hypothesized that deacetylation of cccDNA-bound histones may contribute to the inhibitory activities of curcumin on HBV. Therefore, the effects of curcumin on cccDNA-bound histones and on steady-state levels of HBV cccDNA were investigated in detail in the present study.

MATERIALS AND METHODS

Cell culture and transfection

HepG2.2.15 cells (an HBV stably transfected human hepatocarcinoma cell line) were maintained in DMEM medium (Gibco, Carlsbad, CA, United States) supplemented with 10% foetal bovine serum (Gibco), 1% GlutaMAX-I (Gibco) and 1% MEM Non-Essential Amino Acids Solution (Gibco). Transfection of siRNAs into HepG2.2.15 cells was performed using Lipofectamine 2000 (Invitrogen, Carlsbad, CA, United States). The sequences were 5′-GAAUCCUCACAAUACCGCAtt and 5′-UGAGAGUCCAAGAGUCCUCtt for HBx-siRNA and 5′-GAAUCCUCACAAUACCGCAtt and 5′-UGCGGUAUU GUGAGGAUUCtt for hepatitis B virus S antigen (HBs)-siRNA[28].

Curcumin and deacetylase inhibitor treatments

Cells were seeded at approximately 60%-80% confluence 24 h prior to treatment with different concentrations of curcumin (Sigma, St. Louis, MO, United States) dissolved in dimethyl sulphoxide (DMSO). For histone acetylation blocking assays, cells were co-treated with 20 μmol/L curcumin and either 5 mmol/L sodium butyrate (Sigma) or 1 μmol/L trichostatin A (TSA, Sigma).

Nucleoprotein extraction and Western blot analysis

Nucleoproteins were extracted using a Nucleoprotein Extraction Kit (Sangon Biotech, Shanghai, China) according to the manufacturer's instructions. For Western blot analysis, proteins were subjected to SDS-polyacrylamide gel electrophoresis on 12.5% gels and were then electrophoretically transferred to nitrocellulose membranes (Millipore, Billerica, MA, United States). The membranes were blocked with 5% non-fat milk in Tris-buffered saline (TBS; pH 7.5) with 0.05% Tween 20 for 2 h at RT and were then probed with rabbit polyclonal anti-acetyl-histone H3 (Abnova, diluted 1:1000) overnight at 4 ℃. Mouse monoclonal anti-histone H3 (Beyotime Biotechnology, diluted 1:1000) served as an internal control protein. Horseradish peroxidase-conjugated goat anti-mouse antibody (Biosharp, 1:5000) was used as a secondary antibody. Protein brands were visualized by enhanced chemiluminescence (ECL) using an ECL kit (Millipore).

Extraction and quantification of HBV cccDNA

HepG2.2.15 cells were lysed in 800 μL of lysis buffer [50 mmol/L Tris-HCl (pH 8.0), 10 mmol/L EDTA, 150 mmol/L NaCl and 1% SDS] and incubated for 30 min at 4 ℃. Cell lysates were adjusted to 0.5 mol/L KCl and centrifuged for 1 min at 10000 *g* to precipitate protein-bound DNA. Supernatants were digested with 0.5 mg/mL proteinase K for 2 h at 55 ℃. The cccDNA was purified by phenol/chloroform (1:1) extraction and isopropanol precipitation in the presence of 15 μg of tRNA and 200 mM NaAc (pH 5.2).

Purified DNA was digested with Plasmid-Safe ATP-Dependent DNase (Epicenter, Madison, WI, United States) to degrade contaminating HBV inserted in cellular genomic DNA and OC (open circular) species and was then subjected to PCR amplification to select HBV cccDNA forms, as previously described[15]. The cccDNA was later subjected to real-time-PCR using SYBR Green Real-time PCR Master Mix (Roche, Mannheim, Germany) and cccDNA-specific primers: 5′-TGCACTTCGCTTCACCT (forward) and 5′-AGGGGC ATTTGGTGGTC (reverse). PCR was performed using an Applied Biosystems StepOne Real-Time PCR System. cccDNA copy numbers were quantified according to a standard curve generated from an HBV plasmid in a concentration range of 10^2-10^8 copies.

Extraction and quantification of HBV mRNA

Total RNA was extracted from HepG2.2.15 cells using TRIzol Reagent (Invitrogen) according to the manufacturer's instructions and was then subjected to real-time-PCR using primers for cccDNA quantification; β-actin mRNA transcript levels were used to normalize the expression of each RNA sample.

cccDNA acetyl-histone H3 and acetyl-histone H4 ChIP assays

cccDNA ChIP assays were performed using EpiQuik Acetyl-Histone H3 ChIP and EpiQuik Acetyl-Histone H4 ChIP kits (EpiGentek, Farmingdale, NY, United States). Briefly, cells were collected and *in vivo* cross-linked in fresh culture medium containing 1% formaldehyde for 10 min at RT and were then lysed in 200 μL CP3A for 10 min at RT to isolate nuclear pellets. Chromatin solutions were sonicated for 4 pulses of 12 s each at level 5 using a Branson Microtip probe, followed by a 40-s rest on ice between each pulse to generate 200- to 1000-bp DNA fragments. Supernatants were diluted with CP4 at a 1:1 ratio, and 5 μL was removed as "input DNA". Chromatin was then subjected to

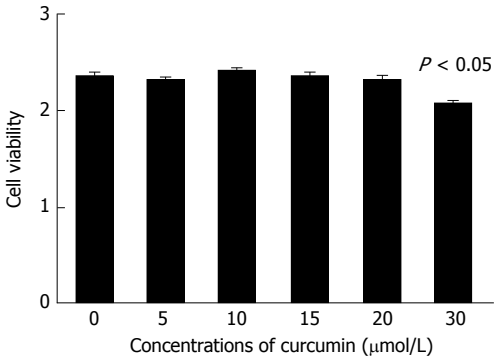

Figure 1 Cell cytotoxicity of curcumin. HepG2.2.15 cells were treated with 0, 5, 10, 15, 20 or 30 μmol/L curcumin for 2 d and then subjected to CCK-8 assay to detect toxic effect. The experiment was performed in duplicate and repeated at least three times.

immunoprecipitation for 1 h at RT using strip wells pre-coated with antibodies specific to acetyl-histone H3, acetyl-histone H4 or normal mouse IgG. After six washes with CP1, immunoprecipitated chromatins and input DNA coated on the strip wells were digested with proteinase K and then purified using collection tubes. Purified DNA was subjected to Plasmid-Safe ATP-Dependent DNase digestion and real-time PCR amplification, as described above.

Quantification of HBV antigens

Culture supernatants of HepG2.2.15 cells were harvested and analysed for HBV surface antigen (HBsAg) and e antigen (HBeAg) levels using a Thermo Scientific Multiskan FC Microplate Photometer and ELISA kits (InTec, Xiamen, China).

Purification of HBV DNA from intracellular core particles and Southern blot analysis

HepG2.2.15 cells were washed twice with ice-cold PBS and lysed in 800 μL of lysis buffer [50 mmol/L Tris-HCl (pH 7.4), 1 mmol/L EDTA and 1% NP-40]. Cell lysates were centrifuged for 1 min at 10000 *g* to precipitate cell nuclei. Cellular genomic DNA and cccDNA were removed by the addition of 10 mM $MgCl_2$ and 100 μg/mL DNase I, and the mixture was incubated for 30 min at 37 ℃. Digestion was stopped by the addition of 25 mmol/L EDTA (pH 8.0). Proteins were digested with 0.5 mg/mL proteinase K and 1% SDS for 2 h at 55 ℃. HBV DNA from intracellular core particles was purified by phenol/chloroform (1:1) extraction and isopropanol precipitation in the presence of 15 μg of tRNA and 200 mmol/L NaAc (pH 5.2)[28,29].

For Southern blot analysis, HBV DNA was subjected to agarose gel electrophoresis, followed by denaturation and transfer to nylon membranes using a Model 785 Vacuum Blotter (Bio-Rad, Hercules, CA, United States). DNA was fixed to membranes using an Ultraviolet Crosslinker (UVP, Upland, CA, United States). DNA hybridization and detection were performed using the DIG High Prime DNA Labelling and Detection Starter Kit II (Roche).

Statistical analysis

Statistical analyses were performed using unpaired *t*-tests. The results were evaluated with GraphPad Prism 5 and are expressed as the mean ± SD. *P* values < 0.05 (a) or < 0.01 (b) were set as the level of significance.

RESULTS

Curcumin inhibits HBV replication and expression

To confirm whether curcumin directly inhibits HBV expression, HepG2.2.15 cells were treated with various concentrations of curcumin for three consecutive days. Cell cytotoxicity was assessed using the CCK-8 assay, which revealed that there was no detectable toxic effect when cells were treated with less than 20 μmol/L curcumin (Figure 1). Cell culture supernatants from each day were collected and analysed for levels of HBsAg and HBeAg. Curcumin decreased HBsAg levels both dose- and time-dependently; HBsAg levels were reduced by up to 57.7%, 2 d after treatment with 20 μmol/L curcumin (Figure 2A). HBeAg was not reduced by 20 μmol/L of curcumin (Figure 2B). HBV cccDNA and HBV DNA from intracellular core particles were assayed 2 d after treatment with 20 μmol/L curcumin. RT-PCR and Southern blot experiments revealed strong reductions in cccDNA (75.5%; Figure 2C), mRNA (24.4%; Figure 2D) and HBV replication intermediates (Figure 2E).

Curcumin mediates the deacetylation of chromosomal and cccDNA-bound histones

To investigate the effects of curcumin on chromosomal histone acetylation, equivalent numbers of HepG2.2.15 cells were treated with various concentrations of curcumin for 2 d or with 20 μmol/L curcumin for different durations. As shown in Figure 3A and B, curcumin decreased histone acetylation levels both dose- and time-dependently. We found that 5 μmol/L curcumin was sufficient to decrease histone acetylation. When cells were treated with 20 μmol/L curcumin, acetylated histone H3 was reduced 30 min after treatment. Using a cccDNA ChIP assay, we found that the acetylation levels of cccDNA-bound histone H3 and histone H4 were significantly reduced when cells were treated with 20 μmol/L curcumin (Figure 3C). This finding is similar to our observed reduction of chromosomal histone acetylation.

Histone deacetylase inhibitors block the inhibitory effect of curcumin

The histone deacetylase inhibitors sodium butyrate and TSA were used to test whether curcumin inhibits HBV by decreasing histone acetylation. HepG2.2.15 cells were treated with 20 μmol/L curcumin for 2 d, which resulted in significant reductions in the

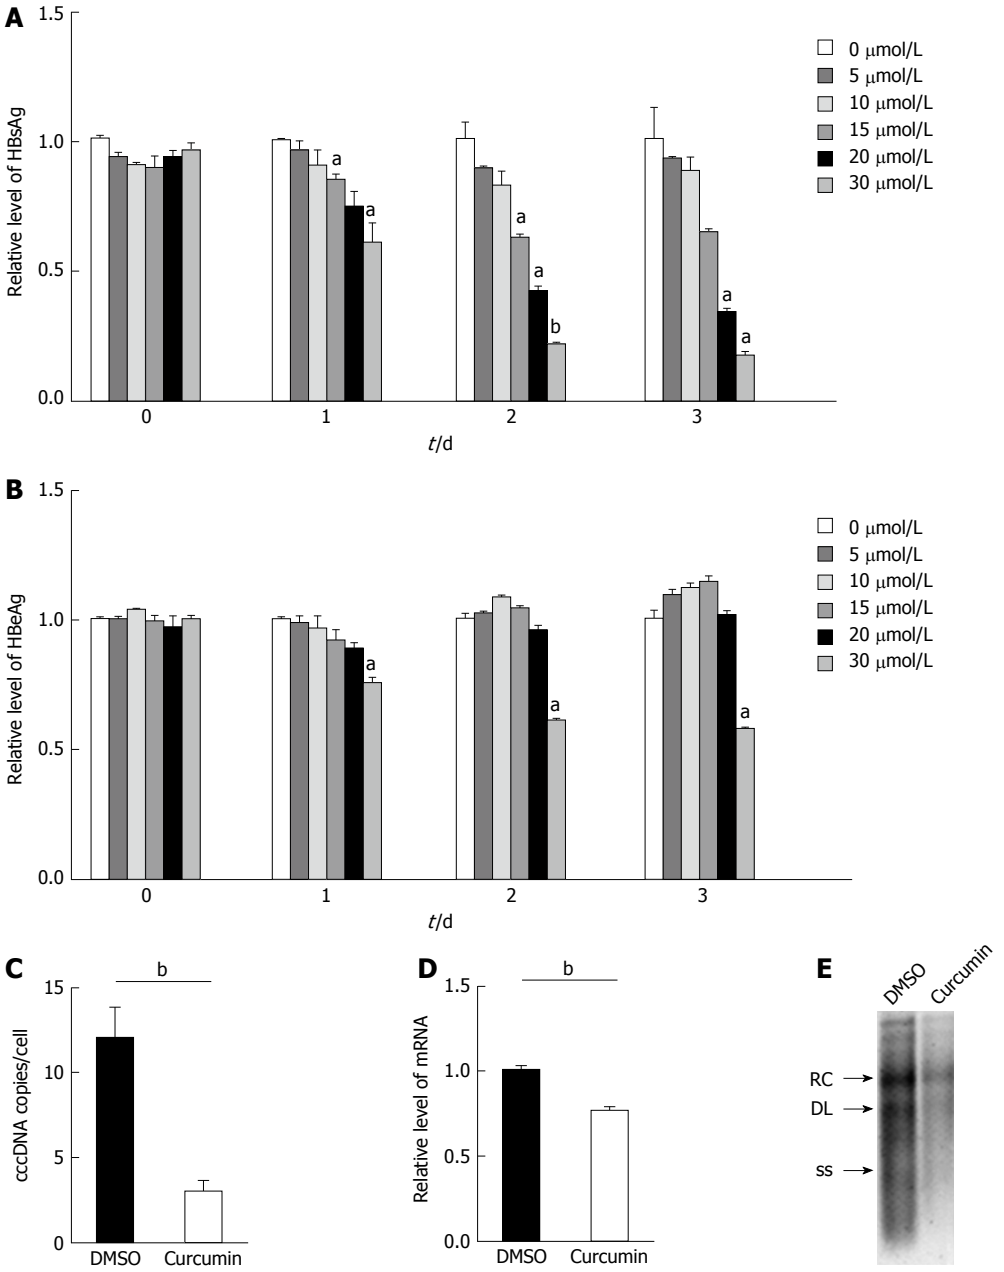

Figure 2 Curcumin inhibits hepatitis B virus replication and expression. A: HepG2.215 cells were treated with 0, 5, 10, 15, 20 or 30 μmol/L curcumin for three consecutive days. Culture medium from each day was collected and analysed for levels of HBsAg; B: Culture medium from each day was collected and analysed for levels of HBeAg; C: Hepatitis B virus (HBV) cccDNA accumulation in HepG2.215 cells treated with 20 μmol/L curcumin or DMSO for 2 d. HBV cccDNA was digested with Plasmid-Safe ATP-Dependent DNase to degrade contaminating HBV that had inserted in cellular genomic DNA and OC species and was then subjected to PCR amplification to amplify HBV cccDNA forms. Results are expressed as numbers of cccDNA copies per cell; D: Total RNA was extracted from HepG2.215 cells treated with 20 μmol/L curcumin or DMSO for 2 d and was subjected to real-time PCR to quantify HBV mRNA transcript levels; E: HBV DNA was extracted from intracellular core particles in HepG2.215 cells treated with 20 μmol/L curcumin or DMSO for 2 d. Southern blot analysis of HBV DNA replicative intermediates. RC, DL and SS represent relaxed circular, double linear and single-stranded forms of HBV DNA, respectively. All experiments were repeated at least three times; ELISA and RT-PCR were performed in duplicate. $^{a}P < 0.05$; $^{b}P < 0.01$. cccDNA: Covalently closed circular DNA; DMSO: Dimethyl sulphoxide.

levels of HBsAg (Figure 4A) and cccDNA (Figure 4B). HBsAg and cccDNA levels increased by 31.3% and 2.4-fold, respectively, when cells were co-treated with curcumin and sodium butyrate compared with cells treated with curcumin alone. The histone deacetylase inhibitor TSA also partially blocked the inhibitory effect of curcumin on HBV, although the effect was much weaker than that of sodium butyrate. These findings suggest that curcumin inhibits HBV by inducing histone deacetylation.

siRNAs against HBV enhance the inhibitory effects of curcumin

Because HBx also regulates epigenetic modifications of cccDNA-bound histones[16], HBx-siRNA and HBs-siRNA were used to enhance the inhibitory effects of curcumin. HepG2.2.15 cells were transfected with 20 nmol/L siRNAs and treated with 20 μmol/L curcumin

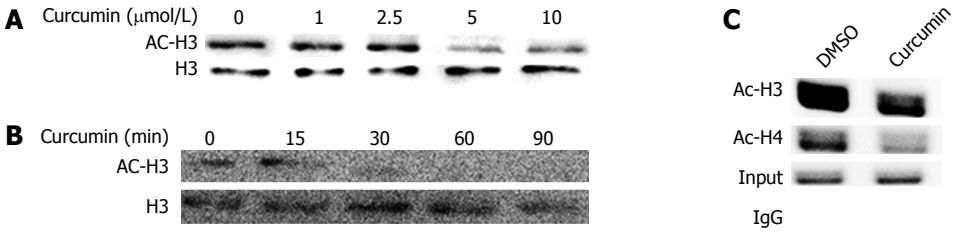

Figure 3 Curcumin mediates chromosomal and covalently closed circular DNA-bound histone deacetylation. A: HepG2.215 cells were treated with 0, 1, 2.5, 5 or 10 μmol/L curcumin and incubated at 37 ℃ for 2 d. The acetylation status of cellular H3 histones was analysed by Western blot; B: HepG2.215 cells were treated with 20 μmol/L curcumin for the indicated periods of time; C: ChIP on HepG2.215 cells treated with 20 μmol/L curcumin or DMSO for 2 d was performed using specific antibodies to acetyl-histone H3 (AcH3), acetyl-histone H4 (AcH4) or control IgG. Immunoprecipitated chromatins were digested with Plasmid-Safe ATP-Dependent DNase to degrade contaminating HBV that had inserted in cellular genomic DNA and OC species and then were subjected to PCR amplification to select HBV cccDNA forms. for 2 subsequent days. Transfection with siRNAs alone significantly reduced HBsAg expression to a level below the limit of detection (Figure 5A). Moreover, a further reduction was observed in HBV DNA levels from intracellular core particles extracted from cells that received combined treatment with siRNAs and curcumin compared with cells treated with curcumin alone (Figure 5B).

DISCUSSION

The present study showed that curcumin not only inhibited intracellular HBV replication and HBsAg and HBeAg expression but also exhibited potent inhibitory effects on HBV cccDNA. Moreover, curcumin also reduced levels of both chromosomal and cccDNA-bound histones H3/H4, and addition of the histone deacetylase inhibitors sodium butyrate and TSA blocked the inhibitory effects of curcumin on HBV. These findings suggest that curcumin may induce the deacetylation of cccDNA-bound histones H3/H4, disrupt the steady state of HBV cccDNA and lead to the potent inhibition of HBV mRNA transcription and protein expression, along with a reduction in DNA replication. Furthermore, enhanced inhibition of intracellular HBV replication was revealed when curcumin was combined with siRNAs against HBV. Since HBx is pivotal for the steady state of cccDNA by regulating epigenetic modifiers of cccDNA-bound histones[16,30], the combination of curcumin with siRNAs, especially those targeting HBx, may lead to a synergistic effect in modulating the cccDNA steady state.

Several host-related factors, including histone proteins, regulate transcription and translation processes of cccDNA minichromosomes. Acetylation status changes of cccDNA-bound histones can regulate cccDNA transcription[16]. Previous studies have indicated that acetyltransferase inhibitors and deacetylase activators inhibit cccDNA transcription[16,31]. Curcumin has been reported to be an inhibitor of histone acetyltransferase (HAT), which specifically represses the activity of the p300/CREB-binding protein (CBP) HAT[26,27]. In the present study, curcumin mediated reductions in the levels of chromosomal and cccDNA-bound histone acetylation, which might result from the induction of histone deacetylation, because the deacetylase inhibitors TSA and sodium butyrate could block the inhibitory effects of curcumin on HBV.

HBV cccDNA is the primary template that allows for HBV gene expression and viral replication, and the steady state of cccDNA minichromosomes in the nuclei of hepatocytes contributes to persistent infection by

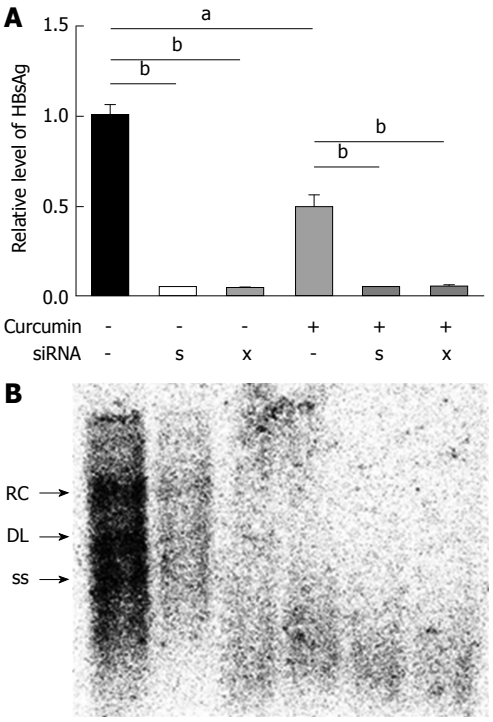

Figure 5 siRNAs against hepatitis B virus enhance the inhibitory effects of curcumin. HepG2.215 cells were transfected with 20 nmol/L siRNAs or negative control (HC) siRNA and were treated with 20 μmol/L curcumin or dimethyl sulphoxide for the next 2 d. HBsAg in cell culture supernatants and intracellular HBV replicative intermediates were detected by ELISA (A) and Southern blot analysis (B), respectively. HBV[32]. While there are no therapeutics currently available that target cccDNA, targeted therapeutics are attractive because the elimination of cccDNA results in the genomic cure of HBV infection[5]. Although genomic editing techniques, such as the CRISPR/CAS9 system, have shown promise in their capacity to edit HBV cccDNA, translating this finding into the clinic will be a challenge, mostly because of the need for the development of safe vectors for gene therapies.

Curcumin has been widely used as a dietary supplement for food colouring and flavouring, suggesting that it is safe for humans. However, poor bioavailability represents the biggest challenge for the clinical application of curcumin[33]. Poor absorption and rapid metabolism of curcumin in the body lead to low levels in the plasma and tissue. Fortunately, various efforts have been undertaken to promote its bioavailability. Removing the β-diketone moiety prevents curcumin from retro-aldol decomposition at physiological pH values[34]. Curcumin conjugated to two folic acid molecules (curcumin-2FA) increases water solubility and exhibits more efficient targeting of cancer cells that overexpress folic acid receptors[35]. Additionally, many other curcumin analogues can improve its bioavailability[36-40]. Moreover, curcumin-modified silver nanoparticles exhibited more efficient inhibition of respiratory syncytial virus[21]. Improving the bioavailability of curcumin will extend its clinical applications, especially in the treatment of HBV infection. Nevertheless, the long-term effects of curcumin on HBV cccDNA and its role in the elimination of cccDNA, along with combined effects of curcumin with other therapeutics, should be investigated in detail.

Taken together, the present study demonstrates that curcumin inhibits HBV by reducing cccDNA-bound histone acetylation and could potentially be developed as a cccDNA-targeting therapeutic for anti-HBV therapy.

COMMENTS

Background

Hepatitis B virus (HBV) covalently closed circular DNA (cccDNA) is the critical template for viral replication and mRNA synthesis. The elimination of cccDNA is indicative of complete cure of hepatitis B. Nucleos(t)ide analogues (NAs) can efficiently inhibit HBV replication but do not result in clearance of residual cccDNA. Curcumin can inhibit HBV; however, its mechanism is unclear. The potential role of curcumin in the regulation of the steady state of cccDNA is thus of interest.

Research frontiers

The steady state of cccDNA minichromosomes can be regulated through deacetylation of cccDNA-bound histones. Hepatitis B virus X (HBx) protein is recruited onto cccDNA minichromosomes and plays a pivotal role in the steady state of cccDNA by regulating epigenetic modifiers of cccDNA-bound histones.

Innovations and breakthroughs

This is the first study indicating that curcumin inhibits HBV gene replication by reducing cccDNA-bound histone acetylation.

Applications

Curcumin has the potential to be developed as a cccDNA-targeting antiviral agent for hepatitis B.

Terminology

HBV covalently closed circular DNA (cccDNA): After the HBV infects hepatocytes, virus genome is released into the nucleus and converted to cccDNA, which, along with histone binding, constitutes a minichromosome and serves as the critical template for viral replication and mRNA synthesis.

Peer-review

The authors have evaluated the effects of curcumin on HBV DNA replication and gene expression in the HepG2.2.15 cell line. Interestingly, curcumin showed robust inhibitory effects on HBV cccDNA. In addition, the authors have described the mechanism underlying the effect of curcumin on HBV cccDNA, which might be through histone deacetylation or reducing histone acetylation.

Abstract

AIM

To investigate the clinical significance of preoperative systemic immune-inflammation index (SII) in patients with colorectal cancer (CRC).

METHODS

A retrospective analysis of 1383 cases with CRC was performed following radical surgery. SII was calculated with the formula SII = (P × N)/L, where P, N, and L refer to peripheral platelet, neutrophil, and lymphocyte counts, respectively. The clinicopathological features

and follow-up data were evaluated to compare SII with other systemic inflammation-based prognostic indices such as the neutrophil-lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) in patients with CRC.

RESULTS

The optimal cut-off point for SII was defined as 340. The overall survival (OS) and disease-free survival (DFS) were better in patients with low NLR, PLR, and SII ($P < 0.05$). The SII was an independent predictor of OS and DFS in multivariate analysis. The area under the receiver-operating characteristics (ROC) curve for SII (0.707) was larger than those for NLR (0.602) and PLR (0.566). In contrast to NLR and PLR, SII could effectively discriminate between the TNM subgroups.

CONCLUSION

SII is a more powerful tool for predicting survival outcome in patients with CRC. It might assist the identification of high-risk patients among patients with the same TNM stage.

Key words: Colorectal cancer; Systemic immune-inflammation index; Neutrophil-lymphocyte ratio; Platelet-lymphocyte ratio; Prognosis

© The Author(s) 2017. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: A preoperative systemic immune-inflammation index based on peripheral lymphocyte, neutrophil, and platelet counts was established, and better prognostic predictive abilities for overall survival and recurrence were found when compared with neutrophil-lymphocyte ratio and platelet-lymphocyte ratio in patients with colorectal cancer. This index might assist the identification of high-risk patients among patients with the same TNM stage in clinical practice.

INTRODUCTION

Colorectal cancer (CRC), the third most frequently diagnosed cancer in men, and the second in women, is the third most common cause of cancer-related mortality worldwide[1]. The incidence of CRC in the United States has decreased owing to the improvements in cancer screening and the removal of precancerous adenomas[2]. However, an increase in the incidence of CRC was observed in many developing countries[3]. Owing to the absence of early symptoms and a hesitation in performing colonoscopy, a considerable number of CRC patients are diagnosed at an advanced stage, with an unfavorable overall survival (OS)[4]. Currently, the TNM staging system for CRC is the most commonly used predictor of OS and recurrence. However, prognostic heterogeneity was observed among patients with the same TNM stage[5], which causes confusion among clinicians when making therapeutic choices. Hence, more potential biomarkers should be included in clinical practice to improve prognostic prediction.

The interplay between systemic inflammation and the local immune response was recognized as the seventh hallmark of cancer, and it has been demonstrated to be involved in the initiation, development, and progression of several types of malignancies[6,7]. Cancer-related inflammation encompasses tumor-derived and host-derived cytokines, immune cells, and small inflammatory protein mediators[8,9], and is determined by the levels of serum leukocytes, neutrophils, lymphocytes, platelets, and acute-phase proteins such as C-reactive protein. Recently, the combinations of these systemic inflammation parameters, including neutrophil-lymphocyte ratio (NLR)[10] and platelet-lymphocyte ratio (PLR)[11], were reported as prognostic factors in some malignant solid tumors, including CRC. However, Hu *et al*[12] reported that systemic immune-inflammation index (SII), an integrated indicator based on peripheral lymphocyte, neutrophil, and platelet counts, was a powerful prognostic marker for patients with hepatocellular carcinoma. However, the SII for CRC has not been reported to date, and little is known about its prognostic value for CRC.

The aim of the present study was to investigate and compare the clinical significance and prognostic value of NLR, PLR, and SII in patients with CRC who underwent radical surgery.

MATERIALS AND METHODS

Ethics statement

The present study was approved by the ethics committee of the First Affiliated Hospital of Sun Yat-sen University. The requirement for informed consent was waived owing to the retrospective nature of this study.

Patients

We retrospectively analyzed the patients with primary CRC who underwent radical surgery at the Department of Gastrointestinal Surgery, the First Affiliated Hospital of Sun Yat-sen University between January 1994 and December 2010. 5-fluorouracil (5-FU)-based adjuvant chemotherapy was administered to stage III/IV patients and high-risk stage II patients. The inclusion criteria for patient enrollment were as follows: (1) primary colorectal adenocarcinoma confirmed by histopathology; (2) patients who underwent radical surgery; and (3) the availability of complete peripheral blood counts and follow-up data. The exclusion criteria

were as follows: (1) clinical evidence of infection; (2) the presence of hematological system diseases; (3) previous treatment with neoadjuvant chemotherapy or radiochemotherapy; (4) bowel obstruction or enterobrosis resulting in emergency surgery; (5) concurrent cancers or CRC recurrence; and (6) the use of anti-inflammatory or immunosuppressive medicines. Finally, 1383 cases were enrolled in the present study.

Data collection

The following variables were analyzed: demographics (age and sex), clinicopathological features (tumor location, tumor size, histological type, and tumor stage), and treatment with chemotherapy. We defined cecum carcinoma, ascending colon cancer, and right-half transverse colon as right-sided CRC, whereas the rest were classified as left-sided CRCs. The well and moderately differentiated adenocarcinomas were histologically categorized as the well-differentiated type, and the poorly differentiated adenocarcinomas included poorly differentiated adenocarcinoma, mucinous adenocarcinoma, signet ring cell cancer, and undifferentiated cancer. Tumor staging was performed according to the 7th edition of the Union for International Cancer Control-American Joint Committee on cancer classification for CRC.

Preoperative blood sampling was performed to measure the neutrophil, lymphocyte, and platelet levels for the calculation of the NLR, PLR, and SII indices. NLR and PLR were defined as the total number of neutrophils or platelets divided by the total number of lymphocytes. SII was calculated with the formula SII = (P × N)/L, where P, N, and L refer to peripheral platelet, neutrophil, and lymphocyte counts, respectively.

Follow-up

Patients were followed every 3 mo in the first 2 years following surgery, every 6 mo in years 3-5, and annually thereafter. As previously described[13], clinical history was taken, physical examination was performed, peripheral tumor biomarker levels were measured, and chest radiography, abdominal and pelvic computed tomography or ultrasonography, and colonoscopy were performed in the follow-up period according to the NCCN Clinical Practice Guidelines in Oncology. The OS and disease-free survival (DFS) were defined as the interval between surgery and time of death or the time from the last follow-up to the time of first confirmed recurrence, respectively.

Statistical analysis

Data was analyzed using the SPSS statistical software for Windows, version 17 (SPSS Inc., Chicago, United States). Receiver operating characteristic (ROC) curve analysis was performed to analyze the area under the ROC curve (AUC), and the Youden Index was used to identify the optimal cut-off values for NLR, PLR, and SII. Pearson χ^2 test or Fisher exact test were performed to compare the different categorical variable groups. Survival analysis was performed using the Kaplan-Meier method and the Log-Rank test was used to compare the survival differences. Univariate and multivariate analyses were performed with the Cox proportional hazards regression model. A P value < 0.05 was considered statistically significant.

RESULTS

ROC analysis

Using cancer-specific death as the end point, ROC analysis was performed to identify the optimal cut-off point with the highest sensitivity and specificity, which was 2.7 for NLR, 210 for PLR, and 340 for SII (sensitivity and specificity: 0.414 and 0.750 for NLR, 0.425 and 0.708 for PLR, and 0.857 and 0.524 for SII, respectively). For each immune-inflammation index, patients were divided into two groups for further analysis [NLR $\leqslant$ 2.7 (low) and NLR > 2.7 (high); PLR $\leqslant$ 210 (low) and PLR > 210 (high); SⅡ $\leqslant$ 340 (low) and SⅡ > 340 (high)].

Baseline characteristics of patients

In total, 1383 cases were enrolled in the present study. Patients in the high NLR group were more elderly compared to the low NLR group (> 60 years old: 54.7% *vs* 46.8%, respectively); however, associations between age and the levels of PLR and SII were not identified. Moreover, there were significant sex distribution differences in the three groups. In addition, cases in the high NLR and PLR groups were more likely to have left-sided CRC; however, the tumor location did not differ significantly between the high and low SII groups. High levels of NLR, PLR, and SII correlated with poor histological differentiation, larger tumor size, advanced T stage, N stage, M stage, TNM stage, and chemotherapy. The associations of NLR, PLR, and SII with clinicopathological parameters are demonstrated in Table 1.

Prognostic value of NLR, PLR, and SII

In the present study, the 5-, 10-, 15-, and 20-year OS rates were 61.2%, 45.1%, 35.6%, and 28.1%, respectively. The patients in the high NLR, PLR, and SII groups showed poorer OS compared to patients in the low NLR, PLR, and SII groups, respectively (Figure 1A-C). In order to identify the prognostic parameters for OS, 13 variables were included in the univariate Cox regression analysis, which showed that the NLR, PLR, SII, age, histological type, tumor invasion, lymph node involvement, distant metastasis, TNM stage, and chemotherapy were the variables that had significant impact on OS. After the exclusion of variables that showed no impact on the OS in univariate analysis, Cox multivariate regression analysis was performed, which identified SII (95%CI: 2.616-3.824), PLR (95%CI: 1.123-1.492), age (95%CI: 1.355-1.798), distant metastasis (95%CI: 1.512-2.517), and TNM stage (95%CI: 1.191-1.518) as the independent

Table 1 Baseline patient characteristics based on neutrophil-lymphocyte ratio, platelet-lymphocyte ratio and systemic immune-inflammation index *n* (%)

NLR: Neutrophil-lymphocyte ratio; PLR: Platelet-lymphocyte ratio; SII: Systemic immune-inflammation index.

prognostic factors of OS (Table 2).

Similarly, the 5-, 10-, 15-, and 20-year DFS rates were 56.5%, 39.1%, 31.3%, and 26.5%, respectively. The DFS rates were lower in patients with high NLR, PLR, and SII compared to those of the patients with low NLR, PLR, and SII, respectively (Figure 1D-F). The DFS data for the three patient groups are demonstrated in Table 3. Univariate Cox proportional hazards regression analysis revealed that age, histological type, tumor invasion, lymph node involvement, distant metastasis, TNM stage, chemotherapy, NLR, PLR, and SII had statistically significant associations with DFS. In addition, multivariate analysis indicated that SII was a significant independent prognostic parameter for DFS, whereas PLR and NLR were not (Table 3).

The AUCs of the NLR, PLR, and SII for OS were 0.602, 0.566, and 0.707, respectively (Figure 2A) and the AUCs for DFS were 0.597, 0.558, and 0.701, respectively (Figure 2B). Hence, among the immune-inflammation indices analyzed in the present study, SII was the best predictor of long-term survival and recurrence in cases with CRC.

Prognostic value of NLR, PLR, and SII stratified according to TNM stage

Further subgroup analyses were performed to investigate the prognostic value of SⅡ, NLR, and PLR in patients with CRC who were stratified according to the TNM stage. The results of the analyses showed that only SⅡ was able to distinguish the OS and DFS for each TNM stage (Figure 3A-F). On the other hand, NLR could identify the survival differences between TNM stages Ⅱ-Ⅳ, while PLR could only detect the prognostic differences of stage Ⅱ-Ⅲ cancers (Figure 4A-F for NLR and Figure 5A-F for PLR). Hence, the results indicated that only SII had prognostic significance for the CRC cases stratified according to TNM stage.

DISCUSSION

In the present study, we established an immune-inflammation-based prognostic index (SII) based on

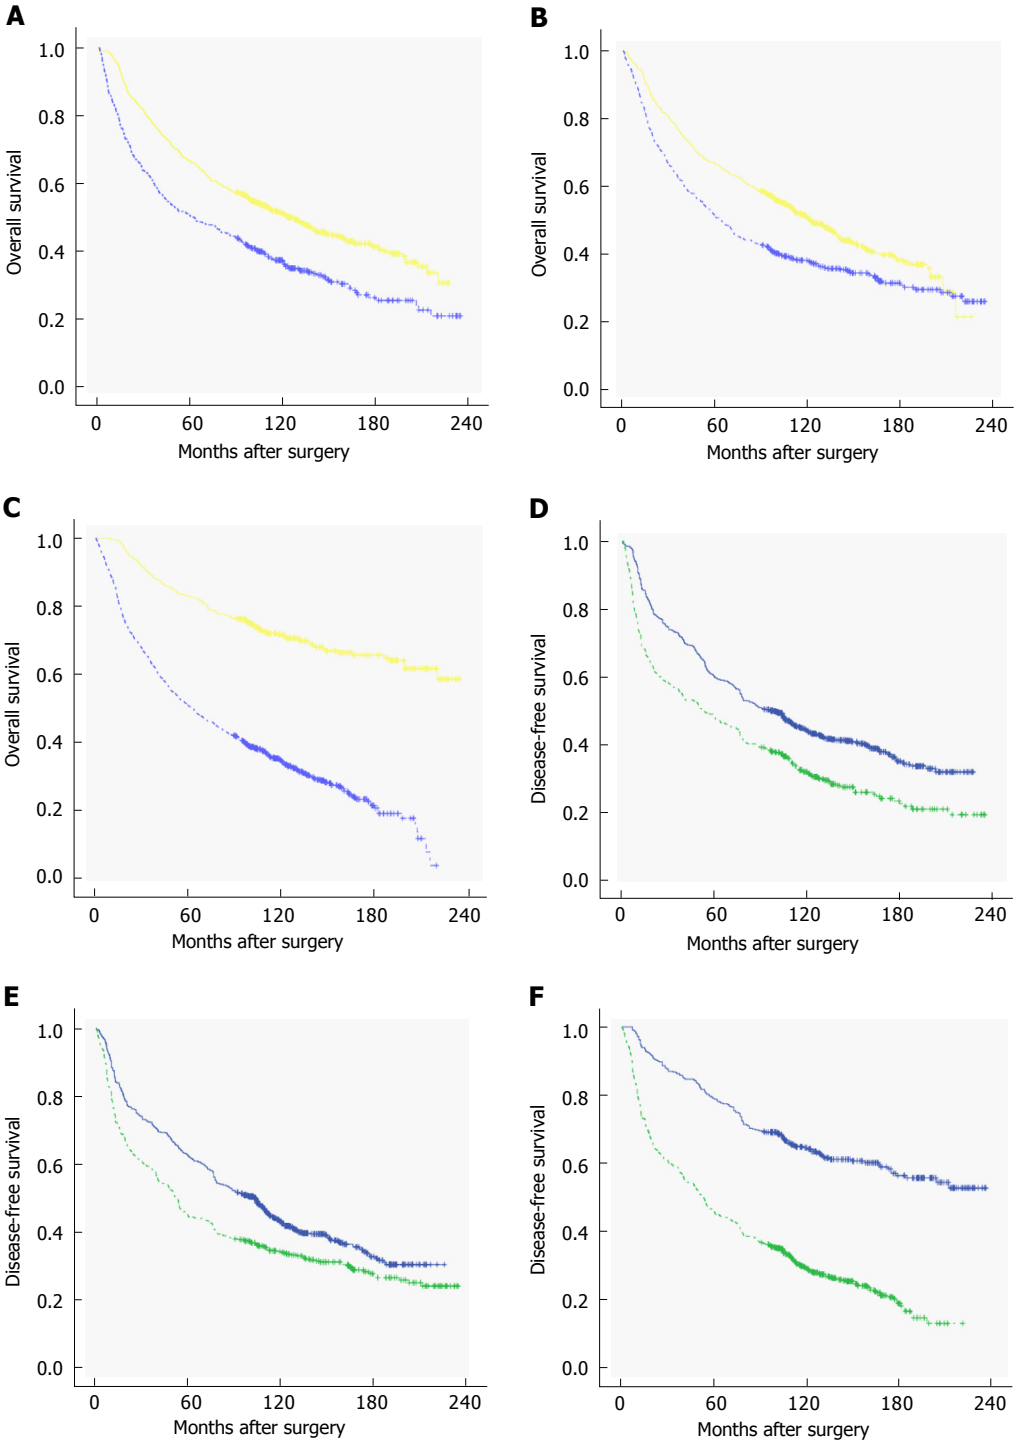

Figure 1 Kaplan-Meier curves of overall survival and disease-free survival of colorectal cancer patients based on neutrophil-lymphocyte ratio (A and D), platelet-lymphocyte ratio (B and E), and systemic immune-inflammation index (C and F).

peripheral neutrophil, platelet, and lymphocyte counts and demonstrated that elevated SII was correlated with poor OS and recurrence in patients with CRC. In addition, SII was a superior prognostic factor for survival outcome compared to NLR and PLR.

It was recognized that inflammatory-based indices were associated with poor tumor behavior and survival outcome in various malignant solid tumors, including CRC. Several combinations such as NLR[14], PLR[15], prognostic nutritional index[16], Glasgow Prognostic score[17], and lymphocyte monocyte ratio (LMR)[18] showed positive correlations between elevated inflammation-based factors and poor survival outcome in patients with CRC. To our knowledge, this was the first report investigating the prognostic value of SII in patients with CRC after radical surgery. Using an integrated index based on peripheral neutrophil, platelet, and lymphocyte counts, Hu *et al*[12] found

that patients having elevated preoperative SⅡ were usually diagnosed with thrombocytosis, neutropenia, or lymphopenia. They believed that a better understanding of the roles of neutrophils, platelets, and lymphocytes in cancer development and progression would help clarify the association between SⅡ and its clinical impact. Neutrophils do not only alter the tumor microenvironment *via* the extrinsic pathway, but they

also secrete some inflammatory mediators to promote tumor cell proliferation, invasion, metastasis to lymph nodes or distant organs, and cellular senescence *via* the intrinsic pathway[19,20]. Accumulating experimental and clinical evidence showed that platelet activation could act as chemoattractants for cancer cells, induce the formation of optimized conditions for metastatic foci, promote the epithelial to mesenchymal transition in tumor cells, and increase the level of circulating tumor cells[21,22]. Lymphopenia was commonly accompanied by leukocytosis and thrombocytosis, which might help tumor cells to escape immune surveillance and prevent damage from the autoimmune response by cytotoxic T cells[23]. There was a good and a bad inflammatory reaction. In other words if the inflammation was based on the production of simply growth factors, the inflammatory reaction has a negative effect. But if the inflammatory reaction consists on neutralizing antibodies produced by activated lymph nodes, this reaction can have a positive effect. Thus, a high SII level reflected alterations in the cancer microenvironment that favor cancer initiation, progression, and metastasis.

The present study revealed interesting associations between inflammation-based indices and clinicopathological features. Consistent with the clinicopathological features associated with NLR and PLR, which are the most common indices, SII was also associated with poor histological differentiation, larger tumor size, more advanced T stage, N stage, M stage, and TNM stage, validating the above hypothesis that the elevated inflammatory response might promote tumor proliferation, progression, and metastasis.

As a simple, convenient, easily obtained, cheap, and non-invasive marker, SII was first described by Hu *et al*[12] in hepatocellular carcinoma. They concluded that preoperative SII might be related to circulating tumor cells and act as a powerful prognostic predictor in patients with hepatocellular carcinoma. Consistent with the results of previous studies, Yang *et al*[24] also reported that elevated SII with a cut-off value of 300 was negatively associated with OS in HBV-related hepatocellular carcinoma[25]. Moreover, SII was reported as a predictor of metastatic CRC in patients who received first-line chemotherapy with bevacizumab[26]. To our knowledge, the present study was the first to investigate the prognostic value of SII in CRC. Confirmed by the Kaplan-Meier analysis using the log-rank method, all the inflammation-based indices were significantly associated with OS and recurrence. However, SII was identified in Cox multivariate analysis to be a superior predictor of OS and DFS compared to other inflammation-based prognostic indices. The discriminative abilities of these three indices were further evaluated and compared; based on the AUC values obtained from ROC curves, SII was the most effective predictor of long-term survival outcome compared to NLR and PLR. The potential explanation of a better prognostic value might be that SII was more comprehensive in reflecting the status of inflammatory and immune response than the other factors.

Pathological TNM staging is presently the gold standard for predicting survival outcome and the treatment choice. However, because TNM staging was performed postoperatively, survival prediction before surgery and decision of further treatment strategies became difficult. Moreover, TNM stage can only reflect the biological behavior of the tumor. To our knowledge, prognosis was not only associated with the clinicopathological characteristics of the tumor, but also with the host inflammatory response[27]. SII is based on peripheral neutrophil, platelet, and lymphocyte counts, and it reflects the status of the tumor microenvironment and the preoperative host inflammatory response, serving as a complementary to the TNM stage for predicting OS. Our findings demonstrated that preoperative SII had powerful prognostic discriminative abilities in terms of each TNM subgroup compared to NLR and PLR. Therefore, using a combination of parameters that reflect both the tumor characteristics and the host systemic inflammatory status might be important for accurately predicting survival outcome in patients with CRC.

The present study had a few limitations. First, it was a retrospective, single-center study. Therefore, a large-scale prospective validation study is required to validate the results of the present study. Second, only the patients who received radical surgery were enrolled and thus, the results of the present study are not applicable in incurable patients or in those for whom the treatment was terminated because of various reasons.

In conclusion, this was the first study to demonstrate that preoperative SII is a simple and powerful prognostic indicator of OS and DFS in patients with CRC. SII might be used along with the TNM staging for individualized treatment in future clinical practice. A larger prospective study is warranted for the validation of the preliminary results obtained in the present study.

COMMENTS

Background

Recently, there were many papers describing mathematical formulas, such as neutrophil-lymphocyte ratio and platelet-lymphocyte ratio, which were considered important prognostic factors for colorectal cancer (CRC). In this article, the authors want to investigate the clinical value of systemic immune-inflammation index (SII), an integrated indicator based on peripheral lymphocyte, neutrophil, and platelet counts.

Research frontiers

The interplay between systemic inflammation and the local immune response was recognized as the seventh hallmark of cancer, and it has been demonstrated to be involved in the initiation, development, and progression of several types of malignancies. Inflammation can produce several cytokines and growth factors which can facilitate the occurrence and development of cancer. We established a systemic inflammation parameter, SII and found that SII had better prognostic predictive abilities for overall survival and recurrence of CRC in this study.

Innovations and breakthroughs

Preoperative SII based on peripheral lymphocyte, neutrophil, and platelet counts was established, and no study investigated the clinical value of SII in CRC before. We found that SII had better prognostic predicting abilities for overall survival and recurrence when compared with neutrophil-lymphocyte ratio and platelet-lymphocyte ratio in patients with CRC. It might assist the identification of high-risk patients among patients with the same TNM stage in clinical practice.

Applications

Patients with high SII showed aggressive tumor biological behavior, poor overall survival and early tumor recurrence. Hence, SII may give help to identify the high-risk patients among patients with the same TNM stage in clinical practice.

Terminology

SII is based on the peripheral lymphocyte, neutrophil, and platelet counts, and is calculated using the formula SII = (P × N)/L, where P, N, and L refer to the preoperative peripheral platelet, neutrophil, and lymphocyte counts, respectively.

Peer-review

This is an interesting study. Obvious conclusions were drawn from a well-known phenomenon: Correlation between inflammation and cancer development and progression. I think the paper should be published to address an important point: To cure or prevent inflammation can prevent cancer formation and progression. The result may give help to clinical doctors.

Abstract

AIM

To investigate the factors predictive of failure when

placing a second biliary self-expandable metallic stents (SEMSs).

METHODS

This study evaluated 65 patients with an unresectable malignant hilar biliary obstruction who were examined in our hospital. Sixty-two of these patients were recruited to the study and divided into two groups: the success group, which consisted of patients in whom a stent-in-stent SEMS had been placed successfully, and the failure group, which consisted of patients in whom the stent-in-stent SEMS had not been placed successfully. We compared the characteristics of the patients, the stricture state of their biliary ducts, and the implemented endoscopic retrograde cholangiopancreatography (ERCP) procedures between the two groups.

RESULTS

The angle between the target biliary duct stricture and the first implanted SEMS was significantly larger in the failure group than in the success group. There were significantly fewer wire or dilation devices (ERCP catheter, dilator, or balloon catheter) passing the first SEMS cell in the failure group than in the success group. The cut-off value of the angle predicting stent-in-stent SEMS placement failure was 49.7 degrees according to the ROC curve (sensitivity 91.7%, specificity 61.2%). Furthermore, the angle was significantly smaller in patients with wire or dilation devices passing the first SEMS cell than in patients without wire or dilation devices passing the first SEMS cell.

CONCLUSION

A large angle was identified as a predictive factor for failure of stent-in-stent SEMS placement.

Key words: Endoscopic stent-in-stent self-expandable metallic stent placement; Predictive factor; Endoscopic retrograde cholangiopancreatography; Malignant hilar biliary obstruction; Self-expandable metallic stent

Core tip: We investigated the factors predictive of failure when placing multiple endoscopic self-expandable metallic stents (SEMSs) to relieve a malignant biliary obstruction. The angle between the target biliary duct stricture and the first implanted SEMS was significantly higher in the failure than in the success group. There were significantly fewer wire or dilation devices passing the first SEMS cell in the failure group than in the success group. The angle was significantly smaller in patients with wire or dilation devices passing the first SEMS cell. In conclusion, a large angle was identified as a predictive factor for failure of stent-in-stent SEMS placement.

Predictive factors for the failure of endoscopic stent-in-stent self-expandable metallic stent placement to treat malignant hilar biliary obstruction. *World J Gastroenterol* 2017; 23(34): 6273-6280 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6273.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6273

INTRODUCTION

A malignant hilar biliary stricture can be caused by several different types of cancer, such as cholangiocarcinoma, pancreatic cancer, liver cancer, and lymph node metastases. A malignant hilar biliary stricture causes obstructive jaundice, and biliary drainage must be accomplished prior to surgical or chemotherapeutic treatment. Two procedures can be used to achieve biliary drainage to treat malignant obstructive jaundice: endoscopic therapy and percutaneous transhepatic bile drainage. Due to its safety and efficacy, endoscopic therapy is the first-choice treatment[1].

Generally, self-expandable metallic stents (SEMSs) are superior to plastic stents in terms of stent patency, cost, and length of hospital stay[2-7]. SEMSs are likewise superior for the treatment of a malignant hilar biliary stricture[8]. Whether it is necessary to multistent a malignant hilar biliary stricture remains a topic of discussion[8-15]. In fact, some patients require multistenting to treat cholangitis and liver abscesses. However, it is sometimes difficult to place multiple metallic stents to relieve a malignant hilar biliary stricture. Moreover, the predictive factors for the failure of biliary multistenting have not been identified.

Therefore, the aim of the present study was to determine the predictive factors for the failure of biliary multistenting.

MATERIALS AND METHODS

Study design

This study was retrospective in design. To evaluate the predictive factors for the failure to place an endoscopic stent-in-stent SEMS, we compared the patient characteristics and the therapeutic endoscopy factors of the groups with successful and unsuccessful stent-in-stent SEMS placement. This study was approved by the ethics committee of Fukushima Medical University.

Patients

We examined 65 patients with an unresectable malignant hilar biliary stricture in whom an endoscopic stent-in-stent biliary SEMS placement was attempted between April 2003 and August 2016 in our hospital. The patients were not required to give informed consent to participate in this study because the analysis used anonymised data obtained after each patient provided

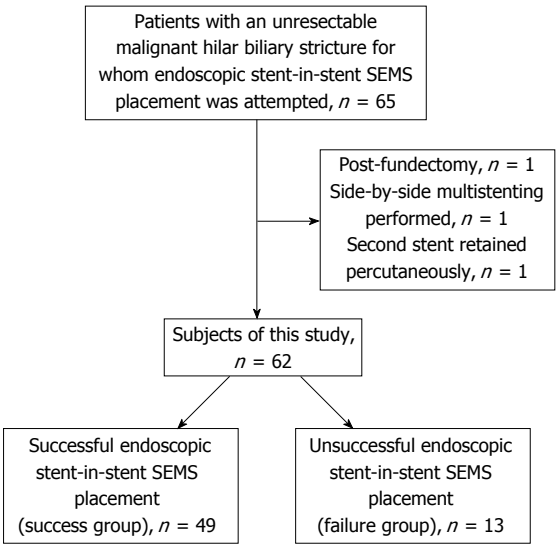

Figure 1 Targets of this study. Among 65 patients with an unresectable malignant hilar biliary obstruction, 62 patients were included. These 62 patients were divided into two groups, the success group, in whom an endoscopic stent-in-stent self-expandable metallic stent (SEMS) placement was successful, and the failure group, in whom an endoscopic stent-in-stent SEMS placement was unsuccessful.

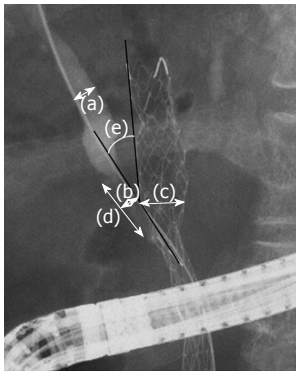

Figure 2 Endoscopic retrograde cholangiography image showing the details of the obstructive state of the biliary duct. We evaluated the obstructive state of the biliary duct by measuring the following four items: (a) The diameter of the target biliary duct, (b) the diameter of the target biliary stricture, (c) the diameter of the first retained self-expandable metallic stent (SEMS), (d) the length of the target biliary duct stricture and (e) the angle between the target biliary duct stricture and the first implanted SEMS.

written consent to undergo the medical examination. We included 62 of the 65 patients in our study, all of whom had Bismuth type II-IV strictures, had not received upper gastrointestinal tract surgery, and had underwent multiple stent-in-stent placements (Figure 1). Moreover, all patients retained the first metallic stent that was placed. We divided the patients into two groups. The 49 patients in whom a stent-in-stent SEMS was successfully placed at the hilar biliary stricture were included in the success group. The 13 patients in whom only one metallic stent was placed at the hilar biliary stricture were included in the failure group.

Endoscopic retrograde cholangiopancreatography procedure

Endoscopic retrograde cholangiopancreatography (ERCP) was performed by specialists of pancreaticobiliary endoscopy who had experience performing at least 2000 ERCP procedures or by trainees under the guidance of specialists. Before the ERCP procedure was initiated, all patients were sufficiently sedated with midazolam. After the ERCP endoscope was placed in the descending portion of the duodenum, biliary duct cannulation was performed, and the strictured region was observed using cholangiography. Endoscopic sphincterotomy (EST) was performed as required. The first metallic stent was placed at the hilar biliary stricture, and a wire was passed to the second targeted biliary duct. If a wire was not passed to the second targeted biliary duct, the procedure was finished. After the mesh was dilated using an ERCP catheter, a dilator catheter, or a balloon catheter, a second metallic stent was placed. Dilation devices were selected randomly by each endoscopist. JF240, TJF240, or JF260V ERCP endoscopes (Olympus, Tokyo, Japan) were used. The guidewires used in this study were Visiglide 1, Visiglide 2 (Olympus, Tokyo, Japan), Jagwire, Hydra Jagwire (Boston Scientific Japan, Tokyo, Japan), RevoWave (Piolax, Kanagawa, Japan), or Tracer Metro (Cook Japan, Tokyo, Japan). A CleverCut 3V or a Needle Knife device (Boston Scientific Japan, Tokyo, Japan) was used for EST. A SMART (Johnson & Johnson, Tokyo, Japan), JOSTENT (Zeon Medical, Tokyo, Japan), Zilver, Zilver 635 (Cook Japan, Tokyo, Japan), Niti-S D-type, Niti-S large-cell D-type (Taewoong-Medical, Gyeoenggi-do, Korea), Wall, or Wall Flex (Boston Scientific Japan, Tokyo, Japan) device was used as a biliary uncovered metal stent deployment system. A Tandem XL or CONTOUR taper tip, CONTOUR ultra-taper tip, CONTOUR 5-4-3 tip (Boston Scientific Japan), PR-233Q (Olympus), or MTW ERCP catheter taper (MTW Endoskopie, Wesel, Germany) was used as the ERCP catheter. A Soehendra biliary 6-Fr or 7-Fr dilation catheter (Cook Japan) was used as the biliary dilation catheter. An RX Hurricane balloon dilatation catheter (Boston Scientific Japan), Zara EPBD catheter (Kaneka Corporation, Tokyo, Japan), or REN biliary dilation catheter (Kaneka Corporation) was used to dilate the first SEMS lumen or mesh.

Variables considered

The following variables of the success and failure groups were considered: age, gender, diagnoses causing the biliary stricture (primary lesions or metastases), bismuth classification, diameter of the targeted biliary duct (Figure 2-a), diameter of the targeted biliary stricture (Figure 2-b), diameter of the first implanted SEMS (Figure 2-c), length of the targeted biliary duct stricture (Figure 2-d), angle between the target biliary duct stricture and the first

implanted SEMS (Figure 2-e), length of the procedure, clinically effective rate, adverse effects, wire passage of the first SEMS cell, catheter usage to dilate the first SEMS cell, catheter passage of the first SEMS cell, dilator usage to dilate the first SEMS cell, dilator passage of the first SEMS cell, balloon catheter usage to dilate the first SEMS lumen, balloon usage to dilate the first SEMS cell, balloon passage of the first SEMS cell, the number of used dilation devices (0: no dilation device was used-3: catheter, dilator and balloon catheter were all used), type of first SEMS used (braided or laser-cutting type), stenting order, number of ERCP sessions, and the area of the first SEMS cell. Improvement in liver or biliary function (ALT or ALP or bilirubin) within 2 wk after ERCP was determined as "clinically effective". The area of the first SEMS cell was not available for two patients in the failure group and three patients in the success group.

Statistical analysis

Student's t test or Mann-Whitney U test and Fisher's exact test were used to calculate the significance of the differences between the continuous variables and the nominal scales of the two groups. The Bismuth classifications were analysed using the Mann-Whitney U test. A P value of < 0.05 was considered to indicate a significant difference. All statistical analyses were performed using the EZR platform (Saitama Medical Centre, Jichi Medical University, Saitama, Japan), which is a graphical user interface for R (The R Foundation for Statistical Computing, Vienna, Austria). More precisely, EZR is a modified version of R commander that was designed to perform functions that are frequently used in biostatistics[16].

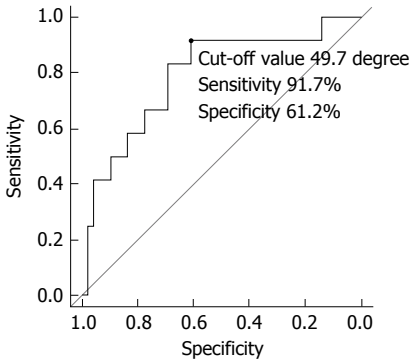

Figure 3 ROC curve of the angle between the target biliary duct stricture and the first implanted self-expandable metallic stent. A cut-off value of 49.7 degrees with a sensitivity of 91.7% and a specificity of 61.2% can be used to predict stent-in-stent self-expandable metallic stent placement failure.

RESULTS

No significant differences in the characteristics of the patients (Table 1) or the details of the target biliary ducts of the success and failure groups (Table 1) were observed with the exception of the following: the angle between the target biliary duct stricture and the first implanted SEMS was significantly different between the success group and the failure group [44.4 (7-119) degree *vs* 75.3 (28-109.3) degree, P < 0.01]. The ROC curve of the angle between the target biliary duct stricture and the first implanted SEMS revealed a cut-off value of 49.7 degrees with a sensitivity of 91.7% and a specificity of 61.2% for predicting stent-in-stent SEMS placement failure (Figure 3).

Regarding the ERCP procedures and outcomes used for the patients in the two groups, clinically effective rate, the rates of wire passage through the first SEMS cell, catheter passage through the first SEMS cell, dilator passage through the first SEMS cell, and balloon catheter passage through the first SEMS cell in the failure group were significantly lower than in the success group (Table 2). No other variables for the ERCP procedures used for the members of the success and failure groups were significantly different.

DISCUSSION

In this study, we investigated the factors predictive of failure in placing a second SEMS. The angle between

[1]Data for one patient were not available; [2]Data for three patients were not available; [3]Data for two patients were not available. ERCP: Endoscopic retrograde cholangiopancreatography; SEMS: Self-expandable metallic stent.

the target biliary duct stricture and the first implanted SEMS was significantly associated with failure to place a second SEMS. In fact, failure to pass the devices was significantly associated with unsuccessful endoscopic stent-in-stent SEMS placement.

Few reports have examined the relationship between failure to place an endoscopic stent-in-stent SEMS and the characteristics of the patients. In one report, metastatic disease was found to be related to the failure to place an endoscopic stent-in-stent SEMS[17]. Although a similar number of patients who were evaluated in the previous investigation were analysed in this study, different results were obtained. However, the relationship between the failure to place an endoscopic stent-in-stent SEMS and the obstructive state of the biliary duct has not been reported. In this study, the effect of the precise details of the biliary obstructive state on the placement of an endoscopic stent-in-stent SEMS was evaluated. Among several features regarding the biliary obstructive state, only the angle between the target biliary duct stricture and the first implanted SEMS was significantly different between the success and failure groups. An angle less than 49.7 degrees, according to the ROC curve, predicted high probability of successful placement of a second SEMS.

Several reports have considered the devices used to treat patients with a malignant hilar biliary obstruction. The efficacy of using a slimmer stent or a large-cell metal stent for bilateral stent-in-stent placement has been reported[18-21]; the large-cell metal stent that was used was in these studies was a Niti-S large-cell stent (Taewoong-Medical), and the slimmer stent that was used was a Zilver stent (Cook Japan). We generally used these types of stents to initially treat the patients recruited in this study. The areas of the first SEMS cell placed in the patients of the two groups were not significantly different. This result is consistent with those of a previous study showing that the cell size did not affect successful bilateral drainage[22].

In studies reporting a high success rate for bilateral drainage, a 7-Fr Soehendra dilator (Cook Japan), a 6- to 8-mm CRE wire-guided oesophageal/pyloric balloon dilatation catheter, or a 6- or 8-mm Hurricane RX dilatation catheter (Boston Scientific Japan) was used[18,21]. In this study, these devices and ERCP catheters, such as the Tandem XL cannula (Boston Scientific Japan), were used to pass the first SEMS. To identify the cause underlying the failure of these devices to pass, we evaluated the influence of the angle between the target biliary duct stricture and the first implanted SEMS on wire or dilation catheter passage using the Mann-Whitney *U* test (Figure 4). The angle was statistically higher in patients in whom the wire or dilation device was unable to pass the first implanted SEMS than in patients in whom the wire or dilation catheter passed the first implanted SEMS [93.0 degrees (55-109.3) *vs* 44.2 degrees (7-119.0),

[1]Data for one patient were not available; [2]Data for two patients were not available. SEMS: Self-expandable metallic stent.

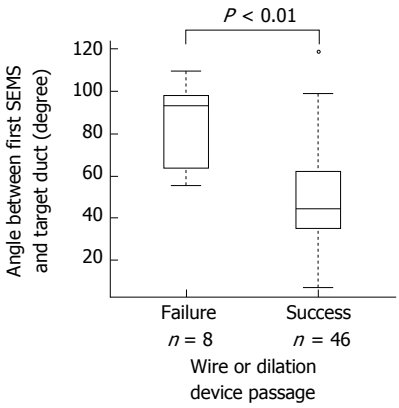

Figure 4 Influence of the angle between the target biliary duct stricture and the first retained self-expandable metallic stent on wire or dilation device passage. The angle between the target biliary stricture and the first implanted self-expandable metallic stent in patients without wire or dilation catheter passage was significantly greater than the corresponding angle in the patients with wire or dilation catheter passage [93.0 degree (55-109.3) *vs* 44.2 degree (7-119.0), $P < 0.01$, median (range)].

$P < 0.01$, median (range)]. Therefore, the findings demonstrate that the angle influences not only the second SEMS placement but also the passage of the wire or dilation device through the first SEMS cell.

Finally, we considered how to increase the success rate of stent-in-stent deployment of SEMSs in patients with larger angles. Upon comparing patients in the success and failure groups with larger angles (Table 3), the diameter of the first implanted SEMS was not significantly different. According to this result, the cause of the failure of the second SEMS insertion was not radial force. The passage of dilation devices was significantly different between the two groups. As described above, we used SEMSs recommended in past reports. Based on this study, we believe that improvements in dilation devices have contributed to overcoming such difficult cases. As the second SEMS insertion was effective in improving liver or biliary function in some patients (clinically effective rate from Table 2), an improvement in dilation devices is desired.

A limitation of this study is that it was a retrospective study that involved a small number of patients at one institution. Most reports regarding stenting to treat malignant hilar biliary obstruction consider the devices used here. It would be difficult to conduct a prospective study of the predictive factors for failure to place an endoscopic stent-in-stent SEMS. However, a larger multicentre study should be performed in the future.

In conclusion, we revealed that the angle between the target biliary duct stricture and the first implanted SEMS has an impact on the passing of both wire and dilation devices through the first SEMS cell and the placement of the second SEMS. We determined that a large angle between the target biliary duct stricture and the first implanted SEMS is a predictive risk factor for endoscopic stent-in-stent SEMS placement failure.

COMMENTS

Background

Endoscopic biliary drainage is the first choice for biliary drainage in unresectable malignant biliary obstruction patients. Among drainage stents, metallic stents are more effective than plastic stents. The placement of multiple endoscopic self-expandable metallic stents (SEMSs) to relieve a malignant biliary obstruction is often challenging. Therefore, we investigated the factors predictive of failure when placing a second SEMS.

Research frontiers

Regarding endoscopic stent-in-stent SEMS insertion, which stents should be used is major topic of discussion. On the other hand, predictive risk factors of endoscopic stent-in-stent SEMS placement failure have not been sufficiently validated.

Innovations and breakthroughs

This is the first report to investigate the relationship between details of the biliary obstructive state and the failure of endoscopic stent-in-stent SEMS placement. We found that a large angle between the target biliary duct stricture and the first implanted SEMS is a predictive risk factor for endoscopic stent-in-stent SEMS placement failure.

Applications

If the risk factors of endoscopic stent-in-stent SEMS placement failure are known, time spent on procedures will not be wasted. The procedure is completed as a unilateral biliary drainage procedure or another rapidly drainage technique, such as percutaneous transhepatic biliary drainage.

Terminology

Endoscopic retrograde cholangiopancreatography: An endoscope is inserted into the descending portion of the duodenum. After a catheter is inserted into the biliary duct or pancreatic duct, a contrast agent is injected to visualize these ducts under X-ray fluoroscopy. Images of the biliary duct or pancreatic duct are observed. SEMSs: This stent is a metallic stent that can expand after it is placed in the malignant biliary stricture.

Peer-review

This is an interesting retrospective study attempting to identify predictive factors for unsuccessful deployment of a second stent when placement of multiple metal stents (MS) was attempted in the stent-in-stent manner for unresectable malignant perihilar biliary obstruction. The authors evaluated many factors, including etiology, findings of cholangiography, and procedural factors, and concluded that the duller (larger) angle between the first deployed stent and the target duct for next placement was the important factor. This is a very interesting issue and your conclusion seems informative.

Abstract

AIM

To determine the inter-observer variability for colon polyp morphology and to identify whether education can improve agreement among observers.

METHODS

For purposes of the tests, we recorded colonoscopy video clips that included scenes visualizing the polyps. A total of 15 endoscopists and 15 nurses participated in the study. Participants watched 60 video clips of the polyp morphology scenes and then estimated polyp morphology (pre-test). After education for 20 min, participants performed a second test in which the order of 60 video clips was changed (post-test). To determine if the effectiveness of education was sustained, four months later, a third, follow-up test was performed with the same participants.

RESULTS

The overall Fleiss' kappa value of the inter-observer agreement was 0.510 in the pre-test, 0.618 in the post-test, and 0.580 in the follow-up test. The overall diagnostic accuracy of the estimation for polyp morphology in the pre-, post-, and follow-up tests was 0.662, 0.797, and 0.761, respectively. After education, the inter-observer agreement and diagnostic accuracy of all participants improved. However, after four months, the inter-observer agreement and diagnostic accuracy of expert groups were markedly decreased, and those of beginner and nurse groups remained similar to pre-test levels.

CONCLUSION

The education program used in this study can improve inter-observer agreement and diagnostic accuracy in assessing the morphology of colon polyps; it is especially effective when first learning endoscopy.

Key words: Colon polyp; Morphology; Education

Core tip: Paris classification is used worldwide in clinical practice to categorize the morphology of gastrointestinal polyps. However, few studies regarding the inter-observer variability associated with this classification have been reported. In this study, we identified that an education program could be helpful in improving inter-observer agreement and diagnostic accuracy when determining the morphology of colon polyps, and that the educational program was especially effective when first learning endoscopy. We suggest that daily practice of morphology assessment of colon polyps and the proper education of the Paris classification are essential in maintaining the quality of colonoscopic examination.

INTRODUCTION

Adenomatous polyps are the most common neoplasm detected during colonoscopic examination, and patients with this type of polyp have a greater risk of developing advanced neoplasia[1-5]. According to the National Polyp Study[6,7], colonoscopy is a useful tool in detecting colorectal polyps, and colonoscopic removal of adenomatous polyps prevents death from colorectal cancer (CRC). The size, location, and grade of polyp dysplasia are correlated with potential risks of malignant evolution[8-10], and the endoscopic appearance of polyps can predict invasion into the submucosa[11-13]. The invasive growth rates of depressed lesions, sessile lesions, and pedunculated lesions are 61%, 34% and 5%, respectively[14,15]. Therefore, polyp morphology is an important factor in determining the therapeutic method of endoscopic treatment or surgery.

When a colon polyp is confined to the mucosa or upper part of the submucosa, it can be safely removed by endoscopic procedure. However, insufficient recognition of lesions, particularly flat lesions including sessile serrated adenoma/polyps (SSA/P), can result in incomplete endoscopic resection, which is strongly associated with interval cancer[16,17]. In 2002, Western and Japanese endoscopists, surgeons, and pathologists gathered and presented the Paris classification of superficial neoplastic lesions in the digestive tract[14]. The Paris classification is now utilized worldwide to classify the morphology of polyps in clinical practice. However, few studies regarding inter-observer variability associated with this classification have been reported. Recently, Van Doorn *et al*[18] assessed the inter-observer agreement for the Paris classification among seven Western expert endoscopists and found that agreement was moderate and did not change after training. They suggested that the usefulness and the educational impact of this classification in clinical practice are questionable, and that the introduction of a simplified classification system is needed. However, additional studies that include Eastern expert endoscopists are necessary in order to generalize these results.

In the current study, we aimed to evaluate inter-observer variability for colon polyp morphology and to determine the effectiveness and persistence of an education program for both Korean experts and beginners.

MATERIALS AND METHODS

Creation of the video clips

For purposes of this study, colon polyps detected by colonoscopy were recorded as photographic images. Two experienced gastroenterologists (Kwon HJ and Choi YJ) performed colonoscopic examinations and recorded several pictures of polyps at various alignments. From these, a study investigator (Nam KS) selected five to seven for each polyp and created a video clip by connecting the pictures using Windows Movie Maker (Microsoft, Redmond, Washington, United States). A total of 80 video clips were created and edited to 10-15 s in length. Sixty video clips were used for the exam and 20 video clips for the learning sets. To minimize any bias in assessing polyp morphology, all video clips were reviewed by two experienced gastroenterologists (Jung K and Kim SE).

Examination and educational program for participants

This study was approved by the Institutional Review

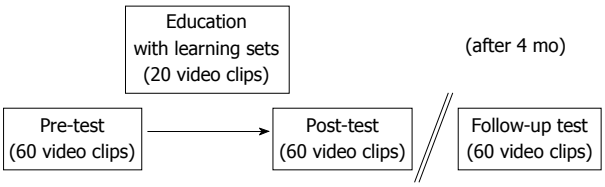

Figure 1 Flowchart of the study.

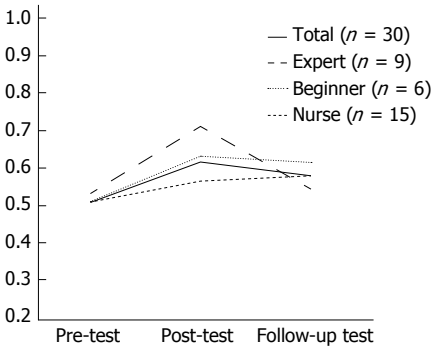

Figure 2 Inter-observer agreement of the estimated polyp morphology.

Board of Kosin University Gospel Hospital. All study participants were provided informed written consent prior to study enrollment. Fifteen endoscopists and 15 nurses participated in the study. Nine of the endoscopists were experienced (expert group) and had performed more than 1000 colonoscopies, six were endoscopic training fellows (beginner group) who had performed fewer than 300 colonoscopies, and 15 were nurses working in endoscopic practice (nurse group). The study included a pre-test, an educational program, a post-test, and a follow-up test, as shown in Figure 1.

On the day of the exam, participants received an explanation about the aim of the study and were asked to assess 60 polyps according to the Paris classification. They watched 60 video clips and recorded (in writing) the polyp morphology (Ip, Isp, Is, Ⅱa, Ⅱb, Ⅱc, or Ⅲ) ("pre-test"). After the first exam, a study investigator presented a 20-min educational program that included a detailed explanation of the Paris classification and 20 learning video clips that consisted of standard pictures illustrating the Paris classification ("education"). Following this, participants completed the second exam, in which the order of 60 video clips ("post-test") was changed. Four months later, we randomly administered the third exam ("follow-up" test) to the same participants to determine if the effectiveness of education was sustained. When analyzing exam results, we assessed inter-observer agreement and the diagnostic accuracy of each exam and compared the results.

Statistical analysis

Inter-observer agreement was evaluated by calculating the Fleiss' kappa value between participants. We assessed inter-observer agreement for all participants and compared expert, beginner, and nurse groups. Kappa values below 0.40 and of 0.41-0.60, 0.61-0.80, and greater than 0.80 were defined as fair agreement, moderate agreement, substantial agreement, and almost perfect agreement, respectively. We also evaluated the assessed category of polyp morphology for each polyp. For example, if the participants all chose Ip for a polyp, it was assessed as one category per one question. If the participants chose Is or IIa for a polyp, it was assessed as two categories per one question. We also estimated and compared the diagnostic accuracy of the three groups. Statistical analyses were performed using SPSS Statistics 20.0 (IBM®, Armonk, NY, United States).

RESULTS

The colon polyp characteristics used in the exam are summarized in Table 1. Figure 2 illustrates the inter-observer agreement of the estimated polyp morphology. The overall Fleiss' kappa value of the inter-observer agreement was 0.510 in the pre-test, 0.618 in the post-test, and 0.580 in the follow-up test. In the expert group, the inter-observer agreement improved after education (0.533 in pre-test → 0.713 in post-test); however, after four months, the agreement decreased to a level similar to that of the pre-test (0.544 in the follow-up test). In the beginner group, the inter-

Total	7 (11.7)	3 (5.0)	4 (6.7)

observer agreement improved after education (0.514 in pre-test → 0.631 in post-test); after four months, the agreement slightly decreased to a value similar to that at the post-test (0.616 in the follow-up test). In the nurse group, the inter-observer agreement improved after education (0.508 in pre-test → 0.566 in post-test); after four months, the agreement was slightly improved to a value similar to that at the post-test (0.576 in follow-up test).

In Table 2, the difference in assessment of polyp morphology was shown for each test. The proportion of one category per one question was 25.0% in the pre-test, 46.7% in the post-test, and 35.0% in the follow-up test. The proportion of two categories per one question was 63.3% in the pre-test, 48.3% in the post-test, and 58.3% in the follow-up test. The proportion of three categories per one question was similar in each test.

The overall diagnostic accuracy of the estimation for polyp morphology in the pre-test, post-test, and follow-up tests was 0.662, 0.797, and 0.761, respectively (data not shown). Figure 3 shows the diagnostic accuracy of the estimation for polyp morphology of each group. In the expert group, the diagnostic accuracy was improved after education (0.715 in pre-test → 0.846 in post-test); however, after four months, the diagnostic accuracy decreased (0.769 in the follow-up test). In the beginner and nurse groups, diagnostic accuracy improved after education (beginner group, 0.703 in pre-test → 0.806 in post-test; nurse group, 0.614 in pre-test → 0.764 in post-test); after four months, the diagnostic accuracy was similar to the value at the post-test (beginner group, 0.794 in follow-up test; nurse group, 0.743 in follow-up test).

DISCUSSION

In this study, 15 endoscopists and 15 nurses participated in a total of three exams to evaluate the validity of the Paris classification in assessing colon polyp morphology. When analyzing exam results, we found that the education improved inter-observer agreement and the diagnostic accuracy of estimated polyp morphology. In addition, the effectiveness of education was sustained over time in the beginner and nurse groups, especially.

The Paris classification is a system that classifies the endoscopic appearance of superficial neoplastic lesions in the digestive tract and distinguishes polypoid and non-polypoid lesions[14]. Polypoid lesions are divided into pedunculated (Ip) or sessile (Is) types, and non-polypoid lesions are divided into superficial slightly elevated (Ⅱa), flat (Ⅱb), superficial depressed (Ⅱc), and excavated (Ⅲ) types[14]. The awareness of non-polypoid lesions and technical advances including chromoendoscopy, high-resolution endoscopy, and magnifying endoscopy have contributed to a higher detection rate of early colorectal carcinoma[19,20]. The detection rate of adenoma has been shown to be closely associated with the risk of interval CRC[21]. In a systematic review, the miss rate for adenomatous polyps was 13% for sizes of 5-10 mm and 26% for sizes of 1-5 mm, and the miss rate for non-adenomatous polyps was 22% with a size < 10 mm[22]. Also importantly, it holds true that we can see only what we already know[23]. Before the endoscopic findings of SSA/P were reported, the detection of SSA/P was rare, and even detected SSA/Ps were considered to be hyperplastic polyps[16,24]. Therefore, proper awareness of the Paris classification in assessing colon polyp morphology could be helpful in increasing polyp detection rates.

We assessed inter-observer agreement and diagnostic accuracy for colon polyp morphology in three exams, pre-, post-, and follow-up tests. After education for 20 min, inter-observer agreement and diagnostic accuracy improved. These results demonstrated that a short, didactic education program was effective in correcting individuals' misunderstandings when assessing the morphology of colon polyps according to the Paris classification. However, after four months,

the inter-observer agreement and diagnostic accuracy of expert groups were markedly decreased, whereas those of beginner and nurse groups were similar to the level of the post-test. Van Doorn *et al*[18] identified that the inter-observer agreement of seven Western experts was moderate and unchanged at three months post-training. In our study, test results for nine experts were similar to those of the Western experts; however, the test results of beginner and nurse groups were different from those of the experts. These results indicate that the effectiveness of education for polyp morphology is lasting for beginner and nurse groups, but not for the expert group. Members of the expert group had performed more than 1000 colonoscopies over an extended time and assessed the morphology of colon polyps according to their own understanding of the Paris classification. This might explain why the educational effect in this group did not last more than a few months. The beginner and nurse groups had little to no experience with colonoscopic examination and had utilized the Paris classification for a short time. For this reason, the education for polyp morphology in the beginner and nurse groups could more easily alter their existing knowledge, and the educational effect could last for several months. These findings suggest that appropriate education at the onset of learning endoscopy is effective in improving inter-observer agreement and diagnostic accuracy when assessing the morphology of colon polyps.

This study has some limitations. First, it was performed in a single medical center in Korea. Although we included a total of 30 participants, our results might not represent the practice of Eastern endoscopists as a whole. However, because data are limited regarding Eastern endoscopists' assessments of colon polyp morphology according to the Paris classification, our results could be helpful in assessing the validity and usefulness of the Paris classification in clinical practice. Second, we did not evaluate inter-observer agreement or diagnostic accuracy according to polyp size. Polyps used in the exam were collected in various sizes (Table 1), in order to minimize selection bias. Third, our study included a small number of type Ⅱb, type Ⅱc, and type Ⅲ polyps (3.4%). According to the results of Kudo *et al*[25] who classified the morphology of 9533 colon polyps, 57% were type I s, 39% were type Ⅱa or Ⅱb, 4% were type Ⅱc, and 0% were type Ⅲ. Therefore, it is difficult to fully assess the inter-observer variability for type IIb, type Ⅱc, and type Ⅲ polyps due to their rarity.

In conclusion, this study is the first to evaluate the validity of the Paris classification system in Eastern countries for evaluating the morphology of colon polyps. Our results indicate that an education program could be helpful in improving inter-observer agreement and diagnostic accuracy when determining colon polyp morphology, and such an educational program is expected to be especially effective upon first learning endoscopy. Based on these study results, we suggest that daily practice of morphology assessment of colon polyps and proper education in the Paris classification are essential in maintaining the quality of colonoscopic examination.

COMMENTS

Background

The Paris classification is an international classification system for describing gastrointestinal tract polyp morphology based on endoscopic appearances. However, there is little data regarding inter-observer variability and the impact of education about this classification on clinical practice. In this study, they aimed to determine the inter-observer variability for colon polyp morphology and to identify whether education can improve agreement among observers.

Research frontiers

This study presents that the education program used in this study can improve inter-observer agreement and diagnostic accuracy in assessing the morphology of colon polyps; it is especially effective when first learning endoscopy.

Innovations and breakthroughs

In this study, a total of 30 Korean endoscopists and nurses participated. This study included a pre-test, an educational program, a post-test, and a follow-up test. The authors assessed inter-observer agreement for all participants and compared expert, beginner, and nurse groups. The authors also estimated and compared the diagnostic accuracy of the three groups.

Applications

Daily practice of morphology assessment of colon polyps and the proper education of the Paris classification are essential in maintaining the quality of colonoscopic examination.

Terminology

Pre-test: a test without any education. Post-test: a test after a 20-min educational program. Follow-up test: a test after four months without an educational program

Peer-review

Based on these study results,a proper education in the Paris classification are important to maintaining the quality of colonoscopicexamination, especially in new learner in endoscopy.

Abstract

AIM

To evaluate the association of body mass index (BMI) with the overall survival of pancreatic ductal adenocarcinoma (PDAC) patients.

METHODS

A retrospective analysis of PDAC patients diagnosed in the National Cancer Center of China between January 1999 and December 2014 was performed. These patients were categorized into four BMI groups (< 18.5, 18.5-22.9, 23-27.4 and ⩾ 27.5 kg/m^2). χ^2 tests for comparison of the proportions of categorical variables, and Student's *t*-test or Mann-Whitney test for continuous variables were employed. Survival analysis was performed with the Kaplan-Meyer method. Their HRs of mortality and 95%CIs were estimated using the Cox proportional hazards model.

RESULTS

With a median age of 59.6 years (range: 22.5-84.6 years), in total 1783 PDAC patients were enrolled in this study. Their mean usual BMI was 24.19 ± 3.53 for the whole cohort. More than half of the patients (59.3%) experienced weight loss during the disease onset and progression. Compared with healthy-weight individuals, newly diagnosed patients who were overweight or obese had more severe weight loss during their disease onset and progression ($P < 0.001$). Individuals who were overweight or obese were associated with positive smoking history ($P < 0.001$). A significant difference in comorbidity of diabetes ($P = 0.044$) and coronary artery disease ($P < 0.001$) was identified between high BMI and normal-weight patients. After a median follow-up of 8 mo, the survival analysis showed no association between BMI and the overall survival ($P = 0.90$, $n = 1783$). When we stratified the whole cohort by pancreatic cancer stage, no statistically significant association between BMI and overall survival was found for resectable ($P = 0.99$, $n = 217$), unresectable locally advanced ($P = 0.90$, $n = 316$) and metastatic patients ($P = 0.88$, $n = 1250$), respectively. The results did not change when we used the BMI at diagnosis.

CONCLUSION

Our results showed no significance of BMI for the overall survival of PDAC patients.

Key words: Body mass index; Pancreatic cancer; Overweight; Smoking history; Survival analysis

Core tip: It remains controversial whether body mass index (BMI) influences the prognosis of pancreatic cancer. The strengths of this study included a large quantity of patients and the accurate BMI categorization according the Asian criterion. To the best of our knowledge, it is the largest study in Asia to evaluate the prognostic role of BMI on the overall survival of pancreatic cancer patients. Our results showed no significant influence of BMI on the overall survival of pancreatic ductal adenocarcinoma patients and are consistent with those of many other studies.

Jiang QL, Wang CF, Tian YT, Huang H, Zhang SS, Zhao DB, Ma J, Yuan W, Sun YM, Che X, Zhang JW, Chu YM, Zhang YW, Chen YT. Body mass index does not affect the survival of pancreatic cancer patients. *World J Gastroenterol* 2017; 23(34): 6287-6293 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6287.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6287

INTRODUCTION

Pancreatic cancer is a devastating malignant cancer, with a 5-year survival rate of < 6%[1]. The survival length of patients is greatly influenced by disease stage at diagnosis, but few other survival markers have been well characterized[2-4].

Excessive adipose can impair both humoral and cellular immunity, which may be important in the development of pancreatic cancer. Although many studies have demonstrated that a high body mass index (BMI), an indirect measure of adiposity, is associated with increased risk of developing pancreatic cancer, it remains controversial whether BMI influences the prognosis of pancreatic cancer. Several studies have reported that a higher BMI is associated with decreased survival of pancreatic cancer patients[5-10], whereas other results informed that BMI was not a statistically significant prognostic factor[11-15]. Tsai *et al*[16] even expressed improved long-term survival of pancreatic cancer patients with higher BMIs. As such, we conducted a single-center, large-scale retrospective study to determine the associations between BMI and overall survival of Chinese pancreatic ductal adenocarcinoma (PDAC) patients.

MATERIALS AND METHODS

Patients

The medical records of all patients diagnosed with PDAC from January 1999 to December 2014 in the Cancer Hospital, Chinese Academy of Medical Science and Peking Union Medical College were studied by retrospective chart review. All patients had histological diagnosis of PDAC confirmed by pathology. Clinical information was systematically abstracted from these patients' medical records using an established abstraction form by trained individuals with a medical background. For the whole cohort, the extracted information included age, sex, weight, height, smoking history, alcohol use history, previous history of cancer, and previous abdominal surgery. The patients' height and weight of 1 year prior to diagnosis and at diagnosis were all recorded. Comorbidities were also recorded, such as diabetes, coronary artery disease and hypertension. Clinical disease stage was defined on the basis of the patients' initial computed tomographic images and endoscopic ultrasound reports, as stated in the American Joint Committee on Cancer Staging Manual using the TNM staging system. Follow-up information was obtained through telephone-based interviews, as well as from the records of outpatient follow-up, if any. The primary outcome variable was overall survival, defined for patients as the period from date of diagnosis to date of death. Informed consent was obtained from all individual participants included in the study.

Statistical analysis

BMI was calculated as weight (kg) divided by the square of height (m^2), using self-reported usual adult height and weight. According to the Asian criterion, BMI was classified as underweight (< 18.5 kg/m^2),

Table 1 Demographics, comorbidity and stage of patients grouped according to body mass index

Characteristic	All patients	BMI category, kg/m^2				*P* value
		< 18.5	18.5-22.9	23-27.4	⩾ 27.5

Data are *n* (%), unless otherwise indicated. BMI: Body mass index.

healthy weight (18.5-22.9 kg/m^2), overweight (23.0-27.4 kg/m^2), and obese (⩾ 27.5 kg/m^2). χ^2 tests for comparison of the proportions of categorical variables, and Student's *t*-test or Mann-Whitney test for continuous variables were employed. The unconditional logistic regression model was used to estimate the ORs and 95%CIs for the associations among BMI, clinical characteristics and overall survival of PDAC patients, and for the PDAC subtypes in different clinical stages. Survival analysis was performed by the Kaplan-Meyer method. The group with BMI 18.5-22.9 kg/m^2 was the reference group. All *P*-values presented were two-sided, and all analyses were carried out using SAS Software Version 9.2 (SAS Institute, Cary, NC, United States). Statistical significance was defined as a *P* value of < 0.05.

RESULTS

Clinical characteristics

Data were extracted from a total of 1783 subjects with PDAC who had complete medical history. Histological or cytological diagnosis was obtained from the primary pancreatic lesion or metastases in all cases. The pathology was confirmed by two pathologists. Baseline characteristics of 1783 patients with pancreatic cancer are listed in Table 1. Of those subjects, 1009 (56.6%) were male, with a median age of 59.6 years. Among the total, 29.6% patients had a positive smoking history, 22.3% had a drinking history, and 22.3%, 13.9% and 15.0% patients had diabetes, coronary artery disease and hypertension at diagnosis of pancreatic cancer as concomitant comorbidities, respectively.

Among those with known disease stage, 217 had potentially resectable tumors at the time of diagnosis, 316 had locally advanced disease, and 1250 had distant metastasis. Their mean baseline BMI was 24.19 kg/m^2, and 44.4% of the patients were classified as overweight and 17.2% as obese. More than half of the patients (59.3%) experienced weight loss during their disease onset progression. Compared with healthy-weight individuals, the newly diagnosed patients who were overweight or obese had more severe weight loss during the disease onset progression ($P < 0.001$). Individuals who were overweight or obese are associated with a positive smoking history ($P = 0.0003$). A significant difference in comorbidity of diabetes ($P = 0.044$) and coronary artery disease ($P < 0.001$) was identified between high BMI values and normal-weight patients.

Survival analysis

The median follow-up duration was 8 mo for all cases. Median overall survival for each BMI category (kg/m^2)

Table 2 Pancreatic cancer survival by usual adult body mass index category

Stage group	BMI category	*n*	Median overall survival, mo (95%CI)	HR	95%CI	*P* value	P_{trend} value
Overall	< 18.5	98	8.0 (5.8-11.3)	1.12	0.83-1.52	0.45	
	18.5-22.9	588	9.7 (8.7-11.1)	1.00	Ref.	Ref.	
	23-27.4	791	9.5 (8.6-10.5)	0.99	0.87-1.14	0.92	
	⩾ 27.5	306	9.8 (7.6-11.2)	1.05	0.88-1.25	0.61	0.90
Resectable	< 18.5	15	11.1 (3.3-19.3)	1.92	0.74-5.01	0.18

BMI: Body mass index.

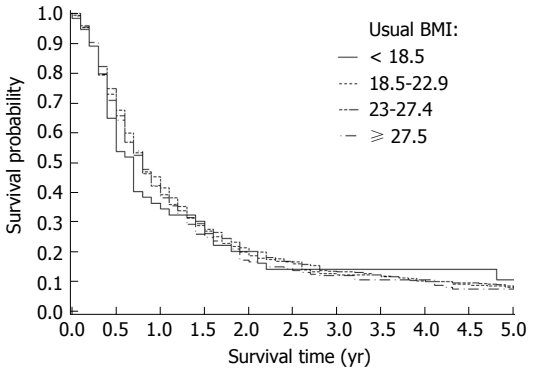

Figure 1 Unadjusted Kaplan-Meier analysis of overall survival among 1783 pancreatic cancer patients according to usual adult body mass index category. BMI: Body mass index.

was as follows: < 18.5: 8 mo; 18.5-22.9: 9.7 mo; 23.0-27.4: 9.5 mo; and ⩾ 27.5: 9.8 mo (Table 2). Kaplan-Meier survival comparisons (Figure 1) showed no association between BMI and the overall survival of pancreatic cancer patients ($P > 0.05$). When we stratified the whole cohort by pancreatic cancer stage, no statistically significant association between BMI and overall survival was found for resectable ($P = 0.99$, $n = 217$), unresectable locally advanced ($P = 0.90$, $n = 316$) and metastatic ($P = 0.88$, $n = 1250$) patients. The multivariate Cox regression survival analysis showed the same results (Figures 2 and 3). Considering the effect of cancer-related weight loss among patients, the results did not change when we used the BMI at diagnosis.

DISCUSSION

Overweight/obesity and its related morbidities represent a growing health problem, claiming 2.8 million lives annually according to the WHO 2010 Global Report[17]. Obesity has been found to be associated with a wide array of morbidities, including cardiovascular disease, chronic kidney disease, sleeping disorder, type 2 diabetes, and several forms of cancer. Obesity is considered to be an adverse prognostic factor in malignancies, such as breast and colon cancers[18,19]. In our study, a significant difference in comorbidity of diabetes and coronary artery disease was identified between high BMI values and normal-weight patients. But survival analysis showed that BMI did not affect the survival of pancreatic cancer patients.

Previous studies conferring the role of BMI were mainly carried out in cohorts of United States adults, which presented a higher percentage of obese (BMI ⩾ 30) and very obese (BMI ⩾ 35) patients and the BMI categorization as opposed to our Asian criterion. For a Mayo Clinic cohort of patients covering all stages of pancreatic cancer respectively, including early-stage patients who underwent surgery, McWilliams *et al*[6] reported that the BMI at diagnosis had a negative impact on survival. This was particularly pronounced in the very obese patients with a BMI of 35 to 39.99 kg/m^2 (HR = 1.32, 95%CI: 1.08-1.62) and > 40 kg/ m^2 (HR = 1.60, 95%CI: 1.26-2.04), respectively. In a case control study designed to assess the risk of developing pancreatic cancer in overweight persons, Li *et al*[5] described a shorter survival period for patients who were overweight or obese during the year prior to diagnosis. Another study from Olson *et al*[11] demonstrated that obesity was non-significantly associated with poorer survival of PDAC patients, particularly in the resected group (HR = 1.62, 95%CI: 0.76-3.44). The experience from Chen *et al*[20] showed that a higher BMI increases the risk for postoperative complications after pancreatectomy in the Chinese population. However, Tsai *et al*[16] reported that obese patients undergoing pancreaticoduodenectomy for pancreatic cancer had improved long-term survival, independent of known

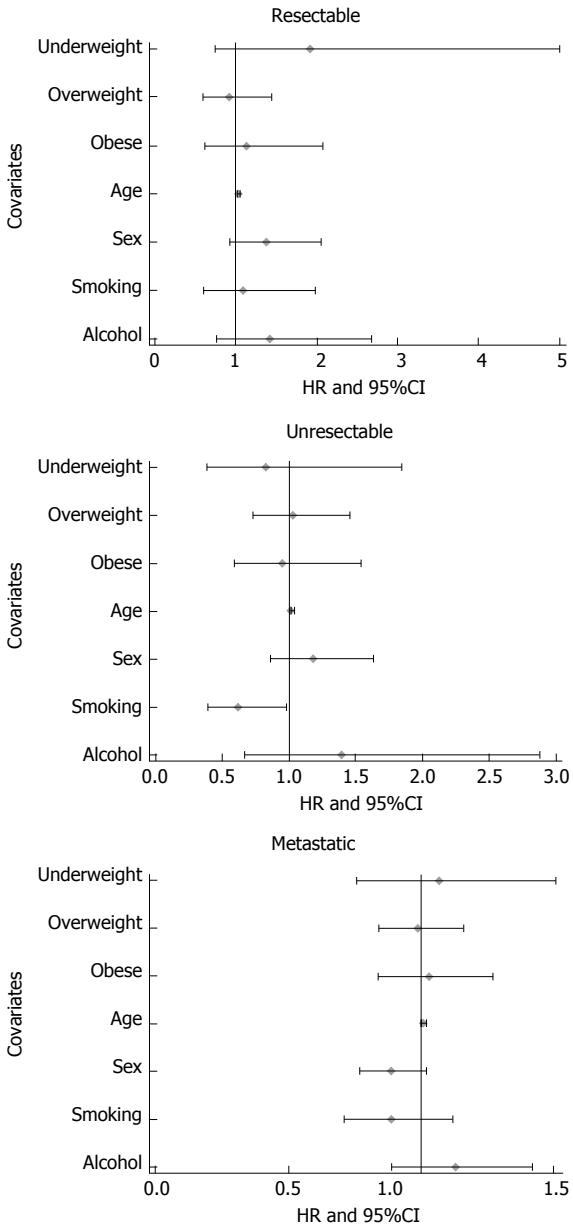

Figure 2 Body mass index and survival of pancreatic cancer patients by stage. Forest plots within stage groupings for resectable, locally advanced and metastatic patients at initial diagnosis of pancreatic cancer are shown.

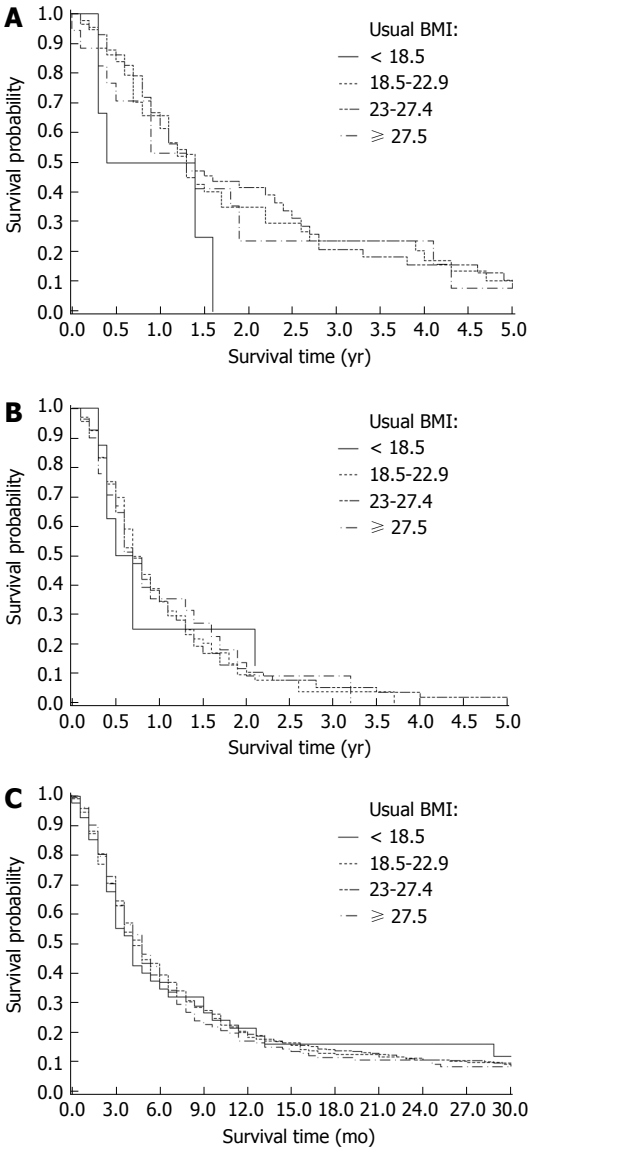

Figure 3 Kaplan-Meier analysis. A: Unadjusted Kaplan-Meier analysis among 217 pancreatic cancer patients undergoing radical resection according to BMI category; B: Unadjusted Kaplan-Meier analysis among 316 unresectable locally advanced pancreatic cancer patients according to BMI category; C: Unadjusted Kaplan-Meier analysis among 1250 pancreatic cancer patients with distant metastasis according to BMI category. BMI: Body mass index.

clinicopathologic factors. Big controversy has lasted about the real role of BMI on pancreatic cancer for years. The results in this study need to be replicated in more studies with larger sample sizes with a greater power.

Limited information was available on the possible effect of weight loss on the survival of PDAC patients. As we know, loss of weight is usual for pancreatic cancer patients either before or after diagnosis. In our study, more than half of the patients experienced weight loss during their disease progression, especially in the obese group, which might explain why the obesity-specific co-morbidities such as diabetes were not more prevalent in the obese group compared with the normal populations. Dalal *et al*[21] believed that obese patients experienced higher loss in weight, skeletal muscle and visceral adipose tissue, which may contribute to poorer survival of pancreatic cancer patients. So, we carried out the survival analysis using patients' BMIs at usual time as well as at diagnosis, but the results did not change.

The strengths of this study included a large quantity of patients and the accurate BMI categorization according the Asian criterion. To the best of our knowledge, it is the largest study in Asia to evaluate the prognostic role of BMI on the overall survival of pancreatic cancer patients. Our results showed no significant influence of BMI on the overall survival of PDAC patients and are consistent with those of many other studies[11-15]. We, however, must admit that

there are several limitations for the current study. The retrospective nature of this study can be associated with selection bias as well as increased risk of differential misclassification bias. Another shortcoming was the limited generalizability because the entire study population came from a single hospital.

In conclusion, BMI has not shown any clear relationship with the survival outcome of pancreatic cancer. More studies are needed to validate this finding and evaluate the mechanism behind the observation.

COMMENTS

Background

Excessive adipose can impair both humoral and cellular immunity, which may be important in the development of pancreatic cancer. Although many studies have demonstrated that a high body mass index (BMI), an indirect measure of adiposity, is associated with increased risk of developing pancreatic cancer, it remains controversial whether BMI influences the prognosis of pancreatic cancer. Several studies have reported that a higher BMI is associated with decreased survival of pancreatic cancer patients, whereas other results informed that BMI was not a statistically significant prognostic factor.

Research frontiers

The authors conducted a single-center, large-scale retrospective study to determine the associations between BMI and overall survival of Chinese pancreatic ductal adenocarcinoma (PDAC) patients.

Innovations and breakthroughs

To the best of our knowledge, this is the largest study in Asia to evaluate the prognostic role of BMI on the overall survival of pancreatic cancer patients.

Applications

In this study, BMI did not affect the survival of pancreatic cancer patients. The results provide more insight into the role of BMI on pancreatic cancer.

Peer-review

The present retrospective study demonstrated that BMI has no relationship with survival of PDAC in a large single center. The paper has high value for inclusion in the current literature on the topic.

Abstract

AIM

To analyze access (availability, affordability and acceptability) to biologicals for Crohn's disease (CD) in ten European countries and to explore the associations between these dimensions, the uptake of biologicals and economic development.

METHODS

A questionnaire-based survey combined with desk research was carried out in May 2016. Gastroenterologists from the Czech Republic, France, Germany, Hungary, Latvia, Poland, Romania, Slovakia, Spain and Sweden were invited to participate and provide data on the availability of biologicals/biosimilars, reimbursement criteria, clinical practice and prices, and use of biologicals. An availability score was developed to evaluate the restrictiveness of eligibility and administrative criteria applied in the countries. Affordability was defined as the annual cost of treatment as a share of gross domestic product (GDP) per capita. Correlations with the uptake of biologicals, dimensions of access and GDP per capita were calculated.

RESULTS

At the time of the survey, infliximab and adalimumab were reimbursed in all ten countries, and vedolizumab was reimbursed in five countries (France, Germany, Latvia, Slovakia, Sweden). Reimbursement criteria were the least strict in Sweden and Germany, and the strictest in Hungary, Poland and Slovakia. Between countries, the annual cost of different biological treatments differed 1.6-3.3-fold. Treatments were the most affordable in Sweden (13%-37% of the GDP per capita) and the least affordable in the Central and Eastern European countries, especially in Hungary (87%-124%) and Romania (141%-277%). Biosimilars made treatments more affordable by driving down the annual costs. The number of patients with CD on biologicals per 100000 population was strongly correlated with GDP per capita (0.91), although substantial differences were found in the uptake among countries with similar economic development. Correlation between the number of patients with CD on biologicals per 100000 population and the availability and affordability was also strong (-0.75, -0.69 respectively).

CONCLUSION

Substantial inequalities in access to biologicals were largely associated with GDP. To explain differences in access among countries with similar development needs further research on acceptance.

Key words: Crohn's disease; Biological therapy; Access; Inequality; Europe

Core tip: We carried out a questionnaire survey with gastroenterologists combined with desk research to analyze access to biologicals for Crohn's disease in ten European countries. Regarding availability, reimbursement criteria were the least restrictive in Sweden and Germany, and the most restrictive in Hungary, Poland and Slovakia. Between countries, the annual cost of biological treatments differed 1.6-3.3-fold. Treatments were the most affordable in Sweden and the least affordable in Hungary and Romania. The number of patients on biologicals per 100000 population was strongly correlated with gross domestic product, although substantial differences were found in the uptake among countries with similar economic development.

Access to biologicals in Crohn's disease in ten European countries. *World J Gastroenterol* 2017; 23(34): 6294-6305 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6294.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6294

INTRODUCTION

Crohn's disease (CD) is a chronic inflammatory disorder of the gastrointestinal tract that is characterized by diarrhea, abdominal pain, rectal bleeding, fever and fatigue. The prevalence of CD in Europe varies from 1.5 to 213 cases per 100000 persons[1,2]. Due to the early onset and chronic character of the disease, patients have to deal with a considerable impairment in health-related quality of life[3,4] and lower work capacity throughout their lifetime, leading to substantial economic burden both on patients and society[5].

Biological drugs have revolutionized the treatment of inflammatory bowel diseases, like CD. Infliximab was the first biological drug that received its marketing authorization in Europe by the European Medicines Agency (EMA) in 2001 for adult patients with moderately to severely active CD[6]. This was followed by adalimumab, registered in 2003, vedolizumab, registered in 2014 and ustekinumab registered in 2016. Recently, biosimilars of infliximab (2013, 2016) and of adalimumab (2017) have been registered as well. These drugs are monoclonal antibodies with different mechanisms of action (infliximab and adalimumab are anti-tumor necrosis agents, vedolizumab is an anti-integrin drug and ustekinumab is an interleukin-12 and -23 inhibitor) but with similar safety profile and comparable efficacy[7-9]. Clinical evidence confirmed the efficacy, safety and effectiveness of these drugs for the treatment of CD, as they substantially improve the ability to achieve disease remission, slow disease

progression, decrease the need of surgery and increase work participation and quality of life[6]. However, biologicals are more costly than standard treatments, annual cost of drug therapy is usually above €10000 per patient. Mainly due to the increase in the use of biological drugs, recent studies indicated that direct healthcare costs have shifted from hospitalization and surgery towards drug therapy[10-12].

Access to biologicals varies significantly between countries. This is largely driven by differences in budgetary constraints[3,13]. Due to the high price and budget impact of biologicals, most countries have regulated the access to reimbursed treatment. Differences in regulations lead to inequalities in access to biologicals even among European countries with a very similar economic situation[3,14]. Rencz *et al*[3] found an up to 96-fold difference in the uptake of biologicals for CD among nine selected countries. The reasons for this heterogeneity in access to biologicals among the Central and Eastern European countries (CEE countries) has not been clarified. However, according to the authors, it is not explained by differences in prevalence and incidence of inflammatory bowel diseases, prices of biologicals, total expenditure on health, geographical access, and cost-effectiveness.

The appearance of biosimilar drugs as potentially cost-effective alternatives is expected to lead to improvements in access to biological therapy. The first biosimilar infliximab drugs (brand names Remsima and Inflectra) were approved in 2013 by the EMA for the same indications as the original biological drug[10]. A couple prospective and a number of retrospective cohorts with biosimilar infliximab in inflammatory bowel diseases have confirmed that its efficacy and safety are comparable to those of the original biological product[3,10,14]. Biosimilars are substantially (20%-70%) cheaper than the originator. Budget impact analyses suggest that significant savings can be achieved with biosimilar infliximab in CD[14,15]. In Belgium, Germany, Italy, the Netherlands and the United Kingdom, the annual projected cost savings are estimated to be €11.95 million (10% price reduction) to €35.85 million (30% price reduction) in the case of CD patients[15]. Total cost savings achievable over three years in Bulgaria, the Czech Republic, Hungary, Poland, Romania and Slovakia are expected to be €8.0 million (switching not allowed) and €16.9 million (switching allowed in 80% of the patients)[16]. These savings can be used either to improve access to biological treatments (*e.g.*, increase the number of patients with access to biologicals), or can be allocated to other areas of care[17].

This study explores three different dimensions of access to biologicals (originators and biosimilars) for CD, namely availability, affordability and acceptability in ten selected European countries (the Czech Republic, France, Germany, Hungary, Latvia, Poland, Romania, Slovakia, Spain and Sweden).

These countries differ not only regarding their economic development but also regarding the organization and financing of their health care system, which might also influence the access to biological treatments[3,14,18]. While Spain and Sweden have a tax-based health care system, France and Germany follow the Bismarkian model with social health insurance. In the CEE countries (except for the Czech Republic) the share of public financing is usually lower than in the Western-European countries. The source of public resources is mainly tax revenue in Sweden and Spain, while it is social health insurance contribution in the rest of the countries (see further in details[19]).

Thus, in our study, we also aim to explore whether differences in availability and affordability of biologicals are associated with the uptake of biologicals (in terms of number of patients on biologicals per 100000 population) and the economic situation of the country or the financing of the health care system.

MATERIALS AND METHODS

Study design

A questionnaire was developed to collect information on access to biologicals and was sent in May 2016 to one expert (gastroenterologist) in each of the ten European countries included in the study, *i.e.*, the Czech Republic, France, Germany, Hungary, Latvia, Poland, Romania, Slovakia, Spain and Sweden. The questionnaire was developed based on questionnaires used in prior studies in rheumatoid arthritis of Putrik *et al*[18,20]. The country experts who were invited to fill in the questionnaire, were selected based on the principle of non-probability convenience sampling, which resulted in a sample drawn through the professional network of the researchers.

The questionnaire was sent to the 10 experts who accepted to take part in the survey (contributors of the paper). The returned questionnaires were checked and in case of missing or incomplete answers, the collaborating experts were contacted to clarify the information. Finally, a preliminary report including the results was sent to all collaborating experts for a review and data check.

The questionnaire-based survey was combined with desk research, where relevant indicators, such as countries' gross domestic product (GDP), population size and health care financing indicators were identified. The number of CD patients on biologicals was extracted from resources provided by the collaborating experts or was calculated from the total number of CD patients and the estimated share of CD patients on biologicals. Furthermore, drug prices and other data derived from the questionnaires, were also checked during the desk research.

Questionnaire

The questionnaire included questions on (1) the

availability, reimbursement status and prices of originator and biosimilar biologicals registered for CD at the time of the survey (Remicade, Remsima, Inflectra, Humira and Entyvio)[Stelara (ustekinumab) and Flexabi (biosimilar infliximab) were not in use at the time of the survey]; (2) the clinical and reimbursement guidelines and eligibility criteria for biological treatment of adults with luminal CD; (3) the number of adult CD patients in the given country and the use of biologicals; and (4) additional dimensions of access to biologicals. The collaborating experts were also asked to indicate the reference for the data they provided (*i.e.*, for drug prices, prevalence data and use of biologicals).

Analysis

The three dimensions of access - affordability, availability, acceptability were analyzed separately.

Availability: We identified the number of biologicals for CD registered and reimbursed in the ten countries based on data from the questionnaire and desk research. Based on these data, we also developed an availability score to assess the restrictiveness of clinical eligibility and administrative requirements to biologicals, based on the following items: (1) whether there is a required level of disease activity [such as Crohn's Disease Activity Index (CDAI)] or disease severity for initiation of biological treatment: not specified (0 point), CDAI > 220 (1 point), CDAI > 300 (2 points); (2) required failure of /intolerance to non-biological treatment before a patient is eligible for a biological: not required (0 point), steroids (1 point), immunosuppressive (1 point), steroids OR immunosuppressive (1 point), steroids AND immunosuppressive (2 points); (3) whether there are other administrative procedures required after the indication of the need of a biological is given: no other procedures (0 point), other requirements (*e.g.*, approval or authorization by the health insurance fund) (1 point); (4) whether only approved centers can administer biological treatment: no restriction to approved centers (0 point), restriction to approved centers (1 point); and (5) whether only specific specialists can indicate and prescribe biologicals for the treatment of CD in adults: gastroenterologist, immunologist and GP/other (0 point), gastroenterologist and immunologist only (1 point), gastroenterologist only (2 points).

For each country, the subscores were summed up to obtain the country availability score within the range 0-8. Higher score indicates more restrictive clinical eligibility criteria and administrative requirements.

Affordability: Based on data from the questionnaire and desk research, the annual drug cost per person (2016) was calculated for each drug available in a given country and was also presented as a percentage of the country GDP per capita, which was the affordability ratio in our study. The annual costs were calculated based on the prices provided by collaborating experts, which were verified in the desk-research. The sources of the acquisition cost of drugs were mainly state institutes for drug control, European drug databases, pharmaceutical companies and national health insurance funds. If prices found during the desk research were not matching with the answers given by the experts, clarification was asked from the respondents to identify the most accurate data. Information on drug dose and frequency of its administration for induction and maintenance therapy was taken from on EMA product information (http://www.ema.europa.eu/docs/en_GB/document_library/EPAR_-_Product_Information/human/002782/WC500168528.pdf).

Acceptability: The questionnaire contained a question on barriers to access to biologicals. The collaborating experts were asked to indicate which of the following items they considered as a barrier to access to biologicals: limited availability of the drugs due to financial reasons; too strict reimbursement criteria; strict monitoring requirements; physicians' preferences; patients' co-payments; patients' preferences; limited access of patients to inflammatory bowel diseases centers (IBD centers); limited access of patients to health care in general. Experts were also asked to give an estimation on out of every 10 of their infliximab patients how many were treated with biosimilars.

We calculated Pearson's correlations between the affordability (defined as the annual cost of treatment as a percentage of GDP), the availability score (explained above), the number of CD patients on biologicals per 100000 population the GDP per capita, and the share of public expenditure in the total health expenditure and the share of governmental expenditure in the total public health expenditure. Significance level of 5% was used.

RESULTS

Availability

Registration, reimbursement: At the time of the survey (May 2016), five biologicals were approved by the European Medicine Agency (Remicade: 01/2001, Humira: 09/2003, Remsima, Inflectra: 09/2013, Entyvio: 05/2014.). Infliximab and adalimumab were reimbursed in all the ten countries. In Latvia and Hungary, only biosimilar infliximab was reimbursed for new patients. Entyvio was only reimbursed in France, Germany, Slovakia, Spain and Sweden. Furthermore, according to the experts, in Slovakia and Spain, Entyvio could not be used as a first line biological therapy, only as a second line after a failure of the first biological.

biological treatment were based on national clinical guidelines in France, Germany, Poland, Spain and Sweden (Table 1). In Latvia and Slovakia, the eligibility criteria were based on reimbursement guidelines since there are no national clinical guidelines available. In Hungary, Romania and the Czech Republic, both clinical and reimbursement guideline existed. While in the Czech Republic both clinical and reimbursement guidelines were followed, in Hungary and Romania clinical practice followed the reimbursement guideline when differences of clinical and reimbursement guidelines occur. The references for the guidelines for each country are shown in Table 1.

An overview of the clinical criteria for eligibility for the initiation of biological treatment and further administration requirements are presented in Table 2. According to the respondents, none of the countries had requirements on disease duration to initiate a biological treatment. In six countries CDAI scale was required to be used for the assessment the disease severity. In the Czech Republic, Romania and Slovakia, a CDAI score $\geqslant$ 220 was required to start biological treatment, while in France, Hungary and Poland, only patients with CDAI score > 300 were entitled for treatment. (There are some exemptions, for example the contributing experts from Poland and Slovakia also mentioned that patients with severe fistulising CD did not have to fulfill the CDAI score requirement.) In the Czech Republic, France, Germany, Romania, Spain and Sweden a failure of one non-biological treatment (steroid OR immunosuppressant) was required to start biological treatment, while in Hungary, Latvia, Poland and Slovakia patients had to fail both steroids and immunosuppressant treatment. In most of the countries there were no specific criteria to satisfy for maintaining biological therapy, but maintenance was based on the clinicians' judgement. Only in Hungary and in Sweden, it was recommended to evaluate maintenance on the CDAI scale.

In six countries (the Czech Republic, Hungary, Poland, Romania, Slovakia and Spain), only approved centers could use biologicals. In Latvia, the treatment could only be started in a center where three different gastroenterologists gave approval. In most countries,

treatment could be started immediately after indication. However, in Slovakia and Romania, the treatment could only start after the authorization process was completed, including a written application to the health insurance company, and/or the purchase and delivery of the medication by the company. In six countries, only gastroenterologists had the permission to indicate and prescribe biologicals to patients with CD. In Germany and France, immunologists could also indicate and prescribe biologicals. In Germany and Sweden, other specialties such as internists, surgeons or GPs were similarly entitled to prescribe and indicate biologicals.

Overall, Sweden and Germany had the lowest availability scores among the ten countries (1 out of 8), while Hungary, Poland and Slovakia had the highest scores (7 out of 8), indicating the most restrictive eligibility criteria and administration requirements (Table 2).

Regarding the availability of the biosimilars, Inflectra and/or Remsima were reimbursed in all of the ten countries at the time of the analysis. Three countries (the Czech Republic, Hungary, Spain) had specific criteria on switching to biosimilars. In Hungary, new infliximab patients had to be treated with a biosimilar, and in Poland, patients receiving the original biological drug were obliged to switch to the biosimilars of infliximab as maintenance therapy once the biological infliximab was used. In Spain switching was mandatory only in some hospitals/regions.

Affordability

The annual cost of treatment per patient ranged from €10638 (Poland) to €29081 Euro (Germany) for Remicade; from €9157 (Sweden) to €23915 (Germany) for Remsima; from €6841 (Sweden) to €22213 (Germany) for Inflectra; from €10625 (France) to €24402 (Germany) for Humira; and from €19243 (Sweden) to €30218 (Spain) for Entyvio. Between countries, the annual therapeutic cost of Remicade showed a 2.7-fold variation, while the difference for the biosimilar Inflectra and Remsima showed a 2.6 and 3.3-fold variation respectively. For Humira and Entyvio, these were 2.3 and 1.6 respectively. According to data provided by the respondents, the appearance of the two biosimilars led to a price reduction for Remicade in some countries, which resulted in the same annual cost of originator and biosimilar infliximab products in five countries (the Czech Republic, France, Latvia, Poland and Slovakia) (Table 3).

Large differences can be seen in the cost of treatment as a percentage of GDP per capita across countries (Table 3). Based on these indicators, treatments are most affordable is Sweden (13%-37% of the GDP) and least affordable in the CEE countries, especially in Hungary (87%-124%) and Romania (141%-277%). Biosimilars made infliximab treatment more affordable, as the cost of the cheapest biosimilar treatment was lower than the GDP per capita (except for Romania).

In half of the countries, all five biologicals were covered at 100% by the health insurance system. Although in two countries, patient co-payments existed. In Germany a 10% copayment was required, in Latvia this was 25%.

Acceptability

Different barriers were selected from a list by the respondents with regard to the access to biologicals, such as "limited availability of the drugs due to

Table 3 Affordability of biologicals - annual costs and annual costs (2016) as a percentage of gross domestic product per capita (2014)

	Cz	Fr	D	Hu	Lv	Pl	Ro	Sk	Es	Se

Annual total drug cost was calculated based on available list prices, and the EMA product information on the recommended drug dose and frequency. For infliximab we calculated with an average body weight of 75 kg. All costs were converted to Euros using the official exchange rate as of May 2016: 1 EUR= 27.025 CZK = 312.44 HUF = 4.3861 PLN = 9.2605 SEK. Cz: The Czech Republic; Fr: France; D: Germany; Hu: Hungary; Lv: Latvia; Pl: Poland; Ro: Romania; Sk: Slovakia; Es: Spain; Se: Sweden; GDP: Gross domestic product.

financial reasons" (the Czech Republic, Poland and Sweden) and "physicians' preferences" (Germany, Poland and Sweden) being the ones most frequently mentioned. Other barriers selected were "too strict reimbursement criteria" (the Czech Republic and Poland), "limited access to IBD centers" (Germany and Poland), "limited access to healthcare in general" (Poland and Romania), "patients' co-payments" (Latvia) and "patients' preferences" (Germany). Other barriers mentioned were time consuming and lengthy authorization process (Slovakia), non-referral of patients to specialist (Germany). According to the experts, after the introduction of biosimilars the access to biologicals became easier/much easier (the Czech Republic, Poland, Slovakia and Sweden) or stayed the same (Germany, Latvia and Romania). No clear opinion was reported for the other three countries.

Use of biologicals and its associations with the affordability availability and the economic development: The estimated number of CD patients, and the number of CD patients on biologicals (with references to the data sources) are presented in Table 4. The estimated number of CD patients treated with biologicals per 1000 patients showed a large variance between countries, ranging from 1.8 in Latvia to 312.6 in France. The number of patients on biologicals per 100000 in the population was the highest in Sweden (53.5), and the lowest in Latvia (0.2).

Experts gave an estimation on how many out of every 10 of their infliximab patients were treated with biosimilars. There were large differences between countries. At the time of the survey, in Romania, less than 1 out of 10 infliximab patients was treated with biosimilar, while in Latvia all infliximab patients were treated with biosimilars. The remaining countries had a treatment rate between 2/10 and 4/10, except for Poland with a treatment rate of 7/10.

In Table 5, we present the correlation matrix of the variables of interest. Correlation between the number of CD patients on biologicals per 100000 population and the availability score and affordability was strong (-0.75, -0.69 respectively). GDP per capita was strongly associated with both prevalence of biologicals in CD population (0.91), availability score (-0.88) and affordability measure (-0.75). According to the results, we found no significant correlations between health care financing indicators and access. Thus, we can conclude that it is rather the wealth of the country than the organization or financing of the health care system, which influences access. The association between prevalence, GDP and the measures of access are also presented as graphs (Figure 1).

DISCUSSION

In this study, we have analyzed three dimensions of access to biological therapy for CD, namely availability, affordability and acceptability in ten European countries. We have also explored the associations between these dimensions and the uptake of biologicals (in terms of number of patients on biologicals per 100000 population) as well as the economic development of the countries.

Regarding availability, there is a wide European consensus on clinical guidelines based on the best available evidence. For instance, the European Crohn's and Colitis Organization regularly publishes their recommendations on the management of CD. However, besides the uniformity in drug registration and international professional guidelines, we found that treatment practices and access to biological treatment are still highly diverse in Europe. We found the least restrictive eligibility criteria and

administration requirements in Sweden and Germany, and the most restrictive criteria in the CEE countries, namely in Hungary, Poland and Slovakia. In most of the CEE countries examined, there are separate reimbursement guidelines followed in the clinical practice. According to these, the eligibility criterion of treatment is usually ⩾ 300 CDAI score, which is higher than the recommendations of national and international clinical guidelines (⩾ 220 CDAI score). Furthermore, in these CEE countries, biological therapy is recommended only if patients fail both corticosteroid and immunosuppressive therapy. Regarding other

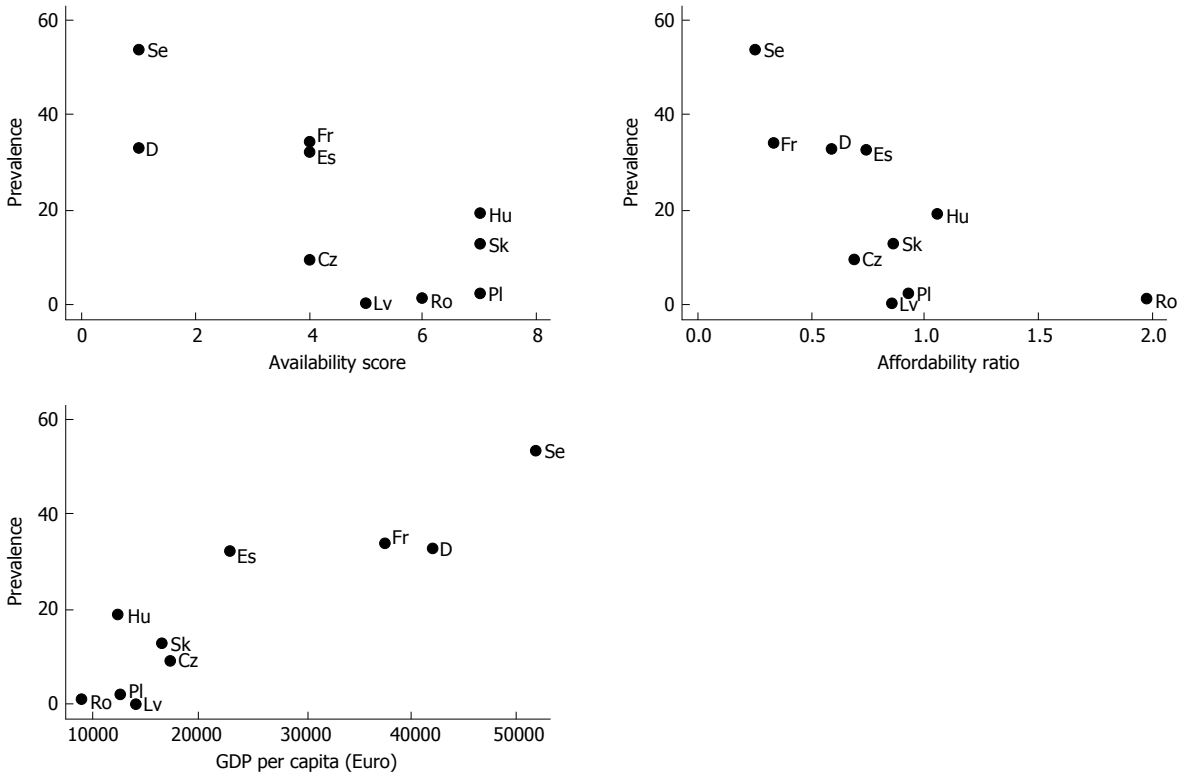

Figure 1 Associations between availability, affordability, gross domestic product per capita and the uptake of biosimilars. Cz: The Czech Republic; Fr: France; D: Germany; Hu: Hungary; Lv: Latvia; Pl: Poland; Ro: Romania; Sk: Slovakia; Es: Spain; Se: Sweden; Prevalence: Patients on biologicals per 100000 population. GDP: Gross domestic product.

requirements, in most of the countries, biologicals may only be indicated and prescribed by gastroenterologist and only approved centers may treat patients with biologicals.

We found large (1.6-3.3 times) differences regarding the annual cost of biological treatments across the countries. Treatments are most affordable in Sweden and Germany, and least affordable in the CEE countries, considering a higher economic burden of the biologicals in these countries. The annual cost of adalimumab treatment exceeds the GDP per capita in four CEE countries (Hungary, Latvia, Poland and Romania). The cheapest available infliximab treatment exceeds the GDP per capita only in Romania. Thus, biosimilars improve the affordability of biologicals. In countries where vedolizumab was available at the time of the survey, the yearly cost of treatment was lower than the GDP per capita only in Sweden and Germany.

The number of patients treated with biologicals per 100000 population varied greatly between the countries (0.2-53.5). The prevalence is the highest in Sweden, followed by Germany, France and Spain and the lowest in Poland, Romania and Latvia. We found that the uptake is strongly correlated with the GDP per capita of the country. However, we can also see large differences between countries with similar economic situation as it was also found by previous papers[3,14]. In the Czech Republic, Hungary and Slovakia, the CD prevalence (9.4-19) is much higher than in Poland and Latvia (2.3 and < 1 respectively). Reimbursement criteria do not necessarily explain the differences in the uptake of biologicals either, as availability scores are the same in Hungary, Poland and Slovakia. Furthermore, in Poland the treatments are slightly more affordable than in Hungary. In Poland, limited access to IBD centers and to healthcare in general were indicated by the collaborating expert as barriers to access in addition to strict reimbursement criteria. Furthermore, Poland is the only country where maximum duration of maintenance treatment is limited to 12 mo. In Latvia, substantial patient co-payments (25%) can also contribute to the low uptake of biologicals.

In a previous study on access to biologicals in CD, Rencz *et al*[3] found that access to biologicals in inflammatory bowel diseases varied greatly (up to 96-fold differences were found) even in some selected CEE countries. We found even higher inequalities in access among Western European and CEE countries. In rheumatology, many more patients are treated with biologicals than in inflammatory bowel diseases, at least in the CEE countries[21]. Similarly to our findings for CD, Putrik *et al*[18,20], Orlewska *et al*[22], and Hoebert *et al*[23] also found that macro-economic indicators (such as GDP or total health expenditure) largely explained the differences in access to biological treatment in rheumatoid arthritis. However, Gulácsi *et al*[14] highlighted that GDP cannot always explain the intercountry differences, which we also showed in our analysis.

We found that the number of patients treated with

biologicals per 100000 population also correlates with availability and affordability, but the correlations among these items are lower than with the GDP per capita. As mentioned before, even though Hungary, Poland and Slovakia have the same availability scores, the uptake of biologicals is much lower in Poland as pointed out by Gulácsi (2016) as well[14]. The same stands for Spain and Latvia. Nevertheless, we observed that the availability and affordability dimensions are also correlated. Thus, in countries where biological therapy is less affordable, reimbursement conditions (eligibility criteria and administrative requirements) are more restrictive.

Acceptability of biologicals, including attitudes of physicians and patients, appears to be an important determinant of the uptake of biologicals and most likely to explain differences among countries with similar economic development, availability and affordability. Thus, this factor needs further research.

We found that biosimilars improved the affordability of biologicals, and drove down the cost of infliximab treatment under the GDP per capita in most of the countries. The decrease in cost leads to budget saving in most of the countries, which could be reinvested to treat more patients and improve access to therapy. The use of biosimilars was the most frequent in Poland (7/10) due to a mandatory switch of all infliximab patients to biosimilar. Furthermore, recently in 2017, as an incentive, the maximum infliximab treatment was prolonged to 24 mo while adalimumab is still limited to 12 mo. In Latvia all infliximab patients received biosimilar. In Hungary, new infliximab patients had to be treated with biosimilar, and also in Spain switching was mandatory depending on the center. For biosimilars, the acceptability of these drugs by health care actors is even more crucial to realized budget savings. According to previous studies, a negative attitude was primarily due to the lack of efficacy and safety data in inflammatory bowel diseases[17]. In a study carried out in 2014 among 51 Hungarian gastroenterologists, 20% had no concerns and 65% some concerns about biosimilars to treat CD[17]. Nevertheless, in a discrete choice experiment, physicians were more willing to use biosimilars when some benefits regarding the access to treatment was offered for patients in return[17,24].

Finally, we also acknowledge some limitations of this study. Only 10 countries participated in the study, although the sample is diverse, as countries with different economic development were selected, which enabled a comparison between Western-European and CEE countries. Country-specific data were provided by a single gastroenterologist in each country. Nevertheless, these data were verified by the desk research. To calculate annual cost of treatments, publicly available official list prices were used as real prices are not known and can vary even within countries. There are uncertainties regarding the epidemiology data used for the analysis. For example, it is also difficult to provide reliable data on the total number of CD patients in the countries, as in most countries registers exist only for patients treated with biologicals. There are considerable differences in the prevalence of CD across the European countries. These differences can show real diversities across countries, but this can also be the result of different methodological approach or time of the epidemiological studies as well as of the different prevalence of undiagnosed CD patients. Thus, we used the number of patients on biologicals per 100000 population in the correlation analysis to disregard the differences in prevalence across the 10 countries. Nevertheless, in some cases we also had to rely on estimations of experts regarding the total number of patients on biologicals, which results in uncertainties in the number of patients on biologicals per 100000 population as well. Also, we carried out a macro level analysis, and did not consider the determinants of access at individual level, such as socio-demographic characteristics of patients. Finally, in this study, we did not aim to explore whether worse access to treatments impacts the patient's health status.

We found substantial inequalities in the access to biologicals for CD among European countries. Access was strongly determined by the economic development of the country. However we revealed large differences even among countries with a similar economic development. These differences cannot be entirely explained by the availability (eligibility criteria) or the affordability of biologicals, thus acceptance of and attitude to biologicals should be explored further.

COMMENTS

Background

Access to biologicals in Crohn's disease (CD) varies significantly between countries, largely driven by differences in budgetary constraints. The aim of our study is to analyze access (availability, affordability and acceptability) to biologicals for CD in ten European countries and to explore the associations between these dimensions, the uptake of biologicals and economic development.

Research frontiers

Affordability of biological treatments greatly varies across countries. Due to the high price and budget impact of biologicals, most countries have regulated the access to reimbursed treatment. Differences in regulations lead to inequalities in access to biologicals even among European countries with a very similar economic situation. Nevertheless, the appearance of biosimilar drugs as potentially cost-effective alternatives is expected to lead to improvements in access to biological therapy.

Innovations and breakthroughs

The authors compared access to biologicals for CD among ten European countries, and we found substantial inequalities. Reimbursement criteria were the least strict in Sweden and Germany, and the strictest in Hungary, Poland and Slovakia. Treatments were the most affordable in Sweden (13%-37% of the GDP per capita) and the least affordable in the Central and Eastern European countries, especially in Hungary (87%-124%) and Romania (141%-277%).

Applications

The authors concluded that access was strongly determined by the economic development of the country. However large differences were revealed even among countries with a similar economic development, which cannot be entirely explained by the availability (eligibility criteria) or the affordability of biologicals. Thus, other factors such as acceptability and attitudes, also strongly determine the use of biologicals in a given country.

Terminology

CD is a chronic inflammatory disorder of the gastrointestinal tract that is characterized by diarrhea, abdominal pain, rectal bleeding, fever and fatigue. Biological drugs have revolutionized the treatment of inflammatory bowel diseases. These drugs are monoclonal antibodies with different mechanisms of action (infliximab and adalimumab are anti-tumor necrosis agents, vedolizumab is an anti-integrin drug and ustekinumab is an interleukin-12 and -23 inhibitor) but with similar safety profile and comparable efficacy. Clinical evidence confirmed the efficacy, safety and effectiveness of these drugs for the treatment of CD, as they substantially improve the ability to achieve disease remission, slow disease progression, decrease the need of surgery and increase work participation and quality of life.

Peer-review

The authors present that the difference of accessibility to biologicals, namely availability, affordability, and acceptability, for CD in ten selected European countries and the associations between these dimensions with the uptake of biologicals and economic development. Because limited data exist describing the accessibility to biologics according to economic development, I regard this to be an important study. The results are thoroughly analyzed and discussed. The manuscript is well-written.

Abstract

AIM

To investigate the temporal trends in the misdiagnosis rate between Crohn's disease (CD) and intestinal tuberculosis (ITB) in South Korea.

METHODS

We retrospectively reviewed the medical records of patients managed for CD or ITB at Asan Medical Center, a tertiary referral hospital, Seoul, Korea between 1996 and 2014. The temporal trends in the misdiagnosis rates between the two diseases were analyzed. The demographic and clinical characteristics were compared between CD patients who were initially misdiagnosed as ITB (final CD group) and vice versa (final ITB group). Final diagnostic criteria for ITB and medication for CD before definite diagnosis of TB were also analyzed in final ITB group.

RESULTS

In total, 2760 patients were managed for CD and 772 patients for ITB between 1996 and 2014. As well, 494 of the 2760 CD patients (17.9%) were initially misdiagnosed as ITB and 83 of the 772 ITB patients (10.8%) as CD. The temporal trend in misdiagnosing CD as ITB showed a decrease (OR = 0.89, 95%CI: 0.87-0.91, $P < 0.001$), whereas the temporal trend in misdiagnosing ITB as CD showed an increase (OR = 1.06, 95%CI: 1.01-1.11, $P = 0.013$). Age at diagnosis, presenting symptoms, and proportion of patients with active/past perianal fistula and active/inactive pulmonary tuberculosis (TB) were significantly different between final CD group and final ITB group. Forty patients (48.2%) in final ITB group were diagnosed by favorable response to empirical anti-TB treatment. Seventeen patients (20.5%) in final ITB group had inappropriately received corticosteroids and/or thiopurines due to misdiagnosis as CD. However, there were no mortalities in both groups.

CONCLUSION

Cases of CD misdiagnosed as ITB have been decreasing, whereas cases of ITB misdiagnosed as CD have been increasing over the past two decades.

Key words: Crohn's disease; Intestinal tuberculosis; Misdiagnosis

Core tip: In South Korea, tuberculosis (TB) is still prevalent, but its incidence has been decreasing. On the other hand, the incidence and prevalence of Crohn's disease (CD) has been increasing as in many Asian countries. In this paper, we demonstrated inverse trends in the misdiagnosis rates between CD and intestinal TB (ITB) over the last two decades. That is, cases of CD misdiagnosed initially as ITB have been decreasing, whereas cases of ITB misdiagnosed initially as CD has been increasing. More attention is needed for the correct diagnosis of CD or ITB, which could improve patients' outcomes with proper management.

Temporal trends in the misdiagnosis rates between Crohn's disease and intestinal tuberculosis. *World J Gastroenterol* 2017; 23(34): 6306-6314 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6306.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6306

INTRODUCTION

Crohn's disease (CD) and intestinal tuberculosis (ITB) frequently show similar clinical and endoscopic features and it is difficult to differentiate between the two diseases, especially in areas with a high prevalence of tuberculosis (TB), such as Asia and Africa[1-5]. In South Korea, the incidence of TB has been decreasing[6], but it is still higher than that of Western countries. According to the Global TB Report 2013 by the World Health Organization, Korea had an incidence of 108 TB cases per 10^5 person-year, as well as a prevalence of 146 TB cases per 10^5 population in 2012[7]. Meanwhile, in the past, CD was considered a rare disease in Asian countries compared to Western countries[8-10]. Due to the low incidence of CD and the clinical inexperience in cases of CD, a significant proportion of patients with CD have been misdiagnosed as ITB, and anti-TB drugs have been administered inappropriately. However, with the increasing incidence and prevalence of CD in Asian countries including South Korea[9-11], and with the increasing attention of Asian physicians to inflammatory bowel diseases (IBD), the proportion of CD cases misdiagnosed as ITB is expected to decrease gradually. On the other hand, ITB cases initially misdiagnosed as CD could be increasing in Asian countries.

It is important to differentiate between CD and ITB because the treatments and prognoses are quite different between the two diseases[3,12,13]. In most cases, ITB can be cured with proper anti-TB drugs

with a favorable outcome, while CD is a chronic disease needing lifelong management. Moreover, the misdiagnosis of ITB as CD can lead to worse outcomes, because immunosuppressive drugs, such as corticosteroids, thiopurines, and anti-tumor necrosis factor agents can aggravate ITB[14]. Conversely, the misdiagnosis of CD as ITB can render the CD patients exposed to the potential toxicity of anti-TB drugs and delay the proper treatment of CD. Therefore, making an accurate differential diagnosis between CD and ITB at the earliest possible stage is very critical[4]. Although previous researchers have suggested clinical, endoscopic, and pathologic clues that could be helpful in a differential diagnosis between these two diseases[3,12,15-25], it is still not easy to tell them apart.

In this study, we aimed to analyze the temporal trends in the misdiagnosis rates between CD and ITB in Korea. In addition, we analyzed the clinical characteristics of ITB cases initially misdiagnosed as CD and CD cases initially misdiagnosed as ITB.

MATERIALS AND METHODS

Study population

Between January 1996 and December 2014, 2723 and 772 patients were managed for CD and ITB, respectively, at the Asan Medical Center, a tertiary university hospital in Seoul, South Korea, and they were included in this study. The diagnosis of ITB was based on Korean diagnostic guideline of ITB[26] and was considered established when at least one of the following criteria was met[16,27,28]: (1) histological demonstration of caseating granulomas; (2) identification of acid-fast bacilli in a histological specimen; (3) positive culture of *Mycobacterium tuberculosis* from a biopsy specimen; (4) clinical, colonoscopic, radiologic, and/or operative evidence of ITB associated with proven TB elsewhere; and (5) response to anti-TB therapy without subsequent recurrence in patients with clinical, colonoscopic, radiologic, and/or operative evidence of ITB. Colonoscopic findings which favor a diagnosis of ITB were as follows; involvement of fewer than four segments, anorectal lesions, patulous ileocecal valve, and scars or pseudopolyps, as described previously[16]. Some of the ITB patients in this study were described previously[27]. CD was diagnosed based on conventional clinical, radiologic, endoscopic, and histopathologic criteria[9,16,29].

Study design

For the characterization of study subjects, we retrospectively reviewed the medical records and the IBD registry of the Asan Medical Center. The IBD registry of the Asan Medical Center and the characteristics of this hospital-based cohort of CD patients has been described previously[30]. To evaluate the initial clinical presentation, we also reviewed the medical records and endoscopic images provided by referring physicians. Through the reviewing process, the following characteristics were abstracted and compared between CD patients misdiagnosed as ITB (final CD group) and ITB patients misdiagnosed as CD (final ITB group): gender, age at diagnosis, interval from misdiagnosis to definite diagnosis, presenting symptoms, active and/or past perianal fistula, active pulmonary TB (PTB), radiologic evidence of old PTB, and institutions where misdiagnosis was made. For the final ITB group, medication for CD before definite diagnosis of ITB was also abstracted. We also analyzed the final diagnostic criteria for ITB in the final ITB group. The study protocol was approved by the Institutional Review Board of the Asan Medical Center (IRB No. 2010-0882).

Temporal trends in the misdiagnosis rates

To evaluate the temporal trends in the misdiagnosis rates between CD and ITB, the number of patients diagnosed with CD at the initial evaluation but finally diagnosed with ITB and vice versa were verified every year between 1996 and 2014. The annual rate of misdiagnosing CD as ITB was defined by the proportion of patients with a preceding misdiagnosis as ITB (final CD group) among the patients diagnosed definitely with CD at that year. The rate of misdiagnosing ITB as CD was calculated by the opposite method.

Statistical analysis

Continuous variables were expressed as the mean with SD or the median with ranges. Discrete data were expressed as numbers and percentages. The clinical characteristics of the final CD group and the final ITB group were compared using the Student's *t*-test or the Mann-Whitney *U* test for continuous variables and the χ^2 test or the Fisher's exact test for categorical variables, where appropriate. The temporal trends in the misdiagnosis rates of CD and ITB were analyzed by the logistic regression analysis. We also calculated the intervals from misdiagnosis to correct diagnosis in each patient and values were expressed as median with interquartile range (IQR). The intervals from initial misdiagnosis to correct diagnosis in periods divided into 6 (1996-1999, 2000-2002, 2003-2005, 2006-2008, 2009-2011, and 2012-2014) were compared using the Kruskal-Wallis test.

A statistical analysis was carried out using IBM SPSS statistics, ver. 21.0 (IBM Co., Armonk, NY, United States) and SAS version 9.3 (SAS Institute Inc., Cary, NC). A P value < 0.05 was considered statistically significant.

RESULTS

During the 19-year study period, 494 of the 2760 patients with CD (17.9%) were initially misdiagnosed as ITB (final CD group). Conversely, 83 of the 772 patients with ITB (10.8%) were initially misdiagnosed as CD (final ITB group). Among 494 patients in final

[1]The *P* value by the χ^2 test; [2]The *P* value by the Mann-Whitney *U* test; [3]The *P* value by the Fisher's exact test; [4]The Median (Interquartile range); [5]Not evaluated in one patient; [6]Not evaluated in four patients; [7]Patients who had active pulmonary TB and patients whose chest X-ray film was unavailable were excluded; [8]Misdiagnoses were made at our institution in 68 patients (13.8%); [9]Misdiagnoses were made at our institution in 7 patients (8.4%). CD: Crohn's disease; ITB: Intestinal tuberculosis; TB: Tuberculosis.

CD group, misdiagnoses were made at primary clinics in 44 patients (8.9%), at secondary referral hospitals in 118 patients (23.9%), at the tertiary referral hospitals other than our institution in 246 patients (49.8%), and at our institution in 68 patients (13.8%). In 18 cases (3.6%), information on the institution where misdiagnoses were made was unclear. Among 83 patients in final ITB group, misdiagnoses were made at primary clinic in 12 patients (14.5%), at secondary referral hospital in 30 patients (36.1%), at the tertiary referral hospital other than our institution in 34 patients (41.0%), and at our institution in 7 patients (8.4%, Table 1).

The yearly trends in the misdiagnosis rates between CD and ITB are plotted in Figure 1. Although the misdiagnosis rates showed variability every year, the rate of misdiagnosing CD as ITB showed a decreasing tendency and the rate of misdiagnosing ITB as CD showed an increasing tendency over time. In 1996, a total of 34.3% of patients in final CD group were misdiagnosed initially as ITB, but the proportion of misdiagnosed cases was decreased to 8.1% in 2014. During the initial 5 years of observation period (1996-2000), 33.2% of final CD group have been misdiagnosed as ITB, but the rate of misdiagnosing CD as ITB went down to 9.9% during the last 5 years (2010-2014) of study period. The temporal trend in the rate of misdiagnosing CD as ITB showed a significant decrease over the 19 years in the logistic regression model (OR = 0.89; 95%CI = 0.87-0.91 per year increase in the study period; $P < 0.001$). In the cases with ITB, no patient was misdiagnosed initially as CD in 1996, but 15.6% were misdiagnosed initially as CD in 2014. During the initial 5 years of observation period (1996-2000), only 3.0% of final ITB group have been misdiagnosed as CD, whereas the rate of misdiagnosing ITB as CD increased to 13.1% during the last 5 years (2010-2014). Therefore, the trend in the rate of misdiagnosing ITB as CD showed a significant increase (OR = 1.06; 95%CI: 1.01-1.11 per year increase in the study period; $P = 0.013$).

We analyzed the temporal trends in the intervals from initial misdiagnosis to correct diagnosis (Figure 2). The median intervals from misdiagnosis to correct diagnosis were 5.2 mo (IQR: 2.3-12.2) in final CD group and 4.0 mo (IQR: 1.6-13.4) in final ITB group. During the study period, the intervals from initial misdiagnosis to final diagnosis were not changed significantly in both final CD group ($P = 0.394$ by Kruskal-Wallis test) and final ITB group ($P = 0.748$ by Kruskal-Wallis test) during study period (Figure 2).

Table 1 shows the demographic and clinical characteristics of the final CD group and of the final ITB group, respectively. The age at definite diagnosis was younger in the final CD group than in the final ITB group (median 23.4 years *vs* 35.8 years, $P < 0.001$). The most frequent symptom of both groups was abdominal pain. However, diarrhea and hematochezia/melena were more common in the final CD group than in the final ITB group ($P < 0.001$ and $P = 0.023$, respectively). Alternatively, an incidental diagnosis without any related symptom was more common in

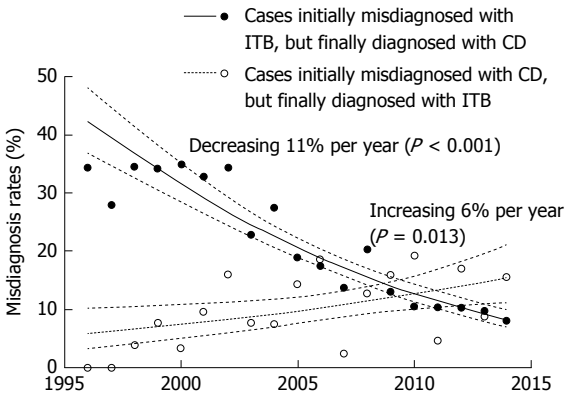

Figure 1 Temporal trends in the misdiagnosis rates between Crohn's disease and intestinal tuberculosis during the study period. Dots represent the observed misdiagnosis rates; lines represent the expected misdiagnosis rates and 95%CI according to the logistic regression analysis. The misdiagnosing rate of Crohn's disease (CD) as intestinal tuberculosis (ITB) decreased to 0.89 (95%CI: 0.87-0.91) fold per year ($P < 0.001$); The misdiagnosing rate of ITB as CD increased to 1.06 (95%CI: 1.01-1.11) fold per year ($P = 0.013$).

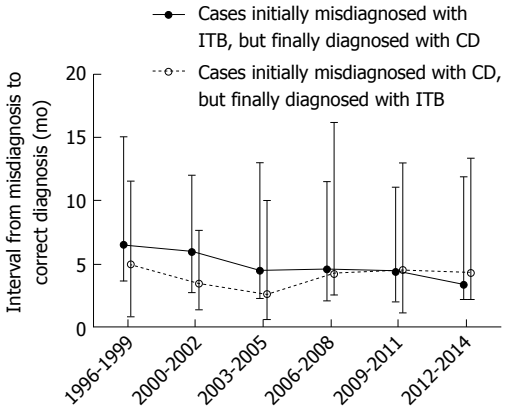

Figure 2 Temporal trends in the interval from misdiagnosis to correct diagnosis in cases of Crohn's disease initially misdiagnosed as intestinal tuberculosis (Final Crohn's disease group) and cases of intestinal tuberculosis initially misdiagnosed as Crohn's disease (Final intestinal tuberculosis group). The data are presented with the median and interquartile range. The interval from initial misdiagnosis to final diagnosis were not changed significantly in final Crohn's disease (CD) group ($P = 0.394$ by Kruskal-Wallis test) and final intestinal tuberculosis (ITB) group ($P = 0.748$ by Kruskal-Wallis test) during the study period.

the final ITB group than in the final CD group ($P < 0.001$). Only seven patients (8.4%) had an active and/or past perianal fistula in the final ITB group, whereas 192 (38.9%) patients in the final CD group had an active and/or past perianal fistula ($P < 0.001$). None of patients in final CD group had active PTB, but 10 patients (12.7%) in final ITB group had active PTB ($P < 0.001$). Inactive PTB in the radiologic evaluation were also more commonly observed in final ITB group (38.9% *vs* 8.4%, $P < 0.001$). Table 2 shows the final diagnostic criteria for ITB and history of inappropriate medication for CD in the final ITB group. In 40 patients (48.2%), favorable response to empirical tuberculosis treatment was applied as diagnostic criteria of ITB. In 17 patients (20.5%), corticosteroids and/or thiopurines were inappropriately given due to misdiagnosis as CD (Table 2). There were no mortalities in two groups.

Table 2 Characteristics of patients finally diagnosed with intestinal tuberculosis who were initially misdiagnosed as Crohn's disease; final diagnostic criteria for intestinal tuberculosis and medication for Crohn's disease before correct diagnosis *n* (%)

	Final ITB group[1] (*n* = 83)
Diagnostic criteria of ITB	
Positive culture of *M. Tb* alone	40 (48.2)
Positive AFB smear alone	1 (1.2)
Positive culture of *M. Tb* + Positive AFB smear	1 (1.2)
Caseating granuloma alone	1 (1.2)
Improvement after empirical anti-tuberculosis treatment in patients without the above findings	40 (48.2)
Medication for CD before definite diagnosis of TB	
No medication	21 (25.3)
5-ASA alone	42 (50.6)
5-ASA + Corticosteroids	12 (14.5)
5-ASA + Thiopurines	1 (1.2)
5-ASA + Corticosteroids + Thiopurines	4 (4.8)
Medication given, but unavailable records	3 (3.6)

[1]Final ITB group: Intestinal tuberculosis patients initially misdiagnosed as Crohn's disease. 5-ASA: 5-amino salicylic acids; AFB: Acid-Fast Bacilli; CD: Crohn's disease; ITB: Intestinal tuberculosis; *M. Tb*: *Mycobacterium tuberculosis*; TB: Tuberculosis.

DISCUSSION

In the present study, we demonstrated the inverse trends in the misdiagnosis rates between CD and ITB over the last two decades in South Korea. Comparing the final CD group and the final ITB group, different characteristics, such as age at diagnosis, presenting symptoms, presence of perianal fistula, and concurrent PTB could be identified.

In this study, we included all patients managed for CD or ITB in our institution and enrolled patients who were finally diagnosed as CD or ITB before referral to our institution to minimize referral bias. In addition, by thoroughly reviewing the IBD registry of our hospital, which has been maintained since 1997[30], as well as medical records and colonoscopic images from referring physicians, we could gather valid information on our study subjects to ensure diagnostic accuracy for study participants.

The incidence of active PTB in Koreans was as high as 393/10^5 person-year between 1988 and 1990, and 202/10^5 person-year between 1992 and 1994[31,32]. However, it appears to be decreasing with time, showing 119.3/10^5 person-year between 2006 and 2008[6]. Although the exact incidence of ITB is not well known, a previous Korean study reported that 32 of 59 patients (54.2%) with active PTB, but without any gastrointestinal symptoms were diagnosed with ITB by total colonoscopy, thereby suggesting a high concurrence of ITB among PTB patients[33]. Although

the actual incidence of ITB is uncertain, the incidence of ITB is also expected to have been decreasing together with PTB. On the other hand, the incidence of CD, which was once thought to be very rare compared to Western countries, has been increasing recently in South Korea[9,34]. There have been several studies showing similar trends in TB epidemiology in other endemic areas, such as South Asia, India, Saudi Arabia, and South Africa[35-37]. For CD, as with Korea, the increasing incidence could be also observed in other Asian and Middle Eastern countries, such as Japan[38], Hong Kong[39], Taiwan[40], and Saudi Arabia[36].

With the changing epidemiology of TB and CD, general practitioners and gastrointestinal specialists in Asian areas could be becoming more concerned with CD than with ITB. In addition, with the decreasing incidence of TB, ITB cases that could have been correctly diagnosed may be misdiagnosed as CD. Actually, for the 19-year period in this study, the misdiagnosis rate of ITB as CD showed a statistically significant increase, and vice versa, although they were relatively stable since 2009. The rate of misdiagnosing ITB as CD overcame the rate of misdiagnosing CD as ITB in 2010. The misdiagnosis between CD and ITB and inappropriate treatments based on the misdiagnosis could cause serious harm to patients, especially for ITB cases. In our study, corticosteroids and/or thiopurines were inappropriately given to 20.5% of ITB patients because of misdiagnosis as CD, which could have led to disseminated TB disease. Therefore, our study results are calling for more attention to the physicians managing patients with inflammatory disorders of the bowel. In the absence of a confirmatory test to differentiate ITB from CD, the current Asia-Pacific consensus recommend 8-12 wk of empirical anti-TB treatment for patients with diagnostic uncertainty[41], and one thing we should remember is that about a half of ITB cases (48.2%) with previous misdiagnosis as CD in our study could have been correctly diagnosed with ITB after anti-TB treatment. The finding that the other half of ITB patients (49.4%) were correctly diagnosed based on positive culture of *M. Tb* emphasizes the importance of *M. Tb* culture study when performing colonoscopy for cases having ileocolonic inflammation which is difficult to make a differential diagnosis.

Unfortunately, there were no significant changes in the lag time from initial misdiagnosis to correct diagnosis during the study period. This is probably because most of the misdiagnosed cases have been referred to the more specialized centers or have been re-evaluated after a few months of unresponsiveness to treatment, which emphasizes the importance of the initial correct differentiation between two diseases. Therefore, we suggest the strict following of guidelines or consensus[26,41] and the application of the appropriate scoring system, diagnostic algorithms, or prediction models according to the regional epidemiology of two diseases[3,16,18-25].

In daily clinical practice, relatively simple clinical information could be helpful in the differential diagnosis between CD and ITB. In the current study, the younger age at diagnosis was observed in CD patients than in ITB patients, which is consistent with the results of previous studies[42,43]. The frequency of initial presenting symptoms was different between the two groups in our study. Diarrhea, hematochezia/melena, active and/or past perianal fistula were common in final CD group, whereas active or inactive pulmonary TB was observed more often in final ITB group. It was in line with a recently published large meta-analysis including 38 studies comprising 2117 CD and 1589 ITB patients, which has shown that diarrhea, hematochezia, presence of perianal disease, and extraintestinal manifestations significantly favored CD, whereas fever, night sweats, lung involvement and ascites significantly favored ITB[25]. However, symptoms are not always helpful for a differential diagnosis, because they are subjective and conflicting results on the frequency of symptoms in CD and ITB patients have been reported, depending on the study population[3,44-47].

According to the previous report from our institution, 43.2% of CD patients showed an active and/or past perianal fistula at the time of CD diagnosis[48]. In line with that study, among the final CD group, 38.9% of subjects showed an active and/or past perianal fistula at initial presentation, which was significantly higher than the figure for the final ITB group. Although a perianal fistula and anorectal lesion could also be manifestations of ITB[49,50], a concurrent perianal fistula could strongly suggest the probability of CD rather than ITB[3].

There has been a report that the features of old or active PTB were found in 35% of Indian patients with ITB[51]. Similarly, in South Korea, active PTB was accompanied in 28%-49% of ITB patients, and evidence of old PTB was shown in 14%-24.8% of ITB patients[27,52,53]. However, in our final ITB group, active PTB was accompanied only in 12.7%, although it was significantly more frequent than in final CD group. Because only cases initially misdiagnosed as CD were enrolled in the final ITB group, a lower proportion of patients might have concurrent active PTB compared with previous studies[27,52,53]. Nonetheless, a simple chest X-ray is always needed for a correct differential diagnosis, because findings of active PTB could be a clue to the diagnosis of ITB.

There are a few limitations to this study. First, the study design was retrospective. However, we made every effort to gather reliable data from electronic medical records, the IBD registry, endoscopic images, and information from referring doctors to avoid information bias. Regardless of our effort, some important variables which would affect the risk of ITB and CD, such as socioeconomic characteristics, could not be analyzed in this study. Second, this study was based on a single referral center and the real-life situations of primary and secondary facilities could be somewhat

different, maybe showing higher rates of misdiagnosis than in this study. However, because about one third of the final CD group and about a half of the final ITB group were initially misdiagnosed at the primary clinics or secondary hospitals, and because misdiagnosed cases in tertiary hospitals were also referred from primary or secondary facilities because of diagnostic uncertainty, our results could represent a general phenomenon in our country.

In conclusion, cases of ITB misdiagnosed as CD have been increasing in Korea over the past two decades. Conversely, CD cases misdiagnosed as ITB have been decreasing. More attention is needed for the correct diagnosis of CD or ITB, which could improve patients' outcome with proper management.

COMMENTS

Background

Differential diagnosis between intestinal tuberculosis (ITB) and Crohn's disease (CD) is a challenging issue in areas with a high prevalence of tuberculosis (TB) and an increasing incidence of CD. However, rates of misdiagnosing CD and ITB as each other disease and their temporal trends are not well known.

Research frontiers

The incidence rate of TB is still high in Asia, but it is declining gradually with socioeconomic development. Meanwhile, the increasing incidence rate of CD is a widely observed phenomenon in most Asian countries. Most recent studies have focused on identifying clinical, endoscopic, radiologic, and histopathologic features which can be helpful to distinguish between two diseases and on suggesting predictive models or scoring systems. However, only a few studies have addressed how many patients are misdiagnosed as each other disease and none of studies have demonstrated how the misdiagnosis rates between CD and ITB have altered with changing epidemiology of two diseases.

Innovations and breakthroughs

This was the first study which has demonstrated inverse trends in misdiagnosis rates between CD and ITB over nearly two decades. That is, cases of CD misdiagnosed initially as ITB have been decreasing, whereas cases of ITB misdiagnosed initially as CD has been increasing.

Applications

The data in this article suggest that clinicians have been becoming more concerned about CD with increasing incidence of CD, leading to improved diagnostic accuracy for CD in recent years. At the same time, however, the rate of misdiagnosing ITB as CD increased and overcame the rate of misdiagnosing CD as ITB and that raises the alarm for physicians so as not to expose patients with ITB to potentially harmful immunosuppressive therapy.

Terminology

ITB is tuberculosis involving intestinal tract, which is one of the forms of extrapulmonary tuberculosis.

Peer-review

In the present original paper, the authors showed temporal trends of the misdiagnosis rates between CD and ITB from a patient cohort managed at a specialized center for inflammatory bowel diseases. As a result, the rates of misdiagnosis as ITB in cases of actual CD has been decreasing and the opposite has been increasing. Overall, findings of this study are novel and this is a well-written and interesting paper.

Abstract

AIM

To detect the existence of isolated cancer cells in the mesentery of colorectum (named as Metastasis V), and investigate its clinical significance in colorectal cancer (CRC) patients.

METHODS

Sixty-three CRC patients who received radical excision between January 2012 and September 2015 were included. All the patients underwent laparoscopy-assisted radical colorectomy or proctectomy [with complete mesocolic excision (CME) or total mesorectal excision (TME)] with R0 dissections at the Department of Gastrointestinal Surgery, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology. The location and size of the primary lesions were recorded immediately after the tumor was removed, with the surrounding mesenterium completely separated along the intestinal wall. Each dissected mesentery sample was analyzed for hematoxylin-eosin staining and immunohistochemistry using cytokeratin 19 antibody. Image Pro Plus Software 6.0 (Media Cybernetics, CA, United States) was used

to semi-quantitatively measure the concentration of the cytokeratin 19 immunohistochemistry. The correlation between metastasis found in mesentery and clinicopathological characteristics was examined. The prognosis of patients was also evaluated by preoperative serum CEA level.

RESULTS

Metastasis V was detected in 14 of 63 (22.2%) CRC patients who underwent laparoscopy-assisted radical colorectomy or proctectomy (with CME or TME) with R0 dissection in our hospital between January 2012 and September 2015. There was no significant difference in age, gender, tumor size, and tumor location in patients with Metastasis V ($P > 0.05$). Metastasis V was more likely to occur in poorly differentiated tumor (5/11; 45.5%) than moderately (8/46; 17.4%) and well-differentiated one (1/6; 16.7%). The Metastasis V in N2 stage (9/14; 64.3%) was more frequent that in the N0 stage (3/35; 8.6%) or N1 stages (2/14; 14.3%). In addition, Metastasis V was positively related to the tumor invasive depth (T1:0/1, 0%; T2:1/12, 8.3%; T3:7/39, 17.9%; T4:6/11, 54.5%). Furthermore, pre-operative serum CEA level in Metastasis V-positive patients was significantly higher than in Metastasis V-negative patients (4.27 ng/mL *vs* 3.00 ng/mL).

CONCLUSION

Metastasis V might be associated with a poor prognosis of CRC patients.

Key words: Colorectal cancer; Colorectal mesentery; Serum CEA level; Radical surgery; Metastasis V

Core tip: Local-regional recurrence of colorectal cancer (CRC) is common in patients who received R0 resection. Our previous study proposed a novel type of metastasis designated as "Metastasis V" in gastric cancer. Metastasis V is defined as the appearance of cancer cells in the mesentery in broad sense, and may be a risk factor for the poor prognosis after radical surgery. In this study, Metastasis V was also detected in the mesentery of colorectum, and it might be associated with the poor prognosis of CRC patients.

Detection of metastatic cancer cells in mesentery of colorectal cancer patients. *World J Gastroenterol* 2017; 23(34): 6315-6320 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6315.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6315

INTRODUCTION

Three decades ago, RJ Heald introduced the total mesorectal excision (TME) in the treatment of rectal cancer[1]. Subsequently, complete mesocolic excision (CME) was popularized by W Hoehenbuerg to reduce tumor relapse and improve prognosis in colon cancer patients[2]. These new approaches greatly contributed to the complete mesentery excision and improved lymph node harvest. Furthermore, with the development of surgical technology, neo-adjuvant chemotherapy and efficient perioperative management, the prognosis of patients with colorectal cancer (CRC) has been improved. However, local-regional recurrence of CRC is still often noted in the patients who received radical R0-resection with no lymphatic metastasis[3].

Direct invasion, lymphatic drainage, hematogenous spread and peritoneal dissemination are the four classical routes for local-regional recurrence or distant implantion of cancer cells. In addition to these pathways, the existence of metastatic cancer cells in the mesentery of colorectum has also been reported, and this type of metastasis was named as "extra-capsular spreads" or "extra-nodal metastasis"[4-7]. In our previous study, we proposed a novel type of tumor metastasis designated as Metastasis V in gastric cancer. Metastasis V is defined as the appearance of cancer cells in the mesogastrium with perigastric adipose tissue, and it may be a risk factor for patient survival after radical surgery[8]. Here, in this study, we further determined whether Metastasis V can be detected in the mesocolorectum, and examined its clinical significance.

MATERIALS AND METHODS

Patients, samples, and sectional tissue analysis

Sixty-three patients who underwent surgery for CRC at the Department of Gastrointestinal Surgery, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology between January 2012 and September 2015 were included in this study. The patients consisted of 25 female patients and 38 male patients. All of these patients received laparoscopy-assisted radical colorectomy or proctectomy (with CME or TME) with R0 dissection. All participants signed informed written consents in this research. This study was approved by the Tongji Hospital Ethics Committee.

Clinical samples of CRC were obtained from the resected colorectal tissue. The location and size of the primary lesions were recorded immediately after the tumor was removed, and then the mesenterium was completely separated from the intestinal wall along with the anterior edge. All specimens were fixed in 10% formaldehyde before processing. The lymph nodes were obtained from the mesenterium. Next, the mesentery was cut into strip-shape with a width of 2 cm in an outward-to-inward manner, vertical to the intestinal wall. The strip-shaped samples were cut into cube samples with a mean length of 2 cm.

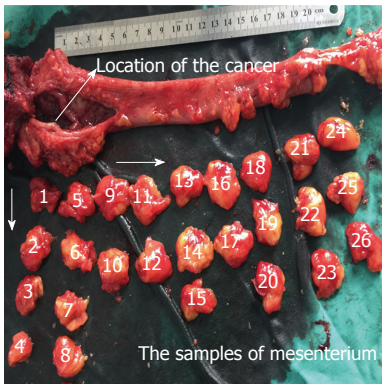

Figure 1 Samples of mesenterium from colorectal cancer patients. Analysis of large cross sectional tissue samples of mesentery of colorectum from surgically resected specimens.

Table 1 Data in 63 colorectal cancer patients

Parameters	Results
Gender	
Female	25
Male	38
Age (yr, mean, range)	55.5 (28-86)
Location of cancer	
Colon	11
Rectum	52
Differentiated grade	
Well	6
Moderately	46
Poorly	11
Affected lymph nodes	
N0	35
N1	14
N2	14
Invasive depth	
T1	1
T2	12
T3	39
T4	11

All of the small samples were numbered from inside (proximal end of the cancer) to outside (Figure 1). These samples were embedded in 10% formaldehyde. Demographic characteristics of the 63 patients are described in Table 1. The clinicopathological stage was determined by the 7th edition of the AJCC Cancer Staging Manual.

Immunohistochemical analysis of Metastasis V

Immunohistochemistry was performed using the cytokeratin 19 antibody. Cytokeratin 19 is specifically expressed in intestine epithelia cells and CRC cells[9]. Hence, it has been proven to be a highly sensitive marker for CRCs.

Immunostaining was performed by the standard streptavidin-biotin method. First, the slices were de-paraffinized and rehydrated. To retrieve antigenicity, the slices were boiled in 0.01 mol/L, pH 6.0 sodium citrate buffer for approximately 15 min. Endogenous peroxidase was restrained with 0.3% hydrogen peroxide for roughly 25 min. After blocking with 3% BSA for 30 min, the anti-cytokeratin 19 monoclonal antibody was arranged in blocking buffers and the slices were incubated at 4 ℃ overnight. After being washed in pH 7.4 PBS 3 times (5 min each time), the corresponding secondary antibody, retained at room temperature for approximately 50 min and marked by HRP was added. After one more wash with pH 7.4 PBS for 15 min, the chromogenic reagent DAB was added to the colorate. The slices were counterstained with Harris hematoxylin, dehydrated in a graded alcohol series (75% alcohol for 6 min, 85% alcohol for 6 min, absolute ethyl alcohol I for 6 min, and absolute ethyl alcohol II for 6 min), cleared in xylene for 5 min, and mounted. Individual tumor cells in mesenteries, separated from primary lesion and lymph nodes, were identified to be Metastasis V.

Immunohistochemistry image analysis

Image Pro Plus Software 6.0 (Media Cybernetics, CA, United States) was used to semi-quantitatively measure the concentration of the cytokeratin 19 immunohistochemistry. This procedure, was split into six steps: (1) discovering and surveying the section of interest; (2) adjusting the optical densities; (3) obtaining, transforming and preserving images; (4) amending the background and background staining; (5) configuration of the section of interest to determine the optical density; and (6) examining optical densities.

Statistical analysis

The Fisher's exact test, χ^2 test, and Mann-Whitney *U* test were used to inspect the significance of the differences between the covariates. We considered a *P* value of less than 0.05 statistically significant. Standard statistical analyses were performed by SPSS version 20.0.

RESULTS

Detection of Metastasis V in mesenterium of CRC patients

Metastasis V was detected in 14 of the 63 (22.2%) patients by immunohistochemistry staining. These isolated cancer cells separated from the primary lesion and lymph nodes were observed in the same slice (Figure 2). In terms of "T" stage, only one case showed limited muscular layer invasion, seven cases had sub-serosal invasion, and the rest had serosal invasion. In these patients, there were three lymph node negative patients with different invasive depths (Table 2).

Correlation between Metastasis V and clinical factors

The demographic characteristics of patients and the pathologic features of tumors with Metastasis V are shown in Table 3. There was no significant difference

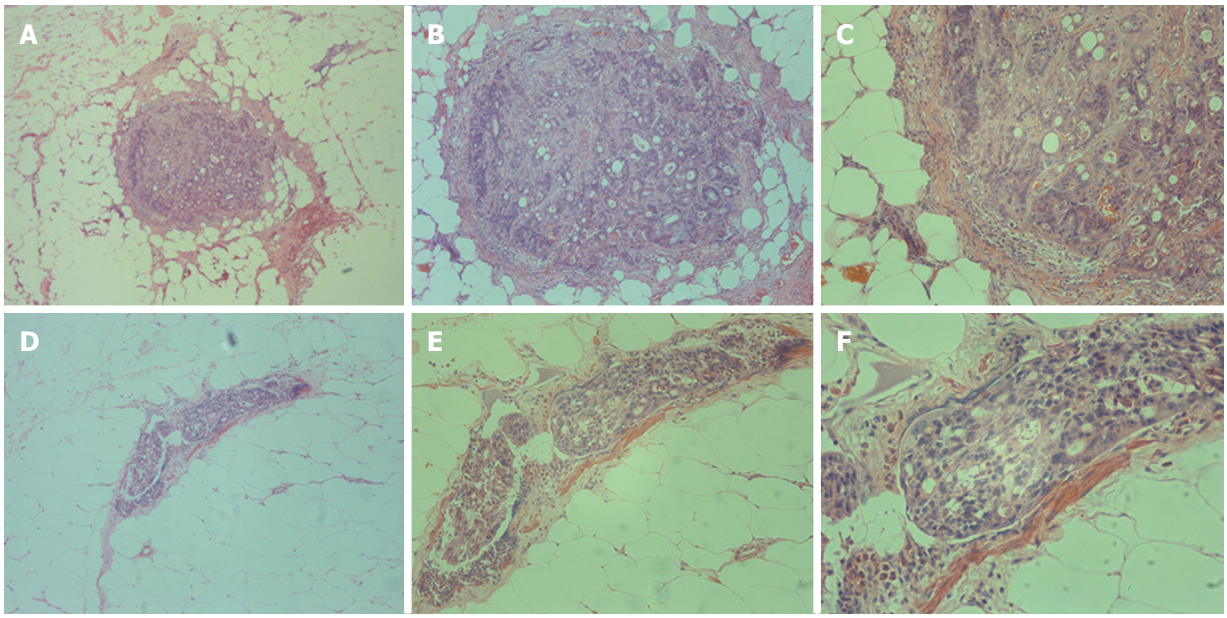

Figure 2 Detection of Metastasis V in colorectal cancer patients. Isolated cancer cells were detected in the mesentery of colorectum by HE staining. A (× 10), B (× 20) and C (× 40) represent the same slide; D (× 10), E (× 20) and F (× 40) represent the same slide.

Table 2 Data in Metastasis V-positive patients

Patients	Sex	Age (yr)	Cancer size (cm)	Cancer location	Differentiated grade	Invasive depth	Affected lymph nodes	TNM
1	F	37	2.5	Rectum	Poorly	Serosal	8/15	pT4N2M0
2	F	42	3	Rectum	Moderately	Subserosal	5/17	pT3N2M0
3	M	33	2	Rectum	Moderately	Serosal	5/15	pT4N2M0
4	M	48	6	Sigmoid	Well	Serosal	12/21	pT4N2M0
5	F	63	3	Rectum	Poorly	Muscularis	0/15	pT2N2M0
6	F	45	3	Rectum	Moderately	Serosal	5/28	pT4N2M0
7	M	58	3	Rectum	Poorly	Subserosal	8/12	pT3N2M0
8	M	64	4	Rectum	Poorly	Subserosal	7/15	pT3N2M1
9	M	54	6	Rectum	Moderately	Subserosal	2/13	pT3N1M0
10	F	60	2	Descending colon	Moderately	Subserosal	0/17	pT3NxM0
11	M	54	3	Rectum	Moderately	Serosal	5/12	pT4N2M0
12	M	58	3	Rectum	Moderately	Subserosal	0/16	pT3N0M0
13	F	57	3	Rectum	Poorly	Serosal	2/21	pT4N1M1
14	M	47	4	Rectum	Moderately	Subserosal	24/32	pT3N2M0

in age, gender, tumor size, and tumor location (P > 0.05). Metastasis V was more likely to occur in poorly differentiated tumor (5/11; 45.5%) than moderately (8/46; 17.4%) and well-differentiated one (1/6; 16.7%). The Metastasis V in N2 stage (9/14; 64.3%) was more frequent than that in the N0 stage (3/35; 8.6%) or N1 stages (2/14; 14.3%). In addition, Metastasis V was positively related to the tumor invasive depth (T1: 0/1, 0%; T2: 1/12, 8.3%; T3: 7/39, 17.9%; T4: 6/11, 54.5%).

Correlation between Metastasis V and preoperative CEA levels

Previous studies have demonstrated the correlation between increased preoperative CEA and the poor prognosis of rectal cancer patients[10,11]. Here, we further determined the correlation between Metastasis V and preoperative CEA levels. Totally 42 CRC patients who underwent operations in our department were retrospectively studied. Metastasis V was detected in nine patients according to the pathological reports. Six patients were excluded because their preoperative CEA data was missed. The CEA levels were divided into two grades. The CEA levels more than 3 times of normal range (15.00 ng/mL) were classified as high grade, while those less than that were designated as low grade. Our data indicated that preoperative serum CEA levels in Metastasis V-positive patients were significantly higher than in Metastasis V-negative patients (4.27 ng/mL *vs* 3.00 ng/mL) (Table 4).

DISCUSSION

In this study, we have shown that metastatic cancer

cells can reside in the mesentery of the colorectum of CRC patients. These tumor cells showed no direct attachment to the primary lesions, with no involvement of vessel-lymphatic drainage system, and are confined to the fatty tissues enveloped by the fascia proper (Figure 1). In our previous study, we proposed a novel type of tumor metastasis designated as Metastasis V in gastric cancer patients[8]. Thus, we believe that Metastasis V could be detected in the mesenteries of both gastric and CRC patients. Similar to our previous studies, the incidence of Metastasis V was closely related to the tumor invasion of CRC patients, which was mainly detected in the T3 and T4 tumors (Table 2). Metastasis V was also correlated with lymphatic metastasis. Lymphatic nodes staging N1-N3 had larger percentages of Metastasis V than N0 (Table 2). Therefore, immunohistochemical analysis of Metastasis V in these patients is strongly recommended in clinical practice.

More interestingly, the preoperative serum CEA levels in Metastasis V-positive patients were significantly higher than in Metastasis V-negative patients (4.27 ng/mL *vs* 3.00 ng/mL) (Table 4). These data indicated that the prognosis of the patients with Metastasis V-positive tumors was worse than that of patients with Metastasis V-negative tumors. Due to the limited number of patients in the current study, a larger sample of cohort study should be enrolled for further analysis.

Little is known about the exact route or mechanism of Metastasis V. It was hypothesized that primary tumor lesions penetrates the intestinal wall, and then the cancer cells could probably scatter into the fatty tissues enveloped by proper fascia. In this way, Metastasis V occurs not only in CRC and gastric cancers, but also in oral head-neck, pancreas and papilla of Vater tumors[12-20].

It has been well known in practice that radical surgery for cancers should include *en bloc* resections of the primary tumor and neighboring tissues. However, it is difficult to determine the exact boundaries of *en bloc* resection within gastrointestinal tumors. "TME" or "CME" can reduce the tumor recurrence and increase patient survival, however, the possible reason is still unknown. In our opinion, the mesenteries of colorectum enveloped by the proper fascia not only propose a precise boundary for resection, but also function as pathologic barriers of Metastasis V spreading. Thus, our findings are clinically significant because TME or CME should be a useful choice for surgical excision of Metastasis V. Further studies on the efficiency of Metastasis V excision *via* TME or CME will be investigated.

ACKNOWLEDGMENTS

We thank Drs. Chao-Ran Yu and Jie Shen for their helpful discussion and paper revision work.

COMMENTS

Background

Local-regional recurrence of colorectal cancer (CRC) is still often noted in the patients who received radical R0-resection with no lymph-node metastasis.

Research frontiers

In addition to the classical four metastatic patterns, the existence of metastatic cancer cells in the mesentery of colorectum has also been reported, and this type of metastasis was named as "extra-capsular spreads" or "extra-nodal metastasis". Examination of the clinical and oncological significance of isolated tumor cells found in mesentery of colorectum in CRC patients is one of the main frontiers in surgical oncology.

Innovations and breakthroughs

Metastasis V is defined as the appearance of cancer cells in the mesogastrium, and may be a risk factor for the poor prognosis after radical surgery. This study demonstrated that Metastasis V was also detected in the mesentery of colorectum, and it might be associated with the poor prognosis of CRC.

Applications

It is clinically useful to be assisted in evaluation of prognosis of CRC patients.

Peer-review

In this paper, the authors well described an interesting study about isolated cancer cells in the mesentery of colorectum (named as Metastasis V). This is an interesting point, and the issue of metastasis in patients with CRC is of main importance.

Abstract

AIM

To explore the natural history of covert hepatic encephalopathy (CHE) in absence of medication intervention.

METHODS

Consecutive outpatient cirrhotic patients in a Chinese tertiary care hospital were enrolled and evaluated for CHE diagnosis. They were followed up for a mean of 11.2 ± 1.3 mo. Time to the first cirrhosis-related complications requiring hospitalization, including overt HE (OHE), resolution of CHE and death/transplantation, were compared between CHE and no-CHE patients. Predictors for complication(s) and death/transplantation were also analyzed.

RESULTS

A total of 366 patients (age: 47.2 ± 8.6 years, male: 73.0%) were enrolled. CHE was identified in 131 patients (35.8%). CHE patients had higher rates of death and incidence of complications requiring hospitalization, including OHE, compared to unimpaired patients. Moreover, 17.6% of CHE patients developed OHE, 42.0% suffered persistent CHE, and 19.8% of CHE spontaneously resolved. In CHE patients, serum albumin < 30 g/L (HR = 5.22, P = 0.03) was the sole predictor for developing OHE, and blood creatinine > 133 μmol/L (HR = 4.75, P = 0.036) predicted mortality. Child-Pugh B/C (HR = 0.084, P < 0.001) and OHE history (HR = 0.15, P = 0.014) were predictors of spontaneous resolution of CHE.

CONCLUSION

CHE exacerbates, persists or resolves without medication intervention in clinically stable cirrhosis. Triage of patients based on these predictors will allow for more cost-effect management of CHE.

Key words: Covert hepatic encephalopathy; Overt hepatic encephalopathy; Natural history; Liver cirrhosis

© The Author(s) 2017. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: Covert hepatic encephalopathy (CHE) was prevalent in clinically-stable cirrhosis in the tertiary care hospital. A history of overt hepatic encephalopathy (OHE) was the only risk factor for CHE in patients with OHE history, while a high model for end-stage liver disease score was the only risk factor for those without OHE history. Natural history of CHE in the absence of medication intervention included development of complications, persistence or spontaneous resolution of CHE. Triage of patients based on predictors for exacerbation and resolution, rather than the degree of impairment in daily work productivity or quality of life, could make clinical management of CHE more cost-effective.

Natural history of covert hepatic encephalopathy: An observational study of 366 cirrhotic patients. *World J Gastroenterol* 2017; 23(34): 6321-6329 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6321.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6321

INTRODUCTION

Hepatic encephalopathy (HE) is a neuropsychiatric syndrome that is most commonly associated with decompensated liver cirrhosis and incorporates a spectrum of manifestations that range from mild cognitive impairment to coma. Generally, HE is subdivided into covert HE (CHE, including minimal HE and West-Haven grade Ⅰ HE) and overt HE (OHE, West-Haven grades Ⅱ-Ⅳ HE)[1,2]. CHE is regarded as the pre-clinical stage of OHE and occurs in 20%-80% of patients with cirrhosis. CHE is associated with increased progression to OHE[3-5], poor health-related quality of life (HRQOL)[6,7], and high risk for traffic violations and accidents[8]. It is also an independent predictor for death, liver-related complications and hospitalizations[9-11]. It is more detrimental for patients in manual labor professions (which involve complex occupational operation and driving of machinery) than those with desk jobs (which involve verbal and intellectual skills). Thus, CHE could endanger patients and their coworkers[12]. The decision to treat CHE depends on the degree of impairment in daily work productivity or quality of life of patients[1,2].

Several studies have investigated the natural history of CHE[3-5,9-11,13-18]. However, in these studies, treatment of other cirrhosis complications [such as antibiotics for infection or gastroesophageal variceal bleeding (GVB), lactulose for constipation, or albumin infusion for ascites or hepatorenal syndrome] was not restricted. The medication used to treat these complications during follow-up could hinder the occurrence of CHE and underestimate its disadvantages. Furthermore, perhaps not all CHE patients need to be treated. Thus, we hypothesized that CHE can persist or resolve spontaneously without medication intervention in some clinically-stable cirrhotic patients. Therefore, the aims of the present study were: (1) to observe the real natural history of CHE without medication intervention before development of cirrhosis related complications; and (2) to determine predictors for exacerbation and spontaneous resolution (SR) of CHE, in order to explore the therapeutic indications for CHE, based on natural course without medication intervention. Our findings will help CHE patient triage and lead to more precise and cost-effective clinical management.

MATERIALS AND METHODS

Subjects, study design and ethics

This was an observational study performed between August, 2014 and November, 2016 at The First Affiliated Hospital of Nanchang University, which is a tertiary care level hospital in China. Ethics approval was obtained from the Ethics Committee of the hospital, and all participants provided written informed consent in accordance with the Helsinki Declaration.

Consecutive cirrhotic patients in the outpatient department of the hospital were screened and included

in the study if they were > 18 and < 65 years of age and had a clinical, radiological or histological diagnosis of cirrhosis. Exclusion criteria included the following: presence or history of malignancy, including liver cancer; history of transjugular intrahepatic porto-systemic stent shunt or shunt surgery; presence of systemic disease, significant head injury, neurological or psychiatric diseases; alcohol or psychoactive medication intake within 6 mo; antibiotics, lactulose, probiotics or L-ornithine-L-aspartate intake or albumin infusion within 6 wk; illiteracy or inability to perform neuropsychometric tests; or refusal to participate in the study. Patients with history of OHE within 6 mo of inclusion were also excluded to ensure total recovery of last OHE occurrence. As patients with resolved OHE may be at a risk for developing CHE, those patients with history of OHE 6 mo before inclusion were included.

OHE history was assessed based on a patient's medical documents of hospitalization before inclusion. Patients were followed prospectively at intervals of 3 mo in the outpatient department of the hospital. Serial psychometric hepatic encephalopathy score (PHES) along with regular clinical and laboratory evaluations were measured at each visit until death, liver transplantation, or a follow-up of 12 mo after initial screening. If the patients did not show up for the 3-mo follow-up, they were tracked by telephone calls from the study staff. The time to death/liver transplantation and the occurrence of the first cirrhosis-related complications requiring hospitalization were recorded. Any medications recommended to treat CHE by established guidelines[1,2], including antibacterial agents, lactulose, probiotics, L-ornithine-L-aspartate and albumin infusion, had not been administered to patients unless necessary. However, these medications were not restricted if patients developed any complications and physicians thought these medications were necessary. In such cases, time to complications were documented. The Child-Pugh classification (CPC) and model for end-stage liver disease (MELD) scoring system were used to evaluate the severity of liver damage. All clinical data and assessment of complications were obtained from interviews or inpatient/outpatient medical documents.

Clinical data documentation and definition of complications

Qualified physicians performed routine physical examinations and documented biochemical blood tests (*i.e.*, complete blood count, alanine aminotransferase, total bilirubin, albumin, creatinine, prothrombin time, international normalization ratio), venous ammonia, virological blood tests [*i.e.*, hepatitis B virus (HBV) DNA and hepatitis C virus RNA levels], and diagnostic imaging (ultrasonography, computed tomography, or magnetic resonance imaging). The etiology of cirrhosis, history of medication use, OHE and severity of ascites were documented.

The complications, which included OHE, gastrointestinal (GI) bleeding, hepatorenal syndrome, infections, primary hepatic carcinoma (PHC) and severe ascites requiring albumin infusion, were documented in mo. OHE was diagnosed clinically on the basis of impaired mental status, as defined by the West Haven Criteria, and impaired neuromotor function (*i.e.*, hyperreflexia, rigidity, myoclonus and asterixis) that required initiation of HE-related therapy with or without hospitalization, and had corroboration from a caregiver[10,19]. GI bleeding was evidenced by melena, hematemesis or hematochezia. Infections were defined as bacterial infections, including pneumonia, sepsis with or without identified infectious focus, urinary tract infection, biliary tract infection, central nervous system infection (*i.e.*, meningitis or brain abscess), and spontaneous bacterial peritonitis. PHC diagnosis was based on imaging findings or liver biopsy.

Definition of CHE and of its persistence and resolution

PHES tests were used to define CHE. All patients underwent PHES tests in one morning session after breakfast in a quiet room without distracting noises. A specially trained medical doctor assisted the enrolled subjects in finishing these tests. Based on the nomograms of healthy volunteers, the PHES tests were described as abnormal if the score was < -4[10,20]. Persistence of CHE was defined if CHE patients survived and continued having abnormal PHES results until completion of follow up, in the absence of any of above-mentioned complication(s) or liver transplantation. As CHE runs a fluctuating course, CHE SR was defined if patients had normal PHES results for at least 6 mo at regular follow-up visits, in the absence of above-mentioned medications, complications or liver transplantation. Alternate forms of PHES tests (three parallel versions for each test in our study) were used at 3-mo interval visits to eliminate practice learning effects[21].

Sample size determination and statistical analysis

Based on a previous study, about 38% of CHE patients developed first OHE episode while about 17% of cirrhotic patients without CHE developed OHE[10]. Based on sample size calculations according to established formulas[22], the minimum sample size necessary for the current study was 78 patients in each group. It is reported that the prevalence of CHE in Chinese cirrhotic patients is about 40%. Thus, a minimum of 195 cirrhotic patients were enrolled to statistically compare the incidence of OHE between the CHE group and unimpaired group.

Continuous variables were expressed as mean ± SD. Categorical variables were described as the number and proportion of each category. Rate differences of OHE development, development of the first cirrhosis-related complications requiring hospitalization and death, between patients with and without CHE, were estimated with Kaplan-Meier analysis and log-rank test. If patients did not develop OHE or other complications

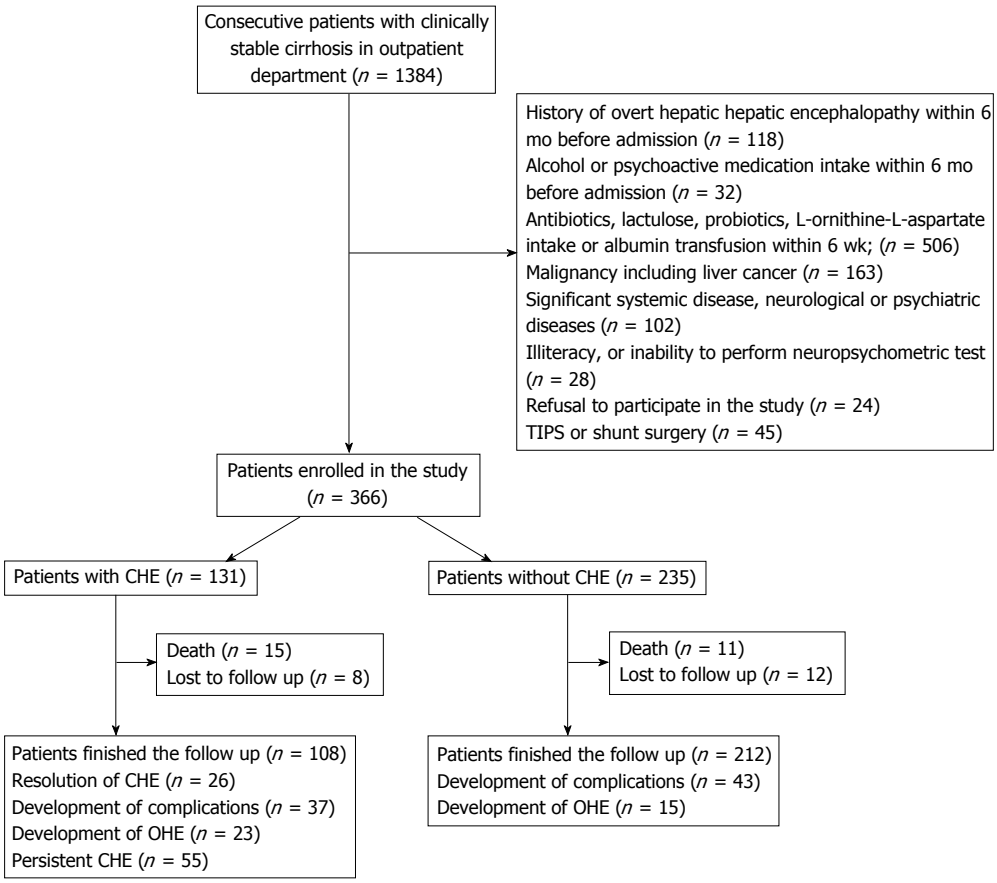

Figure 1 Flow diagram of cirrhotic patients included in the study. CHE: Covert hepatic encephalopathy; OHE: Overt hepatic encephalopathy; TIPS: Transjugular intrahepatic portosystemic stent.

and survived, "truncated" was described in the Kaplan-Meier curve. In order to determine risk factors for CHE and predictors for the resolution of CHE, potential parameters were included and first analyzed in the univariate analysis. All tested variables with *P* values < 0.05 were entered into a logistic regression after adjusting for age, sex and level of education. The χ^2 or Fisher's exact test was used for categorical variables. The analysis of variance was performed as appropriate to determine associations for continuous data. All tested variables with *P* values < 0.05 were entered into a logistic regression after adjusting for age and sex. In order to determine predictors for developing OHE, the first cirrhosis-related complications requiring hospitalization or mortality in CHE patients, potential parameters were analyzed by univariate analysis. All tested variables with *P* values < 0.05 were entered into a Cox regression after adjusting for age and sex. All statistical analyses were two-tailed at the 5% level. We used the Statistical Package for Social Science (SPSS Inc.; Chicago, IL, United States) to analyze our data.

RESULTS

Clinical characteristics and prevalence of CHE in cirrhotic patients

A total of 1384 consecutive outpatient cirrhotic patients were screened, and 366 patients (age: 47.2 ± 8.6 years, male: 73.0%, CPC-A: 43.2%, CPC-B: 50.5%, CPC-C: 6.3%, CPC score: 6.9 ± 1.6, MELD score: 15.4 ± 4.4) fulfilled the criteria and were enrolled in the study (Figure 1). Patients were followed for a mean of 11.2 ± 1.3 mo. CHE was identified in 131 (35.8%) patients. The clinical characteristics of CHE and the unimpaired group are shown in Table 1.

Risk factors of CHE in cirrhotic patients

Compared with unimpaired patients, CHE patients were older and had a more frequent OHE history. After adjusting for age, sex and level of education, logistic analysis indicated that a history of OHE (β: 2.72, OR = 7.18, 95%CI: 3.45-14.92, *P* < 0.001) was the only risk factor for CHE in patients with OHE history, while a MELD score > 20 (β: 1.71, OR = 5.53, 95%CI: 1.33-22.89, *P* = 0.02) was the only risk factor for patients without OHE history.

Complications and mortality in cirrhotic patients

Among the 366 patients included in this study, 323 (88.3%) completed the follow-up and survived. Twenty-three patients (unimpaired: 18.3% *vs* CHE: 28.2%) died, and 20 patients (unimpaired: 5.1% *vs* CHE: 6.1%) were lost to follow-up. None of the patients developed PHC or underwent liver transplantation during follow-

up. The prevalence of cirrhosis-related complications requiring hospitalization and mortality were 28.2% and 11.5% in the CHE group *vs* 18.3% and 4.7% in the unimpaired group, respectively. Patients in the CHE group had higher rates of mortality (P = 0.012) and incidence of first cirrhosis-related complications requiring hospitalization (P = 0.008), including OHE (P < 0.001), compared to patients in the unimpaired group (Figure 2).

Natural history of CHE

After 11.2 ± 1.3 mo of follow-up for 131 CHE patients, 108 patients (82.4%) had completed the follow-up and survived. Thirty-seven patients (28.2%) developed cirrhosis-related complications requiring hospitalization, including 23 patients that developed OHE (17.6%). Fifty-five patients (42.0%) suffered persistent CHE, while 26 patients (19.8%) had CHE SR. The comparisons of clinical characteristics between CHE patients with and without OHE development, between those with and without development of the cirrhosis-related complications requiring hospitalization, between those with and without CHE SR, and between survivors *vs* non-survivors during follow-up are shown in Table 2.

Cox analysis of all the potential parameters (with P values < 0.05 from the univariate analysis shown in Table 2) indicated that only serum albumin < 30 g/L was a predictor for developing OHE. Serum creatinine > 133 μmol/L, MELD score > 20 and blood platelet < 80

Table 2 Comparison of clinical characteristics between 131 covert hepatic encephalopathy patients with and without overt hepatic encephalopathy development, between those with and without development of the first cirrhosis-related complications requiring hospitalization, between those with and without resolution of covert hepatic encephalopathy, and between survivors and non-survivors during follow-up

Data are presented as *n*, *n* (%) or mean ± SD. CHE: Covert hepatic encephalopathy; CPC: Child-Pugh classification; HBV: Hepatitis B virus; INR: International normalization ratio; MELD: Model for end-stage liver disease; OHE: Overt hepatic encephalopathy.

× 10^9/L were predictors for development of the cirrhosis-related complications requiring hospitalization; serum creatinine > 133 μmol/L was the only predictor for mortality of CHE patients (Table 3). After adjusting for age and sex, multivariate logistic analysis showed that CPC-B/C (β: -2.48, HR = 0.084, 95%CI: 0.026-0.264, P < 0.001) and OHE history (β: -1.91, HR = 0.15, 95%CI: 0.03-0.67, P = 0.014) were predictors for CHE SR.

DISCUSSION

Until now, no study has explored the real natural history of CHE in the absence of medication intervention. Our study shows that CHE can worsen, persist, or even spontaneously resolve without medication intervention over a 1-year period. Patients with an OHE history, low serum albumin, high serum creatinine, decreased blood platelet count, or poor liver function should be treated to prevent complications and reduce mortality. Patients with CPC-A and without OHE history may be monitored with caution without treatment. It is our speculation that triage of CHE patients based on predictors for exacerbation and resolution, rather than on the degree of impairment in daily work productivity or quality of life, will make clinical management more precise and cost-effective.

There are many testing strategies focusing on paper-pencil abnormalities, computerized or neurophysiological tests, such as PHES, repeatable battery for the assessment of neuropsychological status (commonly known as RBANS), inhibitory control test (ICT), EncephalApp Stroop smartphone App, critical flicker frequency (CFF), and electroencephalography (EEG). According to the guidelines, the diagnosis of CHE in multi-center studies should utilize at least two of the current validated testing strategies, consisting of PHES and one of the following: computerized (continuous reaction time, ICT, scan reaction time, or Stroop) or neurophysiological (CFF or EEG).

In single-center or clinical routine studies, investigators should use tests with which they are familiar for assessing the severity of HE, provided that normative reference data are available and the tests have been validated for use in the patient population[1,2]. In this single-center study, we used PHES, which has been previously validated in China[20], to define CHE diagnosis, persistence and resolution. In our study, 35.8% of consecutive clinically stable cirrhotic patients were diagnosed with

Table 3 Cox analysis of predictors for developing overt hepatic encephalopathy, the first cirrhosis-related complications requiring hospitalization, and mortality in 131 covert hepatic encephalopathy patients

	Predictor(s)	β	HR	95%CI	*P* value
For developing OHE	Albumin < 30 g/L	1.65	5.22	1.22-22.32	0.03

CHE based on PHES tests, in agreement with previous Chinese studies[7,20].

Only a few studies have discussed risk factors of CHE in cirrhotic patients[23,24]. However, these studies excluded patients with OHE history. As patients with resolved OHE may be at risk for developing CHE, risk factors for patients with OHE history also need to be explored. Yoshimura *et al*[25] enrolled patients with and without OHE history and revealed that OHE history was strongly associated with CHE, while cirrhosis-related symptom scores were associated with CHE for patients without OHE history, which is similar to our findings.

Several studies have focused on searching for predictors of OHE in cirrhotic patients. A recent study reported that CHE and elevated blood NH_3 levels contributed to OHE development in cirrhosis[3]. Another study indicated that OHE history, presence of CHE and an albumin level < 3.5 g/dL were associated with OHE development in cirrhosis[5]. Based on our findings, it is more cost-effective to screen and identify predictors of OHE development in CHE patients rather than in all cirrhotic patients. Our results showed that only serum albumin level < 30 g/L is the predictor for developing OHE in CHE patients. We propose that CHE patients with a low level of serum albumin should be treated rather than being monitored to reduce hospitalizations and mortality.

Several studies have investigated the natural history of CHE[3-5,9-11,13-18]. Recently, five studies showed that CHE is associated with occurrence of OHE and reduced survival rate[9-11,17,18]. Thomsen *et al*[9] enrolled 106 clinically-stable cirrhotic patients with no previous history of OHE and followed them for 230 ± 95 d. They found that 13.3% of CHE patients (defined by CFF, EEG or PHES) developed OHE, and the survival rate was 86.7%. In a multicenter study by Patidar *et al*[10], a total of 170 cirrhotic patients were followed for a mean of 13 mo. They found that 30% of cirrhotic patients developed at least one OHE episode, and that CHE, which was defined by PHES only, increased their risk of developing OHE, hospitalization and death/transplant despite controlling for MELD.

A study by Ampuero *et al*[11] demonstrated that patients with CHE, as defined by CFF, had a reduced 5-year survival rate compared to those without CHE (57.4%-68.6% *vs* 70%-82%). It also predicted the occurrence of OHE (37.1%-38.9% in patients with CHE *vs* 18.3%-24.6% in those without CHE). In a multi-center study by Allampati *et al*[17], a total of 437 cirrhotic patients and 308 controls were followed for 11 mo. The authors reported that 13% of patients developed an episode of OHE, which was predicted by CHE defined by the EncephalApp based on adjusted United States population norms, ICT or PHES.

However, none of the above studies stopped medications used for the treatment of other complications (*i.e*., antibiotics for infection or significant GVB, albumin transfusion for ascites, lactulose for constipation) during follow-up, which can play important roles in preventing occurrence of OHE and help CHE resolution. Persistence and SR of CHE were also not explored in these studies. Therefore, the real natural course of CHE without medication intervention was not evaluated, and therefore the risk of developing complications and mortality in CHE patients could be underestimated due to the medications used during follow-up. Furthermore, though CHE was reported to be associated with a higher risk of developing complications and reduced survival rate in these studies, it remains to be determined if all CHE patients need to be treated.

Our study revealed that CHE can resolve after 3 mo following the initial diagnosis, or can last as long as 1 year in the absence of medication intervention. Predictors for CHE SR were also explored in our study for the first time. Our data indicated that patients with predictors for SR could be monitored without resorting to medications, and receive appropriate medical support if predictors for development of complications and mortality appeared. Our findings also suggested that CHE patients need to be repeatedly evaluated at appropriate time intervals, as CHE can fluctuate over time.

There are some limitations in our study. Firstly, we conducted a single-center observational study with a relatively short follow-up period. However, we are the first to explore the natural history of CHE without medication intervention with a sample size large enough and time period long enough to identify predictors for exacerbation and SR of CHE. In addition, as cirrhotic patients developed complications over time, fewer patients were free of medications at a longer period of follow-up. Then it was of little significance to explore the natural course of CHE due to the limited number of patients. Secondly, a 3-mo interval between

visits was arbitrarily decided by the researchers. As CHE and OHE fluctuate and cognitive changes may be missed by this frequency, shorter intervals of observation would have been more convincing. However, it is our opinion that a 3-mo interval is the minimal time interval to eliminate learning effects for PHES. Thirdly, only some of the medications for treating cirrhosis, including antibacterial agents, lactulose, probiotics, L-ornithine-L-aspartate and albumin, were restricted unless necessary. However, some other medications, such as proton pump inhibitors, diuretics, non-selective beta-blocker and anti-HBV agents, were not restricted during our follow-up, as the potential impact of these agents on CHE is still in debate.

In summary, CHE is prevalent in clinically-stable cirrhotic patients and is associated with an increased risk of complications, hospitalizations and mortality. CHE can evolve into OHE, persist or spontaneously resolve without medication intervention within a short period. Although data are lacking regarding the standard management of CHE in clinical practice, we believe triage of patients based on predictors of exacerbation and improvement of CHE in natural history could make clinical management of CHE more precise and cost-effective.

COMMENTS

Background

Covert hepatic encephalopathy (CHE) is regarded as the pre-clinical stage of hepatic encephalopathy (HE). The natural history of CHE in cirrhotic patients in the absence of medication intervention has not yet been studied. The aim of this study was to explore the prevalence and natural history of CHE in clinically-stable cirrhosis in a tertiary care hospital, and to identify predictors for exacerbation and resolution of CHE without medication intervention.

Research frontiers

Several studies have investigated the natural history of CHE. Their findings indicate that CHE is prevalent in clinically-stable cirrhotic patients and is associated with an increased risk of complications, hospitalizations and mortality. However, medications treating other cirrhosis complications are not restricted in CHE patients. These agents used during follow-up would treat CHE, hinder the occurrence of other complications, and underestimate the disadvantages of CHE.

Innovations and breakthroughs

The present study indicated that CHE could worsen, persist or even spontaneously resolve without medication intervention over a 1-year period. Serum albumin < 30 g/L was the sole predictor for overt HE (OHE) and blood creatinine > 133 μmol/L predicted mortality. Child-Pugh A classification and absence of OHE history can predict spontaneous resolution of CHE.

Applications

To make the clinical management of CHE more precise and cost-effective, patients with an OHE history, low serum albumin, high serum creatinine, decreased blood platelet count or poor liver function should be treated to prevent complications and reduce mortality. Patients with Child-Pugh A classification and those without OHE history may be monitored with caution without treatment. Triage of CHE patients may be based on predictors for exacerbation and resolution rather than on the degree of impairment in daily work productivity or quality of life.

Peer-review

The authors conducted a well-written observational study. The case enrollment and variable choices are appropriate. Despite the fact that this study is a single-center observational study with a relatively short-period follow up, it provides some new insights.

Abstract

AIM

To determine whether circular RNAs (circRNAs) are involved in pathological processes of gastric cancer (GC).

METHODS

Three circRNAs with differential expression in GC and colorectal cancer were randomly selected for validation by quantitative reverse transcription-polymerase chain reaction (qRT-PCR), using 20 pairs of gastric tissues and normal tissues. Based on the predicted circRNA-miRNA network, we then focused on hsa_circ_0000745, which was found to be down-regulated in 20 GC tissues compared with normal tissues. The hsa_circ_0000745

levels were further analyzed by qRT-PCR in 60 GC tissues and paired adjacent non-tumor tissues, as well as 60 plasma samples from GC patients and 60 plasma samples from healthy controls. The associations between the levels of hsa_circ_0000745 and the clinicopathological features of GC patients were statistically assessed. A receiver operating characteristic (ROC) curve was used to evaluate the diagnostic value of hsa_circ_0000745 in GC.

RESULTS

Hsa_circ_0000745 was down-regulated in GC tissues *vs* non-tumorous tissues ($P < 0.001$) and in plasma samples from patients with GC *vs* healthy controls ($P < 0.001$). The expression level of hsa_circ_0000745 in GC tissues correlated with tumor differentiation, while the expression level in plasma correlated with tumor-node-metastasis stage. The area under the ROC curve (AUC) of hsa_circ_0000745 in plasma was 0.683, suggesting good diagnostic value. Plasma hsa_circ_0000745 level combined with carcinoembryogenic antigen (CEA) level increased the AUC to 0.775.

CONCLUSION

Hsa_circ_0000745 plays an important role in GC and its expression level in plasma in combination with CEA level is a promising diagnostic marker for this malignancy.

Core tip: This study demonstrates that expression of hsa_circ_0000745 is down-regulated in human gastric cancer (GC), with significantly lower levels detected in human GC tissues compared to paired adjacent non-tumor tissues, and in plasma of GC patients compared to plasma from normal healthy controls. Detection of this stable circular RNA in plasma may represent a clinically useful and convenient marker for GC diagnosis, with higher sensitivity and specificity when analyzed in combination with carcinoembryogenic antigen.

INTRODUCTION

Gastric cancer (GC) is one of the most common malignancies worldwide, and is the most frequently diagnosed cancer among East Asian populations[1-3]. Despite extensive research attention, the mortality rate of GC remains high due to the fact that it is usually diagnosed at late stages. To improve early diagnosis and reduce the high mortality rate of GC[4-6], it is critical to continue elucidating the molecular mechanisms of GC, which may help identify markers for earlier diagnosis and novel therapeutic targets.

Endogenous noncoding RNAs, including microRNAs (miRNAs), long noncoding RNAs (lncRNAs), and the recently identified circular RNAs (circRNAs), play key regulatory roles in various cellular physiological processes and may contribute to pathological processes such as cancer formation and progression[7,8]. Unlike linear RNAs which terminate with 5' caps and 3' tails, circRNAs form covalently closed loop structures with neither 5' to 3' polarity nor a polyadenylated tail. They are not simply by-products of mis-spliced RNAs or splicing errors, but rather they are the products of regulated back-spliced RNAs with distinct sets of *cis*-elements and/or *trans*-factors[9]. Moreover, the formation of circRNAs involves the occurrence of back-splicing by the canonical spliceosome[10].

Recent research has demonstrated that circRNAs are widely involved in myriad physiological and pathological processes, including neuronal differentiation, synaptogenesis, neurological disorders, angiogenesis, prion disease, and cancer[11-16]. Likewise, circRNAs have been described as a class of biomarkers related to aging in Drosophila[17] and as putative disease biomarkers in human saliva[18]. Li *et al*[19] reported that hsa_circ_002059, a typical circRNA, was significantly down-regulated in GC tissues compared with paired adjacent non-tumorous tissues, suggesting its potential as a novel and stable biomarker for the diagnosis of GC.

The collective findings from the research on circRNAs indicate that they may play crucial roles in the molecular pathways of cancer. However, only a few publications have reported on the relationship between circRNAs and cancer. Whether and how circRNAs expression is dysregulated in GC remains unknown.

In this study, we randomly selected three differentially expressed circRNAs (hsa_circ_0000745, hsa_circ_0085616, and chr16:30740286-30740893|+) from two circRNA databases: CircBase (http://circbase.org/) and circ2Traits (http://gyanxet-beta.com/circdb/), which had been characterized using RNA-Seq analysis of ribosomal RNA-depleted total RNA from three GC or colorectal cancerous tissues and paired normal tissues[20,21] (Table 1). We then focused our attention on circRNA hsa_circ_0000745, which is encoded by the sperm antigen with calponin homology and coiled-coil domains 1 gene (*SPECC1*) that is located at chr17:20107654-20109225. We selected hsa_circ_0000745 for investigation based on preliminary broad sequencing analysis and prediction of its binding to various miRNAs with known relations

Table 1 The three differently expressed circRNAs in human gastric cancer and colorectal cancer samples

to GC. By expanding the numbers of human GC and control samples for investigation, we were able to identify a statistically significant down-regulation of hsa_circ_0000745 expression in both GC tissues and plasma samples from patients with GC. Moreover, we were able to determine that the down-regulated expression correlated with tumor differentiation. Overall, the data identifies hsa_circ_0000745 as a novel potential biomarker for diagnosing GC.

MATERIALS AND METHODS

Patient samples

This study was approved by the Institutional Ethics Review Board of Anhui Provincial Hospital Affiliated to Anhui Medical University (China) and was conducted according to the Ethical Guidelines for Human Genome/Gene Research issued by the Chinese Government. Human samples of GC tissues and paired adjacent non-tumor tissues were prospectively collected from 60 patients at the Anhui Provincial Hospital from January 2016 to January 2017. Upon removal, the respective tissues were immediately submerged in RNAlater RNA stabilization reagent (Qiagen, Hilden, Germany) and stored at -80 ℃ until analysis. None of the patients had undergone chemotherapy or radiotherapy prior to the operation (resection).

The GC diagnosis was confirmed by histopathology. Tumor stages were determined according to the American Joint Committee on Cancer tumor-node-metastasis (TNM) staging criteria.

Before any treatment was applied, each study participant's peripheral blood (2-3 mL) was collected in an ethylenediaminetetraacetic acid tube, centrifuged at 3000 × *g* for 10 min to obtain plasma, and stored at -80 ℃. Following the age- and sex-matching criteria of the study design, fresh normal plasma samples were collected from 60 healthy volunteers.

All research subjects provided written informed consent prior to study enrollment.

RNA extraction and quality control

Total RNA was isolated from three samples of gastric tumor and paired adjacent non-tumor (normal) tissues, as well as from plasma samples, using TRIzol reagent (Invitrogen, Carlsbad, CA, United States) according to the manufacturer's protocol. RNA integrity was assessed using standard denaturing agarose gel electrophoresis. Total RNA from each specimen was quantified and quality assurance was provided using a NanoDrop ND-1000 spectrophotometer (NanoDrop, Wilmington, DE, United States).

Transcriptome high-throughput sequencing and subsequent bioinformatics analysis

Transcriptome high-throughput sequencing and subsequent bioinformatics analysis were performed by Cloud-Seq Biotech (Shanghai, China). The paired-end reads were harvested on a HiSeq 4000 System (Illumina, San Diego, CA, United States). The high-quality reads were aligned to the reference genome/transcriptome with STAR software[22], and circRNAs were detected and identified with DCC software[23]. EdgeR software[24] was used to normalize the data and perform analysis to determine differential expression among the circRNAs.

Quantitative reverse transcription-polymerase chain reaction validation assay

Total RNA samples were reverse-transcribed into cDNA with a random primer using SuperScript™ Ⅲ Reverse Transcriptase (Invitrogen) according to the manufacturer's instructions.

The expression of circRNAs was measured using quantitative polymerase chain reaction (qPCR) SYBR Green Master Mix (Takara, Tokyo, Japan) in a ViiA 7 Real-time PCR System (Applied Biosystems Inc, Foster City, CA, United States). The sequences of the divergent primers for the detection of hsa_circ_0000745 by quantitative reverse transcription-polymerase chain reaction (qRT-PCR) were 5′-GTTGAAAGTAGCCCGAGCAG-3′ and 5′-ACGTG GCACAGACCTCTCTC-3′. The primer sequences for glyceraldehyde-3-phosphate dehydrogenase (GAPDH; used as a control) were 5′-CTCGCTTCGGCAGCACA-3′ and 5′-AACGCTTCACGAATTTGCGT-3′. These primers were synthesized by Invitrogen (Shanghai, China). The reaction conditions were as follows: 95 ℃ for 10 min, and 40 cycles of 95 ℃ for 10 s and 60 ℃ for 60 s. The RNA levels were normalized to human GAPDH. The expression levels were analyzed by the $2^{-\Delta\Delta Ct}$ method.

All of the quantitative PCR reactions were conducted in triplicate. The appearance of a single-peak in the melt-curve suggested the specificity of the PCR products.

Statistical analysis

All experimental data were analyzed using SPSS

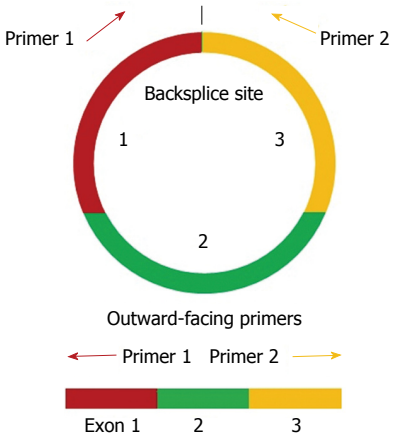

Figure 1 Schematic diagram of the polymerase chain reaction primers used to specifically detect circular transcripts. Divergent polymerase chain reaction primers, rather than the more commonly used convergent primers, were designed for the circRNAs.

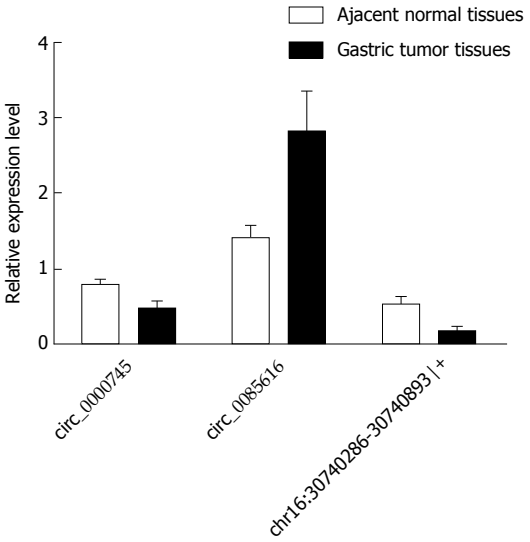

Figure 2 Validation of the expression levels of the three circRNAs using quantitative reverse transcription-polymerase chain reaction analysis. The three differently expressed circRNAs were validated by quantitative reverse transcription-polymerase chain reaction (qRT-PCR) in 20 gastric tumor tissues and paired adjacent non-tumor tissues. The qRT-PCR results are presented as mean and SE of the mean.

software (version 22.0; IBM, Armonk, NY, United States) and GraghPad Prism 5.0 (GraphPad Software, La Jolla, CA, United States). The expression level of each circRNA was represented as fold-change using the $2^{-\Delta\Delta Ct}$ method. Differences of hsa_circ_0000745 levels between GC tissues and adjacent non-tumor tissues, and between plasma samples from patients with GC and healthy controls were assessed using *t*-test. The correlation between hsa_circ_0000745 levels and clinicopathological factors was further analyzed by one-way analysis of variance. The receiver operating characteristic (ROC) curve was established to evaluate the diagnostic value. The cut-off value of hsa_circ_0000745 was analyzed with SPSS software. A

RESULTS

Validation of differentially expressed circRNAs by qRT-PCR

Among the three differentially expressed circRNAs examined (hsa_circ_0000745, hsa_circ_0085616, and chr16:30740286-30740893|+), hsa_circ_0085616 was reported to be up-regulated in colorectal tissues compared to that in normal tissues[20], while hsa_circ_0000745 and chr16:30740286-30740893|+ were found to be down-regulated in GC tissues compared to paired adjacent non-tumor tissues[21]. The observed changes in expression levels were validated by qRT-PCR analysis using 20 sets of gastric tissues and paired adjacent non-tumor tissues.

Divergent primers, rather than the more commonly used convergent primers, were designed for quantitative amplification of the circRNAs (Figure 1 and Table 2). The qRT-PCR results showed that circ_0085616 was up-regulated, while circ_0000745 and chr16:30740286-30740893|+ were down-regulated in the GC tissues compared to the paired adjacent non-tumor tissues (Figure 2), suggesting that the general expression patterns of the three circRNAs in GC were consistent with those in colorectal cancer.

CircRNA binding miRNA prediction by sequence analysis

Given that miRNAs play important roles in the progression of GC, some circRNAs could be involved in GC, likely *via* interacting with miRNAs. We analyzed the potential binding miRNAs for the three circRNAs using sequence analysis. The association of miRNAs with GC indicated that circRNAs may have a regulatory role in GC. A tree diagram of circRNAs and their potential binding miRNAs is shown in Figure 3. Based on these potential circRNA/miRNA interactions, hsa_circ_0000745 was predicted to be able to bind a spectrum of miRNAs, with the known functions

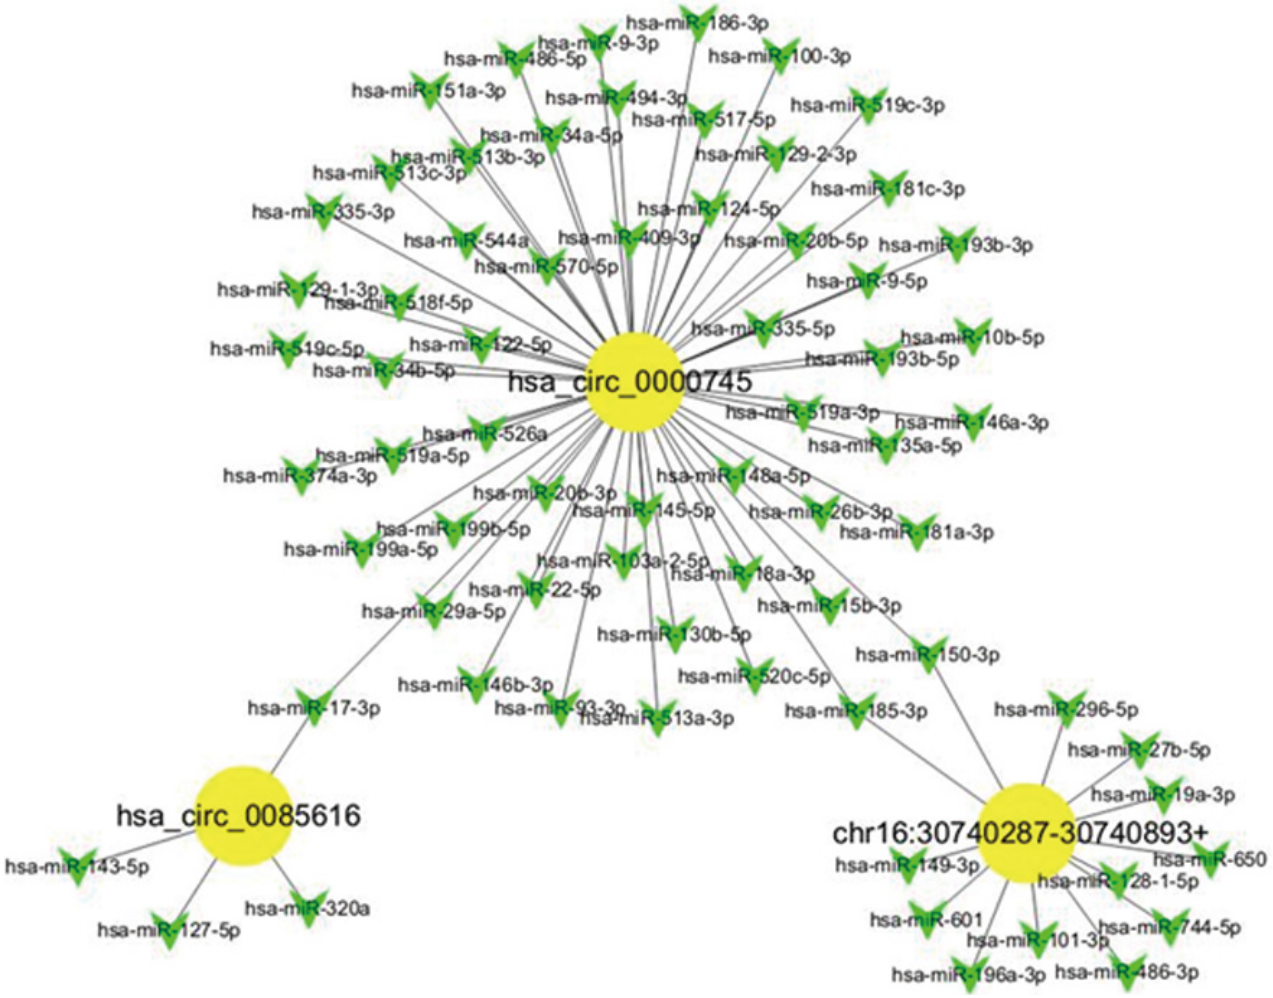

Figure 3 Network of circular RNAs and the predicted binding miRNAs.

suggesting its potential role in the regulation of GC growth.

Hsa_circ_0000745 expression is down-regulated in GC tissues and plasma samples from patients with GC

We tested hsa_circ_0000745 levels in GC tissues and plasma samples from patients with GC. As shown in Figure 4A, hsa_circ_0000745 expression was found to be down-regulated in the GC tissues ($P < 0.001$). Furthermore, hsa_circ_0000745 levels in the plasma samples of patients with GC were lower than those in plasma samples from healthy controls ($P < 0.001$; Figure 4B).

Potential diagnostic values of hsa_circ_0000745 in GC

Since we found that hsa_circ_0000745 expression levels were lower in GC tissues and patients' plasma samples, we further analyzed their association with clinicopathological features of patients with GC. As shown in Table 3, hsa_circ_0000745 levels in the GC tissues were significantly related to tumor differentiation ($P = 0.012$). However, we found no association between its levels with other clinicopathological features, such as age, sex, tumor diameters, lymphatic metastasis, TNM stage and carcinoembryogenic antigen (CEA) levels.

Meanwhile, hsa_circ_0000745 levels in plasma from GC patients were significantly related to TNM stage ($P = 0.046$). Nevertheless, we did not find any association between hsa_circ_0000745 and the other clinicopathological features.

To evaluate the potential diagnostic value, a ROC curve was generated for hsa_circ_0000745 levels in plasma. We found that the area under the ROC curve (AUC) was 0.683 (Figure 5). The sensitivity and specificity were 0.855 and 0.45, respectively. When the expression level of plasma hsa_circ_0000745 was combined with CEA level, the AUC increased to 0.775, while the sensitivity and specificity changed to 0.800 and 0.633, respectively.

DISCUSSION

Gastric carcinogenesis is a complicated biological process that involves a wide array of molecular abnormalities. In recent decades, the molecular

The expression is shown as the $2^{-\Delta\Delta Ct}$ value.

mechanisms of GC have been extensively investigated. Expression arrays for genes and noncoding RNAs, such as miRNAs and lncRNAs, have been applied and recognized as feasible and useful approaches to profiling the molecular signatures of GC[25,26].

Today, circRNAs are the newest type of noncoding RNAs, and their discovery expanded our knowledge of the complexity of noncoding RNAs. The circRNAs were originally thought to be by-products of splicing errors or the mRNA process[27]. They represent a stable, diverse and conserved class of RNA molecules[11,28]. Ongoing research is continuing to provide evidence that circRNAs are involved in the development and progression of diseases, especially cancer[29].

Hsa_circ_002059 was first found to be significantly down-regulated in GC and proposed as a potential novel and stable biomarker for the diagnosis of this particular cancer type[19]. According to other reports, expression of the circular RNA-ITCH is typically down-regulated in esophageal squamous cell carcinoma (ESCC) and colorectal carcinoma, and may exert an inhibitory effect on ESCC and colorectal cancer by suppressing the Wnt/β-catenin pathway[30,31]. Collectively, these findings have suggested that circRNAs play a crucial role in cancers, and that they may serve as the basis for developing new strategies

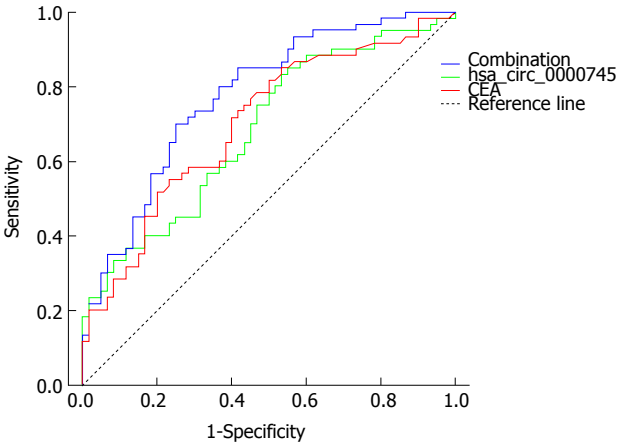

Figure 5 Receiver operating characteristic curve of plasma hsa_circ_0000745 and serum carcinoembryogenic antigen levels. CEA: Carcinoembryogenic antigen.

for diagnosis and therapy. However, the tumorigenesis mechanisms of GC are far from being completely elucidated and this idea is still in its infancy.

In this study, we randomly selected three differently expressed circRNAs, which we characterized using RNA-Seq analysis of ribosomal RNA-depleted total RNA from three GC or colorectal cancer tumor tissues and paired normal tissues. Circ_0085616 was up-regulated in colorectal cancer tissues compared with non-cancerous tissues, while circ_0000745 and chr16:30740286-30740893|+ were down-regulated in GC tissues compared with normal tissues. We further confirmed the RNA-Seq results of three circRNAs in 20 paired normal and cancerous gastric tissues by qRT-PCR analysis; circ_0085616 up-regulation and circ_0000745 and chr16:30740286-30740893|+ down-regulation in the GC tissues suggested that the circRNA sequencing results of GC are consistent with the expression patterns observed in colorectal cancer.

Recent studies have demonstrated that circRNAs can function as miRNA sponges or potent competitive endogenous RNA molecules[27,32-35]. Given that miRNAs play important roles in the progression of GC, it is possible and even likely that some circRNAs are involved in GC *via* interacting with miRNAs. We analyzed the potential binding miRNAs of the three circRNAs by sequence analysis. The association of miRNAs with GC indicated that circRNAs may have a regulatory role in GC. Based on the potential circRNA/miRNA interactions identified, hsa_circ_0000745 is potentially able to bind various miRNAs that may play critical roles in regulating GC growth and migration. However, additional studies are required to clarify whether these circRNAs are truly involved in GC, and whether circRNAs acting as miRNA sponges are a general phenomenon.

In this study, we found that hsa_circ_0000745 was down-regulated in GC tissues as well as in the plasma samples from patients with GC. It was suggested that hsa_circ_0000745 may be involved in other diseases besides GC, including various cancers (*i.e.*, breast cancer, colorectal cancer, hepatocellular carcinoma, lung cancer, ovarian cancer, and rhabdomyosarcoma) and cerebellar neurodegeneration, Waldenstrom macroglobulinemia, cardiac hypertrophy, cardiomyopathy, coronary artery disease, heart failure, myeloproliferative disorder, myocardial infarction, retinitis pigmentosa, and schizophrenia, according to the previous analysis (http://gyanxet-beta.com/circdb/). That is the main reason why we choose hsa_circ_0000745 for further study.

We found that expression levels of hsa_circ_0000745 in GC tissues were associated with tumor differentiation. However, its expression did not show any statistically significant relationship with tumor size, lymphatic metastasis or TNM stage (Table 3). Moreover, we determined its potential diagnostic value, reported herein for the first time. When compared with serum CEA levels, hsa_circ_0000745 had a higher sensitivity and specificity in the screening of GC (Figure 5). The combination of plasma hsa_circ_0000745 and serum CEA levels, however, increased the diagnostic value. In summary, our study revealed that the circular RNA hsa_circ_0000745 may serve as a diagnostic marker for GC.

ACKNOWLEDGMENTS

We are grateful to the members of our laboratory for helpful discussions regarding this study. We thank Cloud-Seq Biotech Ltd. Co. (Shanghai, China) for the transcriptome sequencing service and the subsequent bioinformatics analysis.

COMMENTS

Background

Circular RNA (circRNA) is a recently identified type of noncoding RNA that plays an important role in the biological processes of tumor development and progression. The stability of circRNA makes it an attractive candidate as a serological diagnostic marker for cancer. However, the circRNA expression profiles in gastric cancer (GC) have not been elucidated.

Research frontiers

Recent studies have shown that different tumors have distinctive differential expression profiles of various circRNAs, such as hsa_circ_002059 in GC and hsa_circ_0004277 in acute myeloid leukemia.

Innovations and breakthroughs

This is the first study to demonstrate that hsa_circ_0000745 is differentially expressed in plasma samples of GC patients and normal healthy controls, as well as in gastric tumor tissues and paired adjacent non-tumor tissues. Moreover, the data suggest the possibility that hsa_circ_0000745 may serve as a novel diagnostic marker for GC.

Applications

Expression of hsa_circ_0000745 was found to correlate with tumor differentiation and tumor-node-metastasis stage. When plasma hsa_circ_0000745 expression was combined with serum level of carcinoembryogenic antigen, the diagnostic

ability (especially specificity) for GC was improved.

Terminology

Circular RNA is a type of RNA which, unlike the better known linear RNA, forms a covalently closed continuous loop. GC is also known as stomach cancer, developing from the lining of the stomach. Diagnostic biomarkers are found in blood, urine or tissues and are abnormally expressed, in a trackable manner, in the presence of diseases.

Peer-review

This is the first study to show the promising diagnostic value of measuring circulating hsa_circ_0000745 levels in GC.

Abstract

AIM

To evaluate the role of P2Y1R in visceral hypersensitivity in rats with experimental irritable bowel syndrome.

METHODS

A rat model of irritable bowel syndrome was generated by intra-colonic administration of acetic acid (AA) and assessed by histology and myeloperoxidase (MPO) activity assay. Then P2Y1R expression in the colonic tissue was detected by Western blot. In order to explore the regulatory role of P2Y1R in visceral hypersensitivity, an agonist (MRS2365) and an antagonist (MRS2179) of P2Y1R were intra-colonically administered and effects were tested through a colorectal distension test. The abdominal withdrawal reflex and abdominal electromyography were tested during the course.

RESULTS

Model assessment tests showed an obvious inflammatory

reaction that appeared on the 2nd d after the AA injection, and the inflammatory reaction gradually recovered and almost disappeared on the 7th d. The model finished on day 8 and showed a clear feature of IBS that had no organic lesion. The average expression of P2Y1R was significantly higher in the AA group than in the naïve group (0.319 ± 0.02 *vs* 0.094 ± 0.016, $P < 0.001$). MRS2365 could effectively raise the colonic hypersensitivity status at intervention doses of 10 (AUC value from 0.30 ± 0.089 to 1.973 ± 0.127 mv·s, $P < 0.01$) and 100 μmol/L (AUC value from 0.290 ± 0.079 to 1.983 ± 0.195 mv·s, $P < 0.01$); MRS2179 could effectively reduce the hypersensitivity status at intervention dose of 100 μmol/L (from a mean baseline AUC value of 1.587 ± 0.099 mv·s to 0.140 ± 0.089 mv·s, $P < 0.0001$). Differences between the MRS2179 group (1.88 ± 1.45) and either the MRS2365 group (3.96 ± 0.19) or the combined treatment (MRS2179 and MRS2365) group (3.28 ± 0.11) were significant ($P < 0.01$).

CONCLUSION

P2Y1R plays a regulatory role in visceral hypersensitivity in rats with experimental IBS. Specific antagonists of P2Y1R may have potential therapeutic value in treating abdominal pain in IBS.

Core tip: P2Y1R is believed to be part of a high-sensitivity response to mechanical stimulation but whether it is involved in visceral hypersensitivity of irritable bowel syndrome is discussing. We detected its expression in the colon of a rat model of irritable bowel syndrome, and explored its regulatory role in visceral hypersensitivity with a specific agonist and an antagonist. The abdominal withdrawal reflex and electromyography tests showed effective changes after intervention. It was interesting to note that in case of combined treatment of the two drugs, the antagonist showed higher effects, which indicated that other P2 receptors might be involved in the hypersensitivity of irritable bowel syndrome.

INTRODUCTION

Irritable bowel syndrome (IBS) is characterized by hypersensitivity and pain before defecation in the relative absence of colon inflammation or structural changes[1]. Studies have reported that visceral hypersensitivity could be mediated by purinergic signaling pathways, which participate in pain transmission[2-4] and possibly induce the pain and discomfort experienced by patients with IBS[5,6].

Nucleotides contribute to the sensation of pain in somatic and visceral organs[5-7]. Cells release adenosine triphosphate (ATP) and other nucleotides in response to a variety of stimuli *via* the mediation of a class of receptors termed P2[6]. P2 includes the ionotropic (P2XRs) and metabotropic (P2YRs) subtypes. P2XRs have been identified to contribute to pain transmission and be involved in many organic and functional gastrointestinal disorders including IBS[7,8]. The mammalian P2Y1R cloned thus far is widely expressed in animal tissues[6]. Accumulating evidence has shown that P2Y1R can mediate nociceptive signaling[9] and studies[10-12] have suggested that P2Y1R may provide a high-sensitivity system to mechanical stimulation in functional gastrointestinal disorders. However, whether P2Y1R participates in the generation and regulation of visceral hypersensitivity in IBS remains unknown.

In this study, we produced a rat model of post-infectious IBS by intra-colonic injection of acetic acid (AA), and measured the changes of P2Y1R expression in the colon of this model. Moreover, to further explore the role of P2Y1R in the development of visceral hypersensitivity, a specific agonist (MRS2365) and an antagonist (MRS2179) of P2Y1R were used to alter the functional status of P2Y1R, and the abdominal responses were detected after this alteration.

MATERIALS AND METHODS

Animals

Adult male Sprague-Dawley rats weighing 180-250 g were used. Breeding, maintenance and euthanization of the animals followed the ethical guidelines for the investigations of experimental pain in conscious animals[13], and the study was approved by the Ethical Committee of Xi'an Jiaotong University. All animals were obtained from the standard animal laboratory at the Medical College of Xi'an Jiaotong University and were maintained at a consistent temperature of 20 ± 2 ℃ under a 12 h light/dark cycle with free access to food and water.

Model preparation

A rat model of post-infectious IBS (AA group) was produced in this study. After an overnight fast, the rats were anesthetized with 10% chloral hydrate by intraperitoneal injection at a dose of 1 mL/kg. On day 1, colitis was induced by intracolonic injection of 1 mL of 4% AA at the site 8 cm proximal to the anus for 60 s. Then the rats were allowed to recover for 7 d from the colitis and the modeling finished on day 8. A PBS group was processed in the same manner except that 1 mL of saline was injected instead of 4% AA. A naïve

control group comprised rats that were untreated.

Model assessment

The myeloperoxidase (MPO) activity assay was performed and histological sections of the distal colon were stained to determine the inflammatory condition and ensure the recovery from colitis on the 7th d. Then, abdominal responses and stool features of model rats were detected to assess the hypersensitivity and abdominal features.

Colorectal distension procedure and detection of visceral hypersensitivity: Colorectal distension (CRD) was conducted to assess the visceral perception thresholds in the gut[10,14], which was reported to be the best method to elicit visceral hypersensitivity[15]. Conscious rats of the AA, PBS and naïve groups (n = 8) were studied on the 8th d of modeling. They were fixed in Bollman cages (steel tubes; length, 18 cm; diameter, 6 cm) where they could not move freely, turn around or escape. After 2 d of adaptation, a disposable silicon balloon-urethral catheter (8F, B. Braun Medical Industries, Malaysia) lubricated with liquid paraffin oil was inserted intrarectally 8 cm from the anus and was then fixed to the tail with adhesive tape. The balloon was distended with pre-warmed (37 ℃) water. Ascending-limit phasic distension (0.2, 0.4, 0.6, 0.8, 1.0 and 1.2 mL) was applied for 30 s. Each volume was repeated three times at intervals of 5 min to obtain an accurate estimate.

During the CRD, abdominal hypersensitivity was measured by the abdominal withdrawal reflex (AWR) and electromyography (EMG). AWR is a semi-quantitative scored test for IBS models to assess hypersensitivity[16]. The score was assigned as follows: 0 = no behavioral response to distension; 1 = brief head movements followed by immobility; 2 = contraction of abdominal muscle without lifting of abdomen; 3 = lifting of abdomen; and 4 = body arching and lifting of pelvic structure.

EMG was also used to quantitatively measure visceral motor responses of conscious rats[17] during the CRD. The rats were first briefly anesthetized by diethyl ether inhalation and then fixed in the Bollman cages. A prepared bipolar silver electrode (diameter = 0.8 mm; SBT Co., Ltd., China) was used to link the rats to the biology function laboratory system. One end of the electrode was sunk into the external oblique muscle 0.5 cm above the inguinal ligament. The other end was connected to a BL-420F biology function laboratory system (Chengdu Taimeng Technology Co., Ltd., China) such that activation of the muscle could be recorded and analyzed on a computer.

Total stool weight: Stools were collected every day after the rats were placed into the Bollman cage. Total stool weight (weight of fresh defecation) and dry weight (weight of feces air-dried for 24 h) were measured. Water content of the stool was calculated by the equation: Water content = (dry weight/net weight) × 100%.

MPO activity assay: The MPO activity assay was performed to quantify the inflammation in the distal colon according to the model preparation procedure described previously[17]. Six rats from each group (the AA group, PBS group and naïve group) were randomly chosen to harvest distal colonic tissues on the 2nd and 7th d (3 rats per day for each group) after the injection of 4% AA to produce the model. These two time points were selected according to a previous study[1] to represent the inflammatory phase and the subsiding phase, respectively. Briefly, an 8-cm segment of distal colon was collected *via* laparotomy, minced in 1 mL of 50 mmol/L potassium phosphate buffer (pH 6.0) containing 14 mmol/L hexadecyltrimethylammonium bromide, homogenized and sonicated. The lysates were frozen and thawed three times and then centrifuged for 2 min at 4 ℃ at 15000 rpm. Aliquots of the supernatants were mixed with potassium phosphate buffer containing o-dianisidine-HCL (Sigma-Aldrich, St. Louis, MO, United States) and 0.0005% H_2O_2. The change in absorbance at 460 nm was spectrophotometrically determined. The MPO activity was expressed as units/g of wet tissue. An enzyme unit was defined as the conversion rate of 1 μmol of H_2O_2 per min at 25 ℃.

Histological examination of colonic inflammation: To examine the extent of colonic inflammation, histological tissues were collected at the selected time points (the 2nd and 7th d as mentioned above). The tissues were fixed in formalin for 12 h, and pathological sections were sliced at a thickness of 5 μm and processed for hematoxylin-eosin staining. The slides were observed under an optical microscope, and inflammatory cells were observed by a pathologist blinded to the treatments and time points.

P2Y1R expression in colonic tissue of rats

Protein expression of P2Y1R in the distal colon of rats (n = 8) in the AA, PBS and naïve groups were examined by Western blot. Distal colonic tissue was collected under anesthesia by intraperitoneal injection of 10% chloral hydrate. The tissues were either used immediately or stored at -80 ℃ for later use. P2Y1R antibody was purchased from Santa Cruz Biotechnology (catalog sc-377324).

Briefly, frozen sections of colonic tissue were trimmed and homogenized in RIPA buffer containing 50 mmol/L Tris-HCl (pH 7.4), 150 mmol/L NaCl, 1% NA-40, 0.25% sodium-deoxycholate, 1 mmol/L EDTA, 1 mmol/L PMSF, 1 mg/mL aprotinin, 1 mg/mL leupeptin, 1 mg/mL pepstatin, 1 mmol/L Na_3VO_4, and 1 mmol/L NaF. A total of 20 μg of protein from the intestinal homogenate was mixed with gel-loading buffer, boiled for 5 min, and loaded onto a 12% polyacrylamide gel. Electrophoresis was then

conducted, and the protein was transferred to a nitrocellulose membrane. Then, the membrane was pre-incubated in 1 × Tris-buffered saline containing 5% skim milk at room temperature for 2 h. Subsequently, the membrane was incubated at 4 ℃ overnight with rabbit primary antibody against either P2Y1R (1:500) or β-actin (1:1000, control) in 1 × Tris-buffered saline containing 5% skim milk. After washing, the membranes were incubated with anti-rabbit IgG (1:3000) at room temperature for 2 h. Bands were visualized with a SuperSignal Substrate Chemiluminescence Kit (Pierce 34077).

Changes of visceral hypersensitivity upon intervention with P2Y1R agonist or antagonist

Drug preparation: The P2Y1R agonist MRS2365 (2157/1, R&D Systems China Co., Ltd., China) and the antagonist MRS2179 (ab120414, ABCAM Corporation) were dissolved in phosphate-buffered saline at concentrations of 0.1 to 100 μmol/L, respectively, which had been proven effective in other studies[18,19]. The drugs were administered by intra-colonic instillation using a 0.2 cm diameter tube that was inserted into the colon 8 cm from the anus and held still for 10 min per day. All the rats were shortly narcotized by inhalation with ether before instillation of drugs and CRD was carried out when they recovered consciousness.

Drug concentration selection: Five groups of AA rats, three groups of PBS rats and three groups of naïve rats (n = 8 for each) were set for MRS2365 or MRS2179 treatment each. AA rats were randomly divided into an untreated control group and four treated groups (0.1, 1, 10 and 100 μmol/L). The PBS and naïve groups were divided into an untreated control group and two treated groups (10 and 100 μmol/L). The drugs were administered for 7 d at 10 mL/kg body weight every day. CRD and EMG were carried out at 2, 12, 24, 48, 72 and 168 h from the initiation of treatment to select the most effective concentrations. Our preliminary experimental results showed that distension volumes could cause abdominal responses beginning at 0.8 mL and get the highest response at 1.2 mL. Therefore, we chose 1.2 mL to examine the down-regulatory role of MRS2179 in CRD course, and 0.8 mL for the up-regulatory role of MRS2365.

Drug intervention: AA rats were treated with MRS2365 and/or MRS2179 at their selected concentrations. AA rats were divided into four groups (n = 8 each): no treatment (PBS), MRS2179, MRS2365 and combined treatment (first MRS2365, then MRS2179). The regimen lasted 7 d, and drugs were administered at a dose of 10 mL/kg body weight every day. CRD was carried out under the distension volume of 1.2 mL. The AWR and EMG were observed at 2, 12, 24, 48, 72 and 168 h from the initiation of treatment.

Statistical analysis

All examinations were performed in duplicate. Statistical analyses were performed using SPSS 17.0 software. Quantitative data are expressed as the mean ± SE. The one-way ANOVA approach was used to compare two groups. Two-way ANOVA was used for multiple group comparisons. A value of $P < 0.05$ was regarded as statistically significant.

RESULTS

IBS model assessment

Because IBS characteristically appears with no inflammation or other organic problems in the colon, and a post-inflammatory model has been proven to demonstrate the major features of IBS after acute inflammation in the colon subsides[17], we chose to use this procedure to create a post-inflammatory animal model. The AWR score was significantly increased from distension volumes of 0.8 (3.0 ± 0.54) mL in the AA model compared with the two control groups and overlapped at 1.2 (4.0 ± 0.02) mL on a highest score of 4 which is the highest score that AWR defined (two-way ANOVA, $P < 0.001$, Figure 1A). The areas under the EMG curves (AUC) were significantly increased from volume of 0.8 (0.31 ± 0.11) to 1.2 ml (1.55 ± 0.15) in the AA rats compared with the control groups ($P < 0.001$, Figure 1B). The responses in PBS rats were also increased compared with naïve rats although there was no significant change ($P = 0.224$).

The water content of stools (Figure 1C) from naïve rats, PBS rats and AA rats were weighed and calculated to determine the stool features. Compared with naïve rats, there was an increase in the stool water content in the AA rats (55.1% ± 4.8% *vs* 25.6% ± 4.6%, one-way ANOVA, $P < 0.01$, n = 8), indicating much looser stools from the AA rats. No such effect was observed in the naïve rats and PBS rats (25.9% ± 5.4%).

The results of MPO activity assay (Figure 1D) of colonic tissue in the AA group showed that the enzyme activity was dramatically increased (1.153 ± 0.09 *vs* 0.190 ± 0.01 compared with naïve rats) on the 2nd d of modeling (one-way ANOVA, $P < 0.001$, n = 3); however, no significant difference was found between the PBS and naïve groups on the 2nd d of modeling and among the three groups on the 7th d of modeling (one-way ANOVA, $P = 0.861$, n = 3). These two examinations indicated that an obvious inflammatory reaction appeared on the 2nd d after the AA injection, and the inflammatory reaction gradually recovered and showed almost no inflammation on the 7th d. The model finished on day 8 and showed a clear feature of IBS that had no organic lesion.

Histological examination (Figure 1E and F) showed that many inflammatory cells such as neutrophils and lymphocytes were found in the lamina propria of distal colonic tissues on the 2nd d of modeling. In contrast, no remarkable inflammatory features were observed in the two control groups on the 2nd d of modeling and

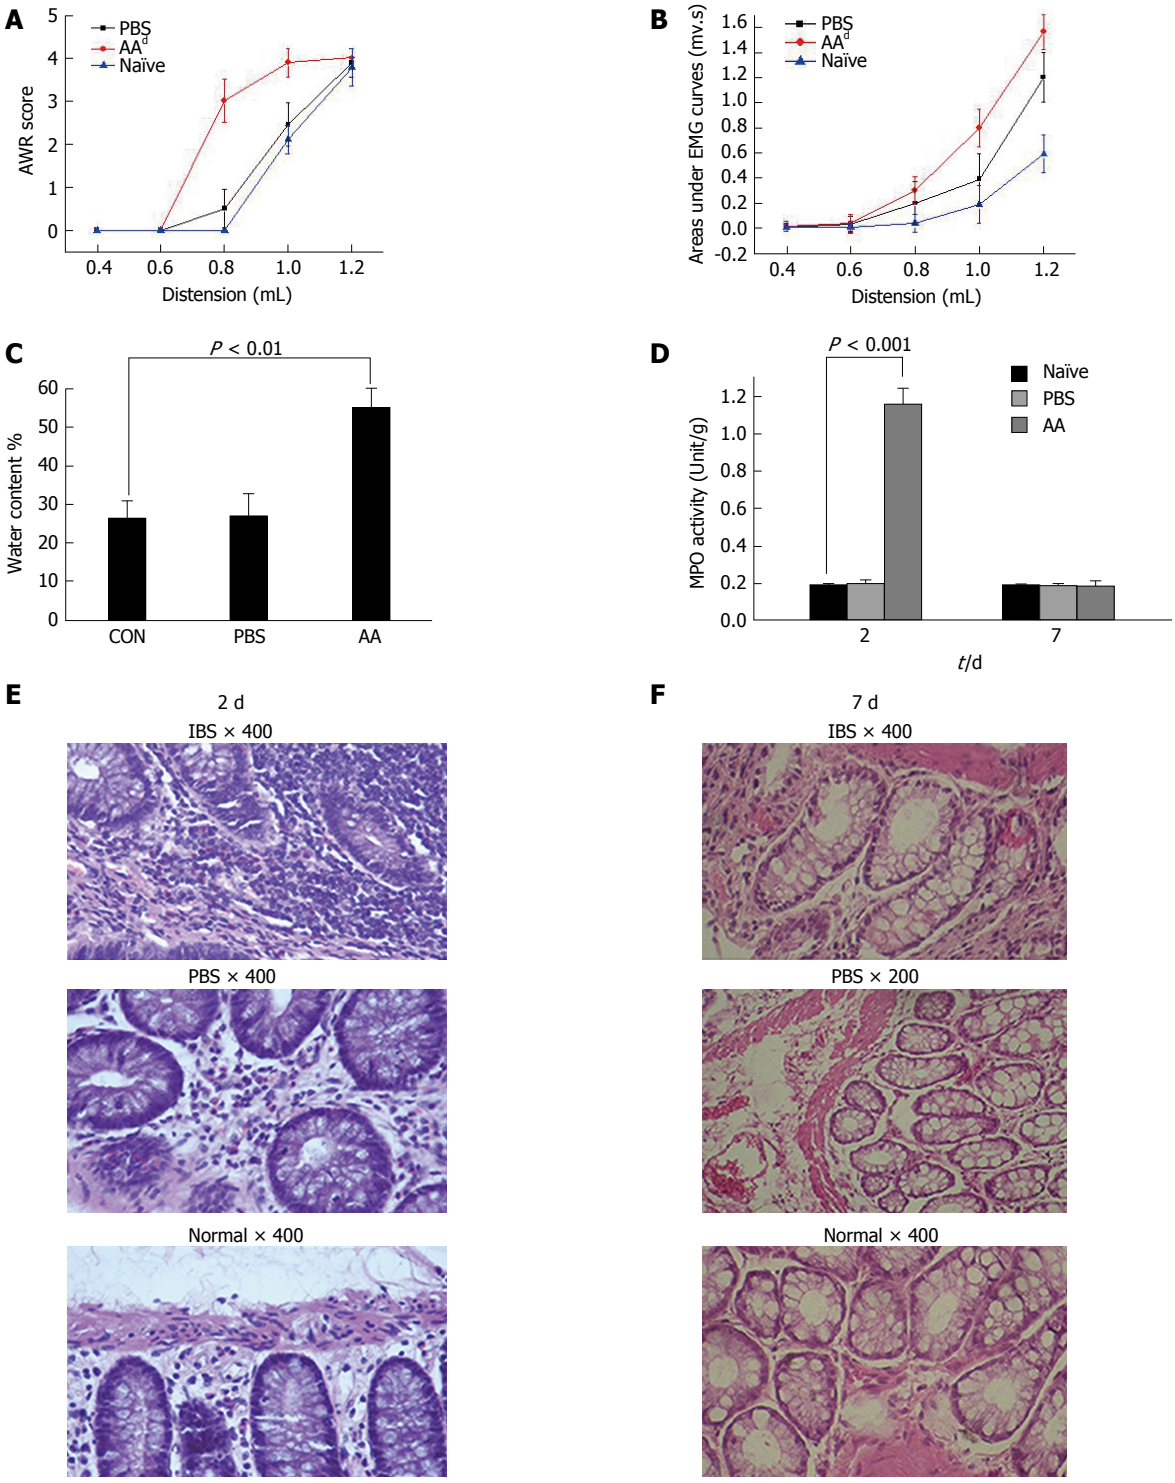

Figure 1 Model assessment using histological sections, myeloperoxidase activity, stool water content and visceral hypersensitivity in the acetic acid rats. A and B: The AWR score was significantly increased at distension volumes of 0.8 and 1.0 mL in the AA model compared with the two control groups and overlapped at 1.2 mL on a highest score of 4. The AUC significantly increased at volumes of 0.8, 1.0 and 1.2 mL in the AA rats compared with the control groups. No significant change was found in the PBS group compared with naïve rats; C: The water contents of stools from the naïve, PBS and AA groups were compared (one-way ANOVA, $P < 0.01$). AA rats showed much looser stool, and the water content was much higher; D: Tissue MPO activity on the 2nd and 7th d of modeling. MPO activity of the AA group was increased on the 2nd d of modeling. No statistically significant difference was detected between the PBS and naïve groups on the 2nd and 7th d of modeling among the AA, PBS and naïve groups (one-way ANOVA, $P < 0.001$ *vs* the control groups); E and F: Histology sections of colonic tissue from AA, PBS and naïve rats on the 2nd and 7th d. On the 2nd d of modeling in the AA group, histological inflammatory features including mucosal hemorrhage, submucosal edema, and inflammatory infiltration in the lamina propria and submucosa were observed. No remarkable inflammatory features were observed in the two control groups on the 2nd d of modeling and in all the three groups (AA, PBS and naïve rats) on the 7th d of modeling. [d]$P < 0.001$ *vs* the control groups. AWR: Abdominal withdrawal reflex; AUC: Area under the electromyography curve; AA: acetic acid; IBS: Irritable bowel syndrome; EMG: Electromyography.

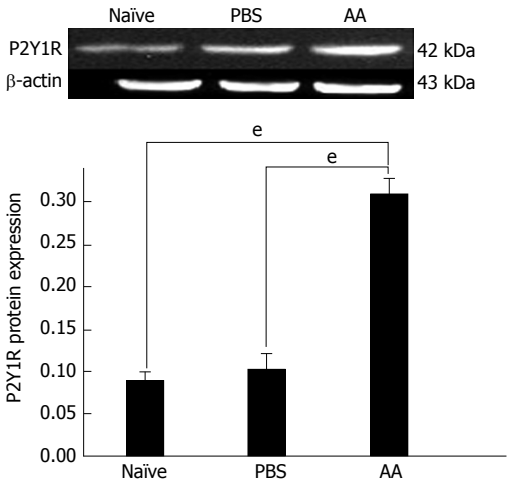

Figure 2 Western blot analysis of P2Y1R expression in the acetic acid, PBS and naïve rats. The average expression of P2Y1R (as determined by densitometry) was significantly higher in the AA group than in the control groups. No significant changes was found between the PBS group and naïve group. β-actin served as an internal control. $^{e}P < 0.001$ *vs* the control groups. AA: acetic acid.

in all the three groups (AA, PBS and naïve rats) on the 7th d of modeling.

High expression of P2Y1R

Compared with naïve rats (0.094 ± 0.016) and PBS rats (0.105 ± 0.013), the protein levels of P2Y1R in the distal colon of AA rats (0.319 ± 0.02) were significantly higher (one-way ANOVA, $P < 0.001$, Figure 2). The P2Y1R expression in PBS rats was higher than that in naïve rats although there was no significant change ($P = 0.398$).

MRS2179 concentration selection

The AUC was detected by two-way ANOVA, in which the dose of the drug ranging from 0 to 100 μmol/L was used as the first factor and the time as the second factor. MRS2179 produced a dose-dependent analgesic effect in the CRD test on AA rats ($P < 0.0001$, Figure 3A). A significant decrease was observed at concentrations of 0.1 to 100 μmol/L at 2 to 168 h time points. Maximal effects of MRS2179 were observed at 100 μmol/L at 72 h after administration (from a mean baseline AUC value of 1.587 ± 0.099 mv·s to 0.140 ± 0.089 mv·s).

While on naïve and PBS rats, MRS2179 at doses of 10 and 100 μmol/L was found to be effective after 48 h and 24 h ($P < 0.05$, Figure 3B and C). One-way ANOVA showed significant effects between AA rats and naïve/PBS rats at doses of 10 and 100 μmol/L ($P < 0.0001$, Figure 3D and E), and effects between naïve and PBS rats were not significant for the two doses ($P = 0.872$ and $P = 0.959$, respectively, Figure 3D and E).

MRS2365 concentration selection

Two-way ANOVA indicated that MRS2365 produced a dose-dependent analgesic effect in the CRD test on AA rats ($P < 0.0001$, Figure 4A). MRS2365 significantly increased AUC at concentrations of 0.1 to 100 μmol/L at 2 to 168 h time points. MRS2365 at 10 and 100 μmol/L showed the most effective increase. Maximal effects of MRS2365 were observed at 10 (AUC value from 0.30 ± 0.089 to 1.973 ± 0.127 mv·s, $P < 0.01$) and 100 μmol/L at 72 h (AUC value from 0.290 ± 0.079 to 1.983 ± 0.195 mv·s, $P < 0.01$).

On naïve and PBS rats, MRS2365 at doses of 10 and 100 μmol/L was found to be effective at 2 to 168 h time points ($P < 0.05$, Figure 4B and C). Significant effects were found between AA and naïve/PBS rats at doses of 10 and 100 μmol/L (one-way ANOVA, $P < 0.0001$, Figure 4D and E), while effects between naïve and PBS rats were not significant for the two doses ($P = 0.792$ and $P = 0.826$, respectively).

MRS2179/MRS2365 intervention

The most effective concentrations above (MRS2179 at 100 μmol/L and MRS2365 at 10 μmol/L) were applied in the drug intervention experiments for the four groups. AWR scoring (Figure 5A) showed that MRS2179 could significantly decrease the abdominal responses (two-way ANOVA, $P < 0.0001$). Differences between the MRS2179 group (1.88 ± 1.45) and the untreated AA rats (3.88 ± 0.33), MRS2365 group (3.96 ± 0.19) or the combined treatment group (3.28 ± 0.11) were significant ($P < 0.01$). No difference was detected among untreated AA rats, MRS2365-treated rats and rats in the combination group ($P = 0.224$).

Significant differences of AUC were also detected (Figure 5B). Compared with the untreated group, a significant decrease was detected in the MRS2179 group (two-way ANOVA, $P < 0.001$), which started at a baseline value of 1.52 ± 0.22 mv·s at time 0 h, peaked to 0.21 ± 0.15 mv·s at 72 h and continued to persist to 168 h. A significant increase was detected in the MRS2365 group ($P < 0.001$) which started at time 0 h (1.60 ± 0.20 mv·s), peaked at 72 h (2.98 ± 0.16 mv·s) and persisted to 168 h. Compared with the MRS2179 group, the difference for the MRS2365 groups and combination group was significant ($P < 0.001$). Compared with the combination group, significant differences were detected for untreated AA rats ($P < 0.05$) and MRS2365-treated rats ($P < 0.01$).

DISCUSSION

Colonic hypersensitivity in patients with IBS has been repeatedly confirmed[15,20,21], and lower colonic pain thresholds exist in most IBS patients[22]. This study investigated the possible role of P2Y1R in visceral hypersensitivity in a rat model of experimental IBS. Our results provided evidence that P2Y1R is involved in generation of visceral hypersensitivity in IBS.

This study was conducted in a post-inflammatory IBS rat model that has been proven to demonstrate

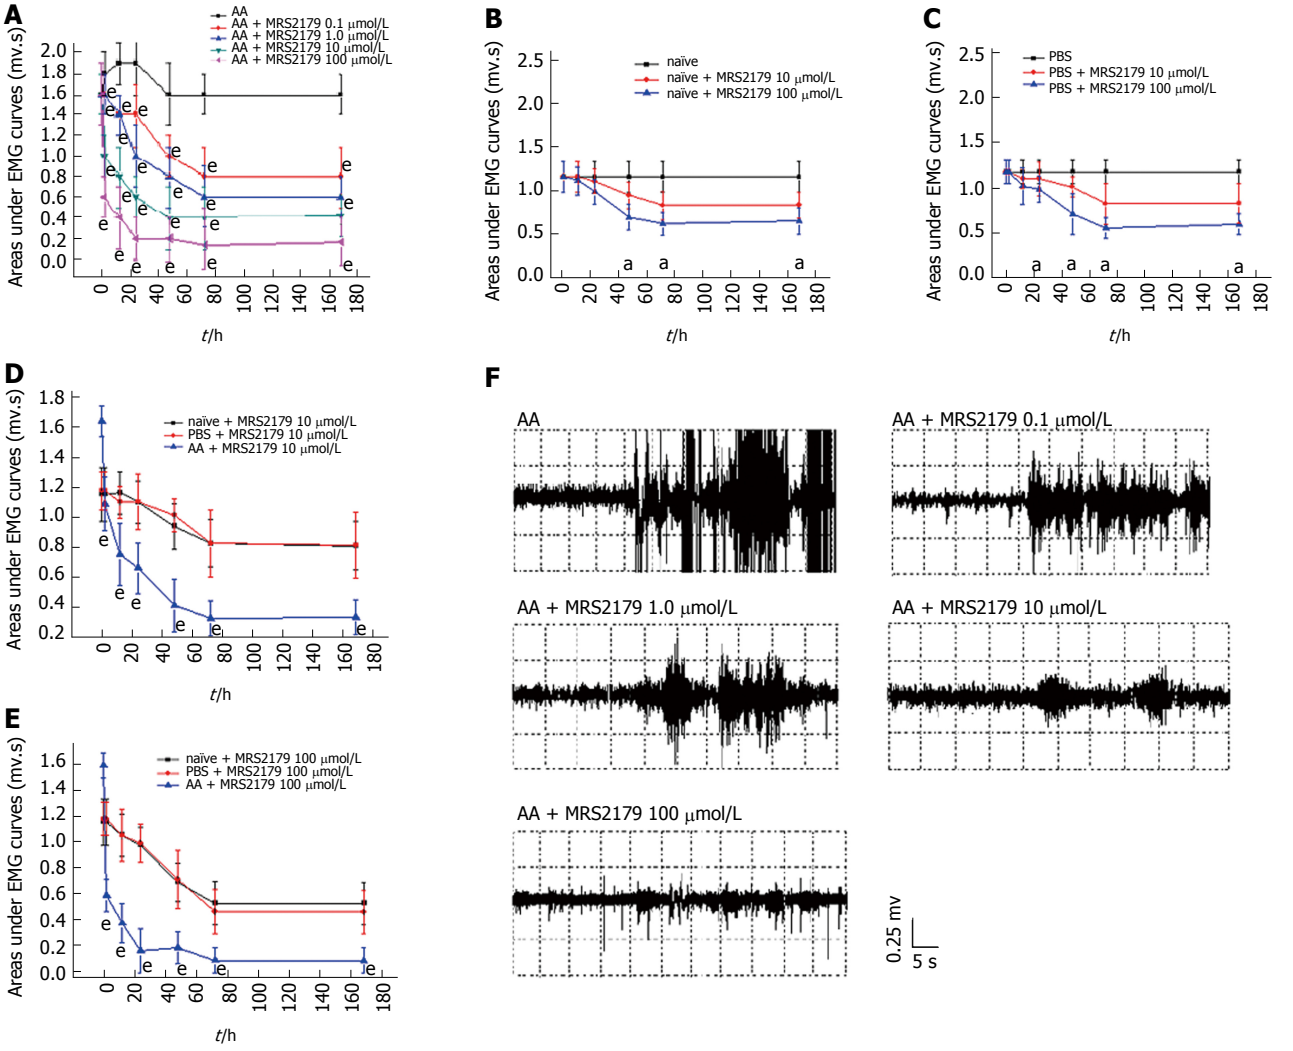

Figure 3 Concentration selection of MRS2179. A: Treatment with the specific P2Y1R antagonist MRS2179 evoked a pain-related visceral motor response in AA rats upon colorectal distension. A significant decrease was observed at concentrations of 0.1 to 100 μmol/L at 2 to 168 h time points. MRS2179 at 100 μmol/L produced the most pronounced result. Maximal effects of MRS2179 were observed at 100 μmol/L at 72 h from a mean baseline AUC value of 1.587 ± 0.099 m.vs to 0.140 ± 0.089 m.vs; B: On naïve rats, MRS2179 at doses of 10 and 100 μmol/L was found to be effective after 48 h; C: On PBS rats, MRS2179 at doses of 10 and 100 μmol/L was found to be effective after 24 h; D and E: AUC of naïve, PBS and AA rats treated with MRS2179 at doses of 10 and 100 μmol/L. There were significant differences between AA rats and naïve/PBS rats at doses of 10 and 100 μmol/L, although differences between naïve and PBS rats were not significant for the two doses; F: AUC of AA rats treated with MRS2179 (from doses of 0.1 to 100 μmol/L) at 72 h time point. $^{a}P < 0.05$, $^{e}P < 0.0001$ *vs* the control group. AUC: Area under the electromyography curve; AA: acetic acid; EMG: Electromyography.

the major features of IBS after subsidence of the acute inflammation in the colon and thus can be used to measure abdominal behaviors in conscious rats[17]. The MPO activity assay and histological examinations in this study proved that inflammation appeared on the 2nd d of model induction but was totally absent on the 7th d. However, the examination of abdominal behaviors and visceral hypersensitivity showed stronger AWR and abdominal EMG responses during the colorectal distention procedure. The AA rats also had a higher stool water content. However, although the differences between naïve rats and PBS rats were not significant, there was also a tiny increase of EMG and AWR scores in PBS rats, which was not expected. These may be caused by epithelial injury resulting from intubation because no intubation was done here for naïve rats, but PBS rats need to be treated by PBS in the anus of the colon. The differences almost disappeared when they were both treated with drugs by intubation in the following part of experiment. Overall, these results showed reserved hypersensitivity and abnormal fecal habits in this post-inflammatory IBS model, and these observations were similar with the reported visceral hypersensitivity in IBS patients.

P2YRs have been claimed to be expressed in intrinsic sensory nerves in the gut[23,24], where sensory neurons can evoke enteric reflex activities and mediate visceral pain *via* the spinal cord and brainstem[25]. Up to now it remains unclear whether P2Y1R is involved in generation and/or modulation of the lower pain thresholds of IBS. In this study, the higher expression of P2Y1R in the colon of AA rats emphasized their relationship with an elevated abdominal response towards mechanical stimuli. This occurrence may be

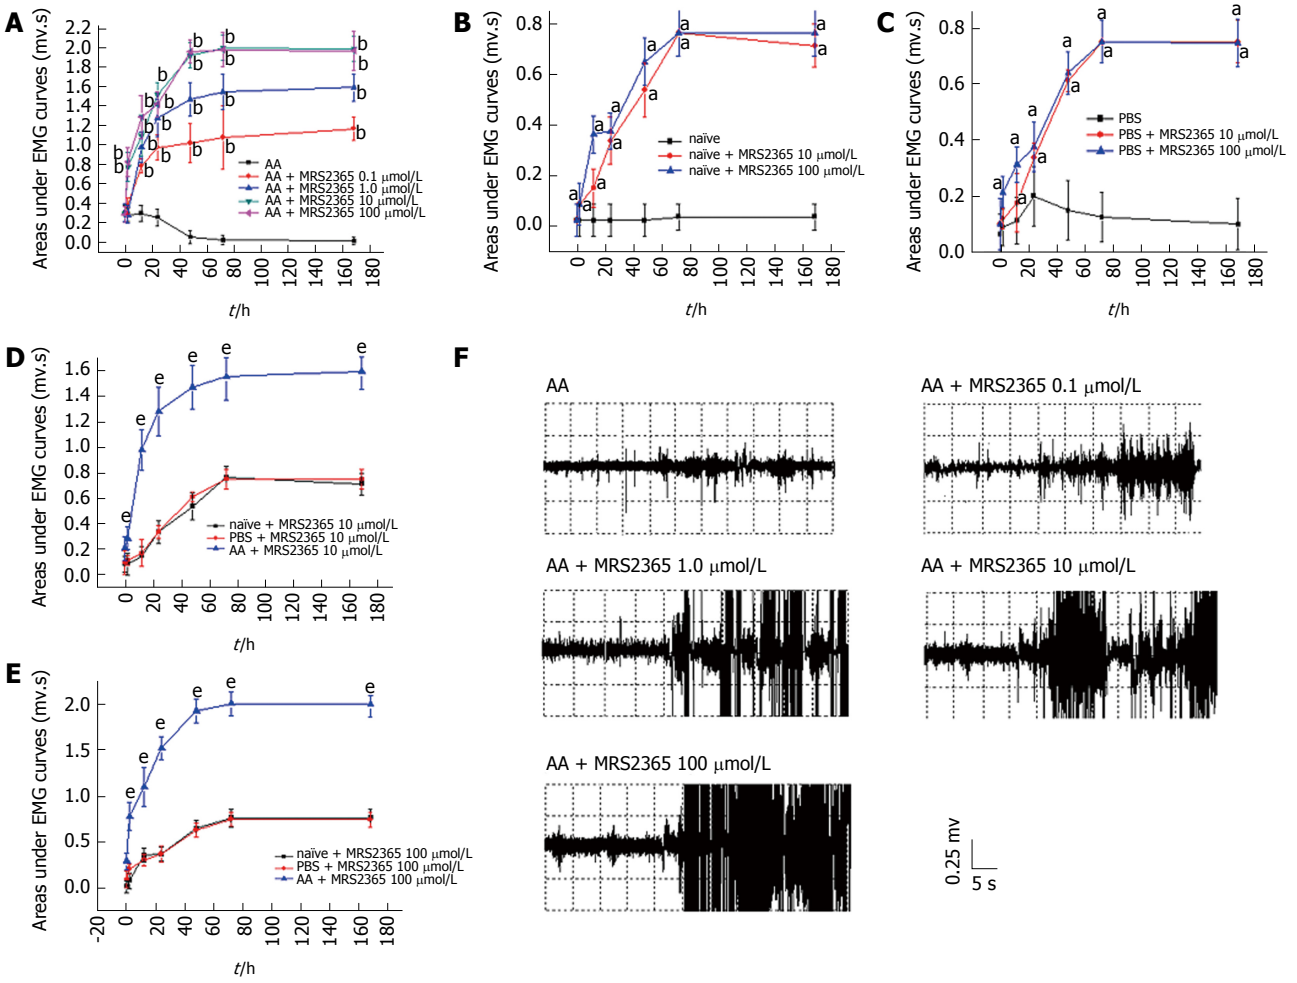

Figure 4 Concentration selection of MRS2365. A: Treatment with the specific P2Y1R agonist MRS2365-evoked pain elicited a visceral motor response in AA rats upon colorectal distension. The AUC was significantly increased in all of the MRS2365 groups (0.1, 1.0, 10 and 100 μmol/L) compared with the AA control group. The MRS2365 doses at 10 and 100 μmol/L elicited the most effective result. There was no significant difference between the concentrations of 10 and 100 μmol/L; B and C: On naïve and PBS rats, MRS2365 at doses of 10 and 100 μmol/L was found to be effective at 2 to 168 h time points ; D and E: AUC of naïve, PBS and AA rats treated with MRS2365 at doses of 10 and 100 μmol/L. Significant differences were found between AA and naïve/PBS rats at doses of 10 and 100 μmol/L, while differences between naïve and PBS rats were not significant for the two doses; F: AUC of AA rats treated with MRS2365 (from doses of 0.1 to 100 μmol/L) at 72 h time point. $^{a}P < 0.05$, $^{b}P < 0.01$, $^{e}P < 0.0001$ *vs* the control group. AUC: Area under the electromyography curve; AA: acetic acid; EMG: Electromyography.

related with excitation of sensory neurons located in submucosal and myenteric ganglia. Related studies[26,27] have suggested a possible mechanism that ATP might indirectly act on TRPV1Rs (which has received much attention in IBS) mediated by the P2Y1R in pain models of chronic ischemia. To further determine the role of P2Y1R, we studied changes of abdominal responses by functional regulation.

Both agonists and antagonists of the P2Y1R have been shown to reduce pain and hypersensitivity. Andó *et al*[18] demonstrated that MRS2365 had an analgesic effect on thermal pain threshold of neuropathic, acute pain and inflammatory pain. Chen *et al*[19] showed that MRS2179 could reverse tactile allodynia and spontaneous pain in a rat model of cancer-induced bone pain. They have indicated a bi-directional regulation of P2Y1R in pain. However, in our study, MRS2365 could effectively increase the colonic hypersensitivity status of AA rats, whereas MRS2179 led to a decrease in response to CRD test evoked visceral pain. The results showed an active role of P2Y1R in the generation/modulation of visceral hypersensitivity in the AA rats. This is in accordance with some other reports which indicated that P2Y1R is involved in the generation/modulation of nociceptive signals such as hypersensitivity in the gut[28-30]. It is not clear what exact role of P2Y1R plays in other pain events, but it will leads to high sensitivity in this IBS rat model. Moreover, specific antagonists of P2Y1R may have potential therapeutic value in treating abdominal pain in IBS.

Combined treatment of MRS2365 and MRS2179 showed a down-regulatory effect in AA rats. MRS2179 could not only effectively antagonize the elevated abdominal responses led by MRS2365, but also cause some more decrease. As a result, MRS2365 is a specific agonist of P2Y1R, whereas MRS2179 is not just a competitive antagonist of P2Y1R, but also selectively antagonizes other receptors, like P2X3R and P2Y2R[31,32]. Although we did not detect the expression

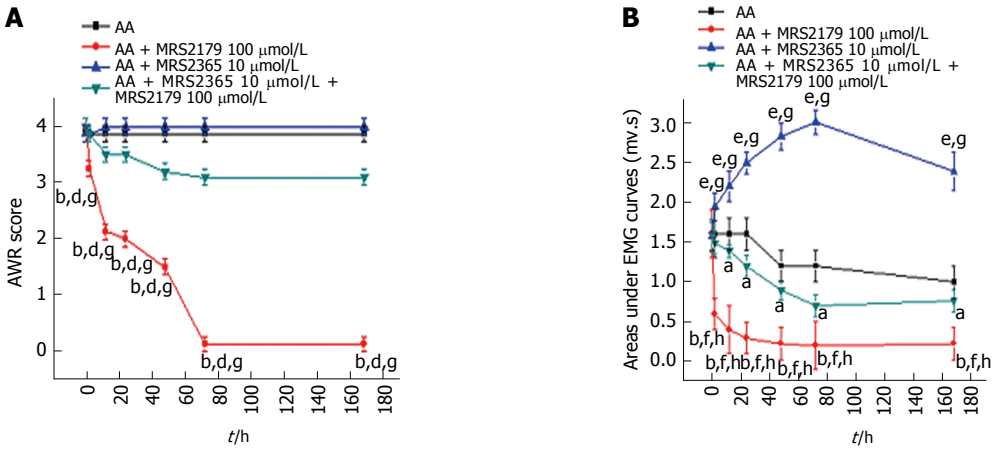

Figure 5 Drug intervention in acetic acid rats. A: AWR scores showed that MRS2179 could significant decrease the abdominal responses. Differences between the MRS2179 group and the untreated AA rats, MRS2365 group or the combined treatment group were significant. No difference was detected between untreated AA rats and MRS2365 treated rats or rats of the combination group; B: Significant differences of EMG curves were also detected. A significant decrease was detected in the MRS2179 group, which reached a peak at 72 h and continued to persist at 168 h. A significant increase was detected in the MRS2365 group (peaked at 72 h). The difference between the MRS2179 and MRS2365 groups or rats of the combination group was significant. Compared with rats of the combination group, significant differences were detected for untreated AA rats and the MRS2365 group. $^{a}P < 0.05$, $^{b}P < 0.01$, $^{e}P < 0.001$ *vs* the untreated control group; $^{d}P < 0.01$, $^{f}P < 0.001$ *vs* the MRS2365 group; $^{g}P < 0.01$, $^{h}P < 0.001$ *vs* the combination group. of P2X3R and P2Y2R, our data suggested that besides P2Y1R, other receptors (which could be inhibited by MRS2179) might also play active roles in visceral hypersensitivity in the AA rats.

Studies on pain events have suggested interesting relationship between P2Y1R and P2X3R. P2Y1R was co-expressed with P2X3R and TRPV1Rs[31,33] in small diameter neurons, and was indicated to be an "ATP counterbalance" following mutual activation of P2Y1R and P2X3R. In the colon, enhanced expression of P2X3R in colon-specific sensory neurons has been found and chronic functional visceral hyperalgesia was associated with potentiation of ATP-evoked responses[34]. However, P2Y1R in this study showed an active role in causing visceral hypersensitivity, but not acted as a "counterbalance". It might be in line with an explanation[10-12] that P2Y1R may provide a high-sensitive system to respond to minor touch-induced fluctuations in extracellular ATP mediated by P2X3R subjected to mechanical stimuli. It may fit with a recent study[35], suggesting that activation of P2Y1R could exert inhibitory control on P2X3R expression and increased P2X3R-mediated nociceptive flinch behaviors by promoting activity of P2Y1R downstream of p38. More research will be needed to clarify the mechanism of P2Y1R and P2X3R in pain of IBS.

P2Y2R is another subtype which has been demonstrated to dedicate to nociceptive events. Studies[30,36] have shown that P2Y1R and P2Y2R transcripts were detected in 80% and 49%-56% of retrogradely labeled colonic neurons, respectively, and agonists of P2Y1R and P2Y2R can evoke comparable sensitization of sensory neurons. However, one study on IBS-D patients[37] suggested that P2Y2R was more likely related to IBS pain. And another study on rat lumbar dorsal root ganglion neurons[38] showed that TRPV1R was co-expressed with P2Y2R. It is controversial whether P2Y1R or P2Y2R is more important for IBS pain. Our data suggested that both receptors may be involved in pain of the AA rats, but more research needs to be done to confirm this speculation.

Comorbidities or extra-intestinal symptoms are frequently in a sub-type of IBS patients. Some pain and hypersensitivity events in IBS patients, like chronic pelvic pain[39], primary headache[40] and higher reactivity to food antigens[41], might be also related to purinergic signaling. More research needs to be done to figure out whether there are connections between P2 receptors and these events, and it might help to understand the mechanism of P2Y1R involved in visceral pain in IBS.

Previous studies[29,42] indicated that P2Y1R may be responsible not only for post-infectious IBS, but also inflammation, like IBD. This study was conducted in a post-infectious IBS rat model and it was a question whether the higher expression of P2Y1R in AA rats was caused by inflammation? The model has been proven to demonstrate the major features of IBS after subsidence of the acute inflammation in the colon and thus can be used to measure abdominal behaviors in conscious rats[17]. The remained high visceral sensitivity without inflammation was a precondition of the study. However, P2Y1R could not be discounted as a potential mechanism contributing to anti-inflammation. It has been indicated in previous studies[36,43] that P2YRs could sensitize visceral afferents to evoke increased firing of colonic sensory of neurons to gut distension which is typically during, or following, an inflammatory insult. To clarify the possible anti-inflammatory role of P2Y1 in this post-inflammatory IBS model, further investigation needs to be done in other IBS models which are not post infectious.

In conclusion, we provided the evidence that P2Y1R is involved in generation and modulation of visceral hypersensitivity in IBS, and specific antagonists of P2Y1R may have potential therapeutic value in treating abdominal pain in IBS. A limitation of the study is that the localization of P2Y1R in the colon of IBS-like rats was not detected, which could help to better understand its role in visceral hypersensitivity. Moreover, studies on other P2 receptors, as well as their connections with the pain and hypersensitivity events in IBS, would help to strengthen our results.

COMMENTS

Background

Visceral hypersensitivity is considered to be a major feature of irritable bowel syndrome (IBS), the mechanism of which is not yet clear. P2Y1R is part of a high-sensitivity response to mechanical stimulation and is believed to dedicate to visceral hypersensitivity in IBS. In this study, the expression of P2Y1R was detected in a post-infectious IBS rat model, and the role of P2Y1R in the development of visceral hypersensitivity was detected by regulating its function.

Research frontiers

P2Y1R has been shown to mediate nociceptive signaling and suggested to provide a high-sensitivity system to mechanical stimulation in functional gastrointestinal disorders, including IBS. However, whether P2Y1R participates in the generation and regulation of visceral hypersensitivity in IBS remains unclear. The results of this study provide the evidence of P2Y1R in IBS.

Innovations and breakthroughs

Using a post-inflammatory IBS rat model, we determined that P2Y1R is involved in the generation and modulation of visceral hypersensitivity in IBS. Moreover, specific antagonists of P2Y1R may have potential therapeutic value in treating abdominal pain in IBS.

Applications

P2Y1R may be positively involve in the generation and modulation of visceral hypersensitivity in IBS. Its specific antagonists may be used for treating abdominal pain and other relative discomfort in IBS.

Terminology

IBS is a kind of functional gastrointestinal disorder, which is characterized by hypersensitivity and pain before defecation in the relative absence of colon inflammation or structural changes.

Peer-review

In the manuscript, the authors demonstrated that P2Y1R is involved in the generation and modulation of visceral hypersensitivity in IBS. This study is interesting in its scientific question, and it contributes to the knowledge of the IBS.

Abstract

AIM

To identify which technique is better for avoiding biliary reflux and gastritis between uncut Roux-en-Y and Billroth Ⅱ reconstruction.

METHODS

A total of 158 patients who underwent laparoscopy-assisted distal gastrectomy for gastric cancer at the First Hospital of Jilin University (Changchun, China) between February 2015 and February 2016 were randomized into two groups: uncut Roux-en-Y (group U) and Billroth

II group (group B). Postoperative complications and relevant clinical data were compared between the two groups.

RESULTS

According to the randomization table, each group included 79 patients. There was no significant difference in postoperative complications between groups U and B (7.6% *vs* 10.1%, P = 0.576). During the postoperative period, group U stomach pH values were lower than 7 and group B pH values were higher than 7. After 1 year of follow-up, group B presented a higher incidence of biliary reflux and alkaline gastritis. However, histopathology did not show a significant difference in gastritis diagnosis (P = 0.278), and the amount of residual food and gain of weight between the groups were also not significantly different. At 3 mo there was no evidence of partial recanalization of uncut staple line, but at 1 year the incidence was 13%.

CONCLUSION

Compared with Billroth II reconstruction, uncut Roux-en-Y reconstruction is secure and feasible, and can effectively reduce the incidence of alkaline reflux, residual gastritis, and heartburn. Despite the incidence of recanalization, uncut Roux-en-Y should be widely applied.

Key words: Gastric cancer; Uncut Roux-en-Y; Billroth II; Bile reflux; Alkaline gastritis

Core tip: Because of the challenge of recanalization, the uncut Roux-en-Y reconstruction is still controversial and needs further study. This study is the first randomized controlled trial concentrating on uncut Roux-en-Y *vs* Billroth Ⅱ reconstruction after distal gastrectomy for gastric cancer. This study aimed to compare uncut Roux-en-Y and Billroth Ⅱ reconstruction in terms of postoperative complications, including biliary reflux and gastritis. Despite the incidence of recanalization, uncut Roux-en-Y reconstruction is secure and feasible, and can effectively reduce the incidence of alkaline reflux, residual gastritis, and heartburn.

Randomized controlled trial of uncut Roux-en-Y *vs* Billroth Ⅱ reconstruction after distal gastrectomy for gastric cancer: Which technique is better for avoiding biliary reflux and gastritis? *World J Gastroenterol* 2017; 23(34): 6350-6356 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6350.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6350

INTRODUCTION

There remains no clear consensus regarding the preferred reconstructive surgical procedure after laparoscopy-assisted distal gastrectomy (LADG) for gastric cancer[1,2]. Compared with Japan[3] and Korea[4], early gastric cancer only accounts for a small percentage in China, and most gastric cancer cases are found in advanced stages at the initial diagnosis. It is inappropriate for surgeons to perform Billroth I anastomosis after subtotal gastrectomy. In 2005, Uyama first combined LADG with uncut Roux-en-Y reconstruction; however, its use remains controversial[5,6]. In our department, we usually prefer Billroth II and uncut Roux-en-Y reconstruction.

The current study aimed to compare these two reconstruction techniques in terms of postoperative complications, including biliary reflux and gastritis.

MATERIALS AND METHODS

This is a randomized controlled trial which was evaluated and approved by the ethics committee at our institution, and registered in clinicaltrials.gov with the number NCT02694081. Between February 2015 and February 2016, a total of 158 patients with gastric cancer treated at the First Hospital of Jilin University (Changchun, China), who met the inclusion criteria and provided informed consent, were randomized into one of two groups: uncut Roux-en-Y group (group U) or Billroth Ⅱ group (group B). Randomization was done after laparoscopic exploration with the randomization table, which was produced using SPSS v18.0 for Windows software by the Division of Clinical Research at our hospital. Patients as well as investigators (assessing outcomes and analyzing data) were masked. The inclusion criteria were: (1) distal gastric cancer diagnosed by endoscopy, CT scan, and pathology study; (2) patients who underwent LADG; and (3) age between 18 and 75 years. The exclusion criteria were: (1) late-stage gastric carcinoma or pyloric obstruction; (2) preoperative esophageal reflux symptoms, esophagitis, or hiatal hernia; and (3) systemic disease including diabetes, severe chronic lung disease, cirrhosis, or esophageal varices.

All included patients underwent LADG with D2 lymphadenectomy, which was performed by the same surgical team. For reconstruction, a 5-cm mini-laparotomy was made to complete a delta-shaped Billroth II anastomosis using a 80 mm linear stapler[7]. In the uncut Roux-en-Y group, gastrojejunostomy was performed at 25 cm distal to the Treitz ligament, and jejunum-jejunum anastomosis at 40 cm from the afferent limb. The blade of the linear stapler (Covidien GIA8038S, Medtronic, Minneapolis, MN, the United States of America) was removed to perform the uncut procedure of the afferent jejunal limb, 5 cm proximal to the gastrojejunostomy in the jejunum (Figure 1A and B).

During the postoperative period, omeprazole 40 mg was given to all patients twice a day. Ambulation was encouraged from the first day after operation, and the nasogastric tube was kept in place for 5 d. All patients

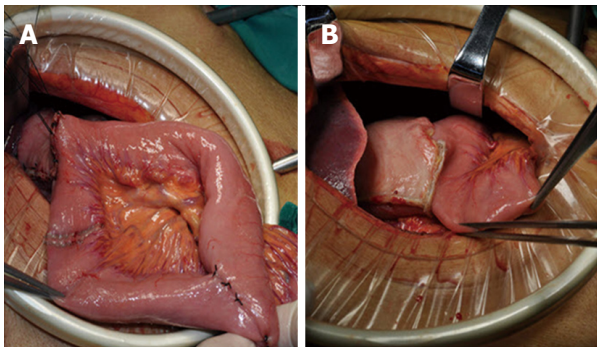

Figure 1 Two kinds of reconstruction after laparoscopy-assisted distal gastrectomy. A: Uncut Roux-en-Y reconstruction; B: Billroth Ⅱ reconstruction. All included patients underwent LADG with D2 lymphadenectomy, which was performed by the same surgical team. Then, two groups underwent different reconstructions as shown.

Table 1 Clinical and pathological data of the patients

Variable	Group U	Group B	*P* value
Age (yr)	58.0 ± 11.4	61.8 ± 11.4	0.030
Gender			0.287
Male	60 (75.9)	54 (68.4)	
Female	19 (24.1)	25 (31.6)	
Pathological tumor stage			0.822
ⅠB	3 (3.8)	2 (2.5)	
ⅡA	31 (39.2)	27 (34.2)	
ⅢB	28 (35.4)	29 (36.7)	
ⅢA	17 (21.5)	21 (26.6)	
Operative time (min)	154.8 ± 17.8	145.5 ± 15.1	0.001
Blood loss (mL)	74.1 ± 26.7	74.0 ± 36.6	0.980

Values are presented as number (%) or mean ± SD.

received uniform diet guidance after discharge.

Demographic data, clinical outcomes, and follow-up data were collected. Change of potential of hydrogen (pH) in the remnant stomach was recorded at 8:00 am on the day before surgery as well as 1-5 d after surgery.

Three months later, an upper esophagogastroduodenal series was performed in each patient with 100 mL of meglumine diatrizoate. The full emptying rate at 30 min and the ratio of partial recanalization were collected.

Twelve months later, items were monitored as follows: (1) number of patients with heartburn symptoms; (2) changes in body weight within 1 year; and (3) gastric residue, residual gastritis, and biliary reflux (RGB; monitored by endoscopy). Combined with standard RGB[8], a modified biliary reflux classification in three grades was applied-grade 0: absence of bile (Figure 2A); grade 1: small amount of bile located in the bottom of residual stomach without overflow (Figure 2B); and grade 2: bile spilled into the jejunum with tidal rhythm (Figure 2C).

Gastric tissue biopsies were taken to compare the degree of gastritis at 2 cm from anastomosis and then evaluated by two pathologists. Classification included three grades: grade 0, normal mucosa with a small amount of lymphocytes and transparent microscopic field (Figure 3A); grade 1, intermediate between grades 0 and 2 (Figure 3B); and grade 2, acute inflammation with fully infiltrated tissue by lymphocytes or inflammatory cells (Figure 3C).

Statistical analysis

All statistical analyses were performed using SPSS v18.0 for Windows software. Continuous variables are expressed as mean and SD and compared by Student's *t*-test. Categorical variables were analyzed by Pearson χ^2 test. The pH variables were compared by repeated measures analysis of variance. A two-tailed *P* value < 0.05 was considered statistically significant.

RESULTS

According to the randomization table, each group included 79 patients. Baseline data are shown in Table 1. There were no significant difference in gender or pathological data ($P > 0.05$), but the average age of group U patients was older than group B patients (58.0 ± 11.4 *vs* 61.8 ± 11.4 years, $P = 0.030$). The surgical time was slightly longer in group U (154.8 ± 17.8 *vs* 145.5 ± 15.1 mins, $P = 0.001$), but there was no difference in blood loss (74.1 ± 26.7 *vs* 74.0 ± 36.6 mL, $P > 0.05$).

There was no significant difference in postoperative complications between the two groups (7.6% *vs* 10.1%, $P = 0.576$). One patient in each group underwent reoperation because of intra-abdominal bleeding. In group U, a patient with ileus required reoperation after 1 mo of conservative treatment. In group B, a patient received emergency endoscopy to insert a stomach tube into the afferent loop to release pressure due to A-loop syndrome. For both groups, no gastroparesis syndrome was found during the postoperative period (Table 2). According to the Clavien-Dindo classification for surgical complications[9], in group U grade Ⅰ complications were recorded in 3.8%, grade Ⅱ in 1.3%, and grade ⅢB in 2.5% of the cases. In group B grade Ⅰ complications were recorded in 3.8%, grade II in 2.5%, grade ⅢA in 1.3%, and grade ⅢB in 2.5% of the cases. There was still no significant difference between the two groups ($P = 0.954$).

The stomach pH was lower in group U patients, with a significant statistical difference ($P < 0.05$) (Table 3).

During the postoperative period, all stomach pH values in group U patients were below 7.00. Conversely, all stomach pH values in group B patients were higher than 7.00 (Figure 4).

Three months later, regarding the postoperative esophagogastroduodenal series after 30 min, a higher ratio of full emptying was seen in group B patients (88.2% *vs* 76.6%, $P = 0.061$), but with no statistical significance.

At the end of the 1-year follow-up period, three patients in group U and one patient in group B were

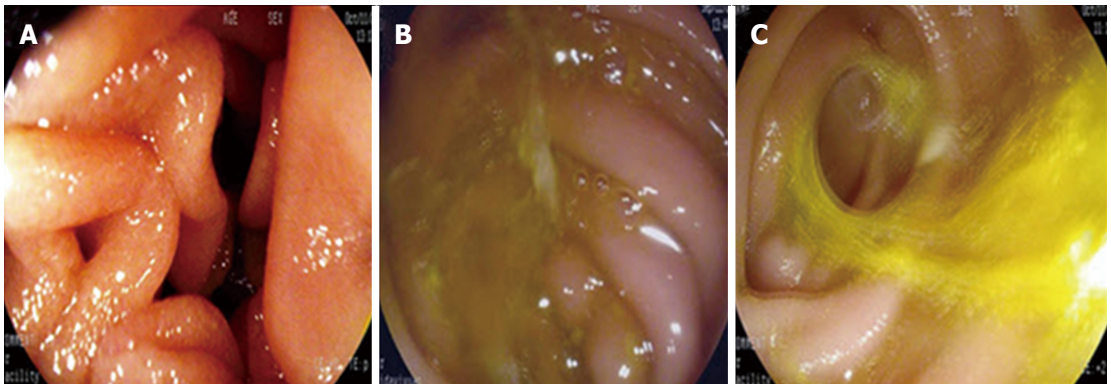

Figure 2 Bile reflux grades. During the endoscopic examination, a modified biliary reflux classification in three grades was applied. A: grade 0, absence of bile (Figure 2A); B: grade 1, small amount of bile located in the bottom of residual stomach without overflow (Figure 2B); C: grade 2, bile spilled into the jejunum with tidal rhythm (Figure 2C).

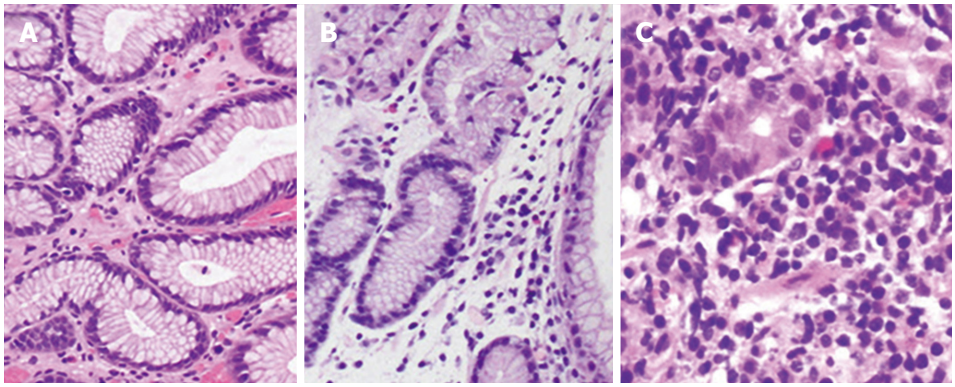

Figure 3 Biopsy for gastritis. Gastric tissue biopsies were taken to compare the degree of gastritis: A: grade 0 [hematoxylin and eosin (HE) staining, × 200], normal mucosa with small amount of lymphocytes and transparent microscopic field; B: grade 1 (HE, × 200), intermediate between grades 0 and 2 with a moderate amount of lymphocytes or other kinds of inflammatory cells; C: grade 2 (HE, × 400), acute inflammation with fully infiltrated tissue by lymphocytes or other kinds of inflammatory cells.

Table 2 Postoperative complications in the two groups *n* (%)

Item	Group U	Group B	*P* value
Duodenal stump leakage	1 (1.3)	3 (3.8)	0.620
Chylous fistula	1 (1.3)	0	1.000
Ileus	1 (1.3)	1 (1.3)	1.000
Anastomotic bleeding	0	1 (1.3)	1.000
Intra-abdominal bleeding	2 (2.5)	2 (2.5)	1.000
Incision infection	1 (1.3)	0	1.000
Gastroparesis syndrome	0	0	-
A-loop syndrome	0	1 (1.3)	1.000
Total	6 (7.6)	8 (10.1)	0.576

Values are presented as number only, or number (%). A-loop syndrome: Afferent loop syndrome.

Table 3 Perioperative stomach pH values

Time	Group U	Group B	*P* value
Preoperative	1.97 ± 0.19	1.99 ± 0.21	
Day 1	6.38 ± 0.18	7.21 ± 0.36	
Day 2	6.28 ± 0.29	7.35 ± 0.32	
Day 3	6.48 ± 0.38	7.27 ± 0.38	
Day 4	6.64 ± 0.22	7.27 ± 0.35	
Day 5	6.56 ± 0.29	7.24 ± 0.42	
			0.000

Values are presented as mean ± SD. Change of potential of hydrogen (pH) in the remnant stomach was recorded at 8:00 am on the day before surgery as well as 1–5 d after surgery.

lost to follow-up. Besides, seven patients in group U and six patients in group B had died. Therefore, the survival rates at 1 year for group U and B patients were 90.79% and 92.31%, respectively, and showed no significant difference (P = 0.735). The biliary reflux incidence in group B was higher than that in group U patients with a significant difference (60.9% *vs* 90.3%, P = 0.000). The ratio of gastritis in group B (72.2%) was significantly higher than that in group U (55.1%). However, the result of biopsy showed no significant difference (63.8% *vs* 70.8%, P = 0.278), but the linear-by-linear association was significant (P_{trend} = 0.015). Besides, there was no significant difference for the incidence of diarrhea, residual food, or gain of weight between the two groups (Table 4).

DISCUSSION

In 1988, uncut Roux-en-Y reconstruction was first

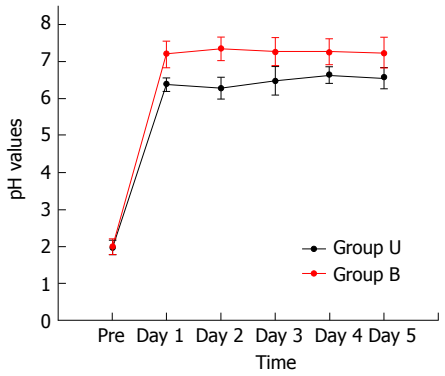

Figure 4 Perioperative potential of hydrogen (pH) in the stomach of the patients. Change of potential of hydrogen (pH) in the remnant stomach was recorded at 8:00 am on the day before surgery as well as 1-5 d after surgery. During the postoperative period, all stomach pH values of group U patients were below 7.00. Conversely, all stomach pH values of group B patients were higher than 7.00.

Table 4 The follow-up data

Item	Group U	Group B	*P* value
3 mo later	*n* = 77	*n* = 76	
Esophagogastroduodenal series			
Full emptying at 30 min	59 (76.6)	67 (88.2)	0.061
Partial recanalization	0	-	-
1 yr later	*n* = 69	*n* = 72	
Heartburn	7 (10.1)	17 (23.6)	0.033
Weight gain (kg)	-0.04 ± 3.6	-0.18 ± 3.8	0.723
Endoscopic finding			
Residual food	8 (11.6)	3 (4.2)	0.178
Grade 0	61	69	
Grade 1	7	3

reported by Stiegman and Goff[10]. Some studies over the years have confirmed that this reconstruction can preserve myoneural continuity to eliminate Roux stasis syndrome[11-13]. Because uncut Roux-en-Y is a modification of Billroth Ⅱ reconstruction, it makes sense to compare Billroth Ⅱ and uncut Roux-en-Y to determine the better procedure after LADG.

Our study showed there was no significant difference for the incidence of postoperative complications between the two groups (7.6% *vs* 10.1%, *P* > 0.05). Moreover, for the severity of postoperative complications, according to the Clavien-Dindo classification of surgical complications, there was no significant difference (*P* = 0.954). A-loop syndrome does not occurred in the uncut Roux-en-Y group, and the incidence of duodenal stump leakage was lower than that of the Billroth II group. The reason for this may be that the Braun anastomosis effectively relieves the pressure of the afferent loop[14], but more cases should be included to confirm this difference.

For biliary reflux, during the postoperative period, all group U pH values were lower than 7.00, thus representing an acidic stomach environment. In group B patients, all pH values were higher than 7.00, representing an alkaline stomach environment with alkaline reflux, which can be considered an important risk factor for gastric stump cancer[15] (Figure 2). In addition, according to patient outcomes at the 1-year follow-up, the bile reflux incidence in group B patients was significantly higher than that in group U (*P* = 0.000). However, the incidence of bile reflux in group U patients was 60.9%, which is higher than the equivalent statistic in Park and Kim's report (less than 30%)[4]. There are two main reasons that can explain these data. On one hand, the incidence of partial recanalization reached 13.0%. In this study, for partial recanalization, all those cases were first observed by endoscopy, and the result would be confirmed by esophagogastroduodenal series if there was doubt. Recanalization eventually allowed bile access to the gastric remnant. On the other hand, for some other cases, the bile reflux happened through the efferent loop, and a small amount of bile was usually found in the bottom of residual stomach with no overflow (grade 1).

Regarding gastritis, the incidence in group B patients (72.2%) was significantly higher than that in group U patients (55.1%), with a higher incidence of heartburn in group B patients as well (23.6%). These results allow us to conclude that uncut Roux-en-Y can reduce the occurrence of residual gastritis and heartburn proportion in Billroth Ⅱ reconstruction. However, the biopsy results showed no significant difference between the two groups (*P* = 0.278).

We draw two conclusions from these results. First, the pattern of bile reflux is different. The majority of group U patients were classified into grade 1 (49.3%), characterized by a small bile amount usually located in the bottom of the stomach as gastric residue, whereas most group B patients belonged to grade 2 (58.3%), characterized by considerable tidal rhythm. Hence, the stomach bile was fresh and temporary, which may be less corrosive to the gastric mucous membranes. Park showed a correlation between bile reflux and the degree of gastritis[4], but perhaps it depends not only on the amount but also on the pattern of biliary reflux. Second, the follow-up time was too short to show differences in the percentage of residual gastritis on biopsy, so the linear-by-linear association *P* value was also calculated. The result showed a significant

difference (P_{trend} = 0.015), meaning that the severity of residual gastritis for group B was worse than that for group U on biopsy.

For residual food, there was no significant difference between the two groups (11.6% *vs* 4.2%, $P > 0.05$). For gastrointestinal anastomosis of both procedures, the stoma was extensive along the greater curvature. No gastroparesis syndrome was found during follow-up, which is perhaps related to myoneural continuity. At 3-mo follow-up, the incidence of full emptying at 30 min reached 76.6% and 88.2% in group U and B patients, respectively (Table 4). As a result, no retention of afferent loop stump was found during the follow-up, and the incidence of residual food was lower than that in other studies[4,16].

This study adopted body weight change to evaluate postoperative nutritional status of patients, and 1 year later, the weight change values of group U and group B patients were -0.04 ± 3.6 kg and -0.18 ± 3.8 kg, respectively, with no significant difference. Moreover, there was no significant difference in survival rates of group U and group B patients after 1 year (90.79% *vs* 92.31%, respectively; $P > 0.05$).

In conclusion, the uncut Roux-en-Y digestive reconstruction procedure is secure and feasible. Moreover, it can effectively reduce the incidence of alkaline reflux, residual gastritis, and heartburn seen in classical Billroth II procedure. Besides, the uncut technique still needs improvement so that the risk of staple line dehiscence is minimized, with a longer follow-up period to reevaluate the exact risk. Despite the incidence of recanalization[17-21], uncut Roux-en-Y should be widely applied.

COMMENTS

Background

In 1988, uncut Roux-en-Y reconstruction was first reported by Stiegman and Goff. Some studies over the years have confirmed that this reconstruction can preserve myoneural continuity to eliminate Roux stasis syndrome. However, because of the challenge of recanalization, the uncut Roux-en-Y is still controversial and really needs further study. Since uncut Roux-en-Y is a modification of Billroth II reconstruction, it makes sense to compare Billroth II and uncut Roux-en-Y to determine the better procedure after laparoscopy-assisted distal gastrectomy (LADG).

Research frontiers

Compared with Japan and Korea, early gastric cancer only accounts for a small percentage in China, and most gastric cancer cases are found in advanced stages at the initial diagnosis. It is inappropriate for surgeons to perform Billroth I anastomosis after subtotal gastrectomy. In 2005, Uyama first combined LADG with uncut Roux-en-Y reconstruction, and since then it has been the hotspot for many years. However, its use remains controversial. Some surgeons believe that it is better than Billroth II and Roux-en-Y reconstructions, while others do not.

Innovations and breakthroughs

This study is the first randomized controlled trial concentrating on uncut Roux-en-Y *vs* Billroth II reconstruction after distal gastrectomy for gastric cancer. It aimed to compare uncut Roux-en-Y and Billroth II reconstruction in terms of postoperative complications, including biliary reflux and gastritis. Despite the incidence of recanalization, uncut Roux-en-Y reconstruction is secure and feasible, and can effectively reduce the incidence of alkaline reflux, residual gastritis, and heartburn.

Applications

There remains no clear consensus regarding the preferred reconstructive surgical procedure after LADG for gastric cancer. In this study, uncut Roux-en-Y reconstruction is secure and feasible, and can effectively reduce the incidence of alkaline reflux, residual gastritis, and heartburn. Therefore, uncut Roux-en-Y should be widely applied in the future. Besides, the uncut technique still needs improvement so that the risk of staple line dehiscence is minimized, with a longer follow-up period to reevaluate the exact risk.

Peer-review

Interesting comparison of two techniques of postgastrectomy reconstruction.

Abstract

AIM

To investigate potential biomarkers for predicting postoperative pancreatic fistula (POPF) after pancreaticoduodenectomy (PD).

METHODS

We prospectively recruited 83 patients to this study. All patients underwent PD (Child's procedure) at the Division of Hepatobiliary and Pancreas Surgery at the First Bethune Hospital of Jilin University between June 2011 and April 2015. Data pertaining to demographic variables, clinical characteristics, texture of pancreas, surgical approach, histopathological results, white blood cell count, amylase and choline levels in the serum, pancreatic/gastric drainage fluid, and choline and amylase levels in abdominal drainage fluid were included in the analysis. Potential correlations between these parameters and postoperative complications such as, POPF, acute pancreatitis, hemorrhage, delayed gastric emptying, and biliary fistula, were assessed.

RESULTS

Twenty-eight out of the 83 (33.7%) patients developed POPF. The severity of POPF was classified as Grade A in 8 (28%) patients, grade B in 16 (58%), and grade C in

4 (14%), according to the pancreatic fistula criteria. On univariate and multivariate logistic regression analyses, higher amylase level in the abdominal drainage fluid on postoperative day (POD)1 and higher serum amylase levels on POD4 showed a significant correlation with POPF ($P < 0.05$). On receiver operating characteristic curve analysis, amylase cut-off level of 2365.5 U/L in the abdominal drainage fluid was associated with a 78.6% sensitivity and 80% specificity [area under the curve (AUC): 0.844; $P = 0.009$]. A cut-off serum amylase level of 44.2 U/L was associated with a 78.6% sensitivity and 70.9% specificity (AUC: 0.784; $P = 0.05$).

CONCLUSION

Amylase level in the abdominal drainage fluid on POD1 and serum amylase level on POD4 represent novel biomarkers associated with POPF development.

Key words: Pancreaticoduodenectomy; Complication; Amylase; Pancreatic fistula

Core tip: In this study, we sought to identify biomarkers that could help predict the risk of postoperative pancreatic fistula (POPF) after pancreaticoduodenectomy. Diagnosis of POPF was based on the International Study Group of Pancreatic Fistula criteria. Association between POPF and various clinical and biochemical parameters was assessed. Amylase level in the abdominal drainage fluid on postoperative day 1 and serum amylase level on postoperative day 4 showed a significant association with POPF and represent novel biomarkers associated with POPF development.

Drainage fluid and serum amylase levels accurately predict development of postoperative pancreatic fistula. *World J Gastroenterol* 2017; 23(34): 6357-6364 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i34/6357.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i34.6357

INTRODUCTION

Pancreaticoduodenectomy (PD) is a common operative approach for treatment of various malignant diseases of the distal biliary duct, the head of pancreas, and the peri-ampullar region. It is also widely acknowledged as one of the most challenging surgical procedures. PD is associated with substantial perioperative mortality (2%-5% even in high-volume centers) and morbidity (30%-50%)[1,2]. Postoperative pancreatic fistula (POPF) is one of the most important complications of PD; reported incidence rates range from 2% to 25%[3]. POPF often leads to further complications, such as hemorrhage and abdominal abscess, and is associated with increased length of hospital stay[3,4]. POPF and other PD-associated complications have necessitated the development of new surgical modalities, like a combination of pancreaticojejunostomy with duct-mucosa pancreaticojejunostomy; however, the incidence of POPF following PD continues to be a concern[5].

Various pre-operative and intra-operative factors, such as preoperative jaundice and diameter of the pancreatic duct, are associated with POPF; however, these factors are not reliable predictors of POPF[6,7]. Biochemical markers in serum and drainage fluid may reflect the disease progression, and it is of translational significance to investigate their correlation with clinical characteristics and their potential value as predictors of POPF. In this study, we sought to identify potential predictors of POPF development, which may help optimize the treatment of these patients in clinical practice.

MATERIALS AND METHODS

Study design

We prospectively recruited 83 patients to this study. All patients underwent PD at the Department of Hepatobiliary and Pancreatic Surgery at the First Bethune Hospital of Jilin University between June 2011 and April 2015. Preoperative, intraoperative and postoperative data were collected for each patient. Preoperative variables of interest included age, sex, history of diabetes, jaundice, plasma protein levels and pre-operative intervention for jaundice (if any). Intraoperative variables included pancreatic consistency, diameter of pancreatic duct, and the technique used for pancreatic anastomosis. Postoperative data included the results of pathological examination, pancreatic and gastric drainage volume, and complications after operation, such as POPF, hemorrhage, acute pancreatitis, delayed gastric emptying (DGE), and biliary fistula (Table 1).

Severity of POPF was classified as grade A, B or C, as defined by the International Study Group of Pancreatic Fistula[8]. Association between surgical outcomes and results of routine serological and biochemical investigations was assessed. The study protocol complied with the principles of the Declaration of Helsinki, and was approved by the Institutional Ethics Committee at the First Hospital of Jilin University. All patients had provided informed consent prior to their enrolment.

Details of clinical management

Forty-three patients received PD with a pancreatic drainage tube (size: 6, 7 or 8) anastomosed to the pancreatic parenchyma during the *pancreaticojejunostomy*; the tube was then drawn out through the distal bowel. In the remaining 40 patients, the standard Child's procedure was performed with placement of external pancreatic drainage tube (size: 6, 7 or 8), which was fixed to the pancreatic parenchyma

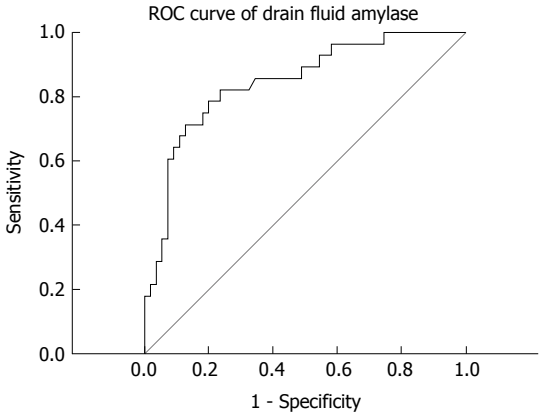

Figure 1 Receiver operating characteristic curve analysis of amylase activity in drainage fluid. A cut-off value of 2365.5 U/L was associated with 78.6% sensitivity, 80% specificity, 66.7% PPV and 88% NPV for POPF (AUC: 0.844, P = 0.009). ROC: Receiver operating characteristic; POPF: Postoperative pancreatic fistula; NPV: Negative predictive value; PPV: Positive predictive value; AUC: Area under the curve.

Table 1 Definitions of postoperative complications after pancreaticoduodenectomy

Complication	Definition
POPF	Drainage fluid amylase activity on or after postoperative day 3 is at least three times the upper limit in normal serum
Ascites	Ultrasound evidence of ascites depth > 5 cm
Hemorrhage	Requires postoperative transfusion of ≥ 2 U isogenic red blood cells
Biliary fistula	Abdominal drainage produces bilious fluid at 50 mL/d after surgery
DGE	Indwelling stomach tube for > 10 d

POPF: Postoperative pancreatic fistula; DGE: Delayed gastric emptying.

and left in the bowel. All patients were treated with cefoperazone and sulbactam (3.0 g/Q12 h) for the first 4 postoperative days (PODs) to prevent infection. Postoperatively, prophylactic intravenous octreotide was administered at a dose of 0.6 mg/24 h for 3 d to reduce the amount of pancreatic secretion.

Statistical analysis

Statistical analyses were conducted using SPSS software (version 19.0; SPSS Inc., IBM, Armonk, NY, United States). Univariate and multivariate analyses were performed to identify factors significantly related to POPF. Receiver operating characteristic (ROC) curve analysis was performed to assess the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the identified variables. A P value of less than 0.05 was considered indicative of statistical significance.

RESULTS

Incidence of POPF

Out of 83 patients, 28 (33.7%) eventually developed POPF. The severity of POPF was classified as grade A in 8 (28%) patients, grade B in 16 (58%) and grade C in 4 (14%) (Table 2).

Table 2 Summary of postoperative complications

Complication	Cases, n = 30	Incidence, %
POPF	28	33.7
Type A	8	28
Type B	16	58
Type C	4	14
Ascites	4	10
Hemorrhage	7	17.5
Biliary leakage	1	2.5
DGE	1	2.5
Postoperative acute pancreatitis	1	2.5

POPF: Postoperative pancreatic fistula; DGE: Delayed gastric emptying.

High amylase level predicts POPF development

We first categorized the patients as POPF and non-POPF groups, and then compared the levels of different parameters between the two groups (Table 3). On univariate analysis, amylase level in the abdominal drainage fluid on POD1 and serum amylase level on PODs 1 and 4 were correlated with POPF development (P < 0.05) (Table 4).

Multivariate logistic regression analysis confirmed that amylase level in abdominal drainage fluid on POD1 and serum amylase level on POD4 were independent predictors of POPF (Table 5). On ROC curve analysis, a cut-off amylase level of 2365.5 U/L in the abdominal drainage fluid on POD1 as predictor of POPF was associated with 78.6% sensitivity, 80% specificity, 66.7% PPV and 88% NPV [area under the curve (AUC): 0.844; P = 0.009] (Figure 1). Similarly, a cut-off serum amylase level of 44.2 U/L on POD4 was associated with a 78.6% sensitivity and 70.9% specificity (AUC: 0.784; P = 0.05; Figure 2). The specificity of these associations was further highlighted by the observation that neither white blood cell (WBC) counts nor choline and albumin levels correlated with POPF development.

DISCUSSION

The Whipple procedure for PD for the treatment of benign and malignant tumors in the head of pancreas and the peri-ampullar region is one of the most technically challenging surgical procedures, with long duration of surgery and a high rate of associated complications[9,10]. The reported rates of postoperative complications following PD range from 30%-70%, and postoperative mortality rates have remained approximately 5% even in high-volume centers[11]. POPF accounts for 2%-25% of all complications of PD[12]. The advent of novel surgical modalities for pancreaticojejunostomy, such as the duct-mucosa pancreaticojejunostomy or pancreatic duct stent

implantation, has not resulted in major improvement. Therefore, early detection of POPF development and adequate timely intervention is important to improve surgical outcomes in these patients[13-17]. There is a paucity of tools to identify patients who are at risk of development of POPF. Here, we report our prospective study to identify potential predictors of POPF. The results suggest that monitoring of amylase levels in drainage fluid and serum as biomarkers is quite promising.

Various factors have been linked to POPF in previous studies. These include pancreatic consistency, pancreatic duct diameter, and the results of assessment by the pathologist[18-22]; however, their predictive value has been shown to be relatively poor and not intuitive. In the present study, we observed an obvious correlation between amylase levels in the ascitic fluid on POD1 and the serum amylase level on POD4 with the occurrence of POPF. Cloyd *et al*[20] reported that serum amylase level on POD1 (> 140 U/L) predicts POPF with 81.5% sensitivity, 55.5% specificity, 29.3% PPV, and 93% NPV[23]. Likewise, some researchers demonstrated that drainage fluid amylase level on POD1 (> 350 U/L) can predict POPF with a 79% specificity, 100% sensitivity, 41% PPV, and 100% NPV. Furthermore, Popiela *et al*[24] showed that the drainage

fluid amylase level (> 5000 U/L) on POD1 is a reliable predictor of POPF. Kawai *et al*[25] also found that the ratio of total amylase in drainage fluid could predict POPF. Our results are consistent with these previous publications, which indicate that amylase level in ascitic fluid on POD1 and blood amylase on POD4 could be used to identify patients who are most likely to suffer from this complication after PD.

Of note, we did not observe a significant association of albumin and WBC counts with POPF. Kawai *et al*[25] reported that serum albumin levels (< 3.0 g/d) and serum WBC count (> 9800 mm^3) on POD4 predicted grades B and C POPF with a 69% sensitivity, a 96% specificity, an 88% PPV, and an 85% NPV. Relles *et al*[26] found that serum albumin (< 2.5 mg/L) and blood urea nitrogen (> 10 mg/dL) on POD1 were important predictors of perioperative morbidity following PD[27]. However, in our study, the level of serum albumin through POD1, POD3 and POD5 did not correlate with the development of POPF. Considering that acute stress can affect serum albumin level and WBC counts[28], these may not be appropriate measures to gauge the risk of POPF. A prospective trial showed that postoperative albumin levels were not associated with risk during abdominal operation[29]. Welsch *et al*[29] also reported poor specificity of serum WBC as a predictor of POPF. Our results are consistent with these reports. In addition, no significant association of POPF with cholinesterase level was observed on POD1, POD3 and POD5, which suggests that POPF may not have an obvious relationship with the postoperative change in hepatic reserve.

In our study, a cut-off amylase level of 2365.5 U/L in ascitic fluid on POD1 predicted POPF with 78.6% sensitivity, 80% specificity, 66.7% PPV, and 88% NPV. We hypothesize that in patients with POPF, the higher level of amylase in drainage fluid on POD1 derives from the failed pancreaticojejunal anastomosis, which

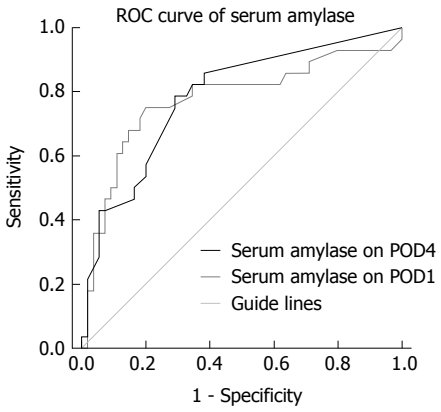

Figure 2 ROC curve analysis of serum amylase activity. A cut-off value of 44.2 U/L on POD4 was associated with a 78.6% sensitivity and 70.9% specificity for POPF (AUC: 0.784, P = 0.05). ROC: Receiver operating characteristic; POPF: Postoperative pancreatic fistula; AUC: Area under the curve.

leads to POPF.

Serum amylase has been used for diagnosis of acute pancreatitis for > 70 years; however, increased serum amylase levels are also observed in other diseases of salivary glands, oviduct epithelium and proximal duodenum, which limits its specificity for the diagnosis of pancreatitis. Intuitively, this should be less of a concern with respect to drainage fluid or generally following PD[30]. Indeed, in our study, serum amylase on POD4 showed a significant correlation with POPF, although serum amylase on POD1 did not effectively predict POPF. We found that serum amylase on POD4 of 44.2 U/L was an effective maker; however, this value is within the normal range of serum amylase, and thus serum amylase level on POD4 higher than 100 U/L is probably more appropriate. Serum amylase on POD4 with a discriminatory threshold of 100 U/L can predict POPF with 42.9% sensitivity, 55% specificity, 75% PPV, and 76.1% NPV. In the early postoperative stage, ischemic injury to pancreatic tissues caused by surgical damage to blood vessels, intraoperative and postoperative hypovolemia, and surgical stress leads to elevation of serum amylase[31]. However, no statistically significant correlation was observed between serum amylase level on POD1 and pancreatic leakage, and no correlation was found between serum amylase and POPF in theory, whereas absorption of exudates from pancreatic anastomosis cannot explain such a phenomenon. On the other hand, we believe that elevation in serum amylase level on POD4 reflects the preliminary establishment of a collateral pancreatic anastomosis, and that correction of hypovolumia may reflect the condition of pancreatic juice derived from accessory pancreatic duct or residual pancreatic section instead of the obstructed main pancreatic duct. Moreover, the erosion effect of amylopsin and trypsin on blood vessel can also increase the absorption speed and the amount of amylopsin into the blood, which reflects the increased serum amylase. Thus, blood amylase level on POD4 is of certain predictive value for the occurrence of POPF.

In our study, we found that amylase activity in drainage fluid on POD1 and serum amylase activity on POD4 could accurately predict POPF, whereas serum albumin and prealbumin did not show a significant predictive value. Measurement of amylase level in drainage fluid on POD1 and the serum amylase level on POD4 is a relatively easy and economical method. Our results support the use of amylase to predict POPF.

This may allow for timely interventions, such as increased duration of antibiotic and octreotide therapies, that may help prevent POPF and allow for timely risk-communication to the patient. It is also another procedure in the processing carried out in our medical center.

COMMENTS

Background

Identification of patients who are at high risk of postoperative pancreatic fistula (POPF) in the immediate postoperative period after is a key imperative to improve surgical outcomes of pancreaticoduodenectomy (PD). Biochemical markers in serum and drainage fluid may reflect disease progression, and it is of translational significance to investigate their correlation with clinical characteristics and their potential use to predict the risk of POPF. In this study, we sought to identify potential predictors of POPF development, which may help optimize the treatment of such patients in clinical practice.

Research frontiers

Although anastomosis techniques used for PD significantly improves, the incidence of PD-associated POPF remains relatively high. POPF is a major threat to patients who undergo PD. Thus, early and accurate prediction of POPF is essential to achieve optimal surgical outcomes.

Innovations and breakthroughs

Previous studies have found several biochemical factors, such as serum amylase level on postoperative day (POD)1, drainage fluid amylase level on POD1, and a combination of serum albumin and leukocyte count as predictors of POPF. However, some of these markers have low positive predictive value. We demonstrate that amylase level in drainage fluid on POD1 and serum amylase level on POD4 are better predictors of POPF than those proposed earlier.

Applications

Measurement of amylase level in serum and drainage fluid is relatively straightforward and inexpensive. These two investigations can help identify patients who are at an increased risk of POPF. This may allow for timely interventions, such as increased duration of antibiotic and octreotide therapies, that may help prevent POPF. It is also another procedure in the processing carried out in our medical center.

Terminology

Although several biochemical factors have been shown to predict POPF in previous studies, we found that just amylase levels in drainage fluid on POD1 and serum amylase level on POD4 could accurately predict POPF, whereas serum albumin and prealbumin were found to have negligible predictive value.

Peer-review

In this manuscript, the authors correlate the postoperative clinical factors with POPF rate, including prospectively 83 patients with PD, and analyzed the potential correlation between biomarkers and postoperative complications such a pancreatic fistula.

Abstract

Heterotopic pancreas (HP) is a relatively uncommon entity that is defined as pancreatic tissue without a true anatomical or vascular connection to the pancreas. HP does not cause symptoms in most cases but can occasionally produce various manifestations, including nausea, vomiting, abdominal pain, and even heterotopic pancreatitis. Here, we report an unusual case in which heterotopic pancreatitis complicated by the formation of a pseudocyst that caused gastric outlet obstruction was diagnosed based on serum hyperamylasemia and findings from endoscopic ultrasonography (EUS)-guided fine needle aspiration (EUS-FNA) cytology. EUS-guided single pigtail stent insertion was successfully performed for recurrent gastric outlet obstruction. The patient has remained healthy and symptom-free during 4 years of surveillance. In the context of the relevant literature, the described case is a rare case of HP complicated by a pseudocyst treated *via* EUS-FNA and stent insertion.

Key words: Heterotopic pancreas; Pseudocyst; Gastric outlet obstruction; Endoscopic ultrasound-guided fine needle aspiration

INTRODUCTION

Heterotopic pancreas (HP) is defined as the presence of pancreatic tissue in an abnormal location without anatomical or vascular connection to the orthotopic pancreas. HP was first described by Jean-Schultz in 1729 and was confirmed histologically by Klobb[1]. Other terms for HP, such as ectopic pancreas, aberrant pancreas, and accessory pancreas, have been used in the literature[2]. In most cases, HP is asymptomatic and found incidentally[1], but it can occasionally produce non-specific symptoms that depend on its location, size, and types of complications. Here, we describe a case involving a 40-year-old man with gastric outlet obstruction secondary to heterotopic pancreatitis with pseudocyst formation.

CASE REPORT

A 40-year-old man was admitted to a community hospital for upper abdominal pain accompanied by nausea and vomiting. He also complained of abdominal distention and moderate fever (38.3 ℃). Physical examination revealed minimal tenderness in the epigastric region without a palpable mass or peritoneal signs, and the patient's vital signs were unremarkable. Routine blood tests showed a significant elevation of the leukocyte count and neutrophil ratio, and biochemical examinations revealed serum amylase of 460 U/L and urine amylase of 3500 U/L. Transabdominal ultrasound was initially performed when the patient was diagnosed with pancreatitis, but no gallbladder stones or common bile duct stones were detected. The patient was treated for acute pancreatitis; his treatments included fasting, injection of a proton pump inhibitor, and somatostatin. All symptoms disappeared 3 d later but recurred after the patient ingested fluids. Subsequently, the patient was transferred to our hospital for further diagnosis. A computed tomography (CT) scan of the abdomen revealed manifestations of a normal pancreas and an ill-defined enhancing mass at the gastric antrum that was causing circumferential narrowing of the pyloric channel (Figure 1A). In an esophagogastroduodenoscopy (EGD) examination, a sub-epithelial lesion without overlying umbilication or dimpling was found in the prepyloric region (Figure 1B). The pyloric channel was only wide enough to allow for the passage of an Olympus Q260 endoscope (OD 9.2 mm), but the duodenum was normal. Radial endoscopic ultrasonography (EUS), which was used as an additional diagnostic tool, confirmed the presence of a cystic lesion measuring 21 mm × 25 mm (Figure 1C) originating from the third layer with anechoic contents and debris. Subsequently, EUS-guided fine needle aspiration (EUS-FNA) was successfully performed (Figure 1D), and a total of 25 mL of clear fluid was aspirated to the greatest possible extent with negative pressure. Cystic fluid analysis revealed an amylase level of 83770 U/L and a carcinoembryonic antigen level of 3.7 μg/L; a cytologic examination of smears revealed clusters of benign-appearing ducts and small acini mixed with inflammatory cells (Figure 2).

The patient was allowed to ingest low-fat fluids 5 d after the procedure, but the aforementioned symptoms immediately re-emerged, and serum amylase increased to 512 U/L. A narrowed pyloric channel was observed in a second EGD examination. The patient refused surgical treatment. Balloon dilation, bougie dilation, and needle-knife puncture of the cyst were not initially selected. In accordance with an endoscopic drainage procedure used for pancreatic pseudocysts, we successfully performed cyst cavity (20 mm × 23 mm) puncture, wire exchange, and the gradual insertion of a single pigtail stent (5 Fr × 4 cm) using a 19-gauge needle (EchoTip Ultra, ECHO-19; Cook Endoscopy, Winston-Salem, NC, United States) (Figure 1E and F). Informed consent was obtained from the patient and his family prior to this endoscopic procedure. No abnormal signs or symptoms were noted during or immediately after the procedure. Shortly thereafter, the patient's abdominal pain and vomiting subsided, and his leukocyte count and serum amylase returned to normal. The patient was discharged on the sixth day after the second drainage procedure.

Five months later, the patient returned for a follow-up examination without any complaints. EGD surveillance revealed no stent at the original position, and radial EUS confirmed the presence of a smaller anechoic cystic lesion measuring 3 mm × 5 mm (Figure 3A and B). The stent had completely passed, as confirmed by abdominal radiography (Figure 4). The patient has remained healthy and symptom-free during 4 years of follow-up.

DISCUSSION

In autopsy studies, HP has generally had an incidence ranging from 0.5%-13.0% and been more common in 30- to 50-year-old subjects, with male predominance[3]. HP is most frequently located in the stomach

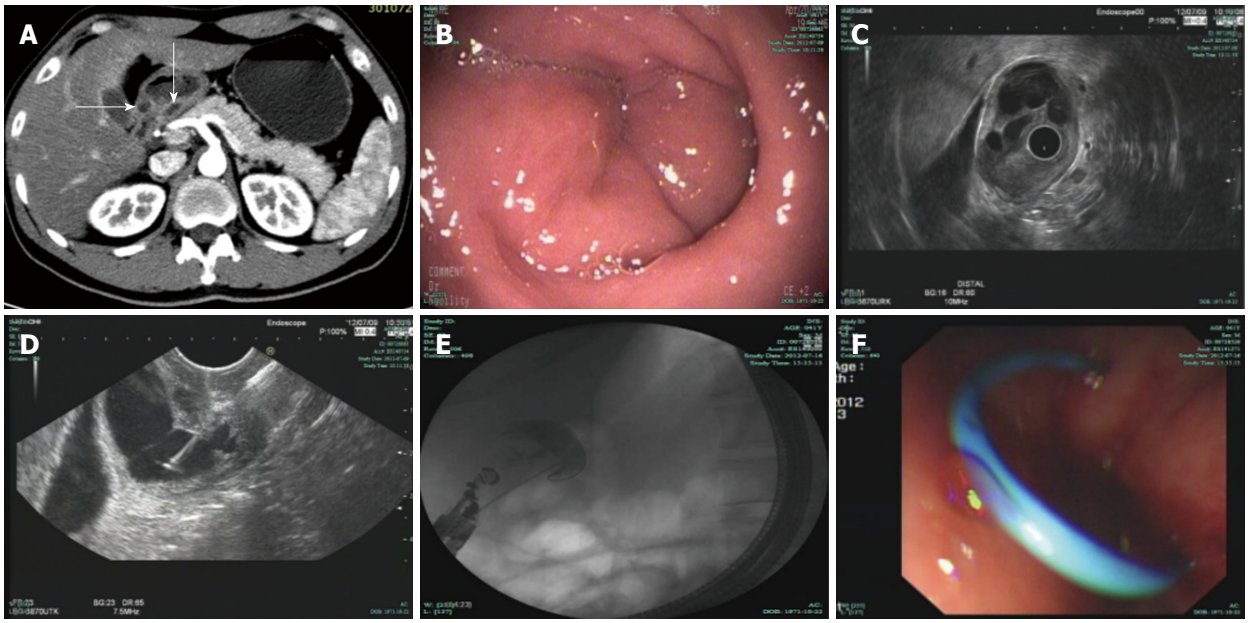

Figure 1 Computed tomography scan and endoscopic treatment of the lesion. A: Contrast-enhanced CT revealed manifestations of a normal pancreas and an ill-defined enhancing mass (arrows) at the gastric antrum that caused circumferential narrowing of the pyloric channel; B: EGD showed a narrowed pyloric channel with normal mucosa; C: Radial EUS imaging confirmed the presence of a cystic lesion measuring 21 mm × 25 mm that originated from the third layer with anechoic contents and debris; D: EUS-guided fine needle aspiration; E: Cyst cavity radiography and guide-wire exchange; F: Successful insertion of a single pigtail stent (5 Fr × 4 cm). CT: Computed tomography; EUS: Endoscopic ultrasonography; EGD: Esophagogastroduodenoscopy.

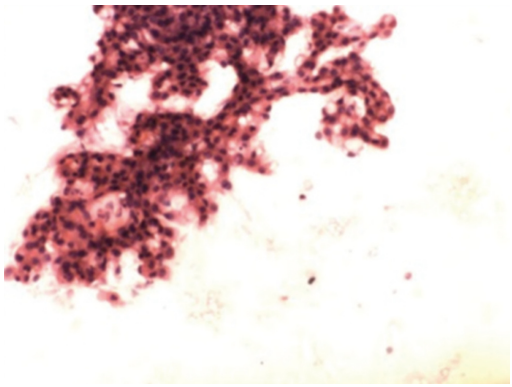

Figure 2 Cytologic examination with hematoxylin-eosin staining (low-power field). A cytologic examination of smears revealed clusters of benign-appearing ducts and small acini mixed with inflammatory cells.

(25%-38%), followed by the duodenum (17%-36%) and the jejunum (15%-21.7%); it is rarely found in the esophagus, common bile duct, spleen, mesentery, mediastinum or fallopian tube[4]. In the gastrointestinal tract, HP is most frequently located only in the submucosa (54%) and is less frequently found in both the submucosa and muscularis propria (23%), only the muscularis propria (8%), the subserosa (11%), and the whole wall (4%)[1].

HP has been classified into four types by Heinrich and Gaspar-Fuentes[5]. Type Ⅰ HP shows the presence of ducts, acini, and islets of Langerhans cells; type Ⅱ HP shows only ducts and acini; type Ⅲ HP has only ducts; and type Ⅳ HP has only islets. Most cases of HP are type Ⅱ. The pathogenesis of HP remains unclear, although the two most widely accepted hypotheses are the misplacement and metaplasia theories. The misplacement theory proposes that ectopic pancreatic tissue develops from misplacement during foregut rotation, whereas the metaplasia theory suggests that heterotopia arises from a pancreatic metaplasia of the endoderm that migrates to the submucosa during embryogenesis[6].

HP is typically asymptomatic; however, depending on its location and size, HP can occasionally cause clinical symptoms, the most common of which are vomiting and abdominal pain. Peptic ulceration and gastrointestinal bleeding are rare presentations, as are malignant transformation, pancreatitis, pseudocyst formation, gastric outlet obstruction, jejunal intussusception, and ileus[3,7-10]. A thorough search of the English literature revealed five cases of gastric heterotopic pancreatitis in the last 20 years, including our case[11-14] (Table 1). These cases involved three male patients and two female patients. The median age of the patients was 32 years. Epigastric pain was reported in four cases, and vomiting occurred in three cases. In our case, the patient presented with recurrent epigastric pain and vomiting, which were mainly induced by gastric outlet obstruction induced by heterotopic pancreatitis. The symptoms of pain and fever in our case might have been attributable to inflammation or chemical irritation of the involved tissue and enzyme secretion.

It is typically complex and challenging to preoperatively diagnose HP due to its varied presentations. Gastric HP is difficult to radiologically diagnose; however, the double contrast barium meal technique may characteristically show a focally raised mucosal

Table 1 Reported cases of gastric heterotopic pancreatitis

area with associated superficial ulceration within the gastric antrum[15]. CT can localize lesions with normal pancreatic tissue but cannot distinguish HP from other submucosal tumors[16]. Upper endoscopy generally reveals a broad-based, umbilicated, submucosal lesion, with superficial biopsies being non-diagnostic in the vast majority of cases[17]. EUS has been reported to be helpful in diagnosing HP; EUS-FNA in particular is especially effective for confirming a diagnosis of HP, with a reported sensitivity of 80%-100%[18,19]. A novel sampling method using submucosal endoscopy with a mucosal flap was recently reported by Kobara *et al*[20]. Submucosal dissection allows for the collection of tissue samples even from small lesions (< 2 cm in diameter) under direct endoscopic view. This method was used to eventually prove that a gastrointestinal submucosal tumor (SMT) was a gastric duplication cyst with HP and an ectopic submucosal gland[21]. This approach can be used for preoperative diagnosis of an SMT, albeit with certain limitations.

Symptomatic HP should be respected. However, the optimal management of asymptomatic HP remains debatable. Surgical resection has been reported in most HP cases[11-14]. In the aforementioned cases (Table 1), four patients underwent partial resection of the stomach because this approach was preferable for the preservation of gastric function. The prognosis after surgery was generally favorable, and complete symptom remission was achieved in these cases. Endoscopic submucosal dissection (ESD) and endoscopic mucosal resection (EMR) have also been reported for symptomatic HP; these approaches offer the possibility of localized treatment for HP with relatively low mortality and morbidity rates[22]. Zhong *et al*[23] reported 60 cases of gastric HP that were treated using ESD or EMR; in particular, 14

patients underwent EMR, and 46 patients underwent ESD. Complications occurred in 12 (20%) patients, including arterial bleeding in nine patients and pneumoperitoneum in three patients; all of these patients were treated conservatively. However, it has been reported that in total, 23% of gastric HP cases are located in the muscularis propria, the subserosa, or the whole wall; the technical difficulty and complication rates of endoscopic procedures may be significantly increased for HP at these locations[1]. Recently, EUS has been increasingly used for pancreatic fluid collection, biliary and pancreatic duct drainage, gallbladder drainage, and other applications[24]. The roles of interventional EUS continue to expand, and growing global experience supports the feasibility and efficacy of this approach[25,26]. In our case, an endoscopic view of the lesion did not reveal the typical umbilicated indentation that has been recognized as characteristic of a central ductal orifice. The absence of communication between the glandular epithelium and the gastric lumen can be attributed to the retention of exocrine secretions that subsequently led to recurrent episodes of acute obstructive pancreatitis, the formation of a retention pseudocyst, and eventually recurrent gastric outlet obstruction. EUS-guided stenting was used to relieve the gastric outlet obstruction by creating an artificial fistula in the pseudocyst. Consequently, this stenting not only rapidly relieved clinical symptoms but also resulted in long-term conversion of symptomatic HP to asymptomatic HP that no longer required surgical treatment. To our knowledge, no previous reports have described heterotopic pancreatitis treated using interventional EUS.

In summary, this case demonstrates the use of a novel endoscopic approach to successfully manage a gastric outlet obstruction secondary to heterotopic pancreatitis with pseudocyst formation. Based on this case, we suggest that HP should be considered in the differential diagnosis of a submucosal gastric mass. EUS-guided intervention can be beneficial for both diagnosing and providing symptomatic relief of heterotopic pancreatitis with pseudocyst formation, and endoscopic treatment should be recommended in selected cases.

COMMENTS

Case characteristics

A 40-year-old male complained of upper abdominal pain, nausea, and vomiting.

Clinical diagnosis

Heterotopic pancreatitis with pseudocyst formation located in the prepyloric region causing gastric outlet obstruction.

Differential diagnosis

Hyperplastic polyp, gastric adenoma, gastrointestinal stromal tumor, and lymphoma.

Laboratory diagnosis

Laboratory workup revealed a significant elevation of the leukocyte count and neutrophil ratio, serum amylase of 460 U/L, and urine amylase of 3500 U/L.

Imaging diagnosis

The abdominal computed tomography scan showed an ill-defined enhancing mass at the gastric antrum. Endoscopic ultrasound (EUS) revealed a cystic lesion measuring 21 mm × 25 mm originating from the third layer with anechoic contents and debris.

Pathological diagnosis

Histology revealed heterotopic pancreatic tissue in the prepyloric mucosa with clusters of benign-appearing ducts and small acini mixed with inflammatory cells.

Treatment

EUS-guided stenting.

Related reports

A total of four cases of gastric heterotopic pancreatitis have been reported in the literature. However, this is the first report of heterotopic pancreatitis with pseudocyst formation treated using interventional EUS.

Experiences and lessons

Heterotopic pancreas (HP) is a rare entity, and should be considered in the differential diagnosis of a submucosal gastric mass. Although surgical resection has been reported in most symptomatic HP cases, interventional EUS can sometimes be an effective minimally invasive treatment procedure for HP.

Peer-review

The authors describe an interesting and rare case of HP complicated with pseudocyst. Heterotopic pancreatitis with pseudocyst formation has been reported previously, but this case is unique in that endoscopic drainage was performed, which has not been previously described to our knowledge.

ABOUT COVER

Editorial board member of *World Journal of Gastroenterology*, J Enrique Dominguez-Munoz, MD, PhD, Associate Professor, Chief Doctor, Director, Department of Gastroenterology and Hepatology, University Hospital of Santiago de Compostela, 15706 Santiago de Compostela, Spain

AIMS AND SCOPE

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. *WJG* was established on October 1, 1995. It is published weekly on the 7th, 14th, 21st, and 28th each month. The *WJG* Editorial Board consists of 1375 experts in gastroenterology and hepatology from 68 countries.

The primary task of *WJG* is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, gastrointestinal imaging, gastrointestinal interventional therapy, gastrointestinal infectious diseases, gastrointestinal pharmacology, gastrointestinal pathophysiology, gastrointestinal pathology, evidence-based medicine in gastroenterology, pancreatology, gastrointestinal laboratory medicine, gastrointestinal molecular biology, gastrointestinal immunology, gastrointestinal microbiology, gastrointestinal genetics, gastrointestinal translational medicine, gastrointestinal diagnostics, and gastrointestinal therapeutics. *WJG* is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

INDEXING/ABSTRACTING

World Journal of Gastroenterology (*WJG*) is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central and Directory of Open Access Journals. The 2017 edition of Journal Citation Reports® cites the 2016 impact factor for *WJG* as 3.365 (5-year impact factor: 3.176), ranking *WJG* as 29th among 79 journals in gastroenterology and hepatology (quartile in category Q2).

Abstract

A world-wide rise in the prevalence of obesity continues. This rise increases the occurrence of, risks of, and costs of treating obesity-related medical conditions. Diet and activity programs are largely inadequate for the long-term treatment of medically-complicated obesity. Physicians who deliver gastrointestinal care after completing traditional training programs, including gastroenterologists and general surgeons, are not uniformly trained in or familiar with available bariatric care. It is certain that gastrointestinal physicians will incorporate new endoscopic methods into their practice for the treatment of individuals with medically-complicated obesity, although the long-term impact of these endoscopic techniques remains under investigation. It is presently unclear whether gastrointestinal physicians will be able to provide or coordinate important allied services in bariatric surgery, endocrinology, nutrition, psychological evaluation and support, and social work. Obtaining longitudinal results examining the effectiveness of this ad hoc approach will likely be difficult, based on prior experience with other endoscopic measures, such as the adenoma detection rates from screening colonoscopy. As a long-term approach, development of a specific curriculum incorporating one year of subspecialty training in bariatrics to the present training of gastrointestinal fellows needs to be reconsidered. This approach should be facilitated by gastrointestinal trainees' prior residency training in subspecialties that provide care for individuals with medical complications of obesity, including endocrinology, cardiology, nephrology, and neurology. Such training could incorporate additional rotations with collaborating providers in bariatric surgery, nutrition, and psychiatry. Since such training

would be provided in accredited programs, longitudinal studies could be developed to examine the potential impact on accepted measures of care, such as complication rates, outcomes, and costs, in individuals with medically-complicated obesity.

INTRODUCTION

The rising prevalence of obesity is a worldwide disorder, and therefore this problem will require a collaborative global approach. One commonly utilized definition of overweight and obesity is based upon the body mass index or BMI, which is calculated from an individual's height and weight (see Table 1). An extensive study has shown that the worldwide percentage of adults who are overweight (BMI 25-29.9 kg/m^2) or obese (BMI 30.0 and higher) increased from 28.8% of men in 1980 to 36.9% of men in 2013, and increased from 29.8% of women in 1980 to 38.0% of women in 2013[1]. Based on their data, the authors by extrapolation estimated that 2.1 billion individuals were overweight or obese by 2013. Similar results were recently reported in a study of 195 countries[2]. In more than 70 countries, the prevalence of obesity has doubled since 1980[2].

Obesity-related medical conditions (see Table 2) include insulin-resistant diabetes mellitus, obstructive sleep apnea, mechanical or degenerative osteoarthritis, non-alcohol steatohepatitis, hypertension, dyslipidemia with secondary coronary artery disease, pseudotumor cerebri, and likely gastroesophageal reflux, deep vein thrombosis, and asthma[3]. Obesity has also been consistently associated with increased risk of kidney, breast, endometrial, colorectal, pancreatic, esophageal, and gall bladder carcinoma[4]. Excess body weight contributes to a significant percentage of cases of cancer[4]. With the increase in the incidence of obesity in Asia, The Gut and Obesity in Asia Workgroup has developed an experts' consensus on obesity and gastrointestinal diseases in Asia[5]. In a worldwide systematic review, it was reported that obesity accounts for 0.7% to 2.8% of a country's total healthcare expenditures and that individuals with obesity have at least 30% higher healthcare costs[6]. In the United States, the medical care costs of obesity in 2008 were estimated to be $147 billion[7].

As one can ascertain from this rise in the worldwide prevalence of obesity, the previously suggested solutions with regards to this serious medical problem have not been effective. One suggested approach is education, with the inference that individuals will then make responsible choices when eating several times every day[8]. In the United States, the National Institutes of Health and the United States Preventive Services Task Force in 1998 and in 2012 suggested behavioral interventions, increased physical activity, and improved dietary intake[9,10]. Expectations of results from these recommendations however must be balanced against the findings of multiple meta-analyses[11-13] that have examined the potential benefits of behavioral interventions, diet and activity programs in individuals with excess weight. Reported "long term" results are for studies of only 12 to 18 mo. Unfortunately, the published weight loss results are modest with 1.5 to 5 kg of weight loss at 12 mo[11] after adopting behavioral interventions (which can include self-monitoring, setting weight loss goals, addressing barriers to change, and strategizing long-term change in lifestyle). These meta-analyses mention that there is higher weight loss reported for those individuals participating in dietary only programs compared to individuals involved in exercise or activity only programs. Combined dietary and physical activity programs tailored to individual metabolic and dietary response needs appear to be more beneficial than solely dietary programs. However, adding physical activity programs appear to increase overall weight loss by only an additional 0 to 3 kg.

Our review of previous contributions in this field included specific searches on PubMed (www.ncbi.nlm.nih.gov/pubmed) on June 11, 2017. The terms "gastroenterology fellow training" yielded 111 abstracts; the terms "gastroenterology fellow nutrition" yielded 35 abstracts; the terms "gastroenterology fellow obesity" yielded 8 abstracts; the terms "nutrition training gastrointestinal medicine" yielded 251 abstracts; and

Table 1 Obesity defined by body mass index

BMI (kg/m^2)	Definition	Obesity class
18.5-24.9	Normal	
25-29.9	Overweight	
30-34.9	Obesity	I
35-39.9	Obesity	II
40.0-	Obesity	III

BMI: Body mass index.

Table 2 Obesity related medical disorders

Diabetes mellitus
Obstructive sleep apnea
Degenerative osteoarthritis
Non-alcohol steatohepatitis
Hypertension
Dyslipidemia with coronary artery disease
Pseudo-tumor cerebri
Gastroesophageal reflux
Deep vein thrombosis
Asthma
Carcinomas (kidney, breast, endometrial, colorectal, pancreatic, esophageal, gallbladder)

the terms "obesity training gastrointestinal medicine" yielded 97 abstracts. All abstracts and all manuscripts consistent with the topic of this present manuscript were reviewed by one of us (TRK).

ONGOING ROLE OF GASTROINTESTINAL PHYSICIANS IN OBESITY CARE AND TRAINING

Gastrointestinal physicians and general surgeons both deliver gastrointestinal care to individuals with medically-complicated obesity, including the performance of endoscopy. These physicians, after completing traditional training programs, are uniformly trained in or familiar with available bariatric care. This notion is not a new concern. A survey of gastroenterologists published in 1976 revealed that obesity was included as one of the five most common diagnostic areas[14]. The author suggested that his findings could be the basis for planning education, training, and research activities in gastroenterology. An editorial published 26 years later described a commitment of the American Gastroenterological Association to nutrition and obesity, including a summary of elements included in advanced or level 2 training in nutrition[15]. A 2006 study in Canada of gastrointestinal clinicians and gastrointestinal fellows reconfirmed the opinion that training in management of obesity was inadequate[16]. A follow-up survey of Canadian gastrointestinal fellows published in 2009 revealed that gastrointestinal fellows considered their knowledge of nutrition and obesity to be suboptimal[17]. A written examination completed by these gastrointestinal fellows confirmed that their knowledge base indeed was suboptimal, especially in the areas of nutritional support, knowledge of micronutrients and macronutrients, obesity, and nutrition in gastrointestinal diseases. Similar findings have been reported in studies of gastrointestinal fellows in Iran[18] and in the United States[19]. One response to these long-standing concerns and weaknesses in nutrition training has been the publication of a potentially extensive curriculum in nutrition as part of the core curriculum for fellows or trainees in gastroenterology[20].

Training of gastrointestinal fellows internationally has involved programs with a traditional pathway which include disease-related training and endoscopy[21], and programs that combine basic elements of gastrointestinal training with time for advanced training in a subspecialty of gastroenterology or hepatology.

The traditional involvement of gastrointestinal clinicians in obesity has involved two levels of medical care: (1) direct care of gastrointestinal medical disorders related to obesity including non-alcohol steatohepatitis, gastroesophageal reflux, colorectal carcinoma, pancreatic carcinoma, esophageal carcinoma, and gall bladder carcinoma; and (2) consultants in collaboration with providers who treat patients for obesity, for example in the care of individuals who have undergone bariatric surgery. More recently, due to advances in therapeutic endoscopy, gastrointestinal physicians have begun to assume a role as the provider directly treating individuals for obesity. The question to now be considered is what pathways should be utilized to expand the role of gastrointestinal physicians in the care of individuals with medically-complicated obesity.

INCORPORATION OF BARIATRIC MEDICINE INTO ONGOING GASTROINTESTINAL PRACTICE

There are two major approaches for a process by which gastrointestinal physicians can evolve into physicians with primary responsibility for the treatment of individuals with medically-complicated obesity. A recent White Paper from the American Gastroenterology Association proposes incorporation of methods for obesity care and "weight management" into existing gastroenterological practices[22]. This approach immediately raises the question of how much weight loss is required for the appropriate treatment of medically-complicated obesity. An overview of treatment of individuals with non-alcohol steatohepatitis summarizes a proposed goal of loss of 10% of total body weight[23]. This weight loss goal can be difficult to reach in individuals with obesity through the use of dietary and activity programs. In agreement with recently published meta-analyses[11-13], a recent study from Cuba again demonstrated that only 10% of participants involved in dietary and activity

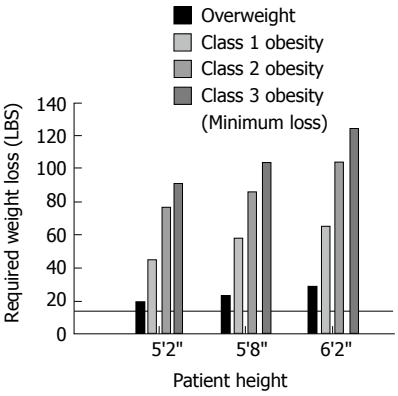

Figure 1 The vertical bars depict weight loss required to reach the normal weight range in overweight and obese individuals of difference heights. The solid line approximates the best published weight loss obtained through diet and activity programs.

Table 3 Weight loss medications approved by the United States Food and Drug Administration

Medication	Published weight loss
Short term use	Range from 3.6 to 8.1 kg
Benzphetamine	
Diethylpropion	
Phendimetrazine	
Phentermine	
Long term use	
Orlistat	2.6 kg
Liraglutide	4 to 6 kg
Lorcaserin	3.2 kg
Naltrexone and bupropion	5 kg
Phentermine and topiramate	8.8 kg

programs were able to lose 10% or more of their total body weight[24]. Again in agreement with ongoing experience[23], liver biopsies revealed that 90% of the participants who lost 10% or more of their total body weight had resolution of non-alcohol steatohepatitis. This study did not address the follow up concern which of course is long-term maintenance of weight loss, or an individual's weight regain.

When considering treatment of individuals with medically-complicated obesity, Figure 1 summarizes weight loss (in pounds) required to reach the normal weight range in overweight individuals and in obese individuals of difference heights. The solid line approximates the best published weight loss obtained through dietary and activity programs. Figure 1 provides a graphic depiction of the extent of weight loss required to improve serious medical disorders in individuals with Type Ⅱ obesity and Type Ⅲ obesity. For this reason, we have previously suggested that bariatric surgery utilizing vertical sleeve gastrectomy will likely become a major consideration for the treatment of nonalcoholic steatohepatitis in those individuals with Type Ⅱ obesity and Type Ⅲ obesity[25].

As step-up therapy for the treatment of medically-complicated obesity, the United States Food and Drug Administration has approved nine medical therapies for weight loss (see Table 3)[26-29]. There are four sympathomimetic drugs, which increase adrenergic stimulus, that have been approved for short term (12 wk) of medical therapy. This group includes Benzphetamine, Diethylpropion, Phendimetrazine, and Phentermine. There are five medical therapies approved for long-term medical therapy, which includes Orlistat, Liraglutide, Lorcaserin, Naltrexone with Bupropion, and Phentermine with Topiramate. As shown in Table 3, the published weight loss results reported for these medications are modest, ranging from 2.6 to 8.8 kg. Prescribing providers should be familiar with the significant risks involved in using these medications. For example, Orlistat can lead to deficiencies of fat soluble vitamin A, vitamin D, vitamin E, and vitamin K. Lorcaserin should not be used with monoamine oxidase inhibitors or selective serotonin reuptake inhibitors. Topiramate is associated with oral clefts when taken by pregnant women.

Table 4 Potential endoscopic methods to treat medically-complicated obesity

Method	Potential physiological mechanisms
Delivery of a Weight Loss Device	
Intragastric Balloon	Stomach distension; reduce volume required for satiety; delay gastric emptying
Orbera[1]	
ReShape[1]	
Obalon[1]	
Duodeno-jejunal bypass sleeve	Delay Gastric Emptying; Induce Malabsorption
Aspiration therapy	Reduce Intragastric Nutrients
Use of intraluminal suturing	
Endoscopic sleeve gastroplasty	Induce early satiation; delay gastric emptying
Transoral gastroplasty	Reduce volume required for satiety

[1]Listed in order of dates the devices were approved by United States Food and Drug Administration.

The next available step-up therapies for treatment of medically-complicated obesity involve the utilization of newer endoscopic techniques that are now available. These techniques can be divided into either the delivery of a weight loss device or the use of intralumenal suturing to promote weight loss[30] (see Table 4). Individualized care with scheduled post-procedural follow up is important for long-term optimization of an endoscopic weight loss program, as has been supported by studies of adjustable gastric banding[31]. Individuals might also benefit from transition to the use of a well selected long-term weight loss medication.

Upper endoscopy has been utilized for placement of an intragastric balloon, a duodeno-jejunal bypass sleeve, or an aspiration tube. Other than The AspireAssist described below, all of these devices are meant to be removed at 6 to 12 mo after their placement. The United States Food and Drug Administration approved the

first intragastric balloon, the Garren-Edwards bubble in 1985. Interest in intragastric balloon has grown due to the United States Food and Drug Administration' s approval of 3 separate intragastric balloon systems in the past 2 years: the Orbera balloon, the ReShape balloon, and the Obalon balloon. All three balloon systems must be removed after 6 mo. Clinical research has examined factors important for weight loss with the use of an intragastric balloon[32]. The mechanism for weight loss from the fluid filled intra-gastric balloon, *e.g.,* delayed gastric emptying, has also been identified[33]. A duodenojejunal bypass sleeve, EndoBarrier, (GI Dynamics, Inc., Lexington, MA, United States) is available in some countries. This bypass sleeve is a fluoroscopically assisted and endoscopically implanted, removable, and impermeable fluoropolymer sleeve with a nitinol anchor. At upper endoscopy, the 60 cm long device is deployed from the duodenal bulb and into the jejunum under fluoroscopic guidance. In 2016, the United States Food and Drug Administration approved The AspireAssist produced by Aspire Bariatrics, King of Prussia, PA, United States which provides a long term option for patients in the higher body mass index range. At upper endoscopy, a specialized aspiration tube is placed percutaneously into the stomach. This aspiration tube has both an intragastric portion with holes to permit aspiration as well as a skin port. Individuals with an aspiration tube are instructed to aspirate their gastric contents 20 min after a meal containing more than 200 kcal. The device is not meant to be placed in an individual with an eating disorder.

The endoscopic sleeve gastroplasty (ESG), first reported from the Mayo Clinic, Rochester, MN, United States in 2013, has eclipsed all prior failed efforts at altering the gastric lumen endoscopically[34,35]. There have been over 2500 ESG procedures performed worldwide with patient follow-up now exceeding 2 years, and a recent multicenter study using this technique to produce an endoscopic sleeve gastroplasty reported 24-mo weight loss data[36]. Publications with individual and multicenter experiences are appearing and demonstrate not only sustained weight loss but improvement in co-morbidities. There is also published experience discussing mechanisms by which ESG is important a patients' weight loss[37]. Others[38,39] are attempting to duplicate successful weight loss using technologies differing from the existing endoscopic suturing device (OverStitch, Apollo Endosurgery, Austin, TX, United States) presently used for the ESG.

The advantages of development of an endoscopic procedure to mimic the popular and effective vertical sleeve gastrectomy are clear, *e.g.* reduced risk of anesthesia and reduced risk of a gastric leak or perforation. The importance of obtaining long term weight loss data to support durability is supported by results from the surgical literature. In the original report from the Mayo Clinic, Rochester, MN, United States of the surgical non-banded vertical gastroplasty, at 4 years of follow up, only 31% of patients were judged to have persistent excess weight lost[40]. In additional studies, risk factors important for treatment failures after vertical gastroplasty were examined[41]. Even with the availability of this information, a study (published 16 years later) involving seven years of follow up after vertical banded gastroplasty reported staple line disruption in 54% of patients[42]. Sixty percent of patients after vertical banded gastroplasty underwent a major re-operation during this seven year follow up period.

After practicing gastrointestinal physicians incorporate these newer endoscopic techniques into their care of individuals with obesity, a major question will arise as to whether reliable follow up will be obtained. In examination of other endoscopic quality measures, the recommendation that endoscopists should track their adenoma detection rates from screening colonoscopy has been supported by results of interval cancers published in 2010[43]. However, in a 2015 survey of training programs in the United States, 63.8% of programs did not assess adenoma detection rates in their trainees[44]. It is similarly likely that it will be difficult to obtain longitudinal results designed to examine the effectiveness of an ad hoc approach for incorporation into an established gastrointestinal practice of new endoscopic methods for treating individuals with medically-complicated obesity.

COMPLICATIONS DURING BARIATRIC CARE

It is expected[45] that physicians providing bariatric care will properly evaluate, diagnose, and treat individuals who develop complications from their weight loss therapy.

Prevention of complications from weight loss therapy begins by screening patients for their suitability to undergo treatment of medically-complicated obesity. Gastrointestinal physicians will need to decide how they will integrate physiologic (*e.g,* low satiety or rapid gastric emptying), psychological, or psychiatric assessment of eating disorders and underlying psychiatric illness into their practice. For example, it is reported that the prevalence of obesity is higher individuals with schizophrenia[46,47].

Following bariatric surgery, a Danish study has described increased risks of self-harm, psychiatric service use, and the occurrence of mental disorders[48]. With regards to the potential for addiction, persistent opioid abuse can result from even minor surgical procedures[49]. A systematic review of postoperative bariatric patients suggested the presence of increased

alcohol use and increased admissions to substance abuse treatment facilities[50]. Physicians involved in primary weight loss therapy will need a program to screen for these potential problems and regimens for appropriate and sufficient treatment.

SUBSPECIALTY TRAINING OF GASTROINTESTINAL FELLOWS IN BARIATRICS

A second, long-term approach for incorporation of bariatric care into gastrointestinal practice would involve adaptation of the training of gastrointestinal fellows for treatment of and long-term control of medically-complicated obesity. Such an approach is supported by studies demonstrating improved bariatric outcomes in hospitals with accredited bariatric fellowships[51]. The evolution of a field of medicine requires individuals who focus on the evaluation of alteration of proposed methods and treatments. This potential approach should be facilitated by the gastrointestinal trainees' prior internal medicine residency training in subspecialties that provide care for individuals with medical complications of obesity, including endocrinology, cardiology, nephrology, and neurology. It is expected that gastrointestinal fellows trained in advanced endoscopy should be capable of learning the proper application of most endoscopic techniques for weight loss therapy in individuals with medically-complicated obesity. Gastrointestinal fellows will also need training to manage post-operative complications (*e.g.,* leaks, fistulas, and endolumenal revision of the Roux en Y gastric bypass and the sleeve gastrectomy) in patients who have undergone bariatric surgery.

The training time commitment would depend upon the specific bariatric care that the future gastrointestinal physician would plan to deliver. The issue of development of a curriculum incorporating one year of subspecialty training in bariatrics to the present training of gastrointestinal fellows needs to be revisited. A one year period of subspecialty training in bariatrics could incorporate additional rotations with collaborating providers in bariatric medicine, bariatric surgery, nutrition, and psychiatry. The trainees could then be instructed in postoperative care of patients who have undergone bariatric surgery. Trainees could be trained in the management of adjustable gastric bands, postoperative nutritional disorders[52], postoperative symptoms and, as mentioned above, complications after Roux-en-Y gastric bypass surgery[3], and the management of major complications of vertical sleeve gastrectomy including gastric perforation or leak[53] and vomiting/dysphagia[54].

As an advantage of this potential organization, since such training would be provided in accredited programs, longitudinal studies could be developed to examine the potential impact on accepted measures of care, such as complication rates, outcomes, and costs, in individuals with medically-complicated obesity.

CONCLUSION

The prevalence of obesity continues to rise worldwide. This rise increases the incidence of obesity-related diseases, and these obesity-related diseases are an important component of health care costs in countries across the world. Diet and activity programs are largely inadequate for the long-term treatment of medically-complicated obesity. Gastrointestinal physicians to date have not been extensively involved in weight loss programs in individuals with medically-complicated obesity. It is certain that gastrointestinal physicians will incorporate new methods into their endoscopic practice for treatment of individuals with medically-complicated obesity. This change will involve incorporation of new endoscopic techniques into present gastrointestinal practices. Improved bariatric care will likely require an organized curriculum in gastrointestinal training programs. Involvement in weight loss programs induces significant psycho-social disorders. Obtaining optimal results will require practice patterns that screen for recognized pre-disposing gastric physiological disorders and psycho-social disorders, and develop ongoing protocols for the management of complications of bariatric care. Optimizing strategies for the long-term maintenance of weight loss after the use of newer endoscopic techniques remain important ongoing issues.

Abstract

Due to the increasing prevalence of clarithromycin resistance, future of management of *Helicobacter pylori* (*H. pylori*) infections need to be recognized. To now, clarithromycin was the best effective, well-tolerated and safe antibiotic used in treatment of the bacterium, but, increasing trend of resistance reduced efficacy of recommended regimens. Indeed, gastroenterologists are mostly unable to start appropriate therapy-according to the sensitivity profile-due to the certain difficulties in routine *H. pylori* culture procedure and being time consuming method. This announcement by World Health Organization (WHO) was an onset to reconsider current challenging dilemma about *H. pylori* clarithromycin resistant isolates. Therefore, investigating of various factors affecting this nomination by WHO is highly welcomed. In fact, WHO enumerated more than 16 pathogens which seriously threats human life and public health, thus better management or effective guidelines are necessary. Here for the first time, we nominated this phenomenon as "gastroenterologist's persistence" which should be equally investigated as antibiotic resistance. The ability of gastroenterologists to win the game against *H. pylori* infections is highly influenced by their collaboration with diagnostic laboratories to apply susceptibility patterns before any prescription. In conclusion, closer collaboration between two important partners (gastroenterologists and microbiologists) in management of *H. pylori* infection may hopefully trigger an era to remedy current crisis in clarithromycin resistance, a later gastric cancer can be practically preventable.

Core tip: Due to the increasing prevalence of clarithromycin resistance, future of management of *Helicobacter pylori* (*H. pylori*) infections need to be rewritten. To now, clarithromycin was the best tolerated and safe antibiotic used in treatment of the bacterium, but, increasing trend of resistance reduced efficacy of therapeutic regimens recommended. In this paper, we discussed that why persistence of gastroenterologists is a critical item need to be considered if we really aim to increase efficacy of prescribed antibiotics against *H. pylori*.

INTRODUCTION

Helicobacter pylori (*H. pylori*) is an infectious agent colonizes half of the world population and must be eradicated with suitable antibiotics[1,2]. Of twenty years ago, *H. pylori* was recognized as a major cause of peptic ulcers, thus many of these clinicians attempted to treat those colonized individuals with antibiotic[3]. Later, the World Health Organization (WHO) recommended that bacterial elimination can be a useful strategy to decrease mortality of gastric cancer in the world. Subsequently, in the first half of 2017, WHO listed the clarithromycin resistant-*H. pylori* in the category of high priority which requires intense attention on the treatment. This announcement by WHO is an onset to reconsider current challenging dilemma about *H. pylori* clarithromycin resistant isolates. Therefore, investigating of various factors affecting this nomination by WHO is highly welcomed. In fact, WHO enumerated more than 16 pathogens which seriously threats human life and public health, thus better management or effective guidelines are necessary. New visions of *H. pylori* treatment as well as the better insight of uncertain prescription of antibiotics in the fight against this bacterium is guaranteeing the solution to address the dilemma. Until 2004, *H. pylori* standard triple therapy include proton pump inhibitor (PPI), amoxicillin and clarithromycin providing the acceptable eradication rate, however, increased prevalence of antibiotic resistance hampered continuing the triple therapy for next years. As such, newer formulations were in the focus of researches among the gastroenterologists and microbiologists. As first line treatment for *H. pylori*-positive subjects, bismuth quadruple therapy or concomitant therapy consisting of a PPI, clarithromycin, amoxicillin, and metronidazole are now highly recommended by many international guidelines[4-11]. Therefore, it seems that clarithromycin has an inevitable role in *H. pylori* treatment and even bacterial resistance seems not be able to remove its existence from therapeutic lines. In next section, we review the importance of clarithromycin and how the bacterium became resistant to this commonly used drug in treating the *H. pylori*.

H. PYLORI THERAPY-CLARITHROMYCIN AS KEY ANTIBIOTIC

Due to the traditional microbiologic rule, an infectious agent should be treated with appropriate antibiotics following the susceptibility tests. Despite many problematic infectious bacteria, the story is different for *H. pylori*. Notably, the success chance of regimen include clarithromycin, if a resistant bacterium exists, is less than 40%. This disappointing rate can apparently reflect the irrefutable role of clarithromycin as a core antibiotic in *H. pylori* therapy. The problem with this critical role is that antimicrobial resistance to this drug is sharply increasing and our hopes to have successful eradication regimens (*i.e.,* consistent treatment success > 90%) including the clarithromycin is unfortunately falling.

CLARITHROMYCIN MECHANISM OF ACTION AND RESISTANCE

Clarithromycin is a bacteriostatic antibiotic mostly used in childhood to treat upper respiratory infections, but, its application to treat *H. pylori* is the most used indication[12,13]. The main action mode of clarithromycin as one of the wide-spectrum antibiotics used in *H. pylori* therapy is to prevent protein translation. Current knowledge about mechanisms of resistance to clarithromycin has shown the importance of several point mutations in the peptidyltransferase region encoded in domain V of 23s rRNA[14-16]. In 1996, versalovic *et al*[14] has shown that responsible mutations in the peptidyltransferase region cause an inhibition in binding space between the ribosomal subunit dedicated to specific antibiotic-related protein synthesis and clarithromycin.

Following the first exposure to the clarithromycin, spontaneously mutations (in both 23S rRNA operons) confer *H. pylori* resistance phenotype and genotype. The direct impact of these mutations is emergence of *H. pylori* strains resistant to clarithromycin. To now, two major mutations A2142G and A2143G were listed as main cause of antibiotic resistance in clinical isolates[17]. Indeed, the problem is started since the first exposure is not occurred against *H. pylori*. Clarithromycin is usually used to treat upper respiratory infections, therefore, colonized *H. pylori* is exposed in childhood

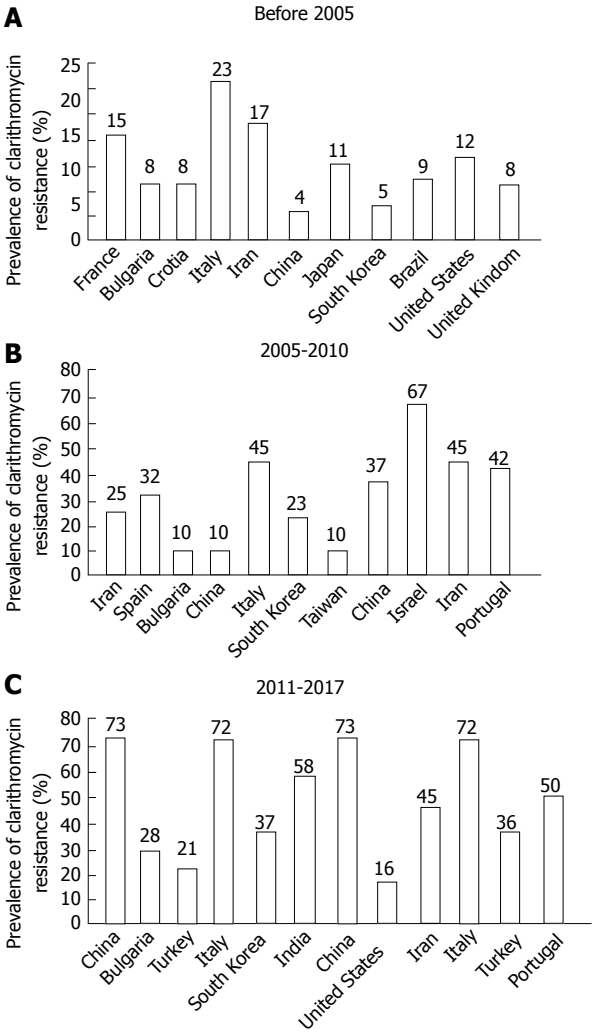

Figure 1 Resistance to clarithromycin among the *Helicobacter pylori* isolates in various countries. A: Before 2005; B: 2005-2010; C: 2011-2017.

already, while no gastroduodenal disorders happened! Another problematic side of this scenario is that antibiotic stress can easily increase the frequency of inducing mutations in cells. This fact in light of relevant usage of clarithromycin for upper respiratory infections in childhood can excuse why we need to be worried about wide-spread prescription of clarithromycin in clinical practice. In brief, our bacteria are almost resistant before we start to use clarithromycin against them in anti-*H. pylori* therapy. In other hands, efflux pump system is also a potential mechanism that confers clarithromycin resistance[18]. Current findings are insisting on at least four families of gene clusters of efflux pumps in *H. pylori* isolates[18,19]. Of them, the family that is found only in Gram-negative bacteria, is the resistance-nodulation-cell division (RND). Bina *et al*[20] was first reported this family of efflux pumps, but additional data are missing to prove exact role of these structures to induce antibiotic resistance in *H. pylori*. The present data show that existence of efflux pumps in *H. pylori* strains can have synergic effect to induce antibiotic resistance in parallel with 23S rRNA mutations. The different angle of the problem is that while we still publishing the papers indicating on increased the emergence of clarithromycin resistance, our holistic view on the rationale for skyrocketing increase in resistance to clarithromycin is missing. Because of antibiotic resistance is a dynamic phenomenon, it may be found with outstandingly different rates even in a state of a country. In reality, the spread of clarithromycin resistant-*H. pylori* has another dimension which remains often undiscussed. Given a sharp increase in clarithromycin resistance during the last decade worldwide (P value < 0.011), *H. pylori* become difficult to eradicate even using various treatment guidelines (Figure 1). Within these three 5 years duration, we can understand the clarithromycin is getting more and more useless antibiotic against *H. pylori* in many countries.

CLARITHROMYCIN RESISTANCE: MOLECULAR DETECTION METHODS

Indeed, in absence of reliable culture-based method to produce data on susceptibility tests, molecular methods were developed rapidly in last decade[17]. Based on available molecular methods tracking 23S rRNA gene, a long list of methods have been developed to quickly identify resistance in colonized *H. pylori* strains to the clarithromycin (Table 1).

Apart from progress have been made, still we are lacking in a quick method with accurate findings. Taking together, real-time PCR can be proposed as best option to be used in hospitals and even smaller centers. During the last years, many companies started to produce this machine and now it is way cheaper than 10 years ago (almost 10 folds). Therefore, we are suggesting to apply this machine to see what kind of mutations are existed 23S rRNA gene and forthcoming susceptibility profile will be easier to present.

NEW DIMENSION OF PROBLEM: GASTROENTEROLOGIST'S PERSISTENCE

Face to face with the problem, we definitely need gastroenterologists more actively involved. So far, due to the clinical and official settings, many of microbiologists do not have any access to the patients. The data for antibiotic susceptibility tests mainly come from laboratories which are dominated by microbiologists. Thus, as a historic conflict between clinicians and basic medical scientists, lack of connection can result in blind antibiotic prescription by the gastroenterologists. Another evidence for this conflict is that almost none of famous microbiologists are co-authored in recently published guidelines on treatment or diagnosis of the *H. pylori.* Moreover, the story is exacerbated when the microbiology journals have no scope for publishing such guidelines. This existed, but, unwanted gap deserves an intense attention to improve management of patients carrying *H.*

Table 1 Molecular methods to identify mutations induce clarithromycin resistance in clinical *Helicobacter pylori* isolates

Methods	Advantages	Disadvantages	PCR-based method	Ref.
Real-time PCR	Quick and reliable High specificity, high sensitivity	Relatively expensive	Yes	[21]
PCR-LiPA	Fast and cheap	Moderate specificity and sensitivity	Yes	[22]
DNA sequencing	Produce many information,	Expensive, Time-consuming protocol	Yes	[23]
3′-mismatch PCR	Fast and high specificity	Produce limited data on the gene, not practically useful	Yes	[24]
RFLP	High specificity, high sensitivity	Risk of contamination Low reproducibility	Yes	[15,25]
FISH	High specificity, high sensitivity	Need invasive approach so not good for children	No	[26,27]

FISH: Fluorescence in situ hybridisation; RFLP: Restriction fragment length polymorphism; PCR-LiPA: PCR line probe assay.

pylori with resistance to clarithromycin. As we described above, in infectious diseases, treatment is highly recommended based on susceptibility pattern, a fact does not follow in the case of *H. pylori*. In other words, treatment of *H. pylori* in many of clinics are based on personal experiences by the gastroenterologists than antibiotic susceptibility tests determined in a microbiology laboratory. With this regard, an incoherent connection between those two populations is a major cause of inappropriate drug prescription ending in increased antibiotic resistance worldwide. Therefore, WHO announced that we are facing with the new generation of resistant *H. pylori* isolates to clarithromycin which endangers effectiveness of current chemotherapy against the bacterium. By continuing the current situation, the replacement of *H. pylori* by WHO in a critical level of priority in a ranking of threatening pathogen is not far from the mind. The next uninvestigated part of the problem is a natural persistence of clinicians on the application of susceptibility patterns reported by microbiologists! For example, metronidazole resistance is not under 60% in many of regions worldwide[28-31], but any trials can show intrinsic tendency among the clinicians who aim to use this ineffective drug for eradicating the *H. pylori*. Taking together, our knowledge about antibiotic resistance has evolved nicely during the relatively short time we treating the *H. pylori*, however, we need new insight on how to increase the reliability among the clinicians to use susceptibility pattern to efficiently eliminate the bacterium especially in patients at least with severe gastroduodenal disorders. Here for the first time, we called this phenomenon as "gastroenterologist's persistence" which should be equally investigated as antibiotic resistance. The ability of gastroenterologists to win the game against *H. pylori* infections is highly being influenced by their collaboration with diagnostic laboratories to apply susceptibility patterns before any prescription. Therefore, two major targets should be considered, (1) antibiotic resistance; and (2) clinician's persistence. Invasive nature of gastroscopy is a considerable factor that influence on rare access to culture-based information on susceptibility tests. Defeating most of the recommended guidelines to eliminate the *H. pylori* can be a major output of neglecting the clinician's persistence.

CONCLUSION

Nowadays, therapeutic failures in anti-*H. pylori* regimens has emerged as major concern for both gastroenterologists and microbiologists. The recent announcement by WHO should be considered as an alarming sound that indicates on emergence of clarithromycin-resistant strains causing global *H. pylori* treatment failure. Since clarithromycin has a critical role in the success of therapeutic regimens against the *H. pylori*, the spread of its resistant strains can easily hamper our attempts to eradicate this microbe. Conclusively, it is not the exaggeration to consider this antibiotic as the main drug in the treatment of *H. pylori*. We need to repeat that all records insisting on using the clarithromycin before recommending as anti-*H. pylori* agent should be considered as serious alarming item. Although the ideal and effective therapy to eliminate the *H. pylori* is not available, but optimizing the current formulations especially, cautious application of clarithromycin in regions with resistance rate > 20% is a likely successful approach. New research direction to produce and suggest novel antibiotics are welcomed to compensate the lacking in antimicrobial agents listed as therapeutic options. In future, application of MALDI-TOF as a novel method can be used directly to detect mutations from biopsy sample; a suggestion which is not far away. To my knowledge, this is one the first paper that pinpoints the gap between gastroenterologists and microbiologists following nomination for *H. pylori* as high priority pathogen by WHO. To be honest, although the persistence of gastroenterologists is a critical factor to increase antibiotic resistance among *H. pylori* strains, but, difficulties in bacterial culture, time consuming procedure of culture and high cost for rapid detection

of resistance are the list which belongs to another side of involving individuals. Finally, closer collaboration between two important partners (gastroenterologists and microbiologists) in management of *H. pylori* infection may hopefully trigger an era to remedy current crisis in clarithromycin resistance, a later gastric cancer can be practically preventable.

Abstract

An awareness of the expected time for therapies to induce symptomatic improvement and remission is necessary for determining the timing of follow-up, disease (re)assessment, and the duration to persist with therapies, yet this is seldom reported as an outcome in clinical trials. In this review, we explore the time to clinical response and remission of current therapies for inflammatory bowel disease (IBD) as well as medication, patient and disease related factors that may influence the time to clinical response. It appears that the time to therapeutic response varies depending on the indication for therapy (Crohn's disease or ulcerative colitis). Agents with the most rapid time to clinical response included corticosteroids, calcineurin inhibitors, exclusive enteral nutrition, aminosalicylates and anti-tumor necrosis factor therapy which will work in most patients within the first 2 mo. Vedolizumab,

methotrexate and thiopurines had a longer time to clinical response and can take several months to achieve maximal efficacy. Factors affecting the time to clinical response of therapies included use of concomitant therapy, disease duration, smoking status, disease phenotype and advanced age. There appears to be marked variation in time to clinical response for therapies used in IBD which is further influenced by disease and patient related factors. Understanding the expected time to therapeutic response is integral to inform further decision making, maintain a patient-centered approach and ensure treatment is given an appropriate timeframe to achieve maximal benefit prior to cessation.

Core tip: There appears to be marked variation in time to clinical response for therapies used in inflammatory bowel disease which is further influenced by disease and patient related factors. The most rapid response can be expected with corticosteroids, calcineurin inhibitors, exclusive enteral nutrition, aminosalicylates and anti-tumor necrosis factor therapy (within 2 mo), while methotrexate, thiopurines and vedolizumab can take several months to achieve maximal response. There is a lack of reporting of the time to response of therapies in clinical trials for inflammatory bowel disease and this remains an area that should be addressed in future studies.

Time to clinical response and remission for therapeutics in inflammatory bowel diseases: What should the clinician expect, what should patients be told? *World J Gastroenterol* 2017; 23(35): 6385-6402 Available from: URL: http://www.wjgnet.com/1007-9327/full/v23/i35/6385.htm DOI: http://dx.doi.org/10.3748/wjg.v23.i35.6385

INTRODUCTION

The therapeutic armamentarium for inflammatory bowel disease (IBD), comprising Crohn's disease (CD) and ulcerative colitis (UC), continues to expand, providing valuable additional opportunities to achieve optimal long term outcomes for patients. Equally, however, there is added complexity, commensurate with the number of options, an enhanced understanding of the risks and benefits, plus the differential effects of treatments on objective disease outcomes (*e.g.*, mucosal healing), clinical remission and/or patient-reported outcomes.

Yet when better outcomes are potentially achievable, there are higher expectations. It is increasingly important with current therapeutics that the physician plans ahead, given delays in escalating treatment are likely just as common and detrimental as delays in diagnosis are in IBD[1]. Hence an awareness of the approximate time expected to achieve a treatment goal is fundamental to making decisions such as whether to persist with a therapy or switch to an alternative. Equally, one does their patient a disservice by prematurely switching therapies before an agent is given an appropriate length of time to achieve efficacy.

Achieving an optimal time to therapeutic response has further benefits in the doctor-patient relationship, as it allows the clinician to provide the patient a cogent framework of the expected period to see response to a new drug and hopefully empower the patient to persevere with, and maintain adherence to therapy. This is particularly relevant for therapies that have a longer time to therapeutic response, such as the immunomodulators, where it might take several months to reach maximal therapeutic efficacy without the patient necessarily experiencing any symptom benefit for a significant part of this.

Hence, time-to-therapeutic response is an important yet underestimated factor in the day-to-day management of IBD and has not been a major focus of attention in the literature to date. This review attempts to address this unmet need by analyzing the available literature relating to the expected time-to-clinical-response for currently available therapies in IBD and measures that can assist the clinician in determining whether a medication has reached its therapeutic potential. We will also analyze disease and patient related factors that may impact on the time-to-clinical-response of therapies. Therapies discussed in the review will include corticosteroids, aminosalicylates (5-ASA), thiopurines, methotrexate, anti-tumor necrosis factor (anti-TNF) therapies, vedolizumab, calcineurin inhibitors and exclusive enteral nutrition.

DEFINING TIME TO CLINICAL RESPONSE AND REMISSION

The concept of time-to-clinical-response is schematically represented in Figure 1. Given the lack of focus on time to response in previous literature, there is no broadly accepted definition. Table 1 provides a summary of some of the important components of time to response. These include the earliest time at which a patient can expect a response, the time at which most patients (*i.e.*, greater than 50%) expecting to benefit from therapy will achieve a response and the time point where therapeutic benefit remains improbable, the so-called time to futility. For this review, time-to-clinical-response refers to the time from the initiation of therapy until the patient achieves a clinical response. It only pertains to patients who attain a clinical response and can thereby aid the

Table 1 Expected time to clinical response for therapeutic agents used in the management of inflammatory bowel disease

Agent	Earliest published clinical response	Earliest published objective response	Time to response in most patients[1]	Time to futility	Use of therapeutic drug monitoring	Comments
Mesalazine (oral)	1 wk[21]	3 wk[148]	4 wk	> 12 wk	N	A higher dose may lead to a more rapid response
Prednisolone (oral)	2 wk[28]	2 wk[28]	3 to 7 wk	8 wk	N	May take longer for CD
Corticosteroids (IV)	3 d[31]	1 wk[127]	3-5 d	7-10 d	N	
Infliximab (IV)	1 wk[48]	8 wk[149]	2-8 wk	> 6 mo	Y	
Adalimumab (SC)	4 wk[59]	8 wk[59]	4-8 wk	> 6 mo	Y	Response time better with 160/80 mg *vs* 40/40 mg induction dosing
Certolizumab (SC)	2wk[61]	10 wk[64]	10 wk	> 16 wk	N	
Golimumab (SC)	6 wk[65]	6 wk[65]	6 wk	> 14 wk	Y	
Certolizumab (SC)	2 wk[61]	10 wk[64]	10 wk	> 16 wk	N	
Vedolizumab (IV)	6 wk[78]	6 wk[78]	19 wk	12 mo	N[2]	Response time may be better for UC *vs* CD
Thiopurines (oral)	2 wk[80]	3 mo[88]	10 to 12 wk	> 6-9 mo	Y	Endoscopic response may take much longer than clinical response
Methotrexate (oral or SC)	9 wk[111]	12 wk[110]	9 wk	> 6 mo	N	Response time and efficacy may be better in 1) CD *vs* UC, 2) SC *vs* oral
Cyclosporin (IV then oral)	1 wk[127]	1 wk[127]	4 to 5 d	> 14 d	Y	
Tacrolimus (oral)	2 wk[122]	2 wk[122]	2 wk	4 wk	Y	
EEN (oral)	10 d[131]	4 wk[139]	3 to 4 wk	8 wk	N	

[1]Clinical response reported in at least 50% of patients who achieve a response to therapy; [2]Therapeutic drug monitoring is not yet widely available. EEN: Exclusive enteral nutrition; IV: Intravenous; SC: Subcutaneous; Y: Yes; N: No; CD: Crohn's disease; UC: Ulcerative colitis.

clinician in judging the likelihood of a response being achieved based upon the elapsed time on therapy. Where available, estimates of timeframes in which the majority of patients who ultimately respond to therapy will be expected to respond to therapy will be reported. The time to futility of therapy is reported in Table 1, however, this will not be a primary focus of this review.

The methods of determining when a "response" has occurred are heterogeneous and include both clinical symptoms and endoscopic (or objectively-assessed) findings. The correlation between symptomatic improvement and achievement of endoscopic remission differs between UC and CD, with improvement in symptoms correlating better with mucosal healing in UC than CD[2-5]. There are data to support early clinical remission, albeit not response, to be predictive of endoscopic improvement and healing at 12 mo[6]. The value of symptomatic improvement, however, cannot be discounted from a patient's perspective given the correlation with long-term steroid-free remission and the inherent part that alleviation of symptoms plays in improving quality of life[5,7]. Moreover, the complex interplay of patient symptoms and structural damage in IBD is being increasingly recognized with both symptoms and endoscopic findings important factors in determining overall disease severity and burden[8].

Thus, response is a multi-faceted concept and this review will primarily address the time-to-clinical-response and time-to-clinical-remission, given that the focus here is to engender a patient-centered approach when clinicians discuss therapeutic options with their patients. Time to endoscopic response and remission will also be reported where data are available, although this is a secondary focus.

Given the heterogeneity across studies in defining clinical response, clinical remission and endoscopic remission, we have used broad outcome measures of "clinical or endoscopic improvement" or "clinical or endoscopic remission or mucosal healing" as defined by the authors of each study. For the purpose of this review, clinical response will consider symptom improvement only rather than an improvement in symptoms and laboratory indices.

A summary of the relative time-to-therapeutic-response of different therapies for IBD is presented in Table 1 and Figure 1. Medication related factors that influence the time to response of different therapies are discussed within each of the therapeutic classes.

AMINOSALICYLATES

Time to clinical response

Aminosalicylates are more effective at inducing response and remission in patients with mild-moderate ulcerative colitis than placebo[9], but their evidence for efficacy in patients with Crohn's disease is poor[10,11]. Therefore, with regards to ulcerative colitis, available data indicate that it generally takes two to four weeks to achieve clinical response with oral and/or topical aminosalicylates. Mesalazine induces endoscopic remission in 67% of patients at 4 wk for active colitis for both 2 and 4 g preparations, while another study found higher endoscopic remission rates of 78% and 69% after 8 wk with multimatrix mesalazine 4.8 g and 2.4 g, respectively, suggesting some patients who will achieve endoscopic remission may take up to 8 wk[12,13].

Therapy-related factors affecting time-to-response

Key issues for aminosalicylates include whether the formulation, the dose and/or the route(s) of delivery

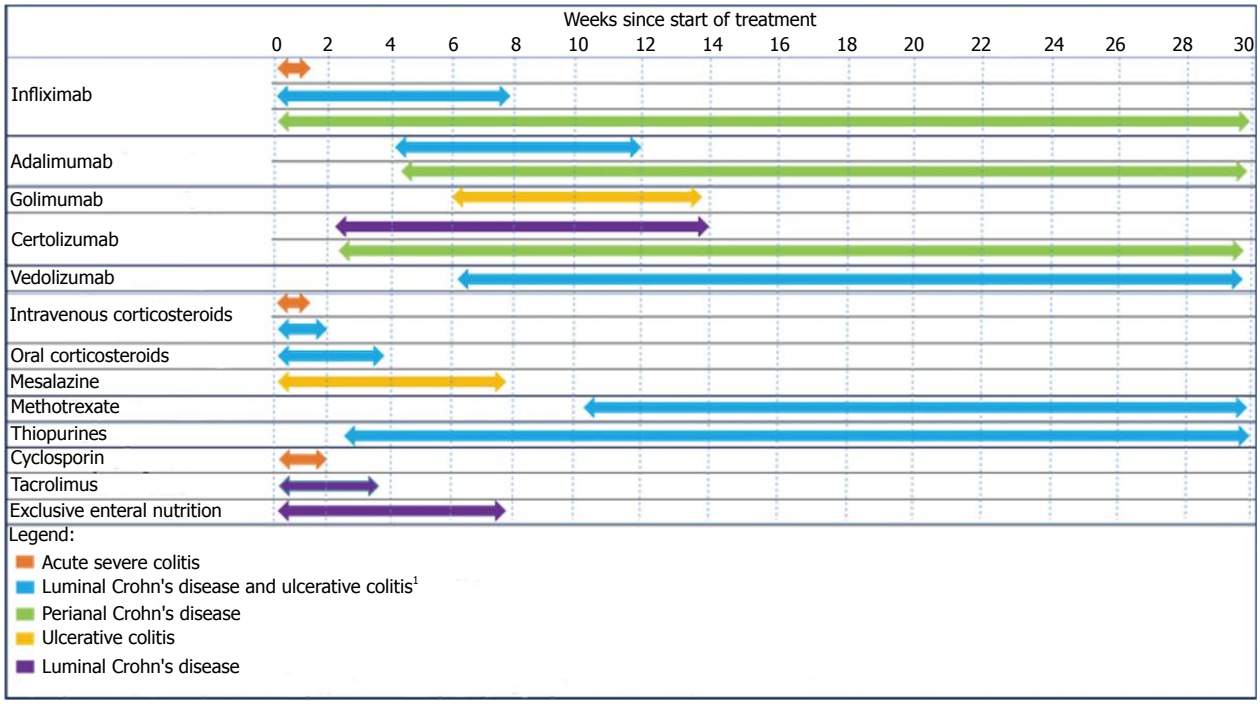

Figure 1 Schematic representation of the range of expected time of clinical response for therapies based on indication. [1]This symbol is used to represent the expected time to response for therapies that can be used in either condition.

influence the speed of onset of action.

Formulation: Trials of sulfasalazine, olsalazine and balsalazide in mild to moderate UC demonstrated an improvement in clinical symptoms and endoscopic response with 2 to 3 wk of therapy in most patients[14-17]. In contrast according to published data, coated mesalazine preparations demonstrated a somewhat slower clinical and endoscopic improvement within 4 to 8 wk[18,19]. Two head-to-head studies suggested that an equimolar dose of balsalazide resulted in a more rapid clinical and endoscopic response than delayed-release mesalazine (using Eudragit S-coated tablets) therapy for patients with left-sided disease[17,20].

Dose: Time to therapeutic response for aminosalicylates may also be dose-dependent as demonstrated by Orchard *et al*[21] who found that 4.8 g daily of mesalazine (delayed release, Asacol MR®) improved and resolved symptoms more rapidly than 2.4 g daily (median 7 d *vs* 9 d, 19 d *vs* 29 d respectively). Another study found a numerically faster time-to-clinical-response with mesalazine 4.5 g than 3 g or 1.5 g daily[22]. Kamm *et al*[13] described numerically higher endoscopic remission rates of 78% after 8 wk with mesalazine MMX 4.8 g *vs* 2.4 g daily (69%), but whether this equates to faster response in those who achieve remission was not reported[12,13].

Route of delivery: Combined oral and topical mesalazine was associated with more rapid resolution of rectal bleeding (mean 11.9 d) than with oral mesalazine only (25.5 d) for left-sided colitis in the only randomized study reporting this end-point[23]. Another randomized trial of sixty patients with distal UC comparing oral mesalazine with mesalazine enemas or combination topical and oral treatment found a median time to resolution of rectal bleeding of 8 d on combination therapy and bleeding were significantly lower after ten days with either topical or combination therapy compared to oral mesalazine only. The findings indicate that topical therapy alone or in combination with oral therapy achieves symptom resolution more rapidly than oral therapy[23,24]. The efficacy of topical 5-ASA does not appear dose-dependent in the single study where this was specifically examined, but rapidity of response was not addressed[25].

CORTICOSTEROIDS

A clinical response to steroids should be expected within 1 to 4 wk of commencing therapy for both CD and UC (not applicable to acute severe colitis) with response occurring more rapidly with intravenous than oral therapy[26,27]. There are several types of corticosteroids available for the treatment of IBD and the influence of route of administration and type of corticosteroid are relevant to determining the time to response, as discussed below.

Time to clinical response

CD: Although most patients with CD can expect a response to high dose oral corticosteroids within 4 wk, some data suggest a more prolonged course

may be necessary to capture response. For example, clinical response after three to seven weeks of 1 mg/kg per day oral prednisolone in a prospective cohort study of 146 patients with active ileocolonic or colonic CD increased from 63% to 92% between weeks 4 and 7 respectively, although only 29% achieved endoscopic remission[2]. These data suggest that a clinician should wait up to 7 wk before deciding that a response to high doses of prednisolone is unlikely if that approach is clinically acceptable.

UC: Response to oral prednisolone is rapid in UC, with 17%-76% achieving clinical remission and 65%-78% endoscopic improvement after 2 wk of oral prednisone in two randomized studies, with the higher response rates noted by Truelove *et al*[28] who used both oral and rectal prednisolone in combination[28,29]. Other studies have also suggested a response within the first two weeks of a tapering dose of oral prednisolone beginning at 40 mg/d in the majority of patients with moderate UC[30].

Therapy related factors affecting time to response

Route of administration: (1) CD: While direct comparisons between intravenous and oral corticosteroids are not available in CD, response appears rapid with intravenous corticosteroids, with 78% of patients having symptom resolution after five days of intravenous hydrocortisone (300 mg daily), which increased to 93% after 10 d in one randomized study comparing intravenous hydrocortisone to corticotrophin, to which response rates were also high (71% and 82% at days 5 and 10, respectively)[27,31]. (2) UC: Moderate UC has been shown to typically improve within five days of intravenous corticosteroids, including patients who failed to respond to high-dose oral prednisolone. Time frames for expected response are well described for acute severe colitis, where most patients appear to respond to therapy within 3 or 5 d of intravenous steroids (methylprednisolone 60 mg/d or hydrocortisone 300-400 mg/d), although these are observational data only[32-35]. A lack of response within 5 d is associated with a higher rate of subsequent colectomies again in observational studies, and therapy beyond 7 d is unlikely to be beneficial[36].

Type of glucocorticoid: (1) CD: Several randomized studies have suggested the mean times to clinical response and remission with budesonide in CD were comparable to systemic corticosteroids, ranging from 22 to 27 d[37-40].

(2) UC: Induction of remission when using budesonide MMX 9 mg daily in mild to moderate UC should occur within 4 to 8 wk of commencing therapy, with 42%-47% of patients achieving an endoscopic or clinical improvement in randomized controlled trials (RCT)[41,42].

Dose: The effect of corticosteroid dose on time to response has not been evaluated. One randomized study assessed response rates with 20 mg, 40 mg and 60 mg daily of oral prednisolone for outpatient management of ulcerative colitis and suggested a higher response rate at both 2 wk and 3-5 wk of follow-up with 40 and 60 mg/d of therapy (both 50% at 2 wk, then 65% at 3-5 wk respectively) compared to 20 mg daily (20% then 30%), but did not specifically assess time to response[30]. Determining the appropriate dose of steroid has traditionally been either empiric or weight-based. Accordingly, corticosteroid dosing evaluated in clinical trials has varied; for instance, studies have used 1 mg/kg/d or 40-60 mg/d of prednisolone, 9 mg of budesonide orally, while for intravenous therapy includes 300-400 mg/d of hydrocortisone (divided doses) or 60 mg/d of methylprednisolone[26,43,44].

TUMOR NECROSIS FACTOR ALPHA INHIBITORS

Pertinent issues relating to time to therapeutic response of anti-TNF therapy include the associations with serum drug levels and antibodies, plus concomitant therapy.

Time to response

Infliximab: (1) CD: Clinical response and remission after administration of infliximab appear to be rapid in luminal CD, taking 8 and 9 d respectively in one observational study of 129 patients[45]. Clinical response rates in RCTs of infliximab in CD were 61% and 81% for weeks 2 and 4 respectively after a single infusion of infliximab[46,47]. Clinical remission rates were reportedly 88% one week after a single infliximab dose for colonic CD although the data were observational only[48]. Rates of mucosal healing in Crohn's disease have ranged from 30%-67% after 6 mo of infliximab, with higher rates typically observed in 'real-world' clinical cohorts than trials[49,50].

(2) UC: Clinical and endoscopic response to infliximab in patients with moderate to severe chronic active ulcerative colitis appears to take several weeks, although this may be due to a lack of reporting of early outcomes after initiation of therapy in the outpatient setting, given that response rates reported for acute severe colitis are generally more rapid than this. Nevertheless, about half of patients previously not responding to either intravenous or oral corticosteroids experienced a clinical response two weeks after the first infusion of infliximab in one prospective uncontrolled study[51]. Such early response rates have not been reported in RCTs, but data from such studies have shown a significantly higher rate of clinical response (69% *vs* 37%), remission (39% *vs* 15%) and mucosal healing (62% *vs* 33%) by week 8 with 5 mg/kg induction dosing versus placebo[52]. For infliximab

use in ulcerative colitis, two large randomized studies of moderately severe ulcerative colitis showed a significantly higher rate of mucosal healing by week 8 with after both 5 mg/kg and 10 mg/kg induction therapy (62% *vs* 33% with placebo)[52].

For acute severe colitis, a clinical response to infliximab therapy should be expected within the first 7 d after therapy[53]. Achieving a higher serum infliximab level during induction has been associated with a higher rate of short term mucosal healing and an accelerated induction regimen of infliximab in acute severe colitis has been associated with a more prolonged time to colectomy than standard induction, although the rapidity of response has not been directly assessed[54,55]. Indeed, recent data suggest that a rebound of higher C-reactive protein, lower albumin and/or symptoms within a few days after the first dose of infliximab should prompt concerns of infliximab non-response and a potentially higher risk of colectomy[55]. A trial is currently underway to assess the utility of an accelerated induction regimen of infliximab in acute severe colitis and this may provide further information on the effect of dose and drug levels on time to response[56].

Adalimumab: (1) CD: An initial response to adalimumab typically occurs within the first few weeks of therapy, as inferred from a phase 2 RCT showing clinical remission rates of 36% at week 4 following induction treatment with 160/80 mg at week 0 and 2 for CD, compared to 12% with placebo[57]. While clinical remission rates were higher from week 1 than placebo in this study (16% *vs* 7% respectively), this only reached statistical significance at week 4. Moreover, the rate of mucosal healing for moderately severe ileocolonic CD with induction 160/80 mg adalimumab followed by 40 mg fortnightly was significantly higher than placebo at 12 wk (27% *vs* 13%) and sustained until 52 wk (24% *vs* 0%) in another RCT[58]. Endoscopic remission rates were 52% and 28% at weeks 12 and 52 respectively in this study, the latter likely reflecting secondary loss of response during maintenance therapy.

(2) UC: Clinical remission and mucosal healing rates with adalimumab induction with 160/80 mg regimen in patients with moderate to severe UC after 8 wk was achieved in 19 and 47% respectively, with separation in clinical remission rates as early as week 4 compared to placebo in a RCT[59]. The lower remission rates in this study may relate to the high proportion (75%) of patients who had failed other therapies prior study enrolment[59]. In another RCT assessing long term remission rates with adalimumab in moderate to severe UC, mucosal healing rates were 41% at week 8 and 25% at week 52 with fortnightly adalimumab 40 mg, compared to 32% and 15% for placebo, respectively[60]. Mucosal healing rates following adalimumab induction for UC have varied between 32% and 47% in RCTs[59,60].

Certolizumab pegol: CD: Certolizumab pegol at a dose of 400 mg given subcutaneously at weeks 0, 2 and 4 wk, about a third of patients with CD will have a clinical response to therapy within 2 wk, increasing to 41% by week 6 based on RCT data[61]. One study found response rates peak at 10 wk of 400mg 4-weekly therapy[62], while another study found response rates, as per a reduction in CDAI of 100, peaked by week 16 and declined thereafter[63]. Endoscopic activity was assessed at week 10 in one prospective, open label clinical trial of patients on 400 mg certolizumab 4-weekly and showed endoscopic remission occurred in 37%, reducing to 27% by week 54 in CD[64].

Golimumab: UC: Golimumab is administered subcutaneously and has been approved for use in ulcerative colitis in many countries. Approximately half of patients will achieve a clinical response by 6 wk with regimens of 100/200 mg and 400/200 mg as induction at weeks 0 and 2 for moderate to severe ulcerative colitis from one large RCT[65]. Observational data suggest that response rates may continue to increase up until week 14, when reported to be between 69% and 86%[66,67]. Mucosal healing appears to be rapid, with 42 and 45% of patients achieving mucosal healing 6 wk after induction therapy with 100/200 mg and 400/200 mg, respectively[65]. Intravenous induction therapy for golimumab does not appear to confer any additional benefit in terms of response rate compared to subcutaneous induction, although time to response of this strategy has not been evaluated[68]. Since there are no data evaluating clinical response rates beyond week 14, the benefits of continuing therapy beyond this time point in patients who have not achieved a response remains uncertain.

Factors affecting time to response

Demographic factors: One study assessed baseline factors that were predictive of a more rapid attainment of clinical remission with induction certolizumab therapy for CD and found that younger age, non-smokers, the absence of previous IBD surgery and a lower disease activity score were associated with a more rapid attainment of clinical remission[69].

Anti-TNF drug levels: Currently, data supporting a correlation between anti-TNF drug levels and time to therapeutic response are limited. For golimumab, drug levels at weeks 2 and 4 were shown to correlate with week 6 clinical response rates, but the effect on time to therapeutic response was not further assessed as response was only evaluated at a single time point in this study[70]. Higher certolizumab plasma concentrations at week 8 are associated with higher rates of clinical remission and endoscopic remission

at week 10, but not a higher clinical response rate[71]. There is a lack of data concerning the relationship between time-to-response for infliximab and adalimumab in relation to drug levels.

Concurrent immunomodulator therapy: While time to response has not been directly compared between anti-TNF monotherapy and in combination with immunomodulator therapy, there was a trend toward a higher rate of clinical remission at week 10 with combination infliximab and azathioprine compared to infliximab alone in the Study of Biologic and Immunomodulator Naive Patients in Crohn's Disease (SONIC) Study, and a significantly higher rate of endoscopic remission at 26 wk with adalimumab and azathioprine, suggesting combination therapy may work faster than either therapy alone[50,72]. Similar findings of more rapid clinical remission have also been found for certolizumab therapy when used with concomitant immunomodulator therapy in CD[69].

VEDOLIZUMAB

Vedolizumab appears to have a generally slower time to response compared to other biologic agents. This may relate to the mechanism of anti-integrin therapy, with inhibition of lymphocyte gut migration taking more time to achieve therapeutic efficacy[73].

Time to response

CD: Clinical remission with vedolizumab appears to take at least 10 to 14 wk in CD. This slower onset of action of vedolizumab, compared to anti-TNF therapies for instance, was evident in the RCTs GEMINI 2 and 3 registration trials of vedolizumab comparing therapy to placebo induction and maintenance therapy in CD[74]. Clinical remission rates increased from 15% to 27% between weeks 6 and 10 while remained stable in the placebo group (12%) at these time points in GEMINI 3 (*i.e.,* those with prior anti-TNF failure), and in GEMINI 2 there was a significant increase in clinical remission after 6 wk compared to placebo[73]. Subsequent real-world observational data have also demonstrated that clinical remission rates tend to increase from week 6 to week 14 and in one study the median time to clinical response was 19 wk[75]. Mucosal healing rates of 30% were attained after a median of 22 wk in CD in one observational study[76]. Furthermore, GEMINI 2 found that almost 40% of initial vedolizumab responders remained in clinical remission to 52 wk although clinical remission rates only became superior to placebo after 30 wk[77].

UC: Response and remission rates appear more rapid in UC than CD. At week 6 after a 2-dose induction, clinical response, remission rates and mucosal healing were significantly higher with vedolizumab than placebo (47%, 17% and 41% *vs* 26%, 5% and 25% respectively) in one RCT[78]. Moreover, maintenance vedolizumab resulted in higher rates of clinical and endoscopic remission at week 52 than week 6 and mean partial Mayo scores continued to decline until week 52, suggesting that maximal response often takes several months.

Therapy-related factors affecting time to response

While immunomodulators appear to reduce the formation of antidrug antibodies to vedolizumab[78], the low proportion of patients who actually formed antidrug antibodies in trials might imply that combination therapy may be unnecessary and hence may not provide additional benefit to time to therapeutic response, in contrast to anti-TNF therapies[78].

THIOPURINES

Thiopurines, including azathioprine and 6-mercaptopurine, appear to exert their effect *via* the metabolites, 6-thioguanine nucleotides (6-TGNs). Thiopurines inhibit the synthesis of DNA, RNA and proteins leading to inhibition of lymphocyte proliferation and apoptosis, thereby immunosuppression[79].

Time to response

CD: Azathioprine or mercaptopurine take at least 4 to 8 wk to achieve clinical remission[80]. A small RCT suggested that a median of 10.7 wk was required to achieve clinical remission with oral azathioprine 2 mg/kg/d[81]. Time to clinical response with 1.5 mg/kg/d of mercaptopurine was assessed in an RCT by Present *et al*[82] in patients with CD failing corticosteroids or sulfasalazine. They demonstrated a wide-ranging time to therapeutic response from two weeks to nine months with a median of 3.1 mo; 19% of cases took more than 4 mo to achieve a sustained clinical response[82]. Similarly, in another RCT, Ardizzone *et al*[83] found a clinical remission rate gain from 33% to 63% from 3 to 6 mo after initiating azathioprine 2 mg/kg/d in patients with corticosteroid-dependent CD. Endoscopic remission rates also appear to be slow to achieve with only 17% of patients on azathioprine in the SONIC study achieving mucosal healing after 26 wk of therapy[50]. Yet another RCT comparing budesonide to azathioprine with 1 year follow up found mucosal healing occurred with thiopurines in 83% of steroid-dependent CD by 12 mo, implying that endoscopic improvement continues to slowly accumulate over extended periods[84].

UC: Both clinical and endoscopic response to thiopurines in UC appear to take a minimum of one month but more typically 3-6 mo for steroid-dependent UC[85,86]. Ardizzone *et al*[87] found that more than half of patients on azathioprine were in steroid-free endoscopic and clinical remission after 6 mo for patients with steroid-dependent UC, which was significantly higher

Table 2 Previously documented and potential/ novel methods of improving time to response to therapy in Crohn's disease and ulcerative colitis

	Clinical scenario	Method	Improves time to response	Improves response rate	Improves tolerability	Published data?	Comments	Ref.
Corticosteroids	CD and UC	Intravenous administration		-	-	Yes		[27,32,150]
Anti-tumour necrosis factor-α	Initial or for flare to recapture response (CD and UC)	Addition of azathioprine			-	Yes		[50]
Thiopurine	CD and UC	Addition of allopurinol	-	-		Yes		[105,108]
		Split dosing of thiopurine	-	-		Yes		[151]
Methotrexate	CD	High dose parenteral with corticosteroids if relapse on lower dose	-		-	Yes	Can recapture response	[152]
Tacrolimus	UC	Target levels of 10-15 ng/mL	-		-	Yes		[123]
Aminosalicylates	UC	Maximize dose			-	Yes		[21]
	Distal UC	Choice of formulation (balsalazide)		-	-	Yes		[17,20]

CD: Crohn's disease; UC: Ulcerative colitis.

than that with mesalazine (53% *vs* 21%) in an RCT. Another RCT showed a significant decrease in a composite disease activity score (including endoscopic, clinical and biochemical findings) at 3 and 6 mo after commencing azathioprine 2.5 mg/kg/d for steroid-dependent UC, implying that time to therapeutic response is likely between 3 and 6 mo[88].

Factors affecting time to response

Metabolite levels: Azathioprine undergoes rapid non-enzymatic conversion to 6-mercaptopurine which is then further metabolized to 6-TGNs in erythrocytes and leukocytes[89]. The therapeutic effect of thiopurines appears commensurate with 6-TGN concentrations, with steady state achieved at two to four weeks, so response can only be expected after this period[90]. Intravenous loading with azathioprine has been associated with a more rapid time to therapeutic response initially (1 wk for clinical response and 4 wk for endoscopic improvement). However, when compared to oral azathioprine at 8 wk, no difference in remission rates or 6-TGN levels had persisted[80,91]. Using dose titration guided by therapeutic drug monitoring, the mean time to therapeutic response decreased from 22 to 19 wk[92]. While prospective studies have not demonstrated a difference in outcomes between patients treated with weight-based and individualized, metabolite-guided dosing of thiopurines[93,94], robust retrospective data elucidated higher rates of clinical remission with 6-TGN levels above 230-260 pmol/8 × 10^8 RBCs[95-97]. Indeed, 78%-90% of patients had improved clinical outcomes from dose optimization after having a sub-therapeutic 6-TGN level[98-100].

Addition of allopurinol: A combination of allopurinol 100 mg and 25%-50% of the standard thiopurine dose has been utilized to overcome a number of thiopurine related side effects and correct an unfavorable metabolite profile (so called hypermethylators), with high clinical efficacy[101-105]. This has piqued interest as to whether combination allopurinol-thiopurine therapy might be able to achieve not only higher rates of, but quicker time to therapeutic response, especially compared to slow-titrating introductory dosing protocols (as advocated by treatment guidelines[26,106] and widely used to mitigate early side effects[107]). The result of controlled trials addressing this issue are awaited[108]. Additional strategies that may affect time to response of therapies are summarized in Table 2.

METHOTREXATE

Methotrexate is a folic acid analogue used in the treatment of multiple autoimmune conditions, including IBD. Methotrexate has been shown effective as an induction and maintenance therapy in CD particularly when administered parenterally. The role of methotrexate in UC is less clear, although a placebo-controlled trial of subcutaneous methotrexate did suggest clinical efficacy in the induction of steroid-free remission[109].

Time to response

CD: A clinical response should be expected within 12 wk on parenterally-administered methotrexate according to an open label, non-randomized trial by Kozarek *et al*[110]. An observational study suggested that the median clinical response time was 9 wk for both oral and parenteral therapy (although 86% were on parenteral therapy in this study) and clinical remission took 22 wk[111]. Despite most patients clinically responding within the first several weeks of therapy, a subgroup may take up to 6 mo to respond[83].

UC: While a placebo-controlled trial of oral methotrexate 12.5 mg in patients with steroid-refractory UC showed no significant difference in clinical remission between the groups, those who reached clinical remission with methotrexate took a mean of 4.1 mo

to do so[112]. Subsequent uncontrolled observations by Kozarek *et al*[110] showed a rapid clinical response (71% within 12 wk) with high-dose intramuscular dosing in UC, albeit in only 7 patients. The METEOR RCT, assessed the efficacy of parenteral methotrexate 25 mg weekly in steroid-dependent UC and found almost a third of patients had corticosteroid-free clinical remission by week 16, which increased to 40% by week 24[109]. Endoscopic remission was achieved in a numerically greater proportion then did the placebo group, but the difference did not reach statistical significance, perhaps due to lack of statistical power.

Factors affecting time to response

Route of administration: It is likely that parenteral methotrexate generally achieves a faster time to therapeutic response in a higher proportion of patients due to greater bioavailability, though supportive evidence is found only in the rheumatological literature[113].

Drug levels: Currently there is no reliable method to apply therapeutic drug monitoring of methotrexate in routine IBD care and this is therefore not useful in predicting time to therapeutic response. Serum methotrexate levels are only detectable for about 24 h post-dose and appear not to correlate with clinical response in IBD[114], adenosine levels do not correlate with efficacy[115], and methotrexate polyglutamates [active metabolite(s) of methotrexate] have displayed inconsistent results[116-118]. Finally, although folic acid is an important adjunct to methotrexate use and may reduce gastrointestinal upset and hepatic dysfunction, it has no apparent impact on time to therapeutic response[119].

CALCINEURIN INHIBITORS

Tacrolimus and cyclosporin are calcineurin inhibitors with evidence in IBD primarily for steroid-refractory UC. Small case series have suggested efficacy of tacrolimus for induction of remission in luminal CD[120]. Cyclosporin is an effective rescue therapy in acute severe colitis and has been used in moderate to severe chronic UC. Oral cyclosporine does not appear to be an effective induction therapy in CD[121].

Time to response

Tacrolimus: (1) UC: When targeting a trough level of 10-15 ng/mL, tacrolimus induces clinical response and mucosal healing rates of 50%-68% and 44%-79% respectively, in patients with UC within 2 wk based on results from two RCTs, with lower rates noted in the larger of these studies[122,123]. In contrast, clinical remission was reported in only 9%-20% after 2 wk in the aforementioned studies, but amongst those who continued tacrolimus, remission rates increased to 29% by week 12, with mucosal healing rates increasing from 67% to 86% over the same time period[122,123]. (2) CD: Small case series suggest a similarly rapid clinical response with tacrolimus in CD refractory to other therapies, occurring within 30-40 d[124,125]. However, time to therapeutic response appears longer than UC, with one study finding that 36% achieved clinical remission by 20 d which increased to 64% at 120 d[125].

Cyclosporin: UC: Clinical response to cyclosporine in acute severe colitis failing to respond to intravenous corticosteroids is usually rapid, with a median response time reported to be 4-5 d, with the vast majority responding within 7 d in two randomized studies[53,126]. Clinical remission rates were approximately 65% with cyclosporine monotherapy and 93% in combination with steroids after 7 d, according to the results of a randomized study by D'Haens *et al*[127] In the above studies, endoscopic response was described within 7 d of initiation, with a continued improvement in endoscopic activity noted between weeks 1 and 4[126,127].

Factors affecting time to response

Dose and drug levels: Targeting high levels (10-15 ng/mL) of tacrolimus for induction appears more effective than low levels (5-10 ng/mL) with possibly a more rapid time to therapeutic response[123]. For ongoing maintenance thereafter, targeting trough levels of 5-10 ng/mL appears sufficient[122-125].

For cyclosporin, no additional benefit in clinical response was achieved with 4 mg/kg compared to 2 mg/kg intravenously in an RCT for acute severe colitis with a median time to response of 4 d in both groups, suggesting that doses above 2 mg/kg do not produce a more rapid time to response[126].

Route of administration: One observational study suggested that oral and intravenous tacrolimus achieved similar rates of clinical response by 14 d in steroid-refractory colitis, with comparable serum tacrolimus levels achieved with both strategies[128]. A retrospective study of oral and intravenous cyclosporin in ulcerative colitis actually found a higher early clinical response rate (exact timing not specified) with oral compared to intravenous cyclosporin (100% *vs* 65%) despite comparable serum drug levels, predominantly due to higher rates of side effects necessitating treatment cessation with intravenous cyclosporin[129]. Time to response was not directly assessed in this study and groups significantly differed with higher proportions of inpatients and intravenous corticosteroid failures in the intravenous cyclosporin group.

EXCLUSIVE ENTERAL NUTRITION

Exclusive enteral nutrition (EEN) involves the administration of a liquid nutrition formula to meet all

Table 3 Factors affecting time to response and response rates of therapies in inflammatory bowel disease

Variable	Parameter	Effect on time to response	Effect on response rate	Medications implicated	Level of evidence[1]	Ref.
Age	> 65 yr	↑	?	Anti-tumour necrosis factor-α (anti-TNF)	2b	Lobatón *et al*[143]
Increased body mass index	BMI > 25	-	↓	Azathioprine	2b	Holtmann *et al*[153]
	Weight > 82 kg	-	↓	Anti-TNF	1b	Reinisch *et al*[59]
Concomitant therapies		↓	↑	Immunomodulators with anti-TNF	1b	Colombel *et al*[50] Sandborn *et al*[69]
Smoking status	Current smoker	↑	↓	Anti-TNF	1b, 2b	Arnott *et al*[154] Sandborn *et al*[69]
Disease duration	> 2 yr	-	↓	Anti-TNF	1b	Colombel *et al*[155] Schreiber *et al*[156] D'Haens *et al*[157]

[1]As per the Oxford level of evidence scoring; The available literature suggests a slower initial response but comparable long-term response rate; The use of "-" denotes an absence of published data addressing this issue.

nutritional requirements, replacing normal diet, either orally or via nasoenteric tube. It is mostly used for induction of remission in CD typically over a duration of 6-8 wk. While most data emanates from pediatric studies, efficacy is also likely in adults[130].

Time to response with EEN seems rapid, with 75% of adult patients with active CD achieving clinical remission after 10 d of an elemental feeding in one small RCT[131]. Other small RCTs have demonstrated clinical remission rates of 25% to 80% within 3-4 wk of commencement[132-138]. In two non-randomized cohort studies utilizing objective disease activity endpoints, 44% of patients achieved mucosal healing after 4 wk of EEN and, in a pediatric cohort, 36% had mucosal healing after 8 wk of EEN[139,140].

ADDITIONAL FACTORS AFFECTING TIME TO CLINICAL RESPONSE

Disease related factors

There are several patient and disease-related factors that appear important when predicting the likelihood of response and time to therapeutic response in individual patients (see Table 3). Agents tend to achieve a more rapid time to therapeutic response in UC than CD. This may relate to the transmural nature of CD thus treatment takes longer to achieve resolution of inflammatory changes. This difference in time to therapeutic response is exemplified by the vedolizumab registration studies, where induction therapy appeared to have higher response rates in UC than CD and the benefits in CD were predominantly observed later during the maintenance phase[73,78].

Patients who have not achieved an adequate response to prior therapies may have a slower response to subsequent therapies. This was noted with vedolizumab induction, where previous anti-TNF failures achieved clinical remission rates that only became significantly different to placebo after 10 wk, in contrast to the overall cohort where clinical remission rates were higher at week 6 compared to placebo[74]. Similar findings of a longer time to clinical remission were found in patients who had received infliximab previously and were subsequently treated with induction certolizumab for CD[69].

Patient related factors

While several additional factors intuitively could affect time to therapeutic response such as nutritional status, age and the intestinal microbiome, published data are lacking. Advancing age is typically associated with a reduced glomerular filtration rate, greater oxidative stress, increased volume of distribution, co-morbid conditions, decreased hepatic metabolism and frailty-any of which may affect treatment choice and a therapy's time to clinical response[141,142]. For instance, one retrospective study found that rates of clinical response to anti-TNF therapy for IBD in patients > 65 years was significantly less at week 10 but not significantly different at 6 mo than matched controls with similar co-morbidities aged < 65 years, suggesting a slower onset of response overall[143]. The limited available evidence also suggests that obesity can affect the rate of response, although the effect on time to response has not been studied. For instance, higher baseline weight was associated with a lower rate of clinical remission following induction therapy with adalimumab in the ULTRA-1 study and has been associated with an earlier loss of response to infliximab and adalimumab in IBD[59,144,145].

Although many of these factors are not modifiable, intervening early in the disease course and/or simple complementary measures such as improving nutrition may allow for a more rapid time to therapeutic response.

DISCUSSION

This review has elucidated multiple important principles

of time to therapeutic response with direct applicability to clinical practice. First, patience is critical (for patients and clinicians alike) to reap the maximal benefits of some agents, particularly thiopurines, vedolizumab and methotrexate, with cumulative gains in response to these agents up to 12 mo after commencement. The clinical benefits indeed might lag significantly beyond the drug reaching therapeutic levels. For instance, this was reflected in a study assessing whether initial intravenous loading of azathioprine might hasten time to response. Indeed, therapeutic levels of 6-TGN were achieved rapidly. However, this did not improve the time to therapeutic response compared to standard oral administration[80]. Thus assessment of response should be delayed until sufficient time has lapsed to reach clinical efficacy. Whilst symptomatic improvement may occur relatively early following the initiation of many therapies, there often appears to be a lag in achieving mucosal healing, which should be considered when interpreting an early endoscopic assessment. This concept was demonstrated in a randomized controlled trial by Sutherland *et al*[146] comparing 4 g aminosalicylate enemas to placebo enemas for the management of distal UC. Clinical response rates and endoscopy were measured at 3 and 6 wk, with response rates reaching 60% by week 3 in the aminosalicylate arm, then plateauing to reach 68% by week 6. The mucosal healing rates over the same period increased from 25% to 42%, suggesting a later rise[24]. Additionally, patients kept a symptom diary for the first two weeks of this trial and rectal bleeding had ceased in over half of patients by day 6, so the symptom improvement may have occurred more rapidly than the time of outcome measurement. Hence, it may be appropriate to delay assessment until after the expected time to therapeutic response has passed.

Secondly, it follows that a prolonged period of bridging therapy such as co-administration of EEN, corticosteroids or even perhaps tacrolimus is an important component of treatment planning, particularly in patients who are acutely unwell, so that relapse is avoided if possible, prior to the expected maximal response of a newly introduced therapy. Thirdly, in agents where a delayed time to therapeutic response is more likely, one must consider whether potential methods of hastening onset of action can be employed, such as thiopurine and allopurinol in combination or perhaps using EEN in combination with an anti-TNF agent in CD as induction therapy.

Significantly, the lack of reporting of time-to-response in clinical trials is a deficiency. Mostly, data must be extrapolated from studies rather than being directly reported. Given its utility in clinical practice and the relatively basic calculations required, this should be addressed in future studies. The expected time-to-response can potentially assist in trial design by providing an estimate of the necessary duration of a study to show maximal efficacy. For example, for vedolizumab for the management of CD, the CDAI-100 response rate was not significant at week 6 and only surpassed placebo around week 28[73]. Similarly, modest early response rates were also noted with another anti-integrin therapy natalizumab at week 10 with response rates increasing during maintenance therapy[147]. The use of week 6 rather than week 10 or later as the response times for vedolizumab has been a criticism of the large randomized studies[77]. Hence, such information can potentially be reported in early studies and thus provide further insight into the rapidity of action of drugs or more widely, drug classes, which can be incorporated into future studies of that therapy, plus into clinical practice.

Finally, the concept of time-to-response is a broad term and it is likely that it can be further divided based on the proportion of patients who have respond to therapy, as shown in Table 1. There is a time point at which most patients will respond and then following this there is progressively diminishing returns in the likelihood of further response, culminating in a point where response is unlikely; the time to futility. This concept remains clinically important, as the yield from persisting with therapy beyond this point is low and thus place patients at higher risk, for minimal or no benefit. Again, such information be ideally included in published data to better aid clinicians with therapeutic decisions.

CONCLUSION

In a chronic disease like IBD, where many therapies are effective yet of relatively slow onset of action, time-to-therapeutic response is of central importance both quantitatively to frame the patient's expectations and the clinician's decision making but also conceptually-encouraging the mindset of forward treatment planning, overlapping bridging therapies and accuracy in determining therapeutic failure. Furthermore, in contrast to the homogenized, group-based reporting of results from the seminal RCTs as the reference standard for each new agent, time to therapeutic response is inherently patient-centric and individualized. This is not only because it has the potential to vary by indication, dosage, demographic, clinical factors and is dependent on which endpoint is chosen (*i.e.*, clinical response, remission, or endoscopic remission) but one can argue that the time to therapeutic response is of far greater relevance to patients and perhaps even to clinicians in day-to-day practice, thus future studies should examine and incorporate this paradigm further.
