AIMS AND SCOPE

The primary aim of *World Journal of Gastroenterology* (*WJG*, *World J Gastroenterol*) is to provide scholars and readers from various fields of gastroenterology and hepatology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online. *WJG* mainly publishes articles reporting research results and findings obtained in the field of gastroenterology and hepatology and covering a wide range of topics including gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, gastrointestinal oncology, and pediatric gastroenterology.

INDEXING/ABSTRACTING

The *WJG* is now abstracted and indexed in Science Citation Index Expanded (SCIE, also known as SciSearch®), Current Contents/Clinical Medicine, Journal Citation Reports, Index Medicus, MEDLINE, PubMed, PubMed Central, Scopus, Reference Citation Analysis, China National Knowledge Infrastructure, China Science and Technology Journal Database, and Superstar Journals Database. The 2022 edition of Journal Citation Reports® cites the 2021 impact factor (IF) for *WJG* as 5.374; IF without journal self cites: 5.187; 5-year IF: 5.715; Journal Citation Indicator: 0.84; Ranking: 31 among 93 journals in gastroenterology and hepatology; and Quartile category: Q2. The *WJG*'s CiteScore for 2021 is 8.1 and Scopus CiteScore rank 2021: Gastroenterology is 18/149.

Abstract

According to data from 2020, Slovakia has long been among the top five countries with the highest incidence rate of colorectal cancer (CRC) worldwide, and the rate is continuing to rise every year. In approximately 80% of CRC cases, allelic loss (loss of heterozygosity, LOH) occurs in the long arm of chromosome 18q. The most important genes that can be silenced by 18q LOH or mutations are small mothers against decapentaplegic homolog (SMAD) 2 and SMAD4, which are intracellular mediators of transforming growth factor (TGF)-β superfamily signals. TGF-β plays an important role in the pro-oncogenic processes, including such properties as invasion, epithelial-mesenchymal transition (commonly known as EMT), promotion of angiogenesis, and immunomodulatory effects. Several recent studies have reported that activation of TGF-β signaling is related to drug resistance in CRC. Because the mechanisms of drug resistance are different between patients in different stages of CRC, personalized treatment is more effective. Therefore, knowledge of the activation and inhibition of factors that affect the TGF-β signaling pathway is very important.

Key Words: Small mothers against decapentaplegic homologs; Transforming growth factor-beta; Colorectal cancer; Marker; Signaling pathway

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: A thorough understanding of the complete transforming growth factor (TGF)-β/small mothers against decapentaplegic homolog signaling pathway is important for defining its functions during pathological processes of colorectal cancer. Inhibitors specifically targeting TGF-β pathway mediators that reduce the expression of a particular protein may lead to fewer/milder adverse effects. However, the dual role of the TGF-β pathway in the onset and progression of cancer complicates the physiological/pathological and, thus, clinical situation. In recent years, research has shown that modification of members of this pathway is a promising approach for clinical procedures. Long-term treatment should emphasize personalized and targeted therapy.

INTRODUCTION

According to data from 2020, Slovakia has long been among the top five countries with the highest incidence rate of colorectal cancer (CRC) worldwide, and this rate continues to rise every year[1]. Although significant progress has been made in the diagnosis, screening, and treatment of patients with advanced CRC, therapeutic options are still limited, requiring the discovery of additional markers to act as prognostic predictors[2].

Up to 60%-65% of colorectal tumors have no family history (sporadic) and are the result of somatic mutations and epigenetic changes due to factors such as a lifestyle with limited physical activity, alcoholism and smoking[3]. CRC can arise as a result of these genetic and epigenetic aberrations (Figure 1): Chromosomal instability (CIN; 65%-85%), methylation of the CpG island (CIMP; 10%-20%), and DNA microsatellite instability (MSI; 12%-15%)[4]. Some authors have noted that patients with a tumor-bearing the CpG island methylator phenotype will have a worse prognosis compared to patients with a CIMP-negative tumor[5-7]. The instability of DNA microsatellite regions is characterized by mutations in the genome that arise due to defects in mismatch repair genes and can affect and inactivate tumor suppressor genes, leading to malignant transformation[8,9]. CIN is caused by the gain or loss of whole or large parts of chromosomes, leading to karyotype variability between cells. CIN results in chromosome imbalance (aneuploidy), subchromosomal genomic amplification, and loss of heterozygosity (LOH)[10].

This type of classification, based on a single molecular marker, is not very informative in the early diagnosis of CRC; thus, a combination of several molecular markers has been proposed as a better classification approach for patients with CRC. Moreover, the joint efforts of the CRC Subtyping Consortium have led to a formal proposal for the stratification of CRC cases into the following four molecular subtypes (referred to as CMS1-4)[11,12] (Figure 2; Table 1).

CMS1 is usually a right-sided (proximal) tumor, commonly diagnosed in older age females, and is associated with worse survival after relapse. This subtype is characterized by hypermethylation of CpG islands, which causes loss of tumor suppressor function and has a low prevalence of somatic copy number alterations (referred to as SCNAs). The hypermethylation of promoter regions of the MMR genes causes MSI[11].

CMS2 is mainly located on the left side (distal part of the colon) and is often diagnosed in men, with a better prognosis and a higher survival rate, even after relapse. This gene expression profile is characterized by low mutation rate. CMS2 also represents over-activation of epidermal growth factor (EGF)-related signaling pathways, with higher expression of the epidermal growth factor receptor (EGFR)[13]. Finally, Guinney *et al*[11] reported that CMS2 has more copy number gains in oncogenes and losses in tumor suppressor genes than the other CMSs.

CMS3 is another right-sided subtype and is the most frequently diagnosed in patients with evident metabolomics disease[13]. Although KRAS mutation is present in every CMS, it occurs more frequently in CMS3[11].

CMS4 tumors exhibit extremely low levels of hypermutation and are defined by an activated transforming growth factor (TGF)-β pathway and by epithelial-mesenchymal transition (EMT), making them generally more chemoresistant[13]. CMS4 tumors tend to be diagnosed at more advanced stages (III and IV); indeed, the poor prognosis of CMS4 (compared to the relatively favorable prognoses of CMS1 and CMS2) in non-metastatic disease have been demonstrated[11].

Table 1 Characteristics of individual colorectal cancer subtypes

CMS1	CMS2	CMS3	CMS4
(MSI immune)	(Canonical)	(Metabolic)	(Mesenchymal)
CIMP high	CIN	CIN, CIMP low	CIN
Hypermethylation			
SCNA-low	SCNA-high	SCNA-intermediate	SCNA-high
BRAF mutant		KRAS mutant	
Activation of immune cells	WNT, MYC activation	Metabolic deregulation	TGF- activation
Worse survival after relapse	Superior survival after relapse		Worse relapse-free and overall survival

SCNA: Somatic copy number alteration; CIN: Chromosomal instability; CIMP: Methylation of the CpG island; TGF: Transforming growth factor.

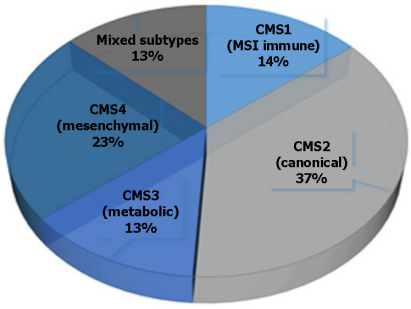

Figure 1 Representation of individual colorectal cancer subtypes.

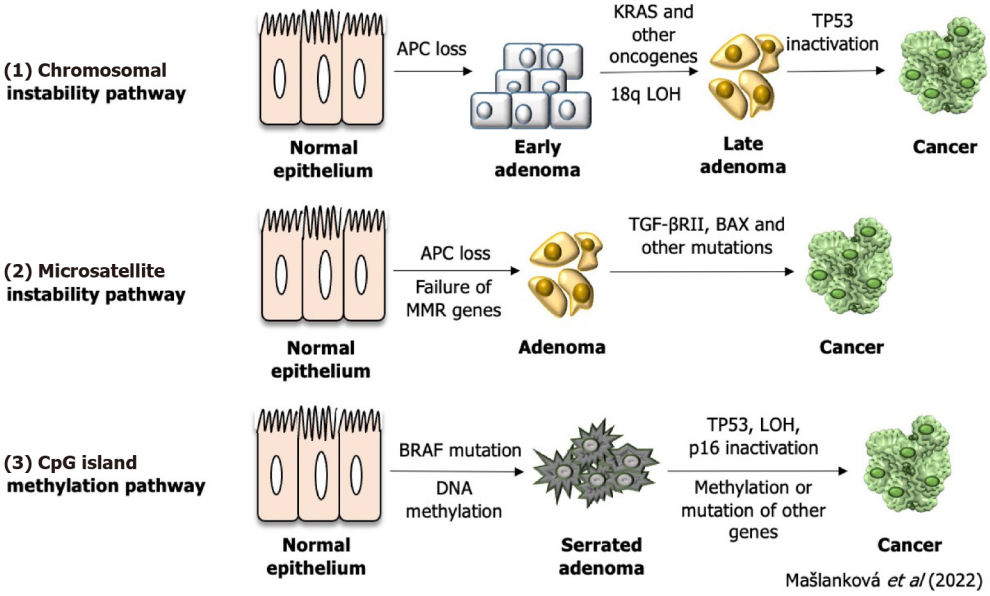

Figure 2 Three genetic and epigenetic aberrations of colorectal cancer formation. LOH: Loss of heterozygosity; TGF: Transforming growth factor.

The basic characteristics of each CRC subtype, CMS1-4, are summarized in Table 1.

Approximately 80% of colorectal tumors have loss of an allele in the long arm of chromosome 18q, followed by LOH on chromosome 17p (75%-80%), 8p (40%), 5q (30%), and finally 22q (20%-30%). Allelic loss in chromosome 18q has been reported in 70% of cases of primary CRC with late-stage adenomas and shows a strong correlation with poor prognosis [14]. Patients with 18q LOH have a particularly poor prognosis in stage II disease, leading to the conclusion that stage II adjuvant therapy is important for these patients[15].

There are many candidate tumor suppressor genes in 18q, including small mothers against decapentaplegic homolog (SMAD) 2, SMAD4, netrin receptor DCC (DCC), and Cdk5 and Abl enzyme substrate 1 *(CABLES1*)[16]. The most important genes that can be silenced by 18q LOH or mutations are SMAD2 and SMAD4, which are intracellular mediators of TGF-β superfamily signaling[17].

TGF-β SUPERFAMILY SIGNALING

TGF-β superfamily signaling is mainly divided into the following two subfamilies: TGF-β-activin-nodal and bone morphogenetic protein (BMP). The TGF-β ligand (comprised of the TGF-β1, -β2, and -β3 isoforms) is a multifunctional member of the cytokine family, playing an important role in such cellular responses as cell proliferation, differentiation, and pathological processes. TGF-β itself plays a key role in the processes of EMT and fibrosis[18].

The canonical (SMAD-dependent) TGF-β signaling pathway (Figure 3) utilizes serine/threonine kinase receptors (TGF-βRI/TGF-βRII) in the plasma membrane and phosphorylates their cytoplasmic effectors SMAD2 and SMAD3. TGF-βRI receptors differ from TGF-βRII by the presence of an N-terminal glycine/serine-rich (GS) domain, which regulates kinase activity and SMAD binding. TGF-βRII receptor phosphorylates serine and threonine residues within the GS domain of TGF-βRI, and activated TGF-βRI receptor phosphorylates the distal C-termini of SMAD2 and SMAD3. An anchor of SMAD receptor activation, a SMAD cofactor that directly interacts with SMAD2/3, is required to anchor SMAD2/3 proteins to the TGF-β receptor. After phosphorylation, SMAD2 and SMAD3 dimers form heteromeric complexes with SMAD4 and then translocate to the nucleus. They act as transcription factors, mediate the expression of various genes, and promote various biological functions in the tumor microenvironment, resulting in tumor suppression[19].

A conserved branch of the TGF-β superfamily involves BMP signaling. BMP canonical signaling is triggered upon the binding of soluble ligands to serine-threonine kinase receptors, BMPRI and BMPRII, in the plasma membrane. Activated BMP receptors stimulate various intracellular signaling pathways. This canonical pathway is characterized by phosphorylation of SMAD1/5/8, which subsequently forms a gene-regulatory complex with SMAD4. Alternative BMP signaling can occur *via* the non-canonical pathway and is due to the presence of multiple intracellular kinases (Figure 3)[20].

While TGF-β-induced extracellular matrix production promotes tumor development, the inhibitory response to TGF suppresses tumor formation. Thus, the level of TGF-β receptor activation can alter the outcome of TGF-β signaling from suppression to oncogenesis. The TGF-β/SMAD signaling pathway has a dual effect; during tumor initiation and early stages, it stops the cell cycle and triggers apoptosis and in later stages, it promotes tumorigenesis and increases tumor progression and invasiveness[21]. TGF-β signaling causes cell cycle arrest and death during tumor initiation, acting as a tumor suppressor. However, it has also been demonstrated to increase tumor cell proliferation, EMT, and stem-like activity during tumor progression, as well as fibrosis, inflammation, and angiogenesis[22-24].

TGF-β AND ITS ROLE IN TUMOR SUPPRESSION

TGF-β signaling regulates cell proliferation mainly by inhibiting cell cycle progression through a mechanism that arrests the cell in the G1 phase. In most epithelial, endothelial, and hematopoietic cells, this arrest occurs through the activation of cyclin-dependent kinase (CDK) inhibitors, such as p21CIP1 and p15INK4b. TGF-β signaling also inhibits c-Myc oncogene transcription as well as DNA-binding protein inhibitors (ID1-3) and nuclear factors, which play key roles in cell differentiation and progression from the G1 to S phase of the cell cycle[25].

The canonical TGF-β signaling pathway can induce apoptosis by modulating the expression of various members of the B-cell lymphoma 2 (Bcl-2) family such as death receptor fibroblast death-associated antigen (FAS), DNA damage-inducible (GADD) 45-β, and kinase associated with by death (DAPK), which depends on the type of cells where the signaling takes place. It can also induce growth arrest and modulate caspases to induce intrinsic and extrinsic apoptosis[18].

TGF-β AND ITS ROLE IN TUMOR PROMOTION

In later stages of cancer, TGF-β may adversely promote tumor progression and metastasis[18]. The TGF-β signaling pathway activates the promoter activity of the translation inhibitory protein 4E-BP1 (regulator of eukaryotic translation initiation factor-4F (eIF4E) through SMAD4, thereby suppressing translation, cell growth and proliferation [26]. TGF-β also promotes the secretion of matrix metalloproteases (MMPs), mainly MMP-2 and MMP-9, and inhibits the activity of their tissue inhibitors (TIMPs) [27].

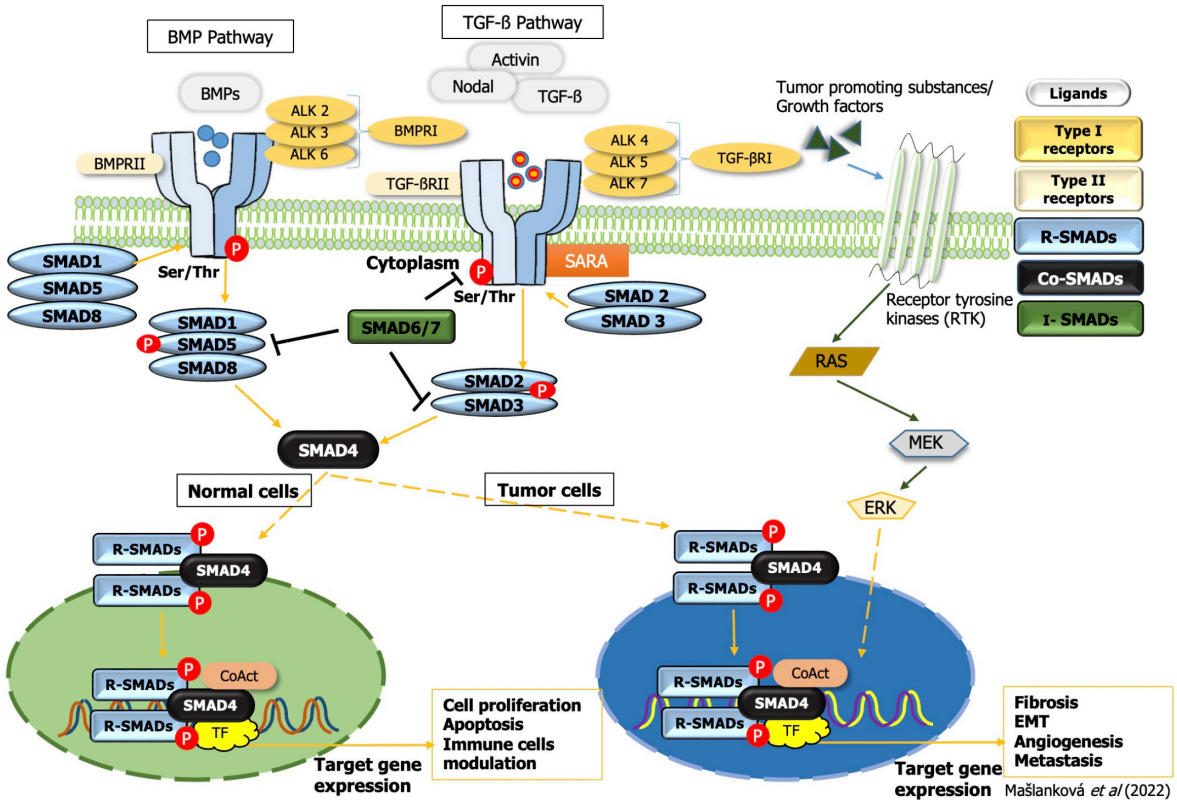

Figure 3 Transforming growth factor-beta superfamily signal transduction. TGF: Transforming growth factor; EMT: Epithelial-mesenchymal transition; ERK: Extracellular signal-regulated kinase; BMP: Bone morphogenetic protein; SMAD: Small mothers against decapentaplegic homolog.

Fibrotic processes are well known to play a key role in promoting malignancy, and TGF-β is one of the most prominent inducers of fibrotic processes. During fibrosis, abundant ECM components accumulate due to activated myofibroblasts. In tumor tissue, solidified stroma stimulates tumor cell proliferation, migration, and survival. Fibrosis plays a vital role in EMT regulation, promotes angiogenesis and hypoxia, and inhibits anti-tumor immunity. Ultimately, the degree of tissue fibrosis is related to tumor aggression and poor patient prognosis[28].

TGF-β collaborates closely with BMP during fibrosis, due to their structural similarity and shared signal transmission modality. Their role is to regulate fibrosis-causing processes, like EMT. The interaction of TGF-β and BMP to form a complex with SMAD4, together with SMAD7 which elicits an inhibitory effect, affects the balance between the activation of SMADs that are members of the TGF-β signaling pathway (SMAD2/3) and SMADs that are part of the BMP signaling pathway (SMAD1/5/8). Therefore, many studies report antagonistic roles of TGF-β and BMP[29,30]; according to them, BMP activity is antifibrotic. Fewer studies support the opposite trend. Specifically, Katsuno *et al*[31] determined that BMP signaling can promote TGF-β signaling through the activation of protein arginine N-methyltransferase (PRMT1), which methylates SMAD6/7. SMAD6/7, in turn, activates SMAD1/3/5, resulting in the promotion of EMT during fibrosis and the maintenance of the tumor cell phenotype in malignancies[29,31].

TGF-β/SMAD RECEPTORS

Each of the isoforms of TGF-β (-1, -2, -3) binds to serine/threonine kinases, which belong to the group of transmembrane receptors and can bind to TGF-βI and TGF-βII. The name of TGF-βRI is also an activin-like receptor kinase (ALK). Seven types of TGF-βRIs have been identified to date (ALK1-7), five types of TGF-βRIIs (TGF-βRII, BMPRII, ACVRII, ACVRIIB, and AMHRII), and two types of TGF-βRIIIs (betaglycan and endoglin). All TGF-βRs consist of a C-terminal cytoplasmatic domain of a serine/threonine kinase, an internal transmembrane region, and an N-terminal domain, which binds ligands [18].

TGF-β receptors, SMAD proteins, and their mutation or inactivation have been described in many publications, along with their role in the progression of malignancies[32,33]. The loss of TGF-β tumor suppressor functions, which play a key role in inhibition in normal epithelial cells as well as in tumor cells, leads to oncogenic processes. Many human cancers, including CRC, are resistant to TGF-β-mediated growth inhibition, however. This resistance may be due to mutation or functional inactivation

of TGF-βRI, decreased expression of TGF-βRI or TGF-βRII, and inactivation mutations of individual members of the TGF-β signaling pathway, such as SMAD2 and SMAD4[25]. Reportedly, approximately 20%-30% of CRCs contain mutations of TGF-βRII, and mostly involve colon cancer cells with MSI. One of the most frequent MSI mutations detected occurs in a coding polyadenine tract in exon 3 of the TGF-β RII gene. Some studies have even suggested that one of the important factors contributing to CRC transformation is the inactivation of TGFβR2, which increases cell proliferation due to prolonged activation of cdk4 expression[34-36].

Not only TGF-βRII but also TGF-βRI may contain a similar hypermutable polyadenine sequence resulting from mismatch repair defects, and the mutant allele (known as TGF-βRI6A) has been described to predispose to colon cancer, with a reported frequency of 100%[37].

SMADs

The mammalian TGF-β receptor family contains five SMAD substrates (SMAD1, SMAD2, SMAD3, SMAD5 and SMAD8); these are commonly referred to as receptor-regulated SMADs or R-SMADs[19]. Bone morphogenetic protein (BMP) and anti-Müeller receptors have high affinity for SMAD 1, 5, and 8 and TGF-β, activin and nodal receptors bind SMAD 2 and 3 proteins. SMAD4 belongs to the co-SMAD group, the second class of the SMAD family, which serves as a common partner for all R-SMADs such as SMAD2, SMAD3, SMAD1, SMAD5, and SMAD8 to form heterotrimeric complexes. These heterotrimeric SMAD complexes are subsequently translocated to nuclei, where they bind to specific promoters to act as DNA-specific transcriptional regulators of target genes[38]. SMAD6 and SMAD7 have inhibitory roles in the TGF-β/SMAD signaling pathway[39,40].

SMAD proteins are composed of approximately 500 amino acids and consist of two globular domains [MAD homology (MH) 1 and MH2] joined by a linker region. The N-terminal domain of MH1 is highly conserved in all R-SMADs and SMAD4, but not in SMADs 6 and 7, and contains a hairpin structure with DNA-binding capability. The MH2 domain contains hydrophobic elements that bind to TGF-βR and BMPR transmembrane receptors. The linker region is quite different between the different subgroups, whereas the C-terminal domain (MH2) is identical in all SMAD proteins[19]. The MH2 domain is involved in SMAD protein homooligomerization and heterooligomerization, cytoplasmic anchoring, and transcription. In normal (healthy) and premalignant cells, the TGF-β tumor signaling pathway has a suppressive role, but this pathway can be inhibited, damaged, or even used by cancer cells to promote oncogenic functions[38]. The known roles of individual SMAD proteins during the onset and progression of CRC are summarized in Table 2.

In 65% of colon adenocarcinomas and 50% of rectal adenocarcinomas, mutations in any of the 43 genes that encode proteins of the TGF-β pathway superfamily have been described[19]. Many proteins interact with the SMADs to modulate their activity. Therefore, by regulating these proteins, we can influence the process of carcinogenesis[41].

Role of SMAD2/3

Many studies describe the significant role of SMAD2/3 in the EMT process, which is activated by the TGF-β signaling pathway. The most important difference between SMAD2 and SMAD3 is that the MH1 region of SMAD2 has two more amino acid fragments than SMAD3. Due to this amino acid difference, SMAD3 can directly bind to DNA and has transcriptional activity, whereas SMAD2 lacks transcriptional activity[42,43].

Although SMAD3 is highly homologous to SMAD2, the roles of SMAD2 and SMAD3 are different in the TGF-β signaling process. SMAD3 plays a very important role as a mediator of EMT, as demonstrated by inhibition or knockdown of SMAD3, which blocked cell migration induced by the TGF-β signaling pathway. Therefore, regulation of SMAD3 protein expression is a very important regulatory step in EMT prevention[44].

The results of Liu *et al*[45] point to other important differences between SMAD2 and SMAD3. SMAD2 is mostly located in the cytoplasm, whereas a large amount of SMAD3 is distributed in the nucleus. Western blot analysis was performed in that study, which provided evidence to support the conclusion that in the absence of TGF-β activation, endogenous SMAD2 is found mainly in the cytoplasm, while large amounts of SMAD3 are found in the nucleus of human embryonic stem cells, kidney cells, and skin fibroblast cells. This otherness in different cell compartments of SMAD2 and SMAD3 proteins may reflect their activity in TGF-beta-induced signal transduction.

Analyses of tissue and experiments with explanted tissue have revealed strongly reduced phosphorylated SMAD3 and increased levels of its inhibitor SMAD7 in Crohn's disease tissue and a moderate reduction in ulcerative colitis (UC) tissue[46]. UC poses a high risk of developing CRC; however, the molecular mechanisms underlying the transition from UC to CRC are unclear[47].

Wang *et al*[48] showed that it was possible to increase the transcriptional activity of SMAD3, phosphorylation of SMAD2, and reduction of SMAD7 expression by knocking out signal transducer and activator of transcription 3 (STAT3), which ultimately led to the suppression of tumor progression in CRC. STAT3 is a member of the STAT protein family and can promote oncogenesis of CRC through

Table 2 Roles of individual small mothers against decapentaplegic homolog proteins in the onset and progression of colorectal cancer

Type of SMAD	Role in colorectal cancer	References
SMAD1	Participates in the modification of cell growth, differentiation, apoptosis and other processes that are essential in the regulation of the body's immune system	[39-42]
	Promotes epithelial-mesenchymal transition process	
	By increasing the expression of ATG5 induces autophagy	
SMAD2	Inhibits the expression of related functional genes, cell proliferation and regulates the transcriptional response that promotes cell apoptosis	[43,44]
	Expression of SMAD2 is correlated with patient survival	
SMAD3	In the formation of a tumor, depending on the stage of the cancer, it plays the double role of an oncogene or a tumor suppressor gene	[45-48]
	Reduces its expression through mir-4429, and inhibits the appearance, development and metastasis of cancer cells	
SMAD4	Plays a very important role in the transduction of the TGF-β signaling pathway	[32,49]
	Maintains the cell cycle in the G1 phase, which leads to abnormal tumor proliferation	
	Is a tumor suppressor gene	
	High mutation rate of SMAD4 in CRC patients was associated with poor prognosis, but not with clinical stage	
SMAD5	Mediates TGF-β superfamily ligand signaling pathway and thus influences cancer progression	[50]
	No relevant studies on the role of SMAD5 in CRC patients have been found in the last 5 years	
SMAD6	Regulates TGF-β signaling pathway, promotes angiogenesis, stimulates extracellular matrix, and inhibits immunity, thus contributing to tumor growth, diffusion, and metastasis	[51]
	No relevant studies on the role of SMAD6 in CRC patients have been found in the last 5 years	
SMAD7	Plays a dual role in different tumor stages, acting as a tumor suppressor gene by inhibiting proliferation and promoting apoptosis in the early stage, and increasing invasion in the late stage, promoting epithelial-mesenchymal transition, which correlates with the degree of malignancy	[52,53]

SMAD: Small mothers against decapentaplegic homolog; ATG5: Autophagy-related gene 5; CRC: Colorectal cancer; TGF: Transforming growth factor.

various pathways.

Liu *et al*[49] reported that treatment with exogenous interleukin 6 (IL-6) stimulated STAT3 activation, increased TGF-β-induced SMAD3 and Snail expression, and inhibited the EMT process, suggesting that the Janus kinase/signal transducer and activator of transcription 3 (JAK/STAT3) pathway is required for TGF-β-induced EMT and cancer cell migration and invasion by upregulating SMAD3 and Snail expression. Moreover, Xu *et al*[50] showed that the expression of SMAD2 is correlated with patient survival. Their results demonstrated that the MIR22 host gene (MIR22HG) has been shown to play a role in suppressing colorectal tumors by binding competitively to SMAD2, thereby preventing the interaction between SMAD2 and SMAD4. These data suggest that the MIR22HG silencing promotes the EMT process and thus tumorigenicity in CRC.

Many papers have been published in recent years that link the action of the TGF-β signaling pathway to other pathways. The mitogen-activated protein kinase (MAPK) pathway may phosphorylate a group of proteins that are responsible for altering cell behavior, or conversely, proteins of this pathway may be activated by extracellular molecules such as cytokines produced by the TGF-β signaling pathway. The extracellular signal-regulated kinase (ERK) pathway inhibits the TGF-β pathway by phosphorylating SMAD2 and SMAD3 without translocating them to the nucleus[51,52].

Despite the important roles of SMAD2 and SMAD3 in the TGF-β signaling process, the prevalence of mutations was estimated up to 6%. Fleming *et al*[53] showed that the percentage of mutations increased with the combined prevalence of SMAD4, SMAD2, and SMAD3 mutations to 14.8% in primary sporadic CRCs.

Lin *et al*[54] described that nitrilase 1 (NIT1) suppresses the proliferation of CRC cells through a positive feedback loop between NIT1 and the TGFβ/SMAD signaling pathway because SMAD3 transcriptionally upregulates at the transcriptional level. NIT1 belongs to the carbon-nitrogen hydrolase superfamily and plays an important role in the suppression of CRC.

Role of SMAD4

A key component of TGF-β signaling is SMAD4, which plays an important role as a so-called switch in deciding whether to stop the cell cycle or progress to the spread of cancer[32]. Impaired TGF-β signaling

due to the deletion of SMAD4 is detected in 16%-25% of CRCs[55]. Sadeghi *et al*[56] found SMAD4 mutations in 33.3% of analyzed tissues collected from patients with CRC.

Most SMAD4 mutations occur in the MH2 domain, although this domain represents only 41.5% of the coding sequence of the entire SMAD4 protein[56-58]. The MH2 domain is essential for homodimerization and heterooligomerization with SMAD2 or SMAD3 proteins. Therefore, mutations in this region can cause blocks to the growth, inhibition, and apoptosis that is otherwise generally induced by TGF-β. Moreover, SMAD4 mutations promote inflammation by TGF-β and thus may expand genetically damaged cells during tumorigenesis[56]. The most frequent mutation of the SMAD4 gene has been described in CRC which leads to the formation of a salt bridge between Arg361 and Asp351 and which affects homodimerization and heterooligomerization with SMAD2 and SMAD3[59,60].

Sadeghi *et al*[56] further described in their publication that the other significant mutations in CRC are at codons 264 and 271 of SMAD4 protein, which are located in the linker domain, a region required for subcellular localization and transcriptional activation.

Analyzes of tissue sections by immunohistochemical methods of carcinomas from various organs, including the gastrointestinal tract have shown a loss of SMAD4 expression in > 50% of colorectal carcinomas, which is associated with lymph node metastases. SMAD4 loss has been seen in 58% of pancreatic adenocarcinomas, 27% of appendiceal adenocarcinomas, 16% of cholangiocarcinomas, 10% of lung adenocarcinomas, and < 5% of esophageal, breast, gastric, and mucinous ovarian adenocarcinomas [61]. Although the LOH on chromosome 18q can be the main cause of SMAD4 loss in CRC, there are other posttranscriptional and posttranslational mechanisms that may contribute to SMAD4 protein loss or dysfunction, such as ubiquitylation, sumoylation, or interference with regulatory microRNA (miRNA)[62].

Regarding the correlation between SMAD proteins and clinicopathological characteristics, Yang *et al* [63] showed that SMAD4 concentrations in CRC patients were significantly higher in the N0 stage compared to patients with NI stage. Regarding patients in advanced stages (TNM III-IV), reduced concentrations of SMAD4 were recorded in them compared to patients in early stages (TNM I-II). In addition, SMAD4 was significantly decreased in patients who were older than 65 years.

Szeglin *et al*[64] determined probes and corresponding genes from analysis of SMAD-binding elements (SBEs) that were correlated with SMAD4 expression. They subsequently confirmed that a SMAD4-modulated gene profile predicted disease-free survival in stage II and III CRC. According to them, this gene profile has prognostic potential in selected CRC patients.

Role of SMAD7

SMAD7 acts as an inhibitor of SMAD in the TGF-β/SMAD pathway and may prevent TGF-β-dependent SMAD2/SMAD4 complex formation and inhibit SMAD2 accumulation in the nucleus (Figure 4). SMAD7 may also promote the dephosphorylation and inactivation of TGF-βRI with cooperation of the E3 ubiquitin ligase SMURF1/2. SMAD7 may also localize to the nucleus and limit the binding of the SMAD2-3/SMAD4 complex to specific SMAD-responsive DNA sequences[65]. So, SMAD7 plays an important role in both the cytoplasm and the nucleus, thereby maintaining the balance in the TGF-β induced signaling pathway. Inactivation of any component in this pathway will result in accelerated cell growth and dysregulation of apoptosis signals, leading to uncontrolled cell growth and differentiation, and the induction of cancer cells[66]. Therefore, overproduction of SMAD7 leads to significantly decreased EMT in response to TGF-β[67].

Several studies have reported the significant role of SMAD7 in sporadic CRC. According to results published by Li *et al*[66], SMAD7 is a target of miR-424, which is implicated in the regulation of SMAD7 expression *via* the circTBL1XR1/miR-424 axis.

Boulay and colleagues, in 264 biopsy samples from CRC patients, showed that the deletion of SMAD7 is less common than deletion of SMAD4 and SMAD2, and patients with such a SMAD7 deletion have a significantly better prognosis than patients without a deletion. Their findings demonstrated that patients with SMAD7 deletions had a low ratio of death risk and relapse, which clearly defined SMAD7 as a negative prognostic marker in CRC patients[68,69].

SMAD7 and SMAD4 genes are deregulated in CRC, whereas there is a markedly higher increase in SMAD7 expression (~ 11.3-fold) than SMAD4 expression (approximately 2-fold) in tumor cells[70]. SMAD7 protein expression is closely related to Dukes' stage, CRC invasion depth, and lymph node metastases, and positively correlates with CRC expression[66].

Less frequently, it has been reported that SMAD7 also has an anti-cancer effect. Gastrointestinal carcinomas, such as CRC, are characterized by frequent genetic alterations in SMAD components. Furthermore, depending on the stage of the tumor, SMAD7 activity can transition from tumor-suppressive to tumor-promoting (*i.e.*, early *vs* advanced). Given the opposing roles of TGF signaling, these seemingly contradicting functions are not surprising[71,72].

REGULATION OF TGF-β SIGNALING PATHWAY BY NON-CODING RNAs

Genes that encode proteins represent less than 2% of the total human genome, while approximately 90%

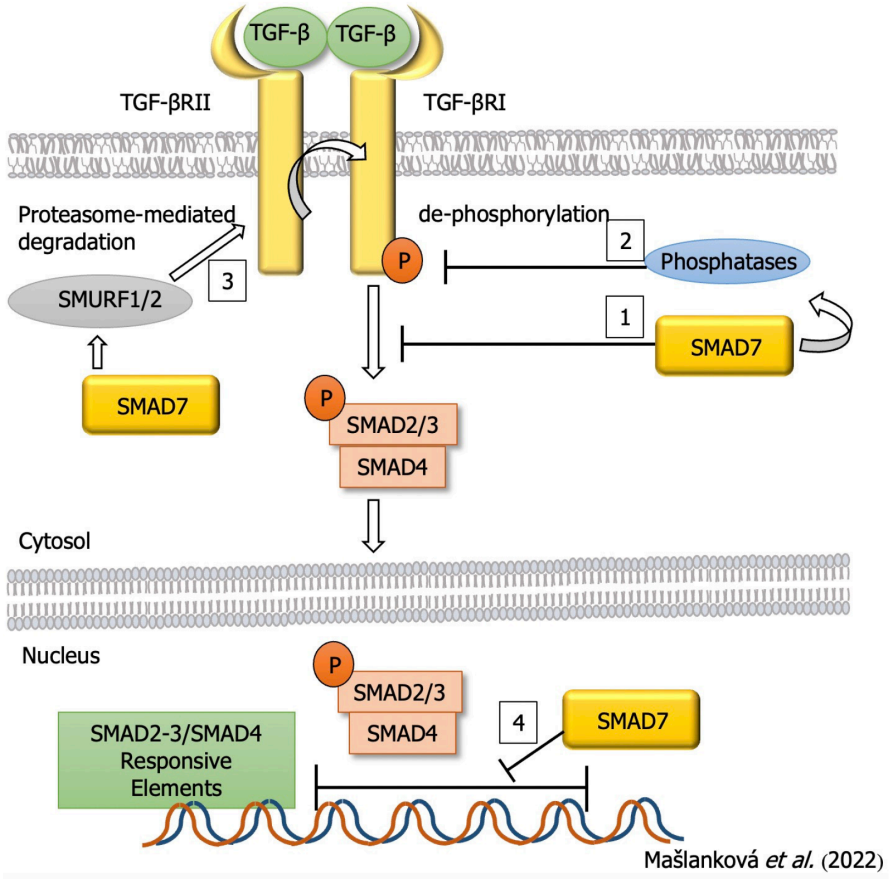

Figure 4 Inhibitory effect of small mothers against decapentaplegic homolog 7 on the process of colorectal cancer development. TGF: Transforming growth factor; SMAD: Small mothers against decapentaplegic homolog.

of the human genome consists of non-coding RNAs (ncRNAs) that do not encode proteins. ncRNAs are divided into two larger groups[73]; in one are the housekeeping ncRNAs, including the very abundant rRNAs and tRNAs, and in the other are the regulatory ncRNAs, including long ncRNAs (lncRNAs), microRNAs (miRNAs), circular RNAs (circRNAs), PIWI-interacting RNAs, small tRNA-derived RNAs (tRFs), small nuclear RNAs (snoRNAs), siRNAs and others. The most studied classes of ncRNAs are lncRNAs, miRNAs, and circRNAs. These types of ncRNAs very significantly regulate or are regulated by the TGF-β signaling pathway[74].

LNCRNAs AS REGULATORS IN CRC

lncRNAs influence gene expression through several mechanisms, such as silencing of the X chromosome, modification of chromatin, imprinting of the genome, activation of transcription, and nuclear transport. Imbalance in regulation of lncRNA transcription has been associated with apoptosis, angiogenesis, proliferation, invasion, metastasis and drug resistance of CRC[74].

The lncRNAs cancer susceptibility candidate 9 (CASC9) and small nucleolar RNA host gene 6 (SNHG6) can positively regulate the TGF-β pathway in CRC. CASC9, in particular, increases the stabilization of TGF-β2 mRNA[75], and a study by Zhang *et al*[76] showed that it targets miRNA-542-3p and could also increase chemoresistance. The lncRNA SNHG6, on the other hand, targets miR-26a-5p and increases the resistance of CRC cells to 5-fluorouracil (5-FU).

The lncRNA nuclear paraspeckle assembly transcript 1 (NEAT1) has been verified to participate in the development and progression of colon cancer[77].

CTBP1-AS2 has an important role in CRC proliferation and metastasis. While CTBP1-AS2 has been shown to significantly promote activation of the TGF-β/SMAD2/3 signaling pathway, miR93-5p (a downstream molecule of CTBP1-AS2) has been shown to target the 3′-untranslated region (UTR) of TGF-β. Furthermore, investigations of the functionally of miR-93-5p showed that its overexpression exerts an anti-cancer effect by inhibiting the TGF-β/SMAD2/3 pathway[78].

miRNAs AS REGULATORS IN CRC

miRNA regulates the transcription of genes encoding proteins at the post-transcriptional level. They perform this task by binding to complementary sequences located in the 3′-UTRs of their target mRNAs [79]. miRNAs are also competitively inhibited by lncRNAs[24].

In TGF-β signaling, miRNAs can play a stimulatory role, as shown in cells treated with anti-metabolites and anti-microtubule medicines; this is similar to what has been reported in cases of chemo-resistance against DNA damaging agents. In particular, miR-423-5p, miR-552, miR-34a, and the miR-17-92 cluster (miR-17, miR-18a, miR-19a, miR-19b, miR-20a, and miR-92a) are examples of miRNAs that regulate TGF-β signaling in CRC. Furthermore, SMAD2, SMAD4, and TGF-βRII genes are markedly associated with miRNA-155 and miR-22, both of which strongly correlate with tumor properties, suggesting clinical utility in immunotherapy[24]. miR-4666-3p and miR-329 act as tumor suppressor genes, affecting TGF-βR1 and thus preventing the activation of the TGF-β1/Smad pathway[80]. Finally, miR-147 overexpression has been shown to inhibit EMT and the TGF-β/SMAD pathway in colon cancer cells[81].

circRNAs AS REGULATORS IN CRC

circRNAs are formed by back-splicing of linear RNA and connections *via* covalent linkage. circRNAs can prevent miRNAs from binding to the 3′-UTR sequence of a particular gene, by attachment to miRNAs, ultimately regulating gene expression by activating mRNA cleavage or subsequent translation [82].

circPTEN1 is significantly downregulated in CRC and its expression is positively correlated with patient prognosis. circPTEN1 binds to the MH2 domain of SMAD4 and prevents the interaction between SMAD4 and SMAD2/3, which leads to suppression of translocation of the SMAD complex into the nucleus, followed by the activation of the transcription of downstream genes that regulate the EMT by the TGF-β signaling pathway[83].

circPACRGL acts as a miR-142-3p/miR-506-3p sponge to promote TGF-β1 expression and, thus, promote the differentiation of N1 to N2 neutrophils[84].

Gaining a more comprehensive understanding of the role of ncRNAs in CRC may lead to new approaches in the treatment of this disease; however, currently, only a limited number of identified and characterized lncRNAs and circRNAs with a confirmed regulatory role in CRC are known. There remains an urgent need to investigate the role of other lncRNAs and circRNAs that may facilitate the prognosis, diagnosis and treatment of CRC.

TREATMENT OF CRC

Over the last 10 years, researchers have developed a new anticancer therapy for patients with advanced or metastatic cancer. Several recent studies have shown that drug resistance in the treatment of various cancers, including CRC, is associated with the activation of TGF-β signaling[24]. 5-FU, an anticancer agent that belongs to the category of antimetabolites, is widely used to regulate metabolic pathways that are essential for cancer cell proliferation and survival. 5-FU is a standard chemotherapeutic used for the treatment of CRC patients, and a large proportion of these patients relapse or metastasize during the course of treatment. In patients with CRC, drug resistance is a key cause of chemotherapy failure and disease progression[85,86]. Recent research suggests that SMAD4 expression levels correlate with the prognosis and response to 5-FU and can help guide therapeutic decisions regarding its administration [87,88]. Reduced concentrations of SMAD3 or loss of SMAD4 suppress the expression of tumor suppressor genes that are induced by the TGF-β signaling pathway, which in turn leads to the expression of anti-apoptotic proteins Bcl-2 and Bcl-Wand increased survival of cancer cells resistance to 5-fluorouracil in CRC[89].

The role of TGF-β/SMAD signaling in tumor radiotherapy is controversial. It has been described in some studies that fibrosis is induced by upregulation of SMAD2/3 after radiation exposure. Reactive oxygen species (ROS) are involved in irradiation (IR)-induced fibrosis through TGF-β signaling. SMAD molecules that are activated by the TGF-β signaling pathway regulate ROS production by upregulating *NADP oxidase* 4[89,90]. Mutations in some genes, such as tumor protein p53, Ras, SMAD4, and EMT, are important in radioresistance or radiosensitization and can be controlled by SMAD-dependent or SMAD-independent TGF-β pathways[91]. Publications in recent years suggest that TGF-β signaling through various mechanisms, especially through miRNA-mediated regulation, plays an important role in the resistance of tumor cells to DNA-damaging agents. In CRC, miR-34a interacts directly with the 3′-untranslated region of SMAD4 and suppresses TGF-β/SMAD4 signaling. In patients with oxaliplatin-resistant CRC, miR-34a is downregulated to increase macroautophagy by activating the TGF-β/SMAD pathway[92,93].

ANTI-TGF-β THERAPIES

The objective of targeting TGF-β signaling as a therapeutic approach to treat cancer is supported by a plethora of findings from genetic and preclinical studies. Several strategies have been tested thus far that aim to block the TGF-β signaling pathway (Figure 5). These include: (1) Preventing TGF-β production or expression of its receptor by antisense oligonucleotides (ASOs; short synthetic single-stranded nucleic acids that bind to RNA to regulate gene expression); (2) preventing TGF-β activation *via* integrin-blocking antibodies, in which the antibodies compete with the TGF-β ligand to bind to its receptor, as well as the ability to block the activation of latent TGF-β (both steps are crucial for TGF-β to elicit its protumorogenic and immunosuppressive responses); (3) inhibiting the interaction between TGF-β and its receptor with neutralizing antibodies to TGF-β, blocking antibodies to TGF-βRII or ligand traps (engineered soluble forms of the receptor that compete with the cell-bound receptor); (4) preventing intracellular TGF-β receptor signal transduction *via* small-molecule *kinase* inhibitors, which bind to the ATP-binding domain of TGF-β kinase and inhibit *ATP kinase* activity, thereby blocking the downstream signaling cascade[94]; (5) immune checkpoint inhibitors (ICIs), which have essential roles in modulating the immune system. This group includes monoclonal antibodies that send inhibitory signals to T cells, enhancing T cells' antitumor immune response and improving antitumor defense. In addition to immunoregulatory cells such as regulatory T cells (Tregs), M2 macrophages, and myeloid-derived suppressor cells (MDSCs), the cytokine TGF-β also has the ability to control and modulate T cell functions. This is facilitated by the release of molecules that are able to activate specific ICIs. In this way, activation of inhibitory immune checkpoints, such as cytotoxic T-lymphocyte-associated protein-4 (CTLA-4), programmed cell death-1/Ligand (PD-1/PD-L1), lymphocyte-activation gene 3 (LAG3), or T-cell immunoglobulin-and mucin domain-3-containing molecule 3 (TIM-3) can disrupt cytotoxic T-lymphocyte (CTL) proliferation in CRC and reduce the immune response against cancer[95]; (6) vaccine-based approaches to modulate TGF-β signaling, which have been applied with the aim of facilitating the immune destruction of cancer cells in many different tumor types. It is important to realize that tumors are able to prevent the activation of the immune system by hiding tumor cell antigens and also suppress the immune system. Thus, cancer vaccines will help to activate and maintain an anti-tumor immune response; and (7) adoptive cell therapy, which is a form of passive immunotherapy that involves transferring immune cells or molecules to the host[96].

Many of these agents have been or are being evaluated in clinical trials to treat CRC (Table 3).

SMALL MOLECULE INHIBITORS OF SMAD EXPRESSION AND PHOSPHORYLATION

Since SMAD molecules have an important role in the TGF-β signaling pathway, great efforts have been made for the search of SMAD activation inhibitors. Indeed, it has been shown that SMAD3 silencing can suppress cancer cell growth and metastasis by increasing the cancer-killing activity of natural killer (NK) cells. Thus, the selective inhibition of the SMAD3 protein with a potent, low toxicity drug could provide a promising anticancer treatment. Some compounds have shown good inhibitory activity against SMAD 2 or SMAD3 through direct or indirect downregulation of their respective expressions and phosphorylations[97].

Peptide aptamers or DNA aptamers are artificial short peptides, respectively single-stranded DNA or RNA nucleotides, which are antibody-like in function. Aptamers can bind specific molecules with high specificity and affinity. SMAD2-and SMAD3-binding aptamers have also been established. Upon binding to SMAD2 or SMAD3, the aptamer prevents their binding and complex formation, thereby arresting TGF-β signaling[98,99]. Aptamers also have the potential to be used more frequently in clinical practice, from disease diagnosis to targeted delivery of therapeutic agents. Their simplicity in manufacturing and lengthy shelf life significantly improve this potential[100].

The specific inhibitor of SMAD3 (SIS3) is a synthetic substance that specifically inhibits the phosphorylation of SMAD3 and thus its binding to SMAD4[101]. Furthermore, targeting the inhibition of SMAD3 is currently considered a promising therapeutic strategy in the treatment of cancer[102].

MEDICATION THERAPEUTIC STRATEGIES THROUGH THE TGF-B /SMAD SIGNALING PATHWAY

The effects of several potential molecules that induce tumor growth or inhibit the proliferation and metastasis of carcinoma cells through regulation of the TGF-β/SMAD signaling pathway have been described[103]. Baicalein is a major flavonoid, originally extracted from the edible medicinal plants of *Scutellaria baicalensis* and *S. lateriflora*. Baicalein reduces the concentrations of phosphorylated SMAD2 and SMAD3, without affecting the total levels of SMAD2 and SMAD3 and thus inhibits the TGF-β /SMAD2/3 signaling pathway in fibroblasts in vitro and in vivo without affecting SMAD 1, 5, and 8 in the BMP signaling pathway[104].

Table 3 Clinical trials of drugs for the treatment of colorectal cancer (United States National Library of Medicine; ClinicalTrials.gov)

Clinical trials (phase)	Drug	Target	Mechanism of action
Antisense oligonucleotides			
NCT00844064 (I)	AP12009 (trabedersen)	TGF-β2	By binding to TGF-βII mrna, its expression is reduced
Antibodies			
NCT04952753 (II)	NIS793	TGF-β	Reduction of active cytokine, reduction of SMAD2/3 phosphorylation, and reduction of TGF-β target gene expression
NCT02947165 (I)	NIS793	TGF-β	Reduction of active cytokine, reduction of SMAD2/3 phosphorylation, and reduction of TGF-β target gene expression
NCT01646203(I)	IMC-TR1	TGF-βRII	Reduction of active cytokine, reduction of SMAD2/3 phosphorylation, and reduction of TGF-β target gene expression
Ligand traps			
NCT03436563 (I/II)	M7824	TGF-βRII	Bifunctional anti-PD-L1/TGF-βRII trap fusion protein
NCT02517398(I)	Bintrafusp alfa	TGF-βRII and PD-L1	First-in-class bifunctional fusion protein composed of a mab against PD-L1 fused to the extracellular domain of the TGF-β receptor II
NCT04856787 (II/III)	SHR-1701	TGF-βRII	Bifunctional anti-PD-L1/TGF-βRII agent
Small molecule receptor kinase inhibitors			
NCT04031872 (I/II)	LY3200882; capecitabine	TGF-βRI	By blocking ATP binding to TGF-βR, receptor kinase activity and signal transduction are reduced
NCT05400122 (I)	Vactosertib	TGF-βRI	Inhibits the activity of TGF-βR1
NCT03724851 (I/II)	Vactosertib + Pembroli-zumab	TGF-βRI	Inhibits the activity of TGF-βR1
NCT03470350 (I/II)	Galunisertib	TGF-βRI	Inhibits the activity of TGF-βR1
Immune checkpoints			
NCT04540159		TGF-β1	Measuring the level Active TGF-β1 by flow-cytometric analysis in the intraabdominal ascites
Adoptive cell therapy			
NCT03431311 (I/II)	ACT	TGF-βII	ACT with Radium-1 TCR + T cells transiently redirected against the TGF-βRII frameshift antigen which is expressed in MSI+ colon cancer.
NCT05040568 (I)	CB-NK-TGF-Î²R2-/NR3C1		Immunotherapy with ex vivo preactivated and expanded CB-NK cells in combination with cetuximab

ACT: Adoptive cell therapy; TGF: Transforming growth factor.

Ginseng is valued as the most important medicinal plant in traditional Chinese medicine. The major constituents of ginseng are ginsenosides. Ginsenoside Rg3 has an inhibitory effect on the TGF-β/SMAD and ERK signaling pathways in keloid fibroblasts and increases mRNA expression levels in SMAD7 [105]. Dai *et al*[106] showed that ginsenoside Rb2 can inhibit the expression of SMAD4 and phosphorylated SMAD2/3 in CRC cells.

Kaempferol is a natural flavanol, a type of flavonoid, found in a variety of plants and plant-derived foods, including kale, beans, tea, spinach, and broccoli. It binds to the TβRI, leading to its inactivation. This results in inhibition of the TGF-β/SMAD signaling pathway due to reduced phosphorylation of SMAD2/3[107].

Loureirin B, a flavonoid extracted from *Dracaena cochinchinensis*, is used in traditional Chinese medicine (TCM). Loureirin B upregulates the expression of MMP-1, MMP-3, MMP-9, and MMP-13 and thus causes degradation of extracellular matrix, inhibits the phosphorylation of SMAD2 and SMAD3 and thus effectively suppresses the TGF-β/SMAD pathway[108].

Galangin is a polyphenolic compound derived primarily from different medicinal herbs, the effect of which is the downregulation of SMAD2 and SMAD3 phosphorylation without altering the expression of total SMAD2, SMAD3, SMAD4, SMAD6, and SMAD7[109].

Celastrol is a pharmacologically active substance extracted from *Tripterygium wilfordii* Hook F, which is used in TCM to treat cancer and other inflammatory diseases[110]. Zhang *et al*[111] showed that celastrol reduces the levels of SMAD4 and phosphorylated SMAD2/3. Together, celastrol may inhibit

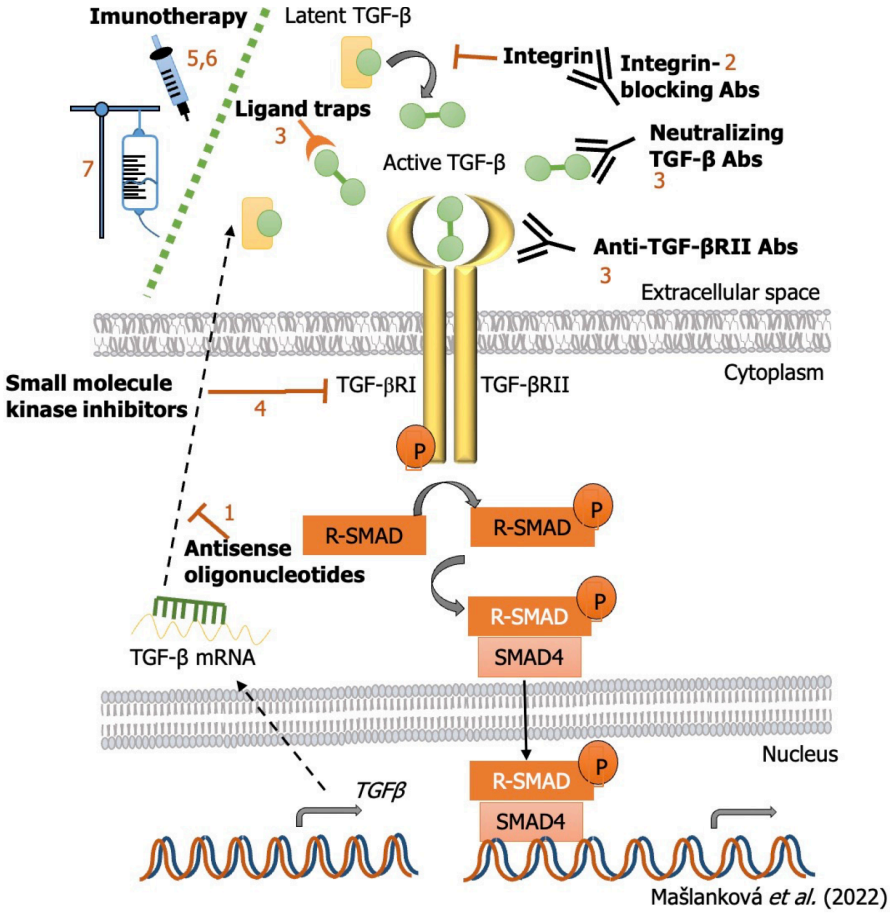

Figure 5 Inhibition strategies of transforming growth factor-β signaling pathway and miRNAs targets for colorectal cancer treatment.
TGF: Transforming growth factor; SMAD: Small mothers against decapentaplegic homolog.

CRC through TGF-β, which is a promising treatment for CRC.

Qingjie Fuzheng granules are TCM comprising a 4-herb mixture, composed of *Hedyotis diffusa* Willd, malt, *Astragalus*, and *S. barbata* D. Don significantly inhibits the expression of several key proteins in the canonical TGF-β/SMAD pathway, including TGF-β, phosphorylated SMAD2/3, and SMAD4. This inhibition leads to a decrease in the ratio of N-cadherin to E-cadherin, indicating that EMT is inhibited [111].

CONCLUSION

Antitumor immunity is mediated by macrophages, NK cells, granulocytes (polymorphonuclear leukocytes, PMNs), T cells, and antibodies. In recent years, the particular role of PMNs in regulation of adaptive immunity, especially in cancer, has emerged. PMNs in cancer are functionally diverse, with some authors describing their antitumor activity, but the number of publications in which the authors confirm their negative regulation of immune responses and their presence in cancer patients associated with poor prognosis and therapeutic outcomes is increasing. These cells suppress the physiological role of T and B lymphocytes and NK cells, and also promote tumor progression and metastasis through non-immune mechanisms. Cytokines produced by tumor cells [vascular endothelial growth factor (VEGF), TGF-β] also play a similar role when they inhibit T cell development and function. TGF-β, as an immunosuppressive factor, significantly affects the proliferation, activation, and differentiation of immune effector cells. Epigenetic changes that may be affected by the TGF-β pathway in CRC should be carefully studied because the mechanisms of drug resistance are different between patients in different stages of cancer and personalized treatment is more effective. Therefore, knowledge of the activation and inhibition of factors that affect the TGF-β signaling pathway is very important.

ACKNOWLEDGEMENTS

This review is a summary work consisting of the results of many authors. We would like to thank all the authors whose work we have included in this review article and apologize to the authors whose relevant work has not been included in this review article.

FOOTNOTES

Author contributions: Maslankova J, Vecurkovska I, Rabajdova M, Katuchova J, Kicka M, Gayova M, and Katuch V contributed equally to the study's conception, design and undertaking, and to manuscript preparation; all authors have read and approve the final manuscript.

Conflict-of-interest statement: The authors declare having no conflict of interests for this article.

Abstract

Fecal microbiota transplantation (FMT) is a successful method for treating recurrent *Clostridioides difficile* (*C. difficile*) infection (rCDI) with around 90% efficacy. Due to the relative simplicity of this approach, it is being widely used and currently, thousands of patients have been treated with FMT worldwide. Nonetheless, the mechanisms underlying its effects are just beginning to be understood. Data indicate that FMT effectiveness is due to a combination of microbiological direct mechanisms against *C. difficile*, but also through indirect mechanisms including the production of microbiota-derived metabolites as secondary bile acids and short chain fatty acids. Moreover, the modulation of the strong inflammatory response triggered by *C. difficile* after FMT seems to rely on a pivotal role of regulatory T cells, which would be responsible for the reduction of several cells and soluble inflammatory mediators, ensuing normalization of the intestinal mucosal immune system. In this minireview, we analyze recent advances in these immunological aspects associated with the efficacy of FMT.

Key Words: Fecal microbiota transplantation; Immunity; Mechanism; Dysbiosis; Pseudomembranous colitis; *Clostridioides difficile*

Core Tip: Fecal microbiota transplantation (FMT) is an excellent treatment option of pseudomembranous colitis due to *Clostridiodes difficile* infection (CDI) because of its remarkable effectiveness. Moreover, FMT is a promising therapy for several other disorders in which dysbiosis is an important pathological factor. The mechanisms of FMT have begun to be dissected and include the restoration of the commensal microbial community structure and the modulation of several components of the immune system. This minireview focus on the FMT immune-related mechanisms for CDI.

INTRODUCTION

The human microbiota is a complex community of microorganisms that reside on the skin and mucosal surfaces, with gut microbiota being by far the most studied microbial subcommunity[1]. Firmicutes and Bacteroidetes are the most prevalent phyla in the human gut, followed by Actinobacteria and Proteobacteria[2]. Interestingly, mammals directly or indirectly receive signals from the microbiota for adequate development and functioning throughout life[3]. These signals are important for several systems of the human body. The interaction of the microbiota with the immune system is probably the best example of how important the commensal microbiota is for the host, given that the absence of microbiota results in an immune system with fewer and less varied components, as well as delayed immune responses[3,4]. Moreover, the presence of a normal microbiota restricts the colonization of pathogens by direct and indirect mechanisms. This function of the microbiota is known as colonization resistance[5,6]. Furthermore, the alteration of intestinal microbiota composition is called dysbiosis and commonly results in disease development.

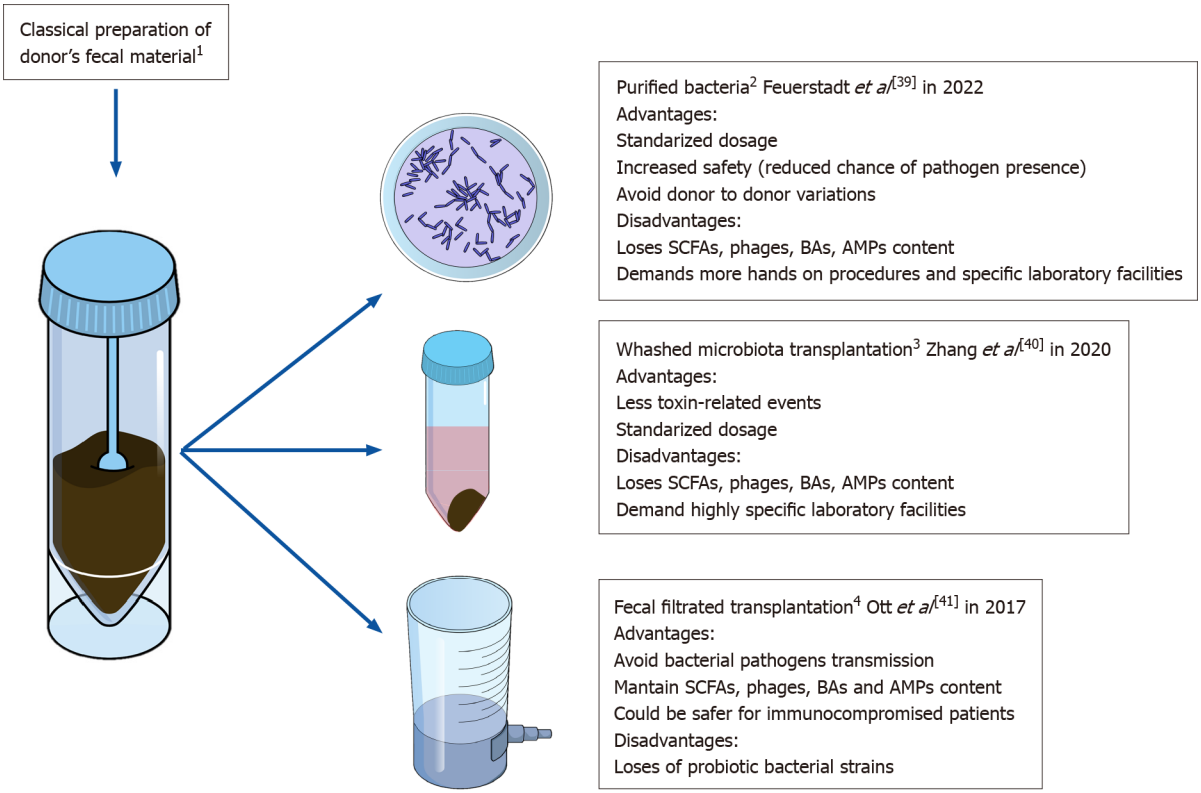
CLOSTRIDIOIDES DIFFICILE INFECTION AND INTESTINAL DYSBIOSIS CORRECTION WITH FMT

Clostridioides difficile (*C. difficile*) is a spore-forming bacillus with the capacity to retain crystal violet staining, denoting that its cell wall is rich in peptidoglycans and, therefore, becomes positive in the staining procedure created by Hans Christian Gram in 1884[7]. Although *C. difficile* could be part of the intestinal commensal microbiota, toxin-producing strains are pathogenic. Nonetheless, the ingestion of toxin-producing *C. difficile* does not necessarily result in disease development because the microbiota is able to avoid colonization and overgrowth of this pathobiont[8]. However, *C. difficile* infection (CDI) is well known to occur due to a combination of two factors: (1) Ingestion of the bacillus spores during hospitalization, where the circulation of strains capable of expressing toxins A, B, and C - which damage the intestinal epithelium - is more common; and (2) Receiving or having recently received broad-spectrum antibiotic therapy, which will cause intestinal dysbiosis[8,9]. Thus, antibiotic exposure followed by acute episodes of diarrhea is the main clinical indicator of CDI. The detection of toxins associated with colonoscopic and/or histopathologic findings will confirm the diagnosis of pseudomembranous colitis[10]. Elderly persons are more affected by the disease; however, CDI is becoming more frequent in younger populations and with no association with previous hospitalizations[8,11]. The emergence of hypervirulent and antibiotic-resistant *C. difficile* strains contributed to the burden of worldwide cases of antibiotic-associated diarrhea and pseudomembranous colitis[8,10]. In fact, CDI may range from mild or self-limiting diarrhea to severe cases and the development of sequelae, including toxic megacolon and fulminant colitis. CDI is commonly treated by antibiotics (Metronidazole, Vancomycin, and Fidaxomicin) with efficacy rates ranging from 76% (Metronidazole) to as high as 97% (Vancomycin and Fidaxomicin)[12,13]. However, as with many other broad-spectrum antibiotics, *C. difficile* can also develop resistance mechanisms to these and other antibiotics[14]. Furthermore, antibiotic therapy, which treats CDI, will enhance dysbiosis and will predispose the patient to CDI relapse[15]. In fact, it is well known that 20%-30% of antibiotic-treated CDI cases subsequently develop recurrent episodes of the infection (rCDI)[16-18].

FMT is primarily indicated for treating pseudomembranous colitis due to rCDI[19,20]. The use of FMT for rCDI is based on several studies reporting the effectiveness of FMT, supporting it as the most effective treatment for this disease. In a systematic review on FMT effectiveness against rCDI that included 45 studies (36 cohort studies and nine randomized clinical trials), it was shown that FMT has

91% effectiveness after eight weeks of repeated treatment - far superior to the use of antibiotics[21]. According to the United States Food and Drug Administration, FMT may be performed after two failed courses of antibiotics[22]. The fecal material for FMT may be obtained from a relative or unrelated donor and administered using a nasogastric or nasoduodenal tube or by colonoscopy[19,20,23,24]. More recently, successful FMT treatments using lyophilized solutions and capsules have been reported[25-27]. Commonly, the administration of one or two courses of FMT results in clinical remission as early as one day after the first FMT[23,24,28]. Its effects are based mainly on the restoration of eubiosis[29]. This implies that FMT effectiveness relies on microbiologic mechanisms, or in other words, the restoration of colonization-resistance-related mechanisms[30-32]. However, indirect mechanisms of colonization resistance include the crosstalk with different components of the immune system, which will be important for both maintaining the integrity of the intestinal mucosa or restoring that integrity if the disease is already present, as is the case of pseudomembranous colitis due to CDI[9,33].

Notably, FMT restores the capacity of the microbial community to convert primary bile acids (BAs) into secondary BAs, such as deoxycholic acid and ursodeoxycholic acid, which can inhibit *C. difficile* germination and epithelial apoptosis[34]. Although not directly shown in FMT, the optimal biotransformation of BAs by microbiota also modulates the repertoire and functions of colonic RORγt+ T regulatory (Treg) cells, contributing to intestinal homeostasis[35]. Moreover, higher levels of primary BAs in the stool, such as taurocholic acid - which can promote the spore germination of *C. difficile* - have been reported in rCDI patients compared to healthy individuals as well as compared to patients experiencing their first episode of CDI[36]. This is compatible with the bile salt hydrolase (*BSH*) gene abundance reduction - which metabolizes BAs - in rCDI patients compared to healthy and first episode CDI individuals[24]. Furthermore, BSH functional activity is rapidly restored in rCDI patients after FMT [23]. Taken together, these data indicate that gut microbial BAs metabolism is one of the molecular mechanisms of FMT to successfully treat rCDI.



Similarly, the recovery of microbiota functions after FMT is linked to the repopulation of short-chain fatty acids (SCFAs) producer bacteria - mainly members of the Clostridiales clade that include several butyrate producers[37]. SCFAs are known to serve as the main source of energy for colonocytes but also play a role in homeostasis maintenance, inducing the differentiation into effector and Treg cells in the intestinal lamina propria (LP)[38]. BAs and SCFAs are bacterial metabolites with pleiotropic effects on the immune system but, acting together, they may play a crucial role in reducing the inflammation in the intestine after FMT[35].

One important aspect of FMT refers to means of improving it by using simpler preparations that could offer more standardized formulations, being more patient-friendly, and avoiding any type of potential risks by not using an undefined combination of living microorganisms, as is the case with FMT. In this regard, Feuerstadt *et al*[39] have recently reported the use of oral capsules composed of live purified Firmicute bacterial spores in a phase 3 clinical trial of patients with rCDI. Of the 89 patients treated with this formulation and followed for eight weeks, they observed recurrence in 11 patients (12%) compared to 37 patients (40% of recurrence) in the placebo group[39].

On the other hand, Zhang *et al*[40] proposed to submit the fecal material of standard FMT to a combinatorial method of filtration and centrifugation to offer a safer, more precise and quality-controllable microbiome transplant. The authors called this material "washed microbiota transplantation" (WMT) and provided evidence of reduced levels of pro-inflammatory molecules such as leukotriene B4, corticosterone, and prostaglandin G2 in mice which were intraperitoneally injected with WMT. Despite that washed microbiota has been used successfully to treat ulcerative colitis and Crohn's disease since 2014, it has not been evaluated in the context of rCDI[40].

Interestingly, Ott *et al*[41] showed that a single administration of sterile fecal filtrate (FFT), which contains bacterial components, bacteriophages, and bacteriocins but not whole bacterial cells, was able to eliminate symptoms and avoided the recurrence of CDI in 5 patients. This finding could overturn the necessity of living bacteria and successful engraftment of donor microbiota to reach the protective effect of FMT in rCDI patients. A possible explanation for this result could be that bacteria cell wall components and DNA fragments, which remain after filtration, stimulate the host's innate immune responses, with subsequent reprogramming of the mucosal immune mechanisms against the pathogen while promoting the restoration of homeostasis. The authors also proposed an additional explanation in which the massive transfer of bacteriophages from the donor to the host would be able to correct dysbiosis in rCDI patients. Although the study does not assess BAs or SCFAs content in the FFT, it is reasonable to consider that these metabolites could also participate in the effects reached by FFT since they are expected to persist after the filtration process. The absence of potential bacterial pathogens in the transplanted material - as is the case when using FFT - could represent an important advantage for the use of FFT in immunodeficient patients instead of living bacteria. In addition, FFT could also be better standardized. Therefore, FFT needs to be explored in detail in a larger group of patients and compared to FMT. Figure 1 summarizes these FMT variations and their key features.

Taking together all these studies, one may conclude that immune pathways activated during the response to *C. difficile* are important not only to identify the mechanisms that effectively contribute to its elimination but also to determine which immune components are activated or respond to FMT.

Figure 1 Advantages and disadvantages of non-classical preparations methods of donor's fecal material prior to fecal microbiota transplantation. [1]Classical preparation consist in dissolve donor's fecal material by blending with saline water and filter out residual solid feces through gauze or fabric. [2]Isolation of different bacteria strains directly from donor's fecal material. [3]Basically, this method consists in consecutively centrifugation of microbiota from donors to remove the supernadants. [4]Uses filtration systens to retain debris and bacterial load from the donor's fecal material. SCFAs: Short-chain fatty acids; AMPs: Antimicrobial peptides; BAs: Bile acids.

ESSENTIAL CONCEPTS OF THE IMMUNE RESPONSE DURING CDI

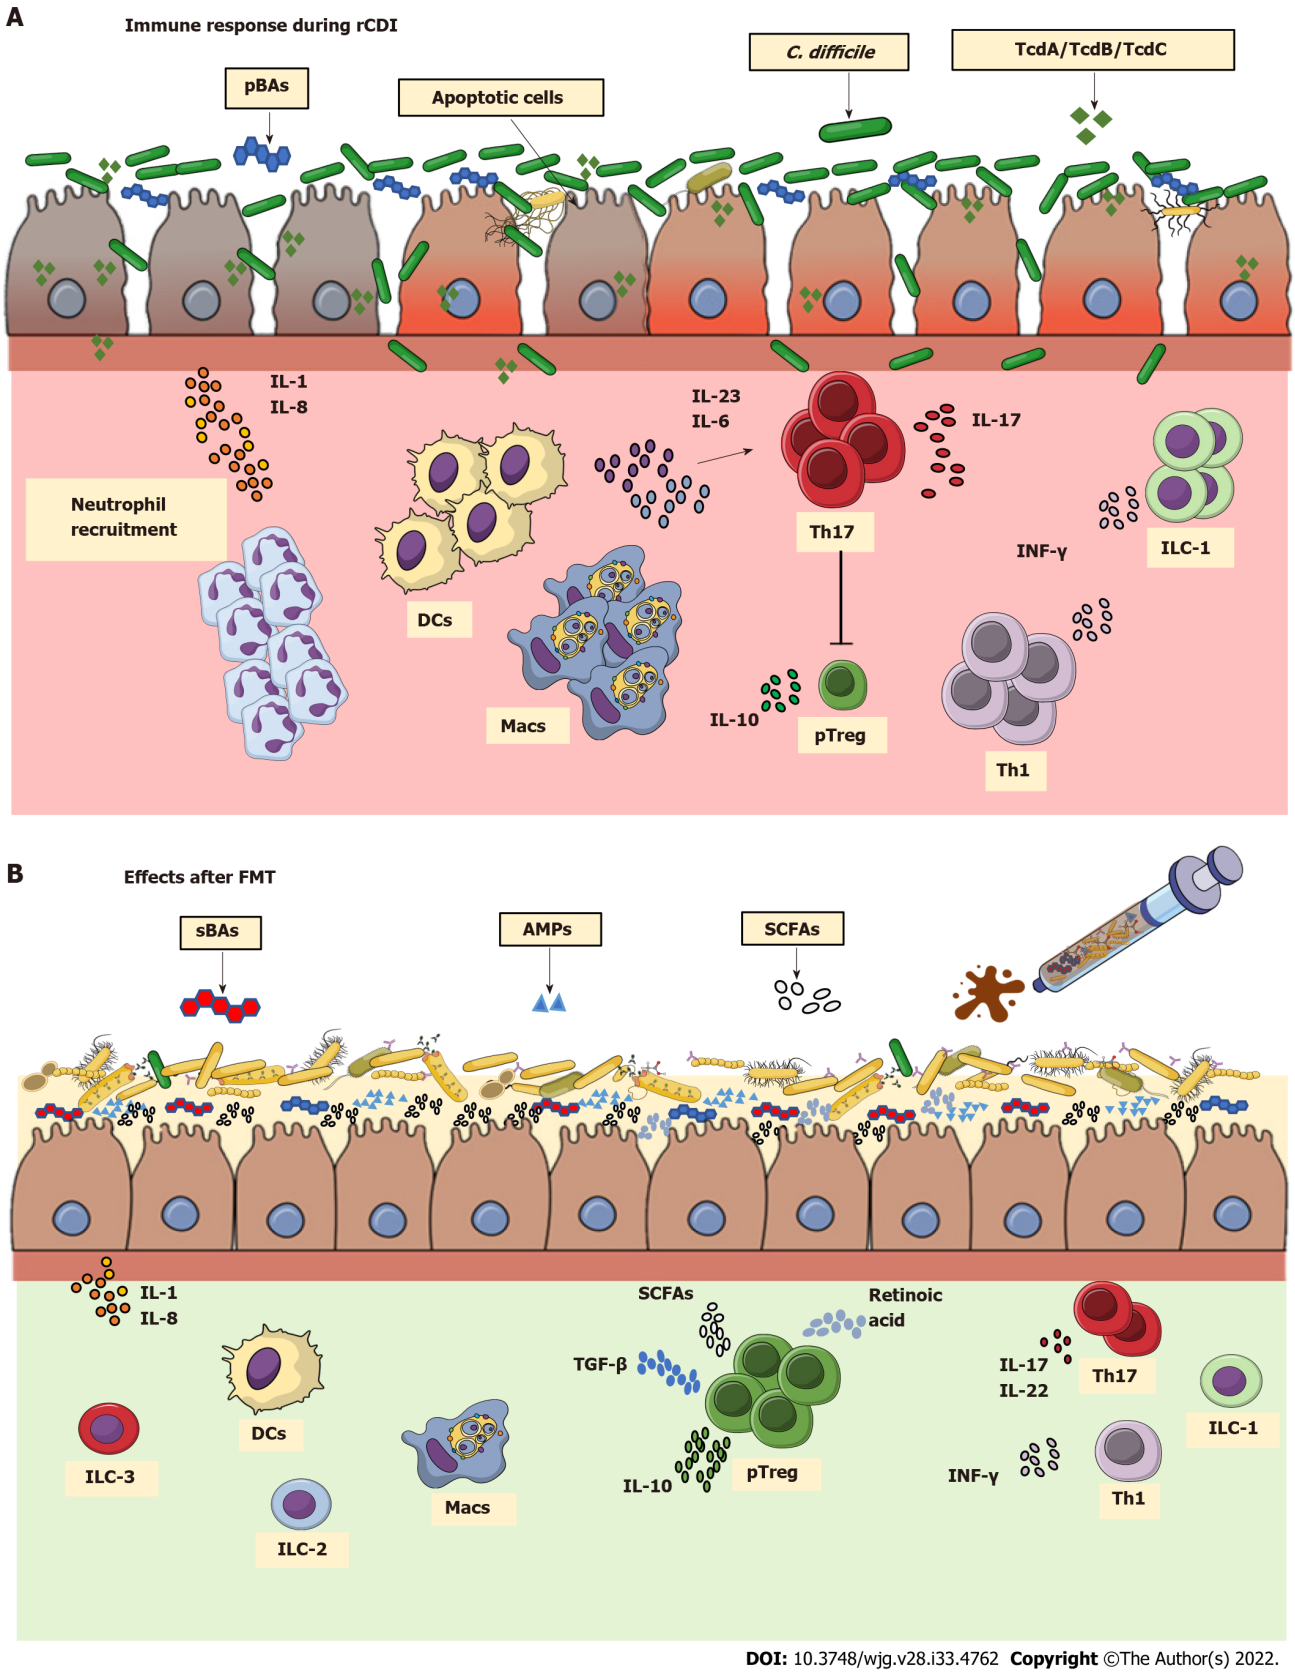
As there are recent and excellent reviews on the immune response to *C. difficile*[10,42,43], in this section, we present the main characteristics of this host-pathogen interaction.

The immune response to *C. difficile* is characterized by the development of an inflammatory reaction with Th1 and Th17 components. This response starts with bacterial sensing by epithelial cells and the release of interleukin (IL)-1 and IL-8 with high capacity to attract neutrophils[44,45]. Type-1 innate lymphoid cells (ILC-1) also participate in the response by secreting interferon-γ (IFN-γ)[46]. Antigen-presenting cells (APCs), including macrophages and dendritic cells (DCs), are important to capture and process *C. difficile* antigens, migrate to draining lymph nodes, and activate specific T cells[47]. Under these circumstances, Th1 cells are generated, but the secretion of IL-6 and IL-23 provide sufficient stimuli for the expansion of Th17 cells[48]. While these aspects of the immune response could be pivotal for appropriate enhancement of several bacteria-killing mechanisms by innate cells, it is already known that an exacerbated immune response signifies the development of pseudomembranous colitis, which is the histopathological lesion caused by the inflammatory response taking place in the colon[49]. To avoid the development of an immunopathological response, two important branches of immunity are required. First, the activation of Treg cells with the secretion of immune regulatory cytokines IL-10 and transforming growth factor-β (TGF-β)[50]. The source of these regulatory cytokines may also be enriched from other cell subsets such as intestinal epithelial cells, for example, which have the ability to secrete relevant quantities of TGF-β[50,51]. Secondly, recent studies have indicated the importance of active Th2 components present in patients with CDI who do not develop histopathological lesions but, instead, resolve the infection. These elements include mainly ILC-2 and eosinophils as the main cell populations[52,53], as well as type 2 cytokines, including IL-4, IL-5, IL-13, IL-25, and IL-33[54-56].

While the participation of Th1, Th17, and Treg cells during the response to bacteria with the characteristics of *C. difficile* is easy to understand, the type 2 component - which appears to have remarkable importance for the host to avoid an overreacting inflammatory response - is unexpected. Therefore, the antigenic components responsible for the activation of ILC-2 and eosinophils during CDI are new essential factors to be identified to better understand the effective immune response against *C. difficile*.

Table 1 Main clinical and experimental studies about the immunological mechanisms associated to fecal microbiota transplantation efficacy

Ref.	Model / clinical study	Main findings
Ekmekciu *et al*[57], 2017	Mice treated with antibiotic cocktail followed by FMT	Recovery of INF-γ, IL-17, IL-22 and IL-10 producer CD4+ T cells in intestinal LP. FMT failed to recover CD8+ T and B cells in LP after antibiotic exposure
Burrello *et al* [58], 2018	Mice treated with DSS followed by oral gavage of mucus and feces from healthy mice	Treatment increased Camp, S100A8, Muc1 and Muc4, reduced MHC-II+ cells and normalized populations of ILC-2, ILC-3, F4/80+ macrophages and CD11b+ Ly6G+ neutrophils
	In vitro stimulation of LPMCs stimulated with FMT or DSS-derived microbiota	FMT reduced IL-1β, TNF-α and IFN-γ and increased IL-10
	IL-10 receptor blockade in DSS mice prior of FMT treatment	Blockade of IL-10 resulted in reduction in colon length, increased weight loss and expression of *IL-1β, TNF and IFNγ* genes
Littmann *et al*[59], 2021	Use of different KO mice to evaluate B and T (CD8+, Th1, Th17 and Treg) cells	Treg cells play a pivotal role for FMT to achieve the effects against CDI
Monaghan *et al*[60], 2021	Multiomic analysis of fecal, sera and PBMC samples of patients with severe (n = 3) or fulminant (n = 1) CDI treated with FMT in 6 occasions plus fidaxomicin (severe cases) or vancomycin and metronidazole (fulminant case)	One patient (severe CDI) did not respond to treatment. The fulminant case responded after FMT in 10 occasions plus antibiotics. 78 features were identified differentiating responders to the non-responder. Non responsiveness was associated to higher levels of MMP-2, TWEAK, IL-26, sTNF-R1, sTNF-R2, effector memory CD8 T cells and circulation of senescent T cells; and lower TCR diversity repertoire, B cell and regulatory B cell frequencies



IL: Interleukin; FMT: Fecal microbiota transplantation; INF: Interferon; LP: Lamina propria; DSS: Dextran sodium sulfate; LPMCs: Lamina propria mononuclear cells; Muc: Mucin; TNF: Tumor necrosis factor; Treg: T regulatory; KO: Knockout; CDI: *Clostridioides difficile* infection; PBMC: Peripheral blood mononuclear cell; ILC: Innate lymphoid cells.

IMMUNOLOGICAL EFFECTS ASSOCIATED WITH FMT EFFICACY TO TREAT RCDI

One important attempt to gain knowledge to elucidate the immunological events elicited by FMT to successfully treat rCDI was made by Ekmekciu *et al*[57]. In this article, the investigators evaluated the effects on the immune system of mice treated for eight weeks with a cocktail of five antibiotics followed by FMT to resolve the dysbiosis caused by the antibiotic exposure. After successfully showing the depletion of the intestinal microbiota and reduction of proliferating cells in the intestines, as well as the restoration of both parameters soon after FMT, the authors evaluated different populations of the immune system. The investigators found that CD4+ T lymphocyte frequencies decreased after antibiotic treatment in the gut LP and mesenteric lymph nodes and presented recovery from the seventh day after FMT. Paradoxically, the absolute number of CD4+ T lymphocytes increased in the spleen and did not return to normal levels 28 d after FMT. CD8+ T cells showed the same profile as CD4+ T cells in LP, mesenteric lymph nodes, and the spleen, but not in the colon. The number of colonic CD8+ T cells presented a huge reduction after the antibiotic treatment, and FMT failed to induce the recovery of these cells. In parallel, B cells presented equivalent alterations to those of T cells in the gut (including an important reduction in the colon with no recovery after FMT), mesenteric lymph nodes, and the spleen, yet only in absolute cell numbers and not in cell frequencies[57].

The microbiota depletion due to the antibiotic treatment also resulted in a reduction of T cells with memory/effector phenotype ($CD44^{hi}$), Tregs, and co-stimulatory molecules in DCs, with the restoration of all these parameters after FMT. The authors also found that IFN-γ, IL-17, IL-22, and IL-10-producing T cells decreased with antibiotic treatment but were restored with FMT[57].

Subsequently, using the classical dextran sodium sulfate (DSS) colitis model, Burrello *et al*[58] provided a more profound and dynamic analysis of the effects of FMT in resolving intestinal inflammation. They used the $CXCR6^{egfp}$ reporter mice, in which T cells may be tracked, including the invariant natural killer T cell population. The investigators treated mice with DSS for seven days and, after a two-day recovery period, the mice received FMT on three consecutive days. The mice received a preparation of intestinal mucus on the first day and feces from healthy donor mice on the second and third days. Evaluations were performed one and five days after the last FMT. They found that FMT reduced the production of IL-1β and increased the production of antimicrobial peptides (Camp and S100A8) and mucins (Muc1 and Muc4), all in the colonic epithelium. In parallel, they observed effects on the innate and adaptive immune systems in DSS colitic mice treated with FMT. In the innate immune system, DSS inflammation induced the expansion of ILC-2 and ILC-3, F4/80+ macrophages, and CD11β+ Ly6G+ neutrophils, followed by a reduction of these populations after FMT. Furthermore, FMT strongly reduced MHC-II+ cells, indicating that the bacteriotherapy also affected APCs. These observations were correlated with the evaluation of LP mononuclear cells (LPMCs) stimulated with FMT or DSS-derived microbiota, *in vitro*. They found that innate and adaptive LPMCs stimulated with FMT-derived microbiota produced less IL-1β, tumor necrosis factor-α, and IFN-γ pro-inflammatory cytokines while increasing the production of IL-10. Moreover, the investigators went further, attempting to determine

Figure 2 The immune response during recurrent *Clostridioides difficile* infection and after fecal microbiota transplantation treatment. A: During recurrent *Clostridioides difficile* (*C. difficile*) infection, the depletion of commensal microbiota results in higher levels of primary bile acids (BAs). These molecules are known to trigger the *C. difficile* vegetative state and its expansion, resulting in production of toxin (Tcd) A, TcdB, and TcdC, which cause apoptosis of enterocytes and release of interleukin (IL)-1 and IL-8 in the lamina propria (LP). Consequently, there is extensive recruitment of neutrophils dendritic cells, and macrophages and type 1 innate lymphocytes (ILC-1) in an attempt to cope with the infection. These cells produce pro-inflammatory cytokines including IL-6, IL-23, interferon (IFN)-γ, which induce Th17 and Th1 differentiation. This inflammatory state dominated by IL-17 and IFN-γ promotes tissue damage, which could spread along the intestines, and is accompanied with absence of innate ILC-2 and reduction of peripheral T regulatory (Treg) cells; B: The therapeutic effects of FMT involve

the reestablishment of a wide variety of commensal microorganisms that directly and indirectly antagonize *C. diffcile*. Commensal strains that produce secondary Bas and short chain fatty acids are re-established, as well as the production of antimicrobial peptides by epithelial cells together with the reconstitution of the barrier integrity. These effects allow to reduce the activation of innate immunocytes, the expansion of Treg cells which produce IL-10, and subsequent normalization of Th1 and Th17 cell frequencies in the LP. IL: Interleukin; FMT: Fecal microbiota transplantation; TNF: Tumor necrosis factor; INF: Interferon; SCFAs: Short-chain fatty acids; AMPs: Antimicrobial peptides; TGF: Transforming growth factor; pBAs: Primary bile acids; sBAs: Secondary bile acids; DCs: Dendritic cell; ILC: Innate lymphoid cells; rCDI: Recurrent *Clostridioides difficile* infection; Treg: T regulatory; Macs: Macrophages.

the importance of IL-10 secretion for the beneficial effects of FMT to treat DSS colitis. Using a concomitant administration of IL-10 blockade in DSS mice during the FMT treatment, the authors demonstrated the pivotal importance of this regulatory cytokine for inflammation resolution, including the normalization of the histological score and intestinal weight[58].

More recently, Littmann *et al*[59] were able to confirm the importance of IL-10-producing cells for the host to be able to respond effectively to FMT. Their 2021 report started by considering that if the host immune system is not important for FMT to resolve the intestinal inflammation during CDI, then immune-deficient mice should be equally effective as wild-type animals to respond to FMT. To test their hypothesis, they used *Rag1* double knockout animals (*Rag1*$^{-/-}$), which lack T and B cells, and compared CDI course before and after FMT. They observed that CDI persisted in *Rag1*$^{-/-}$ animals but not in wild-type (WT) littermates nor *Rag1*^{HET} controls. Importantly, they confirmed this observation by excluding the possibility that the microbiota composition of *Rag1*$^{-/-}$, which is known to be different from the microbiota of *Rag1*^{HET} mice, was indeed the reason for the differential responses to FMT. They were able to do so by performing three additional control experiments. First, they analyzed and compared the microbiota composition of *Rag1*$^{-/-}$, *Rag1*^{HET}, and WT mice. Second, they transferred WT or *Rag1*$^{-/-}$ microbiota to antibiotic-treated *Rag1*$^{-/-}$ and *Rag1*^{HET} mice. Third, they employed germ-free C57BL/6 mice, which were cohoused with *Rag1*$^{-/-}$ or *Rag1*^{HET} mice. These mice were treated with antibiotics, infected with *C. difficile*, and then treated with FMT. All these experiments confirmed that the difference in the responses to FMT in *Rag1-/-* or *Rag1*^{HET} depended on an adaptive immune cell population and not on differences in microbiome composition prior to FMT. Next, the investigators focused on determining which adaptive immune cell population is important for FMT efficacy. By using specific knock-out animals, they excluded the importance of B cells, CD8+ T cells, Th17, and Th1 CD4+ cells. In contrast, the transient specific ablation of Treg cells using the diphtheria toxin Foxp3-DTR mice demonstrated that Treg cells are pivotal to observing the effects of FMT against CDI. Moreover, Littman *et al*[59] also showed that FMT engraftment is different depending on the immune activation status of the host, as well as that the microbiota post-FMT is metabolically distinct depending on the functionality of the host immune system.

Finally, Monaghan *et al*[60] performed a systems biology-based study to interrogate the interaction among microbiome-metabolome-immune system in the context of FMT applied to patients with severe or fulminant CDI. They studied four patients unresponsive to antibiotic therapy and treated with sequential FMT. Three patients were responders against one non-responder. The evaluations included microbiome and associated metabolome profile in fecal samples as well as the evaluation of blood samples to access the epigenomic, metabolomic, glycomic, immune proteomic, immunophenotyping, functional immune assays, and the T cell receptor repertoire. Although the small sample size did not allow the authors to draw clear conclusions, they suggest that immunosenescent signals could be associated with non-responsiveness to FMT, since they found strong correlations between peripheral senescent T cells and host factors including butyrate, serum hydroxybutyrate, fecal urso- iso- and hyodeoxycholic acids, serum immunoglobulin G Fc N-glycopeptides, and microbial taxa including *Pseudomonas* at the genus level[60]. The main findings of the studies recently discussed are listed in Table 1.

In summary, the studies described here indicate that FMT effectiveness rely not only on the capacity of donor eubiotic microbiota to be able to expulse *C. difficile*, but also to produce key metabolic products as secondary BAs and SCFAs. These metabolites, together with the displacement of the pathogen which represents less injury and consequently reduction of pathogen-derived antigens for innate and adaptive immunity activation, allow Treg cells to expand and increase the production of IL-10. This regulatory activity becomes pivotal for different types of immune cell populations and their produced cytokines to return to normal levels dampening inflammation, as shown in Figure 2.

CONCLUSION

The findings discussed here provide a new perspective on the therapeutic effects of FMT to restore eubiosis. This ability refers, in our opinion, two key aspects: (1) The material to be transplanted must contain the appropriate elements to displace the pathogen and modulate the immune system of the patient effectively; and (2) The status of the immune system of the patient is decisive at the moment of receiving the transplant, which means that the patient's immune system must be able to respond

adequately to the FMT stimuli.

FMT is an effective option for the resolution of rCDI and is being used around the world increasingly. Moreover, recent studies show its efficacy in treating the first episode of CDI as well as its repeated use can treat severe and fulminant CDI forms[60]. Although the concept of the method is simple, it is a labor-intensive procedure and requires the acceptance of the patient to be treated with this kind of transplant, even if FMT-derived capsules are used. Nonetheless, as FMT is increasingly showing its benefits in a variety of clinical situations (*e.g.*, autism spectrum disorders, type 2 diabetes, and, of course, different types of inflammatory bowel diseases), this should guarantee not only the continuing use of FMT but also the advancement of basic research seeking to identify the molecular microbiological components that are pivotal for FMT efficacy. In addition, the new evidence discussed here shows the importance of disclosing in detail the immunological pathways that must be activated/deactivated during the FMT process. At the same time, it is necessary to consider that several of these observations came from animal studies, and where FMT was used to treat colitis induced by DSS or antibiotic cocktails but not by *C. difficile* infection. Nonetheless, all these efforts should lead to the identification of molecular factors that may become candidates for the development of new and more conventional therapeutic products that could replace FMT in the future or improve its results.

FOOTNOTES

Author contributions: Soveral LF, Korczaguin GG, and Schmidt PS collected the literature and wrote the first draft, conceptualized the table and figures, and contributed equally to this work; Nunes IS and Fernandes C corrected the first draft; Zárate-Bladés CR conceptualized the structure of the text and critically revised the manuscript for important intellectual content; and all authors read and approved the final version of the manuscript.

Abstract

Mortality in cirrhosis is mostly associated with the development of clinical decompensation, characterized by ascites, hepatic encephalopathy, variceal bleeding, or jaundice. Therefore, it is important to prevent and manage such complications. Traditionally, the pathophysiology of decompensated cirrhosis was explained by the peripheral arterial vasodilation hypothesis, but it is currently understood that decompensation might also be driven by a systemic inflammatory state (the systemic inflammation hypothesis). Considering its oncotic and nononcotic properties, albumin has been thoroughly evaluated in the prevention and management of several of these decompensating events. There are formal evidence-based recommendations from international medical societies proposing that albumin be administered in individuals with cirrhosis undergoing

large-volume paracentesis, patients with spontaneous bacterial peritonitis, those with acute kidney injury (even before the etiological diagnosis), and those with hepatorenal syndrome. Moreover, there are a few randomized controlled trials and meta-analyses suggesting a possible role for albumin infusion in patients with cirrhosis and ascites (long-term albumin administration), individuals with hepatic encephalopathy, and those with acute-on-chronic liver failure undergoing modest-volume paracentesis. Further studies are necessary to elucidate whether albumin administration also benefits patients with cirrhosis and other complications, such as individuals with extraperitoneal infections, those hospitalized with decompensated cirrhosis and hypoalbuminemia, and patients with hyponatremia.

Key Words: Cirrhosis; Albumin; Paracentesis; Spontaneous bacterial peritonitis; Acute kidney injury; Hepatorenal syndrome

Core tip: Mortality in cirrhosis is mostly associated with clinical decompensation. Albumin has oncotic and nononcotic properties, which may contribute to the prevention and management of such complications. This review discusses the current recommendations and the novel perspectives regarding the use of albumin in cirrhosis.

INTRODUCTION

Cirrhosis and chronic liver diseases rank as the conditions with the 10th highest mortality rate worldwide[1]. Deaths are mostly related to the development of clinical decompensation of cirrhosis, and 4%–12% of individuals with cirrhosis present with at least one episode of decompensation annually[2]. This is why preventing and treating decompensating events in cirrhosis are constant concerns of gastroenterologists and hepatologists.

Albumin administration has been studied in the prophylaxis and management of different forms of decompensation of cirrhosis for many years. Albumin is exclusively synthesized by hepatocytes, and it is characterized as a water-soluble, negatively charged, 67-kDa protein, with a half-life of approximately 20 d in normal conditions. It is the most abundant protein in serum and in extracellular fluids, and it has multiple roles, including oncotic, antioxidative, detoxifying, anti-inflammatory, endothelium stabilizing, and immunomodulatory functions[3]. Traditionally, most decompensating events of cirrhosis were explained by the peripheral arterial vasodilation hypothesis[4], and albumin was considered potentially useful mainly due to its oncotic property, as it is responsible for 75% of plasma oncotic pressure[3]. However, with the current understanding that decompensation of cirrhosis is at least partly driven by a systemic inflammatory state (the systemic inflammation hypothesis)[5-8], the nononcotic properties of albumin have gained much attention[3].

This article reviews the current role and novel perspectives for albumin administration in cirrhosis. Table 1 shows the main indications for which there are formal recommendations for the use of albumin in cirrhosis as well as other potential situations in which albumin may play a role.

LARGE VOLUME PARACENTESIS

Large volume paracentesis (LVP) is the current standard of care for the management of refractory and tense ascites due to its efficacy and low rate of complications[9-11]. However, the drainage of large volumes of ascitic fluid increases cardiac output and reduces peripheral vascular resistance and effective circulating volume, leading to arterial hypotension, acute kidney injury (AKI), hepatic encephalopathy (HE), worsening of hyponatremia, and decreased survival rates. This severe condition is termed paracentesis-induced circulatory dysfunction (PICD) and is defined by a rise of more than 50% in the basal plasma renin activity a few days after the procedure, indicating the detrimental effect of volume depletion on effective volemia[12-15].

Table 1 Current recommendations and potential indications for albumin administration in cirrhosis

Current recommendations[1]	Potential indications
Large-volume paracentesis	Modest-volume paracentesis
Acute kidney injury	Extraperitoneal infections
Hepatorenal syndrome	Long-term albumin administration in cirrhosis with ascites
Spontaneous bacterial peritonitis	Decompensated cirrhosis with hypoalbuminemia
	Hepatic encephalopathy
	Hyponatremia
	Cirrhotic cardiomyopathy
	Acute-on-chronic liver failure

[1]Recommendations for albumin administration according to the European Association for the Study of the Liver[9] and the American Association for the Study of Liver Diseases[11].

Several randomized controlled trials (RCTs) have shown that PICD can be prevented by intravenous human albumin administration, particularly in cases of paracentesis exceeding 5 L and that albumin is more effective than other plasma expanders[13,16-18]. In the seminal study by Ginès *et al*[13] for instance, 105 patients were randomized to be submitted to paracentesis with or without albumin infusion, and individuals receiving albumin developed less episodes of hyponatremia ($P < 0.01$) and renal impairment ($P < 0.05$).

In 2012, a meta-analysis of 17 RCTs, including 1225 patients with ascites undergoing LVP, showed that in comparison to alternative treatments albumin reduced the incidence of PICD [odds ratio = 0.39, 95% confidence interval (CI): 0.27-0.55], hyponatremia (odds ratio = 0.58, 95%CI: 0.39–0.87), and mortality (odds ratio = 0.64, 95%CI: 0.41–0.98), which appeared to be definitive evidence regarding the role of albumin infusion in LVP[19]. However, in 2019 another meta-analysis, including 25 RCTs, revisited this issue. According to this systematic review, there was no evidence of significant reduction in mortality or renal impairment when any volume expansion was compared to no volume expansion at all, but it should be highlighted that only one and two RCTs using albumin actually contributed to the analyses of these outcomes, respectively. When albumin was compared to other plasma expanders, there were significant benefits of using albumin regarding prevention of PICD [risk ratio (RR) = 1.98, 95%CI: 1.31–2.99] and hyponatremia (RR = 1.49, 95%CI: 1.03–2.14), but there was no evidence of significant differences between treatments regarding renal impairment (RR = 1.17, 95%CI: 0.71–1.91) and mortality (RR = 1.03, 95%CI: 0.82–1.30)[20].

The use of vasoconstrictors, such as vasopressin, midodrine, and noradrenaline, has been proposed as an alternative to albumin in order to overcome the marked arterial vasodilation and arterial hypotension associated with PICD, but evidence on the clinical utility of such drugs is limited in this context. An RCT compared the effect of midodrine and standard albumin doses in preventing PICD in 50 patients with cirrhosis and tense refractory ascites. Midodrine therapy was associated with higher incidence of AKI, worsening of hyponatremia, and higher plasma renin activity and plasma aldosterone concentration, suggesting that this drug is not as effective as intravenous albumin in preventing PICD after LVP[21].

Despite the existence of some doubts concerning the benefits of albumin on hard outcomes (renal impairment and mortality), its clear benefits on important surrogate outcomes (PICD and hyponatremia) allow albumin to be recommended in patients with cirrhosis undergoing paracentesis of more than 5 L. According to the European Association for the Study of the Liver, it should be administered at a dose of 8 g/L ascitic fluid removed[9], while the American Association for the Study of Liver Diseases recommends it is used at doses of 6–8 g/L ascites removed[11].

Modest volume paracentesis (< 5 L) seems to have less serious impacts on hemodynamic and neurohumoral systems, and therefore it might be safe to perform the paracentesis without administering albumin[22]. The exception to this seems to apply to patients with acute-on-chronic liver failure (ACLF) undergoing paracentesis < 5 L because these individuals usually have an intense hemodynamic impairment that theoretically increases the risk of PICD. A recent study randomized 80 subjects with ACLF undergoing paracentesis < 5 L to receive standard doses of albumin or no fluid expansion and demonstrated that PICD was significantly more common in the control group than in the albumin group (70.0% *vs* 30.0%, $P = 0.001$), with significantly higher incidences of HE (50.0% *vs* 27.0%, $P = 0.04$), hyponatremia (67.5% *vs* 22.5%, $P < 0.001$), AKI (62.5% *vs* 30%, $P = 0.001$), and short-term mortality (62.5% *vs* 27.5%, $P = 0.003$)[23].

AKI AND HEPATORENAL SYNDROME

AKI is a common complication of cirrhosis, reported in up to one-third of hospitalized patients with advanced liver disease[24-27]. The diagnostic criteria of AKI in cirrhosis have evolved over the years and are currently based on an acute increase in serum creatinine by ≥ 0.3 mg/dL or ≥ 50% from baseline [28]. The new definition and classification proposed by the International Club of Ascites has allowed for earlier recognition of AKI and implementation of therapeutic strategies, such as intravenous albumin use.

Hypovolemia accounts for about one-half of all cases of AKI in cirrhosis, and it is often driven by excessive use of diuretics and/or fluid losses from lactulose-induced diarrhea. In addition to diuretic withdrawal, intravenous albumin at 1 g/kg/d (maximum 100 g/d) for 2 d has been recommended for volume expansion, especially in patients with AKI stage ≥ 1b[9,11] since mortality appears to significantly increase from this stage on[24,29-32]. Response failure to a 2-d fluid challenge with albumin is suggestive of hepatorenal syndrome (HRS), formerly classified as type 1 and currently as HRS–AKI, once structural kidney injury has been excluded. Recent history of shock, nephrotoxic drugs, proteinuria, microhematuria, and hydronephrosis on renal ultrasound must be ruled out for the diagnosis of HRS–AKI, which is one of exclusion[9,11,28,33].

The benefits of albumin in HRS, a functional kidney injury driven by reduction in renal blood flow, extend beyond just plasma volume expansion. This has been demonstrated in a study comparing albumin with hydroxyethyl starch, a synthetic colloid, in patients with spontaneous bacterial peritonitis (SBP). Administration of albumin resulted in significant improvement on systemic hemodynamics, whereas this effect was not appreciated in the starch group[34]. Furthermore, albumin carries important anti-inflammatory and antioxidant properties, and it has been shown to bind circulating bacterial products, thus preventing their negative consequences on the systemic circulation[35,36]. This has led to the extension of albumin use past the initial fluid challenge at a recommended dose of 20–40 g/d[9,11,28]. Although albumin alone has a limited role in HRS–AKI[37,38], the benefit of added albumin to vasoconstrictor therapy in HRS has been demonstrated in one nonrandomized study comparing terlipressin with terlipressin plus albumin. Despite being a small study, it demonstrated that the combination therapy group had a significantly higher response rate compared to terlipressin monotherapy (77% *vs* 25%, $P = 0.03$)[39].

It is important to note that excessive albumin use in AKI and HRS can be detrimental and contribute to development of pulmonary edema and respiratory failure. This concern has been raised in the recently published CONFIRM study, a large RCT comparing terlipressin with placebo[38]. Concomitant albumin was given in > 80% of patients in both arms at a mean total dose of 200–240 g over 5 d (40–50 g/d). A higher incidence of respiratory failure was observed in the terlipressin group (14% *vs* 5%), presumably secondary to pulmonary edema because of the known cardiovascular effects of terlipressin in combination with excessive albumin use[40]. Thus, volume status should be closely monitored in these patients and judicious albumin use is recommended.

SBP

Bacterial infections occur in 25%–35% of the patients hospitalized with advanced cirrhosis[41], and they are associated with increased morbidity and mortality[42,43], particularly when acquired in the hospital or in healthcare facilities, due to the presence of multidrug resistant organisms[44-48]. SBP is frequently reported as the most common infection in subjects with cirrhosis and ascites[44,45] and one of the main precipitants of ACLF[49]. It is diagnosed in the presence of a polymorphonuclear cell count > 250/mm^3 in the ascitic fluid, and it is usually treated with third-generation cephalosporins in those patients with community-acquired infection[9,11].

However, since the publication of the pivotal RCT by Sort *et al*[50] in 1999, it is clear that this infection should not be treated exclusively with antibiotics. In that study, 126 hospitalized patients with SBP were randomized to receive intravenous cefotaxime *versus* intravenous cefotaxime plus albumin administered at a dose of 1.5 g/kg body weight at baseline, followed by 1 g/kg on day 3. The authors described a threefold reduction in the incidence of renal impairment favoring the albumin group (33% *vs* 10%, $P = 0.002$). More importantly, 3-mo mortality was also significantly lower in the albumin group (41% *vs* 22%, $P = 0.03$), which was attributed to the decrease in the incidence of AKI[50].

The benefit of using albumin in SBP was initially attributed to plasma expansion and/or prevention of circulatory dysfunction[34,50,51], but it actually seems that albumin infusion leads to a reduction of plasma levels of nitric oxide, tumor necrosis factor-α, endotoxin and interleukin-6[52]. These findings favor the concept that albumin is more than a colloid and that it has anti-inflammatory properties in individuals with decompensated cirrhosis[53].

In the study by Sort *et al*[50], renal impairment was negligible in both groups of patients in the presence of baseline bilirubin levels < 4 mg/dL and serum creatinine level < 1 mg/dL, suggesting that albumin administration might be restricted to higher-risk subjects. Nevertheless, subsequent data have disputed those findings[54,55]. In this regard, a meta-analysis including four RCTs[34,50-52] evaluated

the role of albumin in SBP and concluded that albumin was associated with a lower incidence of renal impairment and mortality, not identifying a significant difference in albumin effects according to baseline levels of bilirubin or renal function[56]. Since then, several international guidelines recommend the use of high-dose albumin in patients with SBP, even in patients at lower risk for renal impairment[9,11,57]. However, there still is some controversy regarding albumin dosing and schedule since the use of lower doses of albumin were associated with a reduction in proinflammatory cytokines in an RCT[52], and no major differences in outcomes were observed in a subsequent Brazilian trial comparing standard *versus* lower doses of albumin in SBP[58].

EXTRAPERITONEAL INFECTIONS

Infections (not only SBP) characterize state 6 (end-state) in the clinical course of cirrhosis[59], as they increase the risk for AKI, HRS, organ failure, and ACLF[60]. It has also been recently demonstrated that infections are the most important precipitating factor for acute decompensation of cirrhosis, even in patients without ACLF[61]. On the other hand, in compensated cirrhosis, the role of infections is not completely understood. A recent cohort study has demonstrated that 17% of patients with compensated cirrhosis developed infections, particularly respiratory and urinary tract infections, which led to decompensation of cirrhosis in 26% of cases and to an increased mortality rate[62].

Therefore, considering the importance of infections in the prognosis of cirrhosis, improving the efficacy of therapeutic strategies would be of the utmost importance. In SBP, as previously discussed, the addition of albumin to antibiotic treatment represented an important improvement in the therapeutic strategy[50], and it was natural to study if a similar intervention could reach the same results in extraperitoneal infections. The rationale behind this proposal is that albumin is a multifunctional protein, which also has important nononcotic properties, as previously mentioned[3]. Furthermore, individuals with cirrhosis are not only quantitatively deficient in albumin but also qualitatively, which highlights the concept of the effective albumin concentration[63,64].

Some RCTs have evaluated the subject of albumin administration in infections other than SBP. In the first of them, patients with cirrhosis and extraperitoneal infections were randomized to receive antibiotics plus albumin (same doses as for SBP) or antibiotics alone, and albumin led to improved circulatory and renal functions. In that study, there was no significant difference in 3-mo survival between groups, but albumin use was an independent predictive factor of survival after adjusting for other factors[65].

In the second RCT, despite delaying the onset of renal failure, albumin was not able to significantly reduce its incidence or improve survival. Besides, 8.3% of subjects receiving albumin developed pulmonary edema as a complication[66]. It is noteworthy, however, that the study had important methodological limitations.

In the third RCT, albumin was associated with a higher resolution of ACLF as well as with lower incidence of nosocomial infections. Nevertheless, once again, there was no significant difference between groups regarding mortality[67]. An important limitation of this study is the fact that only 23% of the estimated sample was actually enrolled in the trial[68].

In order to further examine this subject, our group has performed a meta-analysis of RCTs evaluating the role of albumin in extraperitoneal infections. In that meta-analysis, there was no evidence of significant benefit of albumin in reducing renal dysfunction (RR = 0.55, 95%CI: 0.25–1.19, P = 0.13) or mortality in 30 d (RR = 1.62, 95%CI: 0.92–2.84, P = 0.09) and 90 d (RR = 1.27, 95%CI: 0.89–1.83, P = 0.19)[69]. Therefore, at this moment, a general recommendation cannot be made regarding the administration of albumin in patients with cirrhosis and extraperitoneal infections[9]. Still, there might be a role for albumin in a subgroup of extraperitoneal infections, particularly the most severe of them[70].

LONG-TERM ALBUMIN ADMINISTRATION

Ascites is the most common among severe complications of cirrhosis[71], and it marks state 4 in the natural history of this disease[59]. Ascites is associated with a 5-year mortality of 50%, and persistent ascites predicts mortality independently of the Model for End-Stage Liver Disease score[59,72]. Therefore, strategies aiming at the increase in survival of patients with cirrhosis and ascites are constantly pursued.

Long-term albumin administration has been studied in the management of patients with cirrhosis and ascites for many decades. The rationale for its use relies on the hypothesis that albumin could reduce effective arterial hypovolemia through plasma expansion and that the nononcotic properties of albumin could act against the systemic inflammation that is behind decompensation of cirrhosis[3,5]. Once again, the concept of effective albumin concentration should be highlighted in this context[63]. As albumin is quantitatively and qualitatively deficient in cirrhosis, leading to alterations in the transport and metabolism of substances as well as to the impairment of systems associated with the redox balance, inflammation, and coagulation, it is hypothesized that albumin supplementation could prevent

the decompensation of cirrhosis[73-77].

Five RCTs evaluated the role of long-term albumin administration in patients with cirrhosis and ascites. The first study evaluated a small sample of subjects with persistent ascites already under treatment with diuretics. Albumin was used at doses of 25–100 g every 1–2 d according to serum colloid osmotic pressure, and 25–100 g every 1–2 wk thereafter. The osmotic pressure was improved in individuals receiving albumin, but mortality was not different between groups[78].

After that, two Italian RCTs evaluated the matter. Gentilini *et al*[79] enrolled patients with ascites unresponsive to a low-sodium diet, while Romanelli *et al*[80] studied individuals with their first episode of grade 2–3 ascites. Both studies randomized patients to receive albumin at doses of 25 g every week for 12 mo and every other week thereafter[79,80]. In the former study, albumin led to significantly lower cumulative probabilities of recurrence of ascites and hospitalization, but there was no benefit regarding mortality[79]. In the latter, though, patients receiving albumin had a significantly lower probability of recurrence of ascites and a higher cumulative survival rate[80].

Finally, in 2018, two more RCTs on long-term albumin administration were published. Solà *et al*[81] evaluated albumin at doses of 40 g twice a month in combination with midodrine for patients with cirrhosis and ascites in the waiting list for liver transplantation, but there was no significant difference in survival or in complications of cirrhosis between study groups. The high rate of transplantation in that study might have led patients to be treated with albumin for an insufficient period of time (since they were quickly transplanted). The fact that the renin–angiotensin–aldosterone system activity did not completely normalize in subjects receiving albumin also supports the hypothesis that higher doses and longer duration of albumin administration might have been necessary[81].

On the other hand, Caraceni *et al*[82] randomized patients with persistent ascites to receive albumin 40 g twice a week for 2 wk and once a week thereafter or no plasma expansion. Individuals receiving albumin had significantly better results than their counterparts regarding mortality, need for paracentesis, SBP, extraperitoneal infections, HE, renal dysfunction, HRS, hyponatremia, and hyperkalemia [82].

Considering the differences in the results of these studies, we have performed a meta-analysis on this issue. Pooling the data from all five RCTs, it was demonstrated that albumin significantly reduced recurrence of ascites/need for paracentesis (RR = 0.56, 95%CI: 0.48–0.67, $P < 0.001$). There was also a trend towards a lower risk of mortality favoring albumin, but it did not reach statistical significance (RR = 0.88, 95%CI: 0.67–1.14, $P = 0.33$). There was no evidence of significant differences between groups regarding refractory ascites, SBP, HE, gastrointestinal bleeding, or adverse events[83].

We understand the main reason for the study by Caraceni *et al*[82] having reached such outstanding results relates to the doses of albumin used. In a recent study, the effects of different doses of long-term albumin administration were compared. While high-dose albumin (1.5 g/kg/wk) led to normalization of serum levels of albumin, improvement of circulatory and cardiac function, and reduction in plasma levels of cytokines, low-dose albumin (1.0 g/kg every 2 wk) did not[84]. It is noteworthy that the trial by Caraceni *et al*[82] was the one using the highest dose of albumin among the five RCTs on this issue, and, even so, the dose used was only slightly higher than that considered insufficient in the abovementioned study[84]. Moreover, while changes in serum levels of albumin were not different between groups in the trial by Solà *et al*[81], the intervention group had a normalization of serum albumin in the study by Caraceni *et al*[82], which reinforces the idea of insufficient doses of albumin in the former trial.

Furthermore, in a *post hoc* analysis of the study by Caraceni *et al*[82], the authors demonstrated that a serum level of albumin of 4 g/dL at 1 mo should be the target in long-term albumin administration in order for the highest survival rates to be achieved. In that publication, the authors suggested the hypothesis of the albumin gap, associating the amount of albumin required not only to baseline albumin levels but also to the severity of liver disease and highlighting the importance of the concept of effective albumin concentration[63].

Therefore, considering the abovementioned evidence, we believe that long-term albumin administration in patients with cirrhosis and ascites will probably become a formal recommendation in the near future. It must be emphasized, though, that the most recent guidelines still did not include this indication of albumin use in cirrhosis[11,85]. Hopefully, the ongoing PRECIOSA trial (NCT03451292) will provide us with more definitive data on this issue.

OTHER INDICATIONS

Decompensated cirrhosis

A recent RCT (the ATTIRE study), including 777 patients hospitalized for decompensated cirrhosis with baseline serum albumin levels < 3 g/dL, evaluated the effects of increasing these levels by daily intravenous administration of albumin. In that study, albumin administration was not superior to placebo in preventing a composite endpoint of infection, AKI and death[86].

Nevertheless, there are important points to consider. (1) No information on the distribution of patients between groups according to the Child–Pugh classification was provided. This is of great importance due to the recognized heterogeneity of such a group of patients. In fact, this could influence

the response to albumin infusion; (2) Ascites relates to the severity of circulatory dysfunction in patients with advanced cirrhosis. Although ascites was present in 62% of patients in the albumin group and in 71% in the control group, there was no information about its grade, the percentage of individuals with refractory ascites, use of diuretics, and their doses. Furthermore, there were no data on serum sodium concentration, another important marker of circulatory dysfunction; (3) There were no data on the severity or type of infections and their effects on circulatory function. Previous research suggests that giving albumin to patients with cirrhosis may be especially effective in the subset of patients with circulatory and renal dysfunction[50]; and (4) Finally, evidence shows that high doses of albumin are required for individuals with cirrhosis to benefit[84] and that the target level of serum albumin should be 4 g/dL[63]. Patients in the trial by China *et al*[86] reached levels barely over 3 g/dL. Therefore, it is likely that they did not receive enough albumin to benefit from the intervention.

The results of the ATTIRE study should be interpreted with caution, as it seems that rather than trying to make a general recommendation on albumin administration in decompensated cirrhosis, it might be more appropriate to define the best albumin administration strategy and the subgroup of patients with cirrhosis who could benefit most from its effects.

HE

The understanding of the pathophysiology of HE has increased in recent years. Thus, besides the traditional concept that implies cerebral exposure to ammonia as the basic mechanism for HE occurrence, new proposals suggest that the activation of inflammatory mediators, cerebral blood flow alterations due to circulatory dysfunction, and oxidative stress altogether contribute to the astrocytic injury leading to HE[87]. Albumin, a multifunctional protein, as previously mentioned in this review, could therefore play an important role in the treatment of HE.

In 2004, a pilot study evaluated the effects of plasma expansion with albumin in patients with cirrhosis and diuretic-induced HE. Albumin was more effective than a gelatin-based colloid solution in improving HE grade and lowering plasma concentrations of malondialdehyde, an oxidative stress marker[88]. After that pilot study, a multicenter, double-blind RCT found no significant differences between albumin or saline solution in the resolution of HE in patients with cirrhosis hospitalized with this complication. However, the same study demonstrated a significant improvement in 90-d survival in the albumin group (69.2% *vs* 40.0%, P = 0.02)[89]. In yet another RCT that compared lactulose plus albumin (group 1) *versus* lactulose alone (group 2) for the treatment of HE, 75% of patients in group 1 and only 53% of those in group 2 had complete reversal of HE (P = 0.03). Moreover, mortality was significantly lower in group 1 (18.3% *vs* 31.6%, P = 0.04)[90]. In this regard, a recent meta-analysis of RCTs aimed at clarifying the role of albumin in HE. In that study, albumin administration was able to significantly improve HE (RR = 0.60, 95%CI: 0.38–0.95, P = 0.03) and mortality (RR = 0.54, 95%CI: 0.33–0.90, P = 0.02)[91].

In another clinical context, that of the prophylaxis of TIPS-induced HE, Riggio *et al*[92] compared patients receiving albumin to a historical control group and found no significant difference in the incidence of overt HE[92]. However, the important methodological limitations of that study must be kept in mind when appraising its results.

Considering what was presented, despite the absence of a formal recommendation for the administration of albumin in the treatment of HE, it seems that there is initial evidence favoring its use. Further studies should be encouraged in this regard.

Hyponatremia

Hyponatremia is an important marker of prognosis in cirrhosis as it can induce neurological complications, and it is associated with reduced survival. Hyponatremia in cirrhosis results from a reduction in free water excretion due to nonosmotic secretion of antidiuretic hormone caused by splanchnic vasodilation. The use of albumin may decrease antidiuretic hormone secretion by improving relative hypovolemia, and therefore it might be useful in the management of hyponatremia[9].

In a small series, McCormick *et al*[93] observed complete reversal of hyponatremia after albumin infusion to three patients with decompensated cirrhosis. Moreover, an RCT evaluated the role of albumin infusion in hyponatremic subjects with cirrhosis, showing a significant improvement in serum sodium concentration, an increase in free water clearance, and a reduction in vasopressin concentration in the albumin group when compared to the placebo group[94]. Furthermore, in a large cohort of patients with cirrhosis and hyponatremia, albumin use was independently associated with the normalization of serum sodium levels[95]. More recently, in an analysis of the ATTIRE trial database, albumin infusions also led to an improvement in hyponatremia, which did not translate into benefits regarding hard outcomes[86]. Therefore, due to the scarcity of data, other studies are needed before albumin infusion can be recommended as a therapeutic option in patients with cirrhosis and hyponatremia.

Cirrhotic cardiomyopathy

Albumin seems to prevent cardiac output reduction and plasma renin activity increase in patients with cirrhosis more effectively than other plasma expanders[3]. The increase in cardiac output induced by albumin seems to be independent of volume expansion[96], which might be explained by the reversal of

the negative effects of tumor necrosis factor-alpha and oxidative stress on cardiac contractility[97].

ACLF

Considering the exacerbated systemic inflammatory state associated with the pathophysiology of ACLF and the anti-inflammatory properties of albumin, it could be hypothesized that albumin might play a role in the treatment of ACLF. There are limited data on this issue at the moment[98], but an RCT on albumin in extraperitoneal infections has demonstrated that individuals receiving this intervention had higher rates of ACLF resolution than their counterparts. Moreover, subjects receiving albumin had evidence of suppression of the systemic inflammation (decrease in white blood cells, C reactive protein, and interleukin-6), which was not specific for those with ACLF[67].

On the other hand, there remains a concern that administered albumin could be modified and added up to the pool of pathological albumin of such severely ill patients[98]. It is noteworthy that patients with cirrhosis, particularly those with advanced disease, have an impairment of albumin function in all of its domains and, therefore, a reduction in effective albumin concentration[64,76]. In this regard, research on ways of improving the quality of commercially available albumin is of the utmost importance since it could lead to an increase in albumin effectiveness as well as to a reduction in costs [3].

PREDICTION OF RESPONSE TO ALBUMIN ADMINISTRATION

Not all patients receiving albumin will benefit from it, and biomarkers capable of identifying those most likely to benefit from it would be extremely useful[3]. Effective albumin concentration, which reflects the portion of the albumin pool with normal structure and function, is superior to total albumin in stratifying individuals with compensated cirrhosis, acute decompensation, or ACLF as well as in distinguishing patients with or without complications of cirrhosis. Therefore, effective albumin concentration seems to be promising as a predictor of prognosis and treatment response in these patients. However, further studies are required not only regarding effective albumin concentration but also for other biomarkers[64,99].

ADVERSE EVENTS

Albumin infusion is generally safe, but careful evaluation of the patient is necessary in order to avoid complications, particularly volume overload and pulmonary edema[38,86]. Other uncommon complications of albumin might relate to contamination by blood-derived pathogens as well as to its administration to individuals allergic to albumin and to those with severe anemia, severe coagulopathy with pulmonary hemorrhage, or with subcutaneous bleeding[98,100].

ECONOMIC ASPECTS

Albumin administration has traditionally been considered costly. However, its cost has decreased over time. More importantly, albumin administration was proven cost-effective in different settings when evaluated using a decision-tree economic model. In that study, when compared to saline, gelatin, and no fluid expansion, albumin was the dominant treatment (more effective and less costly) for patients undergoing LVP. Regarding individuals with SBP, combining albumin and antibiotics was more cost-effective than using antibiotics alone in all three evaluated countries, and it was the dominant strategy in two of them. Finally, in HRS, combining albumin and a vasoconstrictor was the dominant strategy when compared to using a vasoconstrictor alone. Therefore, the concept of albumin administration being costly should be revisited since it is not only cost-effective but also cost-saving in most settings [101].

CONCLUSION

Due to the pathophysiological mechanisms behind decompensations of cirrhosis, albumin plays an important role in their prevention and management through its oncotic and nononcotic properties. International medical societies have made formal evidence-based recommendations for albumin administration in LVP, AKI, HRS and SBP. Promising evidence suggests that long-term albumin in patients with ascites, albumin in modest-volume paracentesis in individuals with ACLF, and albumin in HE are also probably beneficial. Further studies are needed to elucidate the role of albumin in other clinical scenarios, such as extraperitoneal infections, decompensated cirrhosis with hypoalbuminemia, and hyponatremia.

Abstract

BACKGROUND

Colorectal cancer (CRC) is the second leading cause of cancer-related mortality. Cancer stem cells (CSCs) in CRC, which are spared by many chemotherapeutics, have tumorigenic capacity and are believed to be the reason behind cancer relapse. So far, there have been no effective drugs to target colon CSCs. Diiminoquinone (DIQ) has shown promising effects on targeting colon cancer. However, there is limited research on the effects of DIQ on eradicating CSCs in CRC.

AIM

To investigate the anticancer potential of DIQ on colon CSCs in two-dimensional

(2D) and three-dimensional (3D) models using colonospheres and patient-derived organoids.

METHODS

Various 2D methods have been used to assess the effect and the mechanism of DIQ on HCT116 and HT29 cell lines including cell proliferation and viability assays, migration and invasion assays, immunofluorescence staining, and flow cytometry. The potency of DIQ was also assessed in 3D culture using the sphere formation assay and colon cancer patient-derived organoid model.

RESULTS

Our results showed that DIQ significantly inhibited cell proliferation, migration, and invasion in HCT116 and HT29 cell lines. DIQ treatment induced apoptosis along with an accumulation of HCT116 and HT29 cancer cells in the sub-G1 region and an increase in reactive oxygen species in both CRC cell lines. DIQ reduced sphere-forming and self-renewal ability of colon cancer HCT116 and HT29 stem/progenitor cells at sub-toxic doses of 1 μmol/L. Mechanistically, DIQ targets CSCs by downregulating the main components of stem cell-related -catenin, AKT, and ERK oncogenic signaling pathways. Potently, DIQ displayed a highly significant decrease in both the count and the size of the organoids derived from colon cancer patients as compared to control and 5-fluorouracil conditions.

CONCLUSION

This study is the first documentation of the molecular mechanism of the novel anticancer therapeutic DIQ *via* targeting CSC, a promising compound that needs further investigation.

Key Words: Diiminoquinone; Anticancer activity; Colorectal cancer; Cancer stem cells; Patient-derived organoids; Colonospheres

Core Tip: Diiminoquinone has anticancer activity against colorectal cancer. Diiminoquinone targets chemoresistant cancer stem cells in three-dimensional *in vitro* models by downregulating the main components of stem cell-related -catenin, AKT, and ERK oncogenic signaling pathways. Our findings highlight diiminoquinone's novel therapeutic potential against colorectal cancer.

INTRODUCTION

Colorectal cancer (CRC) ranks as the third most common cancer worldwide in 2020 in terms of incidence in men and women, and the second most common cause of cancer deaths in 2020 reaching 935000 deaths according to GLOBOCAN 2020 data[1].

Current medical treatment of CRC includes a wide array of systemic therapies, which include chemotherapeutics [such as 5-fluorouracil (5FU)], targeted therapy (such as epidermal growth factor receptor inhibitors), in addition to immunotherapy, depending on the stages of CRC. High mortality and recurrence rates of CRC are mainly correlated to metastasis, treatment resistance[2,3], and presence of chemoresistant cancer stem cells (CSCs)[4,5]. Although 5FU is the standard chemotherapy for CRC, either alone or in combination with other treatments, it has been ineffective and found to cause drug resistance[6,7]. Around 75% of patients with metastatic CRC receiving chemotherapy develop recurrence within 18 mo[8]. Although the field has witnessed several advances on the quest to control advanced and metastatic colon cancer with some newly developed drugs, there is still a pressing need to fully understand colon cancer biology, develop novel treatment approaches and pre-clinical models, and identify useful therapeutics targeting CSCs and chemoresistant cells and aiming at increasing patient survival.

Recently, we have witnessed the development of different types of *in vitro* three-dimensional (3D) culture systems to recapitulate the *in vivo* cancer growth[9,10]. 3D culture systems mainly include organoid models and multicellular spheroid models[11]. Cancer treatment, particularly using 3D culture

for targeting CSC, is rapidly progressing toward personalized medicine taking into consideration the individual molecular biology and genetic variability of tumors. Introducing *in vitro* patient-derived organoid culture systems to 3D models have revolutionized CRC research[12,13].

CSCs are characterized by their self-renewal, pluripotency, and tumor expansion potential of differentiated cell populations with altered molecular and cellular phenotypes[14]. They are responsible for angiogenic induction and apoptotic resistance. This small subpopulation is associated with tumor invasion and metastasis, therapeutic resistance, cancer relapse, and poor prognosis in patients[15]. CSCs are present within solid tumors, and they are recognized to be resistant to chemotherapies such as 5FU or oxaliplatin[4]. Intriguingly, there are no effective drugs to target CSCs in CRC. Therefore, targeting this population holds hope for treatment response.

Studies have reported that some quinones, which are often secondary metabolites derived from plants, possess anticancer activity[16]. They are present and clinically used in a variety of cancer treatments, such as the anthracyclines daunorubicin, doxorubicin, and mitoxantrone, acting through the redox quinone-hydroquinone system[17]. Anthraquinones are a class of natural compounds that possess anticancer properties against various skin cancer cells and breast cancer cells[18]. Studies have shown that thymoquinone, which has a basic quinone structure, induces apoptosis and halts metastasis in CRC [19,20]. Also, iminoquinone exerts anticancer effects through inhibition of cell survival/proliferation and inhibition of oncogene expression[21].

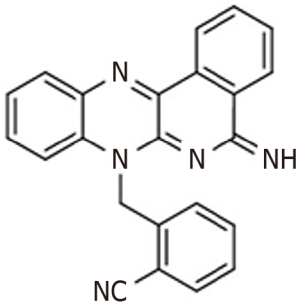
The novel diiminoquinone (DIQ) compound has recently shown potent anticancer effects against the HCT116 CRC cell line as reported in our previous study[22]. The activity of DIQ is believed to be based on the structural similarities between quinones and diiminoquinones. Here, we investigated the anticancer activities and targeting mechanism(s) of DIQ against human colon CSCs using colonosphere cultures and patient-derived organoids. This study represents the first comprehensive documentation of the activity of DIQ against colon CSCs, findings that will provide the basis for proposing this stable and non-toxic compound for clinical testing and future discovery of new effective treatments for patients with colon cancer.

MATERIALS AND METHODS

Cell culture condition

Human CRC cell lines HCT116 and HT29 and non-tumorigenic fetal human intestinal FH74Int cell line were purchased from ATCC (ATCC, Manassas, VA, United States). HCT116 and HT29 cell lines were cultured and maintained in RPMI 1640 (Sigma-Aldrich, St. Louis, MO, United States) and L-glutamine (Sigma-Aldrich). FH74Int cells were grown in DMEM (Lonza, Verviers, Belgium) supplemented with 10 μg/mL insulin and 1% sodium pyruvate. Cell culture media was supplemented with antibiotics [1% penicillin-streptomycin (100 U/mL)], 10% heat-inactivated fetal bovine serum (FBS) (Sigma-Aldrich), and 5 μg/mL Plasmocin™ Prophylactic (InvivoGen, San Diego, CA, United States). Cells were maintained in an incubator at 37 °C in a humidified atmosphere of 5% CO_2 and 95% air and were routinely checked for mycoplasma contamination. All cells were mycoplasma free.

DIQ preparation and treatment



The purified compound DIQ (Figure 1) was synthesized by Professor Makhlouf Haddadin (Department of Chemistry, American University of Beirut)[22]. Stocks of the purified compound DIQ were prepared by dissolving 5 mg in 1 mL 100% dimethyl sulfoxide (Pan Biotech, Aidenbach, Germany). DIQ dilutions were stored at -20 °C. The stock solutions were then dissolved in cell culture medium such that the percentage of dimethyl sulfoxide on cells was less than 0.1%.

MTT cell viability assay

The anti-proliferative effects of DIQ were measured *in vitro* by using MTT [3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide] (Sigma-Aldrich) assay according to the manufacturer's instructions. HCT116 WT, HT29, and FHSInt74 cells were seeded in 96-well culture plates at a density of 10000 cells per well and incubated overnight. Then, the subconfluent cells were treated in triplicate with different concentrations of DIQ diluted in 100 μL complete media for 24, 48, and 72 h. For each time point, 10 μL of 5 mg/mL [in 1 × phosphate-buffered saline (PBS)] MTT reagent was added to each well and incubated at 37 °C for 4 h. The reduced MTT dye was solubilized with absolute isopropanol (Sigma-Aldrich) (100 μL/well) after which MTT optical density was measured at 595 nm by an ELISA reader (Multiskan Ex; ThermoFisher Scientific, Waltham, MA, United States). The percent cell proliferation with respect to control was determined for each drug dose.

Trypan blue exclusion assay

HCT116, HT29, and FHSInt74 cell lines were seeded in duplicates in 24-well culture plates at a density of 50000, 80000, and 100000 cells/300 μL complete media per well, respectively. Cells were incubated overnight then treated in duplicate with various concentrations of DIQ (1, 4, and 10 μmol/L) for 24, 48,

DOI: 10.3748/wjg.v28.i33.4787 **Copyright** ©The Author(s) 2022.

Figure 1 Chemical structure of the diiminoquinone compound.

and 72 h. Attached live cells were harvested by trypsin EDTA and added to the supernatant. The cell pellet was resuspended in 300 µL media. Live cells were counted using a hemocytometer. The percentage cell viability was expressed as percentage growth relative to the control condition of each time point and are derived from the mean of triplicates wells. Each experiment was repeated at least three times.

Wound healing assay

For wound healing, or scratch assay, CRC cells were seeded in 24-well plates and incubated until they reached 80%-90% confluence. Cells were then treated with 10 µg/mL mitomycin C (Sigma-Aldrich) to block cellular proliferation. A sterile 200 µL tip was used to scratch wounds of the same width on each monolayer. After washing the plates twice with PBS (Sigma-Aldrich) to remove the detached cells, the remaining cells were cultured in complete media with or without DIQ treatment at the IC_{50} concentration. Images using bright-field microscopy were subsequently taken at 0 h and 72 h to compare the wound width. The wound width was measured and expressed as a percentage of the relative wound width. The experiment was repeated three times with duplicate measurements in each experiment.

Transwell invasion assay

For the transwell invasion assay, 0.3×10^5 HCT116 and 0.5×10^5 HT29 cells were seeded in serum-free medium in the top chamber of 24-well inserts (pore size, 8 µm; Falcon, ThermoFisher Scientific) coated with 1:10 dilution in cold PBS of Matrigel™ (BD Bioscience, Franklin Lakes, NJ, United States). A medium supplemented with 10% FBS was used as a chemoattractant in the lower chamber. Cells with or without DIQ treatment were allowed to migrate through the membrane coated with Matrigel™ at 37 °C in a 5% CO_2 incubator for 72 h. Non-migratory cells in the upper chamber were then gently scraped off with a cotton-tip applicator. Invading cells on the lower surface of the membrane were fixed and stained with hematoxylin and eosin. After staining, the total number of invading cells was counted using an inverted light microscope (10 × objective) from six consecutive fields for each well.

Reactive oxygen species

The level of intracellular reactive oxygen species (ROS) in HCT116 and HT29 was measured using the fluorescent probe dihydroethidium (DHE). For DHE staining, cells were seeded at a density of 50000 cells on coverslips in 24-well cell culture plates and allowed to become 40%-50% confluent. Following 48 h incubation with DIQ treatment at the IC_{50} dose, CRC cells were fixed in 4% formaldehyde for 20 min. After fixation, CRC cells were washed twice with 1 × PBS, then incubated with 20 µmol/L DHE dye (Invitrogen, Carlsbad, CA, United States). After 45 min staining, the DHE stain was removed, and the cells were washed with 1 × PBS. Mounting media with 4',6-diamidino-2-phenylindole dye was added. Fluorescence images were taken immediately under a Zeiss LSM710 Laser confocal microscope (Carl Zeiss, Oberkochen, Germany) equipped with Zen software to process the images.

Cell cycle analysis

Cells were seeded at 5×10^5 cells in 6-well cell culture plates and incubated overnight prior to drug treatment for 24 and 72 h. Cells were then harvested and washed in PBS then fixed in 70% ice-cold ethanol added dropwise to the cell pellet while vortexing for 30 min on ice. To ensure that only DNA was stained, fixed cells were incubated for 30 min at 37 °C with 100 µL of propidium iodide (PI) (Sigma) solution [6 µL RNase, 30 µL PI (1 mg/mL)] in the dark in a flow tube (BD Falcon, ThermoFisher Scientific). A total of 10000 gated events were acquired in order to assess the proportions of cells in different stages of the cell cycle. Cell cycle analysis was performed by flow cytometry using Guava EasyCyte8 Flow Cytometer-Millipore. GuavaSoft™ 2.7 Software.

Annexin V-PI staining

HCT116 and HT29 cells were seeded at a density of 5 × 10^5 cells in 6-well cell culture plates and incubated overnight prior to drug treatment for 72 h. Cells were then harvested and washed in cold PBS. The pellet was resuspended in 100 µL binding buffer and stained with 5 µL annexin V-FITC and 5 µL PI in the dark for 30 min at room temperature. Then, 400 µL binding buffer was added, and apoptotic cells were analyzed with fluorescence-activated cell sorting flow cytometry.

Sphere formation assay

Self-renewal capacity is deemed to be one of the major defining hallmarks of stem/progenitor cells. Thus, to determine whether DIQ was able to target the self-renewing CSC pool, we investigated sphere formation capability over 5 generations. The sphere formation assay was used as previously reported by our laboratory[23,24]. Briefly, 1000 single cells/well in 96-well culture plate were suspended in cold Matrigel™/serum-free medium (1:1) in a total volume of 10 µL. Cells were seeded uniformly in a circular manner around the bottom rim of the well and allowed to solidify in the incubator at 37 °C for 1 h. Subsequently, 100 µL of RPMI with 5% FBS treated with DIQ was added gently in the middle of each well. Each experimental condition was performed in duplicate. Spheres were replenished with warm media as in the original seeding every other day. Spheres were counted in the 96-well plate dishes after 8 to 12 d of sphere culture, and bright field images of the spheres were obtained using Axiovert microscope from Zeiss at × 10 magnification. Images were analyzed by Carl Zeiss Zen 2012 image software to determine sizes. Sphere-formation unit (SFU) was calculated for each generation as follows: SFU = number of spheres formed/number of cells originally plated. Results were represented as percentage of the SFU of each condition.

Sphere propagation assay

To enrich the stem-like population of cells, the media was aspirated from the well. Collected spheres using cold media were incubated in 300 µL of Trypsin/EDTA at 37 °C for 1-3 min and then passed through 27-gauge syringes three times. Single cells resulting from the dissociation of spheres were replated and treated at the same density of 1000 cells/well in 96-well culture plates as previously described. We believe that at least 5 generations of colonospheres were required to enrich the subpopulation of progenitor/stem-like colon cancer cells.

Immunofluorescence imaging of colonospheres

Spheres at generation 1 were collected with cold RPMI media and centrifuged to washout all Matrigel™ debris. After centrifugation, spheres were fixed in situ in 4% paraformaldehyde (PFA) at room temperature for 20 min. The PFA was aspirated gently, and spheres were permeabilized with 0.5% Triton X-100 for 30 min at room temperature. After carefully aspirating the permeabilization solution, spheres were blocked using the sphere blocking buffer [0.1% bovine serum albumin (BSA), 0.2% Triton X-100, 0.05% Tween-20, and 10% normal goat serum in PBS] for 2 h at room temperature. Spheres were washed in PBS then incubated overnight with different primary antibodies for assessment of treatment and characterization including Ki67, CD44, Gamma H2A histone family member X (γH2AX), cytokeratin (CK)19 and CK8 (refer to Table 1 for details on antibodies used). After gentle washing with PBS containing 0.1% Tween-20, spheres were incubated with Alexa-488 and/or 568-conjugated IgG (Invitrogen) for 2 h at room temperature. Spheres were mounted with the antifade Fluorogel II with 4′,6-diamidino-2-phenylindole (Abcam, Cambridge, United Kingdom). Confocal fluorescent images were acquired and analyzed using the Carl Zeiss LSM 710 Laser scanning microscope.

Western blot analysis

For two-dimensional (2D) western blot results, cells were plated in 12-well plates, treated with DIQ, and then collected. For 3D western blot results, HCT116 and HT29 cells were plated in 24-well plates (3 × 10^5 cells/well) with or without treatment to form spheres. At day 8-10, spheres were collected with cold RPMI media then washed with PBS to remove any residual media. Proteins were then extracted with RIPA lysis buffer (sc-24948; Santa Cruz Biotechnology, Dallas, TX, United States). Protein extracts were quantified using the DC Bio-Rad Protein Assay (Bio-Rad Laboratories, Hercules, CA, United States) according to the manufacturer's protocol. Equal amounts of protein lysate were mixed with 5% β-mercaptoethanol and 2X Laemmli Sample Buffer (Bio-Rad Laboratories), electrophoresed in 12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis, and then transferred to 0.45 µm nitrocellulose membrane (Bio-Rad Laboratories) for 2 h. Membranes were blocked for 1 h with 5% skim milk in tris-buffered saline with 0.1% tween 20, then blotted with primary antibodies (antibodies used are listed in Table 2) overnight at 4 °C. The next day, membranes were washed three times with tris-buffered saline with 0.1% tween 20 and blotted with corresponding secondary antibodies for 1 h at room temperature. Hybridization with GAPDH-HRP (6C5) coupled antibody was performed for 1 h at room temperature as the housekeeping gene. Membranes were developed, and target proteins were detected using the enhanced chemiluminescence system (Bio-Rad Laboratories). Images were generated and quantified using ChemiDoc™ Imaging Systems (Bio-Rad Laboratories).

Table 1 List of primary and secondary antibodies used in immunofluorescent staining

Antibody name	Species	Dilution	Catalog number	Company

Ethical consideration of patient derived-organoid culture

The study with all its experimental protocols was conducted under the Institutional Review Board approvals of the American University of Beirut and American University of Beirut Medical Center to obtain patient information and human colorectal tissue samples from consenting patients. All protocols were performed in accordance with The Code of Ethics of the World Medical Association (Declaration of Helsinki) and in agreement with all ethical considerations of the Institutional Review Board for experiments involving human subjects. Oral consent was obtained from all patients, and confidentiality was maintained. For colectomy specimens, a core biopsy was taken from the area most likely to be involved with cancer according to the surgeon and pathologist recommendations.

Tissue processing and patient-derived organoid culture

Colon tumor tissue from patients was rinsed with PBS and manually minced using sterile scalpels. The majority of minced fragments was employed for organoid culturing; remaining fragments were transferred directly to 4% PFA for histological examination. According to the protocol described by Boehnke *et al*[25], minced fragments for organoid culturing were digested in advanced adDMEM/F12 (Gibco, ThermoFisher Scientific) supplemented with 1 × P/S, collagenase IV (Sigma-Aldrich), and amphotericin B (Sigma-Aldrich) at 37 °C for 1 h. During incubation, the tissue fragments were repeatedly suspended with a 100 µL micropipette. To exclude undigested tissue fragments, the suspension was filtered through a 100 µm cell strainer (Corning, Corning, NY, United States). The

flowthrough was subjected to consecutive filtrations when needed. Isolated cells were seeded in 24-well plates with Matrigel at a cell density of 20000 single cells/well. Then, 20 µL drops were plated into the middle of the well. The plate was placed upside down in the 37 °C incubator for 15 min to allow the Matrigel to solidify. Finally, 300 µL of prewarmed human colon growth medium plus Y-27632 was added into each well. Cells were cultured with adDMEM/F12 additional with various factors added to maintain tumor biological traits and growth activity. Medium was changed every 2-3 d. Cultures were passaged when the aggregates reached 800 µm diameter. Organoids were counted at day 8-12 of each passage under Axiovert inverted microscope at × 10 magnification, and then images of organoids were taken at the same magnification. Images were then analyzed by Carl Zeiss Zen 2012 image software to determine size. The organoid formation count (OFC) was calculated at each generation by counting the number of organoids formed, starting with the same number of input cells in all conditions.

Passaging of the established patient-derived organoids

Organoids were collected when they reached the appropriate size and confluency for passaging (8-12 d after plating). To dissolve Matrigel, ice-cold medium was used, and organoids were collected. Organoids were then centrifuged at 200 g for 5 min at 4 °C. After that, the pellet was resuspended in 1 mL ice-cold adDMEM/F12 to dissolve residual Matrigel. After counting the cells in the pellet, the cells were resuspended in 90% cold Matrigel and seeded as a 5 µL drop in 96-well plate. Cells were cultured with adDMEM/F12 additional with various factors added to maintain the tumor's biological traits and growth activity. Medium was changed every 2-3 d with or without DIQ treatment. Cultures were passaged when the aggregates reached 800 µm diameter. The previous steps were repeated for several generations.

Cell line-derived organoid protocol

Briefly, 5000 HCT116 and HT29 single cells/well in 96-well culture plate were suspended in cold Matrigel™/serum-free medium (9:1) in a total volume of 5 µL as drops in the middle of individual wells of 96-well culture plates. Plated colon cells were allowed to solidify in the incubator at 37 °C for 30 min. Subsequently, 200 µL/well of advanced DMEM/F12 media with several factors, with or without DIQ treatment, was added. Each experimental condition was performed in duplicate. Organoids were replenished with warm media as in the original seeding every other day. Organoids were counted in the 96-well plate dishes after 8 to 12 d of organoid culture, and bright field images of the organoids were obtained using Axiovert microscope from Zeiss at × 10 magnification.

Immunofluorescence and morphological analysis of colonospheres and colorectal organoids

Spheres/organoids were collected with cold RPMI media and centrifuged to wash all Matrigel™ debris. After centrifugation, spheres/organoids were fixed in situ in 4% PFA at room temperature for 20 min. The PFA was aspirated gently, and spheres/organoids were permeabilized with 0.5% Triton X-100 for 30 min at room temperature. After carefully aspirating the permeabilization solution, spheres/organoids were blocked using the blocking buffer (0.1% BSA, 0.2% Triton X-100, 0.05% Tween-20, and 10% normal goat serum in PBS) for 2 h at room temperature. Spheres/organoids were washed in PBS then incubated overnight with different primary antibodies for assessment of treatment and characterization (refer to Table 1 for details on antibodies used). After gentle washing with PBS containing 0.1% Tween-20, spheres/organoids were incubated with Alexa-488 and/or 568-conjugated IgG (Invitrogen) for 2 h at room temperature. Spheres/organoids were mounted with the antifade Fluorogel II with 4',6-diamidino-2-phenylindole (Abcam). Confocal fluorescent images were acquired and analyzed using the Carl Zeiss LSM 710 Laser scanning microscope. Paraffin embedding, microtome sectioning, and standard hematoxylin and eosin staining were all performed by the Histology Laboratory at the Diana Tamari Sabbagh building; all steps were performed at room temperature.

Animal experiments

Animal experiments were performed according to approved protocols by the Institutional Animal Care and Use Committee of the American University of Beirut. Mice were housed under optimum conditions of temperature and light set in specific pathogen-free animal housing. Mice were kept in plastic cages covered with sawdust and had unrestricted access to a commercial mouse diet (24% protein, 4.5% fat, 4% fiber) and water. Animals were sacrificed by cervical dislocation following deep anesthesia with isoflurane. For tumor induction in mice, a group of 6-8-wk old non-obese diabetic severe combined immunodeficiency male mice were inoculated subcutaneously into the flanks with 100 HCT116-derived spheres in a total volume of 50 µL growth media and Matrigel™ (1:1). Upon the detection of a palpable tumor post cell/sphere injection, group 1 injected with 3D spheres was treated with saline (control group), and group 2 injected with 3D spheres was treated with DIQ (20 mg/kg). Mice were treated three times/wk until tumor burden necessitated that we sacrificed the animals. Tumor size was measured every other day using Mitutoyo caliper throughout the study. Mice were monitored daily for signs of morbidity. Body weight recordings were carried out biweekly.

Statistical analysis

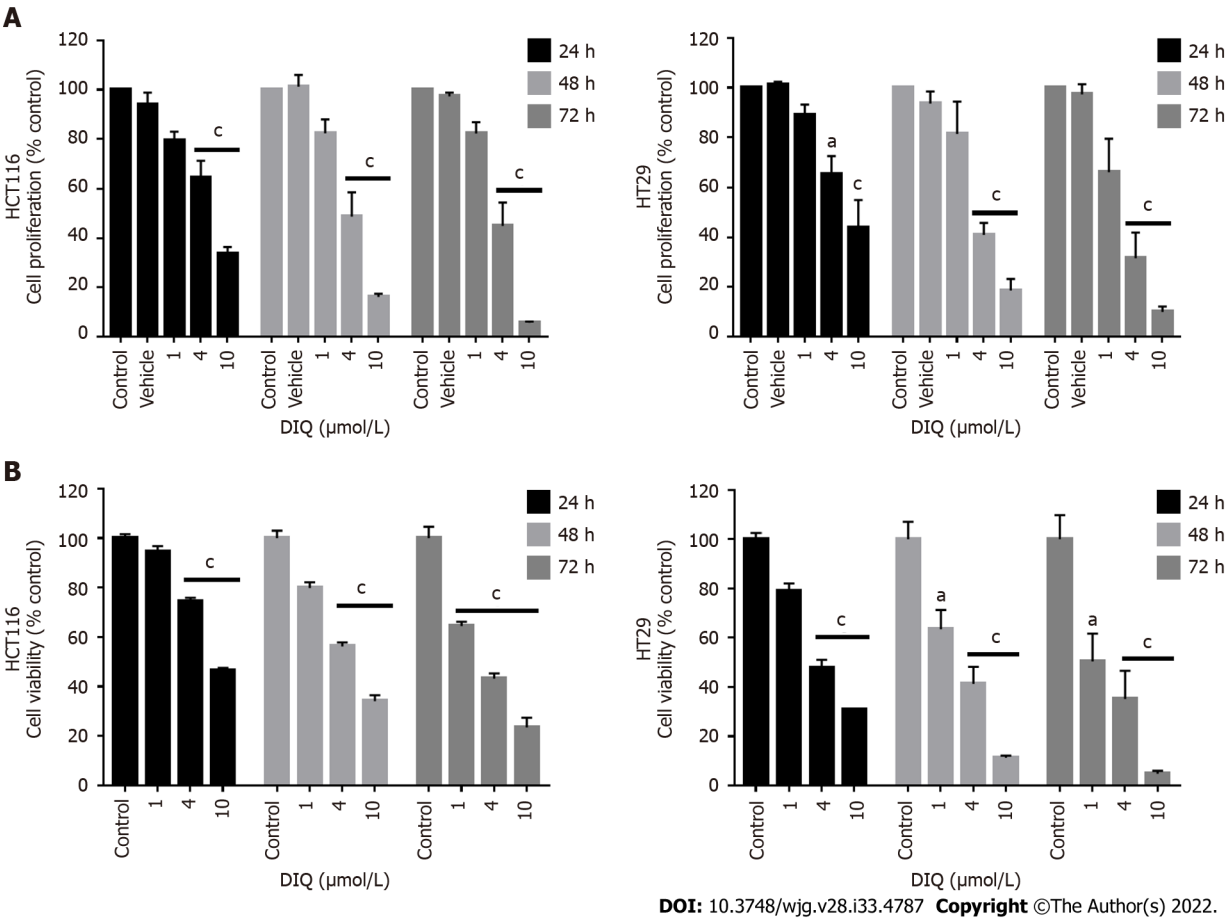
All statistical tests were performed using GraphPad Prism 7 (version 7.0; GraphPad Software Inc., La Jolla, CA, United States). Student's *t* test, One-way or two-way analysis of variance tests were used in this study. In all statistical tests, the mean of treated groups was compared to the mean of control groups. Statistical significance was reported at *P* values of < 0.05. $^{a}P < 0.05$; $^{b}P < 0.01$; $^{c}P < 0.001$. Experimental values were means ± standard error of the mean.

RESULTS

DIQ reduced the cell proliferation of human CRC cell lines in 2D in vitro models

To assess the effect of DIQ compound on the proliferation of human CRC cell lines cultured in 2D monolayers, we employed the MTT assay. Two human CRC cell lines, HCT116 and HT29, were treated with different concentrations of DIQ (1, 4, and 10 μmol/L) for 24, 48, and 72 h. The MTT results revealed that DIQ significantly inhibited the proliferation of HCT116 and HT29 human CRC cells at micromolar concentrations in a time- and dose-dependent manner (Figure 2A). Interestingly, a concentration of DIQ as low as 4 μmol/L was able to inhibit cell proliferation by approximately more than 30% at 24 h in HCT116 and HT29 cell lines and more than 50% cell reduction was observed at 48 h and 72 h in both cell lines. The mean IC_{50} values of DIQ was approximately 4 μmol/L in both cell lines (Figure 2A). The effect of DIQ on the viability of the human CRC cell lines was further confirmed by trypan blue exclusion method, and there was consistency between the MTT results and trypan blue exclusion assay (Figure 2B). Interestingly, DIQ treatment had relatively limited toxicity to the human non-tumorigenic intestinal FHS74Int cells when applied at doses up to 5 μmol/L and over a 72-h period (Supplementary Figure 1A).

DIQ inhibited migration and invasion of CRC cells



One of the most well-known properties of cancer cells is their ability to break away from their site and invade neighboring tissues[26]. Wound healing and transwell invasion assays were employed to evaluate the effects of DIQ on human CRC cell migration and invasion. DIQ at the corresponding IC_{50} concentration significantly suppressed and slowed down the cell migration ability of both cell lines at 72 h compared to the vehicle-treated control cells as determined by the wound healing assay (Figure 3A). The treatments failed to close the wound by more than 70% in both cell lines compared with control conditions, which were able to almost completely close the wound (Figure 3A). In addition, DIQ showed significant inhibitory potential on CRC cell invasion. The number of HCT116 and HT29 invasive cells were remarkably decreased in response to FBS in treated conditions reaching a value of less than two-fold compared to the control condition at 72 h (Figure 3B).

DIQ induced cell cycle arrest and apoptosis in CRC cells

To evaluate the underlying mechanism of growth inhibition by DIQ in CRC, the cell cycle distribution analysis of HCT116 and HT29 cells treated with the IC_{50} concentration of DIQ for 72 h was performed using flow cytometry. As shown in Figure 4A, DIQ treatment in HCT116 cells caused G1 arrest with concomitant decreases in the S and G2/M fractions mainly after 72 h. No changes in the cell cycle were noticed after treating both cell lines with DIQ for 24 h. DIQ effect on the HCT116 cell cycle was pronounced at 72 h. The proportion of HCT116 cells in G1 phase was increased from 45.6% in control cells to 60.2% in cells treated with DIQ for 72 h, while the proportion of cells in G2/M phase decreased from 35.2% to 21.5% (Figure 4A). However, in HT29 cells, DIQ treatment induced S phase (38.35%) cell cycle arrest after 72 h treatment and depleted cells at G1 and G2/M phases. Interestingly, upon treatment with 4 μmol/L DIQ, the percentage of HCT116 and HT29 cells in the sub-G1 phase significantly increased reaching 3.5- and 5.0-fold at 72 h, respectively, suggesting that the reduction in cell viability in response to DIQ could be due to cell death (Figure 4A). To further confirm whether growth inhibition was related to apoptosis, Annexin V and PI staining was performed. As shown in Figure 4A, after treating CRC cells with DIQ at the indicated concentrations for 72 h, the total apoptotic cell populations were significantly increased in both cell lines reaching 61% in HCT116 and 70% in HT29 cells.

DIQ induced the production of ROS in CRC cells

Recently, targeting cancer *via* ROS-based mechanisms has been reported as a radical therapeutic approach[27]. To investigate the effect of DIQ on cellular stress and the involvement of oxidative stress in their anti-proliferative effect in CRC, ROS production was examined by DHE stain intensity. DHE is a fluorescent dye that can easily permeate cell membranes and has been widely used to quantify cellular $O2^{-}$ and H_2O_2 by producing red fluorescent products. Our results showed that a significant increase of the DHE staining intensity was observed in treated cells at 48 h as compared to the control (Figure 4B). Thus, DIQ treatment induced ROS production in both CRC cell lines.

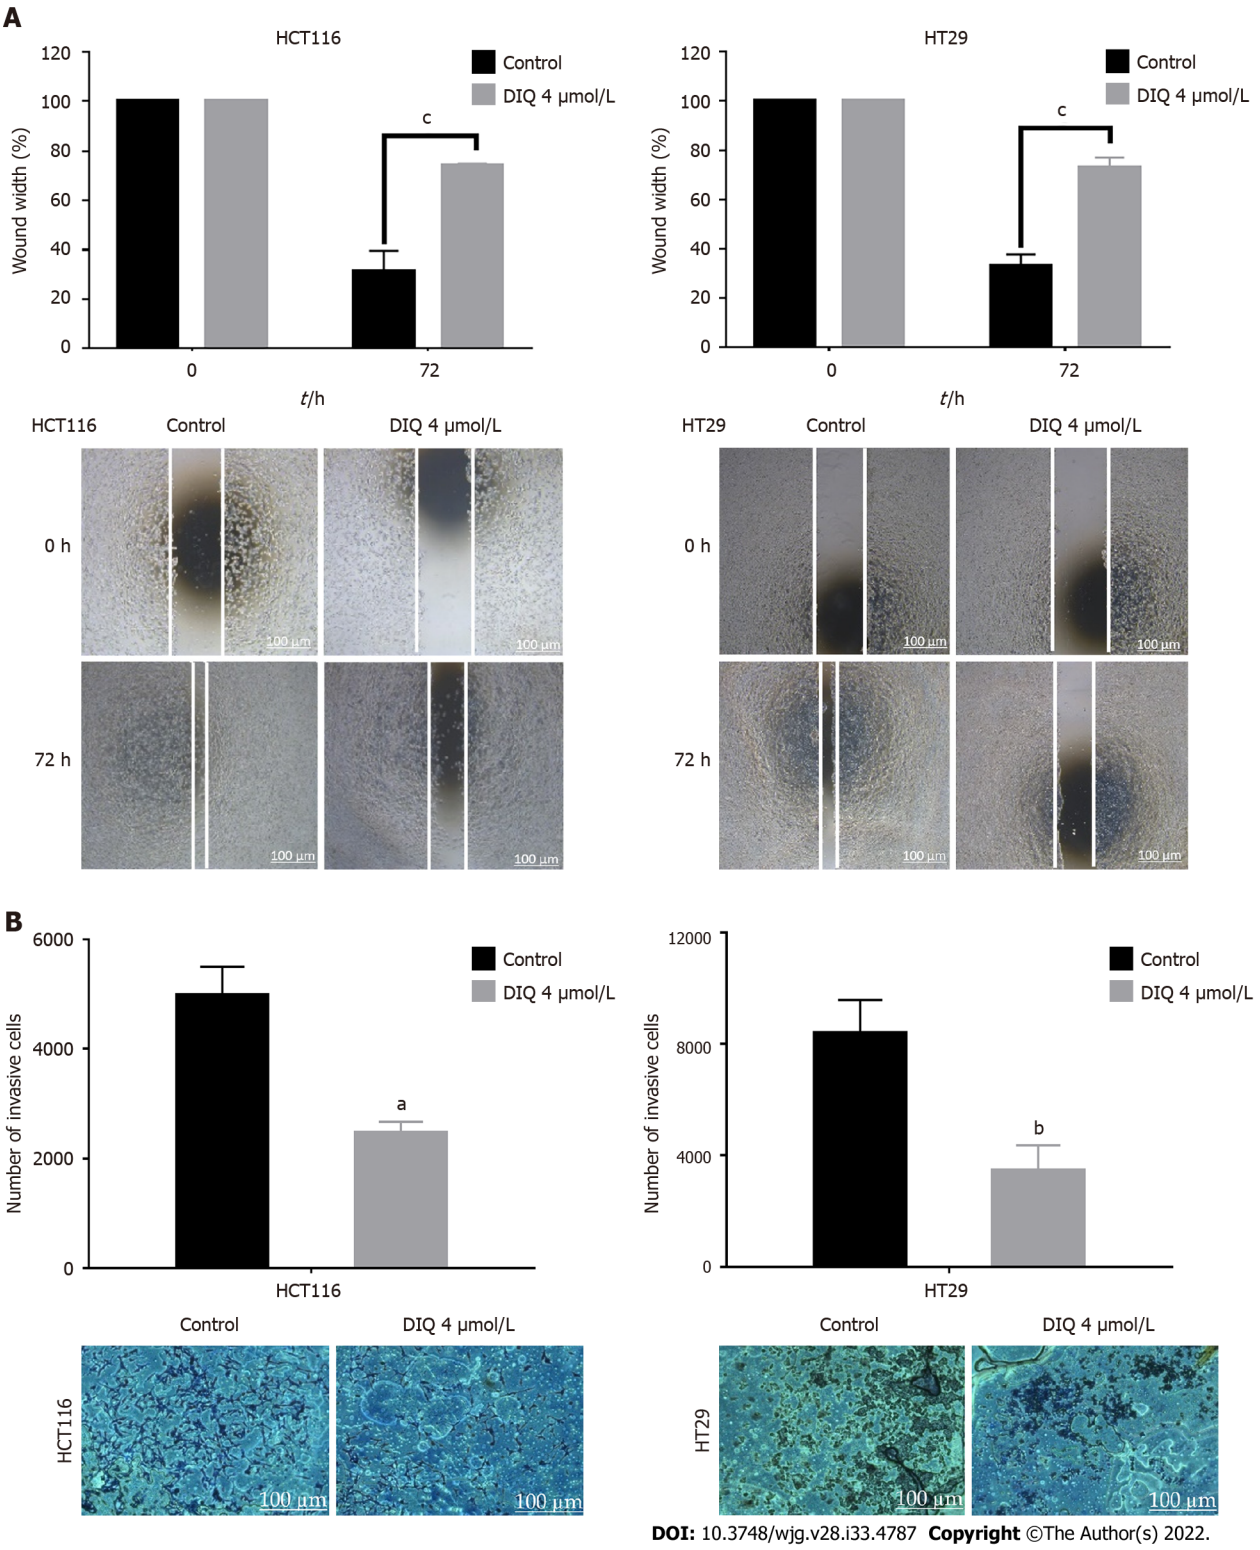

Figure 2 Diiminoquinone reduced the proliferation and the viability of HCT116 and HT29 colorectal cancer cell lines in a time- and dose-dependent manner. A: The anticancer effect of different concentrations of diiminoquinone (DIQ) on the proliferation of HCT116 and HT29 cells using the MTT assay was determined in triplicates at 24, 48, and 72 h. Results were expressed as the percentage of proliferation of the treated group compared to the control at every time point; B: The anticancer effect of different concentrations of DIQ on the viability of HCT116 and HT29 cells using the trypan blue exclusion assay was determined in triplicates at 24, 48, and 72 h. Results were expressed as percentage of viable cells of the treated group compared to the control at every time point. Data represent an average of three independent experiments and is reported as mean ± standard error of the mean ($^aP < 0.05$, $^bP < 0.01$, $^cP < 0.001$).

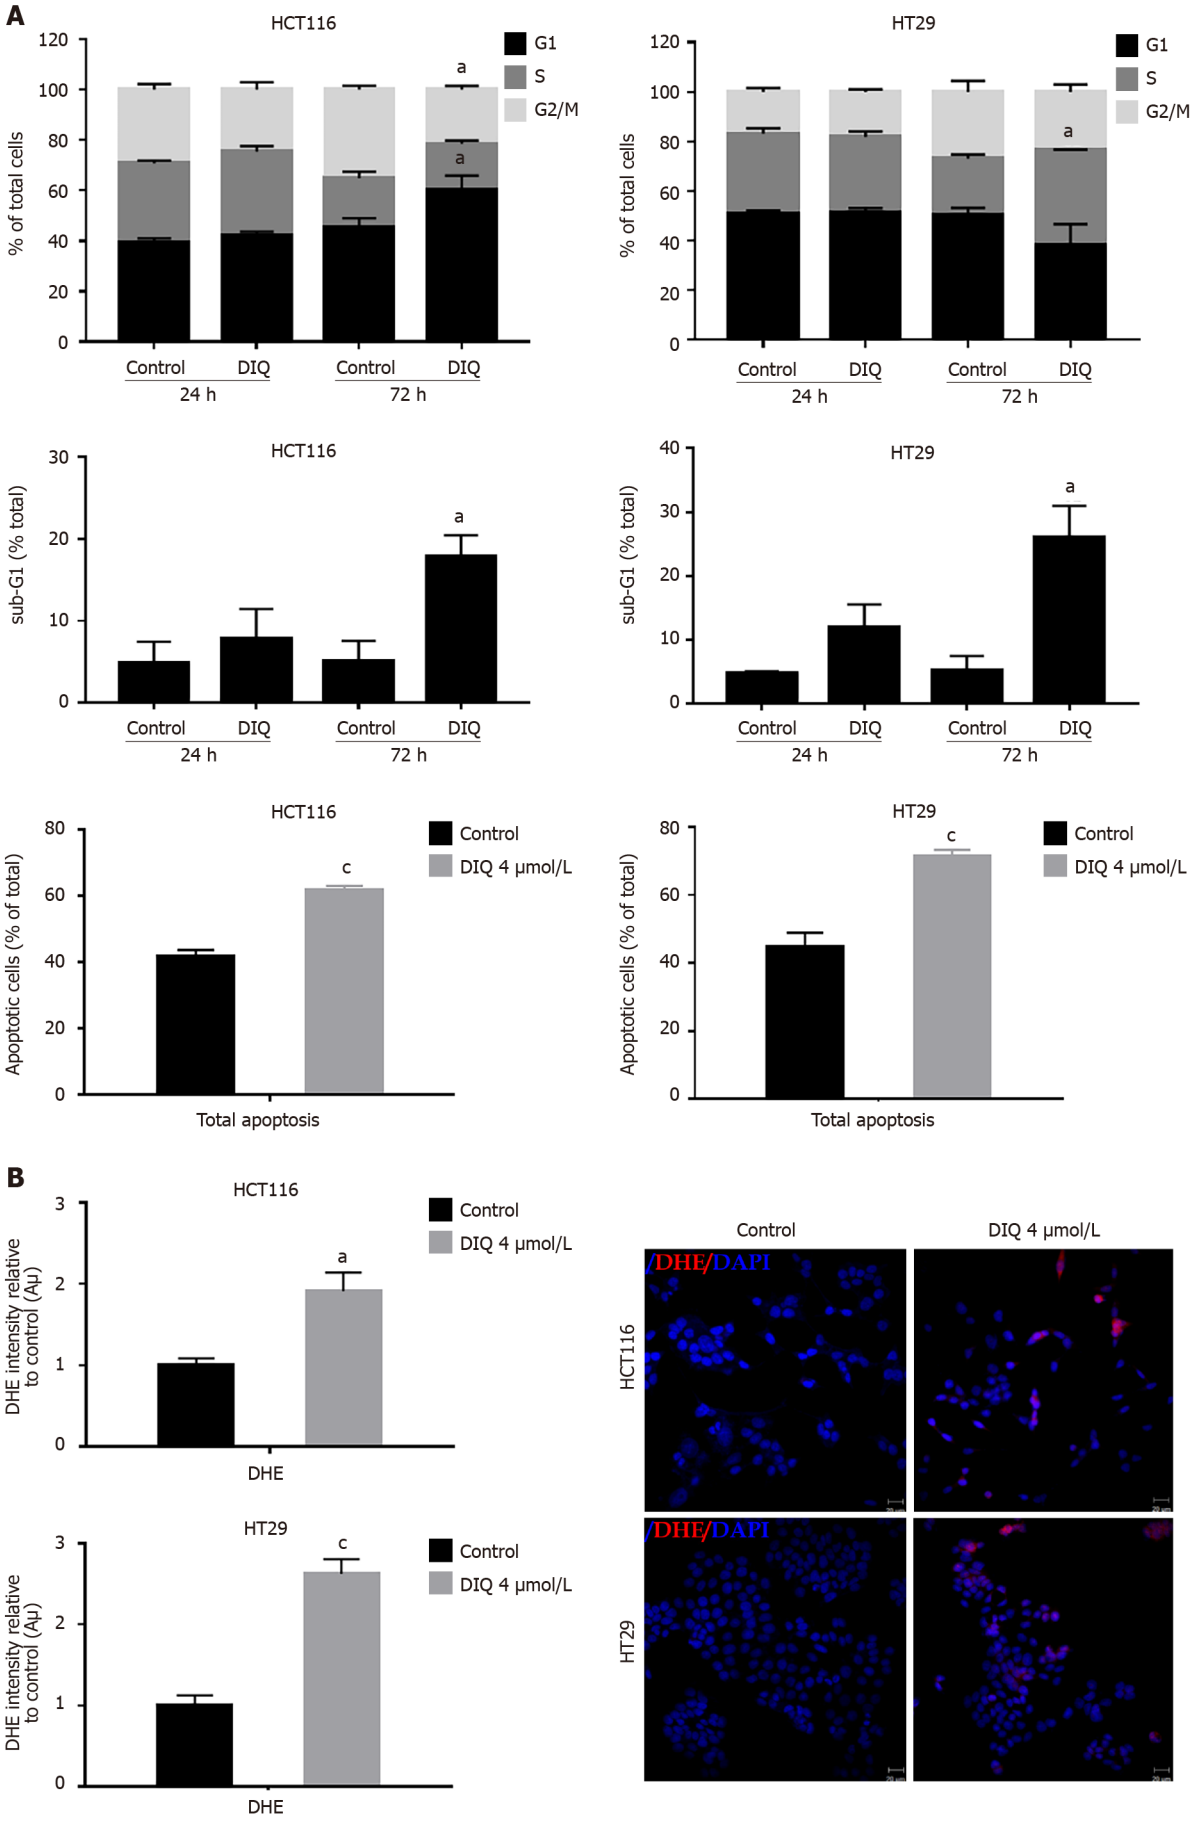
DIQ altered the expression of the cell cycle and proliferation markers in CRC cells

To determine the association between the observed cell cycle arrest and the increased ROS in HCT116 and HT29, western immunoblot analyses were performed on total cell extracts prepared from 2D-treated cells to detect possible changes in the expression of cell cycle and proliferation markers. As shown in Figure 4C, the expression levels of p53 and p21, which are cell cycle regulators of the G1 phase, were upregulated by 1.28-fold and 1.42-fold, respectively, in HCT116 upon DIQ treatment as compared to control conditions. Whereas, in HT29 treated cells, p53 was downregulated and p21 was significantly upregulated by 1.8-fold, suggesting that the inhibitory mechanism of DIQ is different in HCT116 and HT29 cells. The expression of the proliferation-associated proteins, such as AKT, p-AKT, ERK, p-ERK, and proliferating cell nuclear antigen (PCNA), were markedly decreased by DIQ treatment in both cell lines (Figure 4F). In addition, the expression levels of stem cell markers, CD133 and β-catenin, were also downregulated in both CRC cell lines.

DIQ targeted the enriched population of human CRC stem cells in 3D



We investigated colonosphere formation of HCT116 and HT29 cells, a salient feature of CSCs. To better visualize their sphere forming capabilities in 3D cultures, HCT116 and HT29 cells were cultured as single cells in Matrigel™ for 8-12 d in the presence of DIQ. The spheres were then visualized under an inverted light microscope, and bright-field images were taken (Figure 5). Cells that were able to form spheres in the first generation were collected and propagated by dissociating spheres into single cells and reseeding the same number of cells (1000 cells/well). The assay was performed until the fifth generation. Our data showed that both HCT116 and HT29 cells formed spheres, suggesting the presence of a unique population with stem cell-like properties. Notably, a clear dose-dependent attenuation of the SFU at generation 1 for both cell lines was observed when treated with different concentrations of DIQ (0.5 and 1 μmol/L). The SFU was always significantly and remarkably lower in drug-treated cells compared to that of the control condition by more than 50% (Figure 5). Consecutive propagations of

Figure 3 Diiminoquinone reduced the migration and the invasion of HCT116 and HT29 colorectal cancer cells. A: HCT116 and HT29 cells were seeded in 24-well plates. A scratch was made on confluent cells using a 200 μL tip, and images were taken at 0 h and 72 h with or without the indicated treatment. Quantification of the distance of the wound closure was assessed over time. Representative images of wound healing assay at × 5 magnification (scale = 100 μm); B: Colorectal cancer cells were seeded onto the Matrigel-coated membrane in the top chamber of the transwell and were either treated or not with the indicated concentration in the presence of fetal bovine serum in the lower chamber. Cells that invaded to the lower chamber after 72 h were fixed, stained with hematoxylin and eosin, counted, and are represented as the number of invading cells compared to the control. Data represent an average of three independent experiments and is reported as mean ± standard error of the mean ($^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$). DIQ: Diiminoquinone.

formed spheres at each generation with successive treatment with DIQ were performed up to 5 generations. Interestingly, our results showed additional inhibition of the SFU upon DIQ treatment when the cells were propagated from generation 1 up to generation 5 spheres. We observed that 1 μmol/L of DIQ treatment decreased SFU of HCT116 cells by more than 10 times compared to the

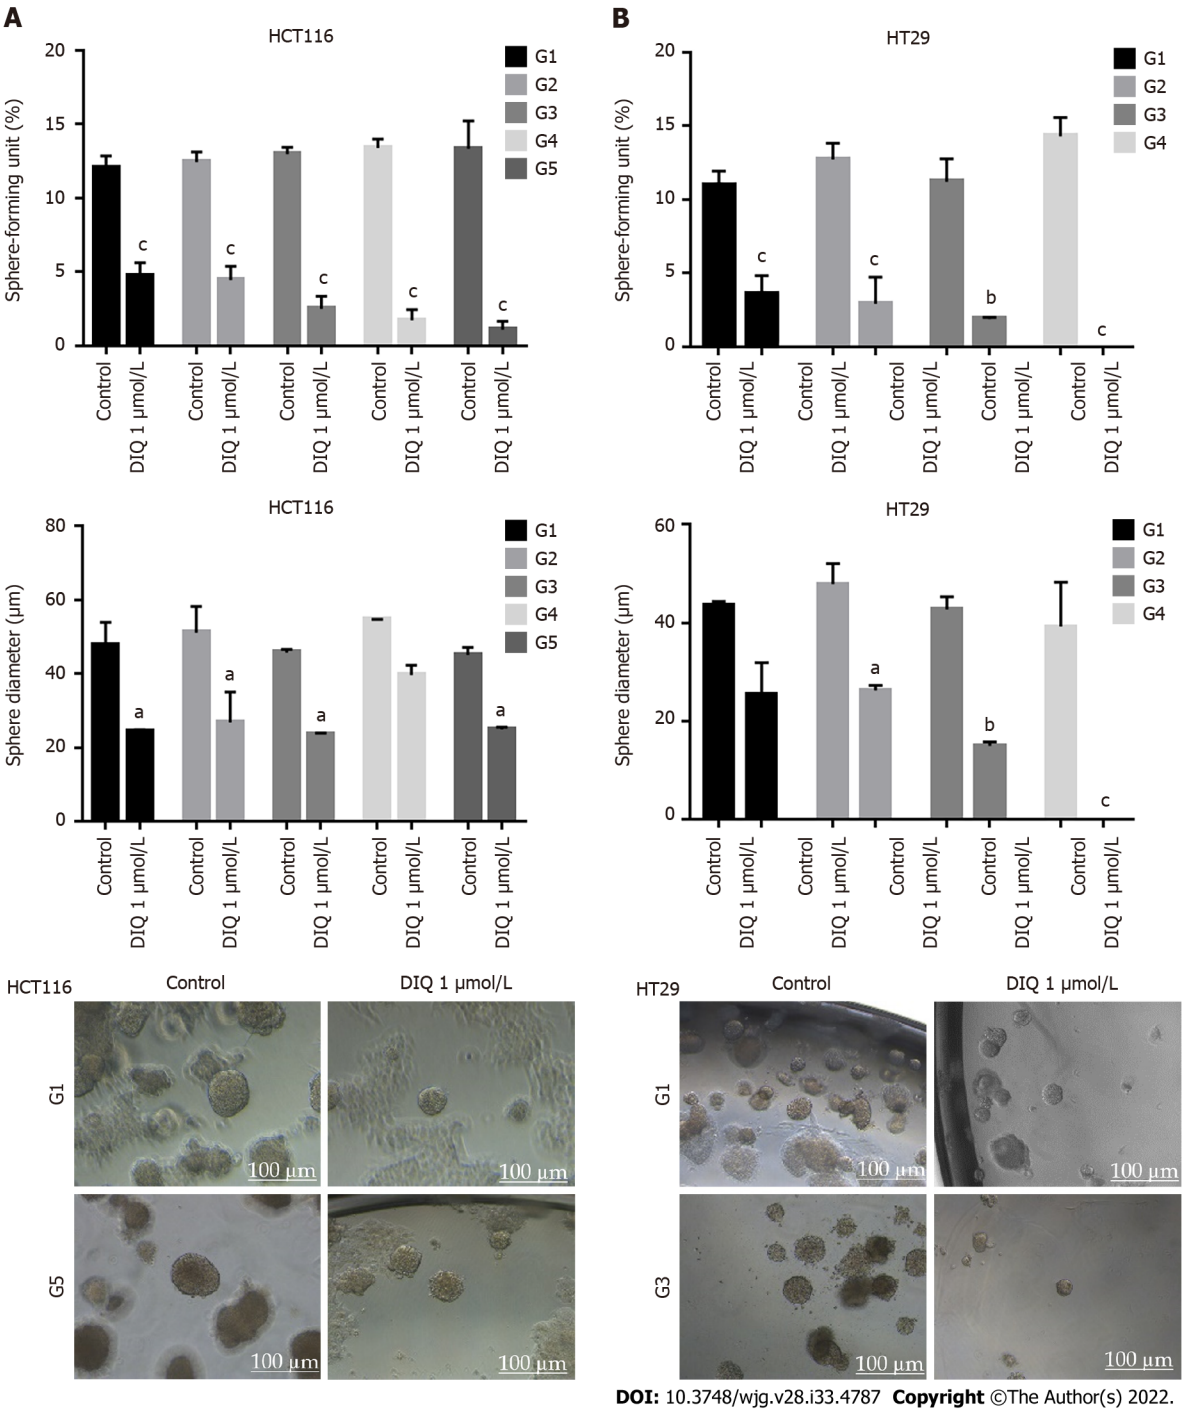

Figure 4 Diiminoquinone induced an accumulation of HCT116 and HT29 cancer cells in the sub-G1 region and apoptosis along with an increase in reactive oxygen species production. A: The distribution of phases of the cell cycle upon diiminoquinone (DIQ) treatment at 24 h and 72 h in HCT116 and HT29 cells using propidium iodide-based flow cytometric analysis of DNA content was shown. Data represent the average of three independent experiments and are reported as mean ± standard error of the mean ($^aP < 0.05$, $^bP < 0.01$, $^cP < 0.001$); B: Reactive oxygen species (ROS) production in HCT116 and HT29 cells was detected by dihydroethidium (DHE) staining. Representative images of colorectal cancer cells exposed to DIQ stained with DHE for ROS content (red color). Cell nuclei were stained with 4',6-diamidino-2-phenylindole (DAPI) (blue). A summary of the quantification of the red fluorescence intensity was represented; C: Lysates of colorectal cancer cells treated with 4 μmol/L DIQ were immunoblotted for p53, p21, β-catenin, p-ERK, ERK, p-AKT, AKT, and proliferating cell nuclear antigen (PCNA). Bands were detected by enhanced chemiluminescence and quantified using ChemiDoc MP Imaging System. Data represent an average of three independent experiments and is reported as mean ± standard error of the mean ($^aP < 0.05$, $^bP < 0.01$, $^cP < 0.001$).

control (13.3%) at generation 5 reaching approximately 1%. Moreover, as shown in Figure 5, HT29 cells were more sensitive to DIQ, and there was an eradication of spheres at generation 4 (SFU = 0%) compared to the control (14.28%). In addition to assessing its effect on self-renewal capacity, DIQ significantly decreased the sizes of the spheres by more than 50% as compared to untreated control conditions. Further decrease in sphere sizes was recognized over the 5 generations in both cell lines depicting pronounced additive effect of the treatments on the formed spheres upon propagation (Figure 5). Thus, DIQ has led to fewer and smaller HCT116 and HT29 spheres. Interestingly, DIQ treatment did not show any significant effect on the size and SFU of FHS74Int-derived spheres over 5 generations (Supplementary Figure 2B). Taken together, these findings suggest that DIQ specifically targeted the colorectal CSC.

DIQ induced apoptosis and inhibited proliferation of human CRC stem cells

Spheres collected at generation 1 were subjected to immunofluorescence analysis of the expression of the proliferation marker Ki67, cytokeratin epithelial markers, CK8 and CK19, and the stem cell marker CD44. Our data revealed that Ki67, CK8, and CK19 expression were significantly reduced in treated spheres derived from HCT116 and HT29 cell lines (Figure 6A-D). The downregulation of the CK19 marker in both HCT116 and HT29 spheres at generation 1 could be an indicator of an inhibition of the epithelial-mesenchymal transition process. Immunofluorescence staining showed high expression of CD44 in control spheres at generation 1 indicating enriched stemness in these cells. Treatment with DIQ showed a significant reduction of CD44 expression in HCT116 and HT29 colonospheres as compared to the control, which is in tune with the downregulation of the CRC stem marker CD133 data (Figure 6C and E). Finally, DIQ effect on DNA damage was studied by assessing the expression of γH2AX. Our results revealed that the expression of γH2AX was markedly increased in treated spheres in both cell types (Figure 6D).

To further assess the effect of DIQ on the enriched CSCs population, we were interested in determining the effect of DIQ on the expression of proliferation markers, stem cell markers, and Wnt signaling molecules of CSCs using western blot. Consistent with the western blot analyses of 2D CRC cells, the expression of the proliferation markers p-AKT and p-ERK were remarkably downregulated by DIQ treatment in both HCT116 and HT29-derived spheres confirming inhibitory effects of DIQ on the proliferation of 3D CSC colonospheres (Figure 6E). Western blot analysis revealed a decrease in the levels of the proliferation marker PCNA post treatment consistent with the data that DIQ decreased the size of HCT116 and HT29-derived spheres (Figure 6E). For the Wnt signaling studies, we investigated treatment effects on β-catenin, which plays an important role in colon cancer stemness properties. Western blot analysis showed a downregulation of β-catenin expression in treated compared to untreated spheres. Analysis of p53 and p21 protein expression in HCT116 spheres upon DIQ treatment showed upregulation of these proteins by 1.32-fold and 1.99-fold, respectively, further confirming apoptosis induction (Figure 6E). Only p21 expression was upregulated in HT29 cells by 1.26-fold as compared to non-treated spheres, whereas the expression of p53 was not affected by DIQ treatment in

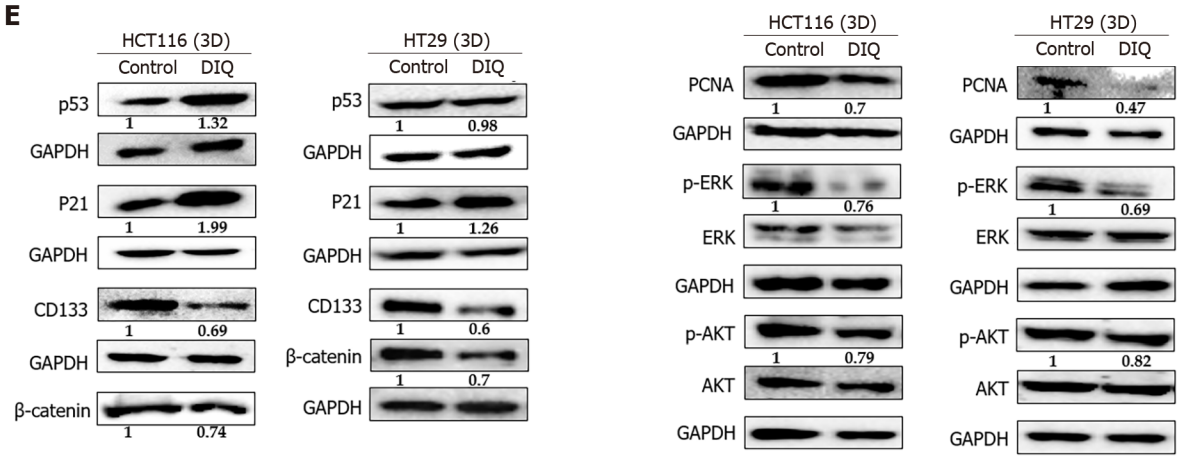

Figure 5 Diiminoquinone reduced the sphere-forming and self-renewal ability of colon cancer stem/progenitor cells. A: HCT116 and B: HT29 cells were seeded at a density of 1000 single cells/well in Matrigel™ for 8 d with and without 1 μmol/L diiminoquinone (DIQ) at generation 1. Spheres were propagated for five generations in duplicates for each condition. Media or treatment was replenished every 2 d. Spheres were counted at day 8-12 of sphere culture. Results are expressed as sphere-formation unit, which was calculated according to the following formula: sphere-formation unit = (number of spheres counted/number of input cells) × 100. Quantification of the average size of generation 1 to generation 5 colon cancer spheres with or without treatment conditions. Spheres sizes were measured by Carl Zeiss Zen 2012 image software. Data represent an average diameter (μm) of 50 measured spheres. Representative bright field images of HCT116 and HT29 colon spheres in Matrigel™ taken by the Axiovert inverted microscope are shown. Data represent an average of three independent experiments and is reported as mean ± standard error of the mean ($^aP < 0.05$, $^bP < 0.01$, $^cP < 0.001$).

HT29 spheres.

DIQ had antitumor potential in non-obese diabetic severe combined immunodeficiency mice injected with HCT116 spheres

To investigate the antitumor effect of DIQ on targeting the CSC population of cells *in vivo*, we subcutaneously injected two groups of non-obese diabetic severe combined immunodeficiency mice with 100 spheres derived from HCT116 cells. Mice developed tumors in 2 wk and were then treated

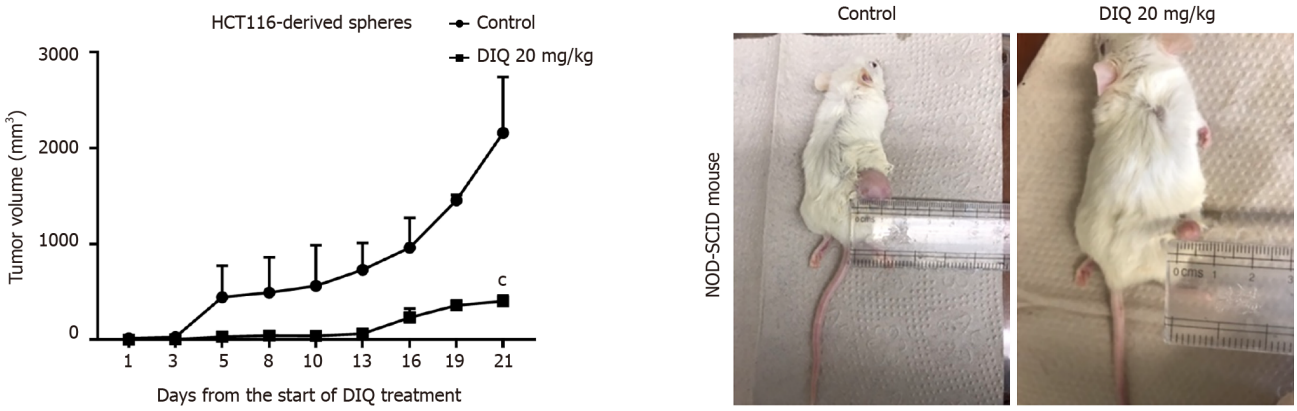
Figure 6 Diiminoquinone induced apoptosis and inhibited proliferation in colon cancer stem/progenitor cells. Representative immunofluorescence imaging of control and diiminoquinone (DIQ)-treated HCT116 and HT29 spheres collected at generation 1. A-D: Spheres stained for cytokeratin (CK)8 (green) and CK19 (red) (A), KI67 (B), CD44 (C), and gamma H2A histone family member X (γH2AX) (D) were obtained using confocal microscopy. The nuclei were stained with anti-fade reagent Fluorogel II with 4',6-diamidino-2-phenylindole (DAPI). The quantification of the intensity of CK8, CK19, CD44, and Ki67 stain in control and DIQ-treated spheres was performed using Carl Zeiss Zen 2012 image software. Stain intensity was normalized to size. Scale bar 20 μm; E: Analysis of p53, p21, CD133, β-catenin, proliferating cell nuclear antigen (PCNA), p-ERK, ERK, p-AKT, and AKT protein expression in HCT116 and HT29 generation 1 spheres upon treatment is shown. GAPDH served as an internal control. Bands were detected by enhanced chemiluminescence using ChemiDoc MP Imaging System. Fold expression changes normalized to GAPDH and to total ERK and total AKT in the cases of p-ERK and p-AKT expression, respectively, are given. Data represent an average of three independent experiments and is reported as mean ± standard error of the mean ($^aP < 0.05$, $^bP < 0.01$, $^cP < 0.001$).

with 20 mg/kg DIQ three times per week for 21 d. DIQ treatment did not cause any change in the body weight or death of mice, indicating no toxicity.



DIQ significantly inhibited tumor growth in the treated group when compared to the control group particularly at day 21 (Figure 7). Interestingly, the average tumor volume was 403.2 mm^3 in DIQ-treated mice at sacrifice, while it was 2158.5 mm^3 in the control group (Figure 7).

Assessment of the effect of DIQ treatment on the established colon cancer patient derived organoids: Organoids as models for DIQ assessment

We established a 3D organoid system from fresh tissue samples obtained from different stages of 5 random colon cancer consenting patients. As described in the methods section, a total of 20000 single cells derived from freshly digested tissues were plated per 20 μL droplets of 90% Matrigel™ in 24-well plates. Cells were plated depending on the total cell count that was successfully derived from the tissue specimens. Despite the expected challenges in modeling colon cancer, we succeeded in establishing colon organoids from patients undergoing colectomy. Organoids formed at generation 1 were dissociated, propagated to generation 2, and the effect of DIQ on the organoids formed was assessed. The growth of organoids was determined by the total number (OFC) and size (diameter) of the organoids formed. The response of colon cancer patient-derived organoids to DIQ was compared to that of 5FU, which is the standard first-line treatment option for CRC. This response was evaluated on 5 random treatment-naïve patients with different clinical data. We succeeded in establishing colon organoids and propagating them. The two different doses of DIQ (0.5 and 1 μmol/L) displayed a highly significant inhibition in the OFC and the size of tumor organoids derived from the 5 studied patients when they were compared to the control group in a dose-dependent manner (Figures 8-10). These results were consistent with the response of HCT116 and HT29 cell line-derived organoids to DIQ treatment. DIQ elicited a statistically significant decrease in both OFC and size of cell line-derived organoids (Supplementary Figure 2).

In Patient 1, organoids were successfully propagated up to generation 6 as shown in Figure 8. Interestingly, an increase in the number of tumor organoids formed was observed with each propagation, thus indicating enrichment of stem cells and enhancement of the establishment of colon organoids. Characterization of the established patient 1-derived organoids was performed by studying the expression of the CRC epithelial lineage markers CK19 and CK8 and the stem cell marker CD44. Using immunofluorescence staining, the tumor organoids showed a positive expression of CK19, CK8, and CD44 confirming the presence of stem-like/progenitor CRC cells within the bulk of our patient-derived organoids.

As shown in Figure 9, a reduction in the OFC and size of the treated organoids was noticed in patient 3 with rectal mucinous adenocarcinoma (pT2 stage). Characterization of patient 3derived organoids and corresponding tissue was assessed by investigating the expression of CK19 and CD44 markers using immunofluorescence staining. These organoids mimicked the heterogeneity of corresponding tumor

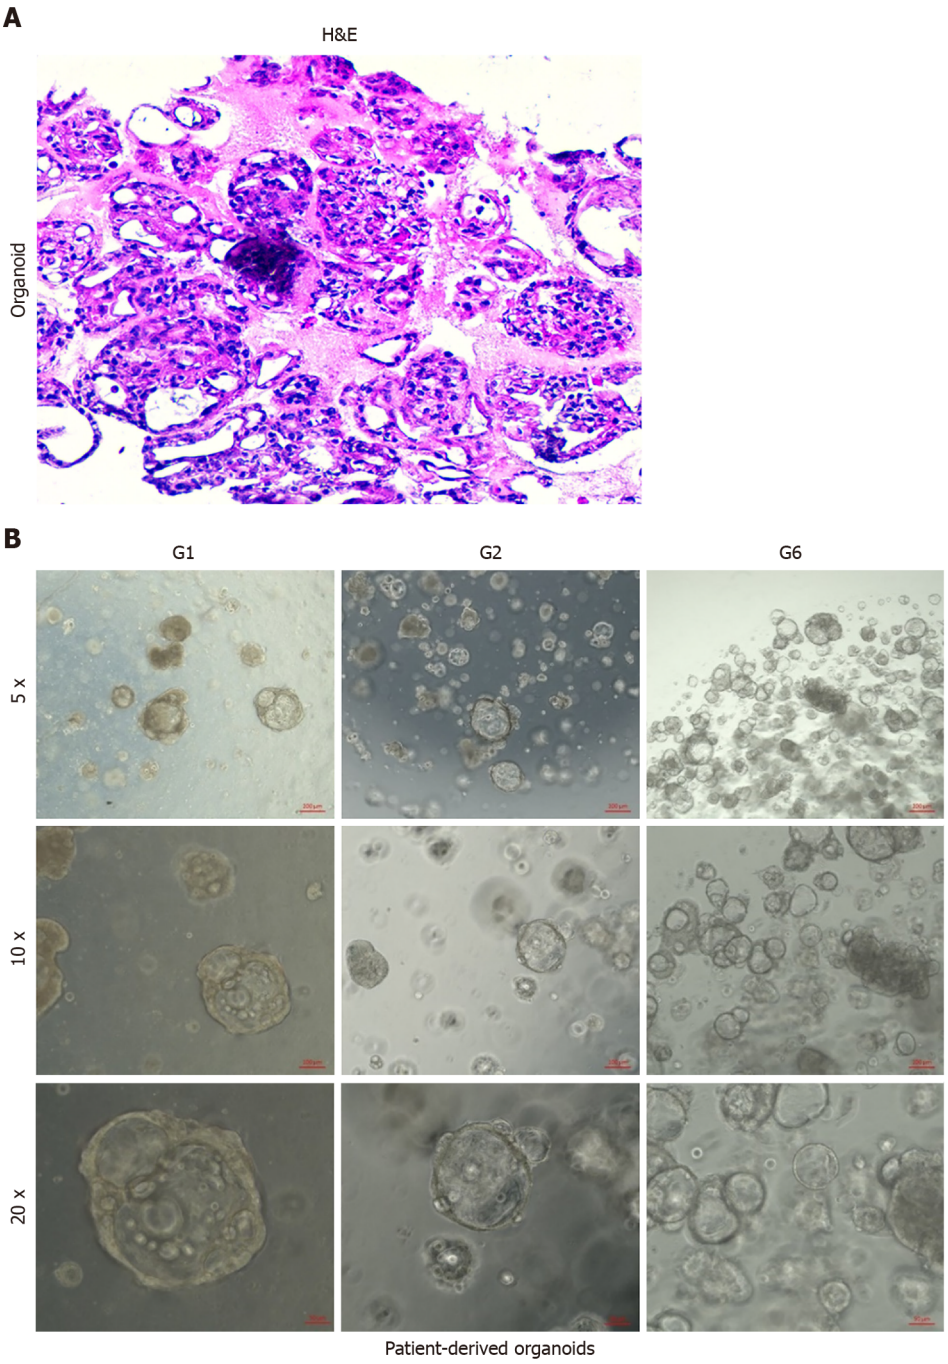
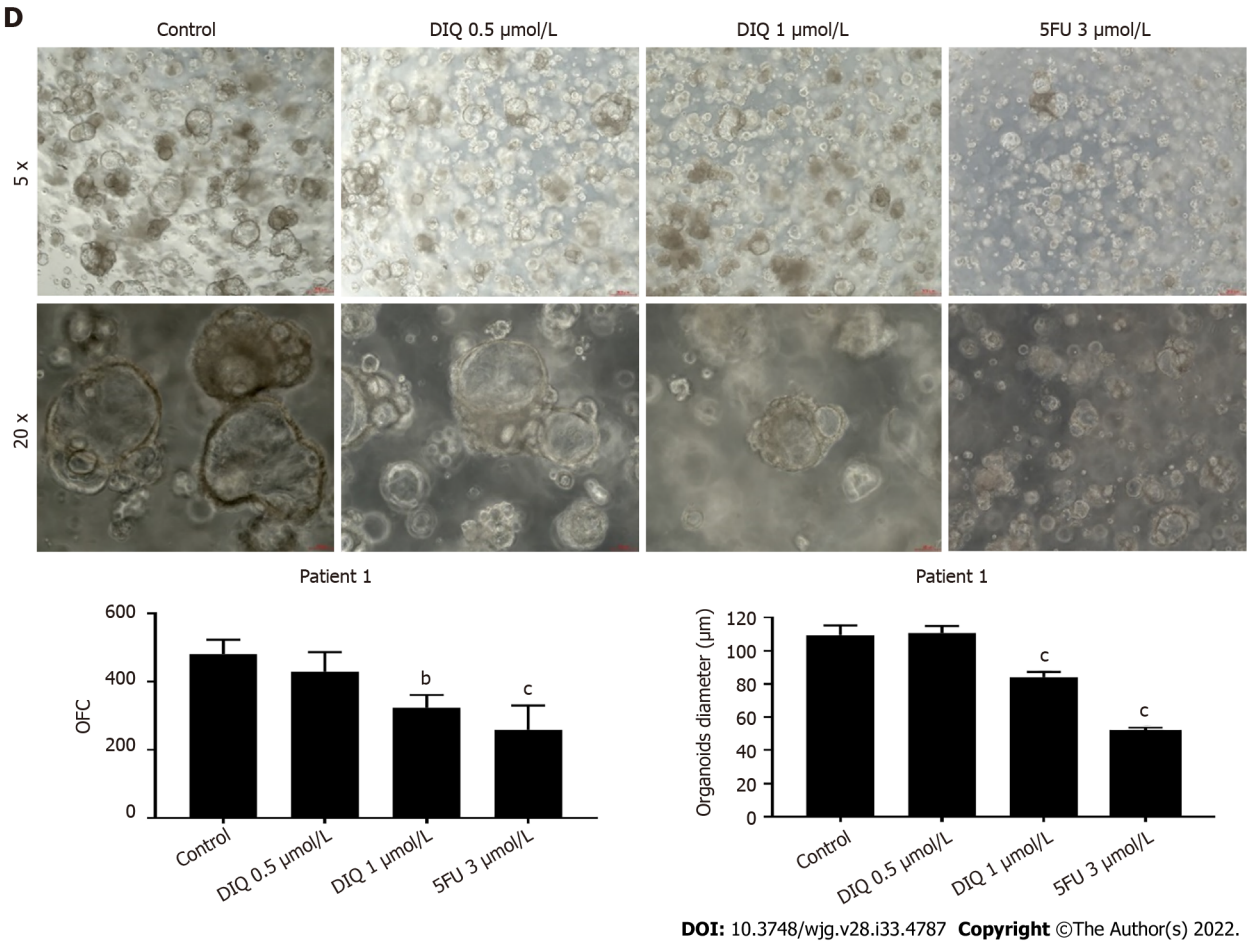
Figure 7 Diiminoquinone reduced tumor growth in non-obese diabetic severe combined immunodeficiency mice. Non-obese diabetic severe combined immunodeficiency (NOD-SCID) mice (5 mice/group) were injected with 100 HCT116 generation 1 spheres. Tumor growth was monitored by measuring the tumor volume during 21 d of treatment (3 times per week) with either 20 mg/kg diiminoquinone (DIQ) or physiologic saline. Representative images of control and DIQ-treated mice at day 21. Data represent an average of two independent experiments and is reported as mean ± standard error of the mean ($^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$).



tissue. Strong expression of CK19 and CD44 was noted in organoids consistent with the corresponding tumor tissue (Figure 9). The co-expression of CK19 and CD44 was decreased upon treatment in a dose-dependent manner (Figure 9B). In Patients 2 and 5, both exhibited similar grade (grade 2) moderately differentiated sigmoid colon adenocarcinoma and were of the same stage (pT3). DIQ treatment at concentrations as low as 0.5 μmol/L displayed a decrease in the growth of the organoids in Patient 2 and an eradication of organoids in Patient 5 (Figure 10). Organoid formation was eradicated upon DIQ (0.5 and 1 μmol/L) treatment in Patient 4, who was diagnosed with moderately differentiated (grade 2) pT2 sigmoid colon adenocarcinoma. Interestingly, the effect of DIQ on the OFC and the size of the organoids was more potent than that of 5FU particularly in patients 2, 4, and 5 (Figure 10).



DISCUSSION

In this study, we investigated the anticancer activity of DIQ in 2D and 3D models of human colon cancer. DIQ reduced the sphere forming and self-renewal ability of CRC HCT116 and HT29 stem cells at sub-toxic doses. Mechanistically, DIQ targeted CSCs by reducing the proliferation marker Ki67 and CRC stem cell markers CD44 and CK19 as well as inducing DNA damage through increasing γH2AX expression and downregulating the main components of stem cell-related -catenin, AKT, and ERK oncogenic signaling pathways. DIQ displayed a highly significant decrease in both the count and the size of the organoids derived from colon cancer patients as compared to control and 5FU conditions. Furthermore, in 2D culture, DIQ significantly inhibited cell proliferation, migration, and invasion of HCT116 and HT29 cell lines. DIQ also induced apoptosis and an increase in ROS along with an accumulation of cells in the sub-G1 region. Consistent with the *in vitro* data, DIQ exhibited reduction in the tumor growth and proliferation *in vivo*.

Our major focus in this study was to evaluate the ability of DIQ to target CSCs in HCT116 and HT29 cells using a 3D sphere formation assay. CSCs are a rare subpopulation of stem-like tumor cells that are responsible for tumor relapse[28,29]. The increase of SFU in both CRC cell lines from generation 1 up to generation 5 suggests an enrichment in CSCs upon propagation, thus confirming the advantage of using the 3D sphere formation assay. Treatment of HCT116 and HT29 cells with DIQ at a concentration as low as 1 μmol/L targeted the subpopulation of stem/progenitor cells over five generations as reflected by the drastic decrease in the SFU and the sphere size in both cell lines. HT29 spheres were more sensitive to 1 μmol/L DIQ, and an eradication of HT29 spheres occurred at generation 3. The interesting finding of DIQ not affecting non-tumorigenic FHS74Int cells makes DIQ somewhat selective to cancer cells, which is the most essential aspect sought after in anticancer drugs.

To understand what molecular pathways could be targeted by DIQ, we focused mainly on the pathways implicated in CSCs. Multiple signaling systems are involved in resistance of CSCs to therapy. It is widely accepted that the Wnt/β-catenin pathway is the most relevant signaling pathway for colon cancer development. Wnt signaling contributes to stem cell development, tumorigenicity, and oncogenesis[30,31]. This pathway is mechanistically responsible for drug resistance of colon CSCs. Increasing evidence validates that this pathway can interact with other oncogenic signaling pathways, such as those involving MAPK, PI3K, AKT, and ERK, which are aberrantly activated in many human cancers[32,33]. Indeed, evidence has shown that AKT and ERK are overexpressed in human CRC[32].

Figure 8 Establishment and characterization of patient-derived organoids from colon cancer patient 1. A: Representative image of organoids derived from patient 1 stained with hematoxylin and eosin (HE); B: Representative bright-field images of organoids at generation (G)1, G2, and G6. Fresh tumor tissues were enzymatically digested, and single cells were plated in 90% growth factor-reduced Matrigel. G1 organoids were successfully propagated up to G6. Images were visualized by Axiovert inverted microscope at × 5, × 10, and × 20 magnification. Scale bar 100 μm; C: Immunofluorescent images of organoids stained with colon lineage epithelial markers cytokeratin (CK)19 and CK8 and stem cell marker CD44. The nuclei were stained with anti-fade Fluorogel II with 4',6-diamidino-2-phenylindole (DAPI). Representative confocal microscopy images were acquired using a Zeiss LSM 710 laser scanning confocal microscope. Scale bar 100 μm; D: Representative bright-field images of G2 organoids treated with diiminoquinone (DIQ) (0.5 and 1 μmol/L) or 5-fluorouracil (5FU) (3 μmol/L). Organoid formation count (OFC) and size were calculated, and mean values were reported as mean ± standard error of the mean ($^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$). Images were visualized by Axiovert inverted microscope at × 5 and × 20 magnification. Scale bar 100 μm.

Thus, identifying drugs that target these oncogenic pathways could make a solid rationale for the targeted therapy of cancers. The result of western blot analysis showed that the ratio of both phosphorylated AKT to total AKT (p-AKT/AKT) and phosphorylated ERK to total ERK (p-ERK/ERK), which are key players of AKT/ERK pathways, were decreased upon DIQ treatment in CRC spheres. These findings suggest that DIQ suppressed sphere growth and formation *via* dual inhibition of AKT/ERK dependent signaling pathways.

We additionally investigated the protein levels of the key stem cell markers in CRC, CD133, and β-catenin, which are involved in chemotherapy resistance. Interestingly, the expression of CD133 and β-catenin were dramatically downregulated after DIQ treatment. Moreover, upon DIQ treatment, there was a significant decrease in the expression of CD44 and CK19 in both CRC cell lines, which were highly expressed in control spheres, along with a decrease in the expression of Ki67 and PCNA. It is interesting to note that CK19, which is considered a tumor marker in CRC, is specifically and stably expressed in primary and metastatic CRC cells. Altogether, this suggests that DIQ could be considered a novel therapeutic compound for suppressing CSC self-renewal.

DIQ-mediated apoptosis and inhibition of cell cycle progression was dependent on the upregulation of p21, which is a known tumor suppressor[34], promotes ROS accumulation, binds to PCNA, and inhibits cell cycle progression[35]. ROS is one of the major inducer of DNA damage. Induction of ROS generation induces increased stress on cancer cells leading to cancer cell death. Interestingly, DIQ treatment induced ROS production in CRC cell lines suggesting that an increase in ROS might also be involved in the anticancer effects of DIQ.

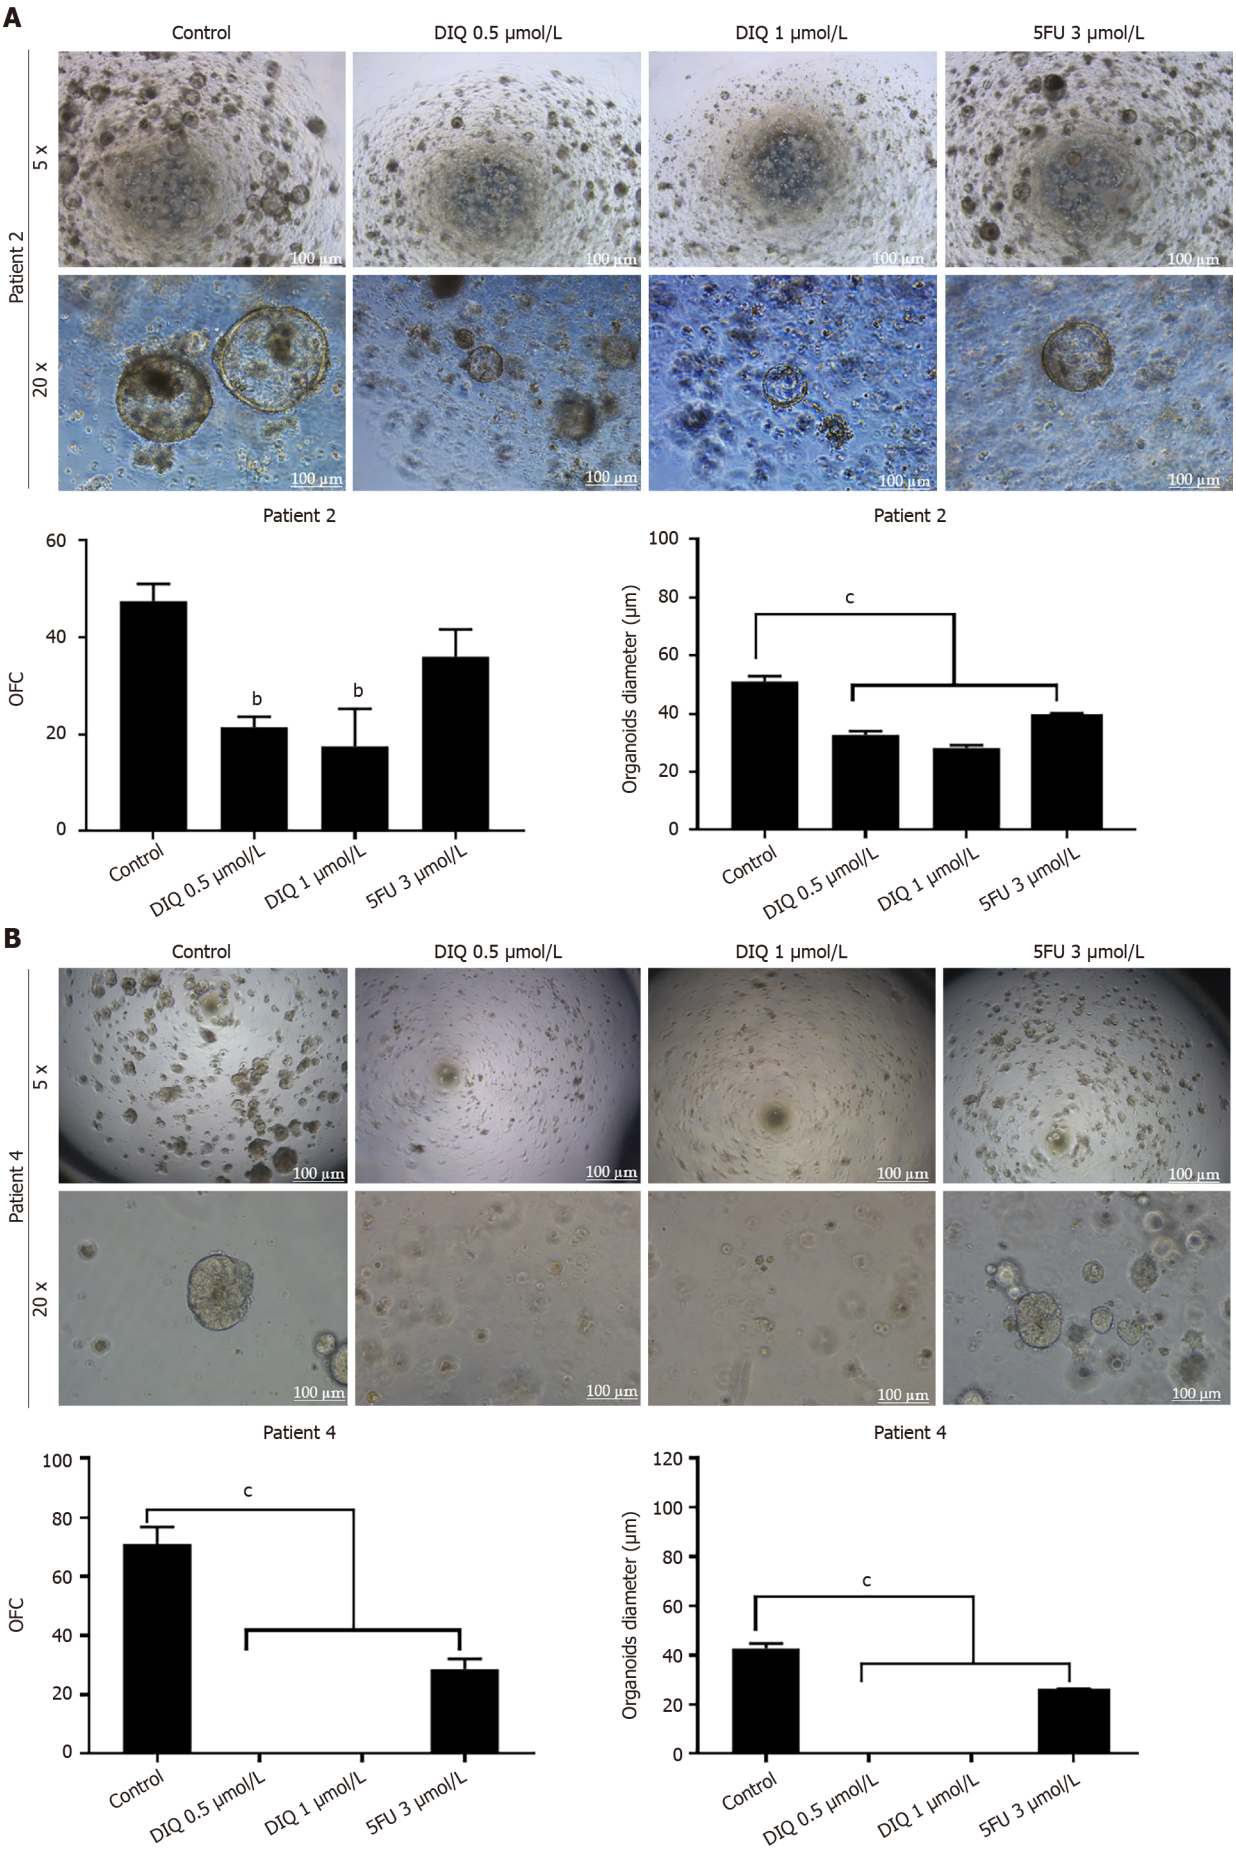
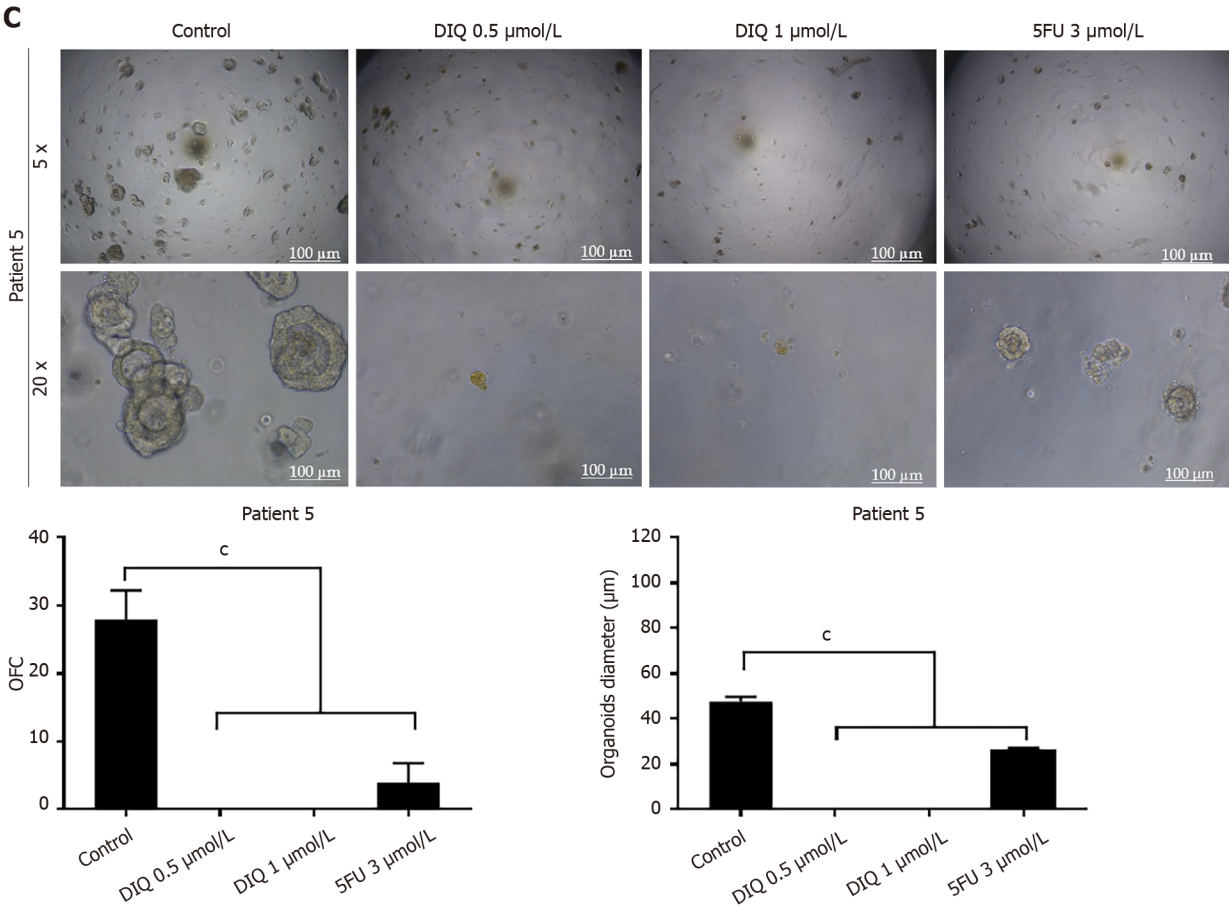
Figure 9 Effect of diiminoquinone on established patient-derived organoids from colon cancer patient 3. A: Immunohistochemistry images of tissue derived from patient 3 stained with hematoxylin and eosin (HE). Immunofluorescent images of tissue stained with colon lineage epithelial markers cytokeratin (CK)19 and stem cell marker CD44. The nuclei were stained with anti-fade Fluorogel II with 4', 6-diamidino-2-phenylindole (DAPI). Representative confocal

microscopy images were acquired using a Zeiss LSM 710 laser scanning confocal microscope. Scale bar 20 μm; B: Immunofluorescent images of organoids derived from colon cancer patient 3 at generation (G)2 in the presence and absence of diiminoquinone (DIQ) treatment (0.5 and 1 μmol/L) stained with colon lineage epithelial markers CK19 and stem cell marker CD44. The nuclei were stained with anti-fade Fluorogel II with DAPI. Representative confocal microscopy images were acquired using a Zeiss LSM 710 laser scanning confocal microscope. Scale bar 20 μm. Representative bright-field images of organoids derived from colon cancer patient 3 at G2 in the presence and absence of DIQ treatment (0.5 and 1 μmol/L). Organoid formation count and size were calculated, and mean values were reported as mean ± standard error of the mean ($^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$). Images were visualized by Axiovert inverted microscope at × 5 and × 20 magnification. Organoid formation count (OFC) and size of G were calculated, and mean values were reported as mean ± standard error of the mean ($^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$). Scale bar 100 μm.



Since DIQ-induced apoptosis in HCT116 colonospheres through an increase in TUNEL positivity as we previously reported[22], we assessed whether DNA damage was activated in the spheres derived from both cell lines. We evaluated the expression of γH2AX, which is a DNA double-strand damage biomarker and could be a classical cancer prognostic factor[36,37]. The loss of DNA damage in CRC is involved in the development of therapeutic resistance[37]. In addition, quinones and oxaliplatin have been shown to induce apoptosis of CRC cells by activating DBS and activating γH2AX expression[7,38]. Interestingly, DIQ increased the expression of γH2AX in both CRC cells; clearly emphasizing that DIQ is a potent inducer of DNA damage.



Interestingly, this study has also demonstrated effects of DIQ in patient-derived organoids. This model closely recapitulates tissue architecture and cellular composition and is used to assess the self-renewal and differentiation capacities of the organoid CSC, including growth kinetics and drug sensitivity[12,13]. Testing drug efficacy in colon patient-derived organoids holds great promise for personalized medicine and exhibits a significant potential to predict patient response and connect compound screening and clinical trials[39,40]. Since drug resistance to chemotherapy is a serious challenge in treating solid tumors, drug exposure studies on the patient-derived organoids help in choosing specific chemotherapy regimens for patients with malignant disease. Since chemotherapy response in CRC treatment varies between patients, the current study used patient-derived CRC organoids to evaluate the antineoplastic effect of DIQ in targeting stem cells. The established colon organoids expressed the CRC epithelial marker lineage CK19 and the CSC cell marker CD44. This observed co-expression recapitulates the architecture and the characteristics of colon tissues. Notably, DIQ caused a prominent inhibitory effect on the growth of CRC organoids from various patients at different CRC stages, emphasizing its antitumor potential in CRC patients. This effect was either more than or as potent as that of 5FU, emphasizing its inhibitory effect. The results of response of HCT116 and HT29 cell-derived organoids to DIQ treatments were consistent with that of patient-derived organoids. We, therefore, for the first time revealed that DIQ targeted the CSC in patient-derived colon organoids.

The present study has several limitations. The two major limitations in organoid establishment and subsequent applications were the small size of the patient tissue and the availability of tissues at the time of the study. As a clinical study, the patient sample size was relatively small. Additionally, the percentage success rate of deriving colon patient derived organoids was not more than 42%; only 5 out of 12 specimens were successfully established as colon organoids. This could possibly be due to limitations in tissue quality as well. A larger cohort is still required to further investigate and evaluate the effect of DIQ in translational medicine.

CONCLUSION

In conclusion, we demonstrated for the first time that DIQ reduces self-renewal capacity of colorectal tumors and prevents therapy resistance in patient-derived organoids through interfering with the stem cell Wnt/-catenin and AKT and ERK pathways that are involved in CRC tumorigenesis. Also, the effect of DIQ was involved in the major cell fate responses including apoptosis, cell cycle arrest, and stress response. DIQ inhibits the key processes of CRC tumorigenesis, including cell growth, proliferation, migration, and invasion. Our findings strongly suggest that DIQ could be a promising compound for treatment of CRC patients and could be clinically used as a non-toxic compound for targeting human colon cancer stem/progenitor cells.

Figure 10 Diiminoquinone reduced the growth of the patient-derived organoids from different colon cancer patients. A: Representative bright field images of generation (G)1 organoids derived from patient 2 (grade 2; stage T3) grown with or without diiminoquinone (DIQ) or 5-fluorouracil (5FU). Organoid formation count (OFC) was calculated in duplicate wells per condition. The quantification of the average diameter was calculated. The data of OFC and size are presented in two separate graphs; B: Representative bright field images of G4 organoids derived from patient 4 (grade 2; stage T2) grown with or without DIQ or 5FU. OFC was calculated in duplicate wells per condition. The quantification of the average diameter size was calculated. The data of OFC and size are presented in two separate graphs; C: Representative bright field images of G2 organoids derived from patient 5 (grade 2; stage T3) grown with or without DIQ or 5FU. OFC was calculated in duplicate wells per condition. The quantification of the average diameter was calculated. The average mean of OFC and size are presented in two separate graphs. All mean values were reported as mean ± standard error of the mean ($^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$). Scale bar, 100 μm.

ARTICLE HIGHLIGHTS

Research background

Colorectal cancer (CRC) is a multistep genetic disorder caused by sequential mutational events in signal transduction pathways occurring along with progression of the cancer. Quinone containing compounds have been reported as one of the promising novel anticancer therapeutics against CRC. However, the effects of diiminoquinone (DIQ) on CRC stem cells have not been extensively investigated yet.

Research motivation

To explore the promising anticancer effects of a novel quinone, DIQ, on CRC.

Research objectives

To investigate the anticancer potential of novel therapeutic DIQ on CRC using two-dimensional and three-dimensional models.

Research methods

MTT and trypan blue exclusion assays were employed to assess the anti-proliferative effect of DIQ on HCT116 and HT29 cell lines *in vitro*. Propidium iodide DNA and dihydroethidium staining were performed to determine cell cycle distribution and reactive oxygen species production in response to DIQ, respectively. Wound healing and transwell invasion assays were used to determine the invasion and migration ability of DIQ, respectively. Then, a sphere formation model was used to evaluate the potency of DIQ on targeting cancer stem cells in CRC cells for up to five generations. Immunofluor-

escent analysis and western blot were performed to elucidate the mechanism of action of DIQ in CRC. Organoid model was used to assess DIQ response on established organoids from fresh colorectal tissue samples from consenting patients.

Research results

DIQ reduced the self-renewal capacity of CRC cells and targeted the growth of colon cancer patient-derived organoids. DIQ downregulated the expression of key markers involved in the oncogenic stem cell Wnt/-catenin, AKT, and ERK signaling pathways that are involved in CRC tumorigenesis. Also, DIQ decreased proliferation, migration, and invasion and induced apoptosis, cell-cycle arrest, and reactive oxygen species.

Research conclusions

Our findings strongly suggest that DIQ could be a promising novel therapeutic for the treatment of CRC patients. This study represents the first documentation of the molecular mechanism of the novel anticancer therapeutics DIQ *via* targeting cancer stem cells, findings that have potential therapeutic implications for colon cancer patients.

Research perspectives

Further research on the DIQ mechanisms that are involved in CRC tumorigenesis is needed to be performed in the future. A larger cohort is still required to further investigate and evaluate the effects of DIQ in translational medicine.

ACKNOWLEDGEMENTS

We are thankful to all members of the Gali-Muhtasib and Abou-Kheir Laboratory and the staff of the core facilities in the DTS Building at the American University of Beirut for their technical help and support.

Abstract

BACKGROUND

The etiology of pancreatic cancer remains unclear. This limits the possibility of prevention and effective treatment. Hepatitis B virus (HBV) is responsible for the development of different types of cancer, but its role in pancreatic cancer is still being discussed.

AIM

To assess the prevalence of previous HBV infection and to identify viral biomarkers in patients with pancreatic ductal adenocarcinoma (PDAC) to support the role of the virus in etiology of this cancer.

METHODS
The data of 130 hepatitis B surface antigen-negative subjects were available for the final analysis, including 60 patients with PDAC confirmed by cytology or histology and 70 sex- and age-matched controls. All the participants were tested for HBV biomarkers in blood [antibody to hepatitis B core antigen (anti-HBc), antibody to hepatitis B surface antigen (anti-HBs) and HBV DNA], and for those with PDAC, biomarkers in resected pancreatic tissues were tested (HBV DNA, HBV pregenomic RNA and covalently closed circular DNA). We performed immunohistochemistry staining of pancreatic tissues for hepatitis B virus X antigen and Ki-67 protein. Non-parametric statistics were used for the analysis.

RESULTS
Anti-HBc was detected in 18/60 (30%) patients with PDAC and in 9/70 (13%) participants in the control group (P = 0.029). Accordingly, the odds of PDAC in anti-HBc-positive subjects were higher compared to those with no previous HBV infection (odds ratio: 2.905, 95% confidence interval: 1.191-7.084, standard error 0.455). HBV DNA was detected in 8 cases of PDAC and in 6 of them in the pancreatic tumor tissue samples only (all patients were anti-HBc positive). Blood HBV DNA was negative in all subjects of the control group with positive results of the serum anti-HBc test. Among 9 patients with PDAC, 5 revealed signs of replicative competence of the virus (covalently closed circular DNA with or without pregenomic RNA) in the pancreatic tumor tissue samples. Hepatitis B virus X antigen expression and active cell proliferation was revealed by immunohistochemistry in 4 patients with PDAC in the pancreatic tumor tissue samples.

CONCLUSION
We found significantly higher risks of PDAC in anti-HBc-positive patients. Detection of viral replication and hepatitis B virus X protein expression in the tumor tissue prove involvement of HBV infection in pancreatic cancer development.

Key Words: Hepatitis B virus; Previous hepatitis B; Occult hepatitis B virus infection; Pancreatic cancer; Pancreatic ductal adenocarcinoma

Core Tip: Hepatitis B viral (HBV) infection is responsible for different types of cancer. Its role in pancreatic ductal adenocarcinoma (PDAC) remains unclear. This study assessed the prevalence of previous HBV infection and to identify viral biomarkers in patients with PDAC to support the role of the virus in the etiology of this cancer. Anti-HBc-positive subjects had an almost 3-fold greater chance of PDAC compared to the controls. Detection of viral replication and hepatitis B virus X protein expression in the tumor tissue show a possible involvement of HBV infection in pancreatic cancer development. Previous HBV infection is currently an underestimated cause of PDAC.

INTRODUCTION

Pancreatic cancer (PC) is an aggressive gastrointestinal malignancy with a low rate of early detection, poor survival and a limited number of therapeutic options. It causes more than 430000 deaths yearly worldwide[1]. This makes PC the third leading cause of cancer-related deaths in the United States and the fourth in the European Union[2,3]. The incidence rate of PC is growing, while the improvement in the survival rates is negligible[4]. Pancreatic ductal adenocarcinoma (PDAC) is the most prevalent type of PC and is found in 85% of cases[5]. The etiology of PC remains unclear, which limits the possibility for prevention and effective treatment. Early detection of PC remains a challenge. Therefore, it is still relevant to explore etiological factors of PDAC further and to identify subjects at risk of the disease. Numerous risk factors for the disease have been identified (smoking, excessive alcohol intake, history of chronic pancreatitis, obesity and diabetes, *etc*)[6]. Some viruses, including hepatitis B virus (HBV), are responsible for the development of different types of cancer, but their role in PC is still being discussed

[7].

In endemic regions, like Southeast Asia, the blood markers of current HBV infection are commonly found in subjects with PC[8]. Some authors from endemic regions report that HBV infection is not associated with the risk of developing PC after adjusting for age, sex, diabetes and smoking[9].

Cohort studies from Northern Europe (Denmark, Sweden), where HBV infection is not widespread, showed conflicting results and made an association between PC and HBV infection questionable[10-12]. In most of these studies, association of PC with previous HBV infection (PBI) was not considered. However, it may be important as the risk of liver cancer development perseveres even after hepatitis B surface antigen (HBsAg) loss[13-15].

Cancerogenic mechanisms of HBV infection may be explained by the integration of viral DNA fragments into the genome of host cells or persistence of the viral genome as a covalently closed circular DNA (cccDNA), which plays the role of viral reservoir and template for life-long synthesis of new virions. Both are responsible for preserved expression of viral proteins (especially HBx), which can lead to potentially oncogenic mutations[16-18].

Thus, not only active hepatitis B, but also previous HBV infection may contribute to PC development. Detection of HBV DNA and viral antigens in the pancreatic tumor tissues may provide direct evidence of the involvement of the virus in the etiology of this cancer. However, only a few studies demonstrated the presence of HBV DNA (cccDNA) and/or viral antigens in pancreatic tumor tissue. Therefore, the aim of our study was to assess the prevalence of PBI and to identify viral biomarkers in patients with PDAC to support the role of the virus in the etiology of this cancer.

MATERIALS AND METHODS

Study population

The study was based on the data of complex examination of patients that applied for PC treatment to Moscow Clinical Scientific Center named after A.S. Loginov from January 2019 to November 2020. Subjects of the control group were also recruited. The study (registered AAAA-A18-118021590196-1, AAAA-A20-120051990006-1 at www.rosrid.ru) was approved by the Local Ethics Committee and was conducted in accordance with the Declaration of Helsinki (1968) and its consequent revisions. All subjects signed a written informed consent form before the enrollment.

Inclusion criteria

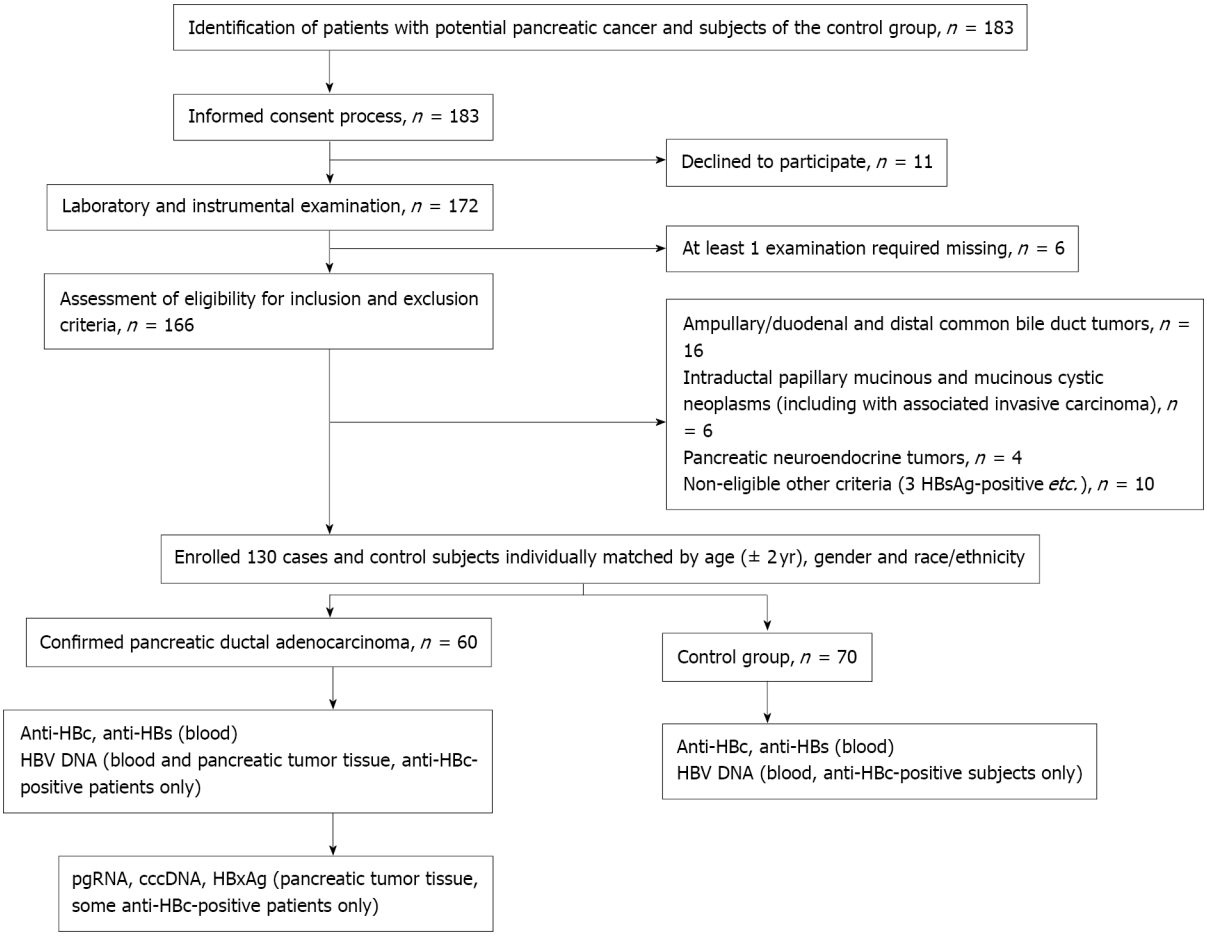
Patients of both sexes, older than 18 years, willing to participate in the study were eligible.

In the group of PC, we enrolled patients with histologically or cytologically confirmed PDAC. In the control group we enrolled generally healthy subjects who applied for routine check-ups or treatment of other non-malignant gastrointestinal conditions and whose data of abdominal ultrasound and/or computed tomography revealed no signs of focal lesions in the pancreas.

Exclusion criteria

Other/indeterminate types of PC or non-malignant lesions beside PDAC (for the main group); positive blood test for HBsAg, hepatitis C virus or HIV antibodies; past surgery for PC; current or previous treatment with interferons, nucleos(t)ide analogues for HBV infection or other reasons; clinically significant diseases or health disorders, making it impossible to perform procedures required by the study protocol.

Confirmation of the conditions of interest



PBI was defined as the presence of antibody to hepatitis B core antigen (anti-HBc) with or without antibody to hepatitis B surface antigen (anti-HBs) or HBV DNA in serum[19]. Control subjects were matched for age (within 2 years), sex and race/ethnicity with the PDAC patients. Study design is shown in Figure 1.

Study procedures

To exclude health conditions able to affect results of the study, all patients underwent routine diagnostic procedures (including but not limited to blood tests, electrocardiogram, abdominal ultrasound and chest X-ray) within standards of care.

All the participants were tested for HBV biomarkers in blood (HBsAg, anti-HBc, anti-HBs). Those HBsAg-negative with positive anti-HBc result were tested for HBV DNA in blood. Anti-HBc-positive patients with PDAC were examined for HBV DNA in the pancreatic tumor tissue.

Tumor tissues of anti-HBc-positive patients with PDAC underwent examination for HBV biomarkers (HBV pregenomic RNA and cccDNA) and immunohistochemistry staining for hepatitis B virus X antigen (HBxAg) and Ki-67 protein in cases of the signed informed consent for these tests and sufficient quantity and good quality of the samples.

Figure 1 Study design and patient allocation chart. cccDNA: Covalently closed circular DNA; HBV: Hepatitis B virus; HBsAg: Hepatitis B surface antigen; anti-HBc: Antibody to hepatitis B core antigen; anti-HBs: Antibody to hepatitis B surface antigen; pgRNA: Pregenomic RNA.

All anti-HBc-positive participants were tested for the presence of HBV DNA in the blood. In addition, all 18 anti-HBc-positive patients with PDAC were tested for the presence of HBV DNA in pancreatic tumor tissue. In 8 of them, the quality and quantity of samples were suitable for additional testing for HBV pregenomic RNA and cccDNA. Five patients had eligible samples according to these criteria and gave additional consent for immunohistochemical staining for HBxAg and Ki-67 protein.

Collection of samples: Blood samples were taken after overnight fasting, coded and processed immediately at the local laboratory according to the standard instructions.

Pancreatic tumor tissue samples were obtained during surgery or diagnostic biopsy, coded and processed locally. They were stained with hematoxylin-eosin and assessed by a qualified morphologist.

Immunology: Serum samples were tested for HBsAg, anti-HBc IgG, anti-HBs, hepatitis C virus and HIV antibodies. These tests were performed with the use of a Sunrise analyzer (Tecan GmbH, Austria) and specific immunoassays kits (Vector-Best Co., Russia).

Analysis of HBV nucleic acids: Plasma HBV DNA was isolated using commercial AmpliSens Riboprep kit (AmpliSens Biotechnologies, Russia) according to manufacturer's instructions and quantified using the PCR assay AmpliSens HBV-FL (AmpliSens Biotechnologies) kit (lower limit of detection of 10 IU/mL).

To isolate nucleic acids from biopsies, samples were first homogenized in the MagNA Lyser (Roche Diagnostics, Switzerland). HBV DNA was isolated by AmpliSens Riboprep kit (AmpliSens Biotechnologies) and quantified by AmpliSens HBV-FL (AmpliSens Biotechnologies) kit.

To quantify cccDNA, nucleic acids were first treated with T5 exonuclease (New England Biolabs, United Kingdom) at 37 °C for 60 min and inactivation at 70 °C for 20 min[20]. HBV cccDNA was quantified with specific sets of primers and probes and normalized to genomic β-globin.

Specific sets of primers (Table 1) and TaqMan fluorescent probes were used for PCR analysis to detect HBV DNA in pancreatic tissue samples.

Table 1 List of specific sets of primers and probes used for the analysis

Target	Sequence	
cccDNA	Fw	CCGTGTGCACTTCGCTTCA
	Rev	GCACAGCTTGGAGGCTTGA
	Probe	FAM-CATGGAGACCACCGTGAACGCCC-BHQ1
β-globin	-	V31-FEP-CE (AmpliSens)
		HPV HCR-Screen (AmpliSens)

cccDNA: Covalently closed circular DNA; Fw: Forward; Rev: Reverse; HPV: Human papillomavirus; HCR: High carcinogenic risk; AmpliSens: AmpliSens Biotechnologies, Russia.

To analyze pregenomic HBV RNA (pgRNA HBV), nucleic acids were treated with RNase-free DNase I (NEB) for 30 min at 37 °C, purified by using AmpliSens Riboprep kit (AmpliSens Biotechnologies), reverse transcribed by AmpliSens Reverta-FL (AmpliSens Biotechnologies) and quantified by AmpliSens HBV-FL (AmpliSens Biotechnologies) kit. CFX96 Real-Time System (Bio-Rad, United States) PCR machine was used for the analysis of plasma and pancreatic tissue samples.

Immunohistochemistry of pancreatic tissues was performed after deparaffinization. Slides were fixed in 4% paraformaldehyde, washed three times in Tris-HCl (50 mM, pH 8.0) followed by incubation with a blocking buffer (0.02% of Triton X-100, 10% horse serum, and 150 mmol/L NaCl in Tris-HCl, 50 mmol/L, pH 8.0) for 30 min and 1 h staining with primary rabbit anti-HBx (ab39716) (Abcam, United Kingdom). Then, slides were washed three times for 5 min in a washing buffer (0.02% of Triton X-100 and 200 mmol/L NaCl in Tris-HCl, 50 mmol/L, pH 8.0) and incubated for 1 h with secondary Alexa Fluor 594 goat anti-rabbit antibodies (ab150080) (Abcam). After that, the slides were treated with primary tagged Alexa Fluor® 488 rabbit anti-Ki-67 (ab197234) and Hoechst 33342 (ab228551) for 1 h, washed three times for 5 min in washing buffer and finally mounted with a Fluoroshield reagent (Abcam). Images were captured using Thunder imaging systems (Leica Microsystems, Germany) with 10 × objectives. Ki-67 and HBxAg staining was analyzed using LAS X (Leica Microsystems). Ki-67 index was counted as the percentage of Ki-67-positive cells[21].

Statistical analysis

Statistica 12.0 software (StatSoft Inc., United States) was used for analysis of the data. Statistical processing of the obtained data was carried out using nonparametric statistics. Quantitative indicators were preliminarily assessed for compliance with the normal distribution using the Kolmogorov-Smirnov and Lilliefors tests. When quantitative indicators' distributions differed from normal, we used medians and the interquartile ranges (25%-75%) for the description and processed the data using the Mann-Whitney *U* test. Nominal data were compared using Pearson $\chi 2$ test with Yates's correction. *P* values < 0.05 were considered significant. Odds ratio (OR) and 95% confidence interval (95%CI) calculations were performed to assess the association between PDAC and PBI marker detection.

RESULTS

Data of 60 patients with PDAC and 70 participants of the control group were available for the final analysis. Demographic and viral characteristics of the participants are shown in Table 2.

In patients with PDAC, anti-HBc antibodies were found more often than in the control group (P = 0.029). Accordingly, the odds of PDAC in anti-HBc-positive subjects were significantly higher compared to those who had no PBI (OR: 2.905, 95%CI: 1.191-7.084, standard error 0.455).

Overall, HBV DNA was found in 8 anti-HBc-positive patients with PDAC. In 2 subjects it was detected in both the blood and pancreatic tumor samples, whereas in the other 6 participants the testing gave positive results only in the pancreatic tumor tissues. No positive results for HBV DNA were obtained in the control group.

The data from special examination of the blood and pancreatic tissue samples are shown in Table 3. The markers confirming replicative competence of HBV (cccDNA with or without pgRNA) were found in the pancreatic tumor tissue samples in 5 patients with PDAC. In 1 subject with a positive test on HBV DNA in the pancreatic tissue examination on cccDNA and pgRNA was not performed.

In those with detectable HBV DNA, viral load in the pancreatic tissue was 632 (390-851) IU/mL [median (25%-75%)].

HBxAg expression and active cells' proliferation was revealed by immunohistochemistry in 4 participants with PDAC in the pancreatic tumor tissue samples (Table 3 and Figure 2). The number of HBx-expressing cells in them did not exceed 10%.

Ki-67 proliferative index in subjects with PDAC in the cohort of special examination was 79.1 (45.2–86.4) [median (25%-75%)]. All HBx-expressing cells were also Ki-67 positive.

DISCUSSION

The results of the present study demonstrate the association of PBI with PDAC and provide direct molecular evidence for the presence of HBV biomarkers in the pancreatic tumor tissue. In 8 of our patients with PDAC, HBV DNA was detected in the pancreatic tumor tissue. In 5 of them, replicative competence of HBV DNA in the pancreas was supported by detection of cccDNA (with or without pgRNA). Identification of cccDNA and pgRNA (transcribed only from cccDNA) additionally suggests that these patients saved a silent replication of the virus in the pancreatic tissue. Detection of the virus nucleic acids in pancreatic tissue only (with no HBV DNA present in blood) in most of subjects excludes

Figure 2 Immunohistochemistry of resected pancreatic tumor tissues (obtained during surgery). Case: Anti-HBc-positive patient with pancreatic ductal adenocarcinoma. Control: Patient with pancreatic ductal adenocarcinoma, who was negative for hepatitis B virus biomarkers. A: Images at magnification × 10; B: Images at magnification × 100. Samples were stained for Ki-67 protein (green fluorescence) and X antigen of hepatitis B virus of (HBxAg) (red fluorescence). Cell nuclei were counterstained by Hoechst33342 dye (blue). Asterisks indicate HBxAg/Ki-67 co-stained cells.

the possibility of artificial contamination of the tumor tissue samples.

Viral infections, including those caused by HBV were recognized among the modifiable risk factors of PC development[22,23]. The data of a meta-analysis of case-control and observational studies (number of subjects with PC: 5883) showed that the odds of PC were significantly higher in chronic or inactive HBsAg carriers [OR: 1.60 (95%CI: 1.26-2.05)] and anti-HBc-positive but anti-HBs-negative individuals [OR: 1.76 (95%CI: 1.05-2.93)] compared to those who were never exposed to HBV infection[7,24]. In our study, the odds of PDAC were even higher, and anti-HBc-positive subjects had an almost 3-fold greater chance of PDAC compared to the controls.

Only a few studies have demonstrated molecular evidence of possible HBV involvement in pancreatic tumor development by identifying HBV DNA (cccDNA) and/or its antigens in pancreatic tumor tissue, and only a limited number of subjects (especially HBsAg-negative but anti-HBc-positive) were involved[25,26]. Although certain pathogenetic mechanisms of PC associated with hepatitis B infection need to be explained in specially planned studies, some assumptions could be made.

HBV is a known carcinogen and is one of the main causes of hepatocellular carcinoma in endemic regions[8]. However, in HBV endemic areas, such as Africa and East Asia, there is a relatively low rate of PC-related deaths. Probably due to high mortality from other causes (including HBV-associated hepatocellular carcinoma), there is not enough time for the development of PC in people with PBI.

HBV integrates into the genome of infected cells, causes genomic aberrations, enhances expression of oncogenes or inhibits tumor suppressors and leads to the cancer development[14]. Similar mechanisms are possible in non-liver carcinogenesis, including the pancreas[25,27]. Pancreatic beta cells and hepatocytes develop from the ventral foregut endoderm during ontogenesis and thus may share characteristics that are favorable for HBV replication and virus-induced tumor development[28]. It seems that malignant transformation in the pancreas is not provoked by direct cellular damage and is caused by the integration of HBV DNA into the genome of pancreatic cells and subsequent disruption of the functions of anti-oncogenes or by stimulation of pro-oncogenes' activity[29]. The replication of HBV in pancreatic tissue may decrease with time. However, DNA fragments of the virus integrated into the genome of host cells continue to express viral proteins (especially regulatory protein X) of HBV responsible for carcinogenesis. The expression capability of HBx from integrated fragments of the viral genome in tumor tissues when replication is absent was confirmed in hepatocellular carcinoma[30-32].

In our study, immunohistochemistry revealed expression of HBx in the pancreatic tumor tissue in 4 out of 5 HBsAg-negative and anti-HBc-positive patients with PDAC. Replicative competence of HBV (detected cccDNA) was found in 3 of them. This may mean that in 1 patient, expression of HBx was caused only by the integration of the virus into the genome of pancreatic cells. These fragments of viral DNA, which preserve the open reading frame and express HBx, may serve as a basis for carcinogenesis in subjects with PDAC. Although this mechanism may play a role in primary cancer development, its role in PC recurrence is not clear, and further studies are necessary. The low-grade replication may also play a role in HBV reactivation, especially in cases when immunodepressants are used. However, this question is insufficiently studied.

It is not clear whether the number of HBxAg expressing cells is important for cancer development. In hepatocellular carcinoma of HBsAg-negative HBV DNA-positive subjects, the relative number of HBxAg-expressing cells is about 30% within the tumor tissue and 20% in the rest of the liver tissue[33]. Similar data for PC are lacking. According to our results, the number of cells producing HBxAg in PDAC is about 4%. It seems that the number of cells producing HBx protein is less important than their presence, at least for PC development. This may be indirectly confirmed by the fact that in all HBxAg-positive subjects in our study proliferative index Ki-67 was significantly higher than 50%, whereas similarly high values of this marker were only found in about 12% of subjects with PDAC[21,34].

Detection of cccDNA in pancreatic tissue in HBsAg-negative subject supports the need for revision of the statements of the Taormina Workshop (2018), which defines occult HBV infection as the presence of replication-competent HBV DNA (*i.e.* cccDNA in the liver and/or HBV DNA in the blood of people who test negative for HBsAg by currently available assays)[16]. As extrahepatic HBV replication may occur in HBsAg-negative subjects (which was confirmed in the course of our study), it is reasonable not to indicate in the statement the specific organ for HBV DNA (cccDNA) detection.

Involvement of PBI in PC development requires revision of the ultimate targets of antiviral treatment. "Sterilizing cure" (undetectable HBsAg in blood in combination with the absence of DNA HBV in any tissues, including cccDNA and integrated viral DNA) was recognized unachievable in the near future [35]. However, "functional cure" (defined as sustained clearance of HBs with or without HBs-seroconversion and non-detectable HBV DNA in blood after the course of treatment) evidently cannot affect the expression of oncogenic proteins of HBV (especially HBx) and thus diminish the chances of cancer development. Although it is impossible to achieve eradication of cccDNA and integrated fragments of the viral genome with currently existing means, this should be stated as the ultimate goal for future therapy options.

The limitation of the study is a relatively small number of patients. Moreover, examination of the tumor tissues on cccDNA, pgRNA and HBxAg was possible for only a few of the 18 anti-HBc-positive subjects with PDAC due to the quality of the obtained specimens. Further randomized multicenter studies are necessary to confirm the obtained results, prove the role of HBV infection in the etiology of PC and clarify carcinogenic mechanisms in them.

CONCLUSION

An almost three-fold risk of PDAC was found in HBsAg-negative but anti-HBc-positive subjects. Detection of silent viral replication and pro-oncogenic HBx protein expression in the tumor tissue suggest involvement of HBV infection in PC development. PBI seems to be an underestimated cause of PDAC at the moment.

ARTICLE HIGHLIGHTS

Research background

The etiology of pancreatic cancer is unclear. This limits possibilities for its prevention and effective treatment. Hepatitis B virus (HBV) is responsible for the development of hepatocellular carcinoma and different types of extrahepatic cancer, but its role in the etiology of pancreatic cancer is still being discussed.

Research motivation

The epidemiological relationship of previous HBV infection (PBI) with pancreatic cancer and identification of viral biomarkers within the tumor tissue may provide support for this. However, there is still a lack of such reports, especially from non-endemic regions for HBV infection.

Research objectives

In our study, we aimed to assess the prevalence of PBI and to identify viral biomarkers in patients with pancreatic ductal adenocarcinoma (PDAC) to support the role of the virus in the etiology of this cancer.

Research methods

The data of 130 hepatitis B surface antigen-negative subjects were included in the final analysis (60 patients with PDAC confirmed by cytology or histology and 70 sex- and age-matched controls). All the participants were tested for HBV biomarkers in blood (antibody to hepatitis B core antigen, antibody to hepatitis B surface antigen and HBV DNA). Those with PDAC were tested for biomarkers in resected pancreatic tissues [HBV DNA, HBV pregenomic RNA and covalently closed circular DNA (cccDNA)]. Additionally, we performed immunohistochemistry staining of pancreatic tissues for hepatitis B virus X antigen and Ki-67 protein. Non-parametric statistics were used for the analysis.

Research results

We have established that 18/60 (30%) patients with PDAC and 9/70 (13%) participants in the control group (P = 0.029) were anti-hepatitis B core antigen-positive. HBV DNA was detected in 8 anti-hepatitis B core antigen-positive patients of PDAC (in 6 of them—in the pancreatic tumor tissue samples only) but in neither subjects of the control group. In 5 patients with PDAC we revealed signs of replicative competence of the virus (cccDNA with or without pregenomic RNA) in the pancreatic tumor tissue samples. Hepatitis B virus X antigen expression and active cells' proliferation was revealed by immunohistochemistry in 4 participants with PDAC in the pancreatic tumor tissue samples.

Research conclusions

PBI seems to be an underestimated cause of PDAC.

Research perspectives

Larger studies are necessary to assess risks of PDAC in subjects with PBI and define HBV-associated mechanisms of carcinogenesis in them.

Abstract

BACKGROUND

Biologic therapy resulted in a significant positive impact on the management of inflammatory bowel disease (IBD) however data on the efficacy and side effects of these therapies in the elderly is scant.

AIM

To evaluate retrospectively the drug sustainability, effectiveness, and safety of the biologic therapies in the elderly IBD population.

METHODS

Consecutive elderly (≥ 60 years old) IBD patients, treated with biologics [inflixi-

mab (IFX), adalimumab (ADAL), vedolizumab (VDZ), ustekinumab (UST)] followed at the McGill University Inflammatory Bowel Diseases Center were included between January 2000 and 2020. Efficacy was measured by clinical scores at 3, 6-9 and 12-18 mo after initiation of the biologic therapy. Patients completing induction therapy were included. Adverse events (AEs) or serious AE were collected during and within three months of stopping of the biologic therapy.

RESULTS

We identified a total of 147 elderly patients with IBD treated with biologicals during the study period, including 109 with Crohn's disease and 38 with ulcerative colitis. Patients received the following biologicals: IFX (28.5%), ADAL (38.7%), VDZ (15.6%), UST (17%). The mean duration of biologic treatment was 157.5 (SD = 148) wk. Parallel steroid therapy was given in 34% at baseline, 19% at 3 mo, 16.3% at 6-9 mo and 6.5% at 12-18 mo. The remission rates at 3, 6-9 and 12-18 mo were not significantly different among biological therapies. Kaplan-Meyer analysis did not show statistical difference for drug sustainability (P = 0.195), time to adverse event (P = 0.158) or infection rates (P = 0.973) between the four biologics studied. The most common AEs that led to drug discontinuation were loss of response, infusion/injection reaction and infection.

CONCLUSION

Current biologics were not different regarding drug sustainability, effectiveness, and safety in the elderly IBD population. Therefore, we are not able to suggest a preferred sequencing order among biologicals.

Key Words: Inflammatory bowel disease; Biologics; Elderly; Efficacy; Safety; Adverse events

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: Data on the efficacy and side effects of biologic therapies in the elderly inflammatory bowel disease (IBD) population is scant. Our single center study evaluates retrospectively the drug sustainability, effectiveness, and safety of approved biologic therapies in this sensitive population. The major finding of our study was that the drug sustainability and safety of the different biologicals were not significantly different in a large real-world, elderly IBD cohort treated in this single tertiary IBD center. As a consequence, we are still not able to suggest a preferred sequencing order among biologicals.

INTRODUCTION

Crohn's disease (CD) and ulcerative colitis (UC) are chronic immune-mediated diseases classified as inflammatory bowel diseases (IBD), which can result in progressive bowel damage and disability. Although more common in young adults, the prevalence and the incidence of IBD are increasing in the elderly[1]. Approximately 10%-15% of new IBD diagnoses occur in individuals over 60 years (elderly-onset IBD), while the majority of older patients with IBD are classified as adult-onset IBD, meaning they were diagnosed with IBD between 18-59 years old[2-4]. There has been a revolution in the medical therapy of IBD with the advent of biological agents in the past two decades leading to improved clinical outcomes. Biological therapies were also associated with adverse events (AEs), including infusion/injection reactions, infections, and malignancies. Elderly IBD patients are in many ways a difficult-to-treat patient population, and may be even more vulnerable to AEs due to advanced age, comorbidities and polypharmacy[5].

The proportion of elderly IBD patients in randomized clinical trials (RCTs) is usually small, therefore there is lack of data concerning effectiveness and safety profiles of biologic therapies in this population. This relative paucity of data together with the higher frequency of comorbidities, polypharmacy, and the perceived toxicity of IBD drug therapies in the elderly patients may likely explain the underuse of biological agents and the reported higher rates of steroid use. As reported by studies from France, Sweden and Hong Kong, only 1%-3% of elderly IBD patients received biologic therapy within five to ten

years of follow-up[6-8].

The expected rate of AE and medication interactions may significantly influence the choice of therapy in the elderly IBD population. In a study from Leuven, advanced age was associated with higher rates of serious AEs (SAEs) on anti-tumor necrosis factor (TNF) therapy, such as infections and malignancy[9]. In contrast, recent data from pooled analyses of RCTs suggest that the advanced age, and not anti-TNF exposure, was associated with increased rates of SAE and hospitalizations[10].

Furthermore, landmark trials evaluating the more recently approved biologic agents, such as vedolizumab (VDZ) or ustekinumab (UST), suggested a more beneficial overall safety profile[11,12]. However, the existing literature is limited regarding effectiveness and safety of these agents in the elderly population. A *post hoc* analysis of the GEMINI trials reported that in IBD patients above 55 years old the efficacy and safety of VDZ was similar to younger IBD patients, while the safety profile was not different from placebo[13]. Relatively few data are available in elderly IBD patients on the efficacy or safety on anti-TNFs and on the new biologicals. One of the first studies in elderly patients was Busquets *et al*[14] which performed a systematic review on efficacy and safety of anti-TNFs in the elderly, however mainly in patients with rheumatic diseases. It concluded that elderly patients on anti-TNF therapy have higher number of AEs, and similar efficacy, when compared with younger patients. The aim of our study was to measure the rates of biologic therapy sustainability in elderly IBD patients, as well as to report their effectiveness and safety profile.

MATERIALS AND METHODS

Study design

Consecutive elderly patients (aged 60 years or over) previously or currently treated with a biologic agent and followed at the McGill University Health Centre Inflammatory Bowel Diseases Center between January 2000 and January 2020 were included retrospectively. The efficacy of treatment with a biologic agent was assessed by clinical score, biochemical and endoscopy. Clinical response and remission using the Harvey-Bradshaw Index (HBI) and Mayo score were measured at baseline, 3 mo, 6-9 mo, and 12-18 mo of follow up. Patients included were patients with IBD, with an age of 60 years or older, whose current or prior treatment included biological agents (anti-TNF, VDZ or UST). Patients with contra-indications to biologic therapy, or patients with less than 3 mo follow-up were excluded. For patients with multiple biological exposure, data for the last biological therapy was collected.

Local electronic medical charts were used to identify elderly IBD patients on infliximab (IFX), adalimumab (ADAL), VDZ or UST. We collected demographic data (age, gender), comorbidities, age at diagnosis, disease duration, disease extent and phenotype (Montreal classification)[15], prior gastrointestinal surgeries, C-reactive protein, fecal calprotectin, radiological or endoscopic reports and clinical symptoms of IBD activity. Additional therapeutic variables measured were treatment duration and dosage, prior or concomitant immunosuppression, parallel steroid therapy. Comorbidity was measured by the Charlson Comorbidity Index (CCI), where a CCI of 0 represents absence of comorbidity[16]. AE, SAE, hospitalizations [duration and reasons (medical, surgical, unrelated) for hospitalization] and mortality were collected. SAE was grouped into four distinct categories: Infection (infection reported during the course of biologic therapy not requiring hospitalization), severe infection (any infection reported during the course of biologic therapy that needed hospitalization), malignancy, IBD-related surgeries (excluding elective surgical management of perianal lesions). If a treatment-related complication did not fit the previously-mentioned criteria for a SAE, then it was considered an AE, including acute infusion reactions (within one hour of dose administration), hypersensitivity reactions, non-allergic skin rash, mild infections and other AE. Patient-related data were collected through the MUHC electronic medical record (Oacis Clinical Information System).

Outcomes

The primary outcome was the drug sustainability and comparative time-dependent safety analysis in elderly patients with IBD (aged 60 years or over) on different biologic therapy. Secondary outcomes included the comparison of rates of clinical, biochemical, and endoscopic remission in elderly IBD patients according to the biologic therapy used. Clinical response was defined as a decrease in the HBI by 3 points or more from baseline for CD or a similar decrease in the partial Mayo Score (pMayo) by 3 or more for UC, while clinical remission was defined as an overall HBI of less than 5 for CD or an overall pMayo of less than 2 for UC[17].

AE or SAE occurring within three months of the last biologic dose were considered to be related to the biologic agent. SAEs were defined as potentially life-threatening or leading to death, hospitalization, or prolongation of hospitalization, or causing significant disruption in normal life functions. Infections and malignancy were separately captured. Reasons for discontinuation of the biologic agent were also evaluated.

Statistical analysis

Statistical analysis was performed using Statistical Package for the Social Sciences (SPSS 20.0; SPSS INC., Chicago, Illinois). Descriptive statistics were used to summarize patient and treatment-related characteristics along with means ± SD, and common themes highlighted using qualitative data analysis. Chi-square test or Fisher exact test was used to compare categorical variables while the Student's unpaired *t*-test was used to compare continuous variables. Kaplan Meier curves were plotted with COX regression analysis to assess differences in drug sustainability, infections or AE stratified by the different biological agents. A $P < 0.05$ was defined as statistically significant.

Ethical considerations

This study was reviewed and approved by the McGill University Health Centre Research Ethics Board under the ethical approval number: 2019-5209. The research protocol conforms to ethical guidelines of the 1975 Declaration of Helsinki (6th revision, 2008) and local regulations. Informed consent was obtained from each patient included in the study.

RESULTS

Demographic and baseline factors

A total of 147 elderly patients with IBD were identified, including 109 patients with CD and 38 patients with UC. The majority of patients (75.5%) were diagnosed before the age of 60, thus adult-onset, elderly IBD patients. Disease location was predominantly ileocolonic (47.7%) in patients with CD and pancolitis for patients with UC (63.2%). Among patients with CD, 21.1% suffered from perianal disease. The CCI was at least 1 in 95.2% of elderly IBD patients, at least 3 in 47.6% and above 4 in 12.9%. Approximately 45.6% (67 patients) of all included patients underwent at least one surgical resection related to IBD. 70 elderly IBD patients (47.6%) had previous exposure to other biologics. Over the study period, 35.4% of patients had received a course of systemic steroids at least once, while 17% were treated with concomitant immunomodulatory therapy. The mean duration of biological therapy was 157.5 (SD = 148) wk. Extraintestinal manifestations had been diagnosed in 10.9% of elderly IBD patients. Table 1 summarizes disease characteristics and history of IBD-related therapy.

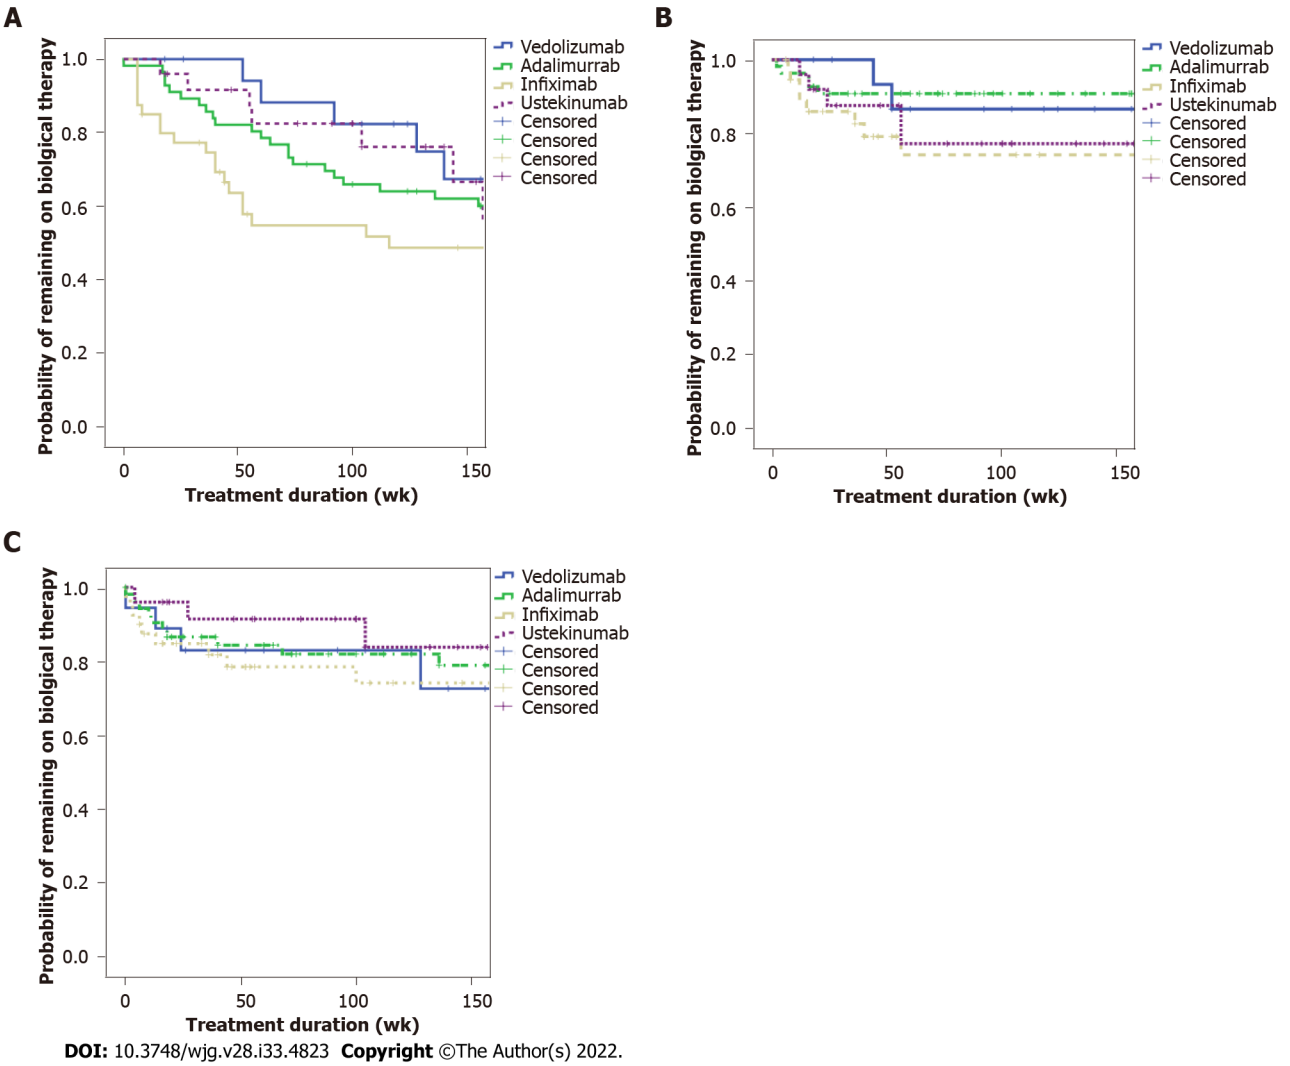
Drug sustainability, time to AE or infection

Figure 1A (see appendix section) shows the time to treatment discontinuation stratified by the biological agent by Kaplan-Meier and Cox regression analysis. No significant difference was found among the four biologicals ($P = 0.195$) (Figure 1A). According to Figure 1B, the time to AE was not significantly different in a Kaplan-Meier and Cox regression analysis among the four biologics ($P = 0.158$). Figure 1C shows the time to infections stratified by the biological agent. There was no statistical difference among the biologicals among the respective time to infection curves ($P = 0.973$). SAE was observed in only one patient (0.6%), who presented fever of unknown origin, needing hospitalization.

Efficacy

Figure 2A (see appendix section) shows the rates of clinical response and remission in elderly IBD patients treated with different biologicals according to HBI or Mayo scores at 3 mo. When assessing the clinical response in patients with CD, 71% of the patients on ADAL, 70% on UST, 65.2% on IFX and 60% on VDZ achieved clinical response at 3 mo. Regarding clinical remission in CD at 3 mo, 61.3% of patients on ADAL, followed by 54.2% on UST, 50% on VDZ and 47.8% on IFX achieved clinical remission. When looking at clinical response at 3 mo in patients with UC, 80% of the patients on ADAL, followed by VDZ with 44.4% and IFX with 40% responded. With regards to clinical remission at 3 mo, 40% patients on ADAL achieved clinical remission, 30% on IFX and 20% on VDZ.

The rates of clinical remission in elderly IBD patients treated with different biologicals according to HBI or Mayo scores at 6-9 mo are show in Figure 2B (see appendix section). Regarding clinical response in CD, 71.4% of patients on UST achieved clinical response at 6-9 mo, followed by 60.9 % on IFX, 58.3% on VDZ and 54.1% on ADAL. As for clinical remission in CD, 56.5% of patients on IFX, 50% on UST, 45.9% on ADAL and 41.7% on VDZ achieved clinical remission at 6-9 mo. When evaluating clinical response in UC, 55.6% of patients on IFX, followed by 45.5% on VDZ, 42.9% on ADAL reached clinical response at 6-9 mo. As for clinical remission in UC, 42.9% of patients on ADAL, 36.4% on VDZ and 33.3% on IFX achieved this outcome.



The rates of clinical remission in elderly IBD patients treated with different biologicals according to HBI or Mayo scores after 12-18 mo are presented in Figure 2C (see appendix section). Regarding clinical remission in patients with CD, 55.6% of patients on ADAL, followed by 40% on VDZ, 37.5% on IFX and 30% on UST achieved remission. As for clinical remission in patients with UC, approximately 62.5% of patients on IFX, followed by 50% on ADAL and 45.5% on VDZ achieved remission. Clinical response and remission rates were not significantly different across biologicals in either CD or UC at any time points (P = ns for each assessment), as shown in Figure 2 (see appendix section). Given the retrospective

nature of the study and the lack of standardization of the collected measurements for endoscopic and biomarkers, the statistical analysis was inconclusive, therefore the data is not presented.

DISCUSSION

The major finding of our study was that the drug sustainability and safety of the different biologicals were not significantly different in a large real-world, elderly IBD cohort treated in this single tertiary IBD center. Peyrin-Biroulet *et al*[18] evaluated the efficacy and safety profile of anti-TNF in IBD patients, showing no difference in the frequency of mortality, malignancies and serious infections between anti-TNF and control group. Similarly, Lichtenstein *et al*[19] reported that the occurrence of death was similar between patients treated with anti-TNF and those who received other treatments only; however, an increased risk of infections was seen in patients treated with IFX. Borren and Ananthakrishnan[20] reported that older age was associated with an increased risk of malignancy compared to younger age. Elderly patients on biologics had a 3-fold increase in risk of infection compared to those who were not using biologics, yet there were no significant differences in odds of malignancy or mortality compared to older patients that were not using biologics.

Figure 2 Clinical response and remission rates in elderly inflammatory bowel disease patients treated with different biologicals according to Harvey-Bradshaw Index or Mayo scores. A: At 3 mo; B: At 6-9 mo; C: After 12-18 mo. CD: Crohn's disease; UC: Ulcerative colitis; IBD: Inflammatory bowel disease.

Regarding efficacy and safety profile of biological therapy in the elderly patients, Asscher *et al*[21]. assessed the safety and effectiveness of anti-TNF therapy in IBD patients over 60 years. Elderly patients on anti-TNF therapy have an increased risk of serious infections compared with elderly IBD patients who are not on anti-TNF therapy, not compared to younger patients who receive anti-TNF, though. However, comorbidity has been shown to be an indicator of SAE in patients exposed to anti-TNF. Effectiveness was similar between elderly and younger patients. Lobatón *et al*[9] also evaluated efficacy and safety of anti-TNF therapy in an elderly IBD population and showed a worse short-term clinical response to anti-TNFs at 10 wk after anti-TNF initiation, meaning that the probability of drug discontinuation during the follow-up (whatever the reason) was higher; but when excluding primary non response, this proportion became similar between the two groups. No differences were found in long-term efficacy among the initial responders (79.5% *vs* 82.8%; $P = 0.64$). As for safety, a higher risk of SAE was found in elderly IBD patients treated with anti-TNFs (risk ratio = 4.7; $P < 0.001$) compared to the

younger subgroup[9]. Along with that, our study also reported statistically similar rates of 3 mo clinical response and 6-12 mo clinical response and remission among the four types of biologics studied (ADAL, IFX, VDZ and UST). Regarding safety, time to AE and to infection were also not statistically different.

The efficacy and safety of the anti-TNFs are extensively studied, less real world or comparative data are available for the new biologicals. In the landmark clinical trials, they appeared to be a safer option compared to the anti-TNFs, although in indirect comparisons. Recently, comparative efficacy and safety data became available in IBD patients. The SEAVUE study compared UST with ADAL for induction and maintenance of biological-naïve patients with moderate to severe CD. With regards to safety, 34.0% of UST-treated and 40.5% of the ADAL-treated patients had infections, 2.6% and 7.2% had SAEs, and 6.3% and 11.3% had AEs leading to therapy discontinuation in non-elderly IBD patients[22]. VARSITY trial compared VDZ with ADAL in patients with moderately to severely active UC, mainly patients without previous exposure to biologics. Numerical differences were observed in the reported AEs. Of note, the exposure-adjusted incidence rate of infection was 23.4 per 100 patients-year in the VDZ group and 34.6 per 100 patients-year in the ADAL group[23].

As for the elderly IBD population on new biologicals, there is still a paucity of data concerning efficacy and safety from real world studies. Cohen *et al*[24] evaluated the efficacy and safety of VDZ in elderly IBD patients compared to non-elderly patients. Equal effectiveness in both groups was reported; however, there was a higher risk of infections among the elderly on VDZ, which could be related to age and due to underlying diseases[24]. Garg *et al*[25] evaluated the safety and efficacy of UST in elderly CD patients. Efficacy and safety were similar in this relatively small cohort in elderly and non-elderly IBD patients; elderly patients were less likely severe, though, and both groups had 95% previous exposure to biologics. Furthermore, the mucosal healing rates observed in the elderly cohort were in check with other real-world studies performed in non-elderly IBD patients. As for safety, UST use in elderly IBD was not associated with higher rates of infusion reaction, infections, or postoperative complications as compared to the non-elderly patients[25]. In line with these studies, ours showed no significant difference in time to AEs and infection among elderly IBD patients treated with anti-TNF, VDZ and UST.

The strength of our study is that represents a single center cohort with harmonized treatment and follow-up strategies across IBD specialists. In addition, a complex analysis of effectiveness and safety was performed in a relatively large elderly IBD cohort. However, the present study has limitations. First, there was a relatively low number of elderly patients on new biological therapies. Second, it consists of a retrospective cohort with intrinsic problems of accuracy and potential biases such as recall bias and reporting bias, specially of AEs and mild infections, which patients may not have announced or may not have been documented. Third, follow-up on biomarkers, fecal calprotectin and endoscopy were not uniform for timing. Fourth and last, rates of previous exposure to biologicals were different for new biologics *vs* anti-TNFs.

CONCLUSION

Current biologic therapies were not different concerning drug sustainability, effectiveness, and safety in the elderly IBD population. Based on these results, a preferred sequencing order among biologicals for this specific population is not possible to be suggested thus, larger studies in elderly IBD population are warranted.

ARTICLE HIGHLIGHTS

Research background

Biologic therapy resulted in a significant positive impact on the treatment of inflammatory bowel disease (IBD) however data on the efficacy and side effects of these therapies in the elderly is scant.

Research motivation

To further evaluate and develop more studies regarding treatment efficacy and safety of biological therapies in a specific and sensitive population, such as the elderly IBD patients, since there is not much evidence about it on medical literature so far.

Research objectives

Retrospectively evaluate the drug sustainability, effectiveness, and safety of the biologic therapies in the elderly IBD population.

Research methods

Consecutive elderly (≥ 60 years old) IBD patients, treated with biologics [infliximab (IFX), adalimumab

(ADAL), vedolizumab (VDZ), ustekinumab (UST)] followed at the McGill University Inflammatory Bowel Diseases Center were included between January 2000 and 2020. Efficacy was measured by clinical scores at 3, 6-9 and 12-18 mo after initiation of the biologic therapy. Patients completing induction therapy were included. Adverse events (AEs) or serious AEs were collected during and within three months of stopping of the biologic therapy.

Research results

A total of 147 elderly patients with IBD were identified and treated with biologicals during the study period, including 109 with Crohn's disease and 38 with ulcerative colitis. Patients received the following biologicals: IFX (28.5%), ADAL (38.7%), VDZ (15.6%), UST (17%). The mean duration of biological therapy was 157.5 (SD = 148) wk. Parallel steroid therapy was given in 34% at baseline, 19% at 3 mo, 16.3% at 6-9 mo and 6.5% at 12-18 mo. The remission rates at 3, 6-9 and 12-18 mo were not significantly different among biological therapies. Kaplan-Meyer analysis did not show statistical difference for drug sustainability ($P = 0.195$), time to adverse event ($P = 0.158$) or infection rates ($P = 0.973$) between the four studied biologicals. The most common AEs that led to drug discontinuation were loss of response, infusion/injection reaction and infection.

Research conclusions

Current biologics were not different regarding drug sustainability, effectiveness, and safety in the elderly IBD population. Therefore, it is not possible to suggest a preferred sequencing order among biologics.

Research perspectives

The authors expect that this article may help other IBD physicians and gastroenterologists in their decision process for treating elderly IBD patients with biological therapy.

Abstract

BACKGROUND

Patients with inflammatory bowel disease (IBD) are prone to several nutritional deficiencies. However, data are lacking on vitamin C deficiency in Crohn's disease (CD) and ulcerative colitis (UC) patients, as well as the impact of clinical, biomarker and endoscopic disease severity on the development of vitamin C deficiency.

AIM

To determine proportions and factors associated with vitamin C deficiency in CD and UC patients.

METHODS

In this retrospective study, we obtained clinical, laboratory and endoscopic data from CD and UC patients presenting to the IBD clinic at a single tertiary care center from 2014 to 2019. All patients had an available plasma vitamin C level. Of 353 subjects who met initial search criteria using a cohort discovery tool, 301 ultimately met criteria for inclusion in the study. The primary aim described vitamin C deficiency (≤ 11.4 μmol/L) rates in IBD. Secondary analyses compared proportions with deficiency between active and inactive IBD. Multivariate logistic regression analysis evaluated factors associated with deficiency.

RESULTS

Of 301 IBD patients, 21.6% had deficiency, including 24.4% of CD patients and 16.0% of UC patients. Patients with elevated C-reactive protein (CRP) (39.1% *vs* 16.9%, $P < 0.001$) and fecal calprotectin (50.0% *vs* 20.0%, $P = 0.009$) had signifi-

cantly higher proportions of deficiency compared to those without. Penetrating disease (P = 0.03), obesity (P = 0.02) and current biologic use (P = 0.006) were also associated with deficiency on univariate analysis. On multivariate analysis, the objective inflammatory marker utilized for analysis (elevated CRP) was the only factor associated with deficiency (odds ratio = 3.1, 95% confidence interval: 1.5-6.6, P = 0.003). There was no difference in the presence of clinical symptoms of scurvy in those with vitamin C deficiency and those without.

CONCLUSION

Vitamin C deficiency was common in IBD. Patients with elevated inflammatory markers and penetrating disease had higher rates of vitamin C deficiency.

Key Words: Inflammatory bowel disease; Crohn's disease; Ulcerative colitis; Vitamin C deficiency; Scurvy; Malnutrition

Core Tip: This study aimed to determine proportions and factors associated with vitamin C deficiency in inflammatory bowel disease (IBD) patients. In 301 patients, 21.6% had vitamin C deficiency, including 24.4% of Crohn's disease and 16.0% of ulcerative colitis patients. Patients with elevated C-reactive protein (39.1% *vs* 16.9%) and fecal calprotectin (50.0% *vs* 20.0%) had higher proportions of deficiency compared to those without, as did patients with penetrating disease (36.2% *vs* 20.8%). This study provides the largest data on vitamin C deficiency in IBD, and demonstrates that deficiency is common in this population, particularly those with markers of active luminal or penetrating disease.

INTRODUCTION

Inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), are chronic inflammatory disorders of the gastrointestinal tract that affect over 1.5 million people in the United States alone[1,2]. Several nutritional deficiencies are well described in patients with IBD, the most common being iron, vitamin B12, vitamin D, zinc, and calcium[3-7]. However, far less literature exists on vitamin C (ascorbic acid) deficiency in this population. While the prevalence of scurvy - the clinical manifestations of vitamin C deficiency - has largely declined in the 21st century, up to 7% of the United States population still possesses vitamin C deficiency. The risk of deficiency is particularly increased in smokers, obese patients, and patients from low-income backgrounds[8]. Among those also at risk are patients with poor vitamin C intake and malabsorptive processes.

Traditionally, in IBD patients, vitamin C deficiency is thought to originate from insufficient consumption, malabsorption, and altered metabolism of vitamin C. Although not routinely recommended, many IBD patients adhere to low-residue diets to decrease gut motility and bacterial fermentation of fiber. Unfortunately, several regimens exclude fresh fruit and vegetables, the main dietary sources of vitamin C[9]. Inadequate consumption is often compounded by malabsorption of vitamin C in these patients. Ascorbate is primarily absorbed in the jejunum and ileum, which are often affected in CD[10]. In addition, patients with IBD have been shown to have polymorphisms in genes encoding vitamin C transporters necessary for vitamin C uptake[11,12]. Lastly, tumor necrosis factor-alpha (TNF-α), a proinflammatory cytokine often elevated in IBD, also downregulates transcription of transporters necessary for vitamin C uptake[13,14].

Vitamin C deficiency can lead to impaired uptake and utilization of iron, poor wound healing, and bleeding[15,16]. The diagnosis of vitamin C deficiency can be all the more challenging to make in patients with IBD, as many nonspecific symptoms of scurvy - fatigue, arthralgias, and cutaneous manifestations - can confound systemic symptoms of CD and UC. Prior studies of patients with IBD have described inadequate vitamin C intake and suboptimal serum vitamin C levels in 22%-70% and 15%-84%, respectively[9,17-20]. Notably, these studies have been small, excluded patients with UC, and occurred prior to the advent of biologic medications. Importantly, cohorts lacked data on clinical, biomarker and endoscopic measures of disease activity to assess for their impact on vitamin C deficiency.

IBD patients are at risk for malnutrition and vitamin C deficiency is an easily reversible condition. Thus, it is essential to understand the prevalence of and factors associated with vitamin C deficiency in this population to better identify those at risk. For this reason, this study aimed to determine rates of vitamin C deficiency in patients with CD and UC and investigate potential factors associated with the development of vitamin C deficiency in this population.

MATERIALS AND METHODS

Patient population

Data were extracted from chart review of patients presenting to the IBD clinic at a single tertiary institution from 2014 to 2019. Patients were identified using a cohort discovery tool (Informatics for Integrating Biology and the Bedside, National Center for Biomedical Computing, Partners HealthCare System, Boston, Massachusetts) at Weill Cornell Medicine, New York. Search criteria included age 18 years and older, diagnosis of CD or UC, and a plasma vitamin C measurement drawn from 2014 to 2019. International Classification of Diseases 10th edition codes were used to identify patients with CD (K50.x) and UC (K51.x). Exclusion criteria included lack of a CD or UC diagnosis, plasma vitamin C level, or IBD-related visit at the time that plasma vitamin C measurement was performed. Three hundred fifty-three subjects matched initial search criteria. In patients with multiple plasma vitamin C levels, the lowest value and associated visit were utilized. This study was conducted retrospectively from data obtained for clinical purposes. The study was approved by the institutional review board at Weill Cornell Medicine, who confirmed that no ethical approval was required.

Data extraction

We extracted covariates readily available in the electronic medical record. Baseline characteristics were collected, including age, sex, race, body mass index (BMI), smoking history, type of IBD (CD or UC), disease duration and prior IBD-related surgeries (*i.e.*, total proctocolectomy, ileocolonic resection, small bowel resection, *etc.*). Endoscopic scores - within six months of plasma vitamin C level assessment - were collected when available. Disease location and behavior were defined by the Montreal classification for IBD[21]. Patients were evaluated for current and prior IBD medications, including biologic agents such as TNF-α inhibitors (infliximab, adalimumab, golimumab, and certolizumab pegol), vedolizumab, and ustekinumab. Additional laboratory values collected within one week of plasma vitamin C levels were included in the analysis. When available, C-reactive protein (CRP), iron, transferrin saturation, ferritin, vitamin B12, vitamin D, 25-hydroxy, and fecal calprotectin were obtained. Iron deficiency was defined as ferritin < 30 ng/mL and transferrin saturation < 16% in those with quiescent disease and ferritin < 100 ng/mL and transferrin saturation < 16% in those with active disease[22]. Vitamin B12 deficiency was defined as serum vitamin B12 level < 200 pg/mL or < 148 pmol/L[7]. Vitamin D deficiency or insufficiency was defined as serum vitamin D, 25-hydroxy level ≤ 20 ng/mL [23]. From the electronic medical record, we also extracted data on symptoms typically associated with vitamin C deficiency (*i.e.*, scurvy) at the IBD visit when plasma vitamin C level was obtained. These included fatigue, arthritis/arthralgias, skin findings (rash, hyperpigmentation, *etc.*), easy bruising, gingivitis, poor wound healing, perifollicular findings (hemorrhage, folliculitis) and alopecia.

Outcomes and definitions

The primary study outcome was the prevalence of vitamin C deficiency in IBD patients. Vitamin C deficiency was defined as plasma vitamin C level < 11.4 μmol/L[24,25]. Inadequate vitamin C level or marginal deficiency was defined as 11.4-28.0 μmol/L, consistent with prior studies[24,25]. Secondary analyses were performed to assess whether clinical, biomarker or endoscopic disease activity were associated with deficiency. Patients were assessed for clinical disease activity using the Harvey-Bradshaw Index for CD[26] and modified partial Mayo score for UC[27]. Clinically active disease was defined as Harvey-Bradshaw Index > 5 for CD. For UC, clinically active disease was defined as either stool frequency or rectal bleeding > 1 on the modified partial Mayo score. Elevated CRP was defined as > 0.9 mg/dL and elevated fecal calprotectin was defined as > 250 μg/g. Endoscopically severe disease was defined as simple endoscopic score CD > 15 for CD and Mayo endoscopic score ≥ 2 for UC[28-30]. Additional outcomes based on biologic plausibility included the association of vitamin C deficiency with IBD type (CD or UC), obesity (BMI ≥ 30), use of biologic medications, disease location in the small intestine, penetrating disease, IBD-related surgery, elevated CRP, elevated fecal calprotectin, iron deficiency, clinically active disease and endoscopically severe disease.

Statistical analysis

The primary outcome described the prevalence of vitamin C deficiency in patients with IBD. To address this outcome, based on previous data in 137 CD patients showing a 15% prevalence of vitamin C deficiency[17], in our exploratory cohort of 301 patients, we expected that a two-sided 95% confidence interval (CI) for the prevalence could be constructed to be within ± 4.0% of the observed prevalence

proportion. Statistical review was performed by the corresponding author, who has extensive experience performing statistical analyses for clinical research.

For secondary outcomes, variables (listed above) were selected based on biologic plausibility for abnormal vitamin C absorption. To address these secondary outcomes, we performed chi-squared tests or Fisher's exact tests as appropriate to compare the proportions of vitamin C deficiency between groups. A multivariate logistic regression was performed on covariates selected based on biologic plausibility. These included presence of small bowel disease, penetrating disease, history of IBD-related surgery, obesity, current biologic medication use, elevated CRP, and clinically active disease. Variables with $P \leq 0.2$ were selected for inclusion in the final model. CRP was selected as the sole objective inflammatory marker for sample size considerations (*i.e.*, fecal calprotectin and endoscopy data had limited sample size) and to avoid multicollinearity with these other inflammatory assessments. All analyses were performed using Stata Version 16.0 (StataCorp, College Station, TX). Continuous variables were expressed as means ± SD. The multivariate analysis was expressed as odds ratio (OR) with 95%CI.

RESULTS

Baseline demographics

A total of 301 CD or UC patients with available plasma vitamin C levels were included in the study. Baseline characteristics of the entire cohort are described in Table 1. The mean age of the cohort was 47.6 ± 17.4 years. One hundred ninety (63.1%) subjects were female, and 230 (76.4%) were Caucasian. A total of 201 (66.8%) patients had a diagnosis of CD and 100 (33.2%) had a diagnosis of UC. The mean duration of disease was 17.0 ± 13.6 years. A total of 109 (36.2%) patients had a history of IBD-related surgery and 133 patients (44.2%) were undergoing treatment with a biologic agent at the time of plasma vitamin C level collection. Six patients (2.0%) were active smokers and 42/291 (14.4%) had a BMI ≥ 30. Fifty-nine of 252 patients (23.4%) had iron deficiency, 1/264 (0.4%) had vitamin B12 deficiency, and 38/259 (14.7%) had vitamin D deficiency or insufficiency. Of 292 patients with available disease activity scores, 134 (45.9%) had clinically active disease. Of 113 patients with available endoscopies, 20 (17.7%) had endoscopically severe disease.

Proportion of IBD patients with vitamin C deficiency

The mean vitamin C level was 35.7 ± 27.8 μmol/L in the entire IBD cohort. For analysis of the primary outcome, 21.6% of IBD patients (65/301) had vitamin C deficiency (< 11.4 μmol/L). An additional 24.6% of IBD patients (74/301) had inadequate vitamin C levels (11.4-28.0 μmol/L). CD patients had numerically higher prevalence of vitamin C deficiency than those with UC, although this result did not reach statistical significance (24.4% *vs* 16.0%, $P = 0.1$, Figure 1).

Secondary outcomes: Factors associated with vitamin C deficiency in all IBD patients

In all IBD patients, those with elevated CRP had higher proportions of vitamin C deficiency (39.1% *vs* 16.9%, $P < 0.001$, Table 2) compared to those without elevated CRP. Similarly, patients with elevated fecal calprotectin had higher rates of vitamin C deficiency (50.0% *vs* 20.0%, $P = 0.009$) compared to those without fecal calprotectin elevation. In a subgroup with available endoscopic data, those with severe inflammation ($n = 20$) had numerically higher deficiency rates compared to those without severe inflammation (35.0% *vs* 22.6% $P = 0.2$). However, comparable rates of deficiency existed between those with and without clinically active disease (26.1% *vs* 18.4%, $P = 0.1$). Obesity (35.7% *vs* 19.7%, $P = 0.02$) and current biologic medication use (28.6% *vs* 15.6%, $P = 0.006$) were associated with increased rates of vitamin C deficiency on univariate analysis. Among patients on current biologic therapy ($n = 133$), there were higher proportions of vitamin C deficiency in those using TNF-α inhibitors (17/48) compared with those using non-TNF-α (16/85) biologics (35.4% *vs* 18.8%, $P = 0.03$). Iron deficiency (28.8% *vs* 20.2%, $P = 0.2$), vitamin D deficiency/insufficiency (28.9% *vs* 21.3%, $P = 0.3$), surgery (25.7% *vs* 19.3%, $P = 0.2$), and active smoking (50.0% *vs* 21.0%, $P = 0.1$) were not associated with higher deficiency rates. On multivariate analysis, elevated CRP was the only factor significantly associated with vitamin C deficiency (OR = 3.1, 95%CI: 1.5-6.6, $P = 0.003$). Presence of small bowel disease, penetrating disease, history of IBD-related surgery, obesity, use of a biologic agent, and clinically active disease were not.

Secondary outcomes: Factors associated with vitamin C deficiency stratified by disease

Among CD patients, patients with penetrating disease had significantly higher rates of vitamin C deficiency compared to patients without penetrating disease (36.2% *vs* 20.8%, $P = 0.03$, Table 2). In CD patients, both elevated CRP (41.2% *vs* 17.9%, $P = 0.001$) and fecal calprotectin (56.3% *vs* 26.3%, $P = 0.04$) were persistently associated with higher proportions of vitamin C deficiency compared to those without elevated biomarkers. In subgroups of CD patients with endoscopic data available, those with endoscopically severe disease ($n = 12$) had numerically increased prevalence of vitamin C deficiency (41.7% *vs* 27.7%, $P = 0.3$). Similarly, CD patients with clinically active disease had numerically higher rates of deficiency (30.2% *vs* 20.2%, $P = 0.1$). CD patients with small bowel involvement did not have higher

Table 1 Baseline characteristics

	All IBD patients (*n* = 301)

[1]Patients with penetrating disease, obesity, biologic use, elevated C-reactive protein and elevated fecal calprotectin had increased frequency of vitamin C deficiency.

Clinically active disease was defined as Harvey-Bradshaw index > 5 for Crohn's disease (CD), and stool frequency or rectal bleeding > 1 on modified partial Mayo score for ulcerative colitis (UC). Endoscopically severe disease was defined as simple endoscopic score CD > 15 in CD and endoscopic Mayo score ≥ 2 in UC. IBD: Inflammatory bowel disease; CD: Crohn's disease; UC: Ulcerative colitis; BMI: Body mass index; CRP: C-reactive protein.

rates of vitamin C deficiency compared to those without small bowel involvement (23.0% *vs* 30.6%, P = 0.3).

In small subgroups of UC patients with available data, numerical differences persisted between those with elevated CRP (n = 13) and those with elevated fecal calprotectin (n = 4) when compared to those without elevated biomarkers (CRP: 30.8% *vs* 15.2%, P = 0.2; fecal calprotectin: 25.0% *vs* 9.1%, P = 0.4). In a small subset of UC patients with available endoscopic data, those with endoscopically severe disease (n = 8) had numerically increased frequency of vitamin C deficiency (25.0% *vs* 10.7%, P = 0.3). However, clinically active disease was not associated with higher rates of vitamin C deficiency when compared to those with quiescent disease (15.8% *vs* 15.3%, P = 0.9).

Figure 1 Prevalence of vitamin C deficiency in inflammatory bowel disease. In total, 21.6% of all inflammatory bowel disease patients had vitamin C deficiency, including 24.4% of Crohn's disease patients and 16.0% of ulcerative colitis patients. IBD: Inflammatory bowel disease; CD: Crohn's disease; UC: Ulcerative colitis.

Symptoms of vitamin C deficiency

When comparing patients with and without vitamin C deficiency, there was no difference in the presence of one or more clinical features of scurvy (66.2% *vs* 58.5%, $P = 0.3$, Table 3). Furthermore, both groups had similar rates of arthritis, cutaneous findings, easy bruising, gingivitis, perifollicular findings and alopecia. Patients with vitamin C deficiency were more likely to report fatigue than those with normal vitamin C levels (43.1% *vs* 27.5%, $P = 0.02$). Moreover, vitamin C deficient patients were more likely to report poor wound healing (4.6% *vs* 0.4%, $P = 0.03$).

DISCUSSION

Though many consider scurvy a historical disease of seafarers, the current study demonstrates that vitamin C deficiency affects a significant minority of IBD patients. In 301 patients, 21.6% of IBD patients had vitamin C deficiency, including 24.4% of CD patients and 16.0% of UC patients. This is approximately three-fold higher than the prevalence of vitamin C deficiency in the overall United States population[8].

Strikingly, in IBD patients with elevated objective markers of inflammation, such as CRP and fecal calprotectin, vitamin C deficiency rates ranged from 39%-50%. Similarly, CD patients with penetrating phenotype had higher deficiency rates. On multivariate analysis, the association between elevated CRP and vitamin C deficiency persisted. To our knowledge, this study uniquely examines the relationship between objectively quantified intestinal inflammation (using endoscopy, $n = 113$, or fecal calprotectin, $n = 80$) and vitamin C deficiency in a large cohort. Subgroup analysis in patients with available endoscopic data was concordant with biomarker data, with numerically higher rates of deficiency in those with significant intestinal inflammation. In UC, biomarkers and endoscopic data were more limited, with few patients in groups with elevated CRP, fecal calprotectin and endoscopic inflammation available. Absolute rates of deficiency were non-significantly lower in UC, but numerical differences between UC patients with and without inflammation were similar to these differences in CD. Notably, even in patients without objective evidence of inflammatory disease - based on CRP, calprotectin, and endoscopic score - rates of deficiency ranged from 17%-23%.

This study is the largest to date to report on the prevalence of vitamin C deficiency in IBD. Additionally, the current study significantly increases available data in both CD and UC by utilizing a well characterized cohort to provide analyses on factors associated with deficiency. Previous smaller studies have shown vitamin C deficiency rates of 15%-84% in CD patients[9,17-20]. The variability of decreased vitamin C levels in these studies largely stems from differences in sample sizes and reference ranges.

While previous studies report inadequate vitamin C intake in UC[31], to our knowledge, there are no prior studies describing proportions with vitamin C deficiency in UC. Vitamin C deficiency would be biologically plausible in CD as CD often affects the primary sites of vitamin C absorption in the small bowel. Interestingly, in UC patients (without small bowel disease), 16% had vitamin C deficiency. While dietary data was not available in this study, avoidance of vitamin C rich foods likely contributed to the development of vitamin C deficiency in patients with UC, as has been reported in previous studies[31]. Moreover, patients with UC often have elevated TNF-α, which has been shown to downregulate

Table 3 Clinical features of vitamin C deficiency

	Vitamin C deficiency (*n* = 65)	Normal vitamin C level (*n* = 236)	*P* value
Presence of ≥ 1 clinical feature(s) of scurvy	43 (66.2%)	138 (58.5%)	0.3
None	22 (33.8%)	98 (41.5%)	-
Fatigue	28 (43.1%)	65 (27.5%)	0.02[1]
Arthritis/arthralgias	27 (41.5%)	96 (40.7%)	0.9
Skin findings (rash, hyperpigmentation)	9 (13.8%)	29 (12.3%)	0.7
Easy bruising	6 (9.2%)	9 (3.8%)	0.1
Gingivitis	3 (4.6%)	6 (2.5%)	0.4
Poor wound healing	3 (4.6%)	1 (0.4%)	0.03[1]
Perifollicular findings (hemorrhage, folliculitis)	2 (3.1%)	1 (0.4%)	0.1
Alopecia	1 (1.5%)	5 (2.1%)	1.0

[1]Patients with vitamin C deficiency were more likely to report fatigue and poor wound healing.
There was no difference in presence of clinical features of scurvy between patients with vitamin C deficiency and those without.

transporters involved in vitamin C uptake[13,14].

The current study found penetrating disease to be associated with vitamin C deficiency. Previously, development of metabolic bone disease has been associated with a penetrating phenotype[32], although few studies have commented on the development of micronutrient deficiency in CD patients with penetrating disease. Penetrating disease often involves the small bowel and also likely reflects more active, refractory CD. Thus, patients with penetrating phenotypes may be at higher risk of both malabsorption - *via* inflamed tissue and enteric fistulas - and poor consumption - *via* dietary avoidance of foods rich in vitamin C that may exacerbate symptoms. These data are consistent with CRP and fecal calprotectin elevations also being associated with deficiency. Interestingly, presence of small bowel disease was not associated with increased risk of vitamin C deficiency in CD, despite the jejunum and ileum being the primary sites of vitamin C absorption. However, historical disease location may have been confounded by patients with inactive small bowel disease. Further studies on patients with active small intestinal disease would be required prior to concluding a lack of association between disease location and deficiency status.

While obesity and biologic medication use have biologic plausibility for deficiency and were associated on univariate analysis[8,13,14,33], the study results in aggregate more strongly support active IBD being associated with vitamin C deficiency. Only CRP was associated with vitamin C deficiency on multivariate analysis. However, it should be noted that in non-IBD populations[8], obesity has been shown to be associated with higher rates of vitamin C deficiency. Prior studies suggest that increased access to low-cost, high-calorie, micronutrient-poor food may explain the association between obesity and multiple vitamin deficiencies[33]. The association of current biologic medication use and vitamin C deficiency is less clear and may be due to this being a marker of a more severe disease course. In a subgroup analysis of patients using biologic therapy, patients on TNF-α inhibitors had higher rates of deficiency compared to those on non-TNF-α agents (*i.e.*, vedolizumab, ustekinumab, *etc.*), which runs counter to our understanding of TNF-α in vitamin C deficiency. TNF-α is known to downregulate transcription of transporters required for vitamin C uptake[13,14], and thus, one might expect that patients using TNF-α inhibitors would have lower, not higher proportions of deficiency. This further supports the use of anti-TNF agents or biologics as a surrogate for disease severity. Future studies may be warranted to better investigate this mechanism.

This study also highlights the difficulty in making a diagnosis of vitamin C deficiency in patients with IBD. In our cohort, there was no difference in the presence of clinical features of scurvy in patients with vitamin C deficiency compared to those with normal vitamin C levels. Many sequelae of vitamin C deficiency are nonspecific and can mimic or coexist with active IBD, including fatigue, arthralgias, oral lesions, bleeding, poor wound healing, anemia, and iron deficiency[15]. Unfortunately, more specific findings in scurvy, such as perifollicular hemorrhage and follicular hyperkeratosis, occur in only a small minority of vitamin C deficient patients, as our study reiterates. Given the challenge of diagnosing scurvy in this population, providers should have a low threshold to test for vitamin C deficiency and counsel on adequate vitamin C intake. Unlike the relapsing and often refractory nature of IBD in many patients, vitamin C supplementation can lead to rapid resolution of symptoms, including some incorrectly ascribed to IBD. Even in IBD patients with unmeasured vitamin C levels, empiric supplementation is not unreasonable, given vitamin C's role as an antioxidant, preventing free radical damage and reducing extracellular oxidants[24]. However, future studies demonstrating that vitamin C supple-

mentation can decrease inflammatory burden or improve clinical symptoms would be necessary prior to recommending empiric supplementation as standard of care for this population.

Study limitations include the use of retrospective chart review. This study did not find an association between clinical disease severity and vitamin C deficiency. However, clinical disease indices, particularly in CD, poorly correlate with mucosal disease[34]. Though this study examined the relationship between endoscopic activity and vitamin C deficiency, analyses on this relationship were limited by the small number of patients with significant endoscopic inflammation (n = 20). Yet, numerical differences based on endoscopic inflammation were consistent with CRP and fecal calprotectin data, suggesting that intestinal inflammation impacts vitamin C deficiency. Multivariate analyses utilized a single objective marker of inflammation to avoid multicollinearity. CRP was selected as few patients had elevated fecal calprotectin (n = 20) or significant endoscopic inflammation (n = 20), whereas 277 patients had CRP data available. Additionally, given the retrospective nature of our study, data are restricted to patients who had plasma vitamin C measurements available; these patients were not necessarily being screened for deficiency. Selection bias may exist as such laboratory values may have restricted the population to those more prone to have vitamin C deficiency. Nonetheless, nearly 40% of our study population had no symptoms of scurvy when their vitamin C level was obtained, indicating a sizable component of our cohort were simply being monitored for standard nutritional deficiencies. An additional limitation of this study was that measurements of all micronutrients were not performed. The retrospective nature of our study also limits our examination of whether inadequate consumption was associated with higher rates of deficiency, or whether fasting status at serum collection impacted vitamin C level, as dietary data was not available. The use of chart review to assess for symptoms of vitamin C deficiency is also a limitation that may have led to under-detection of symptoms related to deficiency. Some providers may not routinely screen for symptoms related to scurvy (*i.e.*, gingivitis, alopecia, *etc.*) and these items may not be reflected in providers' notes. Thus, reporting bias may exist. Despite this, vitamin C deficiency symptoms were infrequently documented. Lastly, this cohort was comprised of patients at an IBD center affiliated with a tertiary care center. Thus, the subjects in this study may have more severe disease, potentially impacting the generalizability of these data.

CONCLUSION

The current study demonstrates that vitamin C deficiency exists in a significant portion of patients with IBD, particularly those with objective markers of active luminal or penetrating disease. Clinical features of scurvy did not differ between patients with and without deficiency, reinforcing the challenge of diagnosing scurvy in this population, as symptoms of vitamin C deficiency and IBD may overlap. In summary, vitamin C deficiency exists in a considerable fraction of IBD patients. Thus, identifying and treating this easily reversible condition in these patients is essential.

ARTICLE HIGHLIGHTS

Research background

Patients with inflammatory bowel disease (IBD) are prone to several nutritional deficiencies, including iron, vitamin B12 and vitamin D. However, there is a lack of data on vitamin C deficiency in this population, as well as the impact of clinical, biomarker and endoscopic disease severity on the development of vitamin C deficiency.

Research motivation

As IBD patients are already at risk of malnutrition and as vitamin C deficiency is an easily reversible condition, it would be valuable to understand the prevalence of and factors associated with vitamin C deficiency in this population.

Research objectives

The primary objective assessed the prevalence of vitamin C deficiency in IBD patients. Secondary objectives evaluated proportions with deficiency between active and inactive IBD - using clinical, laboratory and endoscopic data - to better identify those at risk of deficiency.

Research methods

In this retrospective study, clinical, laboratory and endoscopic data were collected from all Crohn's disease (CD) and ulcerative colitis (UC) patients who had available plasma vitamin C levels presenting to the IBD clinic at a single tertiary care center from 2014 to 2019. Of 353 subjects who met initial search criteria using a cohort discovery tool, 301 ultimately met criteria for inclusion in the study. The primary aim described vitamin C deficiency (≤ 11.4 μmol/L) rates in IBD, with secondary analyses comparing

proportions with deficiency between active and inactive IBD. Multivariate logistic regression analysis evaluated factors associated with deficiency.

Research results

In 301 IBD patients, 21.6% had vitamin C deficiency, including 24.4% of CD and 16.0% of UC patients. Patients with elevated C-reactive protein (CRP) (39.1% *vs* 16.9%, $P < 0.001$) and fecal calprotectin (50.0% *vs* 20.0%, $P = 0.009$) had higher proportions of deficiency compared to those without. Other factors associated with vitamin C deficiency included the presence of penetrating disease ($P = 0.03$), obesity ($P = 0.02$) and current biologic medication use ($P = 0.006$). On multivariable analysis, the objective inflammatory marker utilized for analysis (CRP) was the only factor associated with deficiency (odds ratio = 3.1, 95% confidence interval: 1.5-6.6, $P = 0.003$).

Research conclusions

This study provides the largest data on vitamin C deficiency in patients with IBD, uniquely assesses factors associated with deficiency and provides rigorous assessment of inflammatory status using objective markers. Vitamin C deficiency was common in IBD, particularly those with objective markers of active luminal or penetrating disease. As vitamin C deficiency exists in over one-fifth of IBD patients, it is essential to identify and treat this easily reversible condition in this population.

Research perspectives

Future prospective studies with well characterized cohorts, and data on diet, other micronutrient deficiencies, endoscopic assessment, and vitamin C supplementation, may be warranted to further elucidate factors associated with vitamin C deficiency and the impact of supplementation on clinical course in IBD patients.

Abstract

BACKGROUND

The frequency of acute hypertriglyceridemic pancreatitis (AHTGP) is increasing worldwide. AHTGP may be associated with a more severe clinical course and greater mortality than pancreatitis caused by other causes. Early identification of patients with severe inclination is essential for clinical decision-making and improving prognosis. Therefore, we first developed and validated a risk prediction score for the severity of AHTGP in Chinese patients.

AIM

To develop and validate a risk prediction score for the severity of AHTGP in Chinese patients.

METHODS

We performed a retrospective study including 243 patients with AHTGP. Patients were randomly divided into a development cohort (n = 170) and a validation cohort (n = 73). Least absolute shrinkage and selection operator and logistic regression were used to screen 42 potential predictive variables to construct a risk score for the severity of AHTGP. We evaluated the performance of the nomogram and compared it with existing scoring systems. Last, we used the best cutoff value

(88.16) for severe acute pancreatitis (SAP) to determine the risk stratification classification.

RESULTS

Age, the reduction in apolipoprotein A1 and the presence of pleural effusion were independent risk factors for SAP and were used to construct the nomogram (risk prediction score referred to as AAP). The concordance index of the nomogram in the development and validation groups was 0.930 and 0.928, respectively. Calibration plots demonstrate excellent agreement between the predicted and actual probabilities in SAP patients. The area under the curve of the nomogram (0.929) was better than those of the Bedside Index of Severity in AP (BISAP), Ranson, Acute Physiology and Chronic Health Evaluation (APACHE II), modified computed tomography severity index (MCTSI), and early achievable severity index scores (0.852, 0.825, 0.807, 0.831 and 0.807, respectively). In comparison with these scores, the integrated discrimination improvement and decision curve analysis showed improved accuracy in predicting SAP and better net benefits for clinical decisions. Receiver operating characteristic curve analysis was used to determine risk stratification classification for AHTGP by dividing patients into high-risk and low-risk groups according to the best cutoff value (88.16). The high-risk group (> 88.16) was closely related to the appearance of local and systemic complications, Ranson score ≥ 3, BISAP score ≥ 3, MCTSI score ≥ 4, APACHE II score ≥ 8, C-reactive protein level ≥ 190, and length of hospital stay.

CONCLUSION

The nomogram could help identify AHTGP patients who are likely to develop SAP at an early stage, which is of great value in guiding clinical decisions.

Key Words: Nomogram; Severity; Acute pancreatitis; Prediction model

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: A risk prediction score (referred to as AAP), including age, the level of apolipoprotein A1 and the presence of pleural effusion, was first built to predict the severity of acute hypertriglyceridemic pancreatitis in Chinese patients. After calibration and verification, this score was shown to have high predictive accuracy and good performance. The risk score could help identify patients who are likely to develop severe acute pancreatitis at an early stage. In comparison with other scores, these scores showed improved accuracy in predicting and better net benefits for clinical decisions. AAP could be of great value in guiding clinical decisions as a convenient and specific tool.

INTRODUCTION

Hypertriglyceridemia (HTG) is the third most common cause of acute pancreatitis (AP)[1]. The frequency of acute hypertriglyceridemic pancreatitis (AHTGP) as a type of AP is increasing worldwide[2]. One multicenter study conducted in Beijing found that AHTGP was present in 10.36% of patients with AP[3,4]. Furthermore, some evidence suggests that AHTGP may be associated with a more severe clinical course and greater mortality than pancreatitis caused by other causes[1,5,6]. Patients with severe AP (SAP) characteristically have pancreatic necrosis or distant organ failure with a mortality rate of up to 40%[7]. Early identification of patients with severe inclination is essential for the delivery of specific interventions or intensive care support in a timely manner, as well as for improving prognosis. This indicates the importance of predicting the severity of AHTGP[8].

At present, four commonly used AP scoring systems are available for the early identification of SAP, including the Acute Physiology and Chronic Health Evaluation (APACHE II), Ranson score, the Bedside Index of Severity in AP (BISAP), and the modified computed tomography (CT) severity index (MCTSI). However, they have limitations[9]. APACHE II collects a large number of parameters, making it complicated and inconvenient to use and poor at predicting disease within 24 h of disease onset. The Ranson score consists of 11 indicators, which must be evaluated upon admission and 48 h following admission. Some of these indicators are not routinely collected during early stages of AP, so early

prediction is difficult[10]. BISAP uses five indicators to determine AP severity 24 h after admission. It is easy to use but has low sensitivity for predicting SAP[11]. The MCTSI has outstanding performance in predicting local complications. But it is poor in predicting severity[12]. The AP prediction accuracy could be improved by combining several scoring systems, but it was inconvenient. Without a new scoring system, it was difficult to increase the prediction accuracy[13].

Moreover, many studies have demonstrated that single laboratory indicators can be used to predict the severity of AHTGP, such as the neutrophil-lymphocyte ratio (NLR), white blood cell (WBC) count, red blood cell distribution width (RDW), serum calcium (Ca^{2+}) and C-reactive protein (CRP), which are easy to use in practice but lack high sensitivity or specificity[2,14]. It should be noted that serum triglyceride (TG) levels dose-dependently worsen the outcome of AP[6], but there is still controversy[5]. Recently, several new clinical prediction models have been developed to predict the severity of AP[15,16]. The early achievable severity index (EASY) prediction score as an artificial intelligence model was recently developed based on machine learning for the early and easy prediction of severity in AP[17]. However, almost all of them were developed for all etiologies of pancreatitis and not for HTG-induced pancreatitis separately.

In conclusion, AHTGP may be associated with a more severe clinical course and greater mortality. Early prediction and detection of patients who are likely to develop SAP is of great importance. The purpose of this study is to develop and validate a fast, simple, accurate, and reproducible risk score for predicting severe AHTGP at an early stage.

MATERIALS AND METHODS

Patient selection and data processing

The study involved a retrospective review of 243 patients diagnosed with AHTGP who were admitted to the Intensive Care Unit of a gastroenterology department of Xuanwu Hospital from November 2012 to January 2022. All patients were diagnosed with AHTGP for the first time, and the possibility of other pancreatic diseases (recurrent AP, chronic pancreatitis, or pancreatic cancer) and cases with missing data were excluded. The following data were recorded: Basic demographics, medical history, vital signs, laboratory tests and X-ray of the chest within 24 h. Pancreatic examinations under CT or magnetic resonance imaging within 72 h. All patients received routine management after admission. This study was approved by the Ethics Committee of the Xuanwu Hospital of Capital Medical University; written informed consent was waived considering the retrospective study design.

Diagnosis and scoring systems

The diagnostic criteria for AHTGP were elevated TG level (> 11.30 mmol/L, or 5.65-11.30 mmol/L with lactescent serum) and two or more of the following three symptoms: (1) Abdominal pain consistent with AP; (2) Levels of amylase and/or lipase at least three times above the upper limit of normal; and (3) Abdominal imaging consistent with changes in AP. According to the Atlanta classification revised in 2012, AP severity was divided into three groups based on organ failure status and local and/or systemic complications. The absence of organ failure and local or systemic complications was considered to indicate mild AP (MAP). The presence of transient (within 48 h) organ failure and/or local complications or exacerbation of comorbid disease was regarded as moderately severe AP (MSAP). The presence of persistent (> 48 h) organ failure was considered to indicate SAP. The respiratory, cardiovascular, and renal systems were assessed to identify organ failure, which was defined as a modified Marshall score > 2 for one of these three systems. Acute peripancreatic fluid collection, pancreatic pseudocyst, acute necrotic collection, walled-off necrosis, and infected pancreatic necrosis were defined as local complications[18].

As part of the validation process, five scoring systems were compared to our risk prediction score. Within 24 h of admission, laboratory tests and radiological examinations were conducted to determine APACHE II and BISAP scores. The Ranson score was derived from laboratory tests performed within 48 h of admission. The MCTSI score was determined from CT scans performed within 72 h of admission. The EASY prediction score as an artificial intelligence model was recently developed to predict the severity of AP. It consists of four parts (personal details, anamnestic data, admission data and blood test results) with a total of 23 predictors. We calculated the predicted severity scores for all subjects on a web application (http://easy-app.org/) in the Streamlit Python-based framework.

Potential predictive variables

We selected 42 potential predictive variables based on the literature and previous clinical experience, including demographic variables, medical history, clinical signs, laboratory findings, and imaging results. Demographic variables included continuous and categorical variables: Age, body mass index (BMI), smoking status, and drinking habits. Medical history included categorical variables: Diabetes, hypertension, hyperlipemia, and fatty liver. Clinical signs included continuous variables: Respiratory rate (RR), heart rate (HR), systolic blood pressure, and diastolic blood pressure. Laboratory findings performed within 24 h of admission included WBC, NLR[14], RDW[19], platelet counts (PLT), mean

platelet volume (MPV)[20], platelet distribution width (PDW)[21], total cholesterol (TC)[22], TG[6], high-density lipoprotein cholesterol level to low-density lipoprotein cholesterol level ratio (H/L ratio)[23], apolipoprotein A1 (ApoA1)[24], total bilirubin (TBIL), aspartate transaminase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), albumin (ALB)[25], blood urea nitrogen (BUN)[24], serum creatinine (Cr)[26], free triiodothyronine (fT3)[27], CRP, procalcitonin (PCT), serum sodium (Na), serum potassium (K), serum Ca^{2+}, prothrombin time (PT), activated partial thromboplastin time (APTT), thrombin time (TT), fibrinogen (FIB)[28], and D-dimer levels[29]. Imaging results included the presence of a pleural effusion according to the chest X-ray within 24 h of admission[30].

Outcomes

We defined the severity of AHTGP according to the revised Atlanta classification given the extensive acceptance of this guideline[18]. SAP was defined as persistent organ failure and was used as the clinical outcome measure.

Statistical analysis

Statistical comparisons between the non-SAP (MAP + MSAP) and SAP groups were performed with analysis of variance or the Mann–Whitney U test for continuous variables and the chi-square test or Fisher's exact test for categorical variables. There were 42 variables entered into the selection process, as described here. Least absolute shrinkage and selection operator (LASSO) regression was applied to minimize the potential collinearity of variables measured from the same patient and overfitting of variables. The most predictive covariates were selected by the minimum (λ min). Subsequently, variables identified by LASSO regression analysis and some other important clinical variables were entered into univariable and multivariable logistic regression analyses for further predictor selection. Clinical patient samples were randomly divided (3:1) into development and validation cohorts. We constructed a nomogram and validated the accuracy estimates by using 1000 bootstrap resamples to reduce overfitting. To quantify the discrimination performance of the nomogram for predicting SAP, the concordance index (C-index) was measured in the development set and validation cohort. By plotting the calibration curve, we analyzed the relationship between the observed incidence and predicted probability in the development set and the validation set. Integrated discrimination improvement (IDI) was established to evaluate the improvement of the risk prediction score with other existing scoring systems in the whole set. Decision curve analysis (DCA) was applied to quantify the clinical usefulness of the nomogram in the whole set. All statistical analyses were performed by R software (https://www.r-project.org/, The R Foundation) and Empower-Stats software (http://www.empowerstats.com, X&Y Solutions, Inc., Boston, MA, United States).

Risk group

To determine the risk stratification classification for AHTGP, the best cutoff value for SAP calculated through the ROC curve was used to divide patients into high-risk and low-risk groups. The differences in clinical manifestations and prognoses between the high- and low-risk groups were also compared to evaluate the efficacy of our risk score.

RESULTS

Clinical characteristics

A total of 243 records from patients diagnosed with AHTGP and discharged from the intensive care units (ICUs) during our study period were included for analysis. The baseline characteristics of the study population are summarized in Table 1. The average age of the entire cohort was 40.12 ± 10.12 years, and there were more males (n = 188, 77.37%) than females (n = 55, 22.63%). We divided our AP patients into two groups, non-SAP (MAP + MSAP) and SAP. The total rate of SAP was 25.51%. There was no significant difference in age, sex or BMI between the two groups. Furthermore, there was no significant difference in medical history between the two groups. In terms of vital signs, patients with SAP had a significantly higher heart rate (92.23 ± 16.29 *vs* 107.58 ± 18.65, $P < 0.001$) and respiratory rate (20.47 ± 4.38 *vs* 25.27 ± 6.21, $P < 0.001$) index than patients in the non-SAP group. Patients in the two groups showed no significant differences in laboratory findings, including PLT, MPV, H/L ratio, TBIL, ALT, ALP, fT3, Na, K, and TT. However, there were differences in WBC, NLR, RDW, PDW, TC, TG, ApoA1, AST, ALB, BUN, Cr, CRP, PCT, ESR, Ca^{2+}, PT, APTT, FIB, and D-dimer. For imaging results, pleural effusions were significantly more frequently observed among SAP patients (12.71% *vs* 74.19%, $P < 0.001$).

Predictor selection

Forty-two variables measured at the hospital within 24 h of admission were included in the LASSO regression. After LASSO regression selection (Figure 1), with a lambda of 0.028, 10 variables remained significant predictors of SAP, including age, HR, RR, ApoA1, WBC, Bun, Cr, Ca^{2+}, D-dimer, and the

presence of pleural effusion. According to a previous study, TG levels dose-dependently increase the severity of AP[6]. The presence of metabolic syndrome and its components associated with increasing AP severity were also important factors[31,32]. Therefore, we included TG level, BMI, history of hypertension and diabetes in the regression analysis. Based on the Endocrine Society Clinical Practice Guideline and previously published study, we divided TG levels into three groups as classified by variables (group 1: < 11.3 mmol/L; group 2: 11.3-22.59 mmol/L; group 3: ≥ 22.6 mmol/L) for clinical use [6].

Univariable and multivariable logistic regression

Inclusion of these 14 variables in a logistic regression model resulted in four variables that were independently statistically significant predictors of SAP (Table 2): Age (OR: 1.07; 95%CI: 1.01-1.14; P = 0.033), ApoA1 (OR: 0.02; 95%CI: 0.00-0.12; P < 0.0001), Ca^{2+} (OR: 0.11; 95%CI: 0.01-0.90; P = 0.040) and the presence of pleural effusion (OR: 15.61; 95%CI: 5.05-48.24; P < 0.0001).

Construction and validation of the nomogram

Clinical patient samples were randomly divided (3:1) into development and validation cohorts. Due to the small sample size, we used 1000 bootstrap resamples for development and validation to reduce over-the-fit bias. The multivariable analyses demonstrated that age, the reduction in ApoA1 and Ca^{2+}, and the presence of pleural effusion were independent risk factors for SAP. Considering that the level of

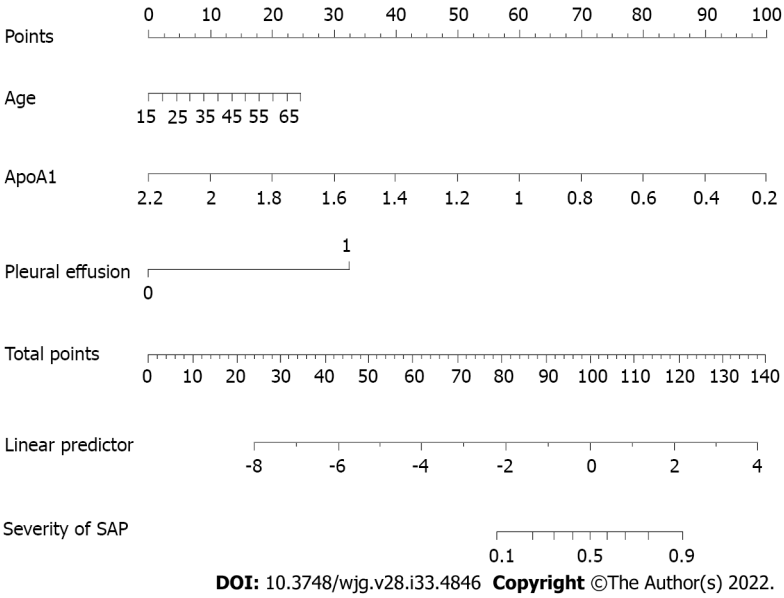
BMI: Body mass index; RR: Respiratory rate; HR: Heart rate; SBP: Systolic blood pressure; WBC: White blood cell; ApoA1: Apolipoprotein A1; BUN: Blood urea nitrogen; Cr: Creatinine; Ca: Calcium; SAP: Severe acute pancreatitis; OR: Odds ratio.

TG, BMI and history of hypertension and diabetes may also be important predictors, we constructed three predictive models based on different combinations of these factors. The logistic regression function was as follows: Model 1 (including age, ApoA1, and pleural effusion): Log (odds of SAP) = -0.15 (constant) + 0.06 × age - 5.49 × ApoA1 + 3.57 × (pleural effusion = 1); Model 2 (including age, ApoA1, Ca^{2+} and pleural effusion): Log (odds of SAP) = 4.86 (constant) + 0.06 × age - 5.32 × ApoA1 - 2.40 × Ca^{2+} + 3.31 × (pleural effusion = 1); Model 3 (including age, diabetes, hypertension, BMI, TG, ApoA1 and pleural effusion): Log (odds of SAP) = -7.30 (constant) + 0.09 × age + 0.15 × BMI - 0.35 × (hypertension = 1) - 1.09 × (diabetes = 1) - 6.72 × ApoA1 + 3.98 × (pleural effusion = 1) +3.39 × (TG = 1) + 3.23 × (TG = 2). ROC curve analysis was applied to evaluate the diagnostic performance of the three predictive models (Supplementary Figure 1). Model 1 had no significant differences in receiver operating characteristic curves (AUCs) and IDI between Model 2 and Model 3 (Supplementary Table 1). For clinical convenience and easy application, we selected Model 1 with the fewest factors as the final risk prediction score and constructed the nomogram (referred to as AAP) (Figure 2). The C-index for the development and validation cohorts after bootstrapping were 0.930 (95%CI: 0.893-0.967) and 0.928 (95%CI: 0.867-0.990), respectively (Figure 3A and B). This suggested a nomogram with good discrimination. The calibration curve of the nomogram is presented in Figure 3C and D. Calibration plots fall on a 45-degree diagonal line, which shows good agreement between the predicted and actual probabilities in SAP patients in the development and validation cohorts.



Clinical use

An ROC curve analysis was applied to evaluate the diagnostic efficacy of the new risk prediction score (referred to as AAP) and other clinical scoring systems, including the BISAP, Ranson, APACHE II, MCTSI and EASY. The AUC values of AAP, BISAP, RASON, APACHE II, MCTSI and EASY to predict SAP were 0.929 (95%CI: 0.889-0.958), 0.852 (95%CI: 0.801-0.894), 0.825 (95%CI: 0.771-0.871), 0.807

(95%CI: 0.752-0.855), 0.831 (95%CI: 0.778-0.876), and 0.807 (95%CI: 0.743-0.871), respectively (Figure 4). AAP achieved the highest AUC in predicting SAP among the scoring systems (Table 3). The improvement in the prediction of SAP was evaluated by calculating the IDI. IDIs were employed to compare the discriminative ability between the new model and the other clinical scoring systems. These results demonstrated that our nomogram has a greater potential for accurately predicting SAP than the other four clinical scoring systems (Table 4).

DCA was used to compare the clinical usability and benefits of the nomogram throughout the whole cohort. DCA plots showed that our nomogram had greater net benefits than other system scores for predicting the severity of AP patients, which demonstrated its utility in clinical decision-making (Figure 5).

Risk stratification based on the Nomogram for SAP

To determine the risk stratification classification for AP, the best cutoff value (88.16) for SAP calculated through the ROC curve was used to divide patients into high-risk and low-risk groups. We further analyzed the relationship between the AAP cutoff value (88.16) and clinical parameters. The high-risk group was closely related to local and system complications: Ranson ≥ 3, BISAP ≥ 3, MCTSI ≥ 4, APACHE-II ≥ 8, CRP ≥ 190, and the length of hospital stay (Table 5).

Table 3 Comparison of diagnostic performance for predicting severe acute pancreatitis between the AAP and other existing clinical scores

Variables	Δ AUC	95%CI	Z statistic	*P* value

DISCUSSION

AHTGP has grown in incidence and importance. According to the previously published literature, HTG is the third most common cause of AP[6]. Clinically, AHTGP is similar to other forms of AP, but it is associated with significantly higher complication rates, severity, and mortality[5,6]. Thus, recognizing risk factors for severe AHTGP in the early stages is very important for triaging patients appropriately to ICUs and providing specific treatments. In the present study, we developed a convenient and specific nomogram based on three predictors for predicting the severity of patients with AHTGP. The nomogram showed great calibration and discriminatory abilities in both the development and validation groups. In addition, our nomogram has shown improved prognostic reliability, accuracy and the best net benefit when compared to other clinical scoring systems, such as BISAP, Ranson, APACHE II, CTSI and an artificial intelligence model, the EASY prediction score. Moreover, the model could distinguish patients into low-risk and high-risk groups according to the best cutoff point (88.16). Patients with higher scores had a higher probability of developing SAP than those with lower scores. The cutoff point can help doctors in making medical decisions.

As mentioned in the introduction, four commonly used AP scoring systems, including APACHE II, Ranson, BISAP, and MCTSI, have limitations on their abilities to identify SAP early. According to our results, our prediction score AAP has three easily available parameters lower than other scoring systems, which is easy for clinical application. Meanwhile, it has better performance in diagnostic efficacy and clinical decision-making for patients with AHTGP. It is worth mentioning that an artificial intelligence model-EASY prediction score consisting of 23 parameters was developed recently based on a multicenter, multinational, prospective and observational study[17]. We applied this model to our research population. Although it achieved a high AUC in predicting SAP, it was still the lowest among the AAP and four commonly used AP scoring systems. This may suggest that the prediction ability of the EASY model is limited for pancreatitis caused by HTG.

Notably, we introduced a new predictor, ApoA1, into our risk score compared with other clinical scoring systems. Recent studies have shown a negative correlation between ApoA1 and the severity of AP, and decreased serum levels of ApoA1 have been linked to the occurrence of SAP in patients[24,33]. The mechanism can be explained as follows: In SAP patients, excessive inflammatory cytokines inhibit synthesis. Recent studies showed a negative correlation between ApoA1 and the severity of AP, and decreased serum levels of ApoA1 have been linked to the occurrence of SAP in patients and lead to lipoprotein degradation[34]. Our previous study showed that the best cutoff point of ApoA1 for

Hospital day, days	13.51 ± 5.45	20.04 ± 8.14	< 0.001

APFC: Acute peripancreatic fluid collection; PPC: Pancreatic pseudocyst; ANC: Acute necrotic collection; WON: Walled-off necrosis; IPN: Infected pancreatic necrosis; SIRS: Systemic inflammatory response syndrome.

predicting severe acute hyperlipidemic pancreatitis was 0.8 g/L, whose sensitivity, specificity and Youden index were 0.877, 0.674 and 0.55, respectively[35]. Another study performed by Li *et al*[33] showed that ApoA1 predicts the optimal critical value of SAP to be 0.8 g/L, whose sensitivity, specificity and Youden index were 0.551, 0.757 and 0.693, respectively[33]. Therefore, ApoA1 has been found to be a reliable and validated indicator of SAP. Therefore, ApoA1 included in our model could increase the specificity and sensitivity of the nomogram.

Pleural effusion is one of the most common thoracic complications in AP patients. According to recent studies, the prevalence ranges from 46.0% to 72.3%[36]. The disruption of the pancreatic duct may result in leakage of pancreatic secretions directly into the peritoneal cavity *via* the transdiaphragmatic lymphatic channels[37]. According to the up-to-date revised Atlanta criteria, pleural effusion is a strong individual predictor of SAP. Additionally, pleural effusion is a valuable indicator of BISAP score. Yan *et al*[30] showed that on the basis of PEV, the AUC of 0.816 for predicting severe AP, with a threshold of 69.00 mL, and the sensitivity and specificity were 84.23% and 81.07, respectively. According to this study, pleural effusion volume can serve as a clinical biomarker to predict the severity and outcome of AP[30].

The evidence indicates that patients with HTG present a more severe form of pancreatitis. A previous study confirmed that HTG dose-dependently increases the complications and severity of AP[6]. However, a meta-analysis including 11965 patients from 16 eligible studies found no significant difference in AP severity based on the extent of HTG[5]. This study also explored the association between HTG levels and the severity of AHTGP. Compared to patients with TGs lower than 11.3 mmol/L, we found that patients with TGs above 22.6 mmol/L had a higher OR (OR: 5.95; 95%CI: 0.56-62.75; P = 0.232) than patients with TGs between 11.3 and 22.59 mmol/L (OR: 4.20; 95%CI: 0.40-44.25; P = 0.138). We speculated that there was a trend for HTG to dose-dependently increase the severity of AHTGP. Previous studies showed that the presence of metabolic syndrome and its components, including obesity, diabetes and hypertension, were significantly associated with increasing AP severity [31,32]. Our study showed that there was a trend that the presence of obesity (OR: 1.08; 95%CI: 0.94-1.24; P = 0.278), diabetes (OR: 1.27; 95%CI: 0.38-4.24; P = 0.693) and hypertension (OR: 1.02; 95%CI: 0.99-1.06; P = 0.201) increased the risk of SAP. However, the P values were not significant, probably because of our small sample size. The small sample size of our study makes it difficult to make extensive recommendations. The next step is to conduct a multicenter prospective cohort study with a large sample size to further explore this important issue.

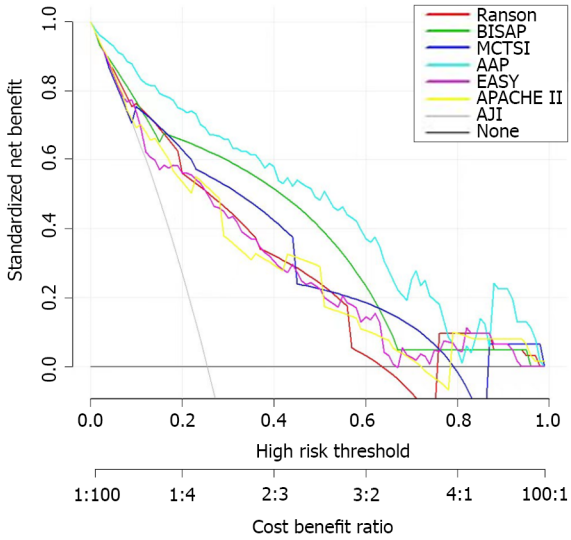
The novelties and strengths of our study include the following: To the best of our knowledge, this is the first study attempting to develop a risk prediction score for HTG-induced pancreatitis. We also compared the risk prediction score with existing scoring systems in a sample of Chinese patients for predicting the severity of AHTGP. Although the established and validated nomogram in our study may provide a convenient and specific tool to assist physicians in clinical decisions, there are some limitations to be taken into account. First, this study was retrospective, so selection and detection bias could exist. Second, it was a single-center study with a small sample size, which lacked multicenter data verification. There is a need to externally validate the risk score prior to clinical use. Furthermore, the data used to develop and validate the score are all from China, which limits their generalizability to other parts of the world.



CONCLUSION

In this study, we developed a risk score to estimate the prediction of developing SAP among patients with AHTGP based on three variables commonly measured on admission to the hospital. Estimating the risk score could help identify patients who are likely to develop SAP at an early stage. It could be of great value in guiding clinical decisions as a convenient and specific tool and optimizing the use of medical resources by supporting appropriate treatment.

ARTICLE HIGHLIGHTS

Research background

The frequency of acute hypertriglyceridemic pancreatitis (AHTGP) is in-creasing worldwide. AHTGP may be associated with a more severe clinical course and greater mortality than pancreatitis caused by other causes. Early identification of patients with severe inclination is essential for clinical deci-sion-making and improving prognosis. Hence, constructing a risk prediction score with high predictive accuracy and clinical utility for assessing the severity of AHTGP patients is of great importance.

Research motivation

Early prediction and detection of AHTGP patients who are likely to develop severe acute pancreatitis (SAP) is of great importance. Almost of existing clinical scores were developed for all etiologies of pancreatitis and not for hypertriglyceridemia (HTG)-induced pancreatitis separately. To the best of our knowledge, this is the first study attempting to develop a risk prediction score for HTG-induced pancreatitis. This risk score may help guide clinical decisions for these patients.

Research objectives

The purpose of this study was to establish a risk prediction score with easy use and high performance for predicting the severity of AHTGP patients in China, which will help doctors make rational clinical decisions.

Research methods

We performed a retrospective study of patients with AHTGP. Least absolute shrinkage and selection operator and logistic regression were used to screen predictive variables to construct a nomogram for predicting the severity of AHTGP. The predictive accuracy of the nomogram was estimated using the concordance index. The performance of the nomogram was estimated using a calibration curve. We evaluated the predictive accuracy and net benefit of the risk score and compared it with existing scoring systems *via* receiver operating characteristic curve analysis and decision curve analysis. We used the best cutoff value for SAP to determine the risk stratification classification.

Research results

A risk prediction score consisting of three predictors commonly measured on admission was constructed to predict the severity of SAP. More importantly, our nomogram exhibited high predictive accuracy and good performance. In addition, our nomogram has shown improved prognostic reliability, accuracy and the best net benefit when compared to other clinical scoring systems, such as Bedside Index of Severity in AP, Ranson, Acute Physiology and Chronic Health Evaluation II, modified computed tomography severity index and an artificial intelligence model, the early achievable severity index prediction score. Moreover, the risk prediction score could distinguish patients into low-risk and high-risk groups according to the best cutoff point. The cutoff point can help doctors in making medical decisions.

Research conclusions

This risk prediction score have potential usefulness in predicting the presence of SAP at an early stage. It could be of great value in guiding clinical decisions as a convenient and specific tool and optimizing the use of medical resources by supporting appropriate treatment.

Research perspectives

To the best of our knowledge, this is the first study attempting to develop a risk prediction score for HTG-induced pancreatitis. But, this was a single-center study with a small sample size, which lacked multi-center data verification. The next step is to conduct a multicenter prospective cohort study with a large sample size to construct specific risk score and externally validate the risk score prior to clinical use.

Abstract

BACKGROUND

The Rome IV criteria eliminated abdominal discomfort for irritable bowel syndrome (IBS), which was previously included in Rome III. There are questions as to whether IBS patients with abdominal discomfort (seen in Rome III but not Rome IV) are different from those with abdominal pain (Rome IV).

AIM

To compare bowel symptoms and psychosocial features in IBS patients diagnosed with Rome III criteria with abdominal discomfort, abdominal pain, and pain & discomfort.

METHODS

We studied IBS patients meeting Rome III criteria. We administered the IBS symptom questionnaire, psychological status, and IBS quality of life. Patients were classified according to the predominant abdominal symptom associated with defecation into an only pain group, only discomfort group, and pain & discomfort group. We compared bowel symptoms, extraintestinal symptoms, IBS quality of life, psychological status and healthcare-seeking behaviors, and efficacy among the three groups. Finally, we tested risk factors for symptom reporting in IBS patients.

RESULTS

Of the 367 Rome III IBS patients enrolled, 33.8% (124 cases) failed to meet Rome IV criteria for an IBS diagnosis. There were no meaningful differences between the pain group (n = 233) and the discomfort group (n = 83) for the following: (1) Frequency of defecatory abdominal pain or discomfort; (2) Bowel habits; (3) Coexisting extragastrointestinal pain; (4) Comorbid anxiety and depression; and (5) IBS quality of life scores except more patients in the discomfort group reported mild symptom than the pain group (22.9% *vs* 9.0%). There is a significant tendency for patients to report their defecatory and non-defecatory abdominal symptom as pain alone, or discomfort alone, or pain & discomfort (all $P < 0.001$).

CONCLUSION

IBS patients with abdominal discomfort have similar bowel symptoms and psychosocial features to those with abdominal pain. IBS symptoms manifesting abdominal pain or discomfort may primarily be due to different sensation and reporting experience.

Key Words: Irritable bowel syndrome; Abdominal pain; Abdominal discomfort; Diagnosis; Psychosocial distress; Quality of life

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: It is generally accepted that abdominal pain is the most predominant symptom of irritable bowel syndrome (IBS), and Rome IV eliminated abdominal discomfort as diagnostic criteria for IBS. Asian studies showed about one-third of IBS patients diagnosed using Rome III criteria had abdominal discomfort alone. In this study, we compared bowel symptoms, extraintestinal symptoms, IBS-quality of life, psychological status and healthcare-seeking behaviors, and efficacy between the abdominal pain and abdominal discomfort groups expecting to find a difference between the two groups but did not. We also assessed risk factors for symptom reporting for IBS patients.

INTRODUCTION

Irritable bowel syndrome (IBS) is a common functional bowel disorder with a global prevalence of 4.1% according to the Rome IV criteria and 10.1% with Rome III criteria[1]. Using the Rome III definition, IBS is characterized by recurrent abdominal pain or discomfort associated with altered bowel frequency or stool form[2]. However, the term "discomfort" was deleted from the 2016 Rome IV diagnostic criteria because some languages do not have a word for discomfort or it has different meanings in different languages or cultures[3,4]. Possibly abdominal discomfort has qualitative and quantitative levels of distinction with abdominal pain[5]. The data from a population-based survey of adults in the United States, Canada, and the United Kingdom showed that eliminating "discomfort" from the criteria for IBS affected diagnostic rates only slightly[6], and only 10% of Rome III-IBS patients among the Swedish cohort did not fulfill Rome-IV IBS diagnosis due to reporting only abdominal discomfort and not pain [7]. However, clinical studies from Thailand and central China revealed that about one-third of patients with IBS diagnosed using Rome III criteria had abdominal discomfort alone[8,9]. This rate is as high as 84.2% from another clinical retrospective report from Tianjin, China[10]. Evidence regarding pathophysiological differences between abdominal pain and abdominal discomfort such as whether these symptoms are categorically different or exist on a continuum of severity is lacking[11,12]. It is also unclear whether there are clinical or phenotypical distinctions with IBS presenting with abdominal pain

vs abdominal discomfort as to how this change of criteria impacts the clinical practice.

This study aimed to: (1) Compare the bowel and extraintestinal symptoms of patients with IBS presenting with abdominal discomfort alone to those with pain alone as well as with pain & discomfort; (2) Evaluate the anxiety, depression, quality of life (QOL), and symptom reporting tendency for patients with pain and discomfort; and (3) Validate whether the discomfort is milder than pain on a continuum of severity for Chinese patients. The clinical data were drawn from the IBS database of Peking Union Medical College Hospital.

MATERIALS AND METHODS

Subjects

Consecutive patients with IBS aged 18-65 years from Peking Union Medical College Hospital gastroenterology clinics were enrolled in this study from June 2009 to February 2016. All patients met Rome III diagnostic and subtype criteria[2], including IBS with diarrhea (IBS-D), IBS with constipation (IBS-C), and mixed IBS. Patients with organic gastrointestinal diseases and metabolic diseases were excluded based on the results of routine tests for blood, urine, stool; liver, kidney, and thyroid function, measurements of carcinoembryonic antigen, erythrocyte sedimentation rate, and C-reactive protein, and abdominal ultrasound and colonoscopy/barium enema in the past year. The participating patients provided oral or written consent to participate before study enrollment. This study was approved by the Peking Union Medical College Hospital Ethics Committee (S-234).

IBS symptom questionnaire

The IBS symptom questionnaire was administered by well-trained investigators in face-to-face interviews. The questionnaire was adapted from a previous symptom-related questionnaire for adult functional gastrointestinal disorders in Beijing[13], the Rome III diagnostic questionnaire for adult functional gastrointestinal disorders, and the Rome III psychosocial alarm questionnaire for functional gastrointestinal disorders[2]. Information collected included demographic data, IBS disease course, frequency and severity of IBS symptoms, defecation-related symptoms, extraintestinal symptoms, physical examination and supplementary examination results, and IBS treatments in the whole disease course and the last year.

Patients were evaluated according to abdominal pain, abdominal discomfort, or both abdominal pain & discomfort just before defecation (pre-defecatory), at IBS onset, and between IBS symptom episodes without association to defecation (ordinary). Patients with the presence or worsening of pre-defecatory abdominal pain and without pre-defecatory abdominal discomfort were categorized as the pain group regardless of whether they had abdominal pain or discomfort during the ordinary period. Similarly, patients with pre-defecatory abdominal discomfort and without pre-defecatory abdominal pain were categorized as the discomfort group, and patients with pre-defecatory abdominal pain and discomfort were categorized as the pain & discomfort group.

The main intestinal symptom score for IBS-D was calculated according to the report by Zhu *et al*[14]. Diagnosis of gastroesophageal reflux disease and functional dyspepsia were made according to the Montreal consensus[15] and Rome III diagnostic and subtype criteria[2], respectively. Patients who did not met Rome IV diagnostic criteria for IBS (including patients with pre-defecatory abdominal discomfort alone or symptom frequency < 1 d/wk) were evaluated for possible diagnoses of other functional bowel disorders using Rome IV criteria, including functional diarrhea, functional constipation, functional abdominal bloating/distension, and unspecified functional bowel disorder[3].

QOL evaluation

The simplified Chinese version of the IBS-QOL instrument was used to evaluate patient QOL[16], which was translated from IBS-QOL[17] and well validated. This instrument was completed by patients according to the instructions provided; the total score and eight domain scores were calculated as in a previous publication[14].

Psychological evaluation

The Hamilton Anxiety (HAMA) and Hamilton Depression (HAMD) scales were used to evaluate patient psychological status by specially trained professionals through conversation and observation. A HAMA score ≥ 14 was judged as anxiety and ≥ 21 as moderate-to-severe anxiety. A HAMD score ≥ 17 was judged as depression and ≥ 24 as moderate-to-severe depression[18,19].

Statistical analysis

All analyses were performed using SPSS version 19.0 (IBM Corporation, Somers, NY, United States). Parametric distribution was evaluated by Kolmogorov-Smirnov test. Parametric and categorical data are presented as mean ± SD or rate, respectively. Nonparametric data were presented as median and interquartile range. Comparisons among the three groups were made by one-way analysis of variance

for parametric data, Kruskal-Wallis test for nonparametric data, and χ^2 test for categorical variables. Spearman's test was performed to assess nonparametric correlations between two quantitative variables. Bonferroni test was used to adjust for pairwise comparison among the three groups after analysis of variance. Multiple logistic regression analysis was used to determine the independent factors for abdominal pain or abdominal discomfort. $P < 0.05$ was considered statistically significant.

RESULTS

Demographic data

In total, 367 patients meeting Rome III criteria for IBS were enrolled in this study (205 males and 162 females), with an average age of 43.0 ± 11.4 years.

There were 233 patients (63.5%) in the pain group, 83 patients (22.6%) in the discomfort group, and 51 patients (13.9%) in the pain & discomfort group. There were more males in the discomfort group than in the pain group (67.5% *vs* 50.2%, $P = 0.01$). There were no significant differences in age, body mass index, educational level, physical work, family economic status, marriage status, the average IBS disease course, and IBS subtype distribution among the three groups ($P > 0.05$) (Table 1).

Characteristics of abdominal pain, discomfort, and pain & discomfort

In the three groups, the locations of abdominal pain, discomfort, or pain & discomfort before defecation were mainly in the umbilical region, lower abdomen, and left lower quadrant. There was no significant difference in distribution of symptom location, even though more patients in the discomfort group reported the symptom location as "others" (indicating varied or obscure locations) than in the pain group (21.7% *vs* 10.3%, $P = 0.009$). There was a significant difference in the severity of pain and/or discomfort among the three groups ($P = 0.007$), and more patients in the discomfort group reported mild symptom than those in the pain group. There was no significant difference in frequency among the three groups (Table 2).

There were significant differences in the prevalence of ordinary abdominal pain or/and discomfort among the three groups ($P < 0.001$). More patients in the pain group reported ordinary abdominal pain than those in the discomfort group and pain & discomfort group, while more patients in the discomfort group reported ordinary abdominal discomfort than those in the pain group and pain & discomfort group. In the pain & discomfort group, 54.9% of patients reported having ordinary pain and discomfort, which was significantly higher than the other two groups (Table 2).

In total, there were 52 patients (14.2%) with onset frequency of < 1 d/wk (*i.e.* 3 d/mo), including 37 cases in the pain group, 11 cases in the discomfort group, and 4 cases in the pain & discomfort group. The proportion of less frequency was 15.9%, 13.3%, and 7.8%, respectively, without significant difference ($P = 0.32$). According to Rome IV diagnostic criteria, a total of 124 patients (33.8%) would not meet an IBS diagnosis (Figure 1).

Bowel movements and stool form

In 345 patients with IBS-D, the average bowel movements during symptom non-onset period of the pain group (1.5 ± 0.9/d) were less than the discomfort group (1.8 ± 1.1/d) and the pain & discomfort group (1.9 ± 1.1/d) ($P = 0.004$), but there were no significant differences in average bowel movements during symptom onset period (3.8 ± 1.5 *vs* 3.8 ± 1.4 *vs* 3.6 ± 1.5, $P > 0.05$) (Figure 2A). There were no significant differences in stool form during symptom non-onset and onset periods among the three groups (all $P > 0.05$) (Figure 2B).

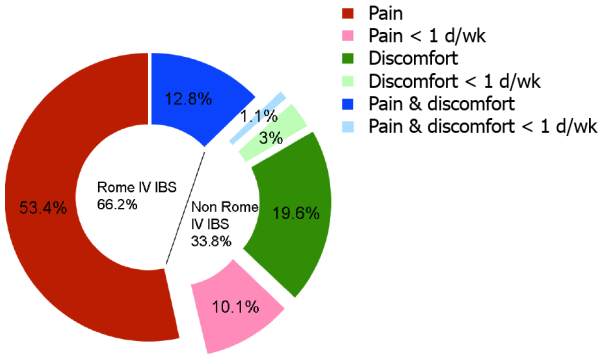
Abdominal pain and/or discomfort improvement after defecation

Abdominal pain and/or discomfort improved after defecation except for 1 patient in the pain group. There was no significant difference in the waiting time and degree for improvement among the three groups (Figure 2C and D).

In IBS-D patients, the main intestinal symptom score was 9.3 ± 1.6 in the pain group, 9.4 ± 1.5 in the discomfort group, and 9.6 ± 1.3 in the pain & discomfort group ($P > 0.05$).

Defecation-related symptoms

The prevalence of defecation related symptoms such as abdominal bloating, urgency, sensation of incomplete evacuation, and passing mucus were high overall for all 3 groups. More patients in the discomfort group reported having urgency, sensation of incomplete evacuation, and passing mucus than those in the pain group (all $P < 0.05$). In the pain & discomfort group, the prevalence of abdominal bloating, abdominal distension, and anorectal pain was significantly higher than that in the pain group (all $P < 0.05$) (Table 2).



Extraintestinal symptoms

There were no significant differences in the prevalence of gastroesophageal reflux disease or functional

Figure 1 Constitution diagram of irritable bowel syndrome patients diagnosed with Rome III and Rome IV criteria. About one-third of irritable bowel syndrome patients (parts dragged out of ring) diagnosed with Rome III criteria failed in irritable bowel syndrome diagnosis with Rome IV criteria because of only having abdominal discomfort before defecation (in green, 22.6%) or frequency of abdominal pain less than 1 d/wk (in light colors, 14.2%), which 3% of patients among them have discomfort alone with less frequency (in light green). IBS: Irritable bowel syndrome.

dyspepsia between the pain group and the discomfort group ($P > 0.05$), but the prevalence of epigastric pain syndrome, mainly epigastric pain was higher in the pain group than the discomfort group (21.0% *vs* 7.2%, 18.5% *vs* 6.0%, $P < 0.05$). More patients in the pain & discomfort group reported early satiation, dyspareunia, and menstrual pain for women than in the pain group (all $P < 0.05$). The prevalence of dyspareunia in the pain & discomfort group was also higher than in the discomfort group ($P < 0.001$) (Table 3).

Comorbid anxiety and depression

There were no significant differences in HAMA score, HAMD score, or the prevalence and severity of anxiety and depression among the three groups (Table 4).

IBS-QOL

The QOL of patients with IBS showed an obvious decrease with an IBS-QOL score of 72.2 ± 17.9 in the

[1]The number of female patients in the abdominal pain, abdominal discomfort, and pain & discomfort groups was 116, 27, and 19, respectively. χ^2 test. Data presented as number (%).
[2]*P* value is difference between the pain group and the discomfort group.
[3]The difference is between the pain group and the pain & discomfort group.
[4]The difference is between the discomfort group and the pain & discomfort group.
P value is the difference among the pain group, discomfort group, and pain & discomfort group, and superscript letters are significantly different at $P < 0.05$. GERD: Gastroesophageal reflux disease.

Healthcare-seeking behaviors and efficacy

There were no significant differences among the three groups in the average number of consultations and colonoscopies in the whole disease course and the average consultations and intermittent and long-term medication use in the last year (all $P > 0.05$). More patients in discomfort group used antispasmodics (muscarinic cholinergic receptor antagonists and selective intestinal calcium channel blockers), and all patients who used the antispasmodics had a reasonably good response (response rate over 50%). The overall satisfaction rate (including complete satisfaction and satisfaction) with medical care showed no significant difference among the three groups ($P > 0.05$) (Table 5).

Risk factors for IBS patients describing pre-defecatory symptoms as abdominal pain alone, discomfort alone, and pain & discomfort

Twelve variables differing between the pain group and the discomfort group at a *P* value with significant difference in Tables 1-3 were utilized for a multiple logistic regression analysis. We found that male patients [odds ratio (OR) = 1.955, 95% confidence interval (CI): 1.104-3.462, $P = 0.021$] and patients with mild defecatory abdominal pain or discomfort (OR = 4.020, 95%CI: 1.436-11.253, $P = 0.008$) were the predictors for patients to describe their pre-defecatory symptoms as abdominal discomfort alone rather than abdominal pain alone (Table 6). Similar analyses were performed between the pain group and the pain & discomfort group (11 variables) and the discomfort group and the pain & discomfort group (10 variables). We found that abdominal bloating (OR = 2.238, 95%CI: 1.080-4.638, $P = 0.030$) and anorectal pain (OR = 2.979, 95%CI: 1.347-6.585, $P = 0.007$) were the predictors for patients to describe their symptom as pain & discomfort rather than pain alone (Table 6), and no predictors were found for patients to describe their symptom as discomfort alone or pain & discomfort.

Table 4 Comorbid anxiety and depression among irritable bowel syndrome patients with abdominal pain alone, abdominal discomfort alone, and abdominal pain & discomfort

Variable	Pain group (*n* = 233)	Discomfort group (*n* = 83)	Pain & discomfort group (*n* = 51)	*P* value
HAMA score	16.1 ± 7.3	15.5 ± 7.3	17.3 ± 7.4	0.36

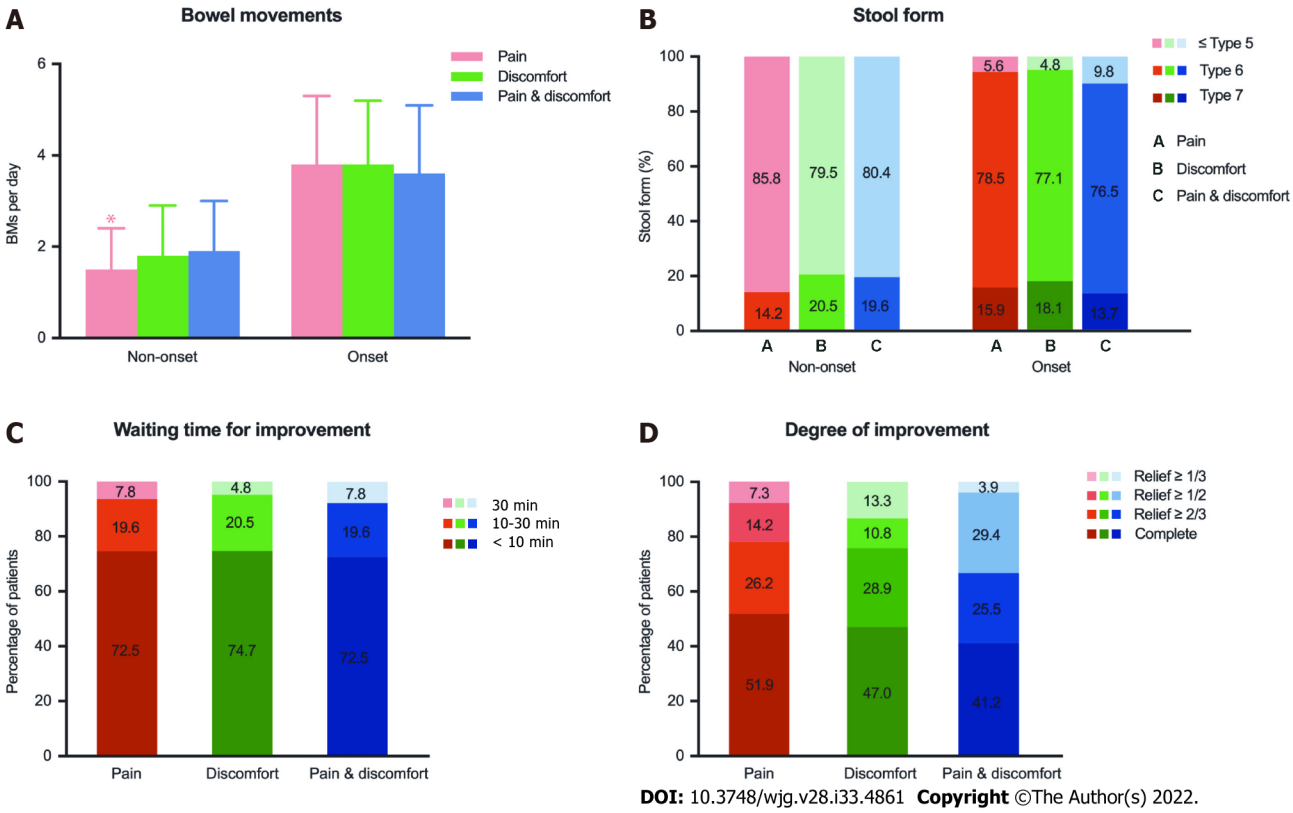
Data presented as mean ± SD or number (%). Analysis of variance and χ^2 test. *P* value is difference among pain group, discomfort group, and pain & discomfort group, and superscript letter is significantly different at a $P < 0.05$.

Diagnosis of patients with abdominal discomfort alone according to Rome IV criteria

Among 83 patients having pre-defecatory abdominal discomfort alone and not meeting Rome IV criteria for IBS, 48 patients (57.8%) met the diagnosis for functional diarrhea, 28 patients (33.7%) for functional abdominal bloating/distension, 2 patients (2.4%) for functional constipation, and 5 patients (6.0%) were classified as unspecified functional bowel disorder.



DISCUSSION

The present study comprehensively compared the bowel symptoms and psychosocial features of IBS

Table 6 Risk factors for irritable bowel syndrome patients describing symptoms as abdominal pain alone, abdominal discomfort alone, and abdominal pain & discomfort

	Partial regression coefficient	Standard error	Wald χ^2	95%CI	*P* value
Abdominal discomfort alone *vs* abdominal pain alone					
Male sex	0.671	0.291	5.293	1.955 (1.104-3.462)	0.021[a]
Severity (mild defecatory pain or discomfort)	1.391	0.525	7.018	4.020 (1.436-11.253)	0.008[a]

Figure 2 Comparison of bowel movements and stool forms in irritable bowel syndrome with diarrhea patients and improvement of abdominal pain or discomfort after defecation in irritable bowel syndrome patients among the abdominal pain alone, abdominal discomfort alone, and abdominal pain & discomfort groups. A: Bowel movements during irritable bowel syndrome with diarrhea non-onset and onset status; B: Stool forms based on Bristol Stool Form Scale during irritable bowel syndrome with diarrhea non-onset and onset status; C: Degree of improvement of abdominal pain and discomfort with defecation; D: Waiting time for improvement of abdominal pain and discomfort with defecation in irritable bowel syndrome patients. Numbers in the column are percentages. [b]$P < 0.01$. BM: Bowel movement.

patients with pre-defecatory abdominal pain alone to pre-defecatory abdominal discomfort alone, and abdominal pain & discomfort. We found that patients with abdominal discomfort had similar bowel and extraintestinal symptoms, comorbid anxiety and depression, QOL, and healthcare-seeking behaviors to those with abdominal pain.

It is generally accepted that abdominal pain is the most predominant symptom of IBS[3]; however, a previous clinical study from the United States found only 21% of IBS patients with moderate to severe symptoms reported their predominant symptom in terms of abdominal pain[11]. Another study conducted by Lembo *et al*[12] showed that the proportions of IBS patients who reported pain or gas

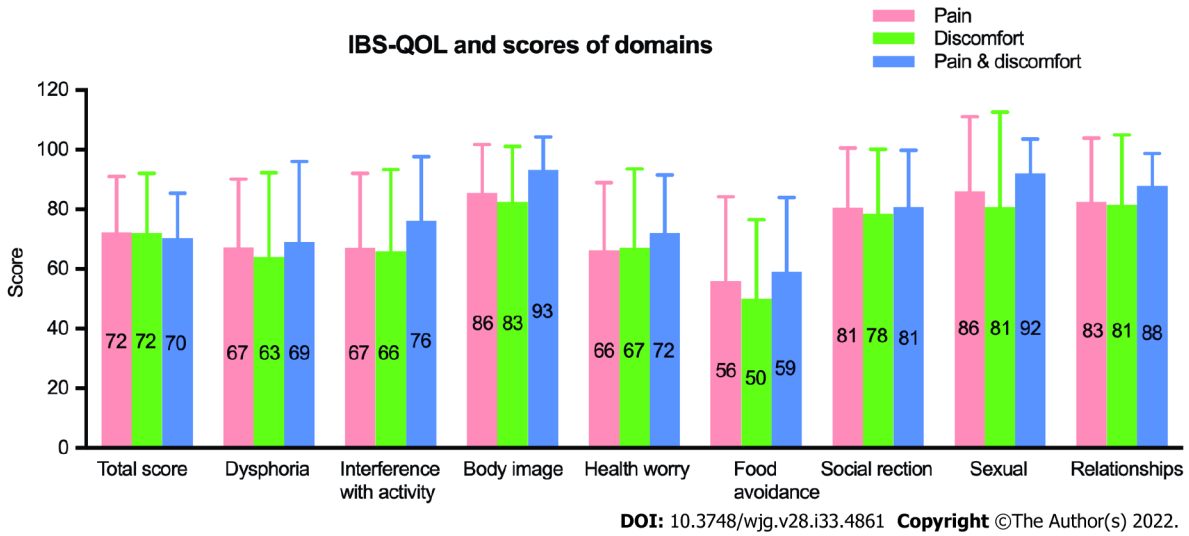

Figure 3 Comparison of irritable bowel syndrome-quality of life. There were no significant differences in the total score and eight domain scores among the three groups. Numbers in the column are percentages. IBS-QOL: Irritable bowel syndrome-quality of life.

(bloating-type discomfort) as one of their viscerosensory symptoms were similar (60% *vs* 66%). Currently, several studies compared the diagnostic rate between Rome III and IV criteria for IBS in the general population and consulting cohorts. The proportions of having abdominal discomfort varied among the western countries (2.4%-9.9%)[6,7,20,21] and the eastern countries (29.8%-84.2%)[8-10]. In this study, IBS patients with abdominal discomfort accounted for 22.6%. The elimination of abdominal discomfort from the diagnostic criteria had little effect on the diagnosis of IBS for the western countries [3], while a significant proportion of IBS patients were no longer IBS in Asian, including in China[8-10].

The significant difference between the western and eastern countries indicates there may be cultural factors that affect the experience and reporting of abdominal symptoms. The definition of abdominal pain is more uniformly accepted, while the definition for abdominal discomfort is ambiguous; "discomfort means an uncomfortable sensation not described as pain" according to the Rome III criteria[2]. Further, there are no comparison studies concerning abdominal discomfort descriptions in cross-cultural cohorts. In this study, Chinese patients with IBS accurately reported abdominal discomfort, including the location and association with defecation (both in pre-defecatory and non-defecatory periods), as well as other defecation related symptoms (*i.e.* urgency and so on). Symptom characteristics were similar with abdominal pain, which indicated that abdominal discomfort was a relatively explicit symptom for Chinese patients, unlike the impression from a cognitive study from American IBS patients [6] in which abdominal discomfort might encompass a wide range of symptoms such as bloating, gas, fullness, flatulence, sensation of incomplete evacuation, and urgency.

Abdominal pain and discomfort are both visceral perceptions of abnormality on the same continuum with pain appearing at the more severe end of the spectrum[11]. In this study, there were no meaningful differences between the pain alone group and discomfort alone group in frequencies as well as the main intestinal symptom score for IBS-D patients except more patients in the discomfort group reported mild symptoms than the pain group. In addition, we found patients with mild defecatory abdominal pain or discomfort were predisposed to describe their pre-defecatory symptoms as abdominal discomfort alone rather than abdominal pain alone, which indicated abdominal discomfort may appear as the milder form of pain. However, it was reported that more IBS patients rank abdominal discomfort as their most bothersome symptom than abdominal pain (60% *vs* 29% in America[12], 15.3% *vs* 4.5% of IBS-C in Japan [22]), and the severity of abdominal discomfort had the strongest independent relationship with QOL impairment[10]. Patients in the three groups had similar healthcare-seeking behavior and satisfaction to medical care in this study. We speculated in terms of the symptom itself, the overall severity of IBS, and occupation of medical resources that abdominal discomfort is as important as abdominal pain.

Nevertheless, more patients in the discomfort group reported accompanying urgency, sensation of incomplete evacuation, and passing mucus than the pain group. Patients with abdominal pain & discomfort had a higher prevalence of abdominal bloating/distension and anorectal pain than patients with abdominal pain alone, and a lower score of QOL than patients with abdominal discomfort alone. In addition, we found that abdominal bloating and anorectal pain were the predictors for patients to describe their symptom as pain & discomfort rather than pain alone, suggesting coexisting symptoms played important roles in the generation of discomfort feeling.

We noticed that the previous studies seldom paid attention to the abdominal symptoms of IBS patients during non-defecatory period. An interesting finding in this study is more patients having pre-defecatory abdominal discomfort alone also reported non-defecatory abdominal discomfort than the other two groups, and a similar report tendency for patients with pain alone and pain & discomfort

during defecatory period and non-defecatory period. In terms of extraintestinal symptoms, more patients in the pain group reported coexisting epigastric pain. The possible explanation for this reporting tendency is individual sensation and reporting experience to the similar stimulations and pathophysiological changes[11].

The relationships between diary stress, psychological distress, and severity of abdominal discomfort symptoms in women with IBS have been noted[23]. In this study, the scores of HAMA and HAMD and comorbid anxiety and depression were comparable between the pain group and the discomfort group. The impact of mental status to the symptom sensation and reporting could be ignored.

To date, studies on the pathophysiology of IBS mainly focused on abdominal pain[12,24-27]. As far as we know, there was no direct evidence focused on mechanism of abdominal discomfort or comparison of the difference of pathogenesis between abdominal pain and discomfort. Abdominal discomfort could simultaneously improve with abdominal pain and/or bloating to antispasmodics tiropramide and octylonium, secretagogue linaclotide, or simethicone and *Bacillus* coagulans for IBS or IBS-C patients[28-31]. It is unclear whether the treatments focused on bloating, diarrhea, or constipation could relieve the abdominal discomfort for those patients having defecatory abdominal discomfort alone while they are diagnosed as other bowel disorders according to Rome IV criteria (as shown in the results). Therefore, we realized that it may be more beneficial to classify patients with bowel-related abdominal discomfort into IBS from a therapeutic consideration.

There are several limitations in this study. We only included the IBS patients with typical changes of bowel habits, *i.e.* IBS-D and IBS-C. Therefore, some mixed IBS and IBS-unclassified patients might be missed[7,31]. We enrolled patients with Rome III criteria and did not concern the abdominal pain and discomfort during or soon after bowel movement. The proportion of Rome III suspected IBS patients with this kind of pain or discomfort was low (2.9% according to Bai *et al*[9]). Moreover, we did not ask patients to describe the difference between abdominal pain and discomfort. The data for response to therapies were retrospective recall, including prescription and over-the-counter. In addition, the prevalence of IBS in the general population for males was lower than females (4.1% *vs* 5.4%)[32], but an equal or higher ratio of male to female consulting patients was reported in clinical studies[9,14]. It is unclear whether male patients have more vigorous healthcare seeking behaviors or priority of medical care than female patients, but more female patients reported frequent consultations and colonoscopies during the whole disease course of IBS than male patients[33]. IBS-D is the predominant subtype, which accounted for 74.1% in the general population of South China[34] and 66.3% in consulting patients[31]. In addition, this was a single-center study.

CONCLUSION

Chinese patients with IBS can differentiate and report abdominal pain or/and abdominal discomfort as their key bowel symptom. The patients with abdominal discomfort had similar bowel symptoms and psychosocial features to those with abdominal pain. There is a tendency for IBS patients to report their defecatory and non-defecatory abdominal symptom as pain alone, discomfort alone, or pain and discomfort. Pre-defecatory abdominal discomfort should be considered as an important symptom for IBS patients. Further studies focused on the pathophysiology and therapeutic response (including the cultural influence) of abdominal pain and discomfort are needed.

ARTICLE HIGHLIGHTS

Research background

The Rome IV criteria eliminated abdominal discomfort for irritable bowel syndrome (IBS), which was previously included in the Rome III criteria. Asian studies showed the rate of IBS patients with abdominal discomfort alone was high.

Research motivation

There are questions as to whether IBS patients with abdominal discomfort (seen in Rome III but not Rome IV) are different from those with abdominal pain (Rome IV).

Research objectives

To compare the bowel and extraintestinal symptoms of patients with IBS presenting with abdominal discomfort alone to those with pain alone as well as with pain & discomfort and to evaluate the anxiety, depression, quality of life, and symptom reporting tendency for patients with pain and discomfort.

Research methods

We enrolled IBS patients and collected their clinical data. Patients were classified to the pain only group,

the discomfort only group, and the pain & discomfort group. We compared bowel symptoms, extraintestinal symptoms, IBS-quality of life, psychological status and healthcare-seeking behaviors, and efficacy among the three groups and tested risk factors for symptom reporting in IBS patients.

Research results

About one-third of patients meeting Rome III criteria failed to meet Rome IV criteria for an IBS diagnosis. There were no meaningful differences between the pain group and discomfort group for frequency of defecatory abdominal pain or discomfort, bowel habits, coexisting extragastrointestinal pain, comorbid anxiety and depression, and IBS-quality of life scores.

Research conclusions

IBS patients with abdominal discomfort have similar bowel symptoms and psychosocial features to those with abdominal pain.

Research perspectives

Further studies focused on the pathophysiology and therapeutic response (including the cultural influence) of abdominal pain and discomfort are needed.

ACKNOWLEDGEMENTS

The authors thank their colleagues in the Department of Gastroenterology, Peking Union Medical College Hospital for their contributions to the enrollment of IBS patients.

Abstract

BACKGROUND

Achalasia is a rare benign esophageal motor disorder characterized by incomplete relaxation of the lower esophageal sphincter (LES). The treatment of achalasia is not curative, but rather is aimed at reducing LES pressure. In patients who have failed noninvasive therapy, surgery should be considered. Myotomy with partial fundoplication has been considered the first-line treatment for non-advanced achalasia. Recently, peroral endoscopic myotomy (POEM), a technique that

employs the principles of submucosal endoscopy to perform the equivalent of a surgical myotomy, has emerged as a promising minimally invasive technique for the management of this condition.

AIM

To compare POEM and laparoscopic myotomy and partial fundoplication (LM-PF) regarding their efficacy and outcomes for the treatment of achalasia.

METHODS

Forty treatment-naive adult patients who had been diagnosed with achalasia based on clinical and manometric criteria (dysphagia score ≥ II and Eckardt score > 3) were randomized to undergo either LM-PF or POEM. The outcome measures were anesthesia time, procedure time, symptom improvement, reflux esophagitis (as determined with the Gastroesophageal Reflux Disease Questionnaire), barium column height at 1 and 5 min (on a barium esophagogram), pressure at the LES, the occurrence of adverse events (AEs), length of stay (LOS), and quality of life (QoL).

RESULTS

There were no statistically significant differences between the LM-PF and POEM groups regarding symptom improvement at 1, 6, and 12 mo of follow-up (P = 0.192, P = 0.242, and P = 0.242, respectively). However, the rates of reflux esophagitis at 1, 6, and 12 mo of follow-up were significantly higher in the POEM group (P = 0.014, P < 0.001, and P = 0.002, respectively). There were also no statistical differences regarding the manometry values, the occurrence of AEs, or LOS. Anesthesia time and procedure time were significantly shorter in the POEM group than in the LM-PF group (185.00 ± 56.89 and 95.70 ± 30.47 min *vs* 296.75 ± 56.13 and 218.75 ± 50.88 min, respectively; P = 0.001 for both). In the POEM group, there were improvements in all domains of the QoL questionnaire, whereas there were improvements in only three domains in the LM-PF group.

CONCLUSION

POEM and LM-PF appear to be equally effective in controlling the symptoms of achalasia, shortening LOS, and minimizing AEs. Nevertheless, POEM has the advantage of improving all domains of QoL, and shortening anesthesia and procedure times but with a significantly higher rate of gastroesophageal reflux.

Key Words: Esophageal achalasia; Gastroesophageal reflux; Deglutition disorders; Heller myotomy; Fundoplication; Randomized controlled trial

INTRODUCTION

Achalasia is a rare benign esophageal motor disorder characterized by incomplete relaxation of the lower esophageal sphincter (LES)[1-3]. For primary or idiopathic achalasia, the underlying etiology has yet to be clearly defined; secondary achalasia results from any one of several systemic diseases including infectious, autoimmune, and drug-induced disorders[4-6]. In both cases, the most common

symptoms are progressive dysphagia, regurgitation, and weight loss. The symptom intensity and treatment response can be assessed with validated scales such as the Eckardt score[2,7,8]. The diagnosis requires the proper integration between reported symptoms and the interpretation of diagnostic tests such as a barium esophagogram, esophagogastroduodenoscopy (EGD), and manometry—either conventional esophageal manometry (EM) or high-resolution manometry (HRM)[9-12].

The treatment of achalasia is not curative but rather is aimed at reducing LES pressure[13-17]. In patients who have failed noninvasive therapy, surgery should be considered[18]. Myotomy with partial fundoplication has been considered the first-line treatment for non-advanced achalasia[19].

Recently, peroral endoscopic myotomy (POEM), a technique that employs the principles of submucosal endoscopy to perform the equivalent of a surgical myotomy, has emerged as a promising minimally invasive technique for the management of this condition[20]. This technique was first described in 1980 and subsequently modified to create what is now POEM[21,22].

This randomized controlled trial (RCT) compared the efficacy and outcomes of laparoscopic myotomy and partial fundoplication (LM-PF) with those of POEM for the treatment of patients with achalasia of any etiology. We also compared the two procedures in terms of the incidence of reflux esophagitis.

MATERIALS AND METHODS

Study design and participants

This was a single-center RCT in which we evaluated 40 treatment-naive patients with esophageal achalasia. We included patients ≥ 18 years of age who had been diagnosed with achalasia based on clinical and manometric criteria (dysphagia score ≥ II and Eckardt score > 3) and who provided informed consent. Patients who had previously undergone endoscopic or surgical procedures involving the esophagogastric junction (EGJ) were excluded, as were those with liver cirrhosis, esophageal varices, Barrett's esophagus, esophageal strictures, premalignant or malignant EGJ lesions, coagulopathies, pseudoachalasia, esophageal diverticulum, severe cardiopulmonary diseases, or severe systemic diseases, as well as those who were at high surgical risk and those who were pregnant or lactating.

Randomization strategy

An investigator who was unaffiliated with the trial created the randomization list. Specific software (www.randomizer.org) was used, and participants were randomly allocated at a 1:1 ratio to the experimental (POEM) group or the comparison (LM-PF) group.

Sample size calculation

The sample size was calculated to identify statistical significance between LM-PF and POEM regarding reflux esophagitis rates, which were assumed to be 5% and 40% after LM-PF and POEM, respectively [23]. To achieve a power of 80% with an alpha of 0.05, we estimated the minimum sample size to be 38 (19 patients in each group). Taking potential losses into consideration, we chose to include a total of 40 patients.

Techniques

POEM: All POEM procedures were performed by a single operator with extensive experience in the technique. Prophylactic intravenous antibiotics and a proton pump inhibitor (PPI) were administered 30 min before intubation and general anesthesia.

After the gastroscope was introduced, the esophageal lumen and mucosa were thoroughly cleaned. This was followed by submucosal injection of 10 mL of 0.5% indigo carmine. An incision was made into the mucosa of the posterior wall, between 5 and 6 o'clock, at 10 cm above the EGJ. The incision was made with a dual-function submucosal dissection knife (HybridKnife; Erbe, Tübingen, Germany) in Endocut Q mode (effect 2, width 3, and interval 5). Subsequently, spray coagulation (effect 2 at 40 W) was used to create a submucosal tunnel extending 3-4 cm beyond the EGJ into the proximal stomach. In all patients, full-thickness myotomy—including the circular and longitudinal muscle layers—was performed in Endocut Q mode. The myotomy was initiated 2 cm distal from the mucosal entry point and extended 3-4 cm into the proximal stomach. The mucosal incision was closed by using through-the-scope clips (Supplementary Figures 1 and 2).

A barium esophagogram was obtained on postoperative day 1. In the absence of complications, the patient was started on a clear liquid diet and subsequently advanced to a full liquid diet for 14 d.

LM-PF: All LM-PF procedures were performed by members of the foregut surgery group. After pneumoperitoneum had been established, five trocars were positioned, after which the left hepatic lobe was retracted to access the EGJ (Supplementary Figure 3). That was followed by division of the phrenoesophageal ligament, dissection, and isolation of the distal esophagus from adjacent structures; and anterolateral dislocation of the distal esophagus. The anterior gastric adipose tissue and the anterior vagus nerve were dissected and separated from the esophagus and stomach, after which myotomy of

the circular and longitudinal muscle layers was performed, extending from 5-6 cm above the EGJ to 2-3 cm below the EGJ. Partial fundoplication between the esophagus and stomach was then performed by placing sutures in three planes: Posterior—two to three sutures; left lateral—four to five sutures (on the left side); and right anterior—a line of sutures covering the myotomy, thus interposed with the gastric fundus on the right. In the absence of complications, patients were started on a clear liquid diet on the morning following the procedure and maintained on a mechanical soft diet for 14 d after discharge.

Diagnosis and follow-up

Clinical assessments: Although achalasia subtyping is defined based on HRM, in this study, the achalasia subtype was evaluated according to the degree of esophageal dilation on the barium esophagogram and esophageal motor activity on EM or HRM. Given that Chagas disease, which often involves the esophagus, is common in Brazil, all patients were screened for anti-*Trypanosoma cruzi* antibodies by enzyme-linked immunosorbent assay and indirect immunofluorescence. Weight loss, dysphagia, and pain were assessed before the procedure, as well as at 6 and 12 mo after the procedure, by using the Eckardt score. Patients with an Eckardt score ≥ 3 were categorized as symptomatic. The clinical evaluation of gastroesophageal reflux (GER) and the diagnosis of GER disease (GERD) was based on the application of the GER Disease Questionnaire (GerdQ)[24] (Supplementary Figure 4).

EGD: We performed EGD before the procedure, as well as at 6 and 12 mo after. Esophagitis was graded according to the Los Angeles classification system[25]. We performed chromoendoscopy with narrow-band imaging and 2.5% Lugol's solution to screen for esophageal cancer. Suspicious lesions were biopsied.

Barium esophagogram: To assess esophageal emptying before and 12 mo after the procedure, we used a timed barium esophagogram, as previously described[26]. The degree of esophageal emptying is qualitatively estimated by comparing 1- and 5-min images or by measuring the height and width (in centimeters) of the barium column at both times, calculating the approximate area, and determining the percentage change in the area.

EM: Conventional EM was performed before and 12 mo after the procedure. It should be noted that HRM technology was not available in Brazil when the trial began. To perform conventional EM, we used an eight-channel computerized polygraph under pneumohydraulic capillary infusion at a flow rate of 0.6 mL/min/channel. Preparation was required with a 12-h fast and suspension of medications that alter esophageal motility. The technique consists of passing a probe through the nostril and checking the position in the stomach through deep inspiration. With the patient in the supine position, the probe is pulled centimeter by centimeter to measure the mean respiratory pressure and pressure inversion point, and then one of the channels is positioned distal to 3 cm from the upper edge of the LES and the other channels are distant 5 cm apart. Finally, the catheter is pulled up to the upper esophageal sphincter. Through the average of the four distal radial channels of the conventional manometry catheter, the maximum expiratory pressure (MEP) was identified, which best represents the LES pressure itself.

Quality of life: To evaluate the quality of life (QoL), we used the Medical Outcomes Study 36-item Short-Form Health Survey (SF-36)[27,28]. The SF-36 comprises 36 questions covering eight domains: Physical functioning, role-physical, bodily pain, general health, vitality, social functioning, role-emotional, and mental health.

Adverse events: Among the adverse events (AEs) recorded, pneumoperitoneum requiring drainage or puncture was categorized as a minor AE, as was minor mucosal damage requiring endoscopic closure. Major AEs were defined as pneumoperitoneum leading to hemodynamic instability and premature interruption of the procedure; bleeding requiring a blood transfusion and accompanied by hemodynamic instability or requiring an additional intervention; major mucosal damage requiring endoscopic closure or increasing the length of stay (LOS); or fistula/dehiscence of the incision with signs of fever or infection associated with hemodynamic instability. For AEs occurring in the LM-PF group, we used the Clavien-Dindo classification[29].

Outcome measures and data collection

For POEM and LM-PF, the following outcome measures were evaluated: Operative time; length of the myotomy in the esophagus and stomach; myotomy site; complications; and LOS. Patient data were collected on the Research Electronic Data Capture platform.

Follow-up

At 1, 6, and 12 mo after the interventions, the Eckardt score was determined, the SF-36 was applied, EGD was performed, and timed barium esophagograms were obtained. Conventional EM was performed at 6 and 12 mo. Patients received the maximum dose of PPI for the first 30 d postprocedure, and those who presented with erosive esophagitis at follow-up endoscopy were maintained on PPI

treatment for 8 wk. Treatment success was defined as symptom improvement (≤ 3-point reduction in the Eckardt score), an LES pressure < 15 mmHg[30-32], and a > 50% reduction in the height of the barium column at 1 min. Treatment failure was defined as symptom persistence in patients with an Eckardt score ≥ 3.

Statistical analysis

We performed descriptive analyses of all study variables. Quantitative variables were expressed as means with standard deviations or as medians with interquartile ranges. Qualitative variables are expressed as absolute and relative frequencies. For the comparison of means between the two groups, the Student's *t*-test was used. When the assumption of normality was rejected, the nonparametric Mann-Whitney test was used. To test the homogeneity between proportions, the chi-square test or Fisher's exact test was used. Repeated-measures analysis of variance was used to compare the groups over the course of the study. When the assumption of normality was rejected, the nonparametric Mann-Whitney test and Friedman test were used. The data were processed with the SPSS Statistics software package, version 17.0 for Windows (SPSS Inc., Chicago, IL, United States). $P < 0.05$ was considered statistically significant.

RESULTS

Population characteristics

Between March 2017 and February 2018, 40 patients diagnosed with achalasia were enrolled and randomized to undergo LM-PF ($n = 20$) or POEM ($n = 20$), as detailed in Figure 1. Nine (22.5%) of the forty patients (five in the POEM group and four in the LM-PF group) tested positive for anti-*T. cruzi* antibodies, indicating exposure to Chagas disease. At baseline, there was no statistical difference between the two groups in terms of sex, age, etiology, grade, symptom duration, weight, body mass index, or Eckardt score (Table 1). The study was terminated after all patients had been followed for at least 12 mo.

Treatment outcomes

Eckardt scores at 1, 6, and 12 mo were lower than the baseline scores in both groups—1.0, 0.5, and 0.50, respectively, *vs* 8.0, in the POEM group; and 0.0, 0.0, and 0.0, respectively, *vs* 8.5, in the LM-PF group—and the differences were statistically significant ($P < 0.001$; Table 2). There were no statistical differences between the two groups for the Eckardt scores at 1, 6, and 12 mo of follow-up ($P = 0.192$, $P = 0.242$, and $P = 0.242$, respectively).

In the POEM group, treatment success was confirmed at 1 mo in all 20 patients, at 6 mo in 18 of the patients (90%), and at 12 mo in 19 (95%). In the LM-PF group, treatment success was confirmed at 1 mo and was maintained at 6 and 12 mo in all 20 patients. As shown in Table 3, there was no statistical difference between the two groups regarding treatment success at 1, 6, or 12 mo ($P = 0.487$ and $P = 1.000$ for 6 and 12 mo, respectively).

In both groups, there were significant postprocedural improvements in dysphagia, although the differences were not significant at 1, 6, or 12 mo ($P = 0.602$; $P = 0.565$, and $P = 0.547$, respectively). However, statistically significant improvements in weight loss, chest pain, and regurgitation were observed in both groups (Supplementary Tables 1 and 2). The postprocedure rate of GER, as assessed with the GerdQ, was higher in the POEM group than in the LM-PF group (64.6% *vs* 11.1%; $P < 0.02$).

Endoscopic findings

At 1, 6, and 12 mo, only 20, 18, and 18 POEM group patients, respectively, underwent EGD, as did only 17, 16, and 17 LM-PF group patients, respectively. The remaining patients declined to undergo EGD because they were asymptomatic. The rates of esophagitis were significantly higher in the POEM group than in the LM-PF group at 1, 6, and 12 mo of follow-up ($P = 0.014$, $P < 0.001$, and $P = 0.002$, respectively). In the LM-PF group, 1 patient had esophagitis (classified as grade A) at 6 mo and 2 patients had esophagitis (classified as grades B and C, respectively) at 12 mo. In the POEM group, esophagitis was observed at 1 mo in 5 patients (being classified as grade A in one, grade B in three, and grade C in one), at 6 mo in 10 patients (being classified as grade A in three, grade B in two, and grade C in five), and at 12 mo in 11 patients (being classified as grade A in five, grade C in four, and grade D in two). At 1, 6, and 12 mo, the rates of esophagitis were 0.0%, 5.6%, and 11.1%, respectively, in the LM-PF group and 29.4%, 62.5%, and 64.6%, respectively, in the POEM group (Table 4).

Barium esophagogram

Table 5 shows the results of the barium esophagogram. In both groups, the heights of the barium column at 1 and 5 min were significantly lower at 1, 6, and 12 mo than at baseline ($P < 0.001$). There was no statistical difference between the two groups regarding the barium column height values at 1 and 5 min in the follow-up periods (intent-to-treat analysis: $P = 0.429$ and 0.773; per-protocol analysis: $P =$

0.505 and 0.922).

EM

In both groups, the MEP values were significantly lower at 6 and 12 mo than at baseline (Table 6). There was no statistical difference between the two groups at either of those time points (intention-to-treat analysis: $P = 0.848$).

AEs, LOS, anesthesia time, and procedure time

Table 7 describes the AEs, LOS, anesthesia time, and procedure time, in the sample as a whole and by groups. There was no statistical difference between the two groups regarding the rate of AEs ($P = 0.605$). The relevant complications observed in the immediate postprocedural period included empyema requiring thoracostomy in one (5%) of the LM-PF patients, and inadvertent intraoperative mucosal damage in three (15%) of the POEM patients (treated with endoscopic clipping). The clinical outcomes were favorable in all patients. The mean LOS was 3.95 ± 3.36 d in the LM-PF group, compared with 3.40 ± 0.75 d in the POEM group ($P = 0.483$). The mean anesthesia time and mean procedure time were both

DISCUSSION

In this single-center RCT comparing POEM and LM-PF in treatment-naive patients with achalasia, a significant proportion of the patients evaluated had achalasia attributed to Chagas disease. In a study by Farias *et al*[33], no statistical difference was observed between idiopathic and Chagas disease-associated achalasia regarding treatment success and AEs with POEM.

For years, LM-PF has been considered the gold-standard treatment for achalasia[34], because it provides good clinical results, has a low reintervention rate, and has adequate reproducibility. In the first study involving the use of endoscopic myotomy[21], conducted in 1980, all 17 of the patients in the sample showed symptom improvement. Although, technical improvements proposed by Inoue *et al*[22] in 2010 and several cohort studies comparing POEM and LM-PF[35-45] over the last decade have proved its safety and efficacy in the management of achalasia, the POEM technique is still not fully standardized[22].

The first RCT comparing the two techniques in the treatment of idiopathic achalasia[46], including 221 patients, demonstrated clinical success rates at 1 year and 2 years of follow-up of 84.8% and 83.0%, respectively, in the POEM group, comparable to the 83.5% and 81.7%, respectively, observed for the LM-PF group. In our study, the clinical success rate at the end of the 1st year was 95% in the POEM group and 100% in the LM-PF group, with no statistical difference between the two techniques. This discrepancy between our results and those of the earlier trial may be related to the fact that approximately 35% of the patients evaluated in that trial had previously received some type of treatment, which could have increased the degree of technical difficulty in dissection secondary to submucosal fibrosis.

Figure 1 Flow chart of the study timeline. EGD: Esophagogastroduodenoscopy; EM: Esophageal manometry (conventional); LM-PF: Laparoscopic myotomy and partial fundoplication; POEM: Peroral endoscopic myotomy; SF-36: Medical Outcomes Study 36-item Short-Form Health Survey.

We observed no statistical differences between the two techniques concerning Eckardt scores for dysphagia, regurgitation, chest pain, and weight loss, at 1, 6, and 12 mo of follow-up, which demonstrates the noninferiority of POEM to the LM-PF.

Immediate postprocedural complications occurred in 10% of the 40 patients evaluated in the present study. There were no cases of death in our sample, and the rate of AEs did not differ significantly between the two techniques. In our study, all POEM procedures involved a full-thickness myotomy, which made pneumoperitoneum an expected event. Pneumoperitoneum is a common finding after POEM and is not indicative of an unfavorable outcome for the patient. We categorized pneumoperitoneum as an AE only if abdominal decompression was required.

Anesthesia and procedure times were shorter for POEM than for LM-PF. That can be explained by the fact that the POEM involved full-thickness myotomy and did not involve fundoplication. There was no difference between the two procedures in terms of LOS and QoL.

We found that POEM and LM-PF both resulted in significant decreases in the 1- and 5-min barium column heights at 1, 6, and 12 mo after the procedures, demonstrating a clear decrease in resistance to the passage of contrast at the level of the EGJ. Sanagapalli *et al*[47] showed an association of significant improvement in symptoms when there is a mean reduction in the residual barium column height by about 53%. The LES pressure (MEP) on conventional EM was significantly lower throughout the follow-up period than at baseline, and there was no significant difference between the two groups.

In this study, the rates of treatment success were comparable between surgical and endoscopic myotomy, both providing symptom improvement, as well as objective improvement in radiological and manometric parameters, at 1, 6, and 12 mo. A recent systematic review and meta-analysis demonstrated that the incidence of GER is higher after POEM than after laparoscopic Heller myotomy[48]. That is in agreement with our findings. The evaluation of GER in our study was based on the typical clinical manifestations of GERD or the identification of erosive esophagitis by EGD. All patients with symptoms and suggestive endoscopic findings of GER received PPI treatment with suspension or maintenance according to the clinical and endoscopic response. A significant limitation of our study was the absence of pHmetry evaluation, which is the main method for GERD evaluation. Prior to our study, we considered that the pHmetry evaluation would be compromised because patients with esophageal achalasia present retention of food residues in the esophageal mucosa and the fermentation of those residues can decrease the intraluminal pH and thus be a confounding factor in the diagnosis of GERD. However, Smart *et al*[49] showed that such fermentation would affect only pre-procedure pHmetry,

without much influence on the post-procedure pHmetry.

Erosive esophagitis, especially grade C or D, is considered indicative of GER after endoscopy in patients without a history of the condition[50]. We consider that patients undergoing POEM have a wider esophagogastric transition that favors a higher rate of GER compared to LM-PF, despite similar LES pressures between the groups. Werner *et al*[46] also showed more GER in patients undergoing POEM despite no differences in manometry compared to LM-PF.

The POEM technique has undergone numerous changes since its initial description by Inoue *et al*[22]. It has been shown that short- to medium-term efficacy is comparable between myotomy of the circular muscle layer only and full-thickness myotomy, as well as that the latter, despite significantly reducing the duration of POEM, may increase the risk of GERD[51,52]. Likewise, there is uncertainty about whether myotomy should be performed in the anterior or posterior wall, the latter technique being associated with a higher incidence of GER[53,54], although other studies have failed to demonstrate that [55,56]. In the present study, we chose a long posterior full-thickness myotomy, because of the greater technical ease[43,57,58].

The results obtained in our study corroborate those of a previous study demonstrating the noninferiority of POEM to LM-PF for symptom control in patients with achalasia, except for postprocedure GER[46]. That raises the question of which technical changes we should study. Therefore, it is valid to perform in-depth analyses of oblique fiber preservation techniques[59], as well as the use of POEM with fundoplication[60,61]. One study[58] demonstrated that preservation of the oblique muscle, using the two penetrating vessels as an anatomical landmark, can significantly reduce the frequency of post-POEM GER, although that should be interpreted with caution because it was a retrospective cohort study, without strict methodological criteria, and with limited reproducibility. In the present study, we employed the conventional POEM technique as previously described[62], and the preservation of the two penetrating vessels was not standardized. The postprocedural occurrence of GERD symptoms in our sample was > 50%, similar to what has been reported by other authors. Despite not including patients undergoing POEM, a recent study[63] showed that achalasia patients with post-treatment reflux symptoms demonstrate esophageal hypersensitivity to chemical and mechanical stimuli, which may determine symptom generation.

Another strategy proposed to minimize the occurrence of GER after POEM is performing transoral incisionless fundoplication. In one pilot study[60], that procedure was reported to have a 100% success rate in terms of symptom control, acid exposure time, and the need for antisecretory drugs. In another pilot study[61], standard POEM combined with endoscopic fundoplication (POEM-F) was employed, and no complications were observed. A recent retrospective study followed patients for 12 mo after POEM-F[64], and showed that the incidence of postprocedural GER was only 11.1%. Albeit attractive, POEM-F has several potential limitations[65]. First, it is necessary to perform POEM in the anterior wall, contrary to the current trend of using a posterior wall approach. Second, it may not be possible to perform POEM-F in patients who have previously undergone anterior myotomy and experience symptom recurrence due to submucosal fibrosis. Third, the long-term durability of this type of fundoplication is still unknown.

In our opinion, it will take some time for the literature to reveal whether endoscopic or surgical myotomy is the best long-term option for the treatment of achalasia. Two crucial points that weigh unfavorably on the POEM procedure, in terms of the possibility that it will come to be widely indicated for the treatment of achalasia[66,67]. The first is the paucity of high-quality (randomized) technical studies comparing POEM with the well-established techniques of pneumatic dilatation of the cardia and laparoscopic myotomy with fundoplication, which could show, at least, the noninferiority of POEM. The second is the lack of studies with long (> 5 years) follow-up periods, which could demonstrate the true reintervention rate, based on the identification of serious late complications, including GER requiring fundoplication and dysphagia resulting from an inadequate myotomy[68]. Currently, the results at 2-3 years are similar between the endoscopic and surgical myotomy techniques concerning the clinical parameters, except for the greater occurrence of GER after the endoscopic technique, which typically responds well to antisecretory drug treatment. However, those data are accompanied by uncertainties that will only be resolved over time.

CONCLUSION

Our results allow us to conclude that LM-PF and POEM are equally effective in controlling the clinical symptoms of achalasia at 1, 6, and 12 mo. Although the use of the POEM technique results in a significantly higher rate of postprocedure GER, it also shortens anesthesia and procedure times. We found no differences between the two methods regarding LOS, the occurrence of AEs, or QoL. In the POEM group, there was an improvement in all domains of QoL.

ARTICLE HIGHLIGHTS

Research background

Achalasia is a rare benign esophageal motor disorder characterized by incomplete relaxation of the lower esophageal sphincter (LES). The treatment of achalasia is not curative but rather aimed at reducing the LES pressure. Surgical myotomy with partial fundoplication is traditional the gold standard method for the management of these patients. Peroral endoscopic myotomy (POEM) use its increasing due to it satisfactory results.

Research motivation

Since there is still no definition of the best treatment for achalasia, the objective of this study was to compare the techniques used.

Research objectives

This study aimed to compare POEM and laparoscopic myotomy and partial fundoplication (LM-PF) regarding their efficacy and outcomes for the treatment of achalasia.

Research methods

This was a single-center randomized controlled clinical trial.

Research results

There were no significant differences between the LM-PF and POEM groups regarding symptom improvement at 1, 6, and 12 mo of follow-up. Rates of reflux esophagitis were significantly higher in the POEM group. There were also no statistical differences regarding manometry values or the occurrence of adverse events or length of stay. Anesthesia time and procedure time were significantly shorter in the POEM group than in the LM-PF group. In the POEM group, there was an improvement in all domains of quality of life.

Research conclusions

POEM and LM-PF are equally effective in controlling symptoms of achalasia. POEM has the advantage of reducing anesthesia and procedure times, but with a significantly higher rate of gastroesophageal reflux.

Research perspectives

Future research should focus on long-term follow-up and outcomes of different techniques. It is possible that the improvement in the POEM technique may contribute to new perspectives on reflux symptoms.

FOOTNOTES

Author contributions: de Moura ETH contributed to the conception and design of the study; de Moura ETH, Ribeiro IB, de Moura DTH, Aissar Sallum RA, Nasi A, Sánchez-Luna SA, Sakai P, and de Moura EGH analyzed and interpreted the data, drafted the article, revised the article for important intellectual content, and approved the final version; Jukemura J, de Almeida Delgado AA, and Coutinho LMA analyzed and interpreted the data, revised the article for important intellectual content, and approved the final version; Farias GFA analyzed and interpreted the data, and approved the final version.

Institutional review board statement: The study was approved by the Research Ethics Committee of the University of São Paulo School of Medicine, No. CAAE: 23460613000000068.

Clinical trial registration statement: The trial was registered at ClinicalTrials.gov, No. NCT02138643.

Informed consent statement: All subjects agreed to participate in this study after informed consent and ethical permission were obtained.

Conflict-of-interest statement: All the authors report no relevant conflicts of interest for this article.

Data sharing statement: No additional data are available.

CONSORT 2010 statement: The authors have read the CONSORT 2010 Statement, and the manuscript was prepared and revised according to the CONSORT 2010 Statement.

Open-Access: This article is an open-access article that was selected by an in-house editor and fully peer-reviewed by external reviewers. Abstract

BACKGROUND

Chronic gastritis (CG) is an inflammatory disease of the gastric mucosa. Shen-ling-bai-zhu san (SLBZS), a traditional Chinese medicine formula, is widely used for treating CG. Nevertheless, its effects are currently unclear.

AIM

To determine the clinical evidence and potential mechanisms of SLBZS for the treatment of CG.

METHODS

We systematically searched 3 English (PubMed, Embase, Medline) and 4 Chinese databases (Cochrane Library Central Register of Controlled Trials, China National Knowledge Infrastructure database, Wanfang Data Knowledge Service Platform, and the VIP information resource integration service platform) without language or publication bias restriction. Qualified studies were selected according to pre-set inclusion and exclusion criteria. RevMan 5.3 software was used for meta-analysis and literature quality assessment, Stata 14.0 software was used for sensitivity analysis, GRADE profiler 3.6 was used to evaluate the quality of evidence. And then, network pharmacology analysis was applied to primary research the mechanisms of action of SLBZS on CG.

RESULTS

Fourteen studies were finally included, covering 1335 participants. Meta-analysis indicated that: (1) SLBZS was superior to conventional therapies [risk ratio (RR): 1.29, 95% confidence interval (CI): 1.21 to 1.37, $P < 0.00001$]; (2) SLBZS was better

than conventional therapies [RR: 0.24, 95% confidence interval (95%CI): 0.11 to 0.55, $P = 0.0007$] in terms of recurrence rate and reversal of *Helicobacter pylori* positivity (RR: 1.20, 95%CI: 1.11 to 1.30, $P < 0.00001$); and (3) The safety of SLBZS for CG remains unclear. According to the GRADE method, the quality of evidence was not high. Besides, SNZJS might treat CG by acting on related targets and pathways such as EGFR tyrosine kinase inhibitor resistance, the PI3K-Akt signaling pathway, and others.

CONCLUSION

SLBZS might be useful in treating CG, but long-term effects and specific clinical mechanisms of it maintain unclear. More samples and high-quality clinical experiments should be assessed and verified in the next step.

Key Words: Chronic gastritis; Shen-ling-bai-zhu-san; Chinese herbal formula; Systematic review; Network pharmacology

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: A 2012 clinical practice guideline recommended Shenling Baizhu Powder for the Pattern of Spleen and Stomach Deficiency chronic gastritis (CG). The 2020 clinical guideline did not recommended Shen-ling-bai-zhu san (SLBZS), possibly because of inadequate clinical evidence and pharmacological mechanisms. We designed our study to focus on evidence of efficacy and potential mechanisms. Our study showed that SLBZS might be useful in treating CG; however, its long-term effects and mechanisms of action are unclear. Due to the poor quality of the evidence, more samples and high-quality clinical studies should be tested.

INTRODUCTION

Chronic gastritis (CG) is a set of inflammatory diseases of the gastric mucosa[1] and is one of the common diseases of the digestive system. The disease often relapses, accompanied by symptoms that severely affect the quality of life. Chronic atrophic gastritis is associated with intestinal metaplasia and intraepithelial neoplasia, increasing gastric cancer risk. Globally, on average, more than 50% of people may have CG at any given moment[2]. A pathological study of 8892 patients in China found that atrophic gastritis, intestinal metaplasia, and dysplasia were prevalent, occurring in 25.8%, 23.6%, and 7.3% of the population, respectively[3].

The treatment of CG with gastric mucosal repair consists of antacids, antacids, and gastric mucosal protective agents[4-7]. Nevertheless, the efficacy of triple or quadruple therapy is not ideal, and there are frequent side effects[8]. For these reasons, complementary and alternative medicine therapies such as acupuncture[9-12], moxibustion[13,14], and Chinese herbal formulas[15,16] are sought as alternative therapies.

The Chinese herb formula Shenling Baizhu Powder, also known as Shen-ling-bai-zhu-san (SLBZS), is a widely used prescription for digestive tract disease in China derived from the classic herb monograph "*Taipinghuiminhejijufang*" written in the Song dynasty[17]. Ten commonly used herbs constitute SLBZS; these include Baizhu (*Atractylodes macrocephala* Koidz), Fuling (*Smilax glabra* Roxb), Yiyiren [*Coix lacryma-jobi var*. ma-yuen (Rom.Caill.) Stapf], Renshen (*Panax ginseng* C.A.Mey), Shanyao (*Dioscorea oppositifolia* L), Baibiandou (*Lablab purpureus subsp*. purpureus), Lianzi (*Nelumbo nucifera Gaertn*), Sharen (*Amomum villosum* Lour), Jiegeng (*Platycodon grandiflorus*) and Gancao (*Glycyrrhiza uralensis* Fisch. ex DC). In China, clinical studies suggested that SLBZS treats CG[18,19] with efficacy. Nevertheless, mechanistic studies based on animal experiments are lacking.

Furthermore, a 2012 Clinical practice guideline[20] recommended Shenling Baizhu Powder for the Pattern of Spleen and Stomach Deficiency CG. The pathogenesis can be summarized as the stomach failing to be nourished because of splenic and gastric qi deficiency and disturbance of qi movement. A 2020 clinical guideline did not recommend SLBZS, possibly because of inadequate clinical evidence and pharmacological mechanisms[21]. Efficacy evidence and potential mechanistic studies are required.

MATERIALS AND METHODS

Study registration

We registered this review and meta-analysis at the PROSPERO website (https://www.crd.york.ac.uk/PROSPERO/#recordDetails), an international prospective system review registration website. The registration number was CRD42020212979. We conducted the study based on the details of this protocol.

Database search

Our investigators independently searched PubMed, Embase, Medline, Cochrane Library Central Register of Controlled Trials, China National Knowledge Infrastructure database, Wanfang Data Knowledge Service Platform, and the VIP information resource integration service platform from their inception to November 2021. There were no limitations on language or publication status. They also searched conference articles and clinical registries for possible related trials.

Search terms

We adopted a search strategy that combined medical subject headings and free words. Two authors (YS, MFL) searched and screened all citations independently. The search strategy was as follows (Table 1): The search strategy followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses statement[22].

Inclusion criteria

Randomized controlled trials (RCTs) or quasi-RCTs that reported the effects of SLBZS on CG were included.

Participants: Studies that evaluated patients with a diagnosis of CG were included. For example, we used diagnostic criteria from the standardized consensus on the diagnosis of CG from the Branch of Spleen and Stomach Diseases of the Chinese Society of Traditional Chinese Medicine, China, that depends on endoscopy and pathological examinations[23]. We excluded studies that included CG patients complicated with hypertension, diabetes, heart disease, or severe allergic diseases. There was no restriction on the setting of interest or other population characteristics.

Interventions: SLBZ powder was the primary prescription, regardless of its dosage form, dosage, or course of treatment. If there were other medications, formulas, or traditional Chinese medicine (TCM) therapies (such as acupuncture, moxibustion, and ear-acupressure) in the treatment group, the control groups must also receive these therapies.

Comparisons: Western medicine, active control, and placebo were acceptable. If SLBZ + western medicine was applied in the experimental group, western medicine in the control group must be consistent.

Outcome measures: We considered efficacy outcomes as primary outcome measures, including effectiveness, recurrence rate, symptom score, *Helicobacter pylori* (*H. pylori*) eradication, and quality-of-life assessment. Secondary outcome measures were adverse events directly related to CG.

Exclusion criteria

The exclusion criteria were as follows: (1) The study was not an RCT, *e.g.*, retrospective study, cross-sectional study, observational study, case study, animal study, or others; (2) for multiple reports or repeated publications from the same study, we retained the one with a more significant number of details; (3) diagnostic criteria were not reported in trials, disease not CG; and (4) studies or trials used SLBZS as a part of complex interventions; for example, SLBZS decoction plus another herbal medicine formula *vs* acupuncture therapies. Western medicine is inconsistent in two groups.

Study selection and data extraction

According to our study registration protocol, two reviewers (WJ, QJL) independently performed trial searches, study selection, and raw data extraction. A third reviewer (JZ) checked the extracted data. We resolved conflicts through consensus.

Risk of bias assessment

According to the Cochrane Handbook details[24], we performed the risk of bias assessment analysis using the Cochrane collaborative bias risk tool in Review Manager 5.3 software. We resolved conflicts by consultation with a third investigator (WWH).

Statistical analysis

We used Review Manager 5.3 and Stata 14.0 software for statistical analysis. We calculated 95% confidence interval (CI) and mean difference for continuous variables and 95%CI and risk ratio (RR) for dichotomous variables. Differences with $P < 0.05$ were statistically significant. We determined the heterogeneity of data using Cochrane χ^2 and I^2 tests. We used a fixed-effect model if there was no significant heterogeneity; otherwise, we used a random-effect model. We conducted subgroup analyses to explore the source of heterogeneity. We determined publication bias by examining funnel plots and Egger's tests for more than ten trials. We used sensitivity analysis to explore the stability of the results. GRADE profiler 3.6 software was applied to evaluate the quality of evidence.

Mechanisms of network pharmacology of SLBZD to treat CG

Collection and screening of pharmacodynamic components in TCM System Pharmacology Database and analysis platform (TCMSP, HTTP://ibts.hkbu.edu.hk/LSP/tcmsp.php) in ginseng, atractylodes, poria cocos, yam, white hyacinth bean, lotus seed, coix seed, amomum fruit, radix platycodi, radix glycyrrhizae as keyword query filter chemical composition. The database contains about 500 drugs listed in the Chinese Pharmacopoeia, providing absorption, distribution, metabolism and excretion, ingredient data, and target and disease information. Oral bioavailability (OB) and drug-like properties (DL) are essential indexes determining whether a compound can be developed into a drug. Based on the relevant literature, OB and DL were set to > 30% and > 0.18, respectively, and the screened compounds were used as candidate ingredients[25,26].

Target prediction of pharmacodynamic components, the simplified molecular Linear Input specification (Simles) number, and Mol structure of each candidate component were retrieved using PubChem. We arranged candidate target genes using PharmMapper online (http://Lilab-ecust.cn/pharmmapper/index.html) and Swiss target prediction (HTTP://www.swisstargetprediction.ch/), and we arranged the standbys in an Excel form.

Prediction of disease Targets Genes associated with CG was identified by searching for "Chronic Gastritis" in GeneCards (http://www.genecards.org/).

Network construction and analysis

SLBZ Powder's candidate components and target genes were screened and imported into Cytoscape 3.7.2 software using Excel to obtain a component-target network diagram. The predicted disease candidate targets were imported into the online protein interaction (String) database, the species organism was set as human (*Homo sapiens*), and the PPI map was obtained. The PPI map was imported into Cytoscape 3.7.2 software. The potential targets of Shenlingbaizhu Powder in chronic gastritis can be obtained by merging the component-target network diagram and disease target PPI diagram using Merge software, which can be imported into the online String database the interaction map of potential targets.

Functional mechanism analysis of potential targets GO enrichment analysis, and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment annotation analysis of potential target genes were performed using the R package clusterProfiler.

RESULTS

Database search results

We retrieved 335 trials from 6 databases. When duplicate records were deleted, 177 remained. We excluded 152 studies by reading the title and abstract of the papers, including seven repeatedly published studies, ninety-five reports on the SLBZS experience of experienced TCM doctors, four retrospective studies, seventeen observation studies, one case report, and twenty-eight studies of diseases that were not CG. We read the full texts of the remaining 25 records. We deleted 11 records because of exclusion criteria (Table 2).

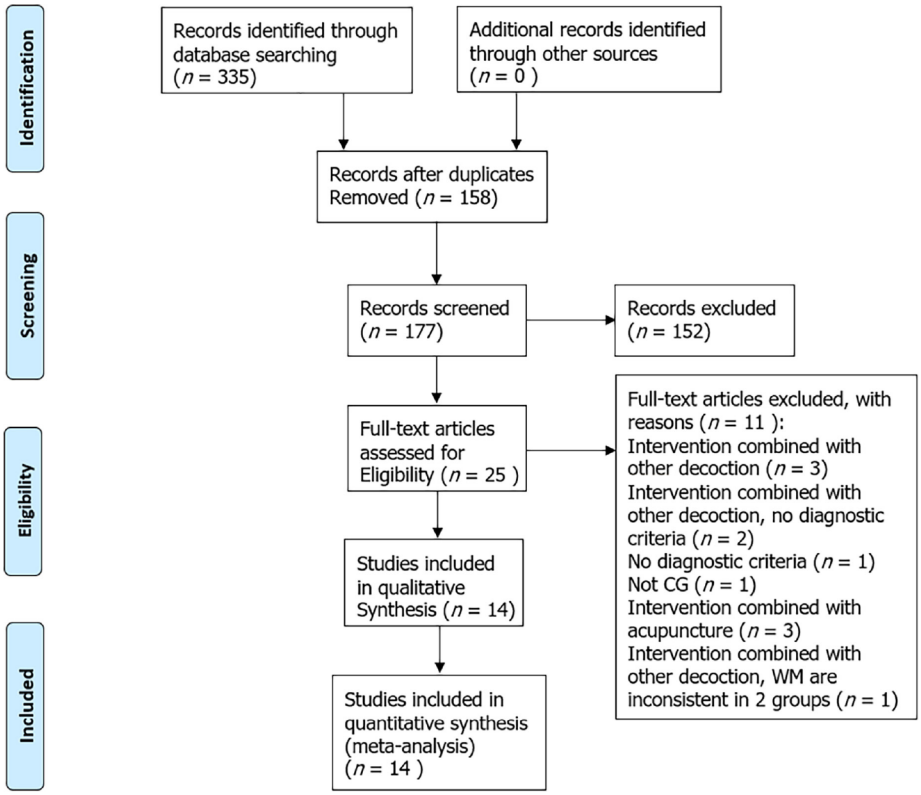
Finally, we included 14 studies in our review (flowchart of database search and study identification is shown in Figure 1).

Study characteristics

There were 14 Chinese-language RCTs, comprising 1335 participants aged 15-68 years[27-40], published between 2008 and 2020. Interventions in these studies were SLBZS *vs* conventional medicine or SLBZS + conventional medicine *vs* conventional medicine. In conventional medicine therapy, there were four methods, including monotherapy in four trials[27,33,34,37], combined therapy in one study[36], triple therapy in seven studies[28,31,32,35,38-40] and two trials of quadruple therapy[29,30]. There were various treatment durations, including 4, 5, 8, and 12 wk.

Total effectiveness was the primary outcome measure in all trials. All trials reported balanced baseline characteristics. Five trials (36%) recorded adverse events[29,31,34,36,38], and three studies reported recurrence rates[34,38,40]. Two studies reported participant withdrawal information[31,34]. No study reported influence on the quality of life as an outcome measure. Characteristics of included studies are shown in Table 3.

Risk of bias assessment



(1) Fourteen trials were consistent at baseline, and all tests referred to RCTs, three studies[28,39,40] mentioned randomization using the "random number table" method; (2) all studies not reported "distribution hidden" method; (3) the "blinding method" was not reported in any study, two studies[31,34] reported "No cases withdrawal and dropped-out," and three studies[34,38,40] reported "recurrence rate"; (4) selective reporting may come out in studies that there were too few indicators were noted; and (5) we considered some support from pharmaceutical companies that the ethics committee would not approve as other bias. If herbs were offered free by pharmaceutical companies, bias might taint the results. Two studies[34,36] reported that an ethics committee approved the study, suggesting a low bias level. For another 12 studies, we could not determine the effects of other potential sources of bias

Table 3 Characteristics of included studies

gastroscopy. The results fall into three categories: Obviously effective, effective, and invalid, according to clinical Research on New Chinese Medicines[41]. The details are as follows. Clinical cure: Epigastric pain and symptoms disappeared, gastroscopy returned to normal, *i.e.*, gastric mucosa repair, the disappearance of active inflammation, and mild chronic inflammation; Obviously effective: Epigastric pain and symptoms disappear or diminish. Gastroscopy showed significant improvement; that is, gastric mucosa was nearly normal, active inflammation was gone, and there was less chronic inflammation; Effective: Relief of epigastric pain and other symptoms. Gastroscopy showed reduced gastric mucosal lesions; that is, gastric mucosa was essentially normal, active inflammation was gone, and less chronic inflammation; and Invalid: no improvement or aggravation of clinical symptoms and signs. Gastroscopy showed no change. There were slight differences in this outcome's composition in various studies due to the non-uniform efficacy assessment criteria. All 14 RCTs compared the total effectiveness rate of SLBZS in patients with CG. SLBZS was superior to conventional therapies (RR: 1.29, 95%CI: 1.22 to 1.37, $P < 0.00001$) (Figure 3A). Heterogeneity in the total effectiveness was very small ($P = 0.91$, $I^2 = 0\%$).

We created subgroups based on the duration of treatment (4, 5, 8, or 12 wk) (Supplementary Table 1), comparison type (SLBZS *vs* conventional medicine or SLBZS + conventional medicine *vs* conventional medicine alone) (Supplementary Table 2), and intervention method (monotherapy, combined therapy, triple therapy, or quadruple therapy) (Supplementary Table 3). These subgroup analyses showed that the effectiveness rate of SLBZS did not differ based on the duration of treatment, combination with other medications, or intervention method (all $P > 0.05$) (Table 5).

Table 5 Subgroup analysis of total effectiveness

Subgroup method (total effective rate)	Items	Number of comparisons	Results (risk ratio, 95%CI)	*P* value for overall effect	I^2	*P* value for subgroup difference
Course of treatment	All comparisons	14	1.29 (1.22,1.37)	< 0.00001	0%	
Supplementary Table 1	4 wk	5	1.27 (1.17,1.37)	< 0.00001	0%

Table 6 Adverse events

Study	Experiment group	Control group
Zhang, 2020	Diarrhea (2/34)	Dizziness (2/34) and dry mouth (1/34)
Chen, 2018	Headache (1/30), diarrhea (1/30), nausea (1/30)	Headache (2/30), diarrhea (1/30), nausea (2/30), constipation (1/30), rash (1/30)
Zheng, 2014	None	Headache and rash (17.39%)

Recurrence rate: Three studies reported recurrence rate[34,38,40]. Pooled raw data showed that SLBZS was better than conventional therapies (RR: 0.24, 95%CI: 0.11 to 0.55, $P = 0.0007$, Figure 3B).

HP negative conversion rate: Four trials noted the reversal rate for *Helicobacter pylori* (*H. pylori*) positivity[29,31,39,40]. Meta-analysis showed that SLBZS was superior to conventional therapies (RR: 1.20, 95%CI: 1.11 to 1.30, $P < 0.00001$, Figure 3C).

Other results

One trial compared the time required for symptom improvement in patients with CG[38]. The experimental group was superior to the control group regarding effects on epigastric stagnation, abdominal distension, belching, acid regurgitation, and nausea ($P < 0.05$).

There were no reports of significant responses or improvement in the quality-of-life data in these studies. One study reported the Questionnaire for Comprehensive Quality of Life Assessment responses pre- and post-treatment in two groups[36]. After two consecutive months of treatment, scores in all dimensions improved, and the treatment group's score was significantly higher than that of the treatment group ($P < 0.05$).

Publication bias

Funnel plots showed the publication bias of the effectiveness rate (Figure 4A). The funnel plot of the effective rate was symmetric, suggesting no significant publication bias. Egger's test results agreed with the funnel plots ($P = 0.005$ and 0.000, respectively).

Adverse events

Of the 14 studies, nine RCTs did not mention adverse events[27,28,30,32,33,35,36,39,40]. Two studies

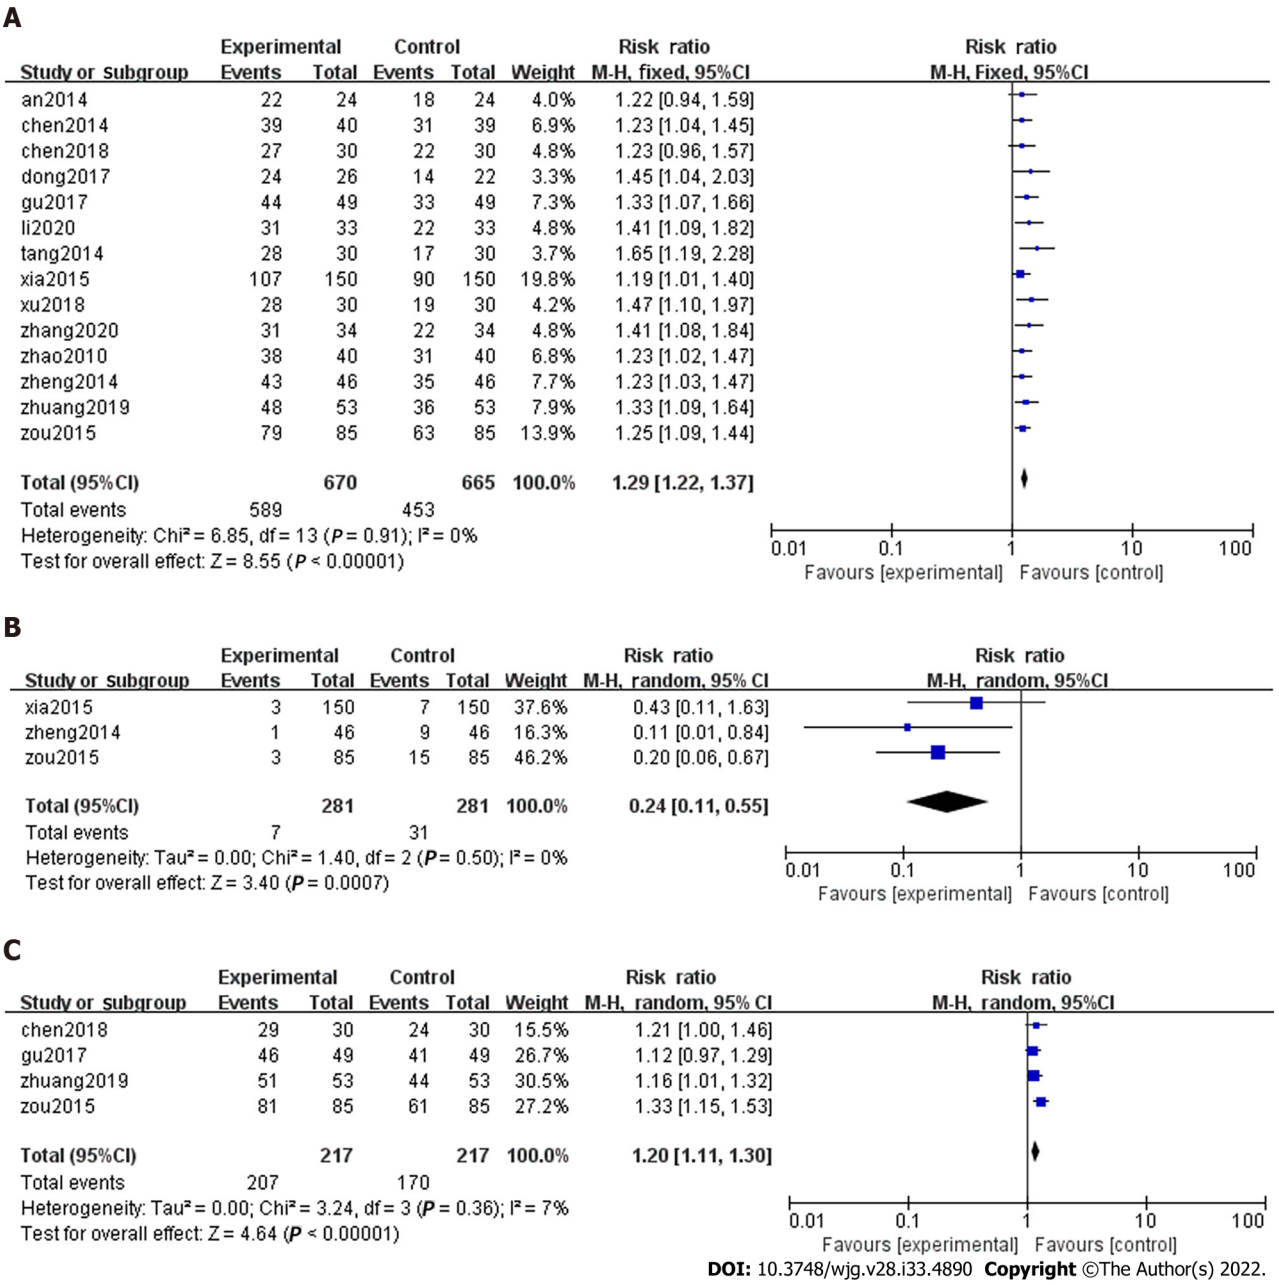
								0.815		163 more per 1000 (from 90 more to 244 more)		

[1]Randomized controlled trial design method is not reported.
[2]The risk of bias assessment is mostly "unclear risk" because there are not enough details in articles.
[3]Studies come from China.
[4]There is significant heterogeneity between studies.



mentioned no prominent adverse events[34,29]. Three trials reported adverse events (Table 6); however, no study commented on methods used to manage these events.

GRADE evidence for the effect of SLBZD

GRADE results of SLBZD is shown in (Table 7). However, the quality of evidence was very low or moderate because of the poor methodological quality.

Network pharmacology results of SLBZS

Composition and targets of SCBZS: According to the OB > 30% and DL > 0.18 standard screening, we screened 189 ingredients, including seven in Baizhu (*Atractylodes macrocephala* Koidz), 15 in Fuling (Smilax glabra Roxb), 9 in Yiyiren [*Coix lacryma-jobi var.* ma-yuen (Rom.Caill.) Stapf], 22 in Renshen (*Panax ginseng* C.A.Mey), 15 in Shanyao (*Dioscorea oppositifolia* L), one in Baibiandou (*Lablab purpureus* subsp. purpureus), 11 in Lianzi (*Nelumbo nucifera* Gaertn.), 92 in Gancao (*Glycyrrhiza uralensis* Fisch. ex

DC), ten in Sharen (*Amomum villosum* Lour.), and seven in Jiegeng (*Platycodon grandiflorus*). The repeated components and components with no target were deleted, leaving 158 candidate components. Each candidate component's top 15 target genes were selected, and duplicated genes were identified, with 693 candidate target genes.

PPI network: The component-target network diagram of Shen-ling-bai-zhu Powder visually shows the interaction between pharmacodynamic components and target genes of Shen-ling-bai-zhu Powder (Figure 4B). The network contains 851 nodes with 2445 sides, among which 158 nodes represent candidate ingredients and 693 nodes represent candidate target genes related to drug candidate ingredients. The average number of neighborhood nodes was 5.561. There were 300 nodes and 3325 edges in the disease target interaction network, and the average number of neighborhood nodes in the network was 34.635. A total of 35 potential targets of SLBZS on chronic gastritis can be obtained by analyzing the component-target and disease target interaction networks. Figure 4C visually shows the interaction relationship between potential targets.

GO enrichment analysis and KEGG pathway enrichment analysis: The results of GO analysis showed that in the BP category, differentially expressed genes were concentrated in the regulation of reactive oxygen species metabolic process, response to oxidative stress, cellular response to chemical stress, and

others. Differentially expressed genes are enriched in vesicle lumen, cytoplasmic vesicle lumen, and secretory granule lumen in the CC category. Differentially expressed genes are enriched in tyrosine kinase activity, protein serine/threonine kinase activity, and phosphatase binding (Figure 5A). KEGG pathway analysis results showed that the differentially expressed genes involved EGFR tyrosine kinase inhibitor resistance and the PI3K-Akt signaling pathway (Figure 5B, Figure 6).

DISCUSSION

Effectiveness and safety of a formula used for CG treatment were evaluated by us. We also summarized the possible pharmacological mechanisms based on collecting as many medical records as possible. Before our study, at least two systematic reviews[42,43] focused on the efficacy of Chinese herbal medicine formulas as CG treatments. However, neither of these reviews included SLBZS as an experimental intervention, and there are no animal studies of SLBZS for CG.

Analysis of the 14 RCTs suggested that SLBZS reverses *H. pylori* seropositivity and recurrence rates in patients with CG more so than in western medicine. SLBZS formula treats CG based on the current evidence. There were insignificant heterogeneity and publication bias. The safety is not yet established. The study designs were not rigorous, and the GRADE assessment presented moderate and low quality. Therefore, large numbers of rigorously designed RCTs are required to obtain conclusive evidence for the effect and safety of SLBZS for CG.

CG is a common digestive system disorder characterized by an inflammatory condition of the gastric mucosa. CG also leads to mental and psychological disorders like interpersonal sensitivity and depression[44]. On the one hand, studies demonstrated that the link between gut flora and depression is strong[45-47], and gut peptides are essential regulators of microbiota-gut-brain signaling in health and stress-related psychiatric illnesses[45]. On the other hand, intestinal flora can be transformed by TCM compounds[48]. Chinese medicine can regulate the composition and metabolism of intestinal flora and regulate intestinal flora by affecting the secretion of brain-gut peptide and monoamine neurotransmitters, thus improving depression behavior[47-49]. Hence, the anti-inflammatory effect of regulating gut microbiota could represent a complementary and alternative direction for CG with depression symptoms.

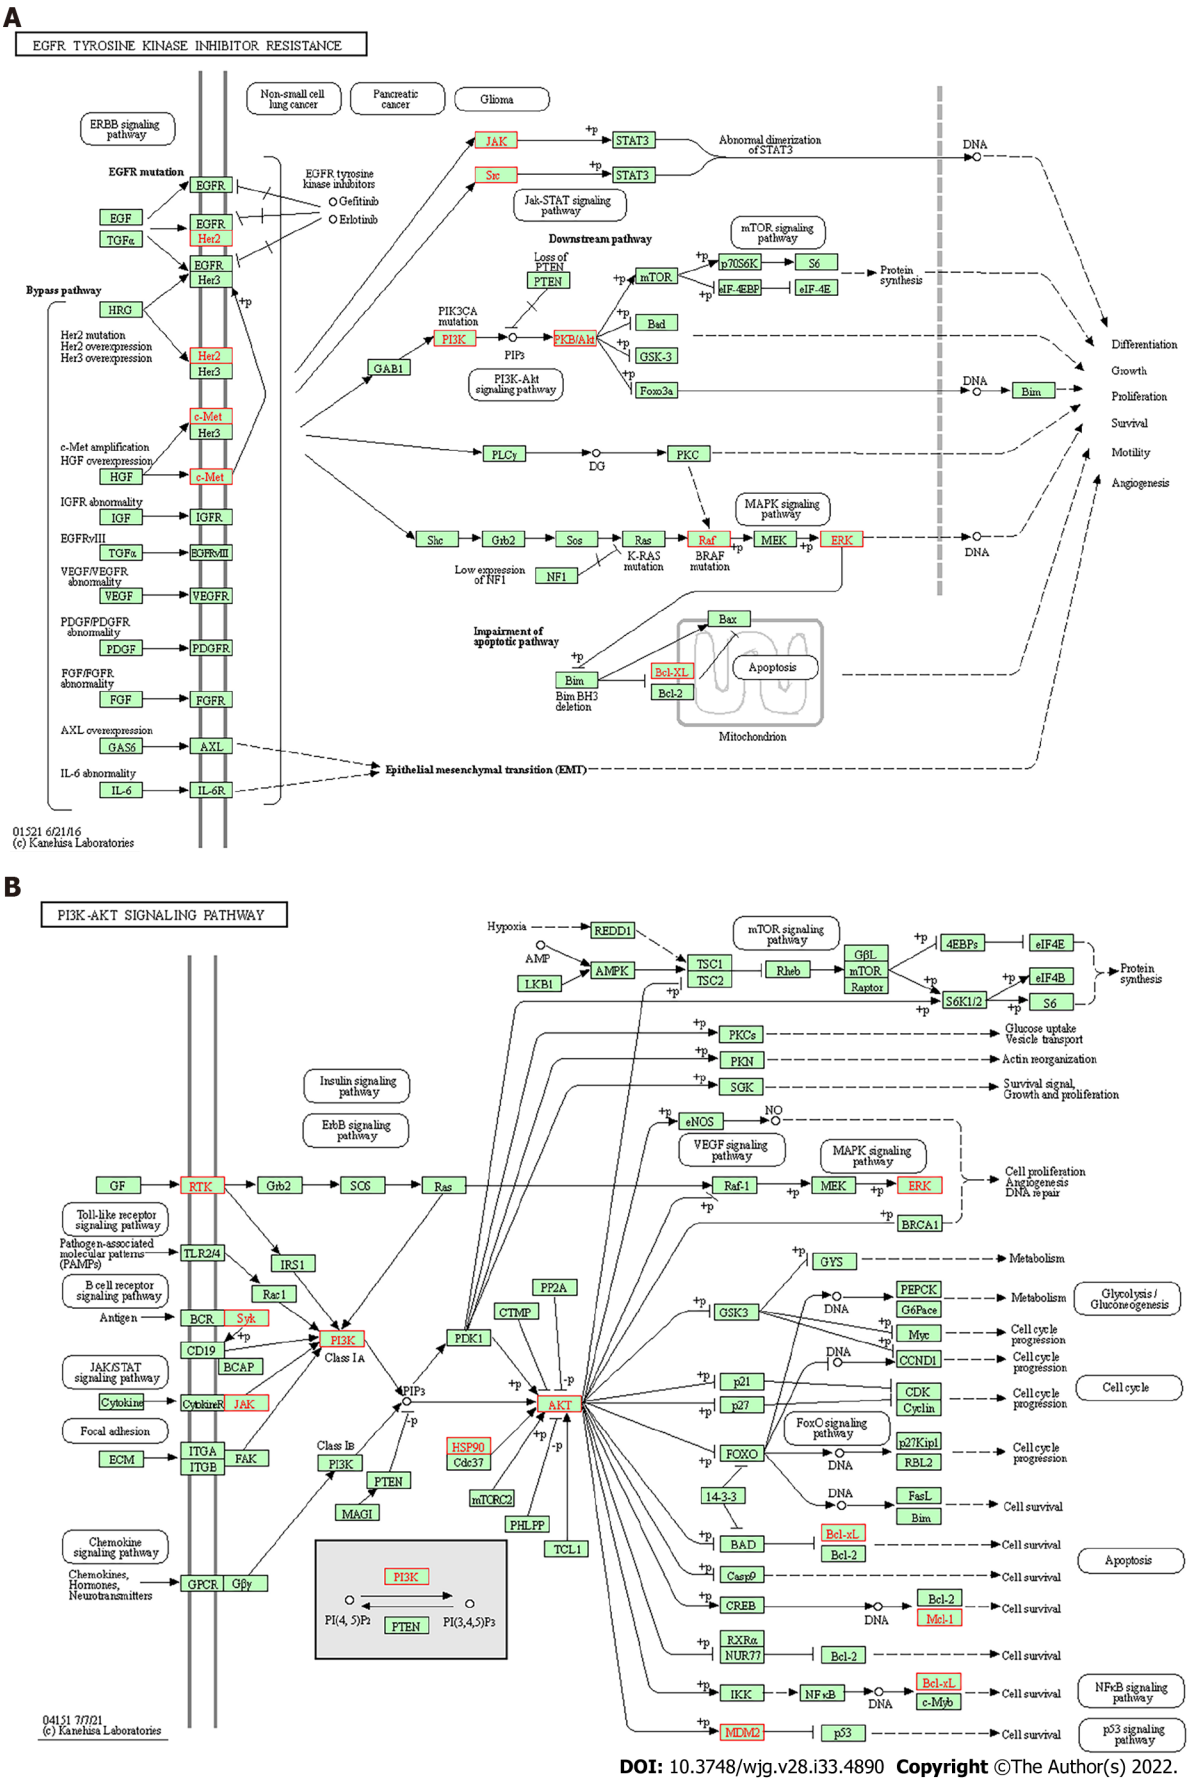
Figure 5 GO analysis and Kyoto Encyclopedia of Genes and Genomes enrichment analysis. A: GO analysis of the critical targets of Shen-ling-bai-zhu san (SLBZS) in treatment for chronic gastritis (CG); B: Kyoto Encyclopedia of Genes and Genomes enrichment analysis of the critical targets of SLBZS in treatment for CG.

Main pharmacological mechanisms

According to a study based on Chinese Medicine theory[50], the mechanism of TCM in treating CG is related to neuroprotective mechanisms, immune protective mechanisms, endocrine protective mechanisms, and other factors. A rat study showed that *Xiangshaliujunzi* decoction improved chronic atrophic gastritis symptoms by activating the TLR2, TLR4/MAPK/NF-κB/iNOS/NO signal pathway [51]. SLBZD reduced intestinal adenoma formation in adenomatous polyposis coli multiple intestinal neoplasia mice by suppressing hypoxia-inducible factor 1α-induced CD4 + CD25 + forkhead box P3 regulatory T cells[19]. Nevertheless, the mechanisms of SLBZS in CG have not been clarified.

In the present study, based on the network pharmacology analysis of drug and disease targets, a collateral relationship revealed the mechanism of SLBZS in the treatment of CG. First, we identified candidate target genes of SLBZS. Then, a protein interaction data network was generated, from which we obtained 36 related protein targets. The most protein targets included SRC, MAPK14, PPARG, and ERBB2. Critical GO entries were included regulation of reactive oxygen species metabolic process, response to oxidative stress, cellular response to chemical stress, protein tyrosine kinase activity, protein serine/threonine kinase activity, phosphatase binding, and others. Key signal pathways were identified in the KEGG enrichment analysis, primarily in EGFR tyrosine kinase inhibitor resistance, the PI3K-Akt signaling pathway, and others.



A study found that alterations in gastric cell stress-adaptive mechanisms due to *H. pylori* appear crucial during chronic infection[52]; therefore, response to oxidative stress of SLBZS to improve CG symptoms may determine the mechanism. In a future study, we will combine chemical analysis with network pharmacology to study the pharmacological effects of complex formulations comprehensively. The candidate target proteins and the formula's active ingredients are predicted by analyzing the corresponding networks. The chemical ingredients may be fully identified through experiments to confirm their presence in the formula. Therefore, further animal and clinical experiments are needed for research and exploration.

Limitations

This study had many limitations: (1) Only small sample sizes Chinese-language RCTs were included, and there were some defects in research design that resulted in the low or moderate quality of evidence; (2) most studies had design flaws like it focused only on results without illustrating a specific implementation of the random method, blind method, and follow-up reporting; (3) despite using validated documents supporting effectiveness assessment criteria, our non-uniform efficacy evaluation approach might influence outcomes and results. It might be challenging to employ the same effectiveness assessment criteria for each trial, as these criteria varied with each update; (4) adverse effects and recurrence rates information is rare reported; (5) the dosage of SLBZS has not been standardized and unified, and therefore the reasonable dosage was difficult to determined; (6) the pharmacology mechanism is unclear, especially the specific analysis of active ingredients and side effects; and (7) conflicts of interest of study investigators or funders may influence the risk of bias due to missing results. None of our included studies clearly reported their Chinese herbal sources, particularly whether pharmaceutical companies provided support. It is difficult to determine whether there were conflicts of interest. Presentation of herb sources in future studies could help determine bias.

CONCLUSION

This meta-analysis included 14 RCTs and summarized the clinical efficacy and potential mechanisms of the Chinese herbal formula SLBZS in treating CG. However, the methodological quality of the studies was not high, the risk of relapses and adverse reactions was underreported, and related mechanisms lacked validation; therefore, rigorous RCTs and basic science studies should be designed further to determine a definitive association between SLBZS and CG.

ARTICLE HIGHLIGHTS

Research background

The effects and safety of Shen-ling-bai-zhu san (SLBZS) are currently unclear.

Research motivation

A 2012 clinical practice guideline recommended SLBZ Powder for the Pattern of Spleen and Stomach Deficiency CG. The 2020 clinical guideline did not recommend SLBZS, possibly because of inadequate clinical evidence and pharmacological mechanisms. We designed our study to focus on evidence of efficacy and potential mechanisms. This controversy needed clarified.

Research objectives

To determine the clinical evidence and potential mechanisms of SLBZS for the treatment of CG.

Research methods

Evidence-based meta-analysis and network pharmacology methods.

Research results

Fourteen articles were eventually included, covering 1335 participants. SLBZS might treat CG by acting on related targets and pathways such as EGFR tyrosine kinase inhibitor resistance, the PI3K-Akt signaling pathway, and others.

Research conclusions

SLBZS might be useful in treating CG, but its long-term effects and specific clinical mechanisms keep unclear.

Research perspectives

More samples and high-quality clinical studies should be tested and verified in the next step.

Abstract

BACKGROUND

Liver cirrhosis is the leading cause of liver-related mortality worldwide. It is currently a global health challenge.

AIM

This research intended to explore and analyse research trends and frontiers in this field during the last 10 years, providing new inspiration for clinical decision-making and scientific research.

METHODS

Publications on hepatic cirrhosis research were retrieved from the Web of Science Core Collection on April 4, 2021. Bibliometric visualisation was conducted through VOSviewer and CiteSpace.

RESULTS

The analytic research was based on original articles and reviews. A total of 7775 records of hepatic cirrhosis published from 2011 to 2020 were retrieved. In the past ten years, the number of related annual publications has increased significantly, especially in the United States and China. All publications were distributed among 109 countries. The United States contributed the most (21.95%) and was consistently the leading driving force, with a solid academic reputation in this area. The University of Barcelona distributed the most related articles (177

articles) and was cited the most frequently. The *Journal of Hepatology* ranked third in the top 10 journals, which has the highest impact factor (impact factor 2019 = 20.582). Jasmohan S. Bajaj was the most productive author (72 articles). Burst keywords (*e.g.*, sofosbuvir, burden, care, sarcopenia, chronic liver failure, human gut microbiome, and nonalcoholic fatty liver disease) and a succession of reference citation bursts have provided clues about research frontiers in recent years.

CONCLUSION

This study identified developing trends in the evolution of liver cirrhosis to provide new inspiration for researchers.

Key Words: Liver cirrhosis; Bibliometric research; Research frontiers; VOSviewer; CiteSpace; Visualization

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: This research explored and analyzed research trends and frontiers in this field during the last 10 years, further providing new inspiration for scientific research. We found sarcopenia, human gut microbiome, and nonalcoholic fatty liver disease are of particular interest in studies of cirrhosis. Treatment of diseases that cause cirrhosis, such as hepatitis C, is also a hot topic.

INTRODUCTION

Liver cirrhosis is a common clinical chronic progressive disease with high mortality caused by one or more factors. It is the fifth leading cause of adult deaths, the top cause of liver-related death worldwide [1], and the eighth of the primary diseases in economic cost[2]. Cirrhosis is a heterogeneous disease classified into two prognosis stages: compensated cirrhosis and decompensated cirrhosis[3]. In the early stage, due to the essential liver compensatory function, there are no visible symptoms. Later, the primary symptoms are liver function impairment and portal hypertension, and multiple systems are affected. Ascites, upper gastrointestinal haemorrhage, secondary infection, hepatic encephalopathy, canceration, and other complications are common in the late stage. Thus, cirrhosis is a high-burden treatment option for patients, health care systems, and the government.

Bibliometric research is a quantitative analytic method that employs mathematics and statistics to determine scientific activity[4]. It can help researchers identify the research focus and trends of a particular subject. In addition, the research results may be beneficial to future research.

Professor Chen (Drexel University) created CiteSpace V, a Java-based information visualisation program for bibliometric analysis. Researchers may assess a discipline's evolution and identify frontier trends intuitively by providing numerous data in the form of knowledge maps[5]. CiteSpace has recently been used for bibliometric analysis in various fields; however, there is yet to be a bibliometric analysis of cirrhosis. In this study, we first used CiteSpace V to analyse articles on liver cirrhosis from 2011 to 2020 utilizing the Web of Science Core Collection (WoSCC) database, providing new inspiration for clinical decision-making and scientific research.

MATERIALS AND METHODS

Data collection and search strategy

Data were retrieved from the WoSCC on a single day, April 4, 2021. WoSCC offers extensive citation index information for over 8000 influential and famous journals globally. It is a comprehensive database, notably in natural science and medicine. The following were included in the search strategy: title = "cirrhosis," database selected = Web of Science Core Collection, time span = 2011–2020. Only original articles and reviews were included. We obtained 7775 records for this study. A flowchart representing the retrieval strategies is shown in Supplementary Figure 1. In addition, high-quality references were retrieved and cited by the Reference Citation Analysis (https://www.referencecitation-analysis.com/) database.

Analysis tool

For bibliometric analysis, Microsoft Excel 2016, VOSviewer, and CiteSpace were chosen. Information on authors, journals, institutions, and countries may be integrated with these computer systems. Parameters such as article count, impact factor (IF), centrality, and occurrence/citation burst were utilized in this article. Productivity was measured by the number of articles published and was used to identify productive individuals or groups. The IF was obtained using Journal Citation Reports (JCR). The IF is a recognized metric for assessing a journal's impact worldwide. The IF in this study was based on JCR (2019). The network visualisation maps were constructed using VOSviewer to examine the cooperative relationships between countries and institutions with highly cocited references. Coauthorship analysis identifies research output. We selected "countries" and "organizations" as the unit of analysis. CiteSpace V adopts a time slicing technique to create a timeline of network models and integrates these individual networks to produce an overview network for the systematic analysis of the relevant publications. In this study, we utilized CiteSpace V to conduct a cocitation analysis of the references and clusters. After that, a timeline view of cocited references was built. As a result, we were able to clarify the origin and period of certain clustering fields[6]. These parameters help identify potential collaborative relationships in the field of liver cirrhosis. Furthermore, an occurrence burst denotes a word that appears often over a specific period, whereas a citation burst denotes a reference that is referenced frequently during a specific period[7]. Keywords and references with the highest citation bursts were selected to demonstrate research hot spots and frontiers because they can identify whether relevant scholars have paid extensive attention to these areas in a specific period[5].

RESULTS

Publication output and temporal trend

A total of 7775 publications satisfied the search criteria. Table 1 lists the top-10 cited articles in descending order based on the number of citations. Figure 1A depicts the global distribution of yearly publications on cirrhosis research from 2011 to 2020. The overall worldwide publishing trend rose from 520 to 955 between 2011 and 2020. However, during the periods of 2015-2017 and 2019-2020, the number of publications showed a modest decrease. The annual publication trends of the top 10 academic output countries are presented in Figure 1B. The number of publications on cirrhosis published by the United States and China has increased remarkably within the last decade.

Distribution by country and institution

All of the publications come from 109 countries and 6902 institutions. The distribution of countries/regions that published no fewer than 100 papers is shown in Supplementary Figure 2. Table 2 contains detailed information on the top 10 countries. The United States had the most publications (1707 publications), followed by China (1672 publications) and Japan (711 publications). Among the top 10 countries, France exhibits high academic quality, and its citation/article ratio (46.67) was far greater than that of other listed countries.

Using VOSviewer, we constructed a network visualisation map for liver cirrhosis research publications to assess international collaborations. Collaborations between countries and institutions are depicted in Supplementary Figure 3. Nodes with higher co-occurrence were classified as the same colour. Nodes with similar colours formed one cluster, indicating that they had closer cooperative relationships. The width of the lines describes the magnitude of the collaboration. As shown, the United States had the highest total link strength, suggesting that it cooperated most with other countries worldwide. The country that collaborated the most with the United States was China. The most productive institutions are listed in Table 3. The University of Barcelona (177 publications) ranked first, followed by Virginia Commonwealth University (120 publications) and University College London (119 publications). The cluster coloured in green was led by the University of Barcelona, collaborating most with Virginia Commonwealth University. Furthermore, three of the top 10 institutions are in the United States, two are in China, and two are in Italy, suggesting that these three countries have many outstanding research groups in this field.

Distribution by journals and authors

Liver cirrhosis research articles were published in 1511 journals. The number of articles in the top 10 journals ranged from 119 to 259, accounting for 22.73% of the total (1767) (Supplementary Table 1). Among these journals, *Liver International* contributed the highest number of publications on cirrhosis research (259 publications, IF 2019 = 5.175), followed by *Hepatology* (242 publications, IF 2019 = 14.679) and *Journal of Hepatology* (212 publications, IF 2019 = 20.582). *Journal of Hepatology* had the highest IF, and its citation/article ratio (68.30) was far more than that of other listed journals. The most frequently cited journal was *Hepatology* (14922 citations). The following most frequently cited journals were *Journal of Hepatology* (14479 citations) and *Liver International* (5721 citations).

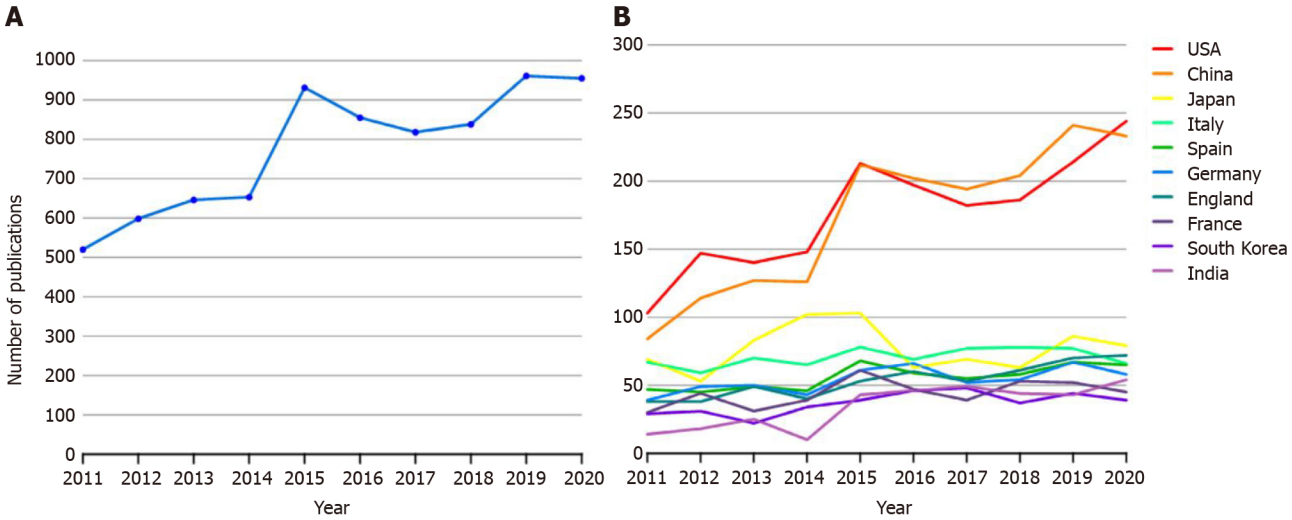
8	France	391	18247	46.67
9	South Korea	310	5077	16.38
10	India	302	3661	12.12



A total of 35653 authors contributed to the overall output. The most productive authors are listed in Supplementary Table 2. Jasmohan S. Bajaj published 72 articles, ranking first in the number of publications, followed by M. Eric Gershwin (70 articles) and Qi Xingshun (61 articles). Pere Gines had the highest citation/article ratio (89.27), followed by Paolo Angeli (74.07) and Guadalupe Garcia-Tsao (69.13).

Analysis of keywords

Figure 2 shows the top 25 keywords with the strongest occurrence burst. The occurrence burst, which demonstrated a sharp rise over a certain period, referred to frontier disciplines and dynamic changes in

Table 3 The top 10 institutions that published articles on cirrhosis research

Rank	Institutions	Number of articles	Number of citations	Country
1	University of Barcelona	177	11087	Spain
2	Virginia Commonwealth University	120	5826	United States
3	University College London	119	5134	England

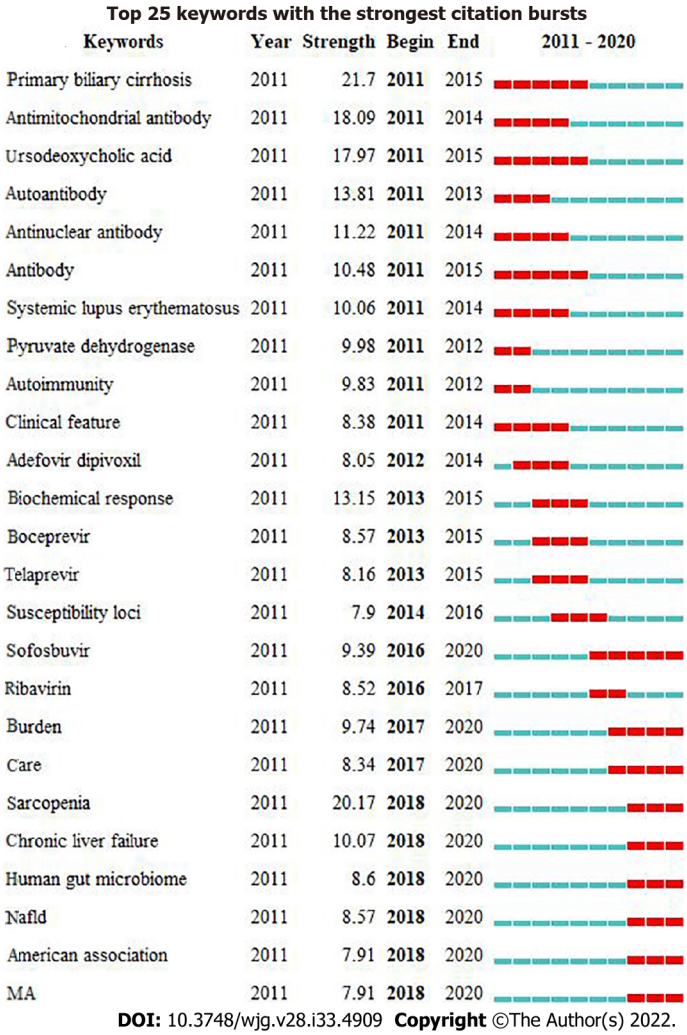
Figure 1 Trends in the number of publications and analysis of countries in the field of cirrhosis. A: The annual worldwide publication output; B: The annual publication output for the top 10 countries.

a particular field. Hot topics were represented by keywords whose occurrence burst lasted until 2020. The most recent burst keywords were "sofosbuvir" (2016–2020), "burden" (2017–2020), "care" (2017–2020), "sarcopenia" (2018–2020), "chronic liver failure" (2018–2019), "human gut microbiome" (2018–2020), "nonalcoholic fatty liver disease (NAFLD)" (2018–2020), "American association" (2018–2020), and "ma" (2018–2020).

Analysis of references

In bibliometric research, reference analysis is an important indication. The pieces of literature with the strongest citation burst are considered to be the knowledge fundamentals of the research frontiers. Clusters along horizontal timelines are depicted in Figure 3, which is a timeline visualisation in CiteSpace. From left to right, each cluster is presented. The publication time legend is displayed at the top. The clusters were arranged vertically and in declining order of size. The largest cluster is presented at the top. Cocitation linkages are shown by the stained curves. Large-sized nodes were especially concerning since they were highly cited. The most cited references in a given year are displayed under each timeline. Clusters were numbered from 0. Cluster #0 was the largest cluster. As shown in the timeline overview, the largest cluster in this study was #0 acute kidney injury, indicating a significant research interest and direction in recent years. This was followed by #1 hepatitis C, #2 clonal selection theory, #3 hepatic encephalopathy, #4 Liver cirrhosis, and #5 variceal bleeding. Some clusters remained active until 2020. Figure 4 depicts cirrhosis-related references with the strongest citation burst during the last 10 years. Citation bursts until the end of 2020 were led by de Franchis *et al* (2015), who had the strongest burst (40.22), followed by Garcia-Tsao *et al* (2017), Tsochatzis *et al* (2014), Vilstrup *et al* (2014),



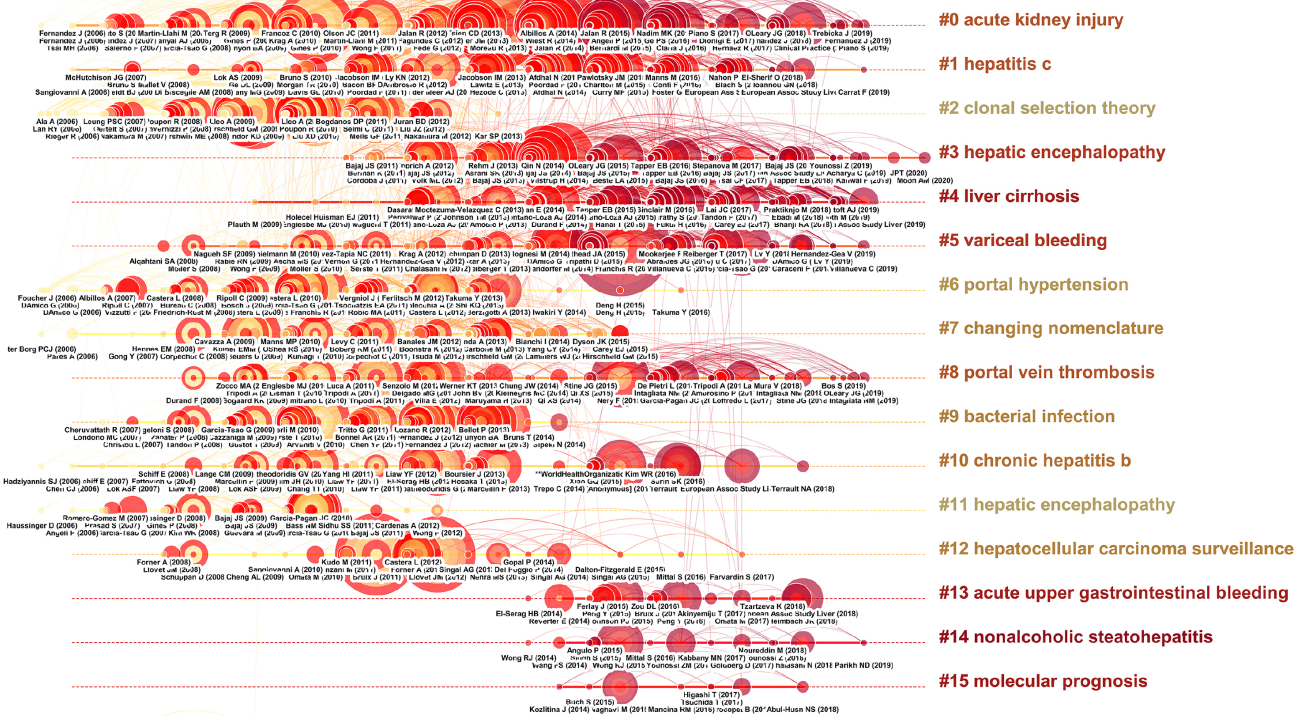


Figure 2 Keywords with the strongest occurrence burst on cirrhosis research.

Mokdad *et al* (2014), Albillos *et al* (2014), Jalan *et al* (2014), and Heimbach *et al* (2018).

DISCUSSION

Liver cirrhosis is a chronic disease with high mortality and is a serious public health problem, afflicting more than 160 million people globally in 2017[8]. The most common cause is chronic viral hepatitis, specifically hepatitis B virus (HBV) and hepatitis C virus (HCV)[3,9]. Previous studies have shown that the prevalence of liver cirrhosis varies by region. East Asia has the most significant prevalence of liver cirrhosis. In contrast, Southern Latin America has the lowest incidence of 12.1%[9]. Furthermore, the worldwide incidence of liver cirrhosis is increasing continuously, and it ranks eighth in terms of economic cost among significant diseases[2], even though various public health measures have been implemented. As a result, to better comprehend the advanced research hotspots in the field of cirrhosis, a study is necessary.

From the retrieved data, we can easily conclude that the general research trend of liver cirrhosis has been growing, especially in China and the United States. Eight of the top 10 countries that most produce related research were developed countries, while 2 were developing countries. The United States had the most publications, followed by China and Japan, and India ranked last. In 2017, among individuals with prevalent liver cirrhosis worldwide, HBV infection accounted for approximately 28.72%. East Asia has the highest prevalence of liver cirrhosis. China had the world's greatest number of patients. Therefore, China and India rank among the top 10 countries in terms of the occurrence of liver cirrhosis and may be relevant for these potential causes. However, in terms of citations per article, although China temporarily ranked in the top position in number of articles, it still has a long way to go to improve the overall quality of articles. China must continue to increase research in this area and strengthen collaborations with other countries. In contrast, although only a few French articles were published, they were of high academic quality.

Figure 3 A timeline visualization of the largest clusters.

Nine of the top 10 institutions were universities, suggesting that universities are the most common research groups. Three of the top 10 institutions were from the United States (Virginia Commonwealth University, Mayo Clinic, and University of California, Davis); thus, the United States is the main domain in the field. Two of the top 10 institutions were from China (Capital Medical University and Zhejiang University), and two institutions were from Italy (the University of Padua and University of Milan). According to the findings of this analysis, the three countries have numerous great research groups in this area.

In this study, we found some great research works from some excellent authors. They made significant contributions to this discipline. For example, Guadalupe Garcia-Tsao ranked 7th among the top 10 authors, and her practice guideline of portal hypertensive bleeding in cirrhosis also ranked among the top 10[10]. Her study effort provides academic researchers and clinical professionals with a better and deeper understanding of risk stratification, diagnosis, and management of portal hypertensive bleeding in liver cirrhosis. Moreau *et al*[11] analysed data from patients with cirrhosis and acute decompensation (AD) to establish diagnostic criteria for acute-on-chronic liver failure (ACLF), which he discovered was distinct from AD. In addition, his research demonstrated that ACLF mortality is linked to loss of organ function and high leukocyte counts and that ACLF is particularly severe in individuals with no prior history of AD.

CiteSpace V was used to detect keyword bursts in this study. These statistics are potentially valuable in forecasting research frontiers. The keywords "sofosbuvir," "burden," "care," "sarcopenia," "chronic liver failure," "human gut microbiome," and the "NAFLD" are expected to appear often in the following years, indicating emerging trends. The top five cirrhosis frontiers are as follows: (1) Sarcopenia: The skeletal muscle is the body's largest organ, and atrophy comes from a change in the balance of protein production and degradation towards protein breakdown. Primary sarcopenia is a loss of skeletal muscle strength, mass, or physical function owing to ageing, whereas secondary sarcopenia is recognized as a loss of skeletal muscle strength, mass, or physical function due to underlying disorders. Liver cirrhosis is one of the representational disorders that might be complicated with secondary sarcopenia. In patients with cirrhosis, muscle mass loss worsens as their liver reserve deteriorates. Sarcopenia and frailty have a negative impact on clinical outcomes and prognosis. It has been convincingly demonstrated that patients with cirrhosis, sarcopenia, and frailty have a lower quality of life and survival, more cirrhotic complications and infections, and poorer outcomes following liver transplant surgery[12-14]. As a result, emphasis must be placed on early detection, active diagnosis, and treatment. Consequently, further investigations in the context of assessment criteria for sarcopenia and frailty are warranted to deepen our current knowledge of sarcopenia and frailty in patients with cirrhosis; (2) Chronic liver failure: ACLF, a clinical syndrome in patients with chronic liver disease, is more often discussed clinically. It is associated with multiple organ failure and increased short-term mortality. It is a significant cause of mortality in people with cirrhosis. Although the precise causative mechanism is

DOI: 10.3748/wjg.v28.i33.4909 **Copyright** ©The Author(s) 2022.

Figure 4 References with the strongest citation burst on cirrhosis research.

unknown, systemic inflammation plays a critical role in its pathogenesis, and the strength of this inflammatory response paralleled the severity of ACLF. Aside from organ failure and a very high risk of short-term death, patients with ACLF exhibited other characteristics that separated them from non-ACLF patients. They were, for example, younger, had more alcoholic cirrhosis and less HCV-related cirrhosis, and mainly had a higher frequency of active alcoholism and severe bacterial infections[11]. More research for new findings into the mechanisms underlying ACLF, risk prediction models, therapeutic targets, and liver transplantation for ACLF is needed; (3) Sofosbuvir: An oral nucleotide analogue inhibitor of the HCV-specific NS5B polymerase has been approved to treat chronic HCV infection. A study showed that ledipasvir-sofosbuvir for eight weeks was associated with a high rate of sustained virologic response among previously untreated patients with HCV genotype 1 infection without cirrhosis[15]. A recent article published in *The Lancet Gastroenterology & Hepatology* stated that ravidasvir plus sofosbuvir was effective in patients with chronic HCV infection. Furthermore, by offering a new affordable, simple, and efficacious public health tool for large-scale implementation, this treatment has the potential to eradicate HCV-related morbidity and mortality[16]; (4) Human gut microbiome: The function of gut microbiota in human health and disease has recently received much attention. Several chronic illnesses have been linked to the gut microbiota, such as obesity[17-19], inflammatory bowel disease[20], diabetes mellitus[21], and NAFLD[22]. Through the hepatic portal and bile secretion systems, the liver interacts directly with the gut. Enteric dysbiosis, namely, the translocation of bacteria and their products over the gut epithelial barrier, is involved in the development of liver cirrhosis. However, the phylogenetic and functional composition alterations in the human gut microbiota associated with this progression remain obscure[23]. Furthermore, research suggests that microbiome manipulation to eliminate manganese and reduce GABA levels in the gut might provide a novel therapeutic approach for treating hepatic encephalopathy[24]. In addition, novel probiotics may be helpful in the prevention of the aggravation of liver cirrhosis. More broadly, microbiome manipulation may offer up new pathways for the treatment of liver cirrhosis. A combination of microbial genes distinguishes patients with liver cirrhosis from healthy individuals with high specificity. This might pave the way for a novel method of monitoring and preventing liver cirrhosis; and (5) NAFLD: NAFLD is a

progressive liver disease spectrum encompassing simple steatosis, nonalcoholic steatohepatitis (NASH), fibrosis, and, eventually, cirrhosis. NAFLD is closely associated with characteristics of metabolic syndrome such as abdominal obesity, insulin resistance, glucose intolerance or type 2 diabetes (T2DM), and atherogenic dyslipidaemia[25]. Over the last few decades, people's lifestyles have become more sedentary, and dietary habits have changed, leading to an increase in the prevalence of obesity and insulin resistance[26,27]. In light of this, NAFLD quickly became the most common cause of abnormal liver biochemistry in both developed and developing countries. Several prior epidemiological studies have identified a strong association between NAFLD and an elevated risk of developing T2DM. In addition, patients with NAFLD, whether adults or adolescents, have several risk factors for cardiovascular disease. A notable minority proportion of NAFLD patients proceed to a more severe disease characterized by NASH and fibrosis and cirrhosis or, in some circumstances, progress to hepatocellular carcinoma[28]. The mechanisms linking NAFLD to the diseases mentioned above and the current pharmacological treatments for NAFLD need to be further explored.

The articles with the strongest citation burst are potentially valuable for exploring research frontiers. In this study, #0 acute kidney injury was the largest cluster, and #3 hepatic encephalopathy remained active until the most recent publication year for a cited reference. References with the top three citation bursts were as follows: (1) de Franchis *et al*[29] contributed to the writing of expanding consensus in portal hypertension, further elaborating the stratifying risk and individualizing care for portal hypertension; (2) Garcia-Tsao *et al*[10] coauthored a practice guideline and elaborated the risk stratification, diagnosis, and management of portal hypertensive bleeding in cirrhosis; and (3) Tsochatzis *et al*[30] reviewed the current understanding of cirrhosis as a dynamic process and outlined therapeutic options for preventing and treating complications of cirrhosis based on the subclassification in clinical stages. Meanwhile, we proposed a new concept for managing patients with cirrhosis and the challenge in the 21st century.

Limitations

To the best of our knowledge, this study was the first bibliometric analysis of cirrhosis in the past ten years. This study, however, has certain limitations. First, we considered the WoSCC database a reputable and reliable service for publications and citations; hence, we extracted data only from it. This may restrict the coverage of all available articles and result in a reduced number of documents included in the analysis. Second, the search method may also have been insufficient because we only searched for publications with the phrase "cirrhosis," which may have resulted in a paucity of papers due to other terminology. Finally, we analysed the data selectively. We mainly utilized a quantitative analysis approach, while little emphasis has been paid to the qualitative aspects of this study. As a result, certain critical points and details may have been missed. All of the considerations mentioned above may lead to bias in the results. Hence, the results should be interpreted with caution.

CONCLUSION

This study might aid researchers in identifying new trends in cirrhosis from 2011 to 2020, thus, providing new inspiration for scientific research.

ARTICLE HIGHLIGHTS

Research background

Liver cirrhosis is a common clinical chronic progressive disease with high mortality caused by one or more factors.

Research motivation

Identifying new trends in cirrhosis from 2011 to 2020, thus, providing new inspiration for scientific research.

Research objectives

This research intended to explore and analyse research trends and frontiers in this field of cirrhosis during the last 10 years.

Research methods

Using VOSviewer and CiteSpace, assess a discipline's evolution and identify frontier trends intuitively by knowledge maps.

Research results

The general research trend of liver cirrhosis has been growing, especially in China and the United States. The keywords "sofosbuvir," "burden," "care," "sarcopenia," "chronic liver failure," "human gut microbiome," and the "NAFLD" are expected to appear often in the following years, indicating emerging trends. The top five cirrhosis frontiers are Sarcopenia, Chronic liver failure, Sofosbuvir, Human gut microbiome and Nonalcoholic fatty liver disease.

Research conclusions

This study identified developing trends in the evolution of liver cirrhosis to provide new inspiration for researchers.

Research perspectives

The top five cirrhosis frontiers are sarcopenia, chronic liver failure, sofosbuvir, human gut microbiome and nonalcoholic fatty liver disease.

Abstract

BACKGROUND

Ectopic bronchogenic cysts are a type of congenital cystic tumor that are extremely difficult to diagnose and can be ectopically located in various organs, with the possibility of malignant transformation. Here we report a case of an ectopic bronchogenic cyst in the liver initially misdiagnosed as a gallbladder diverticulum.

CASE SUMMARY

The patient was a middle-aged woman whose chief complaint was intermittent pain in the upper abdomen. Imaging examination revealed a cystic space in the left inner lobe of the liver. She was admitted to our hospital for treatment. Based on abdominal examination and imaging findings, the initial diagnosis was gallbladder diverticulum with cholestasis combined with chronic cholecystitis. However, following intraoperative observations and postoperative pathologic assessment, the diagnosis was revised to ectopic bronchogenic cyst of the liver.

CONCLUSION

Radiologists, hepatobiliary and pancreatic surgeons, gastrointestinal surgeons, urologists, and even neurosurgeons should be aware and consider a possible diagnosis of ectopic bronchogenic cysts, especially when other types of cyst, cystadenoma, and other diseases are excluded. The disease and its complications should be detected and correctly diagnosed and treated as early as possible in order to avoid adverse outcomes.

Key Words: Ectopic bronchogenic cyst; Misdiagnosis; Gallbladder diverticulum; Benign tumor; Cystadenoma; Case report

Core Tip: Ectopic bronchogenic cysts are the rarest type of bronchogenic cyst and can be ectopically located in different organs. When various specialists diagnose cysts, cystadenomas, and other diseases, the possibility of ectopic bronchogenic cyst should not be discounted. We report a case of an ectopic bronchogenic cyst in the liver that was misdiagnosed as gallbladder diverticulum. Early surgical intervention is the most effective strategy to prevent disease transformation.

INTRODUCTION

A bronchogenic cyst is a rare congenital cystic tumor that can generally be classified as one of three types—namely, intrapulmonary, mediastinal, and heterotopic (the most rare)[1-3]. Bronchogenic cysts often develop ectopically in the neck, retroperitoneum, and stomach wall; very few cases of ectopic cysts in the liver have been reported[4]. Ectopic bronchogenic cysts often have no specific clinical manifestations, imaging characteristics, or changes in laboratory indices, making preoperative diagnosis extremely difficult. The cysts are typically discovered during routine physical examinations or because of complications resulting from the compression of surrounding organs or tissues. Here we report a case of an ectopic bronchogenic cyst in the liver that was preoperatively diagnosed as cholecystic diverticulum with cholestasis.

CASE PRESENTATION

Chief complaints

A 40-year-old woman presented with intermittent upper abdominal pain.

History of present illness

Physical examination at the primary hospital revealed a space-occupying lesion above the gallbladder in the left inner lobe of the liver that was complicated by chronic cholecystitis. The patient was transferred to our hospital for further treatment.

History of past illness

The patient was physically fit.

Personal and family history

Her family history was noncontributory.

Physical examination

A physical examination of the abdomen showed no muscle tension, tenderness, or rebound pain. No abdominal mass was detected; the liver was not touched under the ribs, and the Murphy sign was positive.

Laboratory examinations

Laboratory examinations including routine blood and blood coagulation, liver function, biochemistry, tumor markers, and infection markers revealed no abnormalities.

Imaging examinations

Abdominal color Doppler ultrasound showed a cystic echo beside the gallbladder in the left inner lobe of the liver with a size of 3.2 cm × 1.6 cm. The boundary was clear, the ultrasound transmission was poor, a bile mud echo was observed, there was no blood flow signal, and there appeared to be a

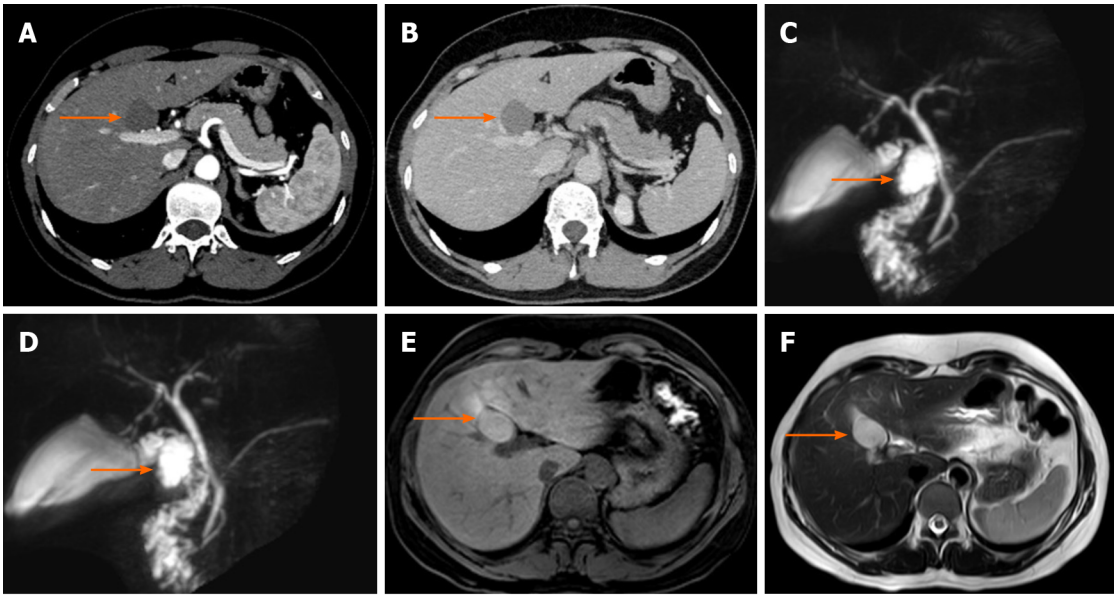
connection with the neck of the gallbladder. Gallbladder diverticulum with cholestasis and chronic cholecystitis was suspected. Hepatobiliary, pancreatic, and splenic multi-slice plain computed tomography (CT) scanning and 3-phase enhanced scans showed an elliptical low-density shadow above the gallbladder in the left inner lobe of the liver, with a CT value of about 55 HU. Intrahepatic bile ducts were not dilated. The gallbladder was not enlarged but the wall was slightly thickened, and there was no abnormal density in the cavity. The cystic space-occupying lesion above the gallbladder in the left inner lobe of the liver strongly suggested gallbladder diverticulum with cholestasis. Magnetic resonance cholangiopancreatography (MRCP) was performed to determine the relationship between the lesion and the gallbladder. There was an oval abnormal signal in the gallbladder fossa area about 2.9 cm × 2.0 cm in size. T1-weighted imaging (T1WI) and T2-weighted imaging (T2WI) and diffusion-weighted imaging showed a high-signal shadow and the apparent diffusion coefficient was consistent with a slightly high-signal shadow; the edges of the shadow were thin, smooth, and clear, and there was no enhancement at the lesion center. The lesion appeared to be connected to the cystic duct given the limited fluid signal shadow in the gallbladder fossa area of the intrahepatic lobe (Figure 1).

FINAL DIAGNOSIS

Based on the patient's symptoms, abdominal examination, and imaging findings, the initial diagnosis was gallbladder diverticulum with cholestasis combined with chronic cholecystitis. However, based on intraoperative findings and postoperative pathologic results, the diagnosis was later confirmed as ectopic bronchogenic cyst in the liver.

TREATMENT

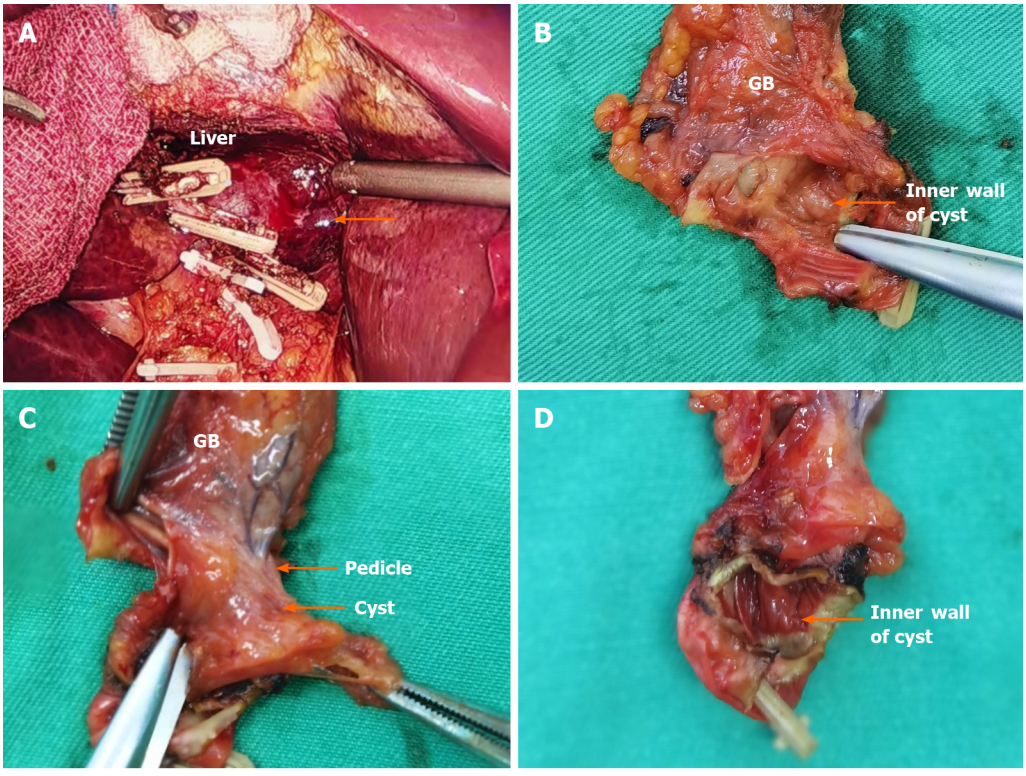
The patient underwent laparoscopic cholecystectomy and cystectomy of the left inner lobe of the liver. During the operation, it was observed that the cyst and gallbladder were connected to a pedicle but not to each other. Dark green bile was drained from the gallbladder, and light yellow turbid fluid was observed inside the cyst (Figure 2).



OUTCOME AND FOLLOW-UP

After the operation, we carried out a pathologic examination on the excised specimen. The outer part of the cyst was connected to the gallbladder; the volume was 2 cm × 2 cm × 2 cm, the wall thickness was 0.1-0.2 cm, and the inner wall was smooth and light brown. The cyst wall was fibrous under microscopic examination, with visible muscle tissue. Part of the mucosal epithelium on the inner surface was absent, and the remaining inner surface was partly lined with pseudostratified ciliated columnar epithelium and mucous epithelium. Serous and mucous glands were observed in the lamina propria, consistent with bronchogenic cysts. The intraoperative findings combined with histopathologic examination refuted the preoperative diagnosis of gallbladder diverticulum complicated by cholestasis (Figure 3). No recurrence was found in the color Doppler ultrasonography 6 mo after the operation.

DISCUSSION



Ectopic bronchogenic cysts can occur at any age, with similar prevalence in men and women. There are few specific manifestations but clinical symptoms can arise when a cyst compresses nearby organs or tissues. For example, a patient developed new abdominal pain and gross hematuria that may have been caused by the aggravation of a lump originating from the left adrenal gland[5]; the pain was intermittent, which may have been related to chronic cholecystitis. Similarly, ectopic bronchogenic cysts have no special imaging findings. Magnetic resonance imaging (MRI) examinations often show isointense shadows on T1WI and high-intensity shadows on T2WI that are not enhanced by the contrast agent. However, in some patients, both T1WI and T2WI show significant enhancement[6]. In our patient, T1WI showed a slightly high-signal shadow and T2WI showed a high-signal shadow; a retrospective analysis of the MRI findings was more suggestive of ectopic bronchogenic cysts, which are associated with elevated levels of the tumor markers carcinoembryonic antigen, carbohydrate antigen (CA)19-9, and CA72-4[7,8].

In countries where bronchogenic cysts are endemic, they are often associated with hydatid disease [9]. The diagnosis and differential diagnosis of ectopic bronchogenic cysts is extremely difficult and they are often confused with other types of cyst and serous or mucinous cystadenoma. The pathogenesis of ectopic bronchogenic cysts in the abdominal cavity is complex and diverse. It has been proposed to

Figure 2 Gross examination of the surgically excised ectopic bronchogenic cyst. A: The gallbladder and cyst were removed under laparoscopy, revealing the smooth wound surface (orange arrow) connecting the cyst and liver; B: The inner wall of the cyst. The cyst contained light yellow turbid liquid; C: The cyst was connected to the gallbladder *via* a pedicle; D: Inner wall of the cyst.

originate in the embryonic foregut, which develops from the primordial malformed trachea and bronchial tree in the early embryo; bacteria shed from this structure migrate to the caudal side of the foregut, which forms the abdominal organ or retroperitoneal bronchus cyst. The thoracic and abdominal cavities are thought to be connected in the early embryonic stage. At 6 wk of gestation, the pleura and

Figure 3 Histopathologic examination by hematoxylin and eosin staining. The cyst wall was fibrous and muscle tissue was visible. The mucosal epithelium of the inner surface of the cyst wall was partially detached, and the remaining inner surface was partly lined with pseudostratified ciliated columnar epithelium (orange arrow) and mucous epithelium. Serous and mucous glands were observed in the lamina propria (green arrow). A: 4 ×; B: 10 ×; C: 20 ×; D: 40 ×.

peritoneum fuse and develop into a mature diaphragm. The body cavity is divided into the mature thoracic cavity and abdominal cavity. The abdominal buds of the tracheobronchial tree are squeezed and migrate into the abdominal cavity at the same time, leading to ectopic bronchogenic cysts in the abdominal cavity[10]. Clarifying the detailed mechanism underlying the development of bronchogenic cysts will facilitate their detection, diagnosis, and treatment.

Most ectopic bronchogenic cysts require surgical removal, and histopathologic examination of surgical specimens must be performed to confirm the diagnosis. Immunopositivity for cytokeratin (CK)7 and thyroid transcription factor 1 and immunonegativity for CK20 and calretinin in the epithelial lining also strongly support a diagnosis of bronchogenic cysts[7,11]. In terms of treatment, as ectopic bronchogenic cysts can be ectopic to different organs, the speed at which they develop and their biological behaviors vary[1,2]. Ectopic bronchogenic cysts are also easily confused with cystic diseases of adjacent organs, patients with bronchogenic cysts or suspected ectopic bronchogenic cysts should be examined by a surgeon, especially when the cyst is small as it may be missed. Thus, immunohistochemistry is useful when bronchial cysts cannot be differentially diagnosed based on histology and microscopic examination alone, and excision by using laparoscopy or robotic surgery and histopathology remain the first choices for treatment and definitive diagnosis[12].

CONCLUSION

Ectopic bronchogenic cysts are a congenital cystic tumor that are extremely difficult to diagnose and can be ectopically located in various organs, and have a risk of malignant transformation. Radiologists, hepatobiliary and pancreatic surgeons, gastrointestinal surgeons, urologists, and even neurosurgeons should be aware of these cysts. During diagnosis and treatment of a suspected cyst or cystadenoma, the possibility of ectopic bronchogenic cysts should be considered. The disease and its complications should be detected and diagnosed and treated as early as possible to avoid adverse consequences.

Abstract

We reviewed a study addressing the development and validation of a prediction model for moderately severe and severe acute pancreatitis in pregnancy. We identified some statistical deficiencies in this article. In addition, we believe that the role of cholesterol as a predictor should be described in more detail.

Key Words: Acute pancreatitis; Prediction model; Statistical analyses; Cholesterol

TO THE EDITOR

We were pleased to read the high-level article published by Yang *et al*[1]. In this article, the authors developed and validated a nomogram with good accordance for the prediction of moderately severe and severe acute pancreatitis in pregnancy (MSIP). The authors reported a nomogram that incorporated numerous blood indices for albumin, lactate dehydrogenase, triglyceride, and cholesterol levels, thus facilitating the early individualized prediction of the severity of acute pancreatitis in pregnancy

(APIP). This study is of great significance for the clinical management of APIP. However, in our opinion, this article has some problems that need to be discussed further.

First, we found that some data that were not suitable for this article. In the result sections, we noticed that 134 patients were classified as having mild acute pancreatitis in pregnancy (MAIP) and 56 as having MSIP. However, Figure 1 (https://www.wjgnet.com/1007-9327/full/v28/i15/WJG-28-1588-g001.htm) and Table 1 (https://www.wjgnet.com/1007-9327/full/v28/i15/1588-T1.htm) showed that the number of patients with MAIP and MSIP was 136 and 54, respectively. This inconsistency should be addressed.

In addition, there are problems associated with the statistical analyses in that the methods used for statistical analyses should be described in more detail. In Table 1 (https://www.wjgnet.com/1007-9327/full/v28/i15/1588-T1.htm) and Table 2 (https://www.wjgnet.com/1007-9327/full/v28/i15/1588-T2.htm), the authors should provide more accurate statistical values, including Student's *t*-values or χ^2 values, instead of just providing *P* values. Most of the variables mentioned by the authors in Table 1 (https://www.wjgnet.com/1007-9327/full/v28/i15/1588-T1.htm) and Table 2 (https://www.wjgnet.com/1007-9327/full/v28/i15/1588-T2.htm), such as cholesterol and platelets, are not labeled with units of measurement. Moreover, *P*-values were not listed in the statistical results for "trimester of pregnancy on admission".

In the Discussion section, the authors mentioned that hypercholesterolemia is a known risk factor for cardiovascular diseases. In fact, high-density lipoprotein (HDL) and non-HDL cholesterol have opposite associations with cardiovascular diseases[2], and plasma HDL cholesterol concentrations correlate negatively with the risk of cardiovascular diseases[3]. The authors mentioned that cholesterol is a predictive factor for MSIP, and the cholesterol levels of patients with MAIP and MSIP were 7.34 ± 5.63 and 12.80 ± 6.64, respectively, in Table 1 (https://www.wjgnet.com/1007-9327/full/v28/i15/1588-T1.htm). The authors mentioned some previous studies in their Discussion section. We took a close look at these studies and found that only one recent study[4] showed that low levels of total cholesterol (TC) and high TC within 24 h of admission were independently associated with an increased risk of severe acute pancreatitis. Other studies[5-7] have suggested that serum levels of HDL cholesterol are inversely correlated with disease severity in patients with predicted severe acute pancreatitis. However, this study showed that cholesterol is a predictive factor for MSIP but not HDL. This is a confusing statement. We believe that the present study is inconsistent with previous studies and that the role of cholesterol as a predictor should be more clearly described.

ABOUT COVER

Editorial Board Member of *World Journal of Gastroenterology*, Abhinav Vasudevan, BMed, MPH, FRACP, PhD, Staff Physician and Medical Lead in Inflammatory Bowel Diseases, Department of Gastroenterology and Hepatology, Eastern Health, Box Hill 3128, Australia

AIMS AND SCOPE

The primary aim of *World Journal of Gastroenterology* (*WJG*, *World J Gastroenterol*) is to provide scholars and readers from various fields of gastroenterology and hepatology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online. *WJG* mainly publishes articles reporting research results and findings obtained in the field of gastroenterology and hepatology and covering a wide range of topics including gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, gastrointestinal oncology, and pediatric gastroenterology.

INDEXING/ABSTRACTING

The *WJG* is now abstracted and indexed in Science Citation Index Expanded (SCIE, also known as SciSearch®), Current Contents/Clinical Medicine, Journal Citation Reports, Index Medicus, MEDLINE, PubMed, PubMed Central, Scopus, Reference Citation Analysis, China National Knowledge Infrastructure, China Science and Technology Journal Database, and Superstar Journals Database. Abstract

Despite stringent selection criteria, hepatocellular carcinoma recurrence after liver transplantation (LT) still occurs in up to 20% of cases, mostly within the first 2–3 years. No adjuvant treatments to prevent such an occurrence have been developed so far. However, a balanced use of immunosuppression with minimal dose of calcineurin inhibitors and possible addition of mammalian target of rapamycin inhibitors is strongly advisable. Moreover, several pre- and post-transplant predictors of recurrence have been identified and may help determine the frequency and duration of post-transplant follow-up. When recurrence occurs, the outcomes are poor with a median survival of 12 mo according to most retrospective studies. The factor that most impacts survival after recurrence is timing (within 1–2 years from LT according to different authors). Several therapeutic options may be chosen in case of recurrence, according to timing and disease presentation. Surgical treatment seems to provide a survival benefit, especially in case of late recurrence, while the benefit of locoregional treatments has been suggested only in small retrospective studies. When systemic treatment is indicated, sorafenib has been proved safe and effective, while only few data are available for lenvatinib and regorafenib in second line. The use of immune checkpoint inhibitors is controversial in this setting, given the safety warnings for the risk of acute rejection.

Key Words: Liver transplantation; Hepatocellular carcinoma; Immunosuppression; Recurrence; Surgical treatment; Locoregional treatment; Systemic treatment

Core tip: Hepatocellular carcinoma (HCC) is becoming the most common indication for liver transplantation (LT). The problem of tumor recurrence after LT, that occurs in up to 20% of cases, is becoming of increasing interest. We reviewed of the available literature on HCC recurrence after LT. The best preventive measures still rely on pretransplant selection criteria, since no dedicated follow-up guidelines exist and no post-LT adjuvant treatments are available. When recurrence occurs, the prognosis is poor. However, aggressive surgical treatment, particularly in the case of late recurrence, may provide a significant survival benefit.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common liver cancer and the fourth leading cause of cancer-related mortality[1,2]. From the time of its initial developments in the early 1960s, liver transplantation (LT) appeared as the ideal cure for HCC on liver cirrhosis because of the perspective to cure at the same time both the tumor and the underlying liver disease. However, the first experiences were disappointing with many authors reporting 5-year survival < 40%, mainly because of recurrences of the primary tumor[3-6]. A retrospective review of these discouraging results progressively led to the observation that survival of patients was directly related to the stage of HCC at the time of LT. This was the basis on which a prospective study was conducted in Milan applying *a priori* restrictive criteria for the selection of HCC candidates for LT (namely a single nodule ≤ 5 cm or two or three nodules ≤ 3 cm, each with no macrovascular invasion at pretransplant imaging). The seminal paper published in 1996 demonstrated that LT under such criteria achieved better long-term results than any other therapy, with outcomes similar to LT for nononcological indications[7]. The so called Milan criteria (MC) were subsequently validated by many other groups reporting 5-year survival rates of ≥ 70%, and became the benchmark for selecting patients with HCC for LT. Pooled recurrence rates have been reported to be around 8% for patients within MC *versus* 28% for patients beyond these criteria, according to a recent meta-analysis[8]. Thus, HCC recurs in a proportion of recipients who are within MC, while LT may provide cure for some patients who are beyond these criteria. When recurrence occurs, survival is poor and post-LT HCC recurrence is the factor that most affects long-term outcomes in this setting. Considering that HCC represents the most common indication for LT in the USA, and that since the introduction of direct antiviral agents against hepatitis C virus the proportion of patients undergoing LT for HCC is increasing worldwide[9,10], the problem of tumor recurrence will probably affect a growing number of patients. However, to date, treatment of HCC recurrence following LT is largely understudied and dedicated guidelines are lacking. The aim of this paper is to provide a review of the current evidence on therapeutic strategies for patients with HCC recurrence after LT.

PREVENTION OF POST-LT HCC RECURRENCE

Tumor recurrence may be linked to remaining (previously undetected) extrahepatic HCC at the time of LT, or result from the post-LT engraftment of circulating HCC clones[11]. It is extrahepatic in 50%–60% of cases, with lung, bones and adrenal glands being the most frequently affected sites[12]. Timing of HCC recurrence is variable, but in most cases it occurs within 3 years after LT. Early recurrence (< 1 year after LT) is associated with a significantly worse prognosis, while later recurrence might result in better outcomes and even in cure in selected cases[13].

Prevention of recurrence through selection criteria

Considering that the risk of post-LT recurrence is strictly related to pretransplant HCC stage and treatment, recurrence is firstly prevented by the application of pre-LT selection criteria able to identify patients at higher risk. Proposals for expansion of MC have been initially developed using tumor morphology, namely size and number of nodules. In fact, these factors have been demonstrated as surrogate markers of microvascular invasion (MVI) and/or poor tumor differentiation, which are the principal determinants of biological aggressiveness and therefore of the risk of post-LT recurrence[14]. Expanded criteria increased the acceptable size and number of HCC nodules with respect to MC, but the considerable heterogeneity coupled with differences in accuracy of liver imaging techniques

probably represent the greatest limitation of criteria based only on morphology.

To overcome these limits, criteria incorporating serum markers as surrogates of biological tumor features such as α-fetoprotein (AFP) have been proposed. In particular, by combining the morphological characteristics of the tumor and AFP values it was possible to develop selection criteria for LT definitively exceeding MC, while even decreasing the risk of post-LT recurrence[15,16]. A strategy combining tumor burden with the assessment of response to pre-LT locoregional treatment (LRT) as a marker of favorable tumor biology has gained broader acceptance[17]. For patients beyond MC, a common strategy is to downstage patients by means of LRT or surgical therapy. In fact, patients successfully downstaged within accepted criteria share the same prognosis as patients within the criteria *ab initio* and so far[18], response to therapies appears as one of the best surrogates of favorable tumor biology and thus an optimal selection tool for candidates for LT[17,19,20]. Patients progressing in the pre-LT period despite LRT have significantly worse post-LT outcomes with respect to patients with stable or responding disease. Finally, tumor differentiation, MVI, presence of circulating cancer cells and genomic markers have also been suggested as selection criteria for LT, but these assessments require biopsy, which might induce tumor seeding. Furthermore, it is well known that tumors are heterogeneous and show areas of varying degrees of differentiation and genomic features.

Post-LT surveillance

Considering that post-LT recurrence is mostly asymptomatic, and that early detection of recurrence may have a positive impact on long-term outcomes, post-LT surveillance has an important role in this setting. However, no guidelines from the major Hepato-bilio-pancreatic societies are available and surveillance protocols are mostly center-specific, often with a high heterogeneity between centers as recently reported[21]. Few retrospective studies on post-LT surveillance have been published to date, and several questions regarding frequency, duration, and imaging modality for a cost-effective surveillance remain open.

For imaging modality, cross-sectional imaging of the abdomen [with either multiphase computed tomography (CT) or magnetic resonance imaging] and noncontrast lung CT scan allow detection of the most frequent sites of recurrent HCC[21,22]. Cross-sectional imaging of the brain, bone scintigraphy or positron emission tomography–CT are indicated only in case of clinical suspicion and not on a regular basis, while it seems reasonable to check for AFP levels at each surveillance visit even if no data is available to support this indication.

Given that the majority of recurrences occur within the first 3 years after LT, there is general agreement to indicate surveillance imaging and visits more frequently in this time frame (*i.e.*, every 4–6 mo) and yearly thereafter[22]. Some authors suggest interrupting surveillance after 5 years. However, recurrences (either *de novo* tumors or true recurrences) have been repeatedly reported up to 10–15 years after LT[23]; considering that late HCC relapse is associated with a better prognosis with respect to earlier events and that it is sometimes curable, it seems reasonable to prolong yearly surveillance for at least ten years.

Ideally, frequency and duration of surveillance would be based on the assessed risk of post-LT HCC recurrence. Several proposals have been made in this sense, and the RETREAT score[24] (that includes AFP at LT, presence of MVI and sum of maximum size + number of vital nodules) is the most recent and promising predictor in terms of discriminative power and validation on a large scale registry. However, no prospective validation is available to date, and the cost-effectiveness of a surveillance program based on the risk of recurrence has yet to be demonstrated.

The impact of surveillance programs on post-recurrence survival has been scarcely studied. A recent multicenter study on 232 patients who experienced HCC recurrence found that increasing number of post-LT surveillance scans (with cut-off at three surveillance scans within the first 2 years) was associated with improved survival and possibility of undergoing potentially curative treatments[25].

Role of immunosuppression

Improvements in the management of immunosuppression reduced rejection episodes favoring long-term graft survival; calcineurin inhibitors (CNIs) tacrolimus and cyclosporine played a fundamental role in this improvement. However, several studies demonstrated that CNI exposure is associated with an increased risk of tumor recurrence with a dose-dependent effect[26]. It is likely that the immunosuppression induced by CNIs prevents the immune system from detecting and destroying circulating or dormant HCC cells and therefore, dosage of CNIs should be maintained with the aim of balancing this risk without increasing the risk of rejection episodes.

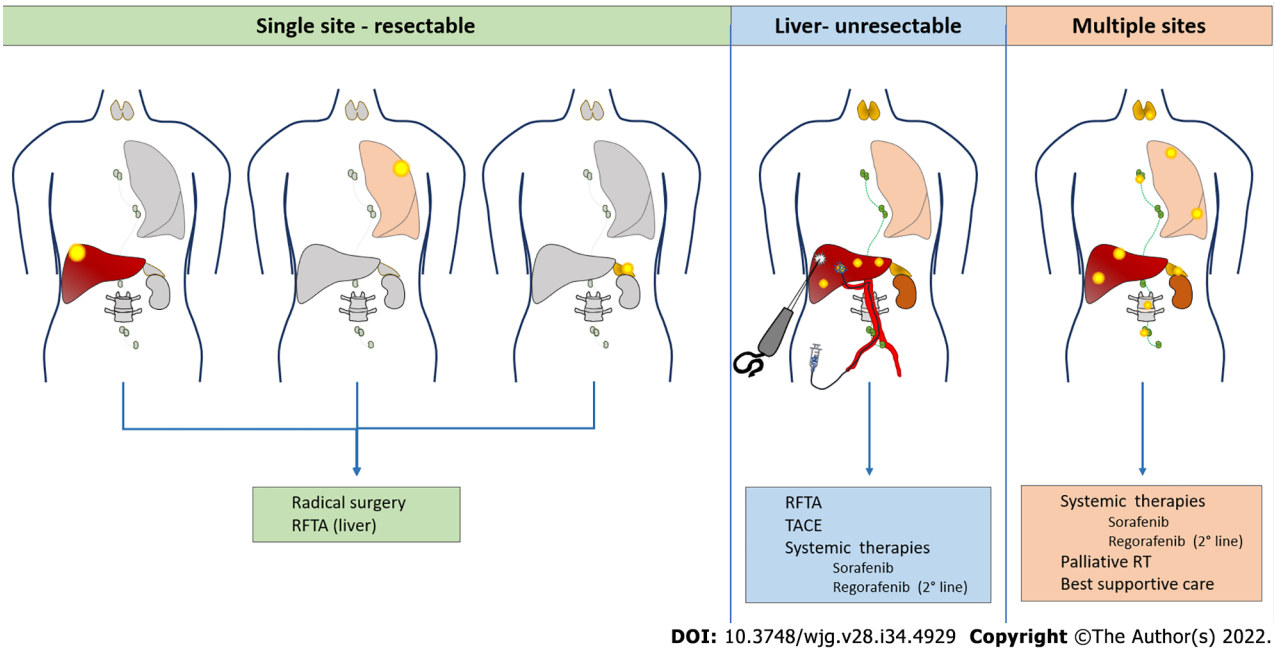
Mammalian target of rapamycin inhibitors (mTORis) sirolimus and everolimus are another class of immunosuppressants targeting some HCC pathways, which showed antiangiogenic and antiproliferative effects in experimental models[27]. Data from retrospective studies and meta-analyses suggest that, compared to CNIs, the use of mTORis reduces the risk of post-LT HCC recurrence and increases long-term survival. In the most recent meta-analysis including 23 comparative studies [17 observational and 6 randomized controlled trials (RCTs)] with 6495 patients, recurrence-free survival (RFS) was significantly increased with mTORi-based therapy at 1 and 3 years with a nonsignificant increase at 5 years[28]. Overall survival (OS) was also significantly improved, as well as recurrence rate being lower in the mTORi arm without differences based on the type of mTORi. However, only one RCT that

compared post-LT immunosuppression containing mTORi (sirolimus) *versus* not containing mTORi [29]. In this international RCT of 525 patients there appeared to be an advantage in the sirolimus group regarding RFS in the first 3–5 years. However, this benefit was subsequently lost with further follow-up and the trial failed to meet the primary endpoint of demonstrating a significant reduction of recurrences in the mTORi-containing immunosuppression group.

Adjuvant treatments after LT

Several attempts had been performed with chemotherapy as an adjuvant treatment to prevent HCC recurrence after LT[30,31]. HCC is a chemoresistant tumor; therefore, cytotoxic systemic therapies have failed to provide any consistent benefit in this setting and have been abandoned in the last decade[32]. Sorafenib, an oral multikinase inhibitor that shows significant improvement in survival of patients with advanced HCC, has been tested in small studies in the setting of adjuvant treatment for HCC after LT. Despite some initial signs of efficacy, with one phase I study showing a significant reduction in the risk of HCC recurrence with a maximum tolerable dose of sorafenib 200 mg twice daily[33], other single-center case series failed to confirm these data and to date no RCTs are available. Lenvatinib, a more recent targeted therapy for advanced HCC, has not been prospectively tested in the adjuvant setting; a small retrospective case series confirmed an acceptable drug safety and patient tolerance but did not show any significant reduction in terms of HCC recurrence[34]. Immune checkpoints inhibitors (ICIs) have emerged as a treatment option for advanced-stage HCC. No studies are available on ICIs as post-LT adjuvant treatment. A recent systematic review and pooled analysis reviewed 14 patients receiving ICIs for recurrent disease after LT for HCC: 11 of them (78.6%) died, and graft rejection was the cause of death in five cases (45.4%). The high rejection rate raises the question of safety of ICIs in transplanted patients, even in the setting of overt recurrence[35]. Thus, to date, no anticancer treatments can be recommended to prevent HCC recurrence after LT, and it is unlikely that they will become available in the near future.

TREATMENT OF POST-LT HCC RECURRENCE



Literature concerning the efficacy of each treatment modality is scarce, with the many limitations related to the small number of patients included, the frequent use of combined treatment and the different patterns of recurrence, all acting as confounding factors. In the majority of cases (50%–60%) recurrence is extrahepatic and affects the following sites: lungs (40%–60%), bones (25%–30%), adrenal glands (10%), lymph nodes (10%) and peritoneum (10%)[12]. Liver-only recurrence occurs in 15%–40% of patients, while combined liver and extrahepatic recurrence accounts for 30%–40% of cases. The therapeutic options clearly depend on location, multifocality and clinical presentation of recurrence (Figure 1).

Surgery

Liver resection is safe and provides a survival benefit in case of intrahepatic oligorecurrence[36,37], with a median survival of 28–65 mo observed for patients receiving surgery, compared to 5–15 mo in those receiving systemic treatment only[38-41]. Surgical treatment is feasible in 25%–50% of cases with higher morbidity rate (60%–80%) with respect to primary liver resections[42-44], mainly because of the risk of infections in the context of immunosuppression.

Sapisochin *et al*[39] retrospectively analyzed 121 patients with HCC recurrence after LT, finding that not being amenable to resection or ablation was an independent predictor of poor prognosis [hazard ratio (HR) = 4.7, 95% confidence interval (CI): 2.7–8.3). An Italian multicenter study analyzed 21 patients with recurrence and reported a significantly better 4-year survival rate in patients treated with surgical resection for intra- and extrahepatic recurrence compared to those with unresectable disease (57% *vs* 14%, P = 0.02)[45]. In another series of 106 patients, treatment for recurrent HCC most commonly included chemotherapy (73.5%), surgical resection (23.3%), external beam radiation (13.6%), and ablation (3.9%), with the majority of patients receiving nonsurgical therapies (59.2%). The highest survival rates at 3 years were observed in patients receiving surgical therapy alone (60%), followed by patients receiving both surgical and nonsurgical therapy (37%), patients receiving only nonsurgical therapy (11%), and patients receiving no treatment (0%)[40]. Time from LT to recurrence is one of the most important prognostic factors, and patients with late recurrence show more favorable 5-year outcomes survival with resection compared to those of patients who recur earlier[46].

Surgery may enhance long-term survival also in patients with pulmonary recurrences amenable to resection, with 5-year survival rates ranging from 34% to 44% in those undergoing metastasectomy[47-52]. A benefit from surgical treatment is also reported for other sites of recurrence in smaller case series, including vertebrae[53], adrenal glands[54,55], lymph nodes[56], peritoneum[57] and pharynx[58]. In patients with multiple recurrences, some benefits have also been gained from repeated resections, probably reflecting less aggressive tumor biology[41].

Figure 1 Hepatocellular carcinoma recurrence after liver transplantation: Treatment possibilities according to disease presentation. RT: Radiotherapy; RFTA: Radiofrequency thermal ablation; TACE: Transarterial chemoembolization.

Locoregional therapies

Radiofrequency ablation (RFA) for liver recurrences may be proposed with a curative intent for small lesions, with the advantages of a percutaneous approach. In a retrospective single-center series, Huang *et al*[44] compared 15 patients with post-LT HCC recurrence treated surgically with 11 patients treated with RFA. This study demonstrated similar 5-year OS (35% for surgery *vs* 28% for RFA) but a tendency to a worse 5-year disease-free survival in the RFA group (16% *vs* 0%). Another study evaluating safety and efficacy of microwave ablation on a series of 11 patients found this technique safe and tolerable, with a 15.8% rate of local tumor progression after treatment and 15.3% survival at 2 years[59].

Multifocal intrahepatic recurrences may be amenable to transarterial chemoembolization (TACE). The largest series collected 28 patients treated by conventional TACE[60]. There were no significant post-treatment complications and the targeted tumor reduced in size by ≥ 25% in 19 patients (67.9%). However, intrahepatic recurrence or extrahepatic metastases occurred in 26 patients (92.9%) within 6 mo. The 3- and 5-year survival rates following TACE were 6% and 0%, respectively, with a mean survival time of 9 mo. A single-center retrospective investigation compared 14 patients treated with TACE with 14 matched controls who did not receive TACE but chemotherapy, radiotherapy or supportive care. Eight of the 14 patients treated with TACE (57%) showed partial tumor response and had a significantly longer survival compared to those who did not[61].

Systemic therapies

The effectiveness of systemic therapies for HCC recurrence following LT is largely unstudied because these patients have been routinely excluded from clinical trials. Sorafenib has been increasingly administered for treatment of post LT recurrences, and some data have been collected in the literature regarding its safety and efficacy in this setting. In a case–control study from Sposito *et al*[62], sorafenib provided improved median survival after HCC recurrence untreatable by surgery or LRT with respect to best supportive care (10.6 *vs* 2.2 mo). A meta-analysis published 2 years later reported a pooled 1-year survival of 36% (range 18%–90%)[63]. The main limitation of sorafenib in transplanted patients is toxicity, often leading to dose reduction, as reported by several studies[62,64]. Close monitoring is warranted for these patients, particularly in case of immunosuppression with mTORis, since this association may lead to severe adverse events[65-70]. Regorafenib may be proposed as a second-line treatment in case of progression under sorafenib[71]. In a recent multicenter study, second line treatment with regorafenib after sorafenib discontinuation provided a median survival of 13.1 mo compared with 5.5 mo with best supportive care in post-LT HCC relapse[72]. Recently approved tyrosine kinase inhibitors (lenvatinib[73] and cabozantinib[74]) and monoclonal antibodies (ramucirumab[75]) will soon be introduced in clinical practice also for the treatment of post-LT recurrence, giving us the opportunity to collect data about their efficacy and toxicity in this setting[76]. Currently, immunotherapy is changing the landscape of systemic therapies for HCC[77-79], but its safety after LT represents a point of concern, since ICIs may cause allograft rejection and other serious adverse events[80-85].

FACTORS IMPACTING SURVIVAL AFTER HCC RECURRENCE

Studies evaluating the outcome of patients with post-LT HCC recurrence mostly consist of small and heterogeneous series burdened by significant biases in terms of transplant criteria, availability of different treatments and patients' selection to curative and palliative options[86]. Survival of post-LT HCC recurrence is dismal and significantly worse than relapse after resection (median OS around 12 mo *vs* nearly 2 years in transplanted and resected patients, respectively), and immunosuppression is a potential driver of such a difference[87,88]. A number of factors have an impact on survival, and there is a small subset of patients with more favorable prognosis in whom curative treatments may be undertaken. Table 1 summarizes the results of studies evaluating the prognostic factors and outcome of treatment for HCC relapse after LT.

Time to recurrence and primary tumor features

Several studies showed that time from LT to recurrence has a primary role on outcomes, with early relapse being associated with poor prognosis either when defined as occurring within 6 mo[89-93], 1 year[39,94,95] or 2 years[96]. Many factors related to the primary tumor biology and aggressiveness affect time to recurrence and/or post-relapse survival: size (with cutoffs > 30 or > 50 mm)[45,97], staging outside MC[45], bilobar spread[97], absence of peritumoral capsule[45], poorly differentiated tumors[91,94,95], total tumor volume[92], presence of micro- or macrovascular invasion and pre-LT lymphocyte to neutrophil ratio[39,40,91,92]. The use of mTORi in the post-LT setting seems to be related to better post-recurrence outcomes, as shown both in eastern and western series[93,95]. Moreover, a history of graft rejection has also been associated with improved outcomes, possibly due to more active anticancer immunity[92].

It has been suggested that the observed difference in outcomes between early and late recurrences lies in different underlying biological mechanisms. However, this does not turn into a difference in the site of recurrence. In fact, occurrence of extrahepatic, combined intra- and extrahepatic or intrahepatic relapses do not seem to be different in early *versus* late recurrences[97]. While early relapses may be due to undetected extrahepatic metastases or circulating HCC clones implanting in a target organ during or soon after LT, late recurrences are possibly related to a second hit leading to late engrafting of HCC cells remaining latent during the initial post-LT period. In the latter, immunosuppression may also play a role[23]. As for intrahepatic late relapses, a further mechanism to be considered is *de novo* occurrence of HCC, usually arising in the context of chronic liver disease or cirrhosis due to recurrence of primary hepatitis, ischemic biliary injury or chronic rejection, several years after LT[98]. In such instances, results are expected to parallel those of nontransplant recipients with localized HCC, in which surgery or LRTs are effective in controlling the disease.

Pattern, features and resectability of recurrence

Aside from primary disease features, other studies have focused on the pattern of recurrence as a relevant prognostic factor for post-recurrence survival. As expected, limited disease spread with localized nodules (oligorecurrence), either hepatic or extrahepatic, has been associated to better outcomes than disseminated multifocal recurrence in several series[36-38,41,45,90]. In addition, a different prognostic impact of hepatic *versus* extrahepatic localization has been repeatedly reported. Hong *et al* showed that liver involvement as the first recurrence site was associated with worse survival, with fewer patients amenable to resection among intrahepatic rather than extrahepatic localizations[93]. A monocentric French series on 70 HCC recurrences also identified intrahepatic location as an unfavorable prognostic factor, which was confirmed in a Latin American series on 105 post-LT recurrences showing a lower probability of treatment in patients with hepatic relapses[41,94]. It may be speculated that this is related to the biological mechanism underlying tumor relapse, with recurrences due to undetected metastases at the time of LT more likely to occur at extrahepatic sites and associated with decreased burden as compared to circulating HCC clones, biologically more aggressive tumors, and being more likely to implant in the new liver. Of note, peritoneal and bone localizations were also reported as a poor prognostic factors[37,91,95]. Nevertheless, evidence deriving from several studies shows that the best outcomes are observed in patients with unifocal, often extrahepatic disease, easily amenable to surgical resection[36-38,41,45]. In the large series by Sapisochin *et al*[39] cited above, not being amenable to curative-intent treatment (resection or ablation) was an independent indicator of poor survival, together with AFP ≥ 100 ng/mL at the time of relapse. In another single-center study from the USA by Bodzin *et al*[40] on 106 recurrences, a prominent prognostic role of recurrence-related factors (AFP at relapse, > 3 nodules, maximum size of recurrence and bone spread) rather than primary disease features was shown. By combining such factors, a risk score model was built, with accurate stratification of recurrent patients into low-risk (median survival of 70.6 mo), medium-risk (12.2 mo) and high-risk (3.4 mo) subgroups.

Due to selection bias of surgical patients towards later recurrences, more favorable localizations, less aggressive disease and better performance status, the independent prognostic role of either recurrence pattern or resectability is questionable. The limited disease spread may make patients more likely to undergo surgical excision on the one hand, or simply reflect a different tumor biology, etiology, and

stage of recurrence on the other hand, as compared to more advanced cases of multifocal recurrence. Even when radical resection cannot be undertaken, it is widely accepted that any kind of treatment of recurrence has a positive prognostic impact. In the multicenter Latin American study, propensity score matching was used to evaluate the adjusted treatment effect considering selection bias. Patients treated with both sorafenib and surgery/TACE had better survival compared to the best supportive care regardless of time to recurrence[95]. Although randomized data are unlikely to be available in this context and retrospective comparisons are impaired by intrinsic differences between single site/oligometastatic and disseminated recurrence, surgical treatment remains an independent predictor of improved outcome following post-LT recurrence[37-39,41].

Serum markers

As for primary disease and post-LT outcome, AFP at recurrence as an indicator of disease spread, MVI and biological aggressiveness was frequently reported as a strong predictor of prognosis, with cutoffs varying from 100 to 1000 ng/mL[39-41,95]. The difference in survival for patients with high AFP was evident regardless of curative-intent treatment, confirming its value as a marker of unfavorable biological features, and its ability to guide the clinical management of patients affected by HCC recurrence. Finally, other biochemical markers at recurrence were associated with shorter survival: High bilirubin, possibly as a reflection of graft dysfunction, and low albumin, related to poor nutritional status as a general prognostic factor outlined in several series[96,99].

CONCLUSION

HCC recurrence after LT is still a dreadful event, occurring in up to 20% of cases. It might be prevented by stringent pretransplant selection criteria incorporating biological markers of aggressiveness (such as response to therapy, serum markers, histological factors) in addition to size and number of tumors. Several advances in this sense have been made in the last decade, allowing patients with HCC broader access to LT with more precise prediction of outcomes. In the post-LT period, surveillance should be driven by post-LT risk stratification, and the RETREAT score seems to be the best cost-effective approach. No adjuvant treatments after LT have been validated to prevent HCC recurrence; however, a balanced use of immunosuppression with minimal dose of CNIs and possibly the addition of mTORi is strongly advisable. Median post-recurrence survival is 12 mo: the interplay between time to recurrence (with a negative impact of earlier events) and the possibility of a radical treatment is the strongest determinant of survival.

Abstract

Gastroenteropancreatic neuroendocrine neoplasms (GEP-NENs) are rare tumors derived from the neuroendocrine cell system, which that have increased in incidence and prevalence in recent years. Despite improvements in radiological and metabolic imaging, endoscopy still plays a pivotal role in the number of GEP-NENs. Tumor detection, characterization, and staging are essential in management and treatment planning. Upper and lower gastrointestinal (GI) endoscopy is essential for correct localization of the primary tumor site of GI NENs. Endoscopic ultrasonography (EUS) has an important role in the imaging and tissue acquisition of pancreatic NENs and locoregional staging of GI neuroendocrine tumors. Correct staging and histological diagnosis have important prognostic implications. Endoscopic operating techniques allow the removal of small GI NENs in the early stage of mucosal or submucosal invasion of the intestinal wall. Preoperative EUS-guided techniques may help the surgeon locate small and deep tumors, thus avoiding formal pancreatic resections in favor of parenchymal-sparing surgery. Finally, locoregional ablative treatments have been proposed in recent studies with promising results in selected patients.

Key Words: Neuroendocrine neoplasms; Gastrointestinal endoscopy; Endoscopic resection; Endoscopic ultrasound; Ablative technique; Tissue acquisition

Core Tip: Gastroenteropancreatic neuroendocrine neoplasms (GEP-NENs) are complex neoplasms that present many clinical challenges. This review reports endoscopic management of patients with GEP-NENs. Endoscopic procedures allow diagnosis, local staging, and tissue acquisition. Early NENs of the stomach, duodenum, or rectum are generally removed by endoscopic operating techniques. New endoscopic ultrasonography-guided operative techniques may help the surgeon locate small and deep tumors or treat small pancreatic NENs.

INTRODUCTION

Gastroenteropancreatic neuroendocrine neoplasms (GEP-NENs) are rare neoplasms arising from neuroendocrine cells distributed in the GEP tract. Most commonly, the primary lesion is located in the gastric mucosa, small and large intestine, rectum, and pancreas[1].

The incidence of GEP-NENs has substantially increased over the last decades. Data from the Surveillance, Epidemiology, and End Results registry show that the incidence of GEP-NENs has increased 6.4 fold since the program's inception in 1973. This phenomenon may be related to the increasing number of radiological imaging and endoscopic examinations performed[1,2].

Approximately 15%-30% of GEP-NENs are functioning tumors with hormone-related symptoms; the remaining 70%-85% are nonfunctioning and detected incidentally or because the patient has symptoms of mass effects or distant metastases[3]. The management of GEP-NENs requires a multidisciplinary approach. Since GEP-NENs are less frequent than other malignancies, endoscopic management of these tumors may not be fully understood.

This review focuses on the endoscopic diagnosis and treatment of GEP-NENs.

Site

The GEP tract represents the most common localization of NENs. Gastrointestinal NENs (GI-NENs) develop from the stomach (23%), appendix (21%), small bowel (15%), and rectum (14%). Esophageal and colonic NENs are rare tumors that account for a small percentage of GI-NENs. Pancreatic NENs (Pan-NENs) represent about 1% of all pancreatic neoplasms but their prevalence is around 10%[1].

Grade

The World Health Organization subclassifies GEP-NENs based on the mitotic count and Ki-67 index (Table 1). This classification defines both well-differentiated neuroendocrine tumors (NETs) and poorly differentiated neuroendocrine carcinomas (NECs). NETs are divided into grade 1 (Ki-67 index < 3, mitotic rate < 2), grade 2 (Ki-67 index 3-20, mitotic rate 2-20), and grade 3 (Ki-67 index > 20, mitotic rate > 20). NECs exhibit poorly differentiated morphology with significant atypia and frequently have geographic necrosis. Tumors involving both neuroendocrine and non-neuroendocrine cells are classified as mixed NENs and non-NENs[4].

Staging

There are two major classifications in current clinical use: the European Neuroendocrine Tumor Society (ENETS) tumor, node and metastasis (TNM) system and the American Joint Committee on Cancer TNM system[5,6].

Functional status

Clinically, GEP-NENs can be classified into nonfunctioning and functioning tumors. The functioning tumors secrete substances that cause appreciable clinical symptoms, whereas the nonfunctioning neoplasms do not secrete any substance or the substance produced is inactive. The hormones produced and clinical symptoms vary by site of the primary GEP-NENs. Clinical symptoms include hypoglycemic syndrome, carcinoid syndrome, Zollinger-Ellison syndrome, watery diarrhea-hypokalemia-achlorhydria syndrome, and glucagonoma (Table 2)[7].

Biomarker levels

Chromogranin A is currently the most commonly used biomarker for GEP-NENs. It has a 10%-35% specificity, and its sensitivity ranges from 32% to 92%. Serotonin and its metabolite 5-hydroxyindole

Table 1 2019 World Health Organization classification of neuroendocrine neoplasms of the gastrointestinal tract and hepatopancreatobiliary organs

NENs	Differentiation	Grade	Mitotic rate	Ki-67 index %
NET, G1	Well differentiated	Low	< 2	< 3
NET, G2	Well differentiated	Intermediate	2-20	3-20
NET, G3	Well differentiated	High	> 20	> 20
NEC, small cell type	Poorly differentiated	High	> 20	> 20
NEC, large cell type	Poorly differentiated	High	> 20	> 20
MiNEN	Well or poorly differentiated	Variable	Variable	Variable

NEN: Neuroendocrine neoplasm; NET: Neuroendocrine tumor; NEC: Neuroendocrine carcinoma; MiNEN: Mixed neuroendocrine-non-neuroendocrine neoplasm.

Table 2 The hormones produced by the primary gastroenteropancreatic neuroendocrine neoplasms

Tissue	Hormones	Symptoms/Syndrome
Gastric	Histamine, CGA	Atypical flush, wheeze, angioedema
Duodenal	CGA, somatostatin, gastrin	Cholelithiasis, steatorrhea, diabetes, ZE syndrome (gastrinoma)
Jejuno-ileal, appendiceal, cecal	Serotonin, CGA, pancreastatin	Carcinoid syndrome
Colorectal	Pancreatic polypeptide	No hormonal symptoms
Pancreatic	Insulin	Recurrent hypoglycemia
	Glucagon	Diarrhea, glossitis, necrolytic migratory erythema, weight loss, hyperglycemia, blood clots
	VIP	Diarrhea, hypokalemia, achlorhydria
	ACTH	Cushingoid facies, weight gain, diabetes, hypertension
	GHRH	Acromegalic features, diabetes
	PTHRP	Hypercalcemia
	Gastrin	Pain, diarrhea (ZE syndrome)
	Somatostatin	Diabetes, cholelithiasis, steatorrhea, weight loss
	Serotonin	Flushing, diarrhea (carcinoid syndrome)

5HIAA: 5-hydroxyindoleacetic acid; ACTH: Adrenocorticotrophic hormone; CGA: Chromogranin A; F-PNET: Functional pancreatic neuroendocrine tumor; GHRH: Growth hormone releasing hormone; MEN1: Multiple endocrine neoplasia type 1; NF1: Neurofibromatosis type 1; PTHRP: Parathyroid hormone-related peptide; VIP: Vasoactive intestinal polypeptide; ZE: Zollinger Ellison.

acetic acid have been measured in blood and urine samples, respectively, as markers of carcinoid syndrome. However, the sensitivity of this biomarker is as low as 35% in the absence of carcinoid syndrome[8].

Several other potential biomarkers include neuron-specific enolase, human chorionic gonadotropin, alpha-fetoprotein, and pancreatic polypeptide. These circulating biomarkers are useful to aid diagnosis, but are of insufficient value to accurately identify the primary tumor site, correlate with tumor grade, and differentiate low-level malignancy from high-grade disease[9].

In recent years, new biomarkers have been evaluated that may correlate with clinical outcomes and be useful as better prognostic indicators. These include microRNAs, long noncoding RNAs, circulating tumor cells, and DNA methylation patterns[10].

Any associated syndromes

Most GEP-NENs are sporadic, but they also can arise as part of inherited familial syndromes. About 5% of patients with GEP-NENs harbor genomic mutations with well-characterized familial syndromes such as multiple endocrine neoplasia type 1 (MEN1), von Hippel-Lindau (VHL) disease, tuberous sclerosis (TSC), and neurofibromatosis type 1 (NF1)[11].

MEN1 is an autosomal-dominant syndrome, characterized by NENs of the anterior pituitary, parathyroid glands, and pancreas. VHL syndrome is an autosomal-dominant syndrome characterized by a variety of benign and malignant neoplasms including clear renal cell carcinomas, pheochromocytomas, hemangioblastomas, retinal angiomas, paragangliomas, and pNENs. TSC is an autosomal-dominant syndrome characterized by widespread, low-grade tumors, and hamartomas in multiple organs including the brain, heart, skin, eyes, kidney, lung, and liver. pNENs are described in only 1% to 5% of cases. NF1 is an autosomal-dominant syndrome characterized by ubiquitous neurofibromas; multiple cafe-au-lait skin spots; and susceptibility to gliomas, myeloid leukemia, pheochromocytomas, and occasionally pNENs[12].

DIAGNOSIS

Gastric NENs

Gastric NENs (G-NENs) are neoplasms derived from the enterochromaffin-like cells of the gastric mucosa. They are classified into types I, II and III according to their clinical and pathophysiological characteristics (Table 3)[13].

Type I G-NENs correspond to the majority of G-NENs found in the stomach (70%-80%) and are associated with autoimmune chronic atrophic gastritis and hypergastrinemia, type II G-NENs lesions are caused by gastrinomas and commonly found in patients with Zollinger-Ellison syndrome (ZES) and MEN1, and type III G-NENs lesions consist of a sporadic lesion and are unrelated to gastrin hypersecretion.

Patients with G-NENs typically present with nonspecific symptoms and the diagnosis is made by upper gastrointestinal (GI) endoscopy for symptoms such as abdominal pain, nausea, bleeding, and anemia. Despite the low incidence of G-NET, recent data have demonstrated an increase due to an expanding use of upper endoscopy, improvement of endoscopes, and more attention to identification and characterization of gastric lesion[14]. Type I G-NENs occur in the corpus and/or fundus and are multiple small reddish polyps, usually subcentimetrics. They are associated with a chronic atrophic gastritis with an excellent prognosis. Tumor extension is limited to the mucosa or submucosa.

Type II G-NENs are similar to type I lesions but the adjacent gastric folds have a hypertrophic gastric mucosa and occasionally have multiple areas of ulceration of gastric and duodenal mucosa. Type II G-NENs are involved in MEN1 and ZES and have a good prognosis, similar to type I. Type III G-NENs are single, large (> 2 cm), sometimes ulcerated, more aggressive and associated with local and distant spread, and involve the muscular layer (Figure 1)[15]. The prognosis of this subgroup is poor.

At the time of diagnosis, biopsy samples should be taken from the lesions and multiple gastric biopsies (antrum, body, and fundus) should be performed for etiologic orientation.

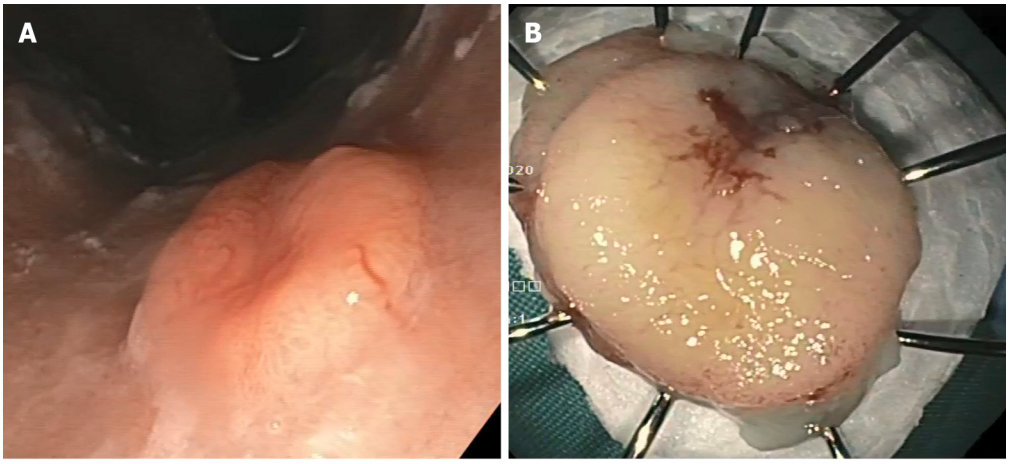
Endoscopic ultrasonography (EUS) should be performed if the lesion is greater than 1 cm in order to assess the layer of origin, tumor size, echogenicity, margins, wall invasion, and regional lymph nodes. At EUS, G-NENs present as rounded isoechoic or hypoechoic tumors, localized in the second (deeper mucosal) or third (submucosal) echo layers. EUS diagnostic accuracy for evaluation of subepithelial lesion including G-NET is suboptimal (43%-67%)[16]. EUS is a very accurate technique for assessing tumor size and muscularis propria integrity, factors that seem to condition the potential for distant metastasis[17].

In type I and II G-NENs, staging EUS is frequently performed to evaluate indication to endoscopic treatment. For patients suspected of having type II G-NENs, EUS evaluation must be performed for the assessment of any duodenal or Pan-NENs. In Type III G-NENs, EUS is indicated to stage the disease by assessing the presence of regional lymph node involvement[18].

Duodenal NENs

Duodenal NENs (D-NENs) are solitary, small lesions generally discovered incidentally on imaging studies or endoscopy. They are generally classified into five different tumor types: duodenal gastrinomas, somatostatinomas, nonfunctional D-NENs, duodenal gangliocytic paragangliomas, and high-grade poorly differentiated NEC[19].

Most D-NENs are localized predominantly in the first and second duodenal portion and are nonfunctioning with a low risk of local or distant metastases. Functioning D-NENs are typically associated with higher metastatic power. The presence of multiple D-NENs should raise suspicion of MEN1-ZES[19].



D-NENs located in the ampullary/periampullary region have more aggressive behavior and poorer overall survival than D-NENs located elsewhere in the duodenum[20,21].

On upper GI endoscopy, D-NENs have the appearance of submucosal tumors with a surface color often identical to the surrounding mucosa (Figure 2). As the tumor enlarges, a depression may form in the center, which is eventually replaced by an ulcer crater[22].

EUS evaluation is useful for duodenal subepithelial lesions characterization; the accuracy of combined endoscopic/EUS imaging for all duodenal lesions is 84.9%[23].

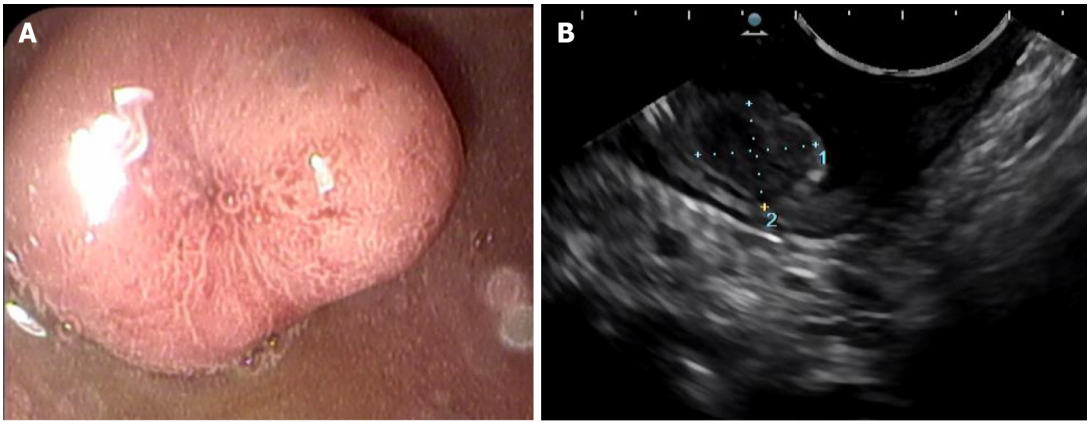


Table 3 Characteristics of the subtypes of neuroendocrine neoplasms of the stomach

Characteristics	Type I	Type II	Type III
Prevalence	70%-80%	5%-10%	10%-20%
Background	Autoimmune chronic atrophic gastritis	Gastrinomas (Zollinger-Ellison syndrome)	Normal mucosa
Number of lesions	Multiple	Multiple	Single
Size of tumors	1-2 cm	1 cm	> 2 cm
Site of tumor	Corpus and/or fundus	Corpus and/or fundus	Anywhere
Serum gastrin levels	Elevated	Elevated	Normal
Gastric pH	High	Low	Normal
Invasion	Rare	More common	Common
Prognosis (5-yr survival)	Excellent (90%-95%)	Good (70%-90%)	Worse (less than 35%)

Figure 2 Duodenal neuroendocrine neoplasm. A: Endoscopic image demonstrates a sessile polyp with central depression; B: Endoscopic ultrasound demonstrates a hypoechoic intramural structure in the submucosal layer of the duodenal wall.

EUS is also useful to exclude locoregional lymph node metastases and thus the indication for endoscopic mucosal resection in case of lesions > 1 cm. At EUS evaluation, D-NENs are usually located in the submucosal layer and are rounded, hypoechoic, well-demarcated small lesions. Fine needle aspiration (FNA) should also be performed in cases of nondiagnostic histopathology[18]. Duoden-

oscopy and EUS are indicated to identify the primary tumor in the case of ZES and in patients with MEN1[24].

Small bowel NENs

Small bowel NENs (SB-NENs) are the most common NENs developing distant metastases; however, their prognosis remains favorable[25]. They tend to present in later stages because clinical symptoms are often insidious and the diagnosis often occurs in the course of an intervention for intestinal obstruction or bleeding[26].

Accurate localization and staging of SB-NENs often involve a combination of several imaging modalities. Endoscopic examinations such as capsule endoscopy and double-balloon enteroscopy are useful in identifying occult SB-NENs when no primary tumor was found on conventional imaging. Macroscopically, most SB-NENs are sessile nodules or ulcerated lesions usually measuring between 1 and 2 cm or as multiple tumors[27,28].

Appendix NENs

Appendiceal NENs (A-NENs) are usually discovered incidentally at final pathological examination after an appendectomy is performed for acute appendicitis. Colonoscopic examination of the entire large bowel is mandatory given the frequency of synchronous colorectal neoplasia[27]. A-NENs usually have a good prognosis. In most cases, appendicectomy alone is considered curative; however, in selected cases with high malignant potential, the right hemicolectomy could be considered[29].

Colorectal NENs

Colonic NENs (C-NENs) and rectal NENs (R-NENs) are two different clinical entities. C-NENs have more aggressive features and much worse prognosis than R-NENs[30]. Nearly 70% of C-NENs are located in the ascending colon, particularly in the cecum with a mean size of 5 cm at presentation. The patients generally experience late symptoms such as abdominal pain, GI bleeding, and weight loss, and most of them have local or distant metastasis[15].

Most R-NENs are diagnosed through screening sigmoidoscopy and/or colonoscopy while only a small fraction have symptoms such as diarrhea, abdominal pain, or rectal bleeding.

The majority of R-NENs are small size lesions less than 1 cm and only 5% present are larger than 2 cm [31].

Endoscopically, R-NENs appear as sessile or semipedunculated polypoid lesions with normal or a yellow-discolored mucosa, frequently located in the midrectum. Larger lesions can have different endoscopic characteristics such as ulcerations, depressions or hyperemic color, which can be suggestive of aggressive disease[30].

At EUS, R-NENs have the aspect of nodular, hypoechoic, or isoechoic submucosal tumor clearly demarcated from the surrounding tissue[18].

EUS-FNA can be helpful to make a differential diagnosis with other subephitelial lesion[32] with a diagnostic accuracy of 85.1%[33].

According to the current ENETS consensus, an EUS should also be performed in order to assess the depth of rectal wall invasion and regional lymphadenopathy prior to endoscopic resection[34].

A complete colonoscopy is indicated after a diagnosis of a R-NENs to exclude concomitant colon cancer and other NENs[35].

Pan-NENs

Pan-NENs comprise 1% to 2% of pancreatic neoplasms[36]. Pan-NENs are classified as functioning or nonfunctioning depending on whether they cause hormonal overproduction syndrome. Functioning Pan-NENs include insulinoma, gastrinoma, VIPoma, and glucagonoma. Nonfunctioning Pan-NENs comprise the largest group of Pan-NENs and do not produce syndromes of hormonal excess. Nonfunctioning Pan-NENs often manifest later in the course of the disease or are discovered incidentally during abdominal imaging examinations performed for other diseases[37].

EUS is a very useful tool in the management of Pan-NENs and has been considered the imaging study of choice to be performed after other negative noninvasive imaging studies are negative[38].

Puli *et al*[39] assessed the diagnostic accuracy of EUS for detection of Pan-NENs. This meta-analysis demonstrated an excellent accuracy of EUS in this setting with a sensitivity of 87.2% and a specificity of 98.0%.

A meta-analysis of 2015 assessed incremental benefit of preoperative EUS for the detection of suspected Pan-NENs after other investigative modalities have been attempted. EUS increased the overall Pan-NENs detection by over 25% and was particularly useful in functioning Pan-NENs, typically smaller in size (*i.e.* insulinomas or gastrinoma)[40].

EUS is also very useful in assessing the presence of multiple lesions, size lesion and especially the distance between the lesion and the main pancreatic duct, a factor that can drive the decision on which surgical approach (*i.e.* enucleation *vs* resection)[18]. Pancreatic enucleation is commonly performed for Pan-NENs with a low risk of malignant progression but post-operative pancreatic fistula risk is higher for neoplasms located close to the duct[41].

EUS is of course useful for differential diagnosis of Pan-NENs with other solid pancreatic lesions. Pan-NENs are solid lesions and on EUS examination, appear as well-demarcated, hypoechoic lesions with a homogeneous pattern. However, because Pan-NENs grow expansively, they may also appear as cystic or indistinguishable from pancreatic adenocarcinomas.

In Pan-NENs EUS guided tissue acquisition is considered the procedure of choice to reach cytologic diagnosis, but also ascertainment of tumor grade by determining the Ki-67 proliferation index and mitotic count (Figure 3).

EUS-FNA provides a cytological specimen with a sensitivity ranging between 80% and 90%, specificity at 96%[18]. The adequacy and concordance of Ki-67 evaluation of EUS-FNA compared with histology remains unclear especially for tumor > 20 mm[42,43]. To overcome these limitations of cytological Ki-67 determination, sampling with needles for EUS-guided fine-needle biopsy (EUS-FNB) have been introduced with good results[44,45]. In a recent retrospective study EUS-FNB outperformed EUS-FNA for Ki-67 proliferation index determination[46].

EUS elastography (EUS-E) is a newer tool of diagnostic EUS for differential diagnosis of solid pancreatic lesions. It is a technique that analyzes pancreatic stiffness being a useful tool for the differential diagnosis of pancreatic masses with a qualitative or quantitative elastographic assessment. A meta-analysis by Zhang *et al*[47] showed a sensitivity and specificity of quantitative EUS-E for the differentiation of benign and malignant pancreatic masses of 0.95 and 0.61, respectively. Iglesias-García *et al*[48] evaluated the accuracy of quantitative EUS-E for the differential diagnosis of solid pancreatic masses. EUS-E was helpful in differentiating pancreatic cancer from Pan-NENs with a sensitivity of 100% and a specificity of 88%. In another study, elastographic analysis was accurate in discriminating between benign and malignant pancreatic lesions, without difference between NENs and other nonmalignant lesions[49].

Recently, shear wave elastography (SWE) has been introduced as a quantitative absolute measurement of tissue hardness. Ohno *et al*[50] compared the diagnostic performances of EUS-SWE and conventional strain elastography for solid pancreatic lesions without significant differences.

To date EUS-E does not provide sufficient diagnostic accuracy to replace tissue diagnosis but it plays a significant role in those cases of suspected pancreatic cancer where biopsy sampling was inconclusive and can help to select the area of the pancreatic lesion to be sampled[51].

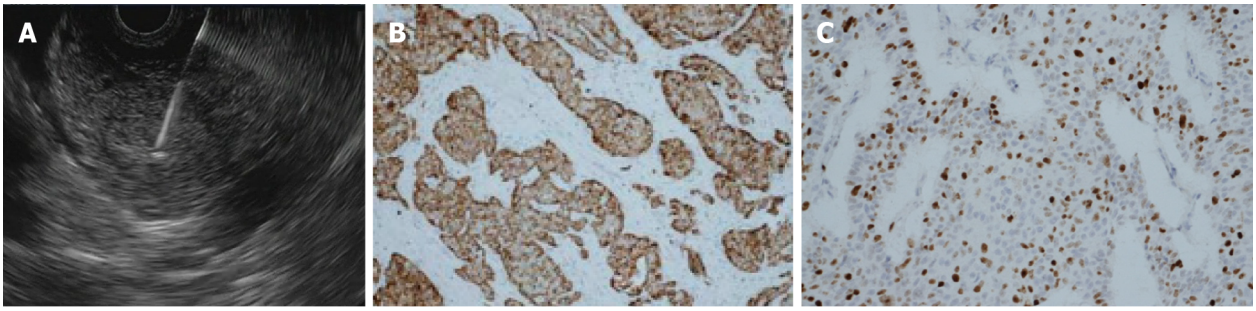
Contrast-enhanced EUS (CE-EUS) consists of an intravenous injection of contrast media during the EUS examination so parenchymal perfusion and the microvasculature of the pancreas can be visualized. Pancreatic cancer is observed as a hypoenhanced heterogeneous lesion whereas Pan-NENs are observed as well-demarcated lesions with hyperenhancement in the arterial phase.

CE-EUS increased the accuracy of EUS for both the detection and characterization of solid pancreatic lesions[52].

Kitano *et al*[53] prospectively evaluated how accurately CE-EUS characterizes pancreatic lesions and hyperenhanced lesions were diagnosed as Pan-NENs with a sensitivity of 79% and specificity of 99%. Several studies have examined CE-EUS in the differentiation between malignant and benign Pan-NENs [39,40]. Heterogeneous enhancement at an early arterial phase with fewer vessels and more fibrosis is associated with an aggressive tumor[54]. Palazzo *et al*[55] reported a sensitivity of 86% and a specificity of 96% in prediction tumor aggressiveness in Pan-NENs with the use of CE-EUS.

NET could be found also in the bile ducts[56]; however, the incidence is very low. In the literature, only 100 cases of biliary tree NETs were described and they have an excellent prognosis[57]. In these cases, complete surgical excision offers optimal treatment with no evidence of chemotherapy or radiotherapy's role in the management.

ENDOSCOPIC THERAPY



In the last 10 years, the approach of GEP-NENs progressively included endoscopic resection technique. The choice of the treatment modality needs of a careful assessment and depends by multiple factors. The indication of endoscopic respective therapy does not include NET of appendix, colon and biliary tree while for pancreatic NET the suitable endoscopic approaches are ablative techniques.

G-NENs

Most type I G-NENs are limited to the mucosa or submucosa and they rarely invade the muscularis propria or metastasize to local lymph nodes if < 10 mm. Current guidelines suggested removing all tumors ≥ 10 mm[16]. EUS is recommended to identify possible involvement of regional lymph nodes and invasion beyond the submucosa prior to resection. Endoscopic resection (ER) either by endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) is the treatment of choice when EUS demonstrates the lesion to be localized to the mucosa or submucosa[58].

Surgical treatment is the option for lesions which are predicted to be T2 (lesion larger than 20 mm or grading G3) or lesions with positive margins[58].

Sato *et al*[59] showed in a low number of cases that about 66% of type I G-NENs resected by EMR had a positive vertical margin, whereas no case with ESD had positive vertical or horizontal margins. Kim *et*

DOI: 10.3748/wjg.v28.i34.4943 **Copyright** ©The Author(s) 2022.

Figure 3 Pancreatic neuroendocrine neoplasm. A: Endoscopic ultrasound revealed a 15 mm hypoechoic lesion of the pancreas; B: Stained immunohistochemically for chromogranin showing diffuse and strong positivity (original magnification 400 ×), consistent with a poorly differentiated neuroendocrine tumor infiltrating the entire thickness of the muscle tissue to the head of the pancreas; C: The proliferation index (Ki-67) < 20%.

al[60] evaluated the clinical usefulness of ESD with that of EMR for resection of type I G-NENs with an estimated size of ≤ 10 mm. ESD yielded a significantly higher histologic complete resection rate than EMR, particularly in the vertical resection margin.

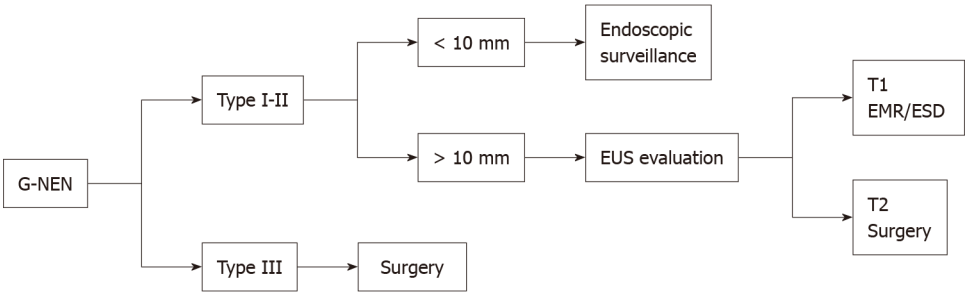
Noh *et al*[61] evaluated outcomes of endoscopic treatment for type 1 G-NENs below 20 mm in diameter. The complete resection rate was significantly higher in the ESD group than in the EMR group with similar procedure-related adverse events. For type II G-NENs local or limited excision can be recommended and indication for treatment type is similar to type 1 G-NENs[24,62]. Type III G-NENs are more associated with deeper invasion of the gastric wall, higher risk of nodal metastasis than type I and II G-NENs and surgery is considered the initial therapeutic approach[58]. ER has been proposed for small lesions. Kwon *et al*[63] investigated the clinical outcomes of type 3 G-NENs (mean tumor size of 10.2 ± 6.3 mm) after endoscopic treatment with a median follow-up of 46 mo. Of the 45 included in the follow-up, no evidence of tumor recurrence was found. Authors concluded that endoscopic treatment could be applied for type 3 G-NENs smaller than 2 cm, confined in the submucosal layer and without lymphovascular invasion. In Figure 4, we summarize the current recommendations for G-NENs.

D-NENs

Most D-NENs are located in the first or second part of the duodenum, with 20% of them occurring in the periampullary region[21]. Current guidelines indicate ER for small (≤ 10 mm) nonperiampullary D-NENs confined to the submucosal layer, without lymph node or distant metastasis. Either endoscopic or surgical resection is allowed, for nonperiampullary D-NENs measuring 10-20 mm without metastatic risk (G1, no muscolaris invasion, no lymph-vascular invasion and no lymph-node metastasis)[24,58].

There are different ER techniques, such as cap technique, EMR, EMR with ligation device and ESD [58].

Gincul *et al*[64] evaluated the feasibility and outcome of endoscopic treatment of D-NENs (including 7 ampullary G1/G2 NETs with ≤ 20 mm) with EMR. The resection rate was R0 only in 51.6% (16/31) of patients. During a median follow-up period of 56 mo, 2 patients (8.3%) presented a tumor recurrence. Morbidity was 38 % (11/29) and mortality was 3% (one severe bleeding).



Nishio *et al*[65] assessed the efficacy, safety and the long-term outcomes of ESD for nonperiampullary D-NENs ≤ 10 mm in diameter. En bloc, R0 and curative resection were achieved in 100% (8/8), 88% (7/8), and 88% (7/8) of tumors, respectively. During a median follow-up of 34.0 mo none of the patients showed evidence of local recurrence or distant metastasis. Perforation occurred in 2 patients (16%) without need for surgery.

In a recent review, Brito *et al*[66] evaluated the effectiveness and complications of ER techniques in patients with D-NETs ≤ 20 mm. Polypectomy was associated with a high occurrence of incomplete resections. Among the mucosectomies, EMR with cap or EMR with injection was associated with lower frequencies of compromised margin and recurrent surgery. Endoscopic submucosal dissection was not associated with recurrence but it was associated with a higher occurrence of bleeding and perforation.

ER of D-NENs is complex and associated with significant morbidity. EMR is associated with a lower R0 resection rate than ESD. ESD is associated with better pathologically confirmed resection but with a higher morbidity rate and should be restricted to expert centers[67]. ESGE guidelines suggests choosing between EMR, ESD, and endoscopic full thickness resection (EFTR) to resect nonampullary, nonfunctional duodenal NENs of < 15 mm, depending on size, location, depth of invasion, and local expertise [16].

Ampullary D-NENs have a less favorable prognosis than nonampullary D-NENs and pancreaticoduodenectomy is recommended regardless of size[24].

Local resection might be sufficient for small highly differentiated ampullary D-NENs without node metastases especially in patients with comorbidities[24].

Figure 4 Algorithm for gastric neuroendocrine neoplasm management. EMR: Endoscopic mucosal resection; ESD: Endoscopic submucosal dissection; EUS: Endoscopic ultrasonography; G-NEN: Gastric neuroendocrine neoplasm.

In one of the largest studies of EMR of D-NENs above reported, Gincul *et al*[64] included 7 ampullary G1/G2 D-NENs with ≤ 20 mm. In this subgroup of patients, R0 resection was achieved in 5 patients (71%) without recurrence with a median follow-up period of 56 mo.

Shimai *et al*[68] reported 3 patients with an ampullary D-NENS, who underwent endoscopic papillectomy without tumor recurrence or metastasis after a follow-up of 2 years. In Figure 5, we summarize the current recommendations for D-NENs.

R-NENs

The current guidelines recommend ER for R-NENs < 10 mm in size with no risk factors for metastasis. R-NENs larger than 20 mm are candidates for surgical resection. There is controversy over R-NENs of intermediate size 10-19 mm (Figure 6). R-NENs with these sizes have a poorer prognosis compared with those < 10 mm[34]. The main factors associated with the risk of lymph-node metastases are atypical endoscopic aspect (presence of mucosal depression or ulceration), suspicious pararectal lymph node at EUS, invasion of the muscularis propria, G2, and lymphovascular invasion. Rectal NET with any risk factor for metastasis should be considered for surgical resection with lymphadenoctomy. For lesions measuring 10-19 mm without factors associated with metastatic risk the most appropriate resection techniques may be ESD or transanal endoscopic microsurgery (TEM)[24-34].

The appropriate endoscopic technique resection should allow for en bloc oncological excision. Optimal endoscopic treatment modality for R-NENs has not yet been achieved.

Conventional polypectomy is associated with a low rate of complete resection as most of the R-NENs are submucosal. Son *et al*[69] reported a complete resection rate by conventional polypectomy of 30.9%.

EMR is simple and has low complication rates but can sometimes cause incomplete resection and difficulty in pathologic evaluation because even small R-NENs can invade the submucosa. Several studies, assessing efficacy of EMR, have reported complete resection rates ranging from 30%-70%[70-74].

Therefore, several m-EMR methods have been reported and included cap-assisted EMR (EMR-C), EMR with a ligating device (EMR-L), and EMR after circumferential precutting (EMR-P).

EMR-L is performed suctioning the lesion into the ligating device and cutting by using a round snare after placing bands around the base of tissue suctioned. EMR-C is performed with a transparent cap fitted to the scope, followed by snare cautery resection. These techniques allow the cutting of the submucosal layer from the muscularis propria[75].

Lee *et al*[75] performed a retrospective study comparing EMR-L and EMR-C, concluding that EMR-L may achieve both a higher endoscopic rate and a histologic complete resection rate. An analysis of 17 studies reported that the complete resection rate of R-NENs using EMR-L was 94.8% compared with 72.4% for EMR-C[76].

EMR-P is performed by lifting the mucosa with a saline injection, making a circumferential incision using the tip of the snare or special endoknives and resecting the tumor with a snare. This technique has the advantages, unlike the other m-EMR procedures, of not being affected by lesion size. Several studies have investigated the usefulness of EMR-P for resection of R-NENs showing a complete resection rate from 81.2% to 96.7% with a short procedure time, and an acceptable safety profile[77-79].

Recently Park *et al*[80] evaluated the safety and efficacy of underwater endoscopic mucosal resection in the treatment of small R-NENs (< 10 mm) with high R0 resection rates similar to ESD.

ESD is an advanced endoscopic technique employing a submucosal injection to lift the lesion away from the muscularis propria layer. Dedicated devices are then used to dissect around the entire lesion in the submucosal plane. This technique results in a high en bloc resection rate although more complicated, time consuming and with higher risk of complications than EMR and m-EMR[81].

Zhou *et al*[82] performed a meta-analysis comparing ESD with EMR and m-EMR in the treatment of R-NENs smaller than 15 mm in diameter. Complete resection rate was significantly higher in the ESD group than in the EMR group and comparable between the ESD group and the m-EMR group. A recent meta-analysis compared efficacy of ESD and EMR in curing R-NENs. This study showed that ESD is

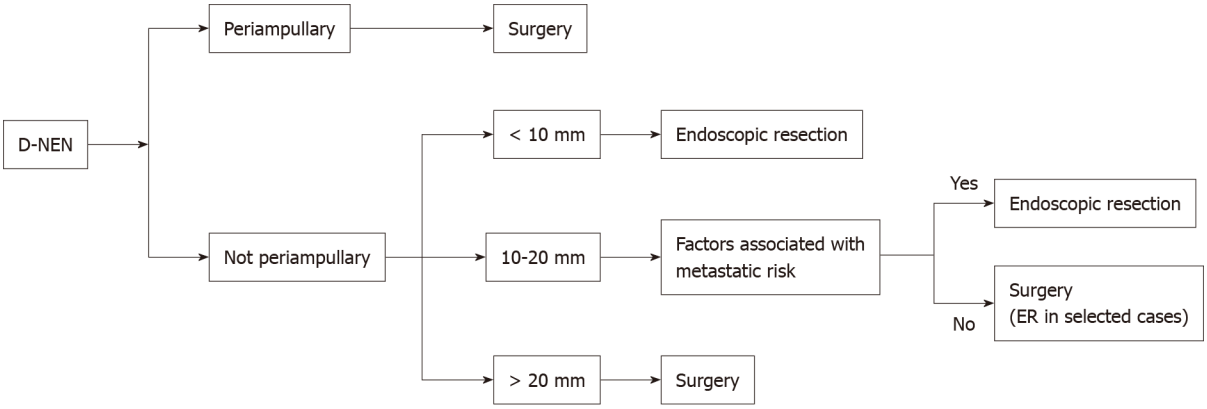

Figure 5 Algorithm for duodenal neuroendocrine neoplasms management. D-NEN: Duodenal neuroendocrine neoplasm; ER: Endoscopic resection.

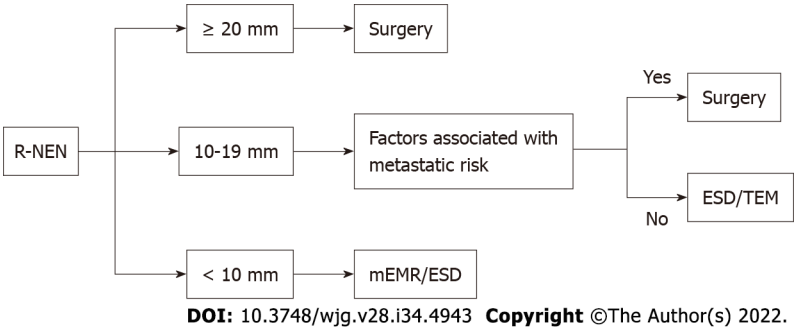

Figure 6 Algorithm for rectal neuroendocrine neoplasms management. ESD: Endoscopic submucosal dissection; mEMR: Modified endoscopic mucosal resection; R-NEN: Rectal neuroendocrine neoplasm; TEM: Transanal endoscopic microsurgery.

more effective in curing R-NENs of 10-20 mm in size than EMR without significant differences for R-NENs smaller than 10 mm[83].

In patients with an incomplete resection from EMR techniques, ESD may be indicated as salvage therapy[24,84].

A recent new endoscopic technique is EFTR, which is performed using a full thickness resection device (FTRD). The FTRD uses a transparent cap with a modified over-the-scope clip (OTSC) mounted over a standard colonoscope. The lesion is pulled into the cap and the pseudopolyp created by the OTSC closure is then resected with the snare preloaded in the tip of the cap. Meier *et al*[85] conducted a study evaluating EFTR in 40 cases of R-NENs showing effectiveness of this method (R0 resection rate in 95%) in addition to feasibility (median time, 18.5 min) and safety.

Pan-NENs

Patients with small Pan-NENs are candidates for pancreatic-sparing procedures such as central pancreatectomy or enucleation. Small Pan-NENs can be difficult to detect intra-operatively by palpation only. EUS-guided techniques to facilitate small Pan-NENs localization especially during laparoscopy surgery are tattooing or fiducial markers implantation. These techniques allow a precise localization of lesions ensuring adequate margins of resection and preserving normal pancreatic parenchyma[86].

Endoscopic ultrasound-guided fine needle tattooing (EUS-FNT) is a safe, easy to perform and useful new method to mark preoperatively small Pan-NENs. Generally, a 22-gauge standard needle allows easy injection of the tattooing solution. The needle is inserted inside the target lesion or immediately near the lesion borders into the normal parenchyma. The most frequently solution utilized is a sterile carbon-based ink which is nondegradable and remains in the tissues indefinitely[87].

Recently Rosa *et al*[88] evaluated EUS-FNT in facilitating intra-operative detection of Pan-NENs (8 insulinoma and 8 nonfunctional Pan-NENs.) The tattoo mark was detected in all but one patient. Only a small hematoma secondary to the EUS-FNT was observed.

The placement of fiducial markers implantation under EUS guidance is another technique to facilitate Pan-NENs localization during surgery. Fiducials are implantable radiographic markers that have been used for many years to mark soft tissue in radiology. The fiducial is easily visible during an intraoperative ultrasound[86].

Law *et al*[89] reported on two consecutive patients with small Pan-NENs who underwent fiducial placement. In both of the reported cases, the fiducials were visualized by intraoperative ultrasound, and the surgical resection was successful without procedure-related complications.

In recent years endoscopic ultrasound-guided ablation therapy has emerged as a new therapeutic option for solid pancreatic tumors, especially for Pan-NENs in elderly patients and candidates unfit for surgery. There are two main techniques used, EUS-guided radiofrequency ablation (EUS-RFA) and EUS-guided ethanol ablation (EUS-EA)[90]. Functioning and multiple Pan-NENs seem to be the ideal target for endoscopic ultrasound -guided ablation therapy resolving symptomatic hormonal syndromes. In case of nonfunctioning Pan-NENs, these techniques could be a therapeutic option in the case of patients unfit to surgery[91].

EUS-EA can be safe and useful for the control of symptoms in patients with small insulinomas[91-93].

Jürgensen *et al*[92] reported the first case of EUS–EA of a 13 mm pancreatic insulinoma in a 78-year-old woman. The patient exhibited no further hypoglycemic episodes with no recurrence of the tumor on follow-up.

Levy *et al*[93] reported a small series of 5 patients for EUS-EA of insulinomas; they observed that symptomatic relief was relieved almost immediately after the procedure and maintained during the follow-up.

Qin *et al*[94] reported a series of 4 patients for EUS-EA of insulinomas with no recurrence of hypoglycemia and complications during follow-up.

Choi *et al*[95] reported the largest cohort of 32 patients with nonfunctioning Pan-NENs treated with EUS–EA. In 24 out of 40 tumors (60%) complete ablation was achieved.

The other less invasive locoregional therapy for Pan-NENs is EUS-RFA. Multiple case reports of EUS-RFA of insulinomas showed complete regression of the clinical syndrome[96-98].

Regarding nonfunctioning Pan-NENs, Barthet *et al*[99] conducted a prospective multicenter study including 12 patients with 14 Pan-NENs (mean size 13.1 mm) treated with EUS-RFA. Among the 14 Pan-NENs, at 1-year follow-up, 12 had completely disappeared (86% tumor resolution). Two adverse events occurred (one pancreatitis, one pancreatic ductal stenosis). Another case series included 11 patients with nonfunctioning Pan-NENs. A complete radiological response was achieved in 8 of 11 patients treated with EUS-RFA. Two cases of mild pancreatitis occurred[100].

CONCLUSION

GEP-NENs are on the rise. The reasons for this phenomenon are a better awareness of an increased and more widespread use of GI endoscopy and advanced radiological imaging[1]. The overall survival rate for patients with GEP-NENs has improved in the last years[2]. This achievement is due to both early detection and better therapeutic strategies of GEP-NENs.

Endoscopy is the only method of choice to detect asymptomatic GI-NENs at an early stage. Most patients with early, GI-NENs can be treated with ER or surveillance.

Pan-NENs are relatively rare tumors but their number is increasing, mainly because of the advances in various diagnostic imaging modalities as EUS. Newer advancement in the field of EUS such as the evolution of needles, EUS-E and CE-EUS can provide useful information with an improvement in the management of Pan-NENs. EUS-guided tumor ablation therapies can be a therapeutic option in selected patients unfit for surgery.

The literature evidence on this field is growing every day. For the nature of our study (mini-review) and the very wide issue, we collected and summarized the most important evidence regarding the endoscopic treatment underlying current guideline. We believe that a systematic review the literature with meta-analysis (when applicable) for every specific GI-NENs is needed to prove and confirm the role of endoscopy in diagnosis and therapy of many types of GI-NENs.

Abstract

For the optimal management of refractory ulcerative colitis (UC), secondary loss of response (LOR) and primary non-response to biologics is a critical issue. This article aimed to summarize the current literature on the use of cytapheresis (CAP) in patients with UC showing a poor response or LOR to biologics and discuss its advantages and limitations. Further, we summarized the efficacy of CAP in patients with UC showing insufficient response to thiopurines or immunomodulators (IM). Eight studies evaluated the efficacy of CAP in patients with UC with inadequate responses to thiopurines or IM. There were no significant differences in the rate of remission and steroid-free remission between patients exposed or not exposed to thiopurines or IM. Three studies evaluated the efficacy of CAP in patients with UC showing an insufficient response to biologic therapies. Mean remission rates of biologics exposed or unexposed patients were 29.4 % and 44.2%, respectively. Fourteen studies evaluated the efficacy of CAP in combination with biologics in patients with inflammatory bowel disease showing a poor response or LOR to biologics. The rates of remission/response and steroid-free remission in patients with UC ranged 32%-69% (mean: 48.0%, median: 42.9%) and 9%-75% (mean: 40.7%, median: 38%), respectively. CAP had the same effectiveness for remission induction with or without prior failure on thiopurines or IM but showed little benefit in patients with UC refractory to biologics. Although heterogeneity existed in the efficacy of the combination therapy with CAP and biologics, these combination therapies induced clinical remission/response and steroid-free remission in more than 40% of patients with UC refractory to biologics on average. Given the excellent safety profile of CAP, this combination therapy can be an alternative therapeutic strategy for UC refractory to biologics. Extensive prospective studies are needed to understand the efficacy of combination therapy with CAP and biologics.

Key Words: Ulcerative colitis; Inflammatory bowel disease; Cytapheresis; Granulocyte and monocyte adsorptive apheresis; Anti-tumor necrosis factor-α antibody; Combination therapy

Core Tip: Management of refractory ulcerative colitis (UC) experiencing primary non-response or loss of response to biologics is a critical issue. We first summarized the efficacy of cytapheresis (CAP) for such patients. Although CAP tended to have lower effects for induction of remission in patients with UC who were refractory to biologics, combination therapies with CAP and biologics induced clinical remission or response in more than 40% of such patients with UC on average. Given the excellent safety profile of CAP, we believe that this combination therapy can be an alternative therapeutic strategy for such refractory UC patients.

INTRODUCTION

Ulcerative colitis (UC) is a chronic inflammatory bowel disease (IBD) of the colon characterized by a relapsing and remittent course[1,2]. Multiple factors, such as genetic background, environmental and luminal factors, and mucosal immune dysregulation, have been suggested to contribute to UC pathogenesis[1]. Several treatments for UC are available to induce and maintain the clinical remission of the disease. For patients with mild to moderate UC, 5-aminosalicylic acid (5-ASA) is generally used, and more than 90% of patients receive 5-ASA within 1 year of diagnosis[3]. Corticosteroids (CSs) are the first-line treatment to induce remission in moderate to severe UC[2]. It was reported that immediate outcomes from CSs were complete remission in 54%, partial remission in 30%, and no response in 16% of patients[4]. Despite the effectiveness of CSs in patients with UC, it has been reported that the rate of steroid dependence was 17%-22% at 1 year following treatment with the initial CS therapy and increased to 38% mostly within 2 years[4-8].

Thiopurines have been conventionally used for the treatment of steroid-dependent UC[9-14]. The rates of the induction of CS-free remission with thiopurines in steroid-dependent patients with UC were reported to be 44% and 53%, respectively[13,14]. However, it has also been reported that thiopurine therapy has failed in approximately 25% of IBD patients within 3 mo after treatment initiation, mostly due to drug intolerance or toxicity[11].

Along with the recent advancements in the treatment for UC, effective treatments, including biologics [anti- tumor necrosis factor-α (TNF-α) antibodies[15-25], anti-integrin monoclonal antibody[26]], Janus kinase (JAK) inhibitor[27] and tacrolimus[28,29], have been developed for refractory UC. A meta-analysis showed that anti-TNF-α antibodies had more clinical benefits than placebo as evidenced by the former's increased frequency of clinical, steroid-free, and endoscopic remission and decreased frequency of colectomy[30]. It has been reported that the rates of induction of steroid-free remission in refractory patients with UC with anti-TNF-α antibodies ranged from 40.0%-76.5%[2,16,18,21,22,24]. Vedolizumab (VDZ) is an anti-integrin monoclonal antibody. Studies on VDZ showed that clinical response and remission were achieved in 51% and 30% of patients with UC by week 14, respectively [31]. However, despite the significant efficacy of biologics for UC, secondary loss of response (LOR) is a common clinical problem. It was reported that the rate of LOR to anti-TNF-α antibodies in UC ranged from 23%-46% at 12 mo after anti-TNF-α initiation[32]. It was also reported that the incidence rates of LOR to adalimumab (ADA) and infliximab (IFX) were 58.3% and 59.1% during maintenance therapy, respectively (mean follow-up: 139 and 158.8 wk, respectively)[33]. Recent data from a systematic review showed that the pooled incidence rates of LOR to VDZ were 47.9 and 39.8 per 100 person-years of follow-up among patients with Crohn's disease (CD) and UC, respectively[34]. Considering these results, secondary LOR as well as primary non-response to biologics, are a critical issue for the optimal management of refractory UC. In this context, recent studies have shown the efficacy of use of cytapheresis (CAP) in such patients with UC[35-51].

CAP is a non-pharmacological extracorporeal therapy and has been developed as a treatment for UC [52-58]. CAP is performed using two methods, namely, granulocyte and monocyte adsorptive apheresis (GMA), which uses cellulose acetate beads (Adacolumn, JIMRO Co., Ltd., Takasaki, Japan), and leukocytapheresis (LCAP), which uses polyethylene phthalate fibers (Cellsorba., Asahi Kasei Medical Co., Ltd., Tokyo, Japan)[42,52]. GMA selectively depletes elevated levels of granulocytes and monocytes

from the patients' circulation, but spares most of the lymphocytes[52]. LCAP exerts its anti-inflammatory effects by removing activated leukocytes or platelets from the peripheral blood through extracorporeal circulation[42]. It has been reported that CAP is an effective therapeutic strategy for active refractory UC with fewer adverse effects[52-59]. In addition, it is notable that there have been no reports showing LOR to CAP during the treatment.

As described above, recent studies have shown the efficacy of the use of CAP in patients with UC showing a poor response or LOR to biologics, but the results of these studies have not been summarized to date. The purpose of this article is to summarize the current literature on the use of CAP as an alternative therapeutic strategy for patients with UC showing insufficient response or LOR to biologics and discuss the advantages and limitations of this strategy. We also summarized the efficacy of CAP for patients with UC showing insufficient response to thiopurines or immunomodulators (IM)[36,37,42,58-62].

LITERATURE SEARCH STRATEGY

Electric search for studies published before December 2021 was performed in the PubMed databases. The search terms used were as follows; ulcerative colitis, inflammatory bowel disease, cytapheresis, GMA, biologics, loss of response, anti-TNF-α antibody, infliximab, adalimumab, golimumab, vedolizumab, ustekinumab, combination therapy, thiopurine, and immunomodulator. Reference lists of all relevant articles were searched for further studies. The search was restricted to articles in the English language and included prospective studies, retrospective studies, case series, case reports, and randomized control studies. Subsequently, we generated a state-of-the-art comprehensive review by summarizing the data on the efficacy of CAP in patients with UC (or IBD) showing insufficient or lost response to biologic therapy, and efficacy of CAP in patients with UC showing insufficient response to thiopurines or IM.

EFFICACY OF CAP IN PATIENTS WITH UC SHOWING INSUFFICIENT RESPONSE TO THIOPURINES OR IM

There were eight studies that evaluated the efficacy of CAP in patients having UC with insufficient response to thiopurines (Table 1)[36,37,42,58-62]. These studies include three prospective studies, two retrospective studies, one historical cohort study, one single-arm, open-label, multicentre trial, and one multicenter cohort study. Among them, four studies showed remission rates, and four studies showed steroid-free remission rates in CAP therapy in patients with UC concomitantly treated with thiopurines or IM. Although the background of the patients in these studies were different, the remission rates in CAP therapy ranged from 40.3%-73% (mean ± SD: 56.25 ± 16.03%, median: 55.85%, interquartile range: 41.475%-71.425%) and the steroid-free remission rates in CAP therapy ranged from 36%-56.3% (mean ± SD: 47.25 ± 9.99%, median: 48.35%, interquartile range: 37.425%-55.975%) (Figure 1). Among these studies, four[37,42,58,59] compared the rates of clinical remission between the patients exposed to thiopurines or IM and the patients unexposed to them. In all four studies significant differences were not observed in the rates of remission between patients exposed to thiopurines or IM and control. In three of the four studies, the remission rates in patients with UC concomitantly exposed to thiopurines or IM ranged from 45%-73% (mean ± SD: 61.57 ± 14.69%, median: 66.7%), and those in patients unexposed to thiopurines or IM ranged from 48%-71% (mean ± SD: 62.7 ± 12.8%, median: 69.1%) (Figure 2A).

Specifically, Yokoyama *et al*[42] used LCAP in their study and demonstrated that the clinical remission rate of the patients concomitantly using thiopurines was 73% and that of the patients without using thiopurines was 71%. They showed that in univariate analysis, concomitant use of thiopurine did not show statistically significant differences between the remission and nonremission groups (P = 0.623). Yamamoto *et al*[37] used GMA in their study and showed that the clinical remission rate of patients exposed to immunosuppressants was 45%, and that of the patients unexposed to immunosuppressants was 48%. They showed that in the univariate analysis, exposure to immunosuppressants did not affect the likelihood of clinical remission in the treatment of GMA (P = 0.61).

Regarding the rate of steroid-free remission, two studies[59,62] compared the rates of steroid-free remission between the patients concomitantly treated with thiopurines or IM and the patients treated without them. These studies showed that significant differences were not observed between the patients concomitantly treated with thiopurines or IM and patients treated without them. The steroid-free remission rates in patients with UC concomitantly treated with thiopurines or IM were 41.7% and 56.3% (mean: 49%) and the rates of steroid-free remission in patients with UC treated without thiopurines or IM were 45.5% and 53.5% (mean: 49.5%), respectively (Figure 2B). Specifically, Ishiguro *et al*[62] showed that in the univariate analysis, IM therapy was not associated with remission induction rate by GMA (P = 1.00). However, they also showed that in the multivariate analysis, only IM therapy was associated with an increased risk of relapse (OR: 37.6877, 95%CI: 2.4178-587.4632; P = 0.0013).

Table 1 Efficacy of cytapheresis in patients with ulcerative colitis showing insufficient response to thiopurine or immunomodulators

Ref.	Study type	Total number of patients included in the study	Number of patients insufficient response to thiopurine or IM	Regimen of CAP	Rate of remission	Rate of steroid- free remission
Cabriada *et al*[60], 2010	Prospective study	18 (SD)	18	GMA or LCAP (5-10 sessions, 1 session/wk)		55%
Takayama *et al*[58], 2013	Historical cohort study	90	14	GMA or LCAP (5-10 sessions, 1-2/wk)	49% (total Pts), pre-use of IM had little effects on the response to therapy	
Yokoyama *et al*[42], 2014	Prospective Observation Study	623 (for efficacy assessment)	196	LCAP (5-10 sessions, mean 8.4), intensive LCAP was performed in > 70% of Pts	73% (Pts concomitantly treated with thiopurine), 71% (Pts treated without thiopurine), $P = 0.623$	
Imperiali *et al*[61], 2017	Prospective multicenter study	33 (SD)	33	GMA (5 sessions, 1 session/wk)		36%
Yamamoto *et al*[37], 2018	Retrospective study	593	159	GMA (5 sessions, 1 to 5 sessions/wk), 5 or 6 GMA were added in Pts who did not achieve clinical remission	45% (Pts exposed to IM), 48% (Pts unexposed to IM), $P = 0.61$	
Dignass *et al* [36], 2016	Single-arm, open-label, multicentre trial	86 (SD)	83	GMA (5-10 sessions, 1 session/wk)	40.3%	
Ishiguro *et al*[62], 2020	Multicenter cohort study	102, SD or SR UC Pts were not included	16	GMA (mean number of GMA 9.9 sessions, 1-3 sessions/wk)		56.3% (Pts concomitantly treated with IM), 53.5% (Pts treated without IM), $P = 1.00$
Iizuka *et al* [59], 2021	Retrospective study	55 (SD: 33, SR: 21)	12	GMA or LCAP [5-20 sessions (mean 8.8), 1-2 sessions/wk (in principle)]	66.7% (Pts concomitantly treated with thiopurine), 69.1% (all Pts), no significant differences	41.7% (Pts concomitantly treated with thiopurine), 45.5% (all Pts), no significant differences

CAP: Cytapheresis; GMA: Granulocyte and monocyte adsorptive apheresis; LCAP: Leukocytapheresis; IM: Immunomodulators (or immunosuppressants); Pts: Patients; SD: Steroid dependent patients; SR: Steroid refractory patients; Intensive LCAP: Defined as performing ≥ 4 leukocytapheresis treatment within the first 2 wk.

In summary, it was suggested that CAP has the same effectiveness for induction of remission in patients with UC with and without prior failure to thiopurines or IM.

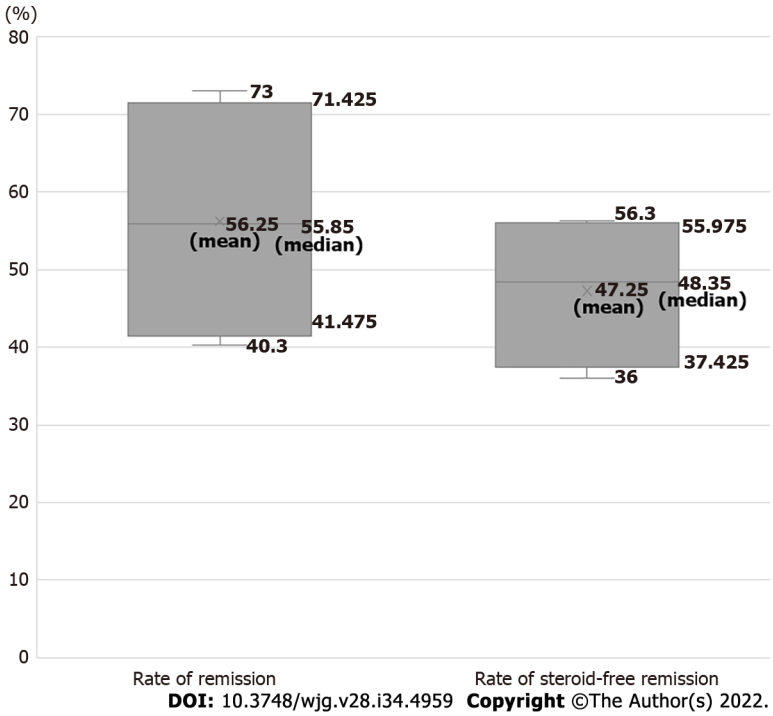
EFFICACY OF CAP IN PATIENTS WITH UC SHOWING PREVIOUS BIOLOGICS FAILURE

Three studies have evaluated the efficacy of CAP in patients with UC showing an insufficient response to anti-TNF-α therapy or exposure to biologics compared with biologic naïve patients with UC[35-37] (Table 2). These studies include two retrospective studies and one single-arm open-label multicentre trial. Among these studies, Yamamoto *et al*[37] showed that the clinical remission rate of the patients exposed to biologics was 31%, and that of the patients unexposed to biologics was 48% ($P = 0.01$). They showed that in the univariate analysis, biologic naïve patients responded well to GMA ($P = 0.01$). In multivariate analysis, exposure to biologics was an independent significant factor affecting the clinical efficacy of GMA ($P = 0.01$). Dignass *et al*[36] conducted a study on a large cohort of steroid-dependent patients with UC refractory to immunosuppressant and /or biologic treatment to provide additional clinical data regarding the safety and efficacy of Adacalumn (GMA). They showed that remission was achieved at week 12 in 31/77 [40.3% (95%CI: 29.2, 52.1)] of patients who failed on immunosuppressants, 10/36 [27.8% (95%CI: 14.2, 45.2)] of patients who failed on anti-TNF-α treatment, and 9/30 [30.0% (95%CI: 14.7, 49.4)] of patients who failed on both immunosuppressants and anti-TNF-αtreatment. Their results suggested that the remission rate using Adacalumn tended to be lower in patients who failed on anti-TNF-α treatment or on both immunosuppressants and anti-TNF-α treatment compared to that of the patients who failed on immunosuppressants. The remission rates in patients with UC exposed to anti-TNF-α treatment in the two studies were 27.8% and 31% (mean: 29.4%), and the remission rates in

Table 2 Efficacy of cytapheresis in patients with ulcerative colitis showing previous biologics failure

Ref.	Study type	Biologics exposure	Number of patients (total number of patients in the study)	Regimen of CAP	Rate of remission	Rate of steroid-free remission
Cabriada *et al*[35], 2012	Retrospective study (results of nationwide Spanish registry)	IFX	33 (total: 142 SD)	GMA (95% of the Pts), 1-10 sessions (median 5 sessions)		37% (all Pts), no differences in clinical remission were found among those Pts with previous thiopurine or IFX failure
Dignass *et al* [36], 2016	Single-arm, open-label, multicentre trial	TNF-α	37 (total: 86 SD)	GMA (5-10 sessions, 1 session/wk)	27.8% (Pts who failed on TNF-α), 40.3% (Pts who failed on immunosup-pressants	
Yamamoto *et al*[37], 2018	Retrospective study	(1) IFX; and (2) ADA	(1) 31; and (2) 36 (total: 593)	GMA (5 sessions, 1 to 5 sessions/wk), 5 or 6 GMA were added in Pts who did not achieve clinical remission	31% (Pts exposed to biologics), 48% (Pts unexposed to biologics), P = 0.01	

CAP: Cytapheresis; SD: Steroid dependent patients; GMA: Granulocyte and monocyte adsorptive apheresis; Pts: Patients; IFX: Infliximab; TNF-α: Tumor necrosis factor-α; ADA: Adalimumab.



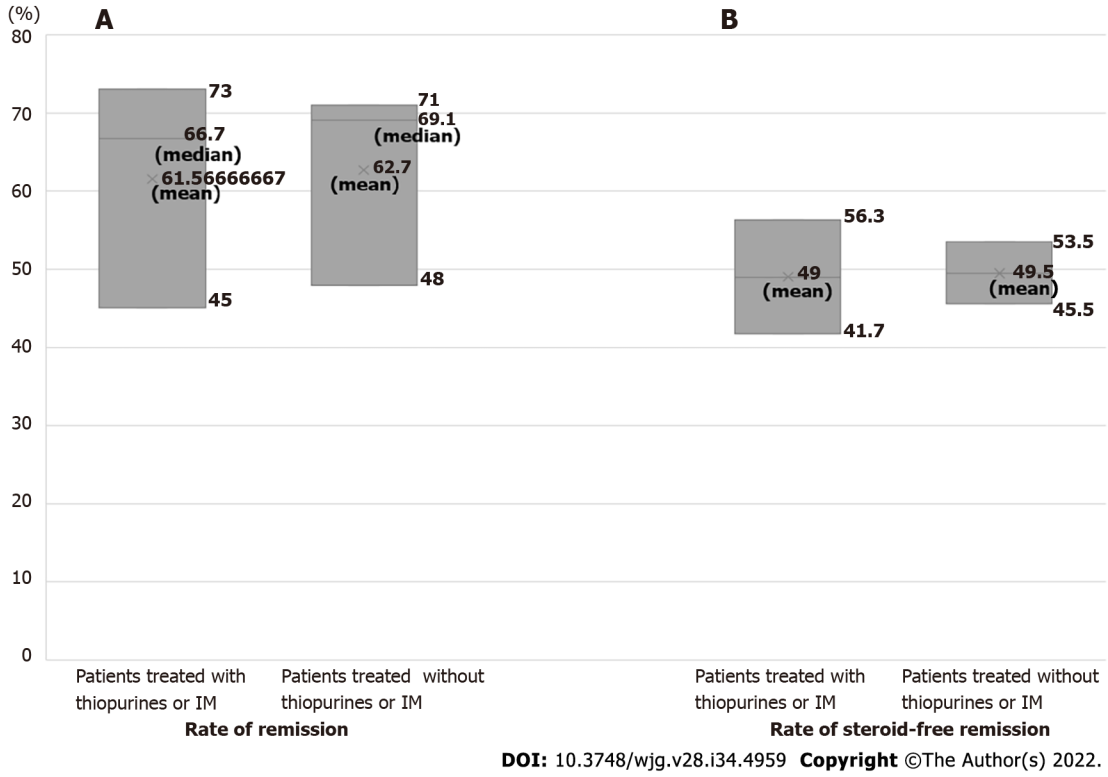


Figure 1 Remission and steroid-free remission rates in cytapheresis therapy in patients with ulcerative colitis concomitantly treated with thiopurines or immunomodulators. Box plot shows that, in cytapheresis therapy, the remission rates range from 40.3%-73% (mean: 56.25%, median: 55.85%, interquartile range: 41.475%-71.425%) and the rates of steroid-free remission range from 36%-56.3% (mean: 47.25%, median: 48.35%, interquartile range: 37.425%-55.975%).

patients with UC unexposed to anti-TNF-α treatment were 40.3% and 48% (mean: 44.15%), respectively (Figure 3).

Cabriada *et al*[35] conducted a clinical study including 142 steroid-dependent patients with UC [previous thiopurines failure 98 (69%), previous IFX failure 33 (23%)] to evaluate the short and long-term effectiveness and safety of leukocytapheresis therapy by means of a nationwide registry of clinical practice. Although the rate of remission in patients who were refractory to thiopurines or IFX was not described in the paper, no differences in clinical remission were found among those with previous thiopurine or IFX failure.

DOI: 10.3748/wjg.v28.i34.4959 **Copyright** ©The Author(s) 2022.

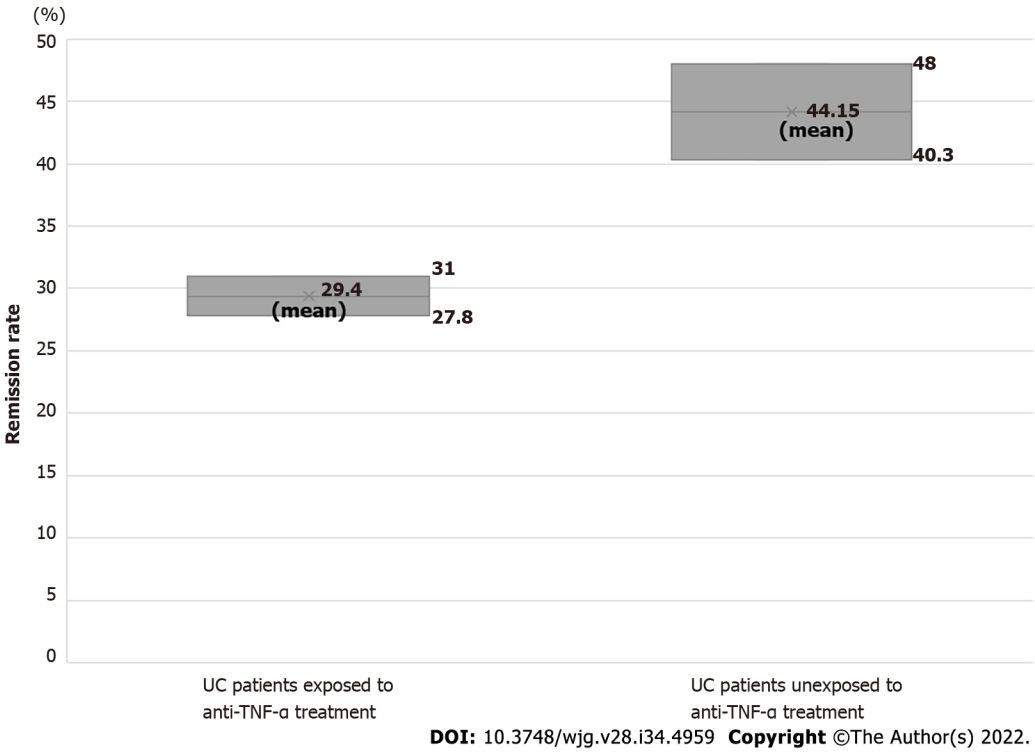
Figure 2 Remission and steroid-free remission rates in cytapheresis therapy in patients with ulcerative colitis concomitantly treated with thiopurines or immunomodulators and in those treated without thiopurines or immunomodulators. A: Box plot shows that the rates of remission in patients concomitantly treated with thiopurines or immunomodulators (IM) and in those treated without thiopurines or IM range from 45%-73% (mean: 61.57%, median: 66.7%) and 48%-71% (mean: 62.7%, median: 69.1%), respectively; B: The rates of steroid-free remission in patients with ulcerative colitis (UC) concomitantly treated with thiopurines or IM are 41.7% and 56.3% (mean: 49%), and those in patients with UC treated without thiopurines or IM are 45.5% and 53.5% (mean: 49.5%), respectively.

In summary, it is controversial whether CAP has a similar clinical effect in patients with UC who failed biologics treatment and in biologic naïve patients with UC due to limited studies. However, based on these studies, it is suggested that CAP tended to have less efficacy for induction of clinical remission in patients with UC who failed on anti-TNF-α treatment compared to biologic naïve patients with UC.

EFFICACY OF COMBINATION THERAPY WITH CAP AND BIOLOGICS IN IBD PATIENTS SHOWING INSUFFICIENT RESPONSE OR LOSS OF RESPONSE TO BIOLOGICS

Efficacy of the combination therapy with CAP and biologics

There have been 14 studies that evaluated the efficacy of the combination therapy of CAP and biologics in IBD patients that were refractory to biologics[38-51] (Table 3). These studies include two prospective studies, four retrospective studies, one preliminary study, and seven case reports. These studies include eight studies evaluating combination therapy with GMA or LCAP and anti-TNF-α (IFX: 6 studies; ADA: 1 study; IFX, ADA, golimumab: 1 study), four studies with GMA and VDZ, one study with GMA and ustekinumab, and one exceptional study with GMA and a pan-JAK inhibitor tofacitinib. Among these 14 studies, seven studies[42,44,45,47-50] examined the efficacy of combination therapies in patients with UC, five studies[38-41,46] examined its efficacy for CD patients, and two studies[43,51] examined its efficacy for both UC and CD patients.



As shown in Table 3, there were differences in the background of the patients and methods of combination therapies among the studies, and heterogeneity existed in the efficacy of the combination therapies with CAP and biologics among the studies. The rates of remission or response to combination therapies in IBD (UC and CD) patients in these studies excluding seven case reports ranged from 32%-100% (mean ± SD: 62.72 ± 26.65%, median: 57.85%, interquartile range: 40.175%-89.275%) and the rates of steroid-free remission ranged from 9%-75% (mean ± SD: 43 ± 27.4%, median: 44%, interquartile range: 16.25%-68.75%), respectively (Figure 4). Regarding the efficacy of the combination therapies in patients with UC, three studies showed the rates of remission or response, and three studies showed steroid-free remission in the combination therapies of CAP and biologics in patients with UC refractory to biologics. The rates of remission or response ranged from 32%-69% (mean ± SD: 47.97 ± 19.0%, median: 42.9%),

Table 3 Efficacy of combination therapy with cytapheresis and biologics in inflammatory bowel disease patients showing insufficient response or loss of response to biologics

Ref.	Study type	Biologics to which insufficient response or LOR was shown	Number of patients	Methods of combination therapy	Regimen of CAP	Rate of remission	Rate of response	Rate of steroid-free remission	Rate of AE (%)

Figure 3 Remission rates in cytapheresis therapy in patients with ulcerative colitis exposed to anti-tumor necrosis factor-α treatment and in those unexposed to anti-tumor necrosis factor-α treatment. The remission rates in patients with ulcerative colitis (UC) exposed to anti-tumor necrosis factor-α (TNF-α) treatment are 27.8% and 31% (mean: 29.4%), and those in patients with UC unexposed to anti-TNF-α treatment are 40.3% and 48% (mean: 44.15%), respectively.

and the rates of steroid-free remission in patients with UC ranged from 9%-75% (mean ± SD: 40.7 ± 33.1%, median: 38%), respectively (Figure 5). On the other hand, the rates of remission or response in CD patients ranged from 46.7%-100% (mean ± SD: 77.5 ± 27.6%, median 85.7%), and the rate of steroid-free remission in CD patients was 50%.

Regarding the efficacy of the combination therapy, Rodríguez-Lago *et al*[47] found no differences in the efficacy depending on the type of anti-TNF received during the combination therapy. They also reported that the response to the combination therapy was inversely proportional to the number of previous anti-TNF agents, but it was not influenced by the presence of primary non-response or secondary LOR. Another important aspect being considered is the regimen of CAP prescribed because an intensified regimen with longer and biweekly sessions has demonstrated rapid and higher efficacy rates without increasing the number of adverse events (AEs)[47,57]. In Table 3, it seems that the studies using a higher frequency of biweekly CAP or intensive CAP tended to demonstrate good clinical efficacy.

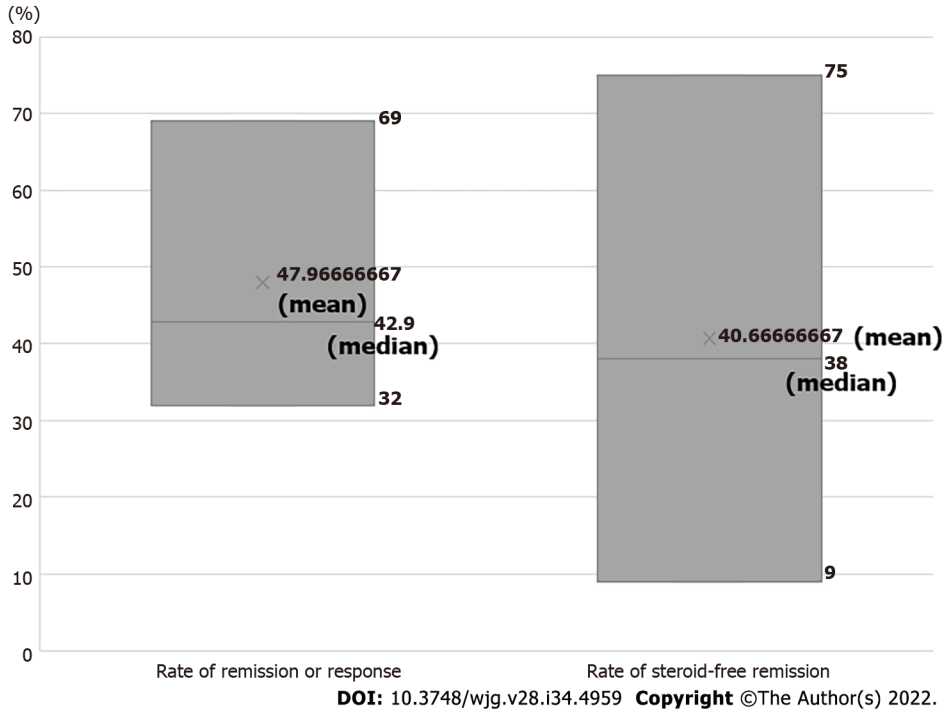
Figure 4 Rates of remission or response and steroid-free remission in the combination therapies of cytapheresis and biologics in inflammatory bowel disease patients showing insufficient response or loss of response to biologics. Box plot shows that the remission rates in the combination therapies of cytapheresis and biologics range from 32%-100% (mean: 62.72%, median: 57.85%, interquartile range: 40.175%-89.275%), and the rates of steroid-free remission in the combination therapies range from 9%-75% (mean: 43%, median: 44%, interquartile range: 16.25%-68.75%).



Safety of the combination therapy

One of the strengths of CAP is its safety profile[63]. Of note, several studies have reported the excellent safety of CAP[36,42,52,56,63]. Among these studies, Hibi *et al*[56] evaluated the safety of Adacolumn in 697 patients with UC in 53 medical institutions. They reported that no serious AEs were observed, and only mild to moderate adverse events were observed in 7.7% of patients. In addition, Motoya *et al*[52] showed that the incidence of AEs among elderly patients was similar in all patients. Regarding the safety of the combination therapy with CAP and biologics, eight out of 14 studies listed in Table 3 reported the rate of AEs[39,41,44,46-48,50,51]. Six of the eight studies reported no adverse events. On the other hand, Rodríguez-Lago *et al*[47] reported 4% (2/47) AEs related to the technique (anxiety and headache), and Tanida *et al*[50] reported 43% (3/7) AEs (one had orolabial herpes, one had a transient increase in creatinine phosphokinase due to intense physical exercise, and one had triglyceride increase). However, Tanida *et al*[50] described that AEs observed in their study were consistent with the AEs reported in the oral clinical trials for tofacitinib in ulcerative colitis induction 1 and 2 trials, suggesting that AEs observed in their study were due to AEs from tofacitinib. In summary, AEs were observed in five out of 86 patients (5.8%) in the eight studies.

Based on these results, combination therapy with CAP and biologics is safe and well- tolerated.

Possible mechanisms of the efficacy of the combination therapy with CAP and biologics

Regarding the mechanism of the efficacy of the combination therapy of CAP and biologics, Rodriguez-Largo *et al*[47] suggested that the benefit may be related to multiple mechanisms of action. They suggested that GMA could reduce the circulating inflammatory burden in addition to direct improvement in disease activity, thus allowing the anti-TNF to restore its response. They also suggested an alternative hypothesis that states that the benefits come from the possible interaction between both treatments. This interaction could be an improvement in blood trough levels of the drug, a reduction of anti-drug antibodies, or both. In this context, several studies supported their hypothesis. Soluble TNF receptors are known to neutralize TNF without invoking a TNF-like response. Saniabadi *et al*[64] reported that blood levels of soluble TNF-α receptors I and II increased in IBD patients who underwent Adacolumn therapy. Hanai *et al*[65] also showed that soluble TNF-α receptor I/II, which are believed to have potent anti-inflammatory actions, were significantly increased in the peripheral blood at the end of the GMA session. Sono *et al*[40] showed an increase in plasma IL-10 and a decrease in circulating immune complexes and anti-nuclear antibodies during GMA therapy in GMA-responder CD patients with LOR to IFX. Furthermore, Yokoyama *et al*[43] showed that upon GMA therapy, the average plasma trough IFX increased from 0.91 μg/mL to 1.46 μg/mL, with concomitant decreases in C-reactive protein, IL-6, and IL-17A in IBD patients experiencing LOR to IFX. In their recent study, Yokoyama *et al*[51]

DOI: 10.3748/wjg.v28.i34.4959 **Copyright** ©The Author(s) 2022.

Figure 5 Rates of remission or response and steroid-free remission in the combination therapies of cytapheresis and biologics in patients with ulcerative colitis showing insufficient response or loss of response to biologics. Box plot shows that the remission rates in the combination therapies of cytapheresis and biologics range from 32%-69% (mean: 47.97%, median: 42.9%), and the rates of steroid-free remission in the combination therapies range from 9%-75% (mean: 40.7%, median: 38%).

showed that the levels of antibodies to IFX in patients with LOR to IFX were significantly elevated compared with those indicating a sustained clinical remission. They also showed that in patients who received IFX + GMA combination therapy, the IBD symptoms significantly improved together with a decrease in antibodies to IFX. These studies suggest the possibility that GMA therapy can decrease IFX antibodies and increase plasma trough IFX in patients with LOR to IFX.

Regarding combination therapy with GMA and VDZ, it was hypothesized that this strategy might target the migration of leukocytes into the inflamed tissue by combining their mechanism of action. The peripheral inflammatory cells affected by VDZ may be removed by the ability of GMA to adsorb multiple immune cells[48]. Nakamura *et al*[49] also suggested that VDZ and GMA were able to strengthen the suppression of the migration of leukocytes into the inflamed tissue by combining their mechanisms of action. Since the migration of peripheral inflammatory cells from the blood vessels is blocked by VDZ, multiple immune cells-including the congested ones in the peripheral blood- can be removed by GMA. Thus, considering the mechanism of action of GMA and VDZ, it is suggested that this combination therapy can synergically strengthen the therapeutic effects of each therapy.

Summary of the combination therapies with CAP and biologics

In summary, combination therapies of CAP and biologics can safely induce clinical remission or response and steroid-free remission in 32%-100% (mean: 62.72%, median: 57.85%) and 9%-75% (mean: 43%, median: 44%) of the IBD patients and in 32%-69% (mean: 47.97%, median: 42.9%) and 9%-75% (mean: 40.7%, median: 38%) of patients with UC refractory to biologics, respectively. In addition, it is a strong point of CAP that there have been no reports showing LOR to CAP during treatment. Given the excellent safety profile of CAP, these results suggest that this combination therapy can be an effective and alternative therapeutic strategy for patients with UC that experienced primary non-response or LOR to biologics. The economic burden of GMA may also be considered in decision-making[63]. A recent study showed that the availability of biosimilars had reduced the costs of anti-TNF agents, but GMA still has a cost slightly below the new biologicals (*i.e.*, ustekinumab and vedolizumab) with an even better safety profile[63]. In this context, Tominaga *et al*[66] evaluated the efficacy, safety, and treatment cost of prednisolone (PSL) and GMA in 41 patients with active UC who had achieved remission with GMA or with orally administered PSL. They showed that adverse events were reported in 12.5% of the GMA group and 35.3% of the PSL group. The average medical cost was 12739.4€/patient in the GMA group and 8751.3€ in the PSL group ($P < 0.05$). From these results, they concluded that the higher cost of GMA is offset by its good safety profile.

CONCLUSION

Summarizing the results of previous studies, it is suggested that CAP has the same effectiveness for induction of remission in patients having UC with or without prior failure of thiopurines or IM. It is controversial whether CAP has a similar clinical effect in patients with UC that failed on previous biologics therapy and in biologic naïve patients. However, it seems that CAP tended to be less effective for induction of clinical remission in patients with UC that were refractory to biologics therapy. Although there was heterogeneity in the efficacy of the combination therapy with CAP and biologics in patients with IBD refractory to biologics, it is notable that combination therapies with CAP and biologics induced clinical remission or response and steroid-free remission in more than 40% of patients with UC that failed on previous biologics therapy on average. Given the excellent safety profile of CAP, it is suggested that this combination therapy can be an alternative therapeutic strategy for patients with UC that were refractory to biologics. However, the number of studies examining this combination therapy has been small and limited to date. Larger prospective studies are needed to better understand the efficacy of the combination therapy of CAP and biologics for refractory patients with UC.

Abstract

BACKGROUND

Long noncoding RNA (lncRNA) ZNFX1-AS1 (ZFAS1) is a newly discovered lncRNA, but its diagnostic value in gastric cancer is unclear.

AIM

To investigate the potential role of ZFAS1 in gastric cancer and to evaluate the clinical significance of ZFAS1 as a biomarker for gastric cancer screening.

METHODS

Quantitative real-time polymerase chain reaction (qRT-PCR) was used to screen for gastric cancer-associated lncRNAs in gastric cancer patients, gastric stromal tumor patients, gastritis or gastric ulcer patients, and healthy controls. Correlations between ZFAS1 expression and clinicopathological features were analyzed. The biological effects of ZFAS1 on the proliferation, migration, and invasion of gastric cancer cells were studied by MTT, colony formation, and transwell migration assays. The potential mechanism of ZFAS1 was demonstrated using enzyme-linked immunosorbent assay and qRT-PCR. The relationship between ZFAS1 and tumorigenesis was demonstrated using *in vivo* tumor formation assays.

RESULTS
The plasma level of lncRNA ZFAS1 was significantly higher in preoperative patients with gastric cancer than in individuals in the other 4 groups. Increased expression of ZFAS1 was significantly associated with lymph node metastasis, advanced TNM stage, and poor prognosis. ZFAS1 regulated the proliferation, migration, and invasion of gastric cancer cells and regulated the growth of gastric cancer cells *in vivo*. LIN28 and CAPRIN1 were identified as key downstream mediators of ZFAS1 in gastric cancer cells.

CONCLUSION
LncRNA ZFAS1 promoted the invasion and proliferation of gastric cancer cells by modulating LIN28 and CAPRIN1 expression, suggesting that ZFAS1 can be used as a potential diagnostic and prognostic biomarker in gastric cancer.

INTRODUCTION

Gastric carcinoma is the 2nd primary cause of death due to carcinoma and the 6th most common cancer worldwide. Approximately 1000000 new cases of gastric cancer are diagnosed each year, and approximately 800000 patients die from the disease, accounting for approximately 8.2% of global cancer-related mortality[1]. The progression-free survival (PFS) rate and prognosis of gastric carcinoma highly depend on the TNM stage of the disease. The high mortality is associated with the faultiness of standard screening protocols and lack of overt early symptoms[1]. Therefore, early detection and optimal treatment are necessary to improve the prognosis of gastric carcinoma. However, current biologic markers, such as carbohydrate antigen 199 (CA-199) and carcinoembryonic antigen (CEA), have low sensitivity and specificity[2]. Therefore, there is an urgent need to find novel biomarkers for early diagnosis of gastric cancer.

Long noncoding RNAs (lncRNAs) are a class of non-protein-coding RNA molecules > 200 nucleotides in length[3]. Recently, some studies have reported that lncRNAs are involved in protein modification and gene expression and that their dysregulation leads to a variety of genetic diseases[4-6]. Published articles have also shown that lncRNAs exhibit significant regulatory effects on transcription patterns in malignant tumors, some of which involve tumor cell invasion and metastasis, with a poor prognosis[6, 7]. For example, H19 and SUMO1 pseudogene 3 (SUMO1P3) are upregulated in gastric cancer, while gastric cancer-associated transcript 1 is downregulated[7-11]. Additionally, HOTAIR overexpression may be associated with tumor escape mechanisms[12]. These studies strongly suggest that lncRNAs underlie the molecular etiology of gastric carcinoma. It is worth noting that the detection of circulating lncRNAs provides a new gastric biomarker for gastric cancer that is expected to be useful for monitoring and screening patients with gastric cancer[13].

Here, we selected 15 candidate cancer-associated lncRNAs. Among these lncRNAs, lncRNA ZNFX1-AS1 (ZFAS1) was found to be upregulated in the plasma of preoperative gastric cancer patients compared with healthy controls, and expression of ZFAS1 was significantly associated with lymphatic invasion, advanced TNM stage, and poor prognosis. We then investigated the biological effects of ZFAS1 on the survival, proliferation, and migration of gastric cancer cells. The underlying mechanism of ZFAS1 and the relationship between ZFAS1 and tumorigenesis were identified. These results showed that lncRNA ZFAS1 is a potential biomarker for gastric cancer.

MATERIALS AND METHODS

Sample collection and ethics statement

All samples were obtained from Peking University People's Hospital between July 2015 and June 2016. Seventy-five matched (pre- and postoperative) whole blood and serum samples were collected from patients who underwent gastrointestinal surgery for gastric resection. In addition, intraperitoneal free cancer cell (IFCC) samples were collected from 60 of these patients. Other whole blood and serum specimens were collected from 60 gastric stromal tumor patients (before surgery), 60 gastritis or ulcer patients (before treatment), and 75 healthy controls. All specimens were collected with the corresponding patient information, such as age, sex, and collection time. In addition, the tumor size, tumor location (evaluated according to the National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology, Version II[14]), pathological type, degree of differentiation (based on the World Health Organization Classification of Tumors of the Digestive System, 4th edition[15]), TNM stage and lymphatic invasion status (based on the American Joint Committee on Cancer Staging Manual, 7th edition[16]) of the corresponding patients were collected.

Plasma and serum samples were collected in BD vacutainer ethylenediamine tetraacetic acid tubes and BD vacutainer somatostatin tubes (BD Biosciences, NJ, United States), respectively. Preoperative samples of patients with gastric cancer were obtained at least 2 mo before surgery or after radiotherapy or chemotherapy. Postoperative samples from these patients were collected 7-10 d after surgery. Samples from patients with gastric stromal tumor or gastritis/peptic ulcer were collected before any treatment was administered. The healthy control samples were randomly collected from normal subjects. For plasma samples, a special centrifugation protocol (2348 × g for 30 min at 4 °C; 4696 × g for 5 min at 4 °C; 10733 × g for 5 min at 4 °C) was performed to prevent contamination with cellular nucleic acids. Plasma and IFCC samples were stored at -80 °C in 3 volumes of TRIzol® reagent (Qiagen, CA, United States) for further analysis. Serum samples were analyzed directly[17]. This study was approved by the Research Ethics Committee of Peking University People's Hospital. Patient data and samples were treated according to the ethical and legal criteria adopted in the 2013 Declaration of Helsinki. Written informed consent for ethical approval and patient consent was obtained from all participants.

RNA extraction and quantitative real-time polymerase chain reaction

This method is the same as that described in our previously published article[17]. LncRNA was extracted from plasma using a Direct-zol™ RNA MiniPrep R2050i Kit (Zymo Research, CA, United States) according to the manufacturer's protocol. The concentration and purity of total RNA were measured using a NanoDrop 2000c spectrophotometer (Thermo Fisher Scientific, MA, United States). Total RNA was then solubilized using RNase-free water, and reverse transcription was immediately performed using PrimeScript RT Master Mix (Takara Bio, Kyushu, Japan) according to the manufacturer's instructions. After reverse transcription, quantitative polymerase chain reaction (qPCR) was performed in a LightCycler 480 Instrument II (Roche Diagnostics, Basel, Switzerland) using TransStart Green qPCR SuperMix (TransGen, Beijing, China) according to the supplier's instructions. The primers used for qPCR were designed with Primer Premier V 5.0 (Premier Biosoft International, CA, United States) and were synthesized by Beijing Sunbiotech Co., Ltd. (Beijing, China). The sequences of all primers, including those specific for GAPDH, are listed in Table 1. PCR was carried out with initial denaturation at 95 °C for 3 min followed by 40 cycles of 1 min at 95 °C and 1 min at 60 °C with subsequent detection. Due to the stability of GAPDH in plasma, it was chosen as the internal control for data standardization. For the calculations, the equation $\Delta C_q = C_{q\ \text{selected lncRNA}} - C_{q\ \text{GAPDH lncRNA}}$ was used, where ΔC_q was defined as the difference in the quantification cycle (C_q) values. Every specimen was analyzed in triplicate, and the experiment was repeated 3 times.

Cell culture

The human gastric cancer cell lines BGC-823 and SGC-7901 were a gift from Peking University People's Hospital Gastrointestinal Surgery Laboratory and were maintained in RPMI 1640 medium (Invitrogen, CA, United States) supplemented with 10% fetal bovine serum (FBS) (Gibco, CA, United States). The flask was incubated in a humidified incubator at 37 °C under 5% CO_2 in air.

LncRNA silencing and overexpression

ZFAS1-siRNA against ZFAS1 was synthesized by GenePharma (Shanghai, China). BGC-823 and SGC7901 cells were grown in 6-well plates (2 × 10^5cells/well) and transfected for 36 h using Lipofectamine RNAiMAX Transfection Reagent (Invitrogen, CA, United States). The ZFAS1 siRNA sequences were as follows: ZFAS1 siRNA1, 5′-AGACGCGAAAGAACGAAUGTT-3′; ZFAS1 siRNA2, 5′-UUACAAGGCAGACUGAAUCTT-3′; and ZFAS1 siRNA3, 5′-UAUGCAGGUAGGCAGUUAGTT-3′. The GAPDH siRNA and negative control siRNA sequences were as follows: GAPDH siRNA, 5'-ACGUGACACGUUCGGAGAATT-3' and negative control siRNA, 5'-ACGUGCAC AGUACUAGGAATT-3'.

The ZFAS1 overexpression short hairpin RNA (ZFAS1-shRNA1), sh-ZFAS1 directed against ZFAS1 short hairpin RNA (ZFAS1-shRNA2), and NC-shRNA short hairpin RNA constructs were synthesized by GenePharma (Shanghai, China). The sequences of ZFAS1-shRNA1, ZFAS1-shRNA2, and NC-shRNA are shown in Table 2. BGC-823 and SGC7901 cells were grown in 6-well plates (2×10^5 cells/well) and transduced for 36 h using Polybrene (GenePharma, REVG0001) and Enhanced Infection Solution (GenePharma, REVG0002).

MTT assay

After transduction with NC-shRNA, ZFAS1-shRNA1, and ZFAS1-shRNA2, BGC823 and SGC7901 cells were trypsinized, and six replicates of 12×10^3 cells per well were seeded in 96-well plates, with wells without cells used as blank wells. Proliferation was measured by an MTT (Sigma Aldrich, St. Louis, MO, United States) transformation assay. Briefly, 20 mL of MTT solution (5 mg/mL) was added to each well, and cells were grown for 4 h at 37 °C. After adding 100 mL of the dissolved solution (10% SDS in 0.01 M HCl solution), cells were further cultured at 37 °C for 3 h. The specific optical density of all wells was then measured at 490 nm.

Transwell migration assay

BGC823 and SGC7901 cells were suspended in serum-free medium after transduction with NC-shRNA, ZFAS1-shRNA1, and ZFAS1-shRNA2 and inoculated into transwell chambers with inserts of 8 μm pore size. Medium containing 10% FBS was placed in the bottom chamber. After 36 h of incubation, cells that migrated through the membrane to the lower surface were fixed with paraformaldehyde, stained with crystal violet, counted, and photographed. The results are shown as the average of three independent experiments.

Colony formation assay

BGC823 and SGC7901 cells transduced with NC-shRNA, ZFAS1-shRNA1, and ZFAS1-shRNA2 were seeded into 6-well plates (1000 cells per well) and cultured in a humidified incubator at 37 °C in 5% CO_2 for 10 d. The medium was changed every 3 d. At the end of the incubation period, the cultured cells were fixed with 4% paraformaldehyde and stained with crystal violet to assess the number of colonies. The results are shown as the average of three independent experiments.

Prediction and expression of ZFAS1 binding proteins

Binding proteins of lncRNA ZFAS1 were predicted based on the starBase V2.0 database (http://starbase.sysu.edu.cn). The primers specific for the mRNA sequences of the genes encoding the binding proteins were designed according to the nucleic acid sequence information for the corresponding proteins in GenBank (https://www.ncbi.nlm.nih.gov/genbank/) with a primer design tool (

ZFAS1: ZNFX1-AS1.

http://www.ncbi.nlm.nih.gov/tools/primer-Blast). The sequences of all primers, including those specific for GAPDH, are listed in Table 3.

NC-shRNA, ZFAS1-shRNA1, and ZFAS1-shRNA2 were transduced into BGC823 and SGC7901 cells, and mRNA was then reverse transcribed. The mRNA expression levels of the genes encoding the candidate lncRNA ZFAS 1 binding proteins were determined by quantitative real-time-PCR (qRT-PCR) using the primers listed in Table 3. The experimental method was the same as that described previously.

Protein extraction and enzyme-linked immunosorbent assay

Stably transfected cells, as well as tumor/lymph node tissue from BALB/c nude mice, were lysed with NP40 cell lysis buffer (Invitrogen, CA, United States) supplemented with SigmaFAST™ protease inhibitor tablets (Sigma Aldrich, St. Louis, MO, United States). LIN28, CAPRIN1, CEA, and CK20 were detected by enzyme-linked immunosorbent assay (ELISA) using a Mouse Protein lin-28 homolog A (Lin28a) ELISA Kit (ELISAGenie, Dublin, Ireland), a Human Caprin 1 (CAPRIN1) ELISA Kit (Abbexa, Cambridge, United Kingdom), a CEA ELISA Kit (Bioss, United Kingdom) and CK20 ELISA kits (FKBIO, Chengdu, China), respectively.

In vivo tumor formation assay

Four-week-old female athymic BALB/c nude mice were maintained under specific pathogen-free conditions and operated on according to the protocol approved by the Beijing Medical Laboratory Animal Management Committee. NC-shRNA-, ZFAS1-shRNA1-, and ZFAS1-shRNA2-transduced BGC823 cells were harvested. For tumor formation assays, 10^7 cells were injected subcutaneously into one side of each mouse. Tumor growth was examined every week, and the tumor volume was calculated using the equation V = 0.5 × D × d2 (V, volume; D, longitudinal diameter; d, latitudinal diameter). The expression of lncRNA ZFAS1 in BALB/c mouse blood was detected by qRT-PCR every week, and the primer sequences are listed in Table 1. The expression of LIN28 and CAPRIN1 proteins in BALB/c nude mouse tumors and the expression of CEA and CK20 in BALB/c nude mouse lymph nodes were detected by ELISA after four weeks. This study was conducted in strict accordance with the National Institutes of Health Guidelines for the Care and Use of Laboratory Animals. The program was approved by the Animal Experiment Ethics Committee of Peking University People's Hospital.

Statistical analysis

The formula $2^{-\Delta\Delta Ct}$ were used to calculate the levels of relative lncRNA expression in plasma[18]. Based on this formula, all relative lncRNA expression levels in plasma were evaluated. Continuous variables were described by the mean ± SD (normal distribution), or the median and interquartile range M (P25, P75) (non-normal distribution). The *t*-test or Mann-Whitney *U* test was used according to the data distribution to identify statistically significant differences. For categorical variables, the percentages of patients in each category were calculated using the χ^2 test or Fisher's exact test. In addition, receiver operating characteristic (ROC) curve analysis was performed to assess the diagnostic value of circulating lncRNA and traditional tumor markers in distinguishing between gastric carcinoma patients and healthy subjects. Statistical analysis was performed using SPSS software version 19.0 (IBM Corp., Armonk, NY, United States). *P* values less than 0.05 were considered significant.

RESULTS

Relative expression of a selected subgroup of lncRNAs (plasma) from 15 gastric cancer patients and 15 healthy control subjects

Fifteen matched samples from preoperative and postoperative gastric cancer patients and samples from 15 healthy control subjects were used as the sample cohort. The general characteristics and clinicopathological features of all subjects are provided in Table 4. The relative expression of the 15 lncRNAs, namely, uc001 Lsz/HOTAIR/CCAT1/H19/GACAT2/ABHD11-AS1/GACAT3 /SUMO1P3/CHET1/TUG1/SNHG12/GAS5/PVT1/LINC00152, and ZFAS1, was evaluated in the plasma of all subjects. As mentioned in Figure 1, the levels of lncRNA ZFAS1 in preoperative patient plasma were significantly higher than those in postoperative patient and healthy control subject plasma ($P < 0.01$).

Relative levels of the lncRNA ZFAS1 in the plasma of healthy control subjects, gastritis/peptic ulcer patients, GIST patients, and preoperative and postoperative gastric cancer patients

The general characteristics and clinicopathological features of 60 healthy control subjects, 60 gastritis/peptic ulcer patients, 60 GIST patients, and 60 patients with matched preoperative and postoperative data are summarized in Table 5. The relative levels of ZFAS1 in the plasma of all subjects were assessed by qRT-PCR. As shown in Figure 2A, the levels of lncRNA ZFAS1 in preoperative patient plasma were significantly higher than those in plasma from the individuals in the other four groups ($P < 0.01$).

Relative levels of lncRNA ZFAS1 (plasma) in preoperative gastric carcinoma patients (different TNM stages)

We used the ΔΔCt formula to calculate the relative levels of lncRNA ZFAS1 in the samples (plasma) of patients with different TNM stages, including 20 patients with stage I and II disease and 40 patients with stage III and IV disease. As mentioned in Figure 2B, the median relative levels of lncRNA ZFAS1 in healthy controls, patients with stage I and II disease, and patients with stage III and IV disease were 0.81, 1.61, and 2.52, respectively. The relative levels in early- and advanced-stage patients were significantly higher than that in healthy controls ($P < 0.01$).

Relative levels of lncRNA ZFAS1 in 60 matched plasma samples from pre-operative and post-operative gastric carcinoma patients

Sixty matched pre-operative and post-operative samples (plasma) were included in our research. We found that the median relative levels of ZFAS1 before and after surgery were 2.22 and 1.01, respectively. The level decreased in 55 of the 60 gastric cancer patients (92%) approximately 10 d after surgery ($P < 0.01$; Figure 2C).

Correlation between the relative level of lncRNA ZFAS1 in IFCC and plasma samples

Sixty matched preoperative patient plasma and IFCC samples were collected. We used the ΔΔCt method to evaluate the relative levels of ZFAS1 in plasma and IFCC. As shown in Figure 2D, the relative levels of ZFAS1 in plasma and IFCC were strongly positively correlated ($R^2 = 0.76$, $P < 0.01$).

Diagnostic accuracy of plasma ZFAS1 and traditional serum biomarkers

ROC analysis revealed that the area under the curve (AUC) value of plasma ZFAS1 for discriminating gastric cancer patients from healthy control subjects was 0.85 (Figure 2E). The highest AUC value of any traditional serum biomarker was 0.63, while the AUC value of the other traditional biomarkers was lower than that of CEA. The highest accuracy of plasma ZFAS1 was obtained at a cutoff level of 1.00, where its sensitivity and specificity for identifying gastric carcinoma patients were 0.82 and 0.72, respectively.

ZFAS1 amplification is correlated with poor prognosis in gastric cancer

To explore the correlations between the relative ZFAS1 level and gastric cancer clinicopathological characteristics, we divided the patients into groups by sex, age, tumor site/size/lymphatic invasion/pathological differentiation status and TNM classification (Table 6). Data analysis indicated that the relative ZFAS1 expression level was strongly associated with tumor size (P = 0.01), TNM classification (P = 0.02), and lymphatic invasion (P = 0.03). We then divided patients into two groups by the median relative ZFAS1 level. Kaplan-Meier survival analysis was used to assess the potential correlation between the relative ZFAS1 expression level and patient prognosis. As shown in Figures 2F and G, patients with a high ZFAS1 level had shorter overall survival (OS) and PFS times than those with a low ZFAS1 level. This result suggests that ZFAS1 is a potential prognostic biomarker in gastric cancer patients.

ZFAS1 knockdown inhibited the viability, migration, and proliferation of gastric cancer cells

The expression level of ZFAS1 was positively correlated with lymph node metastasis, suggesting that ZFAS1 may be involved in tumor metastasis. Therefore, we studied the effect of ZFAS1 knockdown on

gastric cancer cells. To verify the efficiency of ZFAS1 knockdown and prevent off-target effects, we first transfected three targeted siRNAs, ZFAS1-siRNA1, ZFAS1-siRNA2, and ZFAS1-siRNA3, into BGC823 and SGC7901 cells. Fluorescence microscopy was used to test the transfection efficiency. As shown in Figure 3, all three siRNAs significantly reduced the expression level of ZFAS1 in transfected BGC823 and SGC7901 cells. Next, we constructed ZFAS1-shRNA2 (with a sequence based on that of ZFAS1-siRNA2) and transduced it into BGC823 and SGC7901 cells. The MTT and colony formation assay results showed that compared to control cells transduced with NC-shRNA, BGC823 and SGC7901 cells with ZFAS1 knockdown showed significant decreases in viability and proliferation (Figures 4 and 5). The transwell migration assay showed that ZFAS1 knockdown in BGC823 and SGC7901 cells significantly inhibited cell migration (Figure 6). In summary, our data suggest that knockdown of ZFAS1 reduces the viability, proliferation, and migration of gastric cancer cells.

ZFAS1 overexpression enhanced the viability, migration, and proliferation of gastric cancer cells

To further investigate the function of ZFAS1 in gastric cancer, we transduced ZFAS1-shRNA1 into BGC823 and SGC7901 cells to overexpress ZFAS1 and evaluated the transduction efficiency by fluorescence microscopy. As shown in Figure 7, the expression level of ZFAS1 was significantly increased in transduced BGC823 and SGC7901 cells. The MTT and colony formation assay results showed that compared to control cells transfected with NC-shRNA, BGC823 and SGC7901 cells overexpressing ZFAS1 showed significant increases in viability and proliferation (Figures 4 and 5). The transwell migration assay showed that ZFAS1 overexpression in BGC823 and SGC7901 cells significantly promoted cell migration (Figure 6). In summary, our data indicate that overexpression of ZFAS1 enhances the viability, proliferation, and migration of gastric cancer cells.

LIN28 and CAPRIN1 are the key downstream mediators of ZFAS1 in gastric cancer cells

To further investigate the mechanism by which lncRNA ZFAS1 affects the aggressiveness of gastric cancer, we used the starBase V2.0 database to analyze binding proteins of lncRNA ZFAS1[19]. The results showed that a total of 10 proteins had more than three binding sites for lncRNA ZFAS1. These proteins were UPF1, eIF4AIII, IGF2BP1, FMRP, LIN28, IGF2BP2, FUS, ZC3H7B, IGF2BP3, and CAPRIN1. We then analyzed the mRNA expression levels of these proteins in BGC823 and SGC7901 cells transduced with ZFAS1-shRNA1 and ZFAS1-shRNA2. Our goal was to determine which proteins exhibited changes in expression consistent with the change in ZFAS1 expression. The qRT-PCR results showed that ZFAS1 overexpression significantly increased the expression of LIN28 and CAPRIN1 ($P < 0.05$) and that ZFAS1 knockdown significantly decreased the expression of LIN28 and CAPRIN1 ($P < 0.05$) (Figure 8). ELISA showed the same results (Figure 9).

Association of ZFAS1 with the tumorigenesis of gastric cancer cells in vivo

To further investigate whether ZFAS1 overexpression or knockdown affects tumor growth *in vivo*, BGC823 cells stably transduced with NC-shRNA, ZFAS1-shRNA1 and ZFAS1-shRNA2 were inoculated into 4-wk female athymic BALB/c nude mice. The expression of lncRNA ZFAS1 in nude mice was detected weekly by qRT-PCR. The results showed that the expression of lncRNA ZFAS1 in the three groups of nude mice increased over time. The expression level in the ZFAS1-shRNA1 group was higher

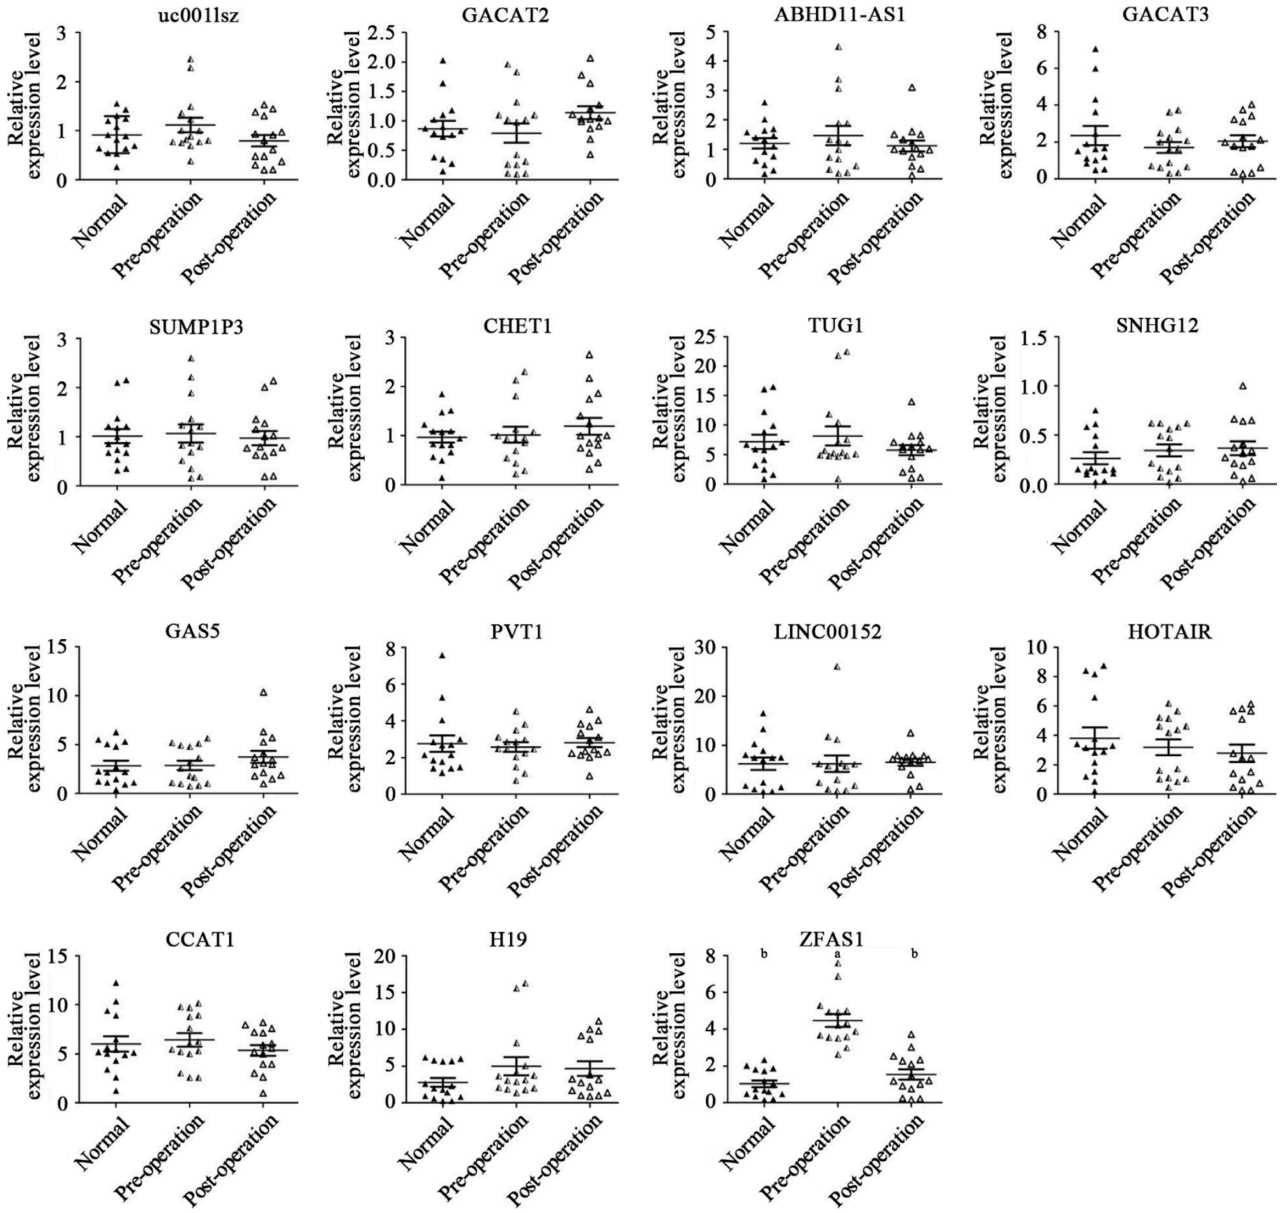

Figure 1 Relative expression levels of a selected subset of plasma long noncoding RNAs in 15 matched preoperative and postoperative gastric cancer patients and 15 healthy control subjects. Scatter plot of long noncoding RNA relative expression levels in the plasma of preoperative patients (preoperative; *n* = 15), postoperative patients (postoperative; *n* = 15), and healthy control subjects (normal; *n* = 15), as assessed by quantitative polymerase chain reaction. The upper and lower bars indicate the ± SD values, and the middle bar indicates the median value. *P* values ($^{a}P < 0.05$; $^{b}P < 0.01$) were determined using the *t*-test.

than that in the control group, and the expression level in the ZFAS1-shRNA2 group was lower than that in the control group (Figure 10A). Images of tumors from nude mice are shown in Figures 10B and C. Tumor size and weight were measured weekly; compared with tumors in the control group, tumors in the ZFAS1-shRNA1 group were significantly larger and heavier, and tumors in the ZFAS1-shRNA2 group were significantly smaller and lighter (Figures 10D and E). Next, in tumor tissue, ELISA confirmed that the expression of LIN28 and CAPRIN1 was significantly increased in tumors in the ZFAS1-shRNA1 group compared with those in the control group ($P < 0.05$), while the expression of LIN28 and CAPRIN1 was significantly decreased in tumors in the ZFAS1-shRNA2 group ($P < 0.05$) (Figure 10F). In addition, ELISA showed significant increases in CEA and CK20 expression in lymph nodes in the ZFAS1-shRNA1 group compared with the control group ($P < 0.05$) and significant decreases in CEA and CK20 expression in lymph nodes in the ZFAS1-shRNA2 group ($P < 0.05$) (Figure 10G), confirming the relationship between lncRNA ZFAS1 expression and lymph node metastasis in gastric cancer cells. In conclusion, our results indicate that ZFAS1 overexpression promotes the growth of gastric cancer cells *in vivo* and that ZFAS1 knockdown inhibits the growth of gastric cancer cells *in vivo*.

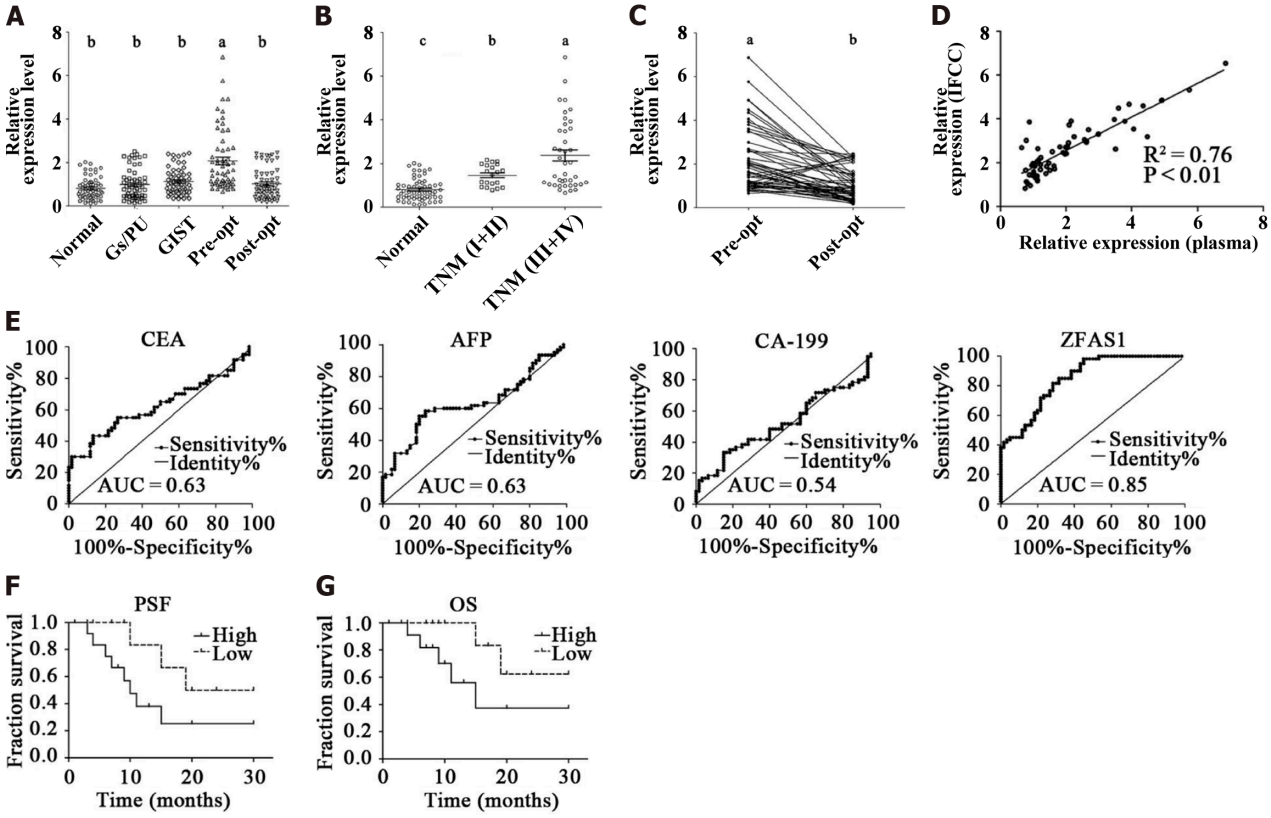

Figure 2 ZNFX1-AS1 is a potential diagnostic and prognostic biomarker. A: Scatter plot of long noncoding RNA (lncRNA) relative expression levels in the plasma of healthy control subjects (normal; *n* = 60), gastritis/peptic ulcer patients (Gs/PU patients; *n* = 60), gastric stromal tumor patients (GIST; *n* = 60), preoperative patients (pre-opt; *n* = 60), and postoperative patients (post-opt; *n* = 60), as assessed by real-time polymerase chain reaction (PCR); B: Scatter plot of lncRNA relative expression levels in the plasma of healthy control subjects (normal; *n* = 60), early-stage patients (TNM I + II; *n* = 20), and advanced-stage patients (TNM III + IV; *n* = 40), as assessed by real-time PCR; C: The endpoints indicate the relative expression levels of lncRNA ZNFX1-AS1 (ZFAS1) in preoperative (pre-opt) and postoperative (post-opt) patient plasma, while the lines connecting the pairs of endpoints indicate the trends in the relative expression levels in the matched preoperative and postoperative patient plasma; D: The linear correlations between the relative expression of lncRNAs in plasma and infrequent clonal complexes were analyzed. *P* values ($^{a}P < 0.05$; $^{b}P < 0.01$; $^{c}P < 0.001$) were determined using the *t*-test; E: Receiver operating characteristic curves showing the area under the curve values of plasma ZFAS1 and traditional serum biomarkers; F: Progression-free survival times indicating the potential prognostic value of ZFAS1 in gastric cancer patients; G: Overall survival times indicating the potential prognostic value of ZFAS1 in gastric cancer patients. Gs/PU: Gastritis/peptic ulcer patients; GIST: Gastric stromal tumor; AUC: Area under the curve; CEA: Carcinoembryonic antigen; AFP: Alpha fetoprotein; CA-199: Carbohydrate antigen 199; OS: Overall survival; PFS: Progression-free survival.

DISCUSSION

Gastric cancer is a common malignancy that is particularly difficult to diagnose early[20]. However, traditional biomarkers have low specificity and low sensitivity. As lncRNA research has intensified, many lncRNAs have been determined to be involved in the development, progression, and prognosis of gastric cancer[21], but their diagnostic value as gastric cancer markers needs further study. By reviewing the literature, we selected 15 candidate lncRNAs that have high expression in gastric tumor tissues. Next, the relative levels of these 15 candidate lncRNAs were evaluated in the plasma of 15 normal subjects and 15 matched samples from preoperative and postoperative patients with gastric cancer. The results showed that the plasma level of only ZFAS1 was significantly higher in preoperative gastric cancer patients than in normal subjects and postoperative gastric cancer patients (Figure 1). Therefore, we selected ZFAS1 as a follow-up research object. Moreover, we confirmed that lncRNAs can exist stably in peripheral blood, consistent with the findings of Li *et al*[22]. Therefore, lncRNA ZFAS1 may be a potential plasma biomarker for gastric cancer.

We recollected plasma from 60 healthy control subjects, 60 gastritis/peptic ulcer patients, 60 GIST patients, and 60 matched preoperative and postoperative patients to further validate the aforementioned results. Our data indicated that the expression of ZFAS1 in the peripheral blood of patients with gastric cancer was significantly higher than that of healthy controls and patients with benign gastrointestinal disease (Figure 2A), consistent with previous reports. Our data also showed that ZFAS1 is significantly associated with advanced TNM stage and lymphatic invasion (Figure 2B). There was a sharp decrease in the relative level of ZFAS1 in peripheral blood after surgery (Figure 2C). We also evaluated traditional serological markers such as CEA, CA-199, and alpha fetoprotein in the 60 preoperative patients. Compared with traditional biomarkers, plasma lncRNA ZFAS1 had higher

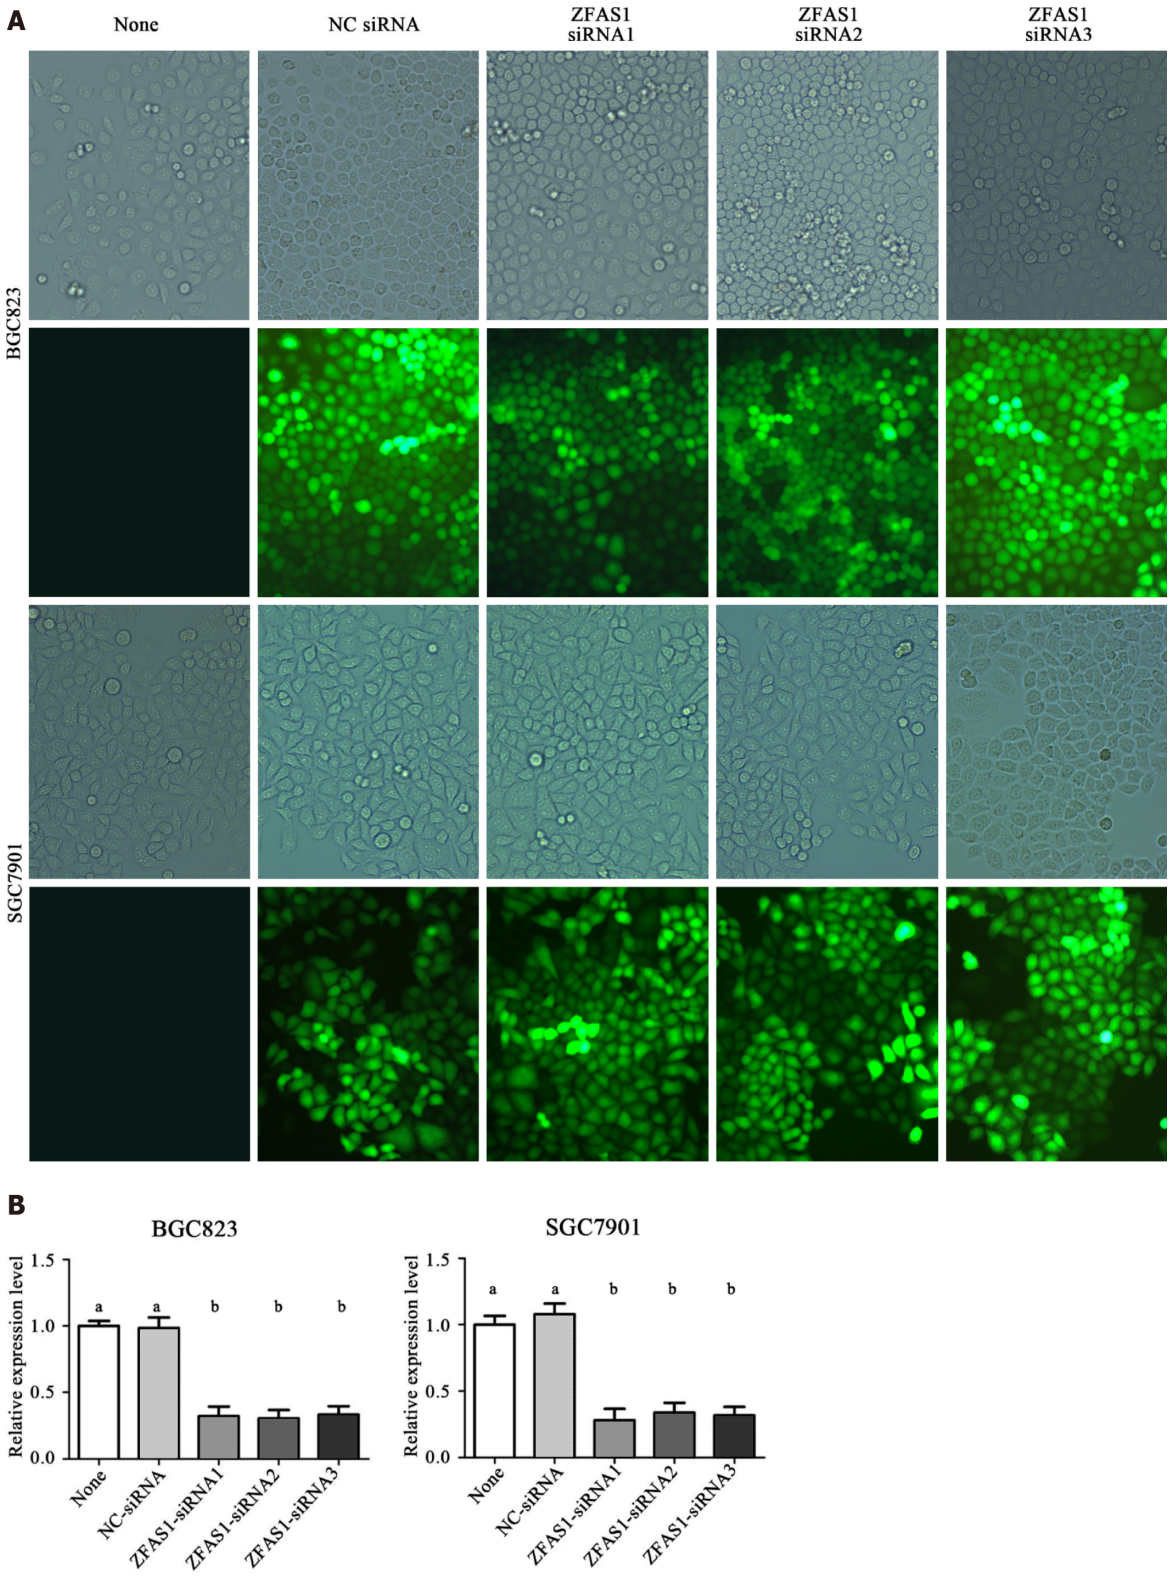

Figure 3 Fluorescence microscopy was used to verify the transfection efficiency of ZNFX1-AS1-siRNA1, ZNFX1-AS1-siRNA2 and ZNFX1-AS1-siRNA3. A: The same position of BGC823 cells and SGC7901 cells under a normal microscope and fluorescence microscope, respectively; B: The relative expression of long noncoding RNA ZNFX1-AS1 (ZFAS1) in five groups of cells (None, NC-siRNA, ZFAS1-siRNA1, ZFAS1-siRNA2, ZFAS1-siRNA3) was evaluated by quantitative reverse transcription polymerase chain reaction. ZFAS1: ZNFX1-AS1. $^{a}P < 0.05$; $^{b}P < 0.01$.

sensitivity and specificity (Figure 2E). In addition, the relative level of ZFAS1 in plasma was significantly correlated with that in IFCCs (Figure 2D). This indicates that lncRNA ZFAS1 is released into the peripheral blood by gastric tumors. This suggests that ZFAS1 may promote the progression of gastric cancer. Both the PFS and OS analysis results showed (Figures 2F and G) that a high level of lncRNAs in peripheral blood was not favorable for patients. Thus, lncRNAs may be used not only for early diagnosis but also for postoperative evaluation of patients.

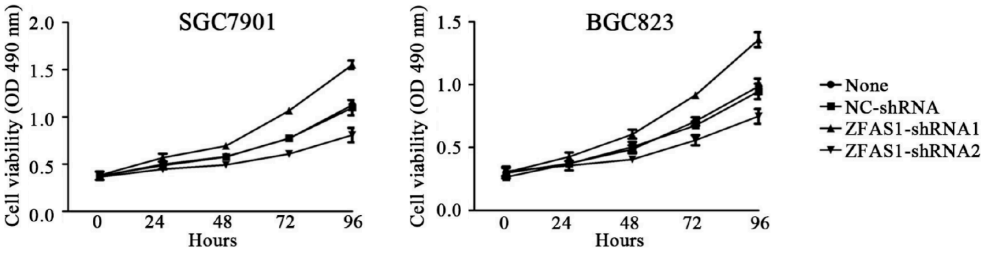

Figure 4 MTT assays were performed to determine the viability of ZGCS1-shRNA1- and ZNFX1-AS1-shRNA2-transduced BGC823 and SGC7901 cells. OD: Optical density.

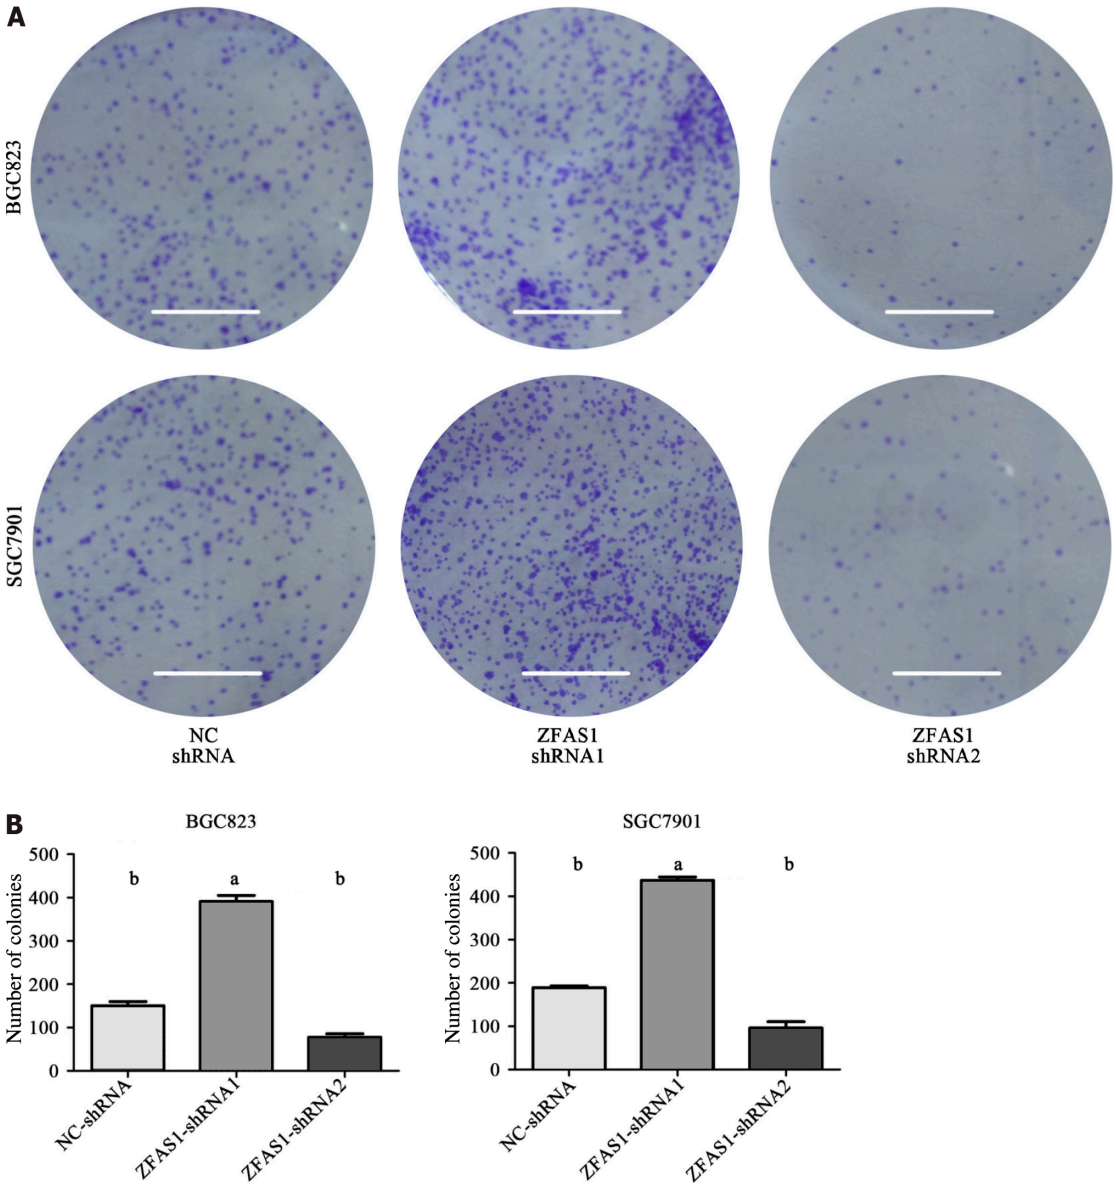

Figure 5 Colony formation assays were performed to determine the proliferation of BGC823 and SGC7901 cells transduced with ZNFX1-AS1-shRNA1 and ZNFX1-AS1-shRNA2. A: BGC823 cells and SGC7901 cells were subjected to colony formation assay after transduction, and the number of spots was analyzed; B: The number of spots for the three groups [NC-shRNA, ZNFX1-AS1 (ZFAS1)-shRNA1, ZFAS1-shRNA2] in the colony formation assays were compared. ZFAS1: ZNFX1-AS1. $^{a}P < 0.05$; $^{b}P < 0.01$.

In addition, ZFAS1 is reported to be involved in metabolism, prognosis, and cell proliferation in liver cancer[23,24]. It has been reported that the expression of ZFAS1 in gastric cancer tissues is significantly higher than that in adjacent tissues and that ZFAS1 expression is related to the prognosis of gastric cancer patients[25,26]. siRNA transfection techniques were used to determine the appropriate lncRNA ZFAS1 interference sequence. We used three types of siRNAs (ZFAS1 siRNA1, ZFAS1 siRNA2, and

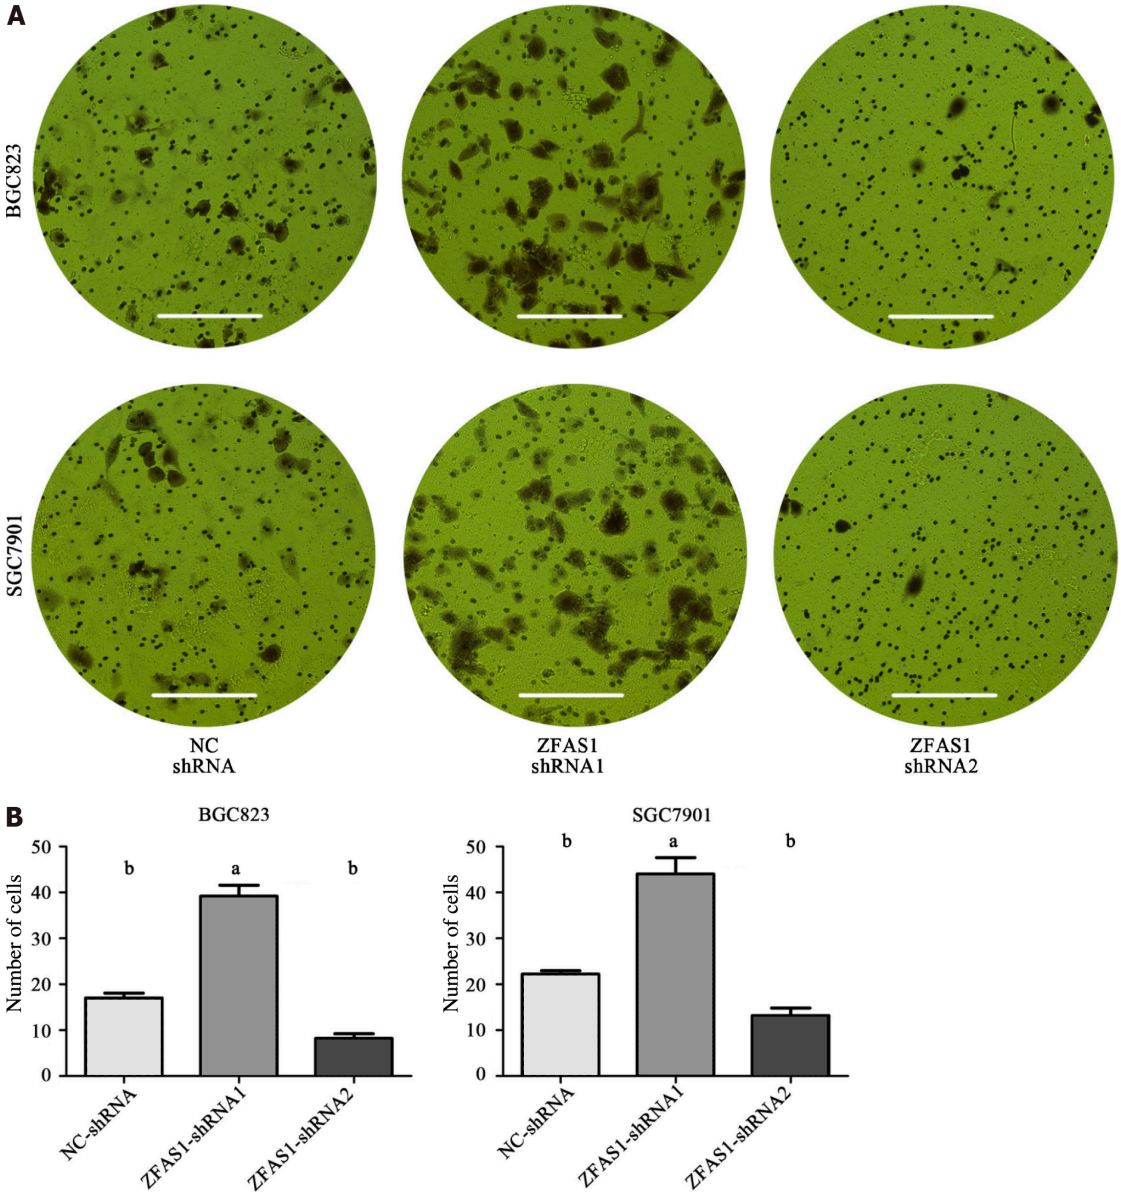

Figure 6 Transwell migration assays were performed to determine the migration ability of ZNFX1-AS1-shRNA1- and ZNFX1-AS1-shRNA2-transduced BGC823 and SGC7901 cells. A: BGC823 cells and SGC7901 cells were subjected to transwell migration assay after transduction, and the number of cell was calculated; B: The number of cells for the three groups [NC-shRNA, ZNFX1-AS1 (ZFAS1)-shRNA1, ZFAS1-shRNA2] in the transwell migration assays were compared. $^{a}P < 0.05$; $^{b}P < 0.01$. ZFAS1: ZNFX1-AS1.

ZFAS1 siRNA3) to interfere with the expression of ZFAS1 in cell lines to prevent off-target effects. All these siRNAs significantly reduced the expression of lncRNA ZFAS1 in BGC823 cells and SGC7901 cells (Figure 3). We finally selected the ZFAS1 siRNA2 sequence to construct ZFAS1-shRNA2 and successfully generated BGC823 cells and SGC7901 cells with low expression of lncRNA ZFAS1. BGC823 cells and SGC7901 cells with stable knockdown of lncRNA ZFAS1 were also successfully cultured. We further employed loss-of-function and gain-of-function studies to assess the role of ZFAS1 in gastric cancer cell proliferation and migration by MTT, transwell, and colony formation assays (Figures 4, 5 and 6). We observed that ZFAS1 knockdown inhibited gastric cancer cell proliferation and migration, whereas ZFAS1 overexpression had the opposite effects.

We then studied the mechanism by which ZFAS1 affects the proliferation and invasion of gastric cancer cells. The starBase V2.0 database was used to analyze the lncRNA ZFAS1 binding proteins[19]. Only 10 proteins had more than three binding sites for lncRNA ZFAS1. We found that the changes in the mRNA expression of LIN28 and CAPRIN1 were consistent with the change in ZFAS1 expression in gastric cancer cells (Figure 8). The LIN28 protein is thought to play an important role in gastrointestinal tumors[27,28]. In colorectal cancer, LIN28 has been shown to enhance tumor cell invasion *via* the Wnt pathway, whereas overexpression of LIN28 also recruits the microRNA let-7 to enhance tumor cell metastasis[28]. In gastric cancer, LIN28 affects the human epidermal growth factor receptor 2 level through posttranscriptional regulation, which in turn affects the invasive ability of gastric cancer cells.

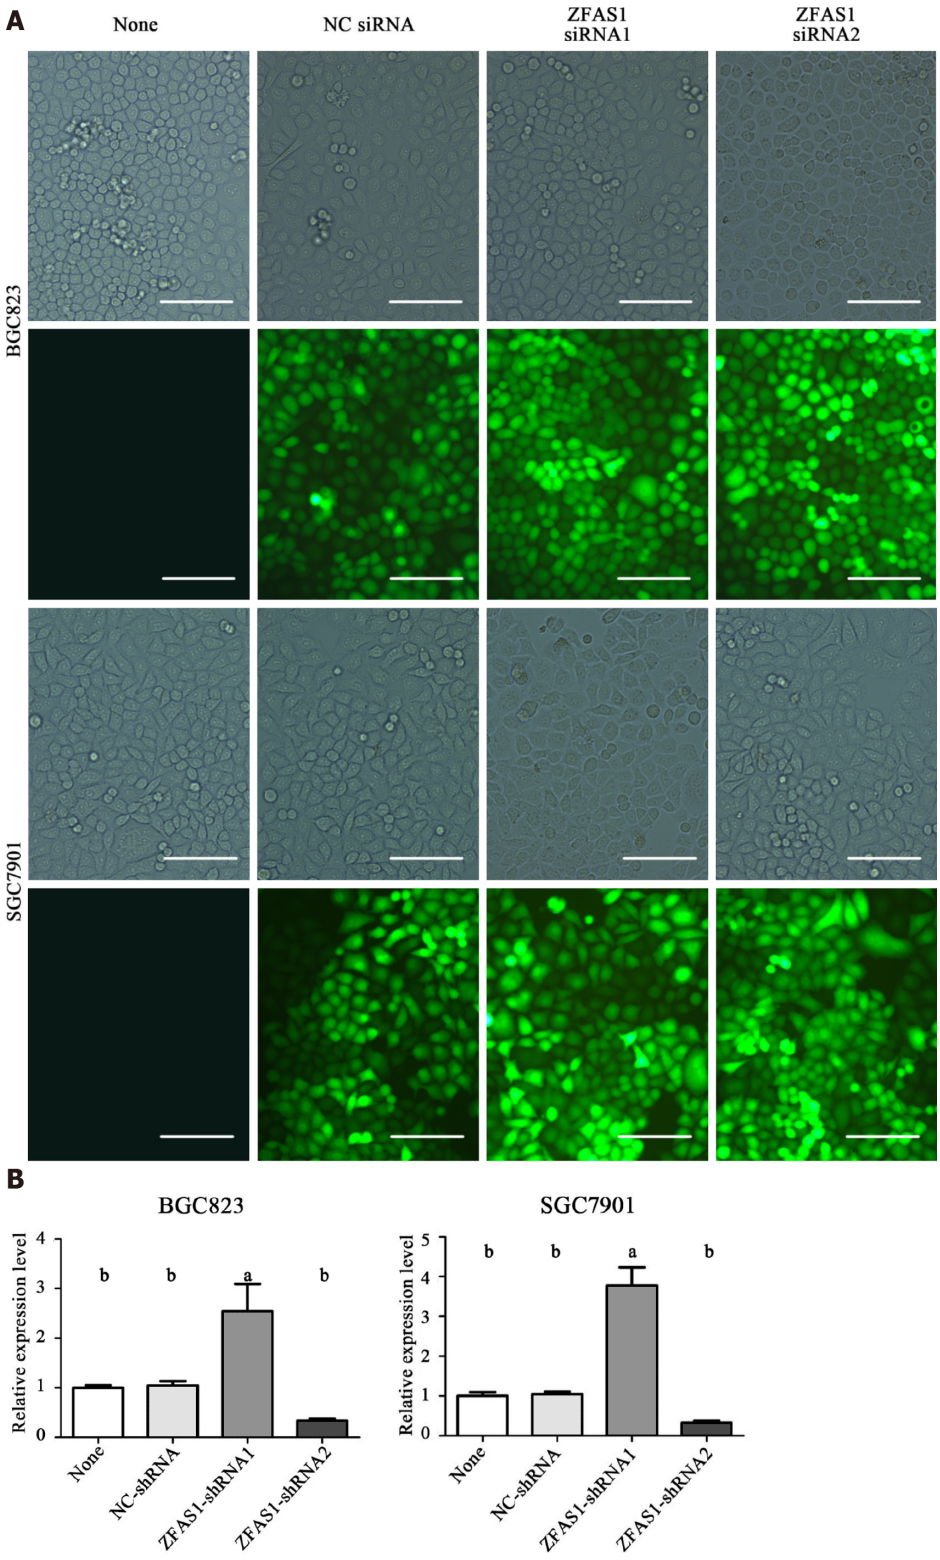

Figure 7 Fluorescence microscopy was used to test the transduction efficiency of ZNFX1-AS1-shRNA1 and ZNFX1-AS1-shRNA2. A: The same position of BGC823 cells and SGC7901 cells under a normal microscope and fluorescence microscope, respectively; B: The relative expression of long noncoding RNA ZNFX1-AS1 (ZFAS1) in four groups of cells (None, NC-shRNA, ZFAS1-shRNA1, ZFAS1-shRNA2) was evaluated by quantitative reverse transcription polymerase chain reaction. ZFAS1: ZNFX1-AS1. $^{a}P < 0.05$; $^{b}P < 0.01$.

In addition, LIN28 is an independent risk factor for the prognosis of gastric cancer. This result suggests that LIN28 may be a key protein downstream of lncRNA ZFAS1 and that lncRNA ZFAS1 may enhance the proliferation and invasion of gastric cancer cells by regulating LIN28. CAPRIN1 is thought to be involved in cell invasion in a variety of tumors[29-31]. In osteosarcoma, CAPRIN1 has been shown to cause cisplatin resistance and abnormal apoptosis of tumor cells *via* the Akt pathway and the ERK1/2 pathway[31], and it can also be used as an independent risk predictor for breast cancer. The changes in

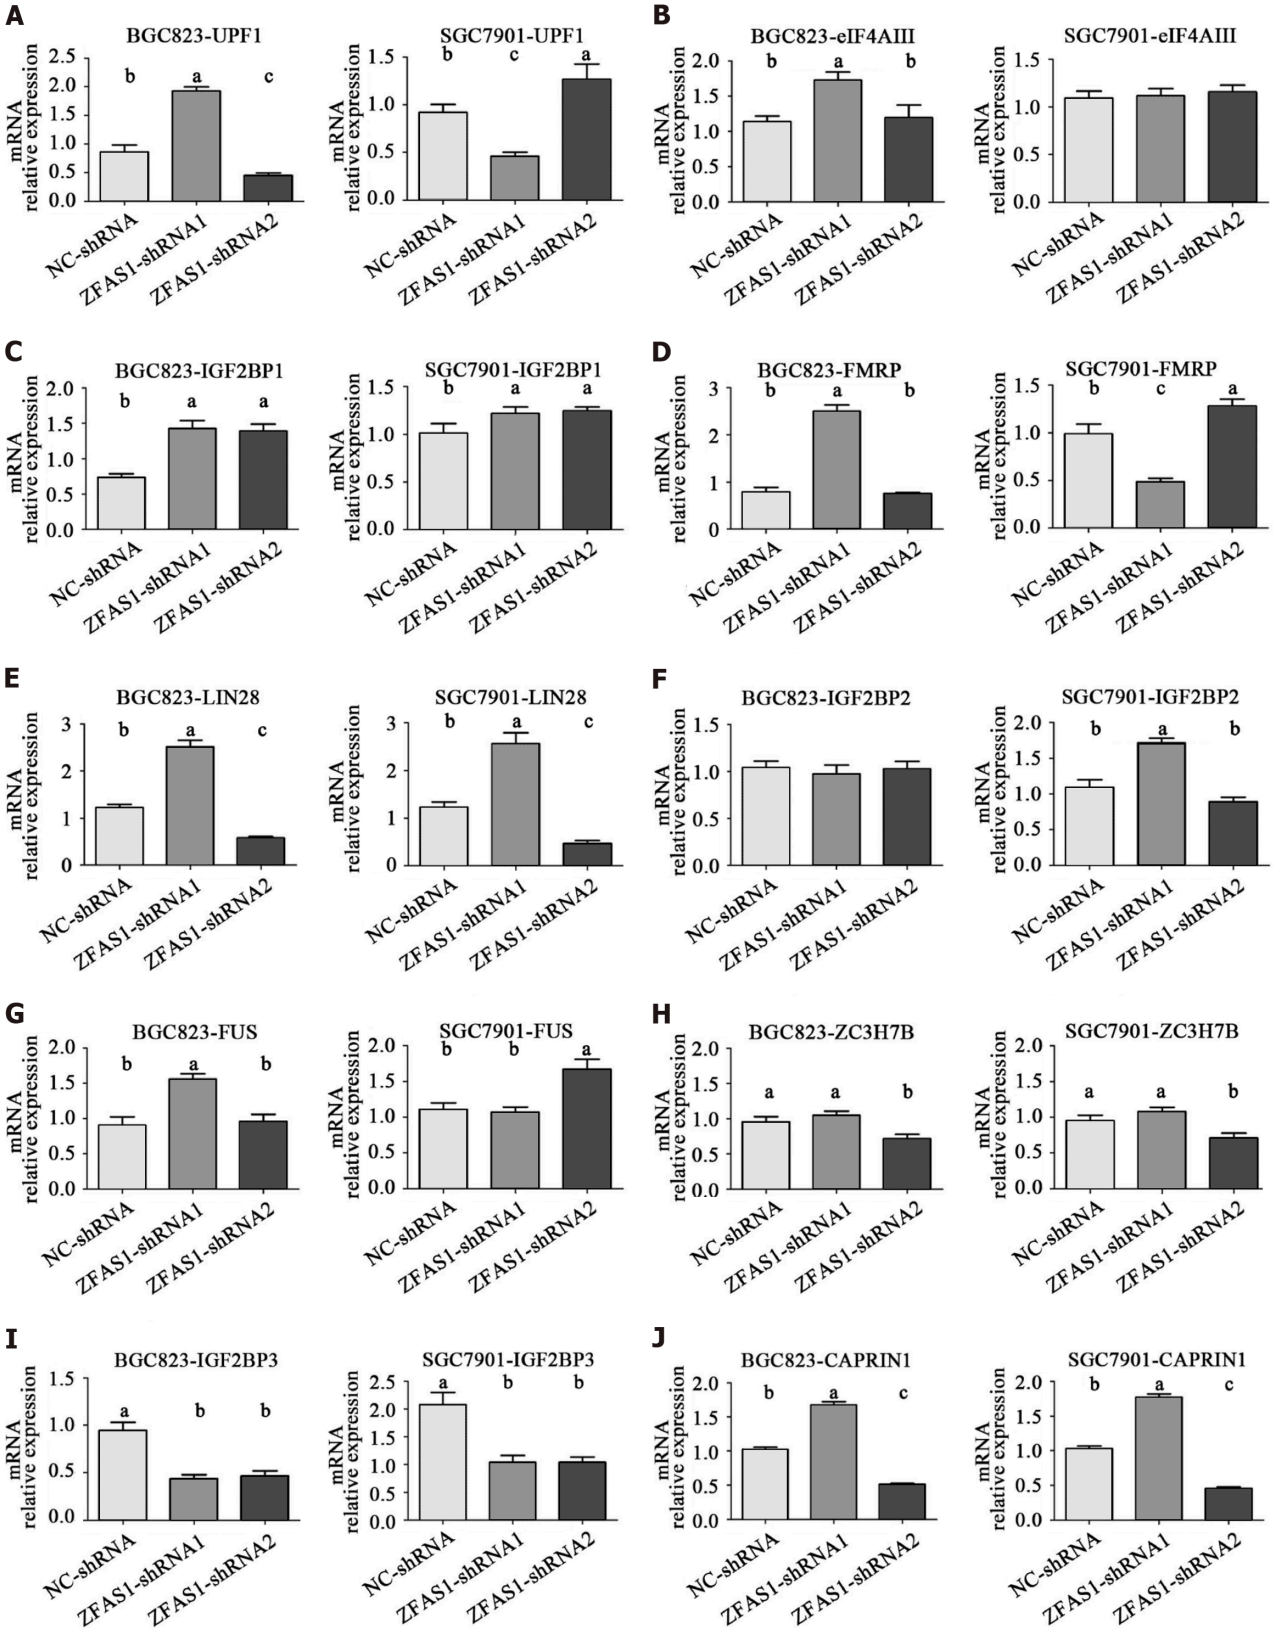

Figure 8 The relative mRNA levels of genes encoding ZNFX1-AS1 binding proteins in transduced BGC823 and SGC7901 cells were determined by quantitative reverse transcription polymerase chain reaction. A: UFP1; B: eIF4AIII; C: IGF2BP1; D: FMRP; E: LIN28; F: IGF2BP2; G: FUS; H: ZC3H7B; I: IGF2BP3; J: CAPRIN1. AFAS1: ZNFX1-AS1. $^{a}P < 0.05$; $^{b}P < 0.01$.

the mRNA expression of LIN28 and CAPRIN1 were consistent with knockdown and overexpression of ZFAS1, whereas LIN28 and CAPRIN1 were significantly associated with tumor invasion, which explains the mechanism connecting ZFAS1 with lymphatic invasion in tumor patients. ZFAS1 has been shown to silence the expression of Kruppel-like factor 2 and naked cuticle homolog 2 by binding to

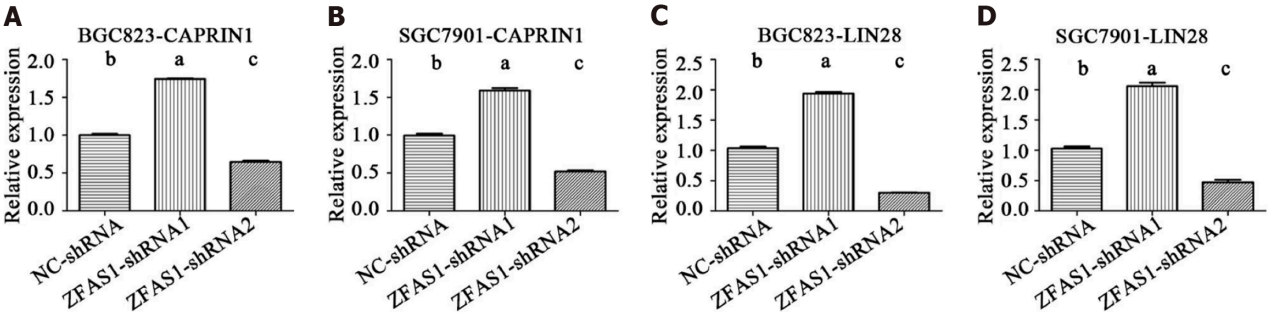

Figure 9 The relative protein levels of LIN28 and CAPRIN1 in transduced BGC823 and SGC7901 cells were determined by enzyme-linked immunosorbent assay. A: The levels of CAPRIN1 in transduced BGC823 cells; B: The levels of CAPRIN1 in transduced SGC7901 cells; C: The levels of LIN28 in transduced BGC823 cells; D: The levels of LIN28 in transduced SGC7901 cells. $^{a}P < 0.05$; $^{b}P < 0.01$.

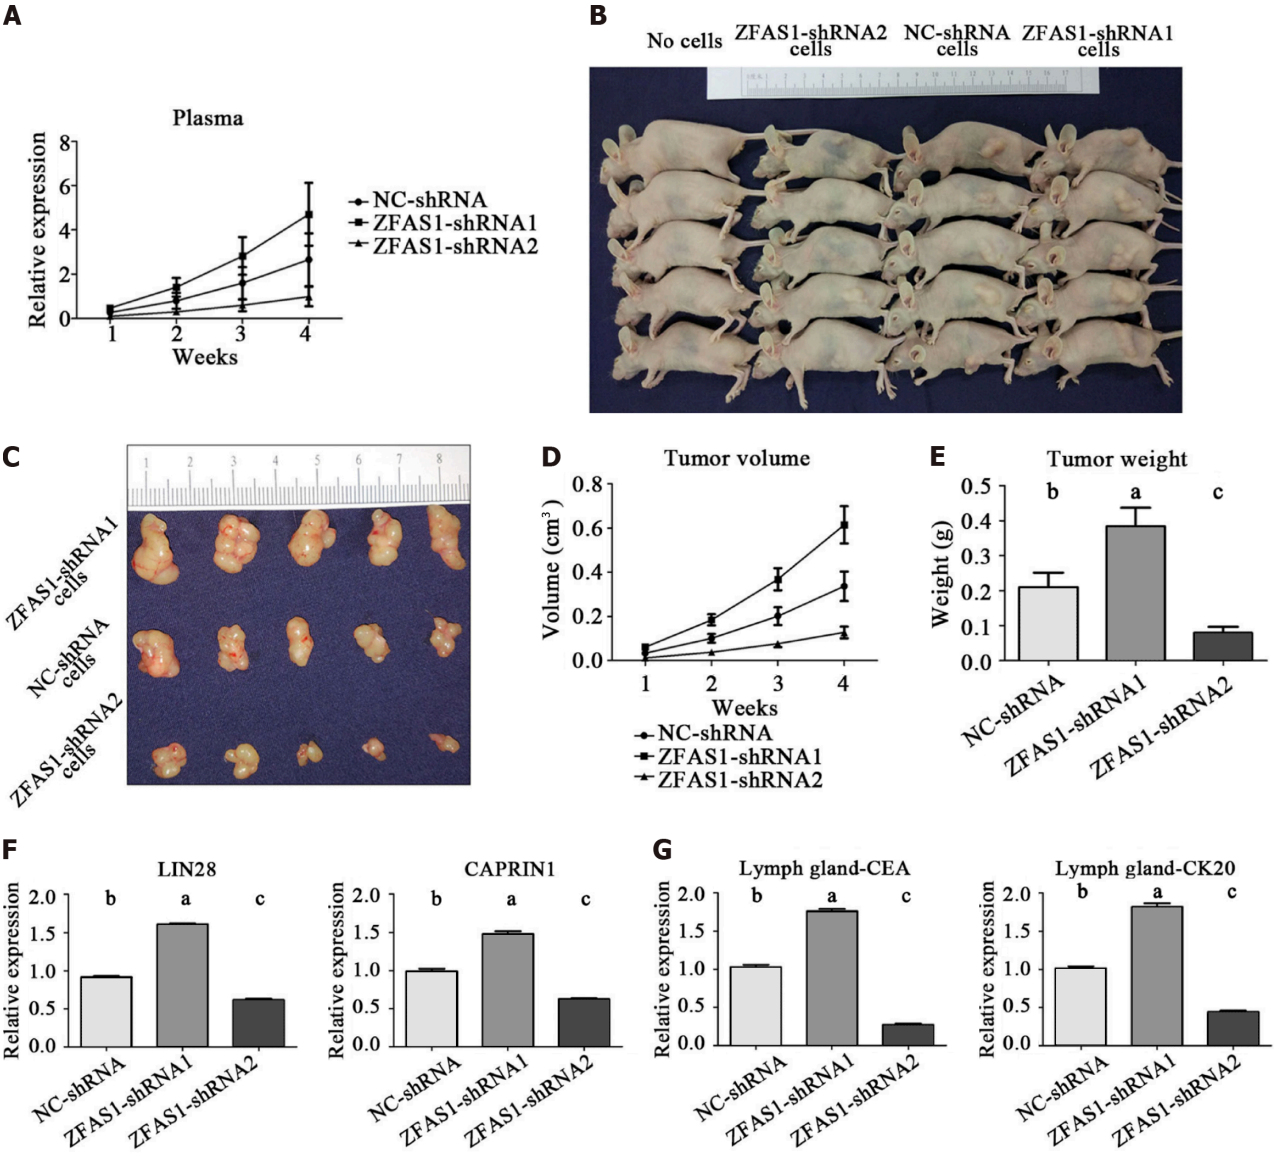

Figure 10 Effect of ZNFX1-AS1 on gastric cancer cell tumorigenesis *in vivo*. A: The expression of long noncoding RNA ZNFX1-AS1 in BALB/c nude mice was detected weekly by quantitative reverse transcription polymerase chain reaction; B and C: Images of tumors from BALB/c nude mice; D and E: Tumor size and weight were measured weekly; F: Expression of LIN28 and CAPRIN1 in tumors of BALB/c nude mice; G: Expression of carcinoembryonic antigen and CK20 in lymph nodes of BALB/c nude mice. CEA: Carcinoembryonic antigen; ZFAS1: ZNFX1-AS1. $^{a}P < 0.05$; $^{b}P < 0.01$; $^{c}P < 0.001$.

polycomb repressive complex 2 and lysine-specific demethylase 1, leading to the development of gastric cancer[25]. In addition, it promotes the development of liver cancer tumor cells[23]. CAPRIN1 may play a key role in the regulation of tumor cell proliferation and invasion *via* lncRNA ZFAS1.

In this study, we validated the above hypothesis by establishing tumor-bearing mice. The expression level of lncRNA ZFAS1 in the plasma of mice injected with tumor cells with high expression of lncRNA ZFAS1 was significantly higher than that in mice in the other two groups (Figure 10A). The *in vivo* experiments also indicated that ZFAS1 overexpression promoted gastric cancer cell proliferation and migration, whereas ZFAS1 knockdown had the opposite effect (Figures 10B-E). The data also demonstrated that LIN28 and CAPRIN1 are still regulated by lncRNA ZFAS1 in mice (Figure 10F). CK20 and CEA are classical biomarkers of gastric cancer cells in tissues. The CEA and CK20 levels in the lymph nodes of nude mice injected with tumor cells with high expression of lncRNA ZFAS1 were significantly higher than those in mice in the other two groups (Figure 10G). This further demonstrated that high expression of lncRNA ZFAS1 may enhance the invasion of gastric cancer cells.

CONCLUSION

In conclusion, we demonstrated in this study that the lncRNA ZFAS1 level is increased in the plasma of gastric cancer patients. LncRNA ZFAS1 promotes the invasion and proliferation of gastric cancer cells by modulating LIN28 and CAPRIN1 expression. These findings indicate that ZFAS1 plays an oncogenic role in gastric cancer and can be used as a potential diagnostic biomarker and a new therapeutic target for gastric cancer.

ARTICLE HIGHLIGHTS

Research background

Long noncoding RNA (lncRNA) ZNFX1-AS1 (ZFAS1) is a newly discovered lncRNA, but its diagnostic value in gastric cancer is unclear.

Research motivation

We investigated the biological effects of ZFAS1 on the survival, proliferation, and migration of gastric cancer cells.

Research objectives

This study aimed to investigate the potential role of ZFAS1 in gastric cancer and to evaluate the clinical significance of ZFAS1 as a biomarker for gastric cancer screening.

Research methods

RNA extraction, quantitative realtime polymerase chain reaction, lncRNA silencing and overexpression, MTT assay, transwell migration assay, Colony formation assay, protein extraction, immunosorbent assay, and *in vivo* tumor formation assay were performed in this study.

Research results

ZFAS1 amplification was correlated with poor prognosis in gastric cancer. ZFAS1 knockdown inhibited the viability, migration, and proliferation of gastric cancer cells. ZFAS1 overexpression enhanced the viability, migration, and proliferation of gastric cancer cells. LIN28 and CAPRIN1 were the key downstream mediators of ZFAS1 in gastric cancer cells. ZFAS1 was associated with the tumorigenesis of gastric cancer cells *in vivo*.

Research conclusions

LncRNA ZFAS1 is a potential biomarker for gastric cancer.

Research perspectives

ZFAS1 plays an oncogenic role in gastric cancer and can be used as a potential diagnostic biomarker and a new therapeutic target for gastric cancer.

ACKNOWLEDGEMENTS

The authors would like to thank Peking University People's Hospital Gastrointestinal Surgery Laboratory for providing the cell lines.

Abstract

BACKGROUND

Oxidized low-density lipoprotein (ox-LDL), which is abnormally increased in the serum of colorectal cancer (CRC) patients consuming a high-fat diet (HFD), may be one of the risk factors for the development of CRC. Ox-LDL exerts a regulatory effect on macrophages and may influence CRC through the tumor microenvironment. The role of ox-LDL in CRC remains unclear.

AIM

To investigate the role of ox-LDL through macrophages in HFD associated CRC.

METHODS

The expression of ox-LDL and CD206 was detected in colorectal tissues of CRC patients with hyperlipidemia and HFD-fed mice by immunofluorescence. We stimulated the macrophages with 20 μg/mL ox-LDL and assessed the expression levels of CD206 and the cytokines by cell fluorescence and quantitative polymerase chain reaction. We further knocked down LOX-1, the surface receptor of

ox-LDL, to confirm the function of ox-LDL in macrophages. Then, LoVo cells were co-cultured with the stimulated macrophages to analyze the CD44 and CD133 expression by western blot.

RESULTS

The expression of ox-LDL and the CD206 was significantly increased in the stroma of colorectal tissues of CRC patients with hyperlipidemia, and also upregulated in the HFD-fed mice. Moreover, an increased level of CD206 and decreased level of inducible nitric oxide synthase were observed in macrophages after ox-LDL continuous stimulation. Such effects were inhibited when the surface receptor LOX-1 was knocked down in macrophages. Ox-LDL could induce CD206+ macrophages, which resulted in high expression of CD44 and CD133 in co-cultured LoVo cells.

CONCLUSION

Ox-LDL stimulates CD206+ macrophages to upregulate CD44 and CD133 expression in HFD related CRC.

Key Words: Oxidized low-density lipoprotein; CD206 positive macrophages; CD44; CD133

Core Tip: Obesity increases the risk of colorectal cancer (CRC), but the mechanism remains unknown. CD206+ macrophages promote CRC. It has been established that the prevalence of CRC was higher in people consuming a high-fat diet (HFD) and HFD fed mice with up-regulated CD206+ macrophages levels in colorectal tissue. Oxidized low-density lipoprotein (ox-LDL) is a lipid peroxide which has been found to be increased in serum of CRC patients. Importantly, ox-LDL exerts a regulatory effect on macrophages and may regulate CRC through the tumor microenvironment. Our study showed that ox-LDL stimulates CD206+ macrophages to up-regulate CD44 and CD133 expression in HFD associated CRC.

INTRODUCTION

Obesity is a widespread health condition. There is ample evidence to suggest that obesity increases the risk of colorectal cancer (CRC)[1]. A prospective cohort study of 85256 women found that obese individuals had a 1.93 times higher risk of CRC by age 50 than normal-weight individuals[2]. Excessive intake of dietary fat, *e.g.*, a high-fat diet (HFD), is the main cause of obesity and one of the important reasons for the increased incidence of CRC[3]. However, the specific mechanism of CRC remains unknown. It is currently believed that HFD promotes intestinal cancer by increasing the number and malignant potential of intestinal stem cells[4,5].

Interestingly, it has been shown that HFD could activate systemic inflammation and increase the malignant potential of intestinal tumors by upregulating the expression of macrophages[6,7]. It has been established that macrophages exhibit multiple phenotypes, like those positive for CD206, CD163, or inducible nitric oxide synthase (iNOS)[8]. Importantly, some types of macrophages promote cell repair and proliferation, like CD206+ macrophages[9]. An increasing body of evidence suggests that CD206+ macrophages in the tumor microenvironment promote CRC development, and a positive correlation has been documented between the level of CD206+ macrophages and the degree of tumor malignancy[10]. Moreover, metastasis can be promoted through the interactions of CD206+ macrophages with CRC cells [11]. Liu *et al*[7] found that the prevalence of CRC was higher in people on a HFD with upregulated CD206+ macrophage levels in colon tissue. Moreover, when mice with intestinal microflora disorder were fed an HFD, it was found that CD206+ macrophages in colon tissues correlated with the number of colon tumors and the degree of malignancy, suggesting that the increased CD206+ macrophage level induced by an HFD could exert a significant promoting effect on CRC.

HFD can cause low-grade inflammation and oxidative stress in the whole body, leading to increased lipid levels such as cholesterol and low-density lipoprotein[6]. Oxidized low-density lipoprotein (ox-LDL) is a lipid peroxide produced under oxidative stress that can be used to assess oxidative stress and lipid metabolism in the body. Several studies on obese people have found that the serum ox-LDL level in CRC patients was higher than that in the control group with a healthy intestinal tract[12-14].

Importantly, ox-LDL exerts a regulatory effect on macrophages and may regulate CRC through the tumor microenvironment[15]. However, the mechanisms underlying macrophage regulation in CRC by ox-LDL remain unclear. In addition, the regulatory role of macrophages on tumors may be related to tumor stem cells. In this regard, Yang *et al*[16] found that CD44 levels were gradually increased in lung cancer tissue with an increase in the level of CD206+ macrophages. Lv *et al*[17] also found that CD133 levels were upregulated in thyroid cancer with the increasing CD206+ macrophages. CD206+ macrophages share a similar relationship with CD44 and CD133 in CRC. In this study, the expression and corresponding effects of ox-LDL in colorectal tissue from hyperlipidemia patients were studied to explore the regulatory effects of ox-LDL on macrophages and the tumor stem cell markers CD44 and CD133 in the colorectal stroma. Our findings will provide a new mechanism of increased CRC susceptibility with HFD.

MATERIALS AND METHODS

Patient samples

Colonoscopy was performed on hyperlipidemia patients with CRC, with no prior radiotherapy, chemotherapy, or surgery. Healthy colorectal tissues were collected from volunteers who underwent colonoscopy in the physical examination. CRC (cancer, n = 16, male:female = 10:6) and normal colorectal tissues (normal, n = 20, male:female = 11:9) were collected. The average age of all patients was 57 ± 6 years old. All tissue samples were examined by experienced pathologists. All the CRC tissues that we collected were adenocarcinoma. After sampling, tissue samples were fixed in 4% paraformaldehyde. All patients were treated at the Guangdong Provincial People's Hospital, and the tissue samples were collected by the same endoscopist. The human study was approved by the Ethics Committee of Guangdong Provincial People's Hospital. Informed consent was obtained from all patients before the beginning of the study.

Animal model

Six C57/BL6 mice aged 4 wk assigned to an HFD group were fed an HFD (#H10141, China) for a total of 12 wk. Another six C57/BL6 mice aged 4 wk were assigned to a control group and fed a normal diet (normal grade, #02, China) for the same duration. After 12 wk, the mice were sacrificed for colorectal tissue harvesting. All tissues were immediately transferred to 4% paraformaldehyde. Animal experiments were also approved by the Ethics Committee of Guangdong Provincial People's Hospital.

Specimen processing

After the above clinical and animal specimens were fixed at room temperature for 24 h, tissue sections were prepared as follows. The tissues were first dehydrated and then embedded with paraffin. The paraffin-embedded tissues were cut into 3 μm-thick sections and cross-sections of the intestinal tissue were observed.

Animal histological analysis

Three- micron-thick mice tissue slices were cut and dried in a 65 °C oven for 120 min. The slices were stained with hematoxylin and eosin, dehydrated, and cleared. Finally, the slices were dried and sealed with neutral gum. All samples were examined by experienced pathologists.

Immunofluorescence staining

The specimens were dried in a 65 °C oven for 2 h for dewaxing and dehydration, and then soaked in deionized water for 5 min. The tissue specimens were soaked in sodium citrate solution overnight in a 60 °C water bath to expose the antigen. The sections were immersed in phosphate buffer solution (PBS) and then incubated with 10% goat serum at 37 °C for 1 h for antigen blocking. The slices were incubated at 4 °C for 12 h with the corresponding primary antibody, rewarmed at room temperature, and washed with PBS. The cells were incubated with 100 μL/well working solution containing Alexa Fluor 594-conjugated goat anti-rabbit secondary antibody at room temperature for 1 h in the dark. 4,6-diamino-2-phenylindole (DAPI; Thermo Fisher Science, United States) was used for nuclear counterstaining. The stained slides were imaged using an inverted fluorescence microscope (magnification, × 400; Olympus Corporation).

For calculation of the rate of ox-LDL positive cells in immunofluorescence (IF) staining, three fields were randomly selected from each section to observe the stroma of colorectal tissue under a 400 × microscope. For iNOS-F4/80 or CD206-F4/80 double staining, the number of iNOS, CD206, and F4/80 positive cells and total cells was counted, and the rate of iNOS and F/480, or CD206 and F4/80 positive cells was calculated. For ox-LDL-CD206 or LOX-1-CD206 double staining, the number of positive cells and total cells was counted, and their rate was calculated. The mean value of the rates from three fields was the positive cell rate of each section. All the analyses were double-blind and graded by two or more observers.

Cell experiments

Cell lines and culture: The human colorectal adenocarcinoma cell line (LoVo) and mouse monocyte-macrophage leukemia cell line (RAW 264.7) were purchased from the American Center for Typical Culture Preservation (ATCC, United States). The human monocytic leukemia cell line was purchased from Wuhan Penoside Company (THP-1, #CL-0233, China). The maintenance medium for cell culture was Dulbecco modified Eagle medium (DMEM, Gibco) containing glucose (4.5 g/L), 10% fetal bovine serum, 100 U/mL penicillin, and 100 mg/mL streptomycin. All cells were cultured under standard cell culture conditions of 37 °C, 5% CO_2, and 95% humidity.

Lipoprotein induction and RNA extraction: THP-1 cells were inoculated in 6-well plates, and 50 μg/mL ox-LDL was added 24 h and 72 h after sample collection. The confluence of cells in both groups was maintained at 60%-70% at the beginning of treatment, while the control group did not receive any treatment. The samples were centrifuged (800 rpm, 3 min) and washed with sterile PBS, and re-centrifuged (800 rpm, 3 min). Then, total RNA was extracted from tissues or cells using TRIzol reagent, according to the manufacturer's instructions. The RNA samples were stored at -80 °C.

Cell fluorescence: RAW264.7 cells were inoculated in 12-well plates and treated with 50 μg/mL ox-LDL for 72 h when the cell confluence reached 60%-70%, while the control group did not receive any treatment. After 72 h, the culture medium was discarded, and the cells were treated with 4% paraformaldehyde for 15 min. The cells were washed with PBS, blocked with 10% sheep serum at 37 °C for 1 h, and incubated with PBS solution dissolved in 1% BSA and 0.1% TritonX-100 followed by primary antibody [rabbit anti-CD206 antibody (1:100, #18704-1-AP, United States)] at 4 °C for 12 h. The cells were then washed with PBS, and incubated with the AlexaFluor594 conjugated secondary antibody (1:500) at room temperature in the dark for 1 h. The cells were washed with PBS, one drop of DAPI was added to each well, and images were obtained under the corresponding fluorescence channel using an inverted fluorescence microscope. The method used to calculate the IF-positive cell rate was the same as above.

Co-culture and protein extraction: LoVo cells and THP-1 cells were inoculated in the lower and upper chambers of 12-well transwell plates, respectively. The cell density was 60%-70%, and cells were incubated with ox-LDL (#S24879, China) for 72 h. There were no THP-1 cells in the upper compartment of the culture plate in the control group, and the other conditions were the same as those for the treatment group. The culture medium was discarded 72 h later, and cells were gently moistened with PBS. Total protein of LoVo cells in each group was extracted with RIPA lysis buffer on ice. Protein concentration was detected by the BCA method, and protein samples were stored at -80 °C.

Quantitative polymerase chain reaction

RNA concentration was determined first, and the samples were diluted to ensure that the concentrations were consistent. The RNA was reverse-transcribed to cDNA in a 20 μL system, and the total RNA content was kept below 1000 ng. Then, the cDNA was used as the template for quantitative polymerase chain reaction (qPCR) amplification. ABI 7300 real-time PCR software was used to analyze the PCR results and detect the Ct value of the sample. *GAPDH* was used as the internal reference gene, and the relative quantitative analysis was carried out by the $2^{-\Delta\Delta Ct}$ method. The primer sequences used are shown in Table 1.

LOX-1 small interfering RNA transfection

Small interfering RNA (siRNA) was used to inhibit the expression of LOX-1 in macrophages. LOX-1 siRNA or siRNA negative control (GenePharma, GenePharma, Suzhou, China) was introduced into THP-1 cells *via* Liposome 3000 (3 μL/mL) for 24 h. The sequence of LOX-1 siRNA used is shown in Table 2.

Western blot analysis

Protein samples (10 μg) were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred to a PVDF membrane. The membrane was then blocked with 5% skim milk. One hour later, anti-CD44 antibody (1:5000, # AB189524, United Kingdom) and anti-GAPDH antibody (1:10000, # AB9458, United Kingdom) were added. After incubating with the primary antibody, the membrane was washed with TBST. The samples were then incubated with horseradish peroxidase-labeled secondary antibody (1:3000) for 1 h at room temperature. After washing with TBST, immune reactive bands were analyzed after protein band visualization with enhanced chemiluminescence reagents.

Statistical analysis

Microsoft Excel 2019 worksheet was used to summarize the experimental results and generate tables. Adobe Photoshop 2020 software was used to process the images, and GraphPad Prism 8.0.2 software was used for statistical analyses. The Chi-square test or unpaired *t*-test was performed to compare the difference between two groups. One-way ANOVA test was performed to compare the difference among

Table 1 Forward and reverse primer sequences of *GAPDH*, inducible nitric oxide synthase, *CD206*, and *LOX-1*

more than two groups, and the Dunnett *post-hoc* test was used for multiple comparisons. The data were assessed for normality before conducting the unpaired *t*-test and one-way ANOVA test. A P value < 0.05 was considered statistically significant. All tests were carried out more than three times.

RESULTS

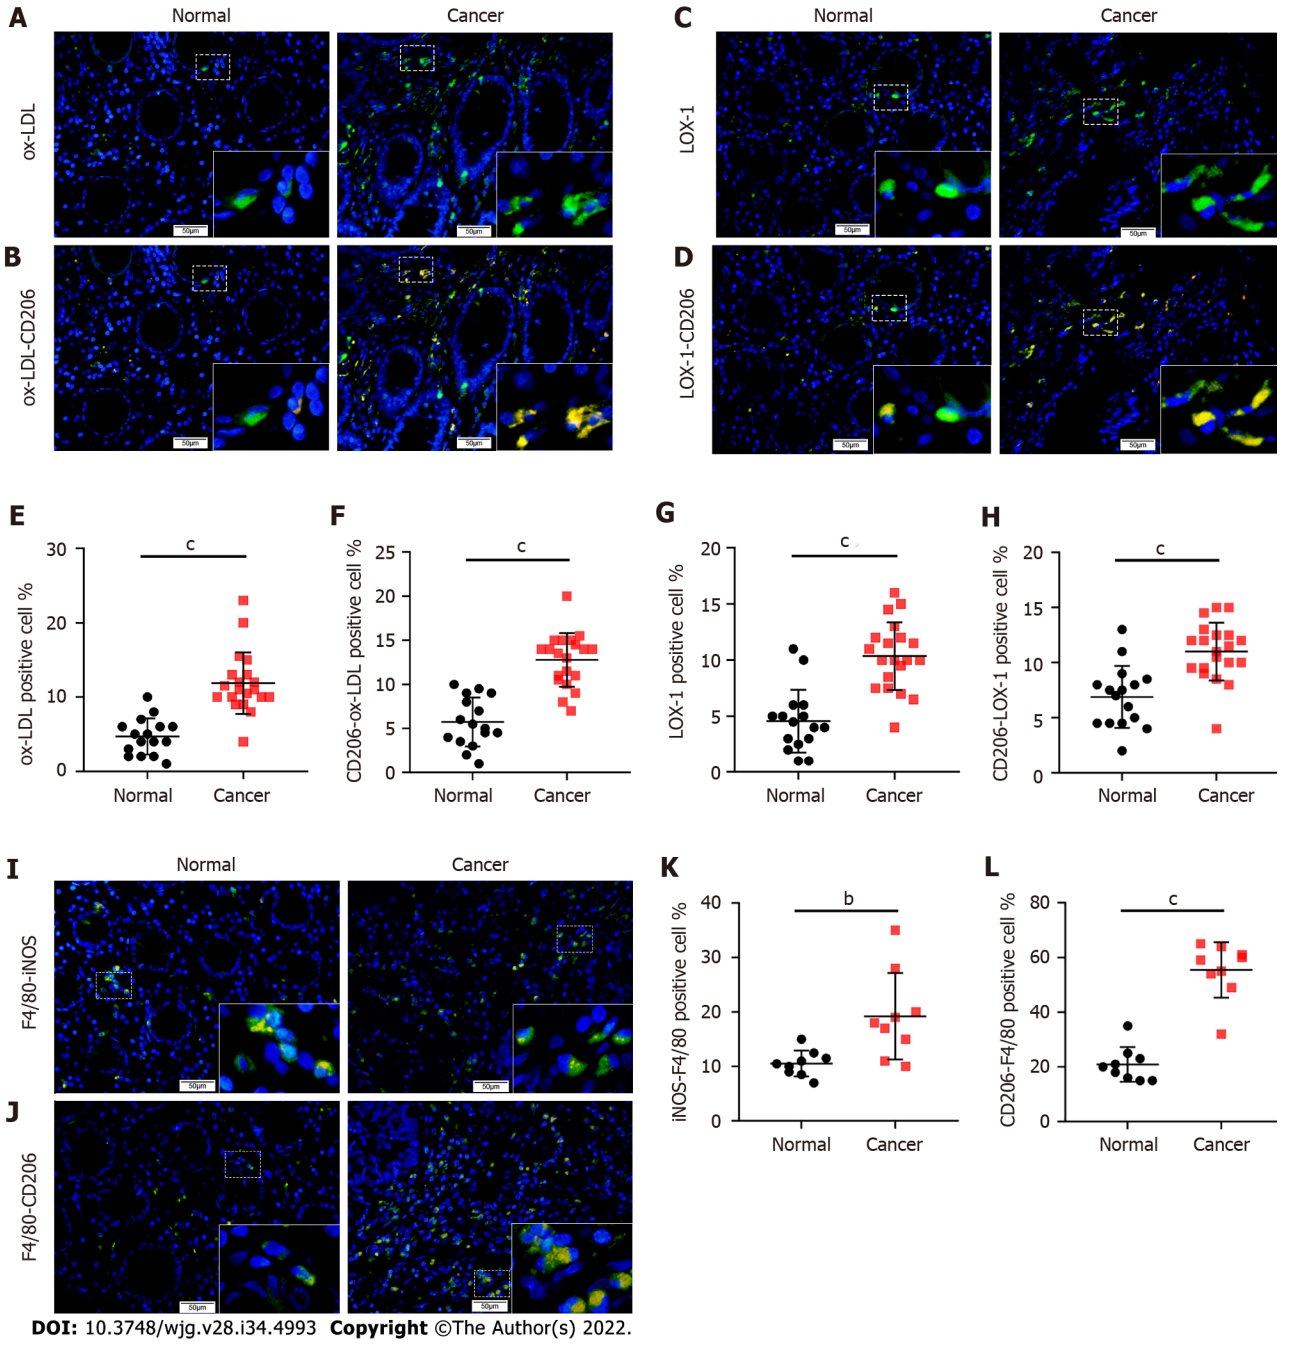
Ox-LDL expression is increased in the stroma of CRC tissue

To explore the distribution and expression of ox-LDL in CRC, we collected tissue samples from CRC patients with hyperlipidemia (n = 16) and normal subjects (n = 20) and performed IF staining for ox-LDL. The results showed that compared with normal colorectal tissues, the expression of ox-LDL was significantly increased in the stroma of CRC tissues (Figures 1A and 1E). It has been reported that LOX-1 is the surface receptor of ox-LDL in macrophages[12]. LOX-1-positive cells were also abundantly detected in CRC tissues (Figures 1C and 1G).

CD206+ macrophages are increased in the stroma of CRC tissue

Double IF for CD206-F4/80 or iNOS-F4/80 showed that the number of CD206+ macrophages increased significantly in the stroma of CRC tissue (Figures 1I-L). Besides, double IF also showed the number of CD206+/ox-LDL+ cells and CD206+/LOX-1+ cells increased abundantly in CRC tissue (Figures 1B, 1D, 1F, and 1H).

Establishment of HFD mouse model

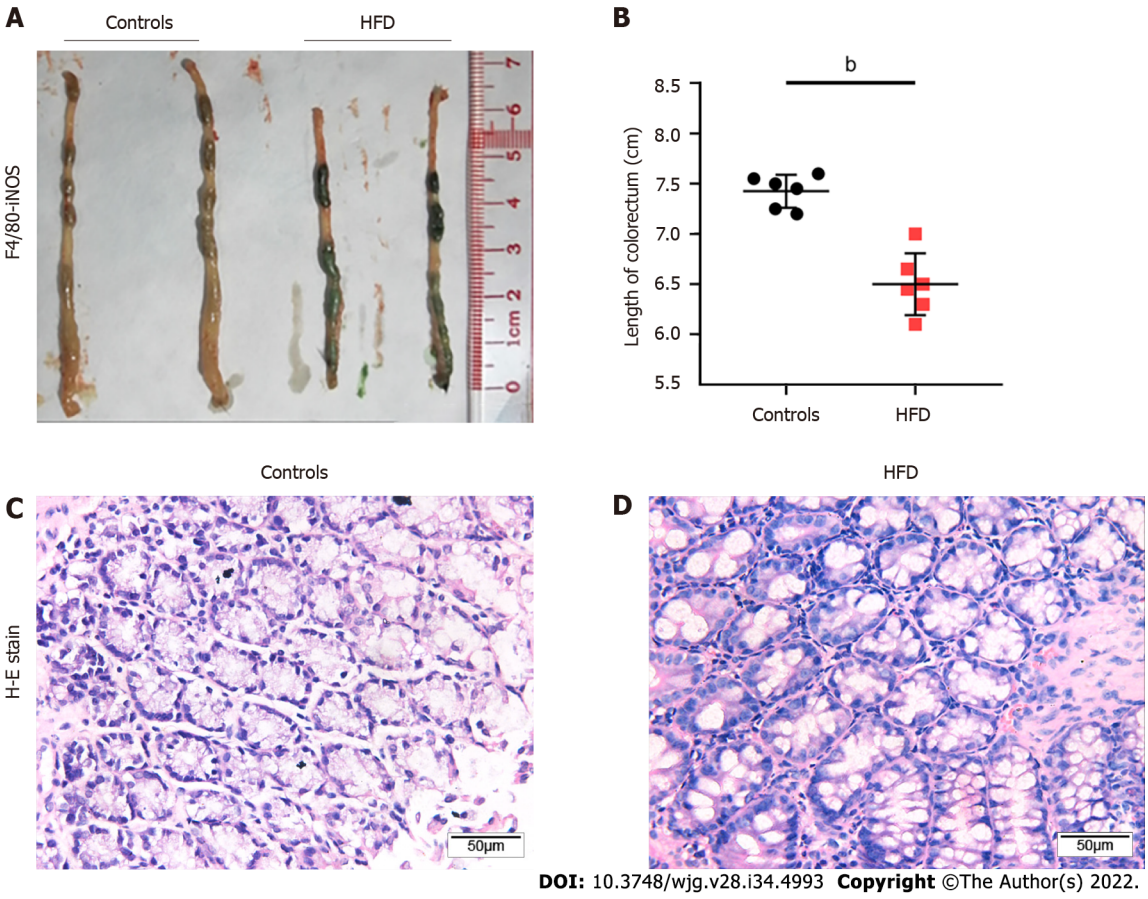


Four-week-old C57 mice were fed an HFD, and mice of the same age were fed a normal diet as controls. After 20 wk, the mice were sacrificed, and colorectal tissue specimens were harvested (n = 6). The colorectal length of control mice and HFD-fed mice was measured, respectively. We found that the colorectal length of HFD mice was shorter (Figures 2A and 2B). Subsequently, the tissue samples were sectioned and stained with hematoxylin and eosin. The staining results showed that glandular nuclei and interstitial cells in the colorectal tissues of HFD mice were slightly enlarged but to a milder degree than those usually observed with intraepithelial neoplasia (Figure 2C).

HFD increases ox-LDL expression and CD206 positive macrophages in the colorectal stroma of mice

After establishing the HFD-fed mouse model, we performed double IF staining for CD206-F4/80 or iNOS-F4/80 in the colorectal tissue sections of the control and HFD-fed mice. We found that the number of CD206 positive macrophages was significantly increased in the colorectal stroma of HDF-fed mice (Figures 3A, 3B, 3E, and 3F). The number of CD206+/ox-LDL+ cells and CD206+/LOX-1+ cells also increased significantly in the colorectal stroma of HDF-fed mice (Figures 3C, 3D, 3G, and 3H).

Continuous ox-LDL stimulation promotes CD206+ macrophages



To explore whether ox-LDL is related to macrophage polarization, we stimulated human monocytic leukemia cells (THP-1) with ox-LDL for 24 h and 72 h *in vitro*. qPCR results showed that the expression level of *CD206* gradually increased with increased stimulation time. However, the expression level of

iNOS increased in a short period and then decreased significantly below the initial level (Figure 4A). In addition, ox-LDL was used to stimulate mouse leukemic monocyte/macrophage cell line (RAW 264.7) for 72 h, and IF detection for CD206 was conducted. The results showed that CD206+ macrophages significantly increased in RAW 264.7 cells 3 d after ox-LDL stimulation (Figures 4B and 4C). Overall, we found that CD206+ macrophages gradually increased with continuous stimulation with ox-LDL, while iNOS+ macrophages initially increased then decreased in the later stages.

In order to confirm the relationship between ox-LDL and CD206+ cells, we transfected LOX-1 siRNA into THP-1 cells to inhibit the expression of LOX-1, the specific receptor of ox-LDL (Figure 4D). After 72 h of ox-LDL stimulation, the inhibition of iNOS expression and the promotion of CD206 expression were significantly weakened in THP-1 cells transfected with LOX-1 siRNA (Figure 4E). Further examination of the function of CD206+ macrophages showed that after 72 h of ox-LDL stimulation, the levels of the CD206+ macrophage-related cytokines interleukin IL-4, IL-10, and tumor necrosis factor TNF-β increased significantly in THP-1 cells except IL-13 (Figure 4F).

Macrophages promote the expression of tumor stem cell markers CD44 and CD133 in an ox-LDL-stimulated high-fat microenvironment

To investigate whether the occurrence of CRC is related to macrophages in the colorectal stroma and a high-fat microenvironment, we simultaneously inoculated human colorectal adenocarcinoma cells (LoVo) and THP-1 cells into transwell culture plates supplemented with 20 μg/mL ox-LDL for 72 h (Figure 5A). Thus, a high-lipid microenvironment was established to stimulate macrophages *in vitro* (n = 5). Western blot analysis showed that CD44 and CD133 expression was significantly increased in LoVo cells co-cultured with THP-1+ ox-LDL compared with ox-LDL alone (Figures 5C and 5D). We further transfected LOX-1 siRNA or siRNA negative control into THP-1 cells, and provided ox-LDL stimulation and co-cultured with LoVo cells again (Figure 5B). After ox-LDL stimulation, the levels of CD44 and CD133 in LoVo cells were inhibited when we knocked down LOX-1 in THP-1 cells (Figures 5E and 5F).

DISCUSSION

An increasing body of evidence suggests that HFD increases the risk of CRC. Importantly, studies have demonstrated the relationship between HFD and cancer by establishing animal models. HFD is often associated with abnormal oxidative stress and elevated lipid levels. Ox-LDL is a metabolite that reflects oxidative stress and lipid metabolism and is associated with various tumors. Ma *et al*[18] hypothesized

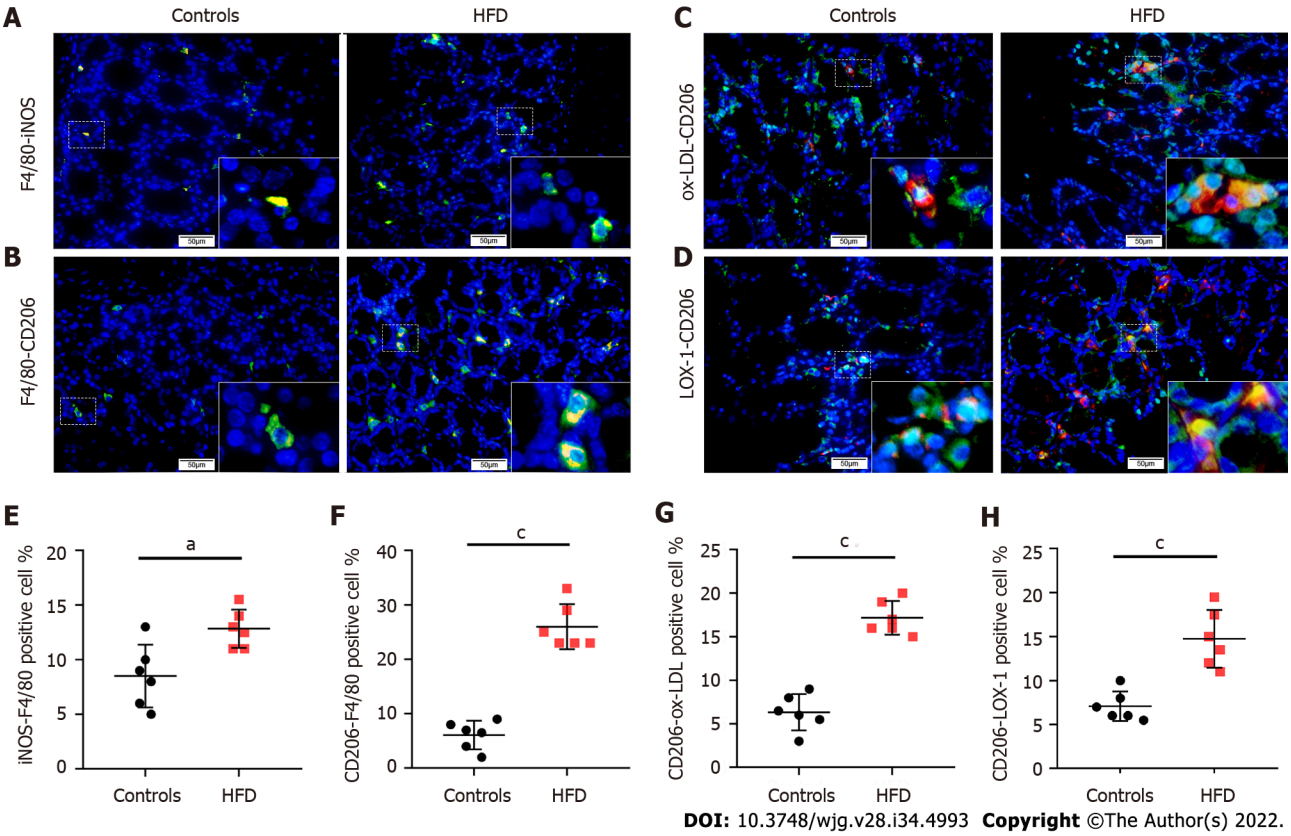

Figure 3 High-fat diet leads to increased expression of oxidized low-density lipoprotein and an increase of CD206 positive macrophages in mouse colorectal stroma. that ox-LDL could promote gastric cancer metastasis and demonstrated that ox-LDL could promote vascular proliferation and lymphatic metastasis in gastric cancer by activating the nuclear factor-kappa B signaling pathway in animal and cell experiments. Ox-LDL may play a potential role in promoting HFD associated CRC. It has been reported that ox-LDL is correlated with CRC in patients with dyslipidemia, and the serum ox-LDL level of CRC patients is higher than that in subjects without tumors[19]. A study from Egypt found that the serum ox-LDL level of obese colon cancer patients was higher than that in obese patients with a healthy intestine; a positive correlation was found between the serum ox-LDL level and the degree of tumor malignancy[13]. Furthermore, it was found that the serum ox-LDL level of patients after surgery was significantly lower than that before surgery[14]. These findings suggest that ox-LDL is a potential predictor and prognostic biomarker of CRC. However, the above experiments were conducted using blood serum tests of CRC patients. To the best of our knowledge, no study has documented ox-LDL expression in colorectal tissue. Herein, we provided compelling evidence that ox-LDL was abnormally expressed in CRC patients with hyperlipidemia at the tissue level. In this regard, the ox-LDL level was upregulated in the cancer tissue of CRC patients, especially in the stroma. Besides, we demonstrated that LOX-1, the surface receptor of ox-LDL, was also upregulated in CRC tissues. Consistently, increased ox-LDL and LOX-1 levels were documented in the colorectal tissues of HFD-fed mice, suggesting the regulatory role of ox-LDL in the tumor microenvironment in CRC.

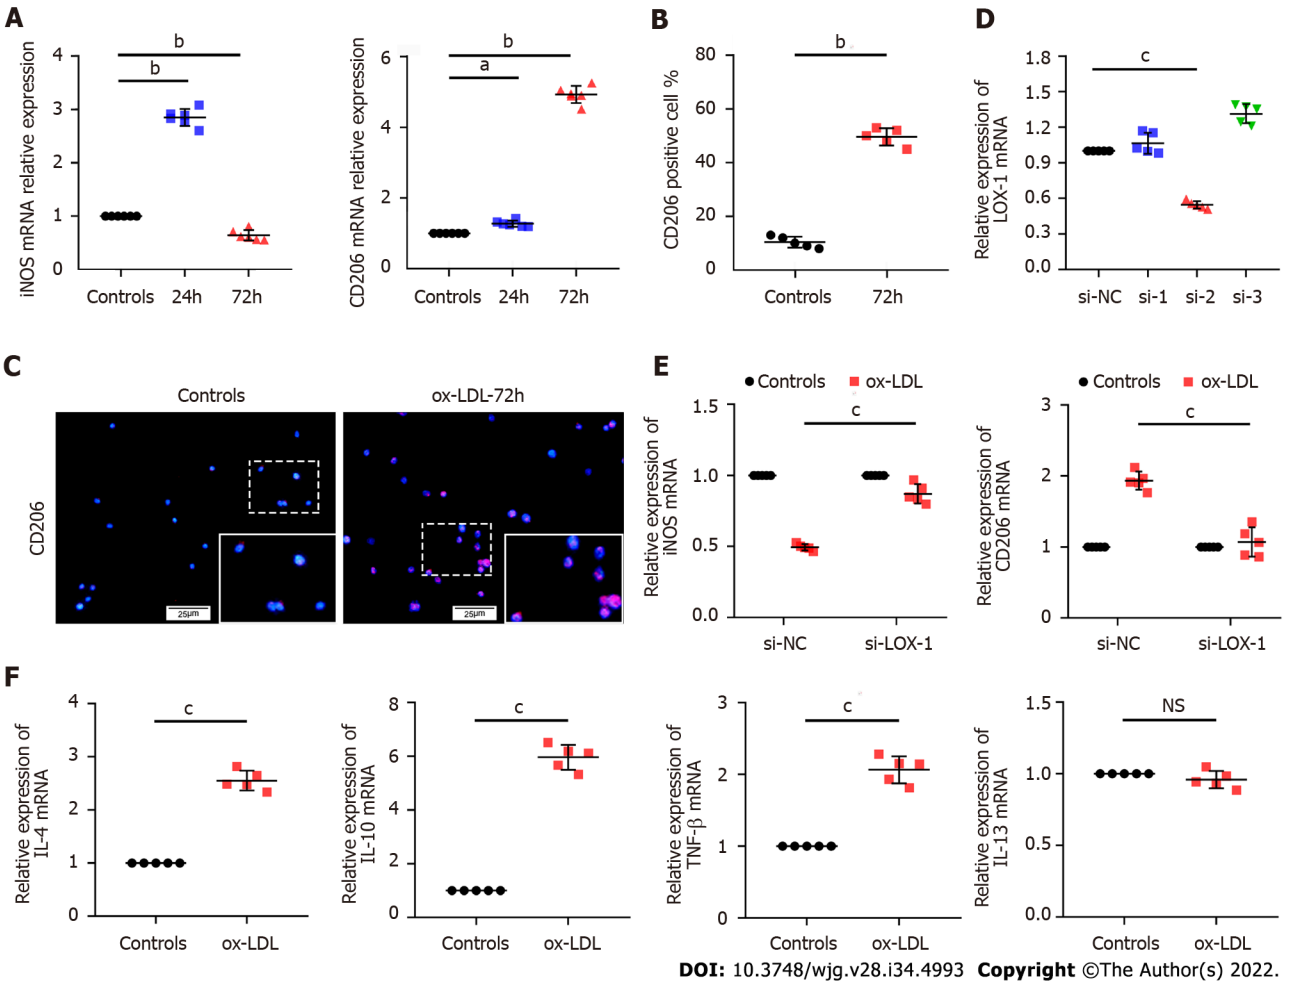
Macrophages, the most important immune cells in the tumor microenvironment, exhibit multiple phenotypes and exert various function[8]. It has been shown that iNOS+ macrophages inhibit tumor progression mainly by playing a pro-inflammatory role[20], while CD206+ macrophages promote cell repair and cell proliferation and growth, thus promoting tumor progression[9]. Different macrophages exhibit dynamic changes in the tumor microenvironment, and CD206+ macrophages are closely related to CRC development[21]. Existing clinical studies have reported that the CD206+ macrophage level is



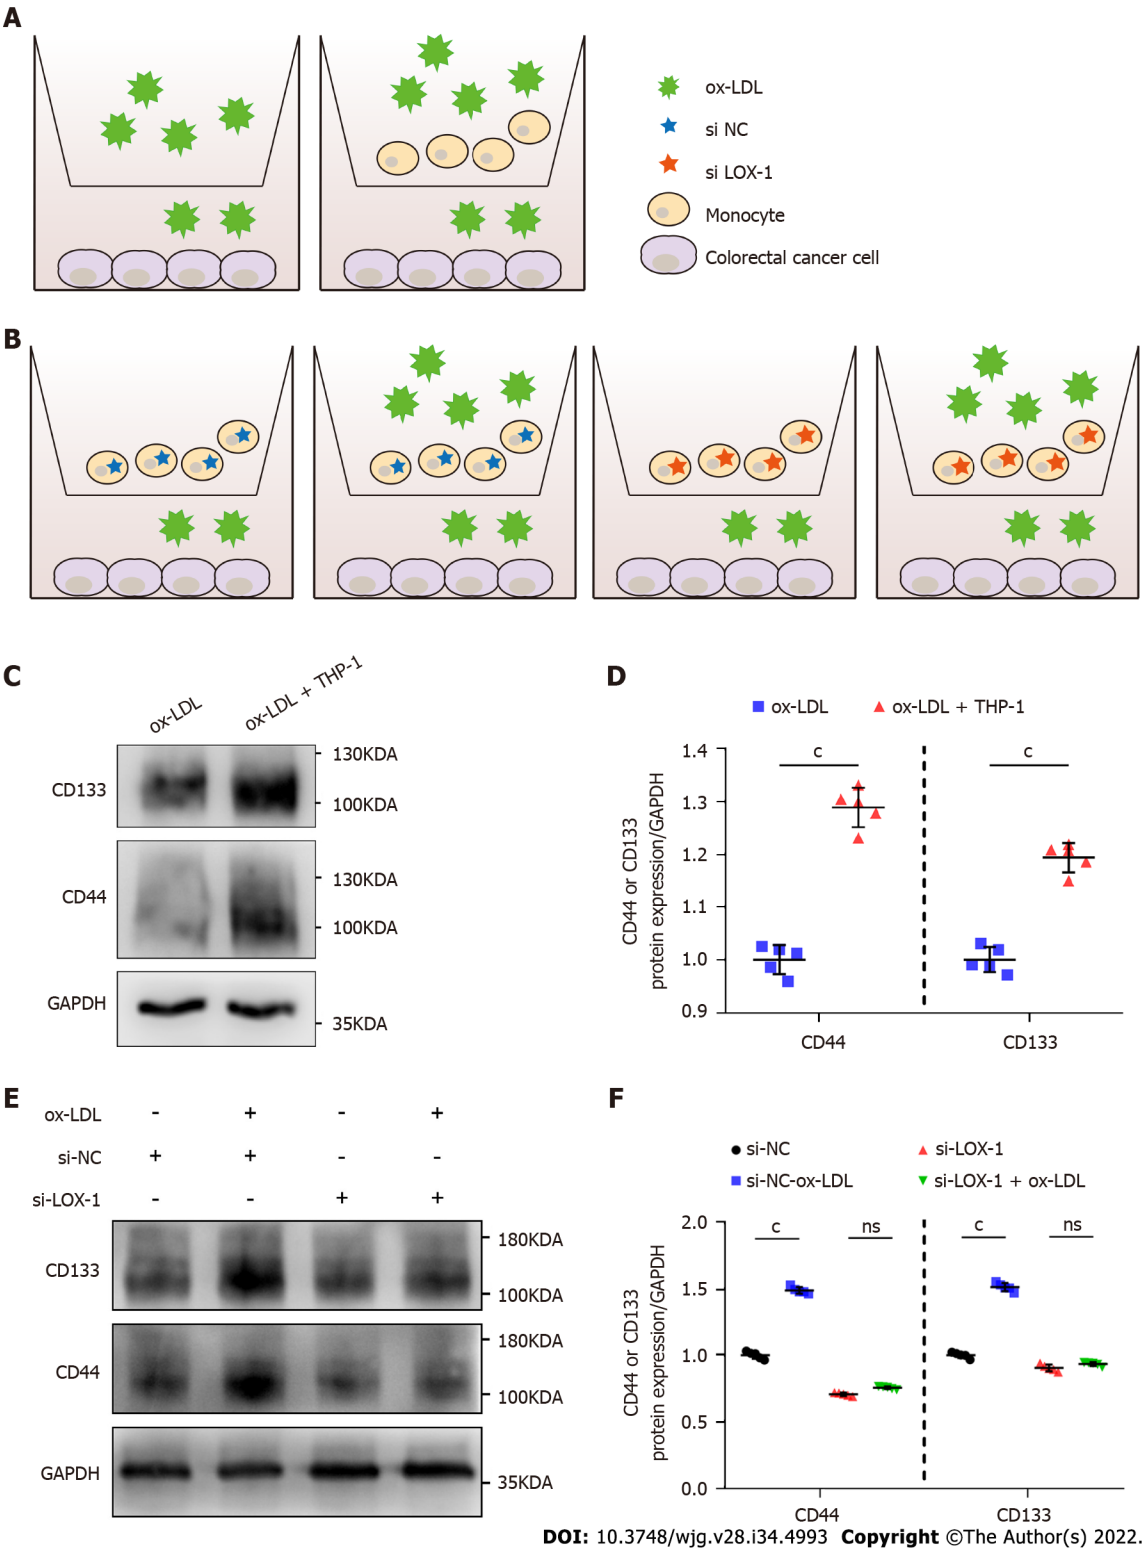


Figure 4 Continuous stimulation with oxidized low-density lipoprotein promotes CD206+ macrophages. Data are shown as the mean ± SD. Statistical analyses were conducted using an unpaired *t* test (Figure 4A, 4D, 4E, and 4F) or one-way analysis of variance followed by Dunnett's multiple comparison test (Figure 4B). The boxed area is enlarged in the bottom right corner. $^{a}P < 0.05$, $^{b}P < 0.01$, $^{c}P < 0.001$. ox-LDL: Oxidized low-density lipoprotein; iNOS: Inducible nitric oxide synthase; IL: Interleukin; TNF: Tumor necrosis factor; si-NC: Small interfering RNA negative control.

positively correlated with the TNM stage, the number of metastasized lymph nodes, and the degree of vascular invasion[22], and high CD206+ macrophage expression suggests a poor prognosis. Han *et al* [11] found that CD206+ macrophages in the tumor microenvironment could promote CRC metastasis through interaction with CRC cells. CD206+ macrophages have been reported to be elevated in colorectal tissues in patients with hyperlipidemia. A higher prevalence of CRC was detected in subjects with an HFD in a retrospective cohort study conducted by Liu *et al*[7]. In the present study, CD206+ macrophages were upregulated in colorectal tissues in patients with hyperlipidemia. In addition, animal experiments also confirmed that an increase in the number of intestinal tumors in HFD-fed mice was accompanied by a higher level of CD206+ macrophages, which correlated with the degree of malignancy of the tumor[7]. Our study demonstrated that CD206+ macrophages were highly expressed in the stroma of CRC tissues compared with normal tissues. These results suggest that the elevated level of CD206+ macrophages induced by HFD exerted a stimulatory effect on CRC. We also found that CD206+/ox-LDL+ cells and CD206+/LOX-1+ cells were highly expressed in the colorectal stroma of HDF-fed mice and CRC patients. In addition, studies confirmed that ox-LDL exert a regulatory effect on macrophages, and iNOS+ macrophages increased 24 h after ox-LDL induction *in vitro*[15]. Our study further found that CD206+ macrophages occurred in THP-1 cells under continuous ox-LDL stimulation. A high level of CD206+ macrophages was observed in RAW264.7 cells after ox-LDL stimulation for 72 h. Further examination of the function of CD206+ macrophages showed that after ox-LDL stimulation for 72 h, the levels of CD206+ macrophage-related cytokines IL-4, IL-10, and TNF-β increased significantly in THP-1 cells. Our study demonstrated that following the knockdown of LOX-1, the number of CD206+ macrophages mediated by ox-LDL was significantly depressed. Based on our results, we hypothesized

that ox-LDL could promote the progression of CRC by continuous stimulation of macrophages to induce CD206+ macrophages.

In addition, ox-LDL is also associated with tumor stem cells. Yang *et al*[23] found that ox-LDL could increase the malignancy of tumor stem cells in bladder cancer, thus promoting the development of bladder cancer. Active cell proliferation has been documented in gastrointestinal tissue from HFD-fed mice, with increased malignancy of tumor stem cells, which has been attributed to the inflammatory environment in colorectal tissue[4,5,24]. The high level of CD206+ macrophages in HFD-fed mice may play a certain role in this process. After THP-1 cells were stimulated with ox-LDL for 72 h and co-cultured with LoVo cells, the levels of the tumor stem cell markers CD44 and CD133 significantly increased in LoVo cells. Further, when we knocked down LOX-1 in macrophages, the increase in the levels of CD44 and CD133 was not that obvious in CRC cells, confirming that ox-LDL mediated the CD206+ macrophages to upregulate CD44 and CD133 expression in colon cancer cells.

CONCLUSION

In this study, we hypothesized that HFD could induce ox-LDL and its surface receptor LOX-1 accumulation in CRC tissue, suggesting the regulatory role of ox-LDL in the microenvironment of CRC. Furthermore, continuous stimulation of ox-LDL on macrophages induced CD206+ macrophages, which could further promote the increase of CD44 and CD133 levels in CRC cells. However, there are many limitations to our study. First of all, this study was a single-center study, and the sample size of included clinical specimens was relatively small. Larger sample size and multi-center prospective studies are needed to confirm our findings. Moreover, the mechanism underlying the effects of ox-LDL and the relevant signaling pathways were not explored, warranting further studies. In conclusion, we demonstrated that HFD causes ox-LDL accumulation in the colorectal tissue and upregulates CD44 and CD133 expression in colorectal cells by inducing CD206+ macrophages. These findings provide evidence for a new mechanism of increased CRC susceptibility with HFD.

ARTICLE HIGHLIGHTS

Research background

Oxidized low-density lipoprotein (ox-LDL), abnormally increased in the serum of patients with colorectal cancer (CRC) associated with a high-fat diet (HFD), may be one of the risk factors for CRC. Ox-LDL exerts a regulatory effect on macrophages, is associated with cancer stem cells, and may regulate CRC through the tumor microenvironment. The role of ox-LDL in CRC remains unclear. It is essential to explore the function of ox-LDL to explore the pathogenesis of HFD associated CRC.

Research motivation

The expression of ox-LDL in human colorectal cancerous tissues and colorectal tissues of hyperlipidemic mice was detected, and the function of ox-LDL in the macrophages in the tumor microenvironment was explored. Our key point is that ox-LDL up-regulates CD44 and CD133 in HFD associated CRC, which is mediated by macrophages. Our study will provide a new idea for the mechanism of HFD associated CRC.

Research objectives

The study aimed to investigate the role of ox-LDL through macrophage in HFD associated CRC.

Research methods

The expression of ox-LDL and CD206 was detected in colorectal tissues of CRC patients with hyperlipidemia and HFD-fed mice by immunofluorescence. We stimulated macrophages with 20 ug/mL ox-LDL and assessed the expression levels of CD206 and cytokines by cell fluorescence and quantitative polymerase chain reaction. We further knocked down LOX-1, the surface receptor of ox-LDL, to confirm the function of ox-LDL in macrophages. Then, LoVo cells were co-cultured with the stimulated macrophages to analyze the CD44 and CD133 expression by western blot.

Research results

The expression of ox-LDL and CD206 was significantly increased in the stroma of colorectal tissues of CRC patients with hyperlipidemia, and also upregulated in the HFD-fed mice. Moreover, an increased level of CD206 and decreased level of inducible nitric oxide synthase were observed in macrophages after the continuous stimulation of ox-LDL. Such effects were inhibited when the surface receptor LOX-1 was knocked down in macrophages. Ox-LDL could induce CD206+ macrophages, which resulted in high expression of CD44 and CD133 in co-cultured LoVo cells.

Research conclusions

Our study found that HFD could induce ox-LDL accumulation in CRC tissue, suggesting the regulatory role of ox-LDL in the microenvironment of CRC. Continuous stimulation of macrophages with ox-LDL induced CD206+ macrophages, which could further promote the increase of CD44 and CD133 levels in CRC cells.

Research perspectives

Our future study will collect more samples. We look forward to make a convincing analysis to identify the correlation between ox-LDL and progression and survival of the enrolled patients in the near future. We will explore the potential signal pathways related to ox-LDL promoting M2-type macrophages by using the technology of single cell sequencing and/or RNA-Seq assay. We are confident that it will provide exciting data in the near future.

ACKNOWLEDGEMENTS

We thank Ms. Lin-Lin Huang (Department of Gastroenterology, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China) for kindly providing LoVo cells. We really appreciate Mr. Ren-Gui Lin and Ms. Yu-Liang Huang (The Third School of Clinical Medicine, Southern Medical University, Guangzhou, China) for kindly assisting in the completion of the experiments.

Author contributions: Zheng SM, Sha WH, Chen H, and Ma J designed and coordinated the study; Zheng SM, Chen XF, Yin JB, Zhu XB, and Zheng ZW performed the experiments; Zheng SM and Yin JB acquired and analyzed the data; Chen XF, Zhu XB, and Zheng ZW interpreted the data; Zheng SM, Sha WH, and Chen H wrote the manuscript; and all authors approved the final version of the article.

Supported by Science and Technology Program of Guangzhou, No. 202102080007.

Institutional review board statement: The institutional review board of the Guangdong General Hospital approved the study protocol. All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Institutional animal care and use committee statement: The animal protocol was designed to minimize pain or discomfort to the animals. The animals were acclimatized to laboratory conditions (23 °C, 12 h/12 h light/dark, 50% humidity, ad libitum access to food and water) for 2 wk prior to experimentation.

Conflict-of-interest statement: All the authors report no relevant conflicts of interest for this article.

Data sharing statement: Technical appendix, statistical code, and dataset available from the corresponding author at email: mjlqh@163.com. Participants gave informed consent for data sharing.

ARRIVE guidelines statement: The authors have read the ARRIVE guidelines, and the manuscript was prepared and revised according to the ARRIVE guidelines.

Open-Access: This article is an open-access article that was selected by an in-house editor and fully peer-reviewed by external reviewers. Abstract

BACKGROUND

Slow transit constipation (STC) is a common intestinal disease with increasing incidence. STC results from various factors, such as the enteric nervous system and metabolic changes. As a classical formula of traditional Chinese medicine, Ji-Chuan decoction (JCD) has been extensively and effectively used in STC treatment, yet its pharmacological mechanism remains unclear.

AIM

To explore the integrated regulatory pattern of JCD against STC through hyphenated techniques from metabolism, network pharmacology and molecular methods.

METHODS

STC model mice were generated by intragastric administration of compound diphenoxylate (10 mg/kg/d) for 14 d. The STC mice in the low dose of JCD (3.04 g/kg), middle dose of JCD (6.08 g/kg) and high dose of JCD (12.16 g/kg) groups

were orally administered JCD solution once a day for 2 wk. The acetylcholine (ACH) level was examined by enzyme-linked immunosorbent assay. The pathological features of colon tissue were observed by hematoxylin and eosin staining. The differentially expressed metabolites and metabolic pathways were tested by nontargeted metabolomics. The main targets and core ingredients of JCD were identified by network pharmacology, and the expression of AKT was confirmed by immunohistochemistry. Finally, the pathways involved in JCD treatment were predicted using a combination of differentially expressed metabolites and targets, and intestinal glial cell apoptosis was demonstrated by immunofluorescence.

RESULTS

JCD significantly promoted intestinal motility, increased the levels of the excitatory neurotransmitter ACH and reduced intestinal inflammation in STC mice. Untargeted metabolomics results showed that JCD significantly restored metabolic dysfunction and significantly affected taurine and hypotaurine metabolism. Network pharmacology and molecular experiments showed that JCD regulates AKT protein expression, and the core component is quercetin. Combined analysis demonstrated that apoptosis may be an important mechanism by which JCD relieves constipation. Further experiments showed that JCD reduced enteric glial cell (EGC) apoptosis.

CONCLUSION

This work demonstrated that reducing EGC apoptosis may be the critical mechanism by which JCD treats STC. These findings call for further molecular research to facilitate the clinical application of JCD.

Key Words: Slow-transit constipation; Ji-Chuan decoction; Taurine and hypotaurine metabolism; AKT; Enteric glial cell; Apoptosis

Core Tip: Slow transit constipation (STC) model mice, which were established with compound diphenoxylate, were effectively treated with Ji-Chuan decoction (JCD). The results show that JCD can promote intestinal motility, increase acetylcholine content, reduce enteric inflammation, improve metabolic dysfunction, and reduce enteric glial cell apoptosis. This work demonstrated that reducing enteric glial cell apoptosis may be the critical mechanism by which JCD treats STC. These findings call for further molecular research to facilitate the clinical application of JCD.

INTRODUCTION

Chronic constipation is a common complaint and can generally be divided into defecatory disorder, mixed constipation, normal transit constipation and slow transit constipation (STC). STC is the major type of chronic constipation characterized by a substantial increase in bowel transit time. STC has become an epidemic that particularly impacts the quality of life of elderly patients[1]. Despite high morbidity worldwide, the etiology of STC is poorly understood. An accumulation of publications indicates that multiple factors have been documented in the pathogenesis of STC[2-4]. Consequently, an interdisciplinary approach is necessary for exploring its pathological characteristics and developing therapies based on multiple components and multiple targets, such as traditional Chinese medicine (TCM)[5,6]. The active components of Ma-Zi-Ren-Wan could safely and effectively relieve the severity of functional constipation. Based on network pharmacology[7], the anti-STC mechanism of Gui-ren-Run-chang granules, another TCM formula, is associated with repairing the SCF/c-kit pathway and reducing aquaporin-4 expression in the colon[8].

Ji-Chuan decoction (JCD) is a representative TCM formula that originated from Jing-Yue-Zhang in the Ming Dynasty. It has been extensively used for STC and other gastroenteric disorders for hundreds of years[9]. JCD, as a typical TCM prescription, is composed of six herbs and includes multiple bioactive ingredients and complex targets. Studies have shown that JCD can effectively shorten colonic transit

time, improve anorectal dynamics, regulate gastrointestinal neurotransmitters, alleviate constipation symptoms in STC patients, and improve the quality of life of STC patients[9,10]. After 1 mo of continuous use, only a few patients experienced adverse reactions such as dizziness (1.7%) and dry mouth (1.7%)[10]. Our clinical practice confirmed that JCD was a useful formula for STC therapy. *Cistanche deserticola* (*C. deserticola*) is the monarch drug for JCD, and the combination of geniposide and Lactobacillus plantarum KSFY06 has been shown to have anti-montmorillonite-induced constipation effects in Kunming mice[11,12]. However, direct experimental study of the effects of JCD against STC remains to be performed. In this work, we attempt to assess the laxative effect of JCD against STC through a multiomics approach, including metabolomics and TCM network pharmacology, to explore the integrated therapeutic mechanism of JCD.

MATERIALS AND METHODS

Reagents and JCD preparation

Rabbit anti-AKT monoclonal antibody (No: bs-0115R) was provided by Bioss. The biotin secondary antibody anti-rabbit working solution (Goat, SP-9001) was provided by Beijing Zhongshan Jinqiao Biological Technology Co., Ltd. Glial fibrillary acidic protein (GFAP) (mouse, code: ab4648) and Caspase3 (rabbit, code: ab4051) were purchased from Abcam. CY3-labeled goat anti-mouse immunoglobulin G (IgG) (code: 202110) and fluorescein isothiocyanate-labeled goat anti-rabbit IgG (code: GB22303) were purchased from Servicebio.

The JCD solution was prepared according to the protocol described by Cui *et al*[13]. A clinical packet of JCD is composed of six Chinese herbs, *i.e.*, *Angelica sinensis* (15 g), *C. deserticola* (9 g), *Achyranthes bidentata* (*A. bidentata*) (6 g), *Fructus aurantii* (*F. aurantii*) (4.5 g), *Alisma orientalis* (3 g) and *Cimicifuga heracleifuga* (3 g). Six packets of JCD were purchased from Chengdu Hospital of Integrated TCM and Western Medicine and identified by Dr. Wan Lin from Chengdu University of TCM. These herbs were then soaked in 2430 mL ddH_2O (w/v 1:10) for 30 min and decocted for 20 min. Combined solutions following three decoctions were filtered by a 0.22-μm filter, concentrated to 0.81 g of crude herb per milliliter by a vapor evaporator, and stored at -20 °C for further use. In the past, scholars have studied the hyphenated to liquid chromatography characteristic fingerprints of JCD substances[14].

STC model-made, JCD treatment and sample collection

This experiment was approved by the Animal Ethics Committee, Chengdu University of TCM (license 2016-16). Thirty C57BL/6J male mice, aged 7 wk and weight 20.21 ± 2.10 g, were purchased from Chongqing Evansville Laboratory Animal Co., Ltd. (Chongqing, China). The animals were adaptively fed for 7 d in an environment with relative humidity of 45%-55%, a 12-h light/dark cycle and temperature of 22 ± 2 °C. The mice were then randomly divided into six groups, with five animals in each group: Healthy control (HC), STC model (STC), positive drug treatment (mosapride, MSP), low dose of JCD (JCDL), middle dose of JCD (JCDM) and high dose of JCD (JCDH). Mice in the HC group were orally administered normal saline (0.1 mL/10 g/d) as a negative control. The other mice were induced as the STC models by oral administration of compound diphenoxylate (10 mg/kg/d) for 14 d. After model identification, mice in the MSP group were orally administered with MSP (2.5 mg/kg); mice in the JCDL (3.04 g/kg), JCDM (6.08 g/kg) and JCDH (12.16 g/kg) groups were orally administered with JCD; and normal saline (0.1 mL/10 g/d) was gavaged in the HC and STC groups. Each mouse was administered treatments once a day for 14 d. Body weight, food intake and water intake were monitored every week. At the end of experiment, the feces of each mouse were collected under sterile procedures, frozen in liquid nitrogen and stored at -80 °C for further use.

The number of defecation particles within 6 h was counted, and the wet weight of the stool samples was evaluated. Then, the dry weight of the stool was weighed after drying at 60 °C for 12 h in a desiccator, and the moisture content of the stool was calculated. The colonic samples were harvested after euthanasia[15]. The acetylcholine (ACH) concentrations were detected by enzyme-linked immunosorbent assay.

Evaluation of the intestinal propulsive rate

The intestinal propulsive rate was measured after the last administration as follows[16]: All mice were fasted for 12 h and allowed free access to water. Then, mice were fed charcoal powder in 10% acacia gum. After 30 min, the abdomen was opened and the intestines were removed. The length from the pylorus to the ileocecal junction, as well as the charcoal transport distance were measured. The intestinal propulsive rate was calculated by the following formula[17]: Charcoal transit ratio (%) = distance of charcoal transport (cm)/length from pylorus to ileocecal junction (cm) × 100%.

Hematoxylin and eosin and immunofluorescence staining

The collected tissue samples were fixed with 10% formalin, dehydrated with alcohol, and embedded in paraffin wax. The embedded tissues were then sliced into 5-μm slices using a microtome (Leica, Buffalo

Grove, United States) and stained with hematoxylin and eosin (HE). The pathological features were imaged by a digital microscope (Xiamen, China), and the optical densities were quantified using Image-Pro Plus 6.0.

Ultrahigh-pressure liquid chromatography coupled with tandem mass spectrometry analysis

Metabolomics was performed with a Vanquish UHPLC (Thermo, Germany) coupled with a Q Exactive™ HF (Thermo, Germany) platform (Novogene, Beijing, China) as previously described. Fecal samples (100 mg) were ground in liquid nitrogen, incubated on ice for 5 min, and centrifuged at 15000 × g for 20 min at 4 °C. The supernatant was diluted with liquid chromatography-mass spectrometry grade water to a final concentration of 53% methanol. After another centrifugation step, the supernatant was injected into the liquid chromatography-tandem mass spectrometry system for analysis. Samples were injected into a Hypesil Gold column (C18) using a 17-min linear gradient at a flow rate of 0.2 mL/min. The eluents in positive polarity mode were Eluent A (0.1% FA in water) and Eluent B (methanol). The eluents for negative polarity mode were Eluent A (5 mmol/L ammonium acetate, pH 9.0) and Eluent B (methanol). The solvent gradient was set as follows: 2% B, 1.5 min; 2%-100% B, 12.0 min; 100% B, 14.0 min; 100%-2% B, 14.1 min; and 2% B, 17 min. The Q Exactive™ HF mass spectrometer was operated in positive/negative mode with a spray voltage of 3.2 kV, a capillary temperature of 320 °C, a sheath gas flow of 40 arb, and an auxiliary gas flow of 10 arb. Then, the data were matched to the mzCloud, mzVault, and MassList databases for accurate qualitative and relative quantitative results. The threshold for differential metabolites was set as variable importance in the projection (VIP) > 1.0, fold change (FC) > 1.5 or < 0.667 and P value < 0.05. The metabolic functions and relevant metabolic pathways were enriched by MetaboAnalyst 5.0 (https://www.metaboanalyst.ca/).

Network pharmacology analysis and immunohistochemical validation

TCMSP (https://tcmsp-e.com/) was applied to find the chemical components and corresponding targets of JCD, with OB ≥ 30% and DL ≥ 0.18. The UniProt database (https://www.UniProt.org/) was used to correct potential targets. The chemical composition and corresponding targets of JCD were checked by BAT-MAN (http://bionet.ncpsb.org.cn/batman-tcm/index.php), with a score cutoff over 500. Then, the targets obtained from TCMSP and BAT-MAN were combined and deduplicated. Taking "slow transfer constipation" as the keyword, the target points with a score greater than 5.0 were collected from the GeneCard database (https://www.genecards.org/), and all the targets collected from OMIM (https://omim.org/) were included in the follow-up study. The common genes of drug targets and disease genes were put into the STRING11.0 (https://string-db.org/) database to construct a protein-protein interaction (PPI) network. The relevant data were imported into Cytoscape (3.7.1) software in tsv format, and the cytoHubba plug-in was used to display the top 30 nodes in the betweenness algorithm as Hub nodes and to display them in Excel. The distribution pattern and expression levels of AKT, which is one of the most important hub nodes in colonic tissues, were analyzed by immunohistochemistry. Rabbit anti-AKT antibody (Bioss; 1:100) was applied overnight at 4 °C, followed by horseradish peroxidase-conjugated goat anti-rabbit IgG incubation at room temperature for 30 min, and diaminobenzidine was used for staining. The graphic processing software Image-Pro plus 6.0 was used to quantify the expression of AKT. Five fields of each slide were randomly observed, and the optical density values were determined. The components acting on AKT are considered core components of JCD.

Integrated analysis of differentially expressed metabolites and target genes

The HGNC database (https://www.genenames.org/) was applied to transform the obtained JCD target genes into mouse genes. The Joint-Pathway analysis of MetaboAnalyst 5.0 was used to enrich differentially expressed metabolites (DEMs) and target genes associated with JCD. Except for those nominated by other diseases, the top 25 pathways were selected for integrated analysis. The degree of apoptosis of enteric glial cells (EGCs) in colon tissue was analyzed by immunofluorescence. Rabbit anti-caspase3 antibody (Abcam; 1:100) was applied overnight at 4 °C, and mouse anti-GFAP antibody (Abcam; 1:100) was stained at 37 °C for 30 min followed by 4',6-diamidino-2-phenylindole for 10 min at room temperature. ImageJ graphics processing software was used to calculate the apoptosis of EGCs. Five fields of each slide were randomly observed, and densitometric values were estimated.

Statistical analysis

Data processing and statistical analyses were performed by Graph Pad Prism 7 (GraphPad, La Jolla, CA, United States). Data are expressed as the mean ± SD. One-way analysis of variance was used to compare the data of six groups. Student's t test was used for the pairwise comparison of data. The results were considered significant when P < 0.05.

RESULTS

JCD promoted intestinal motility, increased excitatory neurotransmitters and reduced intestinal inflammation in STC mice

General restoration of STC symptoms was observed after JCD treatment. The food intake, water intake and body weight in the JCDH and JCDM groups were similar to those in the HC group (Supplementary Table 1). Compared with HC mice, the average number of stool particles collected from STC mice was markedly reduced. After JCD administration, the average number of stool particles collected from the JCDL, JCDM and JCDH groups was significantly increased and was similar to the level of the positive control drug MSP (Figure 1A). Compared with the HC group, the dry weight, wet weight, and water content of the feces in the STC group were significantly decreased, and the dry weight, wet weight, and water content of the feces in the MSP, JCDM, and JCDH groups were significantly increased (Table 1). Compared with the HC group, the intestinal propulsion rate was significantly decreased in the STC mice, whereas the intestinal propulsion rate was significantly increased in the JCDM, JCDH, and MSP groups (Figure 1B). Finally, the concentrations of excitatory neurotransmitters (colon ACH) in STC mice were significantly reduced, while those in the three JCD groups were significantly increased (Figure 1C).

In addition, pathological observations demonstrated that JCD significantly reduced constipation-associated intestinal inflammation. Pathological observation demonstrated typical pathology of intestinal inflammation in STC mice, with inflammatory infiltration and necrosis in the distal colon. JCD repaired the colonic injuries in a dose-dependent manner (Figure 2). Briefly, the results showed that JCD exerts its effects by enhancing intestinal motility, promoting excitatory neurotransmitters and inhibiting intestinal inflammation in STC mice. Therefore, it is considered that the modeling was successful.

JCD beneficially regulated taurine and hypotaurine metabolism

Forty-two DEMs (Supplementary Table 2) (negative ion mode) between the HC and STC groups and 86 DEMs (Supplementary Table 3) between the STC and JCDH groups were identified (the sample chromatogram in negative ion mode is shown in Supplementary Figure 1). Among the DEMs, eighteen were altered by the modeling process but recovered after JCDH treatment (Supplementary Table 4). As shown in Figure 3A, the closely focused cluster of quality control (QC) samples indicated the reproducibility of the experiments. Figures 3B and C display the fecal DEMs observed after modeling and JCDH treatment. Compared with the STC group, the R2 (evaluation of the modeling ability) and Q2 (description of the predictive ability) of the HC and JCDH groups indicated that the orthogonal partial least squares-discrimination analysis model had high predictability and reliability. Compared with the STC group, the R2 intercepts of the HC and JCDH groups were 0.94 and 0.92, respectively, and the Q2 intercepts were 0.72 and 0.88, respectively (Figures 3D and E). Figures 3F and G show the DEMs by volcano maps. Furthermore, taurine and hypotaurine metabolism were the main pathways impacted by JCDH treatment (Figure 3H).

The core target of JCD is AKT, and the core component is quercetin

To further determine the therapeutic mechanism of JCD in STC, we performed a network pharmacology analysis. After data screening, 45 active pharmaceutical ingredients (Supplementary Table 2), 280 related targets, and 1372 disease targets were obtained. Comparing the goals related to JCD and STC, 89 common goals were identified and registered in the STRING database. Cytoscape 3.7.2 software was used to construct a PPI network, including 132 nodes and 2492 interactive edges (Figure 4A). According to the betweenness centrality value, the top 30 hub nodes were identified (Figures 4B and C), and AKT was considered one of the important targets. Immunohistochemistry confirmed that colonic AKT expression was significantly suppressed in STC mice compared with the HC group, whereas JCD significantly reversed this effect (Figures 4D and E). The chemical that acts on AKT is considered to be the core component of JCD, *i.e.,* the quercetin from *A. bidentata* and *C. deserticola,* baicalein, kaempferol and wogonin from *A. bidentata*, and naringenin from *F. aurantii* (Table 2).

JCD inhibited EGC apoptosis

To comprehensively probe the pharmacological mechanism of JCD, a joint-pathway analysis was performed based on DEMs and common genes from network pharmacology. Twenty-five remarkable pathways are presented in Figure 5A. Apoptosis may be an important signaling pathway in the treatment of STC by JCD. GFAP is an EGC marker. Immunofluorescence double-labeling of GFAP and caspase3 showed that compared with the HC group, the apoptotic rate of EGCs in the STC group was significantly increased, while those in the JCDH and JCDM groups were significantly decreased (Figures 5B and C), confirming the predicted results.

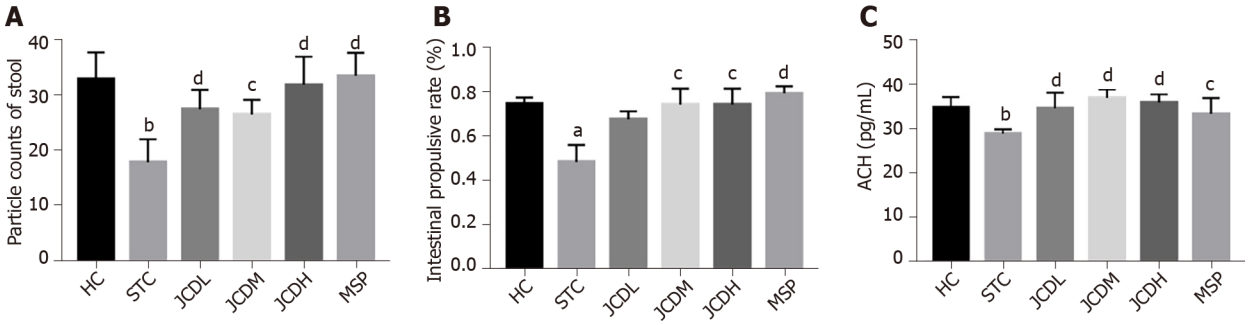

Table 1 Dry weight, wet weight and moisture content of feces of mice in each group

Grouping/feces index	Wet weight (g/mou)	Dry weight (g/mou)	Moisture content (%/mou)
HC	0.26 ± 0.02	0.18 ± 0.01	0.30 ± 0.04

DISCUSSION

JCD is an established TCM formula that is a particularly effective therapy for STC differentiated by TCM as Spleen and Kidney Yang deficiency syndrome[9], yet its pharmaceutical mechanism remains unclear. We explored the therapeutic mechanism of JCD in a dose-dependent manner and observed that the best effect was achieved by JCDH. The compound diphenoxylate is widely used to induce STC in animal models and can inhibit the peristaltic reflex of intestinal mucosa. It is easier to induce constipation than the commonly used loperamide and is more available than morphine[17]. It is easier to induce constipation than other loperamides and easier to obtain than morphine[17]. The holistic view is shared between systems biology and TCM[18]; therefore, we used key disciplines of systems biology, such as metabolomics and network pharmacology, to effectively reveal the integrated mechanism of JCD for STC.

Figure 2 Histological changes in the distal colon. A: Distal colon of the healthy control group; B: In the distal colons of mice in the slow transit constipation group, more severe inflammatory infiltration was observed; C: In the distal colons of mice in the low-dose Ji-Chuan decoction (JCD) treatment group, more severe inflammatory infiltration was observed; D: In the distal colon of mice in the middle-dose JCD group, there was reduced inflammation; E: High-dose JCD treatment restored the normal tissue morphology of the distal colon of constipated mice; F: Mosapride treatment restored the normal tissue morphology of the distal colon of constipated mice. Sections were observed at 400 × using a light microscope.

JCD substantially improved the manifestation of STC in mice

Constipation refers to laborious defecation, dry and hard stools and low stool volume. Effective drugs will increase key indices of constipation, such as the quantity and water content of the feces and the intestinal propulsive rate[19,20]. In this study, we observed that JCD substantially improved almost all indices tested in this work (Figures 1A and B, Table 1). The intestinal propulsive rates, extensively used to evaluate the pathological degree and curative effect of constipation, were significantly decreased after diphenoxylate treatment. Similar anti-constipation effects were obtained among the JCDM, JCDH and the positive reagent MSP groups (Figure 1B). In addition, the three JCD doses could statistically increase the concentration of excitatory neurotransmitter (ACH) (Figure 1C), suggesting that the increase in excitatory neurotransmitter is a critical approach for anti-constipation by JCD[3]. Our colonic pathological observation showed that JCD significantly reduced inflammatory infiltration and repaired pathological damage caused by the compound diphenoxylate in a dose-dependent manner (Figure 2), confirming previous studies[21]. Therefore, our work indicates an integrated effect of JCD on STC by promoting excitatory neurotransmitters, inhibiting gastroenteric inflammation and accelerating intestinal motility.

JCD altered critical enteric metabolites, especially taurine and hypotaurine

The metabolome results showed that the pathways involving taurine and hypotaurine metabolism were important for the anti-constipation effect of JCD. Taurine is a sulfur-containing α-amino acid with anti-inflammatory properties that can be sequentially converted into homocysteine, cystathionine, cysteine and/or hypotaurine[22,23]. The concentration of taurine was significantly reduced in loperamide-induced constipation rats, and red liriope ameliorated constipation and increased the level of taurine[24, 25]. Our work also showed that the contents of taurine and its metabolite hypotaurine were negatively

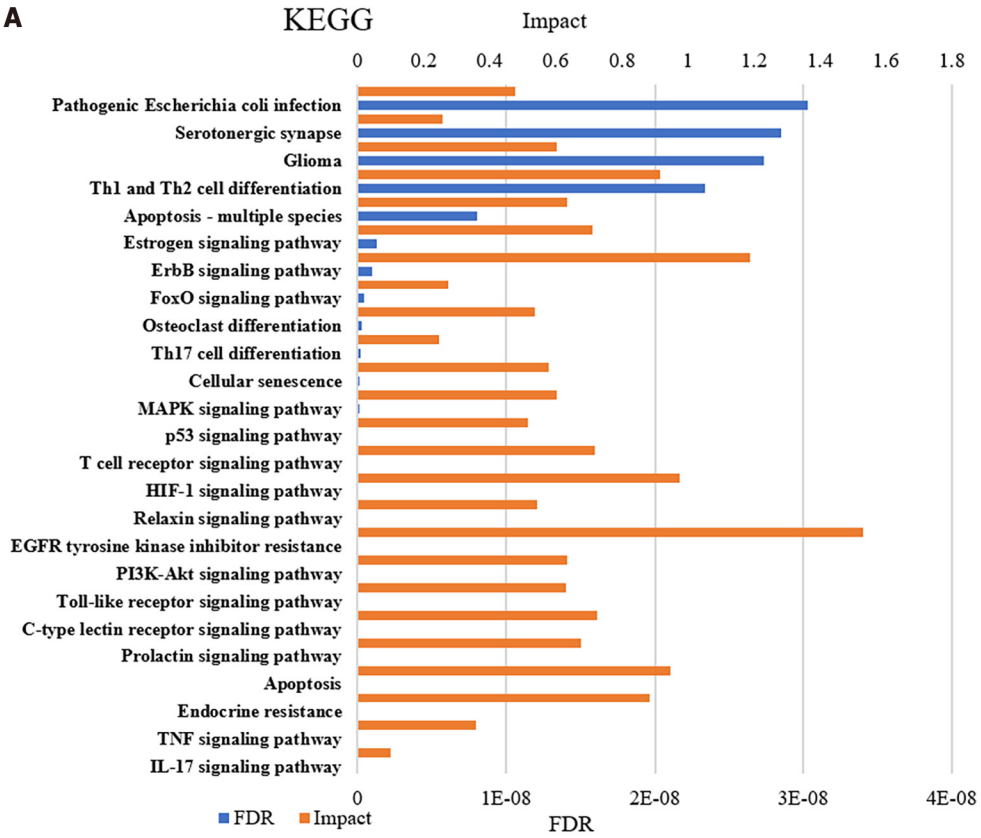
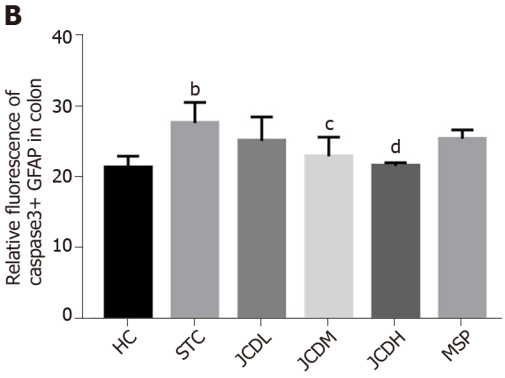
associated with the manifestation of STC and positively associated with intestinal transit rates[26]. However, the molecular mechanism of taurine on gastrointestinal motility and the regulatory mechanisms of JCD remain to be further explored.

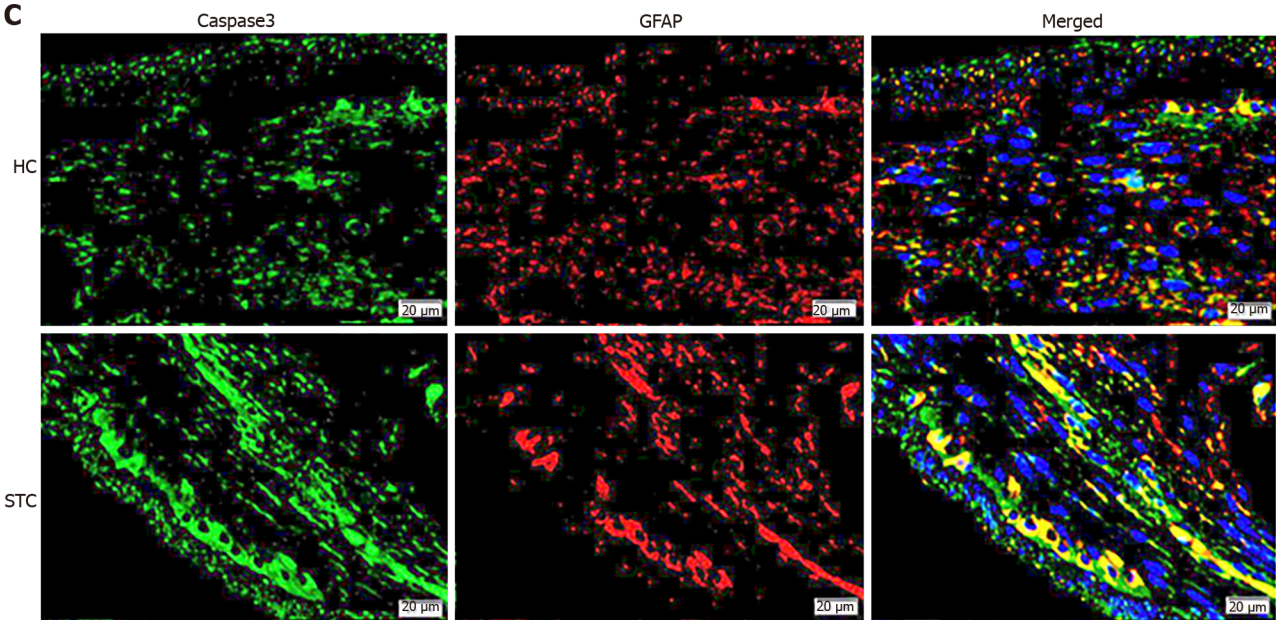
JCD restored the levels of AKT, a key protein involved in apoptosis regulation



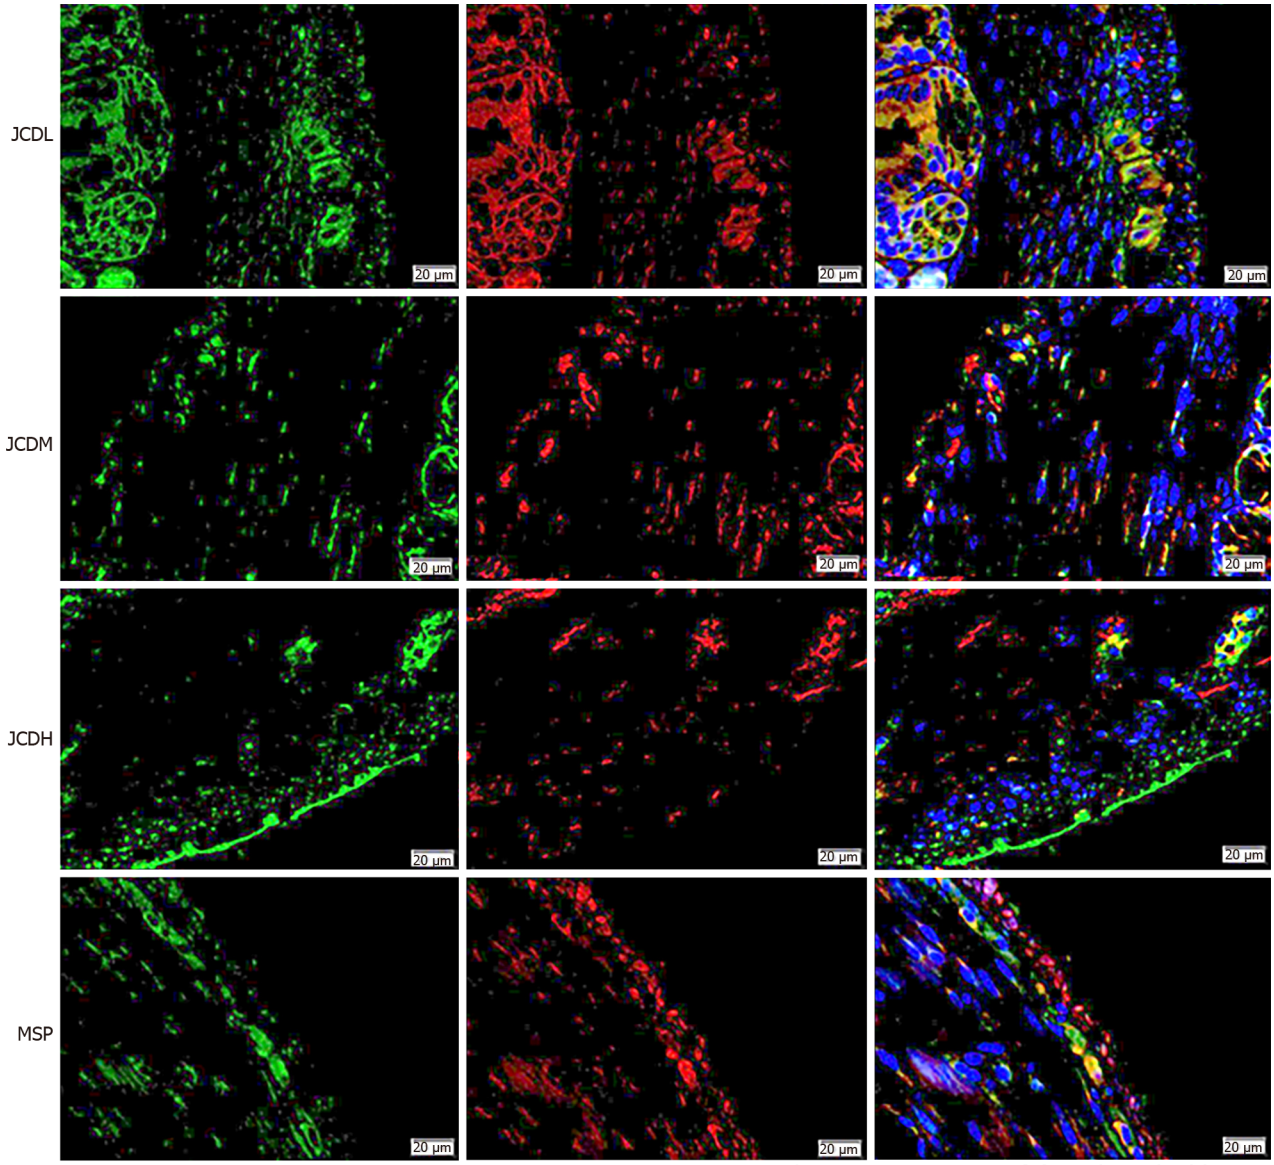
PPI network prediction showed that AKT is the core target of JCD for STC therapy. In our experiments, STC mice showed downregulated expression of AKT, while all three doses of JCD treatment reversed the abnormally reduced expression levels. AKT plays an important role in cell survival and apoptosis. Previous studies have shown that high glucose levels can induce EGC apoptosis through the AKT pathway, which is closely related to intestinal motility[27]. Another study showed that EGCs could protect the nervous system from hyperglycemia-induced damage by activating the Akt/GSK-3β pathway[28]. Therefore, we speculate that the treatment of STC with JCD may be related to EGC apoptosis.



JCD rescued excessive EGC apoptosis



Experimental evidence in humans and animals suggests that EGCs play a key role in regulating gastrointestinal motility and transit[29-32]. A cohort study of twenty-six STC patients showed reduced EGCs compared with ten healthy volunteers[33]. EGC can increase the expression of Akt and ZO-1 by releasing glial cell-derived neurotrophic factor, indirectly regulating the integrity of the intestinal epithelial barrier, reducing intestinal inflammation and improving delayed colonic transit[34,35]. Another study showed that enteric glial LPAR1 signaling regulates gastrointestinal motility through EGCs and may contribute to chronic intestinal pseudo-obstruction in humans[36]. Activation of opioid receptors in EGCs may be associated with morphine-induced constipation[37]. Previous studies have shown that the key components of JCD are associated with neural apoptosis, and many of them also involve changes in AKT protein. For example, wogonin, a key component of JCD identified in this paper, can prevent hippocampal injury after brain trauma through antioxidation and anti-apoptosis, which has been shown to occur through the PI3K/Akt/nuclear factor E2-related factor 2 (Nrf2)/HO-1 pathway[38]. Baicalein reduces sevoflurane-induced neurodegeneration, improves learning and memory retention in rats, and modulates the PI3/Akt/GSK-3β and JNK/ERK signaling pathways[39]. Kaempferol prevents cerebral ischemia-reperfusion injury by interfering with oxidative and inflammatory stress-induced apoptosis[40]. Quercetin is involved in neuroprotection by regulating Nrf2, paraoxonase 2, JNK, tumour necrosis factor alpha, PGC-1α, MAPKs, CREB and PI3K/Akt[41]. Naringenin can effectively inhibit Aβ25-35-induced neuronal injury in PC12 cells by regulating the ER and PI3K/Akt pathways[42]. To our knowledge, the current work is the first to demonstrate that JCD can improve constipation by reducing EGC apoptosis. Our work applied a multiomics strategy to explore the therapeutic mechanism of JCD in the treatment of STC and found some interesting evidence that remains to be elucidated in more detail in the future. The JCDH group of mice exhibited a better effect, suggesting that a suitable dose needs to be further evaluated.



CONCLUSION

This work demonstrated that reduced enteric EGC apoptosis may be the critical mechanism of JCD in STC therapy. These findings call for further molecular research to facilitate the clinical application of JCD.

ARTICLE HIGHLIGHTS

Research background

Slow transit constipation (STC) is a common intestinal disorder without an effective therapeutic regimen. Ji-Chuan Decoction (JCD) is an established formula for STC. However, its pharmacological mechanism is still unclear.

Research motivation

To determine the ingredients and mechanism of JCD for STC treatment.

Research objectives

To explore the integrated regulatory pattern of JCD against STC through hyphenated techniques from metabolism, network pharmacology and molecular methods.

Research methods

STC model mice were generated by gavage of diphenoxylate for 14 d. STC mice in the low- (3.04 g/kg), medium- (6.08 g/kg) and high-dosage (12.16 g/kg) JCD groups were orally administered. The acetylcholine (ACH) level was detected by enzyme-linked immunosorbent assay. AKT expression and enteric glial cell (EGC) apoptosis were demonstrated by immunofluorescence. The differentially expressed metabolites were tested by nontargeted metabolomics. The targets and core ingredients were identified by network pharmacology.

Research results

JCD significantly promotes intestinal motility, increases colonic ACH content and reduces inflammation in STC mice. It markedly restores the misaligned metabolites, including taurine/hypotaurine, and rescues AKT expression with quercetin. Inhibition of EGC apoptosis is a potential mechanism by which JCD relieves constipation.

Research conclusions

Regulating gut metabolites and reducing EGC apoptosis in STC mice may be the key mechanism of JCD for STC treatment.

Research perspectives

Further investigation into the molecular interactions among the JCD ingredients and metabolites, intestinal microbiota and host response in STC mice is necessary.

Abstract

BACKGROUND

Data that assess maternal and infant outcomes in hepatitis C virus (HCV)-infected mothers are limited.

AIM

To investigate the frequency of complications and the associated risk factors.

METHODS

We performed a cohort study to compare pregnancy and fetal outcomes of HCV-viremic mothers with those of healthy mothers. Risk factors were analyzed with logistic regression.

RESULTS

Among 112 consecutive HCV antibody-positive mothers screened, we enrolled 79 viremic mothers. We randomly selected 115 healthy mothers from the birth

registry as the control. Compared to healthy mothers, HCV mothers had a significantly higher frequency of anemia [2.6% (3/115) *vs* 19.0% (15/79), $P < 0.001$] during pregnancy, medical conditions that required caesarian section [27.8% (32/115) *vs* 48.1% (38/79), $P = 0.004$], and nuchal cords [9.6% (11/115) *vs* 34.2% (27/79), $P < 0.001$]. In addition, the mean neonatal weight in the HCV group was significantly lower (3278.3 ± 462.0 *vs* 3105.1 ± 459.4 gms; $P = 0.006$), and the mean head circumference was smaller (33.3 ± 0.6 *vs* 33.1 ± 0.7 cm; $P = 0.03$). In a multivariate model, HCV-infected mothers were more likely to suffer anemia [adjusted odds ratio (OR): 18.1, 95% confidence interval (CI): 4.3-76.6], require caesarian sections (adjusted OR: 2.6, 95%CI: 1.4-4.9), and have nuchal cords (adjusted OR: 5.6, 95%CI: 2.4-13.0). Their neonates were also more likely to have smaller head circumferences (adjusted OR: 2.1, 95%CI: 1.1-4.3) and lower birth weights than the average (≤ 3250 gms) with an adjusted OR of 2.2 (95%CI: 1.2-4.0). The vertical transmission rate was 1% in HCV-infected mothers.

CONCLUSION

Maternal HCV infections may associate with pregnancy and obstetric complications. We demonstrated a previously unreported association between maternal HCV viremia and a smaller neonatal head circumference, suggesting fetal growth restriction.

Key Words: Hepatitis C virus viremia; Mother-to-child transmission; Pregnancy complications; Maternal health; Infant hepatitis C virus infection

Core Tip: Although hepatitis C virus (HCV) affects a significant number of pregnant women, there is limited data regarding the impact of HCV active infection on pregnancy and infant outcomes. The current cohort study compared maternal complications and fetal development of HCV mothers with detectable levels of HCV RNA with those of healthy mothers. The study demonstrates a previously unreported association between maternal HCV viremia and a smaller neonate head circumference. In addition, HCV viremia was an independent predictor for negative maternal outcomes including anemia during pregnancy, medical conditions that required caesarian section, and nuchal cords. These findings increase the need for close antenatal surveillance in HCV mothers with viremia for maternal complications and delayed fetal development.

INTRODUCTION

Hepatitis C virus (HCV) infection is a common infectious disease that affects the liver and remains a significant global health burden[1]. Although spontaneous viral clearance may occur in approximately 15% of patients who have acute HCV infection, the majority develop a chronic HCV infection. Among patients who have chronic hepatitis C, approximately 10%-15% will progress to cirrhosis within the first 20 years of infection, which eventually becomes decompensated without appropriate therapy and places them at high risk of developing liver cancer[2]. The prevalence of antibodies to HCV (HCV-Ab) in pregnant women is 0.1% to 2.4%, although it is much higher in some endemic areas[3]. The proportion of pregnant women with HCV-Ab positivity and active infection with viremia is approximately 60% to 70%[3].

Globally, up to 8% of pregnant women are infected with HCV in highly endemic areas[4]. In the United States, surveillance published in 2017 revealed a nationwide increase in HCV infection among pregnant women, which is an increasing but potentially modifiable threat to maternal and child health [5]. The proportion of infants born to HCV-infected women is also increasing in the United States[6]. It has been reported that vertical transmission is the most common mechanism of HCV infection in children, occurring in approximately 6% of infants born to women with HCV infection[7]. The risk of HCV vertical transmission increases if the maternal serum HCV viral load is above 10^5 copies/mL[8,9]. In addition, published studies have suggested that vertical transmission encompasses several potential transmission routes from an infected woman to her newborn, including intrauterine, intrapartum, and postnatal routes[10-13]. According to the American Association for the Study of Liver Diseases

guidelines, all pregnant women should be tested for HCV infections, ideally at the time of initiation of prenatal care[14].

Although HCV affects a significant number of pregnant women, there are limited data regarding the impact of HCV active infection on pregnancy and infant outcomes. Prior studies of HCV and pregnancy have focused on the vertical transmission rates of HCV infection using limited assessments of the effects of chronic HCV infections on maternal health, complications during delivery, and fetal complications [15]. Therefore, there are data gaps in supporting strategies for the clinical management of mothers with HCV infections during pregnancy. Additionally, the identification of adverse consequences could improve current perinatal care and monitoring recommendations. With that in mind, we conducted a retrospective cohort study to compare the frequency and severity of adverse maternal outcomes during pregnancy, as well as fetal and infant outcomes, between mothers with HCV viremia and healthy mothers.

MATERIALS AND METHODS

Study design, setting, and patient selection

This is a single-center retrospective observational cohort study conducted at a tertiary referral university hospital located in Shijiazhuang city of Hebei province in China, which receives referrals from different levels of community medical clinics and health facilities in the city. The study site mainly included mothers with infectious diseases, including hepatitis B, hepatitis C, and human immunodeficiency virus (HIV). The Institutional Review Board approved the study, and the need for informed consent was waived. Local standards of care for prenatal care include regular clinic visits approximately every 4 to 6 wk during pregnancy for mothers who are infected with chronic viral hepatitis. Mothers received a symptom-directed physical exam, blood tests, and ultrasonography exams from the early second trimester to delivery. Viral hepatitis and HIV screening were performed at the first prenatal visit (often during the first or early second trimester), and hospital delivery was mandated in the entire province except in an emergency event.

In the current study, patients who attended the services in the prenatal care clinic from November 1, 2011 to May 31, 2020 were screened for eligibility. Adult patients (age > 18 years old) who had a diagnosis of HCV-Ab positivity for at least six months and detectable levels of HCV RNA (> 15 IU/mL) during prenatal screening were eligible for enrollment. Major exclusion criteria were the following: Coinfection with hepatitis B virus, hepatitis D virus, or HIV; current or history of intravenous drug use or sexually transmitted diseases; liver cancer; autoimmune liver disease; primary biliary cirrhosis; and alcohol-related liver diseases (consumption of more than 20 g/day of alcohol for > 5 years). Patients with other liver diseases, including inherited liver diseases and drug-induced liver injury, were also excluded. For each patient included in the HCV group, a healthy mother was identified and selected from the Delivery Suite Registry at random. The selection was based on their infants' date of birth (± 30 d) matched to those of the HCV mothers with similar baseline values (matched for gestational days and parity). Based on the ratio of approximately 1:1 to match the number of subjects enrolled in the HCV group, a similar number of subjects was included in the healthy mother group. All patients included in the study were not smoking, drinking alcohol, or using any recreational drugs since these variables may affect the infants' outcomes.

Laboratory measurements for subjects in the study were all performed by the central laboratory in the medical center. HCV-Ab was tested by a chemiluminescent microparticle immunoassay (Autobio, Zhengzhou, China). Serum HCV RNA levels were measured with the real-time quantitative polymerase chain reaction method by using the Cobas TaqMan polymerase chain reaction assay according to the laboratory manuals (Roche Diagnostics, United States). An undetectable level was defined as below the lowest level of quantitation = 15 IU/mL. The comprehensive chemistry panel was tested using a HITACHI 7600 fully automatic biochemical analyzer, with the ULN of alanine aminotransferase (ALT) set at 40 U/L (Wako Pure Chemical Industries, Ltd. Japan).

Patient data collection and outcome assessment

Using an electronic medical record system and paper charts, we collected the following maternal data: Patients' demographic information and pertinent clinical data, including a history of liver disease or hepatocellular carcinoma, pregnancy or obstetric complications; medication lists; positive physical findings, including pelvimetry, labor outcomes, and modes of delivery; laboratory results of completed blood count, coagulation tests, chemistry panels with ALT, and virological tests; and imaging results if available. Pertinent data were assessed at all visits starting from gestational week 12 with a four-week interval before delivery, at delivery, and at postpartum weeks 12, 24, and 36. Perinatal information for fetal development, including birth weight, height, Apgar scores, gestational age, and perinatal complications such as birth trauma and neonatal jaundice, was extracted from the neonatal records. Infant outcomes, such as intrauterine growth restriction, birth defects, macrosomia, low birth weight, and meconium staining stool, were collected.

The primary assessment was to analyze the frequency of maternal complications (both pregnancy and obstetrics complications) and negative fetal outcomes in HCV-infected mothers with viremia *vs* those in healthy mothers. In addition, vertical transmission rates were analyzed among mothers with HCV infection. Secondary assessments were the association between demographic or clinical features and negative maternal or fetal outcomes in a multivariable logistic regression analysis. The current study used the following criteria to define the vertical transmission of HCV and considered the transmission confirmed if any of the following occurred: (1) Detection of HCV RNA in an infant who is 3 to 6 months old; (2) Detection of HCV RNA in the infant on at least 2 occasions; (3) Finding elevated serum aminotransferase levels in an HCV-Ab positive child (ULN = 40 U/mL); or (4) Confirming an identical viral genotype between mother and child[3].

Statistical analysis

Data analyses were performed using the Statistical Package for Social Science for Windows, Version 25.0 (SPSS Inc., IBM, New York, United States). Frequencies and percentages were used to summarize the categorical variables. Fisher's exact tests or chi-squared tests were used when comparing data between and within groups. Depending on the underlying distribution of the data, descriptive values are expressed as the means ± SD or medians and interquartile ranges. The student's t-test was used to assess continuous variables between groups. The maternal outcomes or infant outcomes were calculated *per* pregnant mother and/or *per* infant when appropriate. The baseline demographic or characteristic variables were analyzed as independent variables, whereas the negative maternal or infant outcomes were considered dependent variables. Risk factors identified from the univariate analysis (P value < 0.05) were further analyzed in the multivariate logistic regression model. The aforementioned risk factors associated with negative outcomes are presented with crude and adjusted odds ratios (ORs) with 95% confidence intervals (CIs). All tests were two-tailed with a 95%CI, and a P value < 0.05 was considered significant.

RESULTS

Patient characteristics

Among the 122 consecutive HCV antibody-positive pregnant women screened, 30 were not eligible due to undetectable levels of HCV RNA throughout the pregnancy. In addition, 13 patients were excluded because they were coinfected with HIV (n = 6) or hepatitis B virus (n = 7). As a result, seventy-nine patients who had HCV viremia during pregnancy were eligible for the HCV group. In addition, 115 healthy mothers were identified and selected from the Delivery Suite Registry at random (delivery date ± 30 d matched to those cases in the HCV-infected group with similar baseline variables). As a result, our cohort consisted of 194 pregnant women with 79 and 115 mothers in the HCV group and a healthy mother (noninfected) group, respectively. The patient selection process is shown in Figure 1. All patients in the HCV group had no clinical indicator for liver decompensation. The clinical characteristics of the study patients are presented in Table 1. The demographic characteristics were well matched between the two groups in the majority of variables, including pre-pregnancy mean BMI, the number of parities or pluralities, mean gestational days, and mean ALT at delivery. However, mothers in the healthy group had a significantly older mean age (29.4 ± 4.9 *vs* 25.8 ± 4.7 years, P < 0.001), a low frequency of intertuberous diameter < 8.5 cm (29.6% *vs* 48.1%, P = 0.009) and were taller (160.9 ± 4.0 *vs* 159.6 ± 3.8 cm, P < 0.001) than those in the HCV group.

Maternal outcomes

Data from gestational week 12 to delivery about pregnancy or obstetric complications and maternal laboratory abnormalities were analyzed. The following pregnancy and obstetric complications were identified in both groups (Table 2): Preterm labor, preeclampsia, eclampsia, gestational hypertension, anemia, abnormal renal or thyroid function, oligohydramnios, gestational diabetes, nuchal cord, umbilical cord prolapses, postpartum hemorrhage, premature rupture of membranes, and cesarean section due to medical needs. When comparing the aforementioned outcomes or laboratory abnormalities between the HCV-infected and healthy individuals, a significantly higher frequency of anemia during pregnancy was observed in the HCV group [19.0% (15/79) *vs* 2.6% (3/115), P < 0.001]. In addition, a significantly higher frequency of nuchal cords [34.2% (27/79) *vs* 9.6% (11/115); P < 0.001] and cesarean sections due to medical needs [48.1% (38/79) *vs* 27.8% (32/115); P = 0.004] was reported in the HCV group. The frequencies of other pregnancy or obstetric complications did not differ between the two groups (Table 2).

Fetal and infant outcomes

When comparing the fetal and infant outcomes between the HCV-infected and healthy mother groups (Table 3), we observed a significantly lower mean ± SD body weight in neonates who were born to HCV-infected mothers (3105.1 ± 459.4 *vs* 3278.3 ± 462.0 gms; P = 0.006). However, the frequency of low

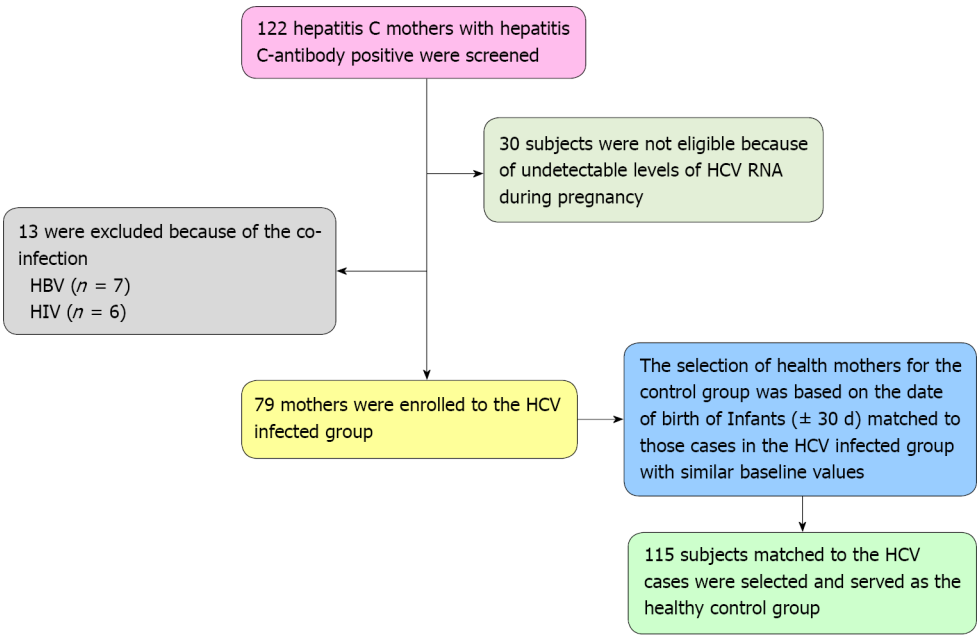
Anemia during pregnancy	15/79 (19.0)	3/115 (2.6)	< 0.001
Obstetric complications			
Rates of cesarean section[1]	38/79 (48.1)	32/115 (27.8)	0.004
Nuchal cord	27/79 (34.2)	11/115 (9.6)	< 0.001
Umbilical cord prolapses	1/79 (1.3)	0/115 (0.0)	0.41
Postpartum hemorrhage	1/79 (1.3)	0/115 (0.0)	0.41
Premature rupture of membranes	3/79 (3.8)	4/115 (3.5)	> 0.99

[1]The rates of cesarean section were calculated based on the number of cases performed due to medical needs. Patients who requested a cesarean section without medical indications were not included.

Among infants who were born to HCV-infected mothers, all were tested HCV-Ab positive at birth, and one had a detectable level of HCV RNA (2165 IU/mL). All infants in the study cohort were breastfed. Their HCV-Ab became negative beyond six months, except for the one who had HCV viremia at birth. This infant continued to have HCV antibodies and detectable levels of HCV RNA measured at the ages of three months and nine months, meeting the criteria of chronic hepatitis C infection. The HCV transmission rate in our study was 1.3% (n = 1/79). In the review of maternal characteristics, the mother was 25 years old with a maternal HCV RNA level of 2.58 × 5 Log_{10} IU/mL at delivery. She had a history of blood transfusion and was diagnosed with chronic HCV infection during prenatal screening. Her pregnancy was uneventful, with normal levels of ALT throughout the entire pregnancy. She delivered a girl with normal physical development at gestational week 39 plus 5 d.

Risk factors associated with negative outcomes

When comparing the pregnancy and obstetric complications between the two groups, we found that a significantly higher frequency of anemia, nuchal cord, and cesarean section due to medical needs occurred among HCV-infected mothers. The crude and adjusted ORs with 95%CIs of each risk factor are presented in Table 4. The analyses indicated that HCV infection was the only factor associated with anemia (adjusted OR: 18.1, 95%CI: 4.3-76.6), increased numbers of C sections due to medical needs (adjusted OR: 2.6, 95%CI: 1.4-4.9), and nuchal cords during pregnancies (adjusted OR: 5.6, 95%CI: 2.4-13.0). Since a significantly smaller head circumference and lower mean birth weight were the only two negative fetal outcomes identified in infants from HCV-infected mothers, we analyzed the maternal risk factors (Table 5) and found that maternal HCV infection was associated with these negative outcomes. The adjusted ORs of maternal HCV infection associated with a smaller head circumference and birth weight ≤ 3250 gms were 2.1 (95%CI: 1.1-4.3) and 2.2 (95%CI: 1.2-4.0), respectively.



DISCUSSION

Although HCV vertical transmission can occur in up to 5.8% of mother-infant pairs[16], many children can clear HCV infection spontaneously[17]. The disease can also be cured with oral antiviral therapy starting at the age of 3[17]. Therefore, the clinical landscape of managing HCV-infected mothers has recently shifted from addressing HCV vertical transmission to the assessment and management of negative pregnancy or neonatal outcomes. Published studies have linked several negative pregnancy outcomes to maternal HCV infection, including intrahepatic cholestasis[18-20], gestational diabetes[21-

Figure 1 Flow Chart for patients enrolled in the study. Data analyses included 194 patients. Among the 122 patients with hepatitis C antibody positive evaluated, 79 were eligible and enrolled. A control group with healthy uninfected patients (*n* = 115) was selected to match the infected patients. Patients were divided into two groups: a hepatitis C patient group and a healthy control group comparison. HCV: Hepatitis C virus; HBV: Hepatitis B virus; HIV: Human immunodeficiency virus.

23], the premature rupture of the membranes[24,25], the requirement for cesarean delivery[24,25], preterm delivery[23], small for gestational age[26], and low birth weight[26]. However, its effect on restriction or disturbance of intrauterine fetal growth remains inconclusive[21,23,26-28].

Our study assessed both maternal and fetal outcomes in viremic mothers with HCV infections. To our knowledge, this is the first study from China to assess pregnancy outcomes in HCV viremic mothers. We found that HCV might be associated with a higher frequency of nuchal cords and a smaller neonatal

[1]Case/exposed: The case refers to the number of patients who presented with the specified variable and the Exposed refers to the total number of patients in the entire study cohort.
[2]The rates of cesarean section were calculated based on the number of cases performed due to medical needs. Patients who requested a cesarean section without medical indications were not included.
BMI: Body mass index; OR: Odds ratio; HCV: Hepatitis C virus.

head circumference, which has not been reported in the literature before. We also found that HCV viremia was linked to pregnancy anemia, cesarean sections due to medical needs, and low gestational weight in neonates. In addition, we observed that lower birth weight was associated with maternal infection, which was consistent with published data from the United States and Europe[23,26]. In the context of all infants in our study being breastfed, the HCV vertical transmission rate was 1.27%, which was within the range (0.2%-6%) of the already published studies[16,29].

Early studies by Jaffery *et al*[30] and Bohman *et al*[31] found that fetal outcomes did not differ between HCV-positive mothers and healthy controls[30,31]. However, in a study by Salemi *et al*[29], the risk of an adverse neurological outcome was higher in infants born to HCV mothers, including feeding difficulties (OR: 1.32, 95%CI: 1.06-1.64) and neonatal seizures (OR: 1.74, 95%CI: 0.98-3.10)[29]. The aforementioned studies have limitations of lacking a well-defined study population because the diagnosis of HCV was based on the HCV antibody, and HCV RNA was not always tested. Paternoster *et al*[24] observed that intrahepatic cholestasis was more common in HCV-RNA-positive mothers than in HCV-RNA-negative mothers, suggesting that HCV viremia may lead to different outcomes[19]. In addition, cofounders such as intravenous drug use or sexually transmitted diseases may not be adjusted in studies based on pregnancy registries[26,32]. These factors could contribute to the discrepancies among the study findings. In the context of the paucity of data and infrequency of fetal negative events, Huang *et al*[33] performed a meta-analysis and found that low birth weight was linked to maternal HCV infection (OR: 1.97, 95%CI: 1.43-2.71)[33].

In our study, birth weight ≤ 3250 gms was associated with HCV exposure. There was also a trend of HCV-exposed neonates with a birth weight of < 2500 gms. More importantly, our cohort demonstrates a previously unreported association between maternal HCV viremia and a smaller neonatal head circumference. Our findings provide new evidence supporting the intrauterine restriction of fetal growth in a well-defined HCV population, which enrolled only HCV-infected mothers with detectable levels of HCV RNA who had no history of intravenous drug use or sexually transmitted diseases.

Although the mechanism of fetal growth restriction is not fully understood, several studies have suggested that HCV-induced inflammation in the placenta may cause fetal development restriction. In an *in vitro* study, HCV infected a human cytotrophoblast and changed its ultrastructure dramatically upon infection[33]. In addition, Hurtado *et al*[34] observed that the cytotoxicity of natural killer cells and natural killer T cells was enhanced in the placenta, and placental natural killer T-cell cytotoxicity was further increased by HCV infections[34]. Several population-based retrospective cohort studies reported higher rates of gestational diabetes in HCV-infected mothers than in noninfected mothers[35,36], but the association was limited to women with excessive weight gain during pregnancy. Our study did not show such complications, which is likely because our patients are Asians with a much lower body mass index than those in other studies[21,24,26].

In this cohort study, some limitations should be addressed. Being a single-center retrospective design, this study has a limited capacity when adjusting or balancing all covariates between the HCV-exposed and HCV nonexposed groups. Additionally, we did not have HCV genotype data. However, published studies in China indicated that the majority of Chinese patients with HCV had genotype 1[36]. Second, cohort data about HCV antibody-positive but nonviremic mothers are limited: These mothers were not enrolled in our study due to the small number of patients in our center ($n = 30$, Figure 1). Further studies in this subgroup will add to the understanding of pregnancy outcomes. Third, the liver fibrosis stages for patients with HCV infection were not assessed in this study, although all patients had no clinical indications of liver decompensation. Therefore, future studies might be needed to investigate whether HCV-infected patients with advanced fibrosis have negative maternal and fetal outcomes. Last, the frequency of negative events in HCV-infected mothers could be underestimated due to the maternal mean age being younger than that of healthy mothers.

CONCLUSION

In conclusion, our study demonstrates a previously unreported association between maternal HCV viremia and a smaller neonatal head circumference. Given our new findings on the intrauterine restriction of fetal growth from HCV exposure, screening all mothers during pregnancy for HCV should be a mandatory practice. More importantly, our findings indicate a need for close antenatal surveillance for maternal complications and delayed fetal development in HCV mothers with viremia. Last, our data support that preconception health management should include HCV screening, so HCV infection can be treated before pregnancy to improve the health of both the mothers and infants.

ARTICLE HIGHLIGHTS

Research background

Hepatitis C virus (HCV) infection remains a significant global health burden, and there is a high proportion of women with antibodies to HCV positive whose active infection with viremia. In addition, HCV infection among pregnant women is an increasing but potentially modifiable threat to maternal and child health.

Research motivation

Although HCV affects a significant number of pregnant women, there is limited data regarding the impact of HCV active infection on pregnancy and infant outcomes. Therefore, there are data gaps in supporting strategies for clinical management of mothers with HCV infections during pregnancy.

Research objectives

We conducted a retrospective cohort study to compare the frequency and severity of adverse maternal outcomes during pregnancy, as well as fetal and infant outcomes between mothers with HCV viremia and healthy mothers.

Research methods

A retrospective observational cohort study was conducted to compare pregnancy and fetal outcomes of HCV-viremic mothers with those of healthy mothers. After HCV mothers with viremia and healthy mothers were enrolled, we collected their demographic information and pertinent clinical data using an electronic medical record system and paper charts. Perinatal information for fetal development and infant outcomes were extracted from the neonatal records. Data analyses were performed using the Statistical Package for Social Science for Windows, Version 25.0 (SPSS Inc., IBM, New York, United States).

Research results

Our study enrolled 79 viremic mothers and 115 healthy mothers. Compared to healthy mothers, HCV mothers had a significantly higher frequency of anemia, caesarian section, and nuchal cords during pregnancy. In addition, the mean neonatal weight and head circumference in the HCV group was significantly lower. In a multivariate model, similar results were found.

Research conclusions

Our study demonstrates the association between maternal HCV viremia and a smaller neonate head circumference. We also confirmed the high frequency of pregnancy and obstetric complications in HCV viremic mothers.

Research perspectives

Multi-center and large sample studies are needed to verify these results in the future and to investigate if HCV-infected patients with advanced fibrosis have negative maternal and fetal outcomes.

ACKNOWLEDGEMENTS

We thank the medical staff in the Department of Obstetrics and Gynecology, The Fifth Hospital of Shijiazhuang, for their support and assistance during our study. We also like to thank Mr. Andrew Park (Northern Valley Regional High School at Old Tappan, United States) for proofreading the manuscript.

FOOTNOTES

Author contributions: Pan CQ provided the concept and designed the study, wrote the manuscript, communicated with the journal, and addressed comments from reviewers; Dai EH and Zhu BS obtained the funding and supervised the study; Pan CQ, Zhang XH, and Dai EH performed data analyses; All other authors contributed to the data collection.

Supported by The Ministry of Science and Technology of China for the National Five-Year Key Projects in Infectious Diseases, No. 2015ZX10004801.

Institutional review board statement: The study was reviewed and approved by the Institutional Review Board of the Fifth Hospital of Shijiazhuang in China.

Informed consent statement: The informed consent was waived.

Conflict-of-interest statement: Dr. Pan received grants from Gilead. He also serves as a speaker for Gilead and Abbvie. Other authors have nothing to be disclosed.

Data sharing statement: The authors agree to share anonymized Individual Patient Data (IPD) upon request or as required by law and/or regulation with qualified external researchers. Approval of such requests is at the authors' discretion and is dependent on the nature of the request, the merit of the research proposed, the availability of the data, and the intended use of the data. Data requests should be sent to Erhei Dai MD at email: daieh2008@126.com

STROBE statement: The authors have read the STROBE Statement—checklist of items, and the manuscript was prepared and revised according to the STROBE Statement—checklist of items.

Open-Access: This article is an open-access article that was selected by an in-house editor and fully peer-reviewed by external reviewers. It is distributed in accordance with the Creative Commons Attribution NonCommercial (CC BY-NC 4.0) license, which permits others to distribute, remix, adapt, build upon this work non-commercially, and license their derivative works on different terms, provided the original work is properly cited and the use is non-commercial. Abstract

BACKGROUND

Severe alcoholic hepatitis (AH) is one of the most lethal manifestations of alcohol-associated liver disease. In light of the increase in alcohol consumption worldwide, the incidence of AH is on the rise, and data examining the trends of AH admission is needed.

AIM

To examine inpatient admission trends secondary to AH, along with their clinical outcomes and epidemiological characteristics.

METHODS

The National Inpatient Sample (NIS) database was utilized, and data from 2011 to 2017 were reviewed. We included individuals aged ≥ 21 years who were admitted with a primary or secondary diagnosis of AH using the International Classification of Diseases (ICD)-9 and its correspondent ICD-10 codes. Hepatitis not related to alcohol was excluded. The national estimates of inpatient admissions were obtained using sample weights provided by the NIS.

RESULTS

AH-related hospitalization demonstrated a significant increase in the USA from 281506 (0.7% of the total admission in 2011) to 324050 (0.9% of the total admi-ssion

in 2017). The median age was 54 years. The most common age group was 45–65 years (range 57.8%–60.7%). The most common race was white (63.2%–66.4%), and patients were predominantly male (69.7%–71.2%). The primary healthcare payers were Medicare (29.4%–30.7%) and Medicaid (21.5%–32.5%). The most common geographical location was the Southern USA (33.6%–34.4%). Most patients were admitted to a tertiary care center (50.2%–62.3%) located in urban areas. Mortality of AH in this inpatient sample was 5.3% in 2011 and 5.5% in 2017. The most common mortality-associated risk factors were acute renal failure (59.6%–72.1%) and gastrointestinal hemorrhage (17.2%–20.3%). The total charges were noted to range between $25242.62 and $34874.50.

CONCLUSION

The number of AH inpatient hospitalizations significantly increased from 2011 to 2017. This could have a substantial financial impact with increasing healthcare costs and utilization. AH-mortality remained the same.

Key Words: Alcoholic hepatitis; Cirrhosis; Fatty liver disease; Alcohol abuse

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core tip: This study demonstrated a significant increase in the number of hospitalizations due to alcoholic-associated hepatitis (AH) throughout the USA, with an overall increase in the cost and financial burden of the disease. These trends were in line with the increase in the incidence of alcohol misuse across the years. This study provides potential data for future prospective research to help trigger more aggressive screening and prevention methods for alcohol abuse to prevent AH. Additionally, there is a need for the development of novel therapeutic agents targeting the disease since AH treatment is limited.

INTRODUCTION

Alcohol-associated liver disease (ALD) comprises a spectrum of liver diseases ranging from reversible fatty liver to severe alcohol-associated hepatitis (AH) and cirrhosis, to acute-on-chronic liver failure[1]. All manifestations of ALD may overlap and can develop after heavy alcohol consumption for at least 6 mo[2]. AH is a clinical syndrome with acute onset jaundice in the presence of heavy alcohol misuse[2]. Mild AH patients with alcohol abstinence can have a good outcome. However, those with severe disease defined by Maddrey's discriminant function ≥ 32, or model for end-stage liver disease score ≥ 20, have a high 30-d mortality rate[1]. ALD is one of the leading causes of cirrhosis and it is the second leading indication for liver transplantation in the USA according to the Scientific Registry of Transplant Recipients data[3]. Alcohol consumption continues to be on the rise, with global data extrapolated from the World Health Organization showing the average annual per capita alcohol consumption has risen from 5.5 L in 2005 to 6.4 L in 2018[4]. Consequently, global alcohol-attributable mortality in 2016 has increased to 38.8 per 100000 people and 1759 disability-adjusted life-years per 100000 people[4]. According to a study from Denmark, during the study period (1999–2008), the annual incidence rate of AH was reported to increase for both men and women from 37 to 46 per 100000 and from 24 to 34 per 100 000, respectively[5]. The 5-year overall mortality in this study was found to be 56% and was significantly higher in patients with cirrhosis compared to patients without cirrhosis (69% *vs* 47%, respectively)[5]. In the USA, a study evaluating the United States National Inpatient Sample (NIS) database showed that out of 325 000 hospital admissions in 2010, 0.8% were AH-related[6]. With the availability of highly effective direct-acting antivirals therapy for chronic hepatitis C, the burden of chronic liver disease (CLD) is shifting towards ALD and non-ALD[7,8]. Studies have demonstrated that there is an increasing trend in consuming alcohol in the USA[9-12], with the initiation of alcohol at younger ages[13-15], and binging representing the most frequent pattern of alcohol consumption[16]. As a consequence of this upward trend in alcohol use disorder, it is anticipated that the correlating rise in ALD will have significant health, social and economic burdens accredited to the increase in hospitalization rate, as well as the elevated support required for these patients in an outpatient setting[8].

According to the 2007 NIS database, a significant healthcare cost and use of resources were reported [17]. Another study using the NIS database from 2012 to 2016, reported a higher admissions rate for CLD with a 26.2% increase in hospitalization costs and an $18.8 billion economic burden in 2016[18]. Despite the advances in medicine, the currently available therapeutics for severe AH are scarce and only limited to corticosteroids, which contributes to the high mortality of this disease[1].

Given the increased prevalence of alcohol misuse in the USA, this study aimed to provide a relatively recent descriptive analysis of trends in AH hospitalization within the USA. Data were obtained using the NIS database from 2011 to 2017.

MATERIALS AND METHODS

Data source

The Healthcare Cost and Utilization Project (HCUP) is a collection of databases and contains the NIS database[19]. The NIS is the largest publicly available inpatient database that encompasses a range of different data encoded by International Classification of Diseases (ICD) codes from more than 1000 hospitals, constituting a 20% sample data of all US hospitals. The database enables data extraction on a broad range of health conditions and specific populations, including cost and quality of health services, medical practice patterns, and outcomes of treatments on a national level.

Study design and study population

This was a retrospective analysis. All subjects in the database ≥ 21 years old who were hospitalized with a discharge diagnosis of AH from 2011 to 2017 were included. To minimize ascertainment bias, we classified hospitalization as AH-related if it was associated with a primary admission diagnosis of AH or a primary discharge diagnosis. A secondary AH-related hospitalization was classified as having the AH diagnosis anywhere in the admission diagnosis (25 diagnoses) or anywhere in the discharge diagnoses. We excluded all non-alcohol-related hepatitis diagnoses using ICD-9 and ICD-10. This included autoimmune hepatitis, acute and chronic viral hepatitis A–E, and nonalcoholic steatohepatitis. All data were weighted using discharge level values, to produce an accurate estimate of the patient population nationwide. AH-related hospitalization was identified by ICD-9 and ICD-10 discharge diagnosis codes. The ICD codes included were alcohol-associated hepatitis, alcoholic fatty liver disease, and alcohol-associated cirrhosis (Table 1). Previous validation studies have shown that the discharge diagnosis captures the cause of hospitalization accurately, such as in primary biliary cholangitis[20], coronary artery disease[21], and hepatitis B and C[11]. Other outcomes examined were inpatient mortality. We identified known risk factors related to mortality in patients with the following: acute renal failure (ARF), gastrointestinal bleeding, and sepsis (Table 2). Patient age, sex, household income, race, and geographic region (Northeast, Midwest, South and West) were obtained. The primary payer for the hospitalization was categorized as Medicare, Medicaid, private insurance, self-pay, or others. The types of hospitals were categorized into teaching, non-teaching community, and rural hospitals. Hospitalization characteristics were presented separately where the primary reason for hospitalization was AH *versus* AH presenting as a secondary condition. These characteristics included in-hospital mortality, length of stay, and discharge disposition.

Statistical analysis

Patients were first screened and selected based on the presence of an AH diagnosis. The temporal trend of the AH-related hospitalization was tested by Cochran–Armitage test. The patient demographics, additional clinical characteristics, and clinical outcome measures were then summarized using the median with interquartile range for continuous variables, or frequencies with percentages for categorical variables. To compare these variables among different years, Kruskal–Wallis and χ^2 tests were used. These demographics and variables were tested against the year. Overall and between-categorical group P values were reported for categorical variables. Prevalence of AH-related diagnosis among HCUP dataset and mortality-related risk factors among AH patients who died during hospitalization in 2011–2017 were tested using the χ^2 test. A multivariable logistic model was fitted and resulting odds ratios (OR) with 95% confidence intervals were used to test for association between the risk factors and the primary outcome of in-hospital mortality, further adjusting for demographics and additional clinical characteristics. Due to the desire to have population-level interpretations, survey weights were applied to all patient-level observations as provided in the NIS database. All reported P values were two-sided, and the significance cut-off was set at 0.05. The Bonferroni adjustment was used to adjust for multiple testing in between-categorical χ^2 test and logistic regression. Data analyses were completed in SAS version 9.4 (SAS Institute Inc., Cary, NC, USA) and R studio (R version 3.6.0, R Foundation for Statistical Computing, Vienna, Austria).

Table 1 Diagnosis to be included International Classification of Diseases-9 and its correspondent International Classification of Diseases-10

ICD-9	Correspondent ICD-10
571.0 alcoholic fatty liver	K.70 alcoholic fatty liver
571.1 acute alcoholic hepatitis	K.70.11 alcoholic hepatitis with ascites
	K.70.10 alcoholic hepatitis without ascites
571.2 alcoholic cirrhosis of liver	Correspondent ICD-10 found
571.3 alcoholic liver damage, unspecified	K70.40 alcoholic hepatic failure without coma
	K70.41 alcoholic hepatic failure with coma
	K70.9 alcoholic liver disease, unspecified

ICD: International Classification of Diseases.

Table 2 Trend of alcoholic hepatitis-related hospitalization 2011 to 2017

Total admission, *n*	38590733	36484846	35597792	35358818	35769942	35675421	35798453	
AH-related admission, *n* (%)	281506 (0.7)	274365 (0.8)	278580 (0.8)	291435 (0.8)	308765 (0.9)	313235 (0.9)	324050 (0.9)	< 0.001
Admission when primary admission diagnosis is AH, *n* (%)	47140 (0.1)	45710 (0.1)	46715 (0.1)	48395 (0.1)	54955 (0.2)	66170 (0.2)	71290 (0.2)	< 0.001

AH: Alcoholic hepatitis.

RESULTS

AH-related hospitalization showed an increase from 281506 (0.7% of the total in 2011) to 324050 (0.9% of the total in 2017; $P < 0.01$) (Figure 1). This included all AH-related admissions when AH was not the primary or secondary diagnosis. There was also an increase in the number of admissions when the primary admission diagnosis was AH (47140 in 2011 to 71290 in 2017) ($P < 0.01$; Table 2).

Results from demographic observations showed that the median age of patients hospitalized with AH was 54 years. The most common age group was 45–65 years (58.4%–60.7%; $P < 0.01$); the most common race was white (63.2%–66.4%; $P < 0.01$); patients were predominantly male (69.7%–71.2%; $P < 0.01$); and the primary healthcare payers were Medicare (29.4%–30.7%; $P < 0.01$) and Medicaid (21.5%–32.5%; $P < 0.01$). The most common geographical location was the southern region of the USA (33.6%–34.4%; $P = 0.017$). Most patients were admitted to tertiary hospitals (50.2%–62.3%; $P < 0.01$) in urban areas. The most common presenting diagnosis was AH (63.5%–69%; $P < 0.01$). The most common outcome was routine discharge (60%–63.3%; $P < 0.01$). The median length of stay was 5.98 d (SD = 7.11) in 2011 which increased to 6.14 d (SD = 7.43) in 2017 ($P < 0.01$). Total charge for hospitalized patients with AH ranged between $46507.47 (SD = 87193.29) and $63574.52 (SD = 108850.63; $P < 0.01$) (Table 3).

The mortality of AH-related hospitalizations was 5.3% in 2011 and 5.5% in 2017 ($P < 0.01$). Risk factors that could be associated with AH mortality were sepsis (increased from 7.4% in 2011 to 48.3% in 2017; $P < 0.01$), renal failure (59.6% in 2011 to 72.1% in 2018; $P < 0.01$), and gastrointestinal (GI) hemorrhage (17.2% in 2011 to 20.3% in 2017; $P = 0.048$) (Table 4). Multivariable regression analysis on death during hospitalization was performed and demonstrated higher odds of mortality in the following group: age > 65 years (OR 3.55; $P < 0.0001$), female (OR 1.13; $P < 0.0001$), large academic hospital (OR 1.3; $P < 0.0001$), sepsis (OR 3.33; $P < 0.0001$), GI hemorrhage (OR 2.31; $P < 0.0001$), and ARF (OR 7.19; $P < 0.0001$) (Table 5).

DISCUSSION

ALD is a spectrum of diseases ranging from hepatic steatosis to fibrosis and eventually cirrhosis, with continued alcohol use[22]. Alcohol consumption has been on the rise in the USA. Previously, a large survey conducted by the National Epidemiologic Survey showed a prevalence of alcohol use over any 12-mo period to rise from 65% to 72%, with an overall increase in alcohol consumption between 2001

Table 3 Summary statistics of demographic of hospitalized alcoholic hepatitis patients, 2011 to 2017

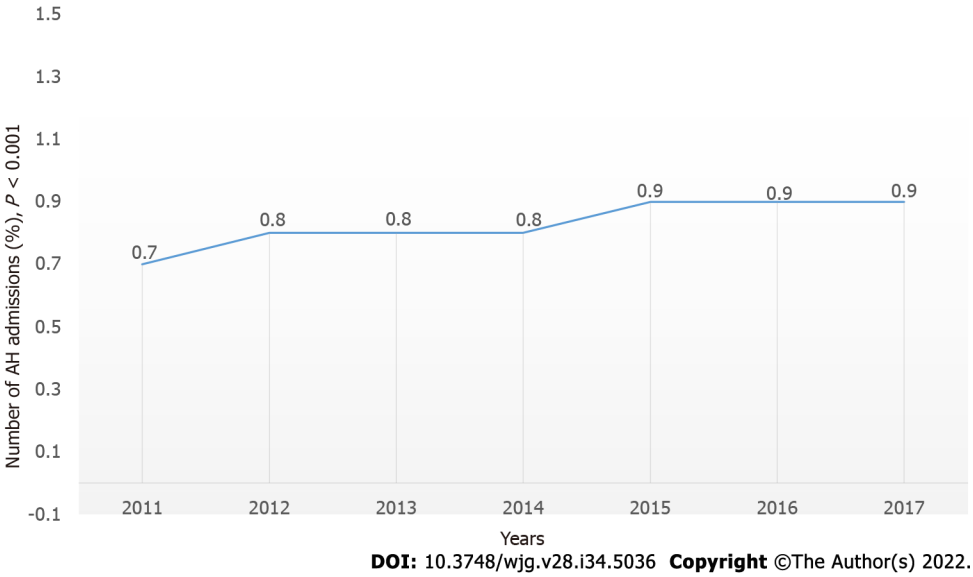
GI: Gastrointestinal.

and 2012[23].



Our study included all AH-related admissions from 2011 to 2017 in the NIS database. Out of the 38.5 million admissions in 2011, about 281 506 (0.7%) were due to AH. This number increased to 324050 (0.9%) out of 35.7 million admissions in 2017 ($P < 0.001$; Figure 1). Moreover, the number of admissions due to a primary diagnosis of AH increased by almost 1.5 times between 2011 and 2017 from 47140 (0.1%) to 71290 (0.2%) ($P < 0.001$). These are alarming figures, and they match the results of increased alcohol consumption and binge drinking in the USA[8,12]. This has major consequences as AH continues to cause significant morbidity and mortality. Additionally, we found that each AH-related admission costs on average $46000 to $63000 with an average in-hospital length of stay of 4 d per admission. About 60% of those patients had Medicare or Medicaid insurance as the primary expected payer. These increasing admissions, as reported previously, escalates the burden on the healthcare system and the public payer funded by tax dollars[24].

Figure 1 Trends in alcoholic hepatitis-related admissions from 2011 to 2017.

The increase in AH burden has a huge impact on trends of liver transplantation and consequently, organ allocation. Recent data showed that in select patients with severe AH, early liver transplantation resulted in high survival rates in the early transplant of AH at 6 mo *vs* no transplant (77% *vs* 23%)[25, 26]. Based on these results, many liver transplant centers around the USA are performing liver transplants for select severe AH patients. Consequently, this has resulted in ALD surpassing chronic hepatitis C virus infection as the leading indication for liver transplantation[27].

Our study showed that the majority of AH hospitalized individuals were middle-aged white men. This is not surprising, as more men consume alcohol above the recommended safety levels compared to women[24]; although women are more susceptible to developing AH within a shorter period and less exposure to alcohol compared to men[28].

We observed that the mortality of hospitalized patients with AH was about 5%, which has remained similar from 2011 to 2017. We also examined some of the major mortality-related risk factors among AH patients who expired during hospitalization. ARF was the most common finding in these patients and increased from 59.6% in 2011 to 72% in 2017. A possible explanation of these results may include the lack of therapy for severe AH with ARF since the benefit of steroids is unknown in this patient population as the steroids or pentoxifylline for AH trial excluded patients with ARF defined as creatinine > 5.7 mg/dL[29]. In addition, hepatorenal syndrome is associated with high mortality, which could be as high as 80% at 2 wk[30]. Sepsis and GI bleeding were also noted as mortality-risk factors in almost 48% and 19%, respectively, in patients who died from AH in 2017. Sepsis had a significant increase from 7.4% in 2014 to 46.7% in 2016 and 48.3% in 2017. This likely resulted from implementing the conversion of ICD-9 to ICD-10 on October 1, 2015. Sepsis is coded for by one code in ICD-9 (995.91), in contrast, there are 26 codes for different types of sepsis in ICD-10, which could potentially explain the sharp rise in sepsis rate. Additionally, AH patients usually present with fever and leukocytosis meeting Systemic Inflammatory Response Syndrome, criteria leading clinicians to code for sepsis even without an active infection present.

A regression analysis was performed that showed that advanced age, female gender, ARF, sepsis and GI bleeding were the most prominent risk factors. These mortality risk factors do not establish causality, since there is no etiology of death in the NIS database. Moreover, there is no information as to whether these risk factors were resolved or not during hospitalization since it was captured by the ICD codes used.

One limitation of this study was the accuracy of the NIS database in capturing ICD-9 and ICD-10 codes. For instance, some AH-related admissions could have been reported as jaundice or hepatic failure, which would exclude those patients from our analysis. There was also no information regarding the outcomes of AH patients once they were discharged. This has resulted in a lower in-hospital mortality rate (about 5%) compared to the established high 30-d mortality of AH patients (30%–50%) [31]. The mortality rate in our study is the percentage of patients who died while hospitalized only.

CONCLUSION

We observed that AH-related hospitalization continued to increase during the study period. This could have a substantial impact on increasing healthcare costs and utilization among patients hospitalized for AH. Mortality remained the same throughout the study period. These findings are alarming and should trigger more aggressive screening and prevention of alcohol abuse to prevent the increasing cases of AH and its consequences.

ARTICLE HIGHLIGHTS

Research background

Alcoholic hepatitis (AH) is a significant healthcare issue with rising alcohol use in the USA. Alcohol-associated liver disease is the second leading indication for liver transplantation after surpassing chronic hepatitis C infection.

Research motivation

With increasing alcohol consumption there is a need to measure the magnitude of AH effects.

Research objectives

The study aimed to examine the trends in hospitalization of AH patients across the USA. The second aim was to look at the mortality of hospitalized patients, along with the risk factors associated with death while hospitalized.

Research methods

Data were extracted from National Inpatient Sample database using discharge diagnosis codes of International Classification of Diseases (ICD)-9 and their corresponding ICD-10. We included hospitalization for the years from 2011 to 2017.

Research results

AH inpatient hospitalization increased from 0.7% of total admissions to 0.9% of total admissions. Mortality for admitted patients remained the same.

Research conclusions

There has been an increase in AH hospitalization that could affect the healthcare system. Acute renal failure, sepsis and gastrointestinal hemorrhage are highly associated with increased mortality in AH patients.

Research perspectives

New studies should focus on finding new therapeutic targets of AH. New studies should look for improved strategies to limit alcohol misuse.

Abstract

BACKGROUND

Solid pseudopapillary tumor (SPT) is a rare pancreatic tumor. Considering its malignant behaviors, SPT has been classified as a low-grade malignant tumor. Indeed, only 9.2% of all SPT patients are initially diagnosed as malignant with invasion or metastasis. Thus, one of the challenges in managing SPT patients is predicting malignant behavior.

AIM

To investigate the malignant behavior and tumor-associated macrophage (TAM) infiltration between different histopathologic features of SPT patients.

METHODS

Twenty-five formalin-fixed paraffin-embedded tissue samples from 22 patients pathologically diagnosed with an SPT between 2009 and 2019 at West China Hospital were included in this retrospective study. Integrity of the capsule and growth pattern of the tumor cells was assessed microscopically in hematoxylin-eosin (HE)-stained sections. Based on the histopathological features, the SPT patients were divided into two groups: capsule or invasion. Clinical features, malignant behavior, and TAM infiltration were compared between the two groups.

RESULTS

Among the 22 SPT patients, 11 were identified for each group, having either a capsule or invasion histopathologic feature. Malignant behavior was more frequent in the invasion group, including 2 patients who had peripheral organ

invasion, 3 with liver metastasis, and 1 with both lymph node and spleen metastases (P= 0.045). Ki-67 index of more than 3% was also more frequent in the invasion group (P = 0.045). Immunohistochemical analysis showed that the invasion group had a significant increase of CD68-positive TAMs in intratumor and peritumor sites in comparison with the capsule group (all P < 0.0001). Similarly, CD163-positive M2-like macrophages were also markedly increased in the intratumor and peritumor sites in the invasion group (all P < 0.0001). At the liver metastasis site, both intratumor and peritumor tissues showed relatively high-level CD68-positive TAMs and CD163-positive M2-like macrophages infiltration. However, the differences between the intratumor, peritumor and normal hepatic tissues did not reach statistical significance (all P > 0.05).

CONCLUSION

SPT patients with invasion evident under microscope were more likely to exhibit malignant behavior and TAM infiltration, especially M2-like macrophages. This finding can help in future investigations of the underlying mechanism of TAM-mediated SPT malignant behavior.

Key Words: Pancreatic neoplasms; Solid pseudopapillary tumors; Malignancy; Tumor-associated macrophages; Histological labeling; Immunohistochemistry

Core Tip: In the present study, we reviewed 22 solid pseudopapillary tumor (SPT) patients to investigate the malignant behavior and tumor-associated macrophage (TAM) infiltration between different histopathologic features. The results showed that invasion detected under microscope was associated with the malignant behavior and TAM infiltration. The phenomenon of increased infiltration of TAMs, especially M2-like macrophages in the invasion feature, might help us to investigate the underlying mechanism of TAM-mediated SPT malignant behavior, as well as to potentially treat recurrent and metastatic SPT by targeting TAMs.

INTRODUCTION

Solid pseudopapillary tumor (SPT) is a rare pancreatic tumor, first reported by Frantz in 1959[1]. Considering its malignant behaviors, including the invasion of peripheral organs and metastasis at diagnosis or recurrence after surgical resection, the World Health Organization (WHO) has classified SPT as a low-grade malignant tumor[2,3]. The overall prognosis of SPT patients is good, with 5-year and 10-year survival rates up to 89.5% and 86.3%, respectively[4]. Reportedly, among all SPT patients, only 9.2% are initially diagnosed as malignant with invasion or metastasis[3]. Thus, one of the challenges in managing SPT patients lies in predicting malignant behavior.

Currently, clinical features are being studied to predict the malignant behaviors of SPT. For instance, patients over 40 years of age have been found to be more likely to develop malignant SPT[5,6]. The computed tomography (CT) imaging features of multiple and geographic uptake type and progressive enhancement during the delayed phase have shown potential predictive power[6,7]. One of the most frequently mentioned predictive factors is capsule or incomplete capsule of SPT, with the latter being significantly correlated with malignancy[1,5,8-10]. However, the capsule or incomplete capsule state is primarily assessed on CT imaging. Assessment of the integrity of a capsule and growth pattern of tumor cells, especially on SPT margins under the microscope, might reflect the real biological behavior of SPT.

Macrophages that infiltrate or surround the tumor microenvironment are termed as tumor-associated macrophages (TAMs)[11]. TAMs, especially those of the M2-like macrophage subtype, could enhance tumor invasion and metastasis[12]. However, only limited studies are available regarding the role of TAMs in the SPT microenvironment and their relationship with malignant behavior of SPT. Herein, we classified SPT patients in either a capsule group or invasion group based on the integrity of capsule and growth pattern of tumor cells determined microscopically, and compared the clinical features and malignant behaviors between the two groups. Furthermore, we used immunohistochemical (IHC) staining to analyze the infiltration of TAMs, especially the M2-like macrophages, in primary SPT and

liver metastasis sites.

MATERIALS AND METHODS

Patients and tissues

Twenty-five formalin-fixed paraffin-embedded tissue samples (including 22 tumors and peritumor tissues, and 3 metastatic sites) from 22 patients pathologically diagnosed with an SPT according to WHO 2010 criteria between 2009 and 2019 at West China Hospital were included in this retrospective study. All the samples were obtained by surgery and reviewed by two expert pathologists blinded to the original data. This study was approved by the biomedical ethics committee from our hospital with written informed consent from all subjects (2014 Trial No. 37).

Data collection and definition

Based on the integrity of the capsule and growth pattern of tumor cells, especially on tumor margins, evident in hematoxylin-eosin (HE)-stained sections under a microscope, SPT patients were divided into two groups: the capsule or invasion group. The invasion feature was defined as a tumor with an incomplete fibrous capsule with tumor cells invasively present in normal pancreatic tissue, as determined microscopically. On the other hand, a capsule feature is considered when the tumor has an intact fibrous envelope (Figure 1).

The malignant behaviors of SPT at diagnosis, including deep infiltration into the surrounding tissue and lymph node or distant organ metastasis, were recorded. The Ki-67 index was measured based on a manual visual counting method[13], and 3% was chosen as the cut-off value, according to findings from a recent study[14].

Clinical data was collected, including sex, age, serum tumor marker CA19-9, CA125, carcinoembryonic antigen, and neuron-specific enolase (NSE). Tumor size (largest diameter of the tumor), tumor location (head and neck or body and tail), component of the tumor (solid and cystic or solid), capsule or incomplete capsule, and calcification were also measured based on the CT imaging data and surgical specimens.

IHC analysis

IHC staining was used to evaluate the intratumoral and peritumoral presence of TAMs (CD68-positive) and M2-like macrophages (CD163-positive), a subtype of TAM, in primary and metastasis site tissues. Five micrometer-thick sequential tissue sections were obtained from paraffin-embedded tissue samples and used for the IHC analysis as described in previous studies[15,16]. The primary antibodies used in IHC staining were antibodies against CD68 (rabbit anti-human, D4B9C, dilution 1:400; Cell Signaling Technology, Danvers, MA, United States) and CD163 (rabbit anti-human, D6U1J, dilution 1:500; Cell Signaling Technology). Anti-rabbit IgG, horseradish peroxidase-linked antibody was used as the secondary antibody. For the assessment of expression of CD68- and CD163-positive cells, the tissue sections were screened using each immunohistochemistry slide at the low power fields (× 4), and the hot spots were selected. Immune cell staining was scored by counting the number of stained immune cells in three high power fields (× 400) in the hot spots. IHC sections were independently assessed by three authors (Yang J, Chen YH, and Zhou L).

Statistical methods

All statistical analyses were carried out using Statistical Package for Social Sciences (SPSS) Version 24 (IBM Corp., Armonk, NY, United States). Categorical variables are expressed as percentages (%), and continuous variables are expressed as medians. Normality and homogeneity of the data were assessed by Shapiro–Wilk's and Levene's tests, respectively. Fisher's exact test and Mann–Whitney test were used to detect di□erences in categorical and continuous variables between groups of patients. A P value < 0.05 was considered statistically significant.

RESULTS

Patient characteristics

Among the 22 SPT patients, 11 were identified for each group based on the capsule or invasion histopathologic feature, respectively. The clinical and pathological characteristics between the capsule and invasion groups are shown in Table 1. The patients included 4 males and 18 females, ranging in age from 12 years to 65 years (median age of 35 years) and showed no difference between the two groups (P = 0.586 and P= 0.146, respectively). Only 3 patients showed CA19-9 or CA125 elevation in the invasion group. Interestingly, 2 patients in the capsule group and 5 in the invasion group showed positivity for NSE, although the difference did not reach statistical significance (P = 0.361). All 22 patients received surgical treatment, which included 4 pancreaticoduodenectomies, 10 distal pancreatectomies, 7 central

[a]1 patient had both spleen and lymph node metastasis.
CEA: Carcino-embryonic antigen; CT: Computed tomography; NSE: Neuron-specific enolase.

pancreatectomies, and 1 total pancreatectomy. All 3 patients with liver metastasis received combined segmental hepatectomy.

No difference was evident in tumor size, location, component, nor calcification between the two groups. However, compared with the capsule group, malignant behavior of SPTs was more frequent in the invasion group, including in 2 patients with peripheral organ invasion, 3 with liver metastasis, and 1 with lymph node and spleen metastases (P = 0.045). Furthermore, Ki-67 index more than 3% was also more frequent in the invasion group (P = 0.045).

TAM infiltration in primary tumor site

Since the invasion group had increased malignant behavior compared with the capsule group, we compared the infiltration of TAMs in the SPT microenvironment between the two groups. All primary tumor samples of the 22 patients showed positivity for macrophage and M2-like macrophage infiltration in IHC analysis. Although the intratumoral macrophage infiltration was increased in both groups compared with normal pancreatic tissue, the invasion group had a significant increase of intratumoral macrophage infiltration compared with the capsule group (all P < 0.0001; Figure 2A-C). A similar trend

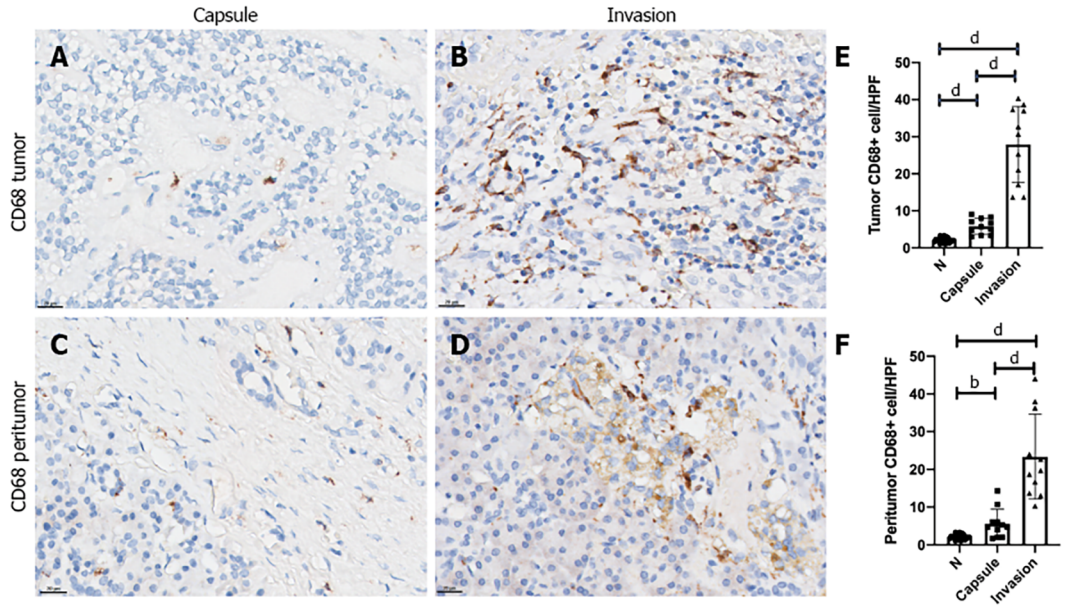

Figure 1 Computed tomography imaging, specimen and histopathologic features of capsulized and invasive solid pseudopapillary tumors. A, C and E: For the capsulized solid pseudopapillary tumors (SPTs), computed tomography (CT) imaging (A) and specimen (C) showed a clear distinction from surrounding pancreatic tissue, and an intact fibrous envelope on the tumor margin on hematoxylin and eosin (HE)-stained section (E); B, D and F: Invasive SPT was indistinguishable from surrounding normal pancreatic tissue on CT imaging (B) and in the specimen (D), and tumor cells showed infiltrative growth into normal pancreatic tissue on HE-stained section (F). N: Normal pancreas tissue; T: Tumor. *Tumor margin.

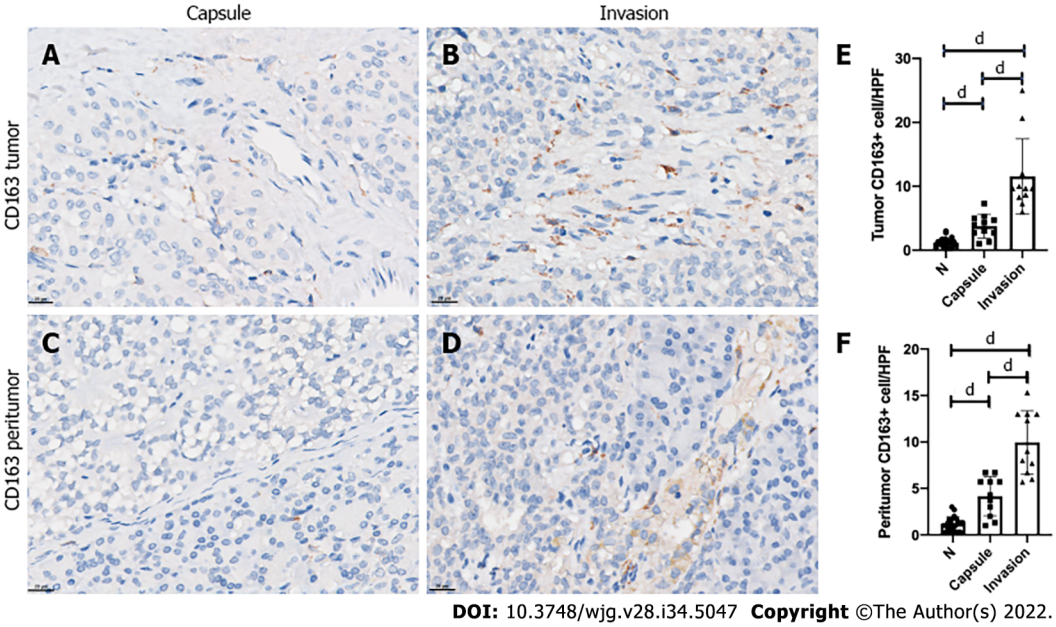
was observed for infiltrated peritumor macrophages. The TAM infiltration in peritumoral tissue, especially in the tumor margin, was markedly increased in the invasion group compared with capsule group ($P < 0.0001$; Figure 2D-F).

As a subtype of TAMs, the expression of CD163-positive M2-like macrophages was relatively low compared with CD68-positive TAMs. Elevation in both intratumor and peritumor sites in both the invasion group and capsule group compared with the normal pancreas tissue was evident by IHC (all $P < 0.0001$; Figure 3). Similarly, the expression of CD163-positive M2-like macrophages was also markedly increased in the intratumor and peritumor sites in the invasion group in comparison to the capsule group (all $P < 0.0001$; Figure 3).



TAM infiltration in liver metastasis site

Tumors in the liver metastasis sites also showed invasion features. Tumor cells were observed as invasively grown into normal hepatic cells, and no complete fibrous capsule was found on HE-stained sections (Figure 4A and B). Liver metastasis of 3 SPT patients showed positivity for macrophage and M2-like macrophage infiltration. Like the primary tumor site of the invasion group, both intratumor and peritumor areas of the metastasis site had relatively high-level CD68-positive TAM infiltration.

Figure 3 Invasion group showed increased tumor-associated CD163-positive M2-like macrophage infiltration compared with capsule group by immunohistochemical analysis. A-F: Immunohistochemical-stained images and analysis of tumor (A-C) and peritumor (D-F) tissues infiltrated with CD163-positive M2-like macrophages in representative patients from the capsule (A, D) and invasion (B, E) groups. N: Normal pancreas tissue. $^{d}P < 0.0001$.

However, there was no difference between the intratumor, peritumor and normal hepatic tissues. The CD163-positive M2-like macrophages had relatively high expression in both the intratumor and peritumor metastasis sites. No statistically significant difference was found upon comparison of the CD163-positive M2-like macrophage infiltration of intratumor, peritumor and normal hepatic tissues.

DISCUSSION

In the present study, we found that the invasion feature evident under a microscope was associated

Figure 4 Tumor-associated macrophage infiltration in liver metastasis sites of solid pseudopapillary tumor patients. A and B: Hematoxylin-eosin staining of the liver metastasis site of representative solid pseudopapillary tumor (SPT) patients; C-H: Immunohistochemical-stained imaging and analysis of intratumor and peritumor CD68 (C-E) and CD163 (F-H) expression in the liver metastasis site of representative SPT patients. N: Normal hepatic tissue; NS: No significance.

with malignant behavior of SPT. Additionally, we elaborated the spatial distribution of TAMs in the SPT tumor microenvironment and showed distinct expression of TAMs and M2-like macrophages between tissues with invasion and capsule features. Furthermore, we also described the intratumor and peritumor distribution of TAMs and M2-like macrophages in the liver metastases site. Considering the malignant behavior of SPTs, this study may provide a histopathological basis for identification of malignant SPTs. The phenomenon of increased infiltration of TAMs, especially M2-like macrophages, in the invasion feature might help in subsequent investigations of the underlying mechanism of TAM-mediated SPT malignant behavior, as well as to potentially treat recurrent and metastatic SPT by targeting TAMs.

The incomplete capsule feature assessed by CT imaging has been widely used and is considered able to predict malignant behavior of SPT[4]. Ye *et al*[1] showed this incomplete capsule group had a larger tumor size, an exogenous growth pattern, a malignant tendency during intraoperative frozen biopsy, and more likely to have invasion into the vasculature or organs. Indeed, in our study, the capsule or incomplete capsule measured by CT imaging was consistent with the capsule or invasion feature detected upon evaluation under a microscope. However, 2 patients in each group had distinct results. Considering the increased malignant behaviors of these SPT patients, we are concerned that assessment by CT imaging might miss patients with invasion features that could be detected with a microscope.

Other tumor types, such as small renal cell carcinoma, colorectal cancer and urinary bladder carcinoma, also have histopathological features of capsule or invasion as growth patterns, and the invasive growth feature has been shown as associated with worse prognosis of patients[17-19].

The intact fibrous envelope in extracellular matrix (ECM) might serve as a barrier for tumor cell invasion[20]. In our study, none of the 11 SPT patients with a capsule feature showed malignant behavior, such as invasion to surrounding tissues and distant metastasis. TAMs can secrete several proteolytic enzymes, including matrix metalloproteinases (MMPs, such as MMP7, MMP2, and MMP9), which can mediate the ECM degradation[21]. Particularly, M2-like macrophages could produce chitinase 3-like protein 1 to upregulate MMP expression and promote the invasiveness of gastric and breast cancer cells[22]. The expression of TAMs and M2-like macrophages in peritumor tissues of patients in the invasion group were significantly higher than those in the capsule group, which may be

related to the pathological characteristics of incomplete fibrous capsule and tumor cells' invasive growth pattern, and thus the malignant behaviors. Furthermore, the epithelial-mesenchymal transition hotpot, another mechanism associated with tumor cell invasiveness that mainly occurred at the peritumor site, was also accompanied by TAM infiltration in abundance in hepatocellular carcinoma patients[23]. Of interest, a recent study found that lipid-loaded TAMs could also sustain invasiveness in prostate cancer[24].

Metastasis to the liver through the portal venous system is a common route for the metastasis of pancreatic tumors. Indeed, 3 SPT patients in our study had liver metastasis. TAMs were involved in vascularization in a tumor environment and intravasation of tumor cells, two major mechanisms for tumor metastasis[11,25]. Vascular endothelial growth factor-A (VEGFA) is one of the primary factors driving expansion of the tumor vascular vascularization[26]. Infiltration of TAMs was associated with increased VEGFA expression and vascular density in tumor microenvironment[27,28]. This is probably because the TAMs could promote the expression of VEGFA in vascular endothelial cells by producing WNT7B[29]. Indeed, elevated expressions of fibroblast growth factor, placental growth factor, and anti-inflammatory cytokines, such as transforming growth factor-beta (TGF-β) and IL-10 in M2-like macrophages, could potentially enhance the vascularization[30,31]. Furthermore, tumor-associated M2-like macrophages could directly facilitate tumor metastasis by binding tumor cells and mediating their intravasation[32]. Therefore, when an SPT has an invasion feature, the increase of TAMs, especially M2-like macrophages, might facilitate metastasis compared with an SPT that has a capsule feature.

In addition to the vascularization and intravasation in primary tumor sites, the metastasis process includes the formation of a pre-metastatic niche followed by the growth phase[33]. TAMs in the pre-metastatic niche show an immunosuppressive phenotype characterized by elevated programmed death ligand-1 and nitric oxide synthase expression[34]. Macrophages are recruited during expansion of the metastatic site in the liver, through the CCL2–CCR2 signaling pathway[35]. Blocking the CCL2–CCR2 signaling axis was shown to reduce macrophage infiltration and metastatic expansion[36]. Few studies have reported the polarization of macrophages within or around liver metastasis sites[37]. In our study, we observed relatively more infiltration of TAMs, especially M2-like macrophages, in both intratumor and peritumor sites after the formation of SPT liver metastases. More importantly, to understand the role of TAMs in the formation of liver metastases, dynamic observation of the temporal and spatial changes of TAMs from a pre-metastatic niche to a pro-metastasis site is required.

Recently, Yang *et al*[14] classified SPT patients by the Ki-67 index based on their similar biological behavior in the 2017 WHO's pancreatic neuroendocrine tumor grade. In that study, the Ki-67 index was significantly associated with recurrence of SPT[14]. Regarding the Ki-67 index in the malignant behavior of SPT, in our research, a Ki-67 index more than 3% was observed in 4 patients in the invasion group, including 1 patient with peripheral organ invasion, 1 with both lymph node and spleen metastases, and 2 with liver metastasis. However, the Ki-67 index was only 1% in the remaining patient with peripheral organ invasion and liver metastasis. Indeed, previous meta-analyses that evaluated the Ki-67 index to predict malignant behavior of SPTs demonstrated distinct results, which might be due to the limited number of patients included and differences in the methods used to assess the Ki-67 index[38,39]. A multicenter study is needed to reveal the role of Ki-67 index in SPT patients. TAMs might be involved in the regulation of tumor cell Ki-67 expression. Lindsten *et al*[40] showed that increased infiltration of macrophages was associated with decreased progesterone receptor (commonly known as PR) expression and increased Ki-67 expression in breast tumor cells. Considering the regular expression of PR in SPT[41], the potential influence of TAMs on Ki-67 index in SPT needs further investigation.

Limitations of the present study should be noted. One of the limitations of this study was that the retrospective design and the paucity of the number of patients did not allow us to investigate causal associations between the TAMs and the invasiveness of SPT. In addition, a single immunohistochemical marker to identify target cells might not reflect the real proportion of M2-like macrophages in TAMs, so we did not compare this proportion between invasion and capsule groups in our study. The dichotomy of M1 and M2 classification of human TAM polarizations was not as obvious as in mouse, so we used M2-like macrophages instead. Further analysis of the specific distribution and function of TAMs in SPT patients using flow cytometry and a single-cell sequencing method might be used.

CONCLUSION

SPT patients with the invasion feature were more likely to demonstrate malignant behavior. These patients also showed increased infiltration of TAMs, especially M2-like macrophages, in both intratumor and peritumor sites compared with patients with the capsule feature.

ARTICLE HIGHLIGHTS

Research background

Solid pseudopapillary tumor (SPT) has been classified as a low-grade malignant tumor, and indeed only 9.2% patients of all SPT patients are initially diagnosed as malignant with invasion or metastasis. Thus, one of the challenges in managing SPT patients is predicting malignant behavior. One of the most frequently mentioned predictive factors is whether the tumor had a capsule or incomplete capsule as assessed by computed tomography imaging. However, assessing the integrity of the capsule and growth pattern of tumor cells, especially on SPT margins, using a microscope might reflect the real biological behavior of SPT. Tumor-associated macrophages (TAMs), especially the M2-like macrophages subtype, could enhance tumor invasion and metastasis; however, only limited studies are available regarding the role of the TAMs in the SPT microenvironment and their relationship with malignant behaviors of SPT.

Research motivation

The present study suggests that an invasiveness feature, as determined using a microscope is a good predictive factor for the malignant behavior of an SPT and illustrates the macrophage infiltration in the tumor microenvironment of an SPT.

Research objectives

Instead of assessing the integrity of the capsule on computed tomographic imaging, we divided SPT patients into two groups, either with invasion or capsule, based on the integrity of capsule and growth pattern of the tumor cells, especially on the tumor margins, under the microscope; we then investigated differences in the malignant behavior and TAM infiltration between these two groups.

Research methods

Hematoxylin-eosin-stained sections of SPT patients were used to assess the integrity of the capsule and growth pattern of tumor cells, especially on tumor margins. Immunohistochemical staining was used to evaluate the intratumoral and peritumoral presence of TAMs (CD68-positive) and M2-like macrophages (CD163-positive).

Research results

Malignant behavior was present more frequently in the invasion group, including in 2 patients with peripheral organ invasion, 3 with liver metastasis, and 1 with both lymph node and spleen metastases. Immunohistochemical analysis found that the invasion group had a significant increase of CD68-positive TAMs and CD163-positive M2-like macrophages in intratumoral and peritumoral sites in comparison with the capsule group.

Research conclusions

SPT patients with invasion detected using a microscope were more likely to have a tumor that demonstrated malignant behavior and TAM infiltration, especially of M2-like macrophages.

Research perspectives

This study may provide a histopathological basis for identification of malignant SPT. The phenomenon of increased infiltration of TAMs, especially M2-like macrophages in the invasion feature, might help us to investigate the underlying mechanism of TAM-mediated SPT malignant behavior, as well as to potentially treat recurrent and metastatic SPT by targeting TAMs.

Abstract

BACKGROUND

A gap remains in documenting the impact of anti-tumor necrosis factor therapy on disease burden in ulcerative colitis (UC) patients treated in a real-world setting. The use of patient-reported outcomes (PROs) has been discussed as a primary endpoint in the context of the FDA PRO Guidance, for labelling purposes. Specifically, the efficacy and safety of adalimumab have been demonstrated in pivotal trials; however, data are needed to understand how clinical results translate into improvements in key aspects of the daily lives of UC patients, such as symptoms, health-related quality of life (HRQoL), and disability.

AIM

To assess real-world effectiveness of adalimumab on PRO measures in patients with moderate-to-severe UC.

METHODS

UCanADA was a single arm, prospective, 1-year multicenter Canadian post-marketing observational study in which multiple PRO questionnaires were completed—with psychologic distress/depression symptoms as the primary endpoint—by patients with moderate-to-severe UC. Assessments were performed during patients' routine care visit schedule, which was at the initiation of adalimumab (baseline), after induction (approximately 8 wk), and 52 wk after baseline. Additional optional assessments between weeks 8 and 52 were collected at least once but no more than two times during this period. Serious safety events and per-protocol adverse events were collected.

RESULTS

From 23 Canadian centres, 100 patients were enrolled and 48 completed the study. Measured with the Patient Health Questionnaire–9 items at week 52, 61.5% (40/65) [95% confidence interval (CI): 49.7%-73.4%] of the patients improved in psychologic distress/depression symptoms, which was slightly higher in completers [65.9% (29/44); 95%CI: 51.9%-79.9%)]. At week 52, clinical response and clinical remission were achieved respectively by 65.7% (44/73) and 47.8% (32/73) of the patients. The odds of improving depressive symptoms for those achieving a clinical remission at week 52 was 7.94 higher compared with those not achieving a clinical remission (CI: 1.42, 44.41; P = 0.018). Significant changes from baseline to weeks 8 and 52 were observed in disability, HRQoL, and fatigue. Meaningful improvement was reported in work impairment.

CONCLUSION

At week 52, over 60% of the UCanADA patients had depressive symptoms significantly reduced, as well as HRQoL, fatigue symptoms, and work impairment improved. No new safety signals were detected.

Key Words: Disease burden; Patient-reported outcome; Depressive symptoms; Ulcerative colitis; Adalimumab; Real-world data

INTRODUCTION

Ulcerative colitis (UC)—an intermittent, idiopathic, and chronic disease of the colon—has a worldwide incidence of 1 to 20 *per* 100000 individuals and a prevalence of 5 to 500 *per* 100000 individuals[1,2]. As of 2018 in Canada, it is estimated that 120000 individuals live with this disease.

The burden of UC has been recognized to extend beyond its clinical signs and physical symptoms such as bloody diarrhea and abdominal pain, including the development of anxiety/depression, a decreased health-related quality of life (HRQoL), an impact on work productivity and social interactions, and impairments in sexual function[3-6]. As such, having access to multidisciplinary, collaborative, chronic disease models of care improves patients' HRQoL[7].

Around 30% of patients with inflammatory bowel disease (IBD) experience psychiatric disorders, and depression/anxiety in these patients have been shown to be three times greater than in the general population[8]. In UC patients, the prevalence of depression symptoms and disorders have been estimated as 16.7% [95% confidence interval (CI): 12.0%-21.4%][9]. Assessing the severity of depression in over 158000 IBD patients, a Patient Health Questionnaire–9 items (PHQ-9) pooled mean score of 7.6 (95%CI: 6.3-8.8, on a 0-27 scale) has been reported, which can be interpreted as a mild depression[9,10].

Among physical symptoms, fatigue, which is not relieved by rest and implies limitations of daily activities[11], has been reported by 42% to 47% of UC patients at diagnosis[12]. Fatigue has been shown to impact IBD patients' QoL and is experienced by those of all ages, with some studies suggesting a

greater burden in women[13-17]. In a recent review on IBD, Nocerino *et al*[18] documented strong associations between fatigue and sleep disturbance and inadequate sleep, highlighting a proportion of more than 50% of both active and inactive IBD patients reporting sleep deficiency.

Consistent with the increasing inclusion of patient's voice in all aspects of health care as in UC therapies[19] and aiming to align with the FDA guidance[20], the use of patient-reported outcome (PRO) questionnaires are more and more used as clinical endpoints in IBD studies[21]. The use of PRO instruments helps understand patients' preferences, which in turn has been shown to be associated with treatment acceptance and adherence[22-25].

In IBD populations, depression/anxiety has been measured with a wide range of tools, including the PHQ-9[9,26-29]. The Inflammatory Bowel Disease Questionnaire (IBDQ) and its short version (SIBDQ) as well as the EuroQol 5-Dimentions, 5 Levels (EQ-5D-5L) questionnaire have been used to assess HRQoL[30-34], fatigue has been assessed by the Functional Assessment Chronic Illness Therapy–Fatigue (FACIT-F) questionnaire[18,35-37], and work productivity with the Work Productivity and Activity Impairment (WPAI) questionnaire[26,30,38-40].

Developed and validated in 2012 in a population-based cohort, the inflammatory bowel disease disability index (IBD-DI) is specific to assess disability in IBD patients[41-43]. On a 0-100 scale, the mean (interquartile range) value of the IBD-DI was 35.3 (Q1 = 19.6; Q3 = 51.8). Higher IBD-DI values were associated with female gender ($P < 0.001$), clinical disease activity ($P < 0.0001$), and disease duration ($P = 0.02$)[42].

To provide real-world data on improvements in daily lives of UC patients, the overall goal of the UCanADA study was to gather evidence on effectiveness, quality of life, disability, and work productivity during an adalimumab treatment. The primary objective was to evaluate psychological distress/depression symptoms using change from baseline in the PHQ-9 after 1 year of a real-world adalimumab treatment in moderate-to-severe UC patients.

MATERIALS AND METHODS

Study design and patients

In this prospective, single arm, 1-year multicenter Canadian post-marketing observational study, adults (≥ 18 years) with a confirmed diagnosis of UC and a moderate-to-severe disease activity–evidenced by either a Mayo endoscopic subscore (MES) of 2 or 3 from endoscopic investigation in the previous 3-mo closest to the baseline visit, or a Mayo rectal bleeding subscore ≥ 2 and a calprotectin value greater than 250 mg/g–were enrolled if they were prescribed adalimumab as part of their treatment by their treating physician. If a patient was previously treated with vedolizumab or any anti-tumor necrosis factor (TNF) agent (except adalimumab), an appropriate washout period took place *per* routine practice, which period varied usually from 2 to 3 mo.

Excluded from the study were patients who either previously received adalimumab, used infliximab or any anti-TNF agent and did not clinically respond at any time unless they experienced a treatment limiting reaction; had a history of subtotal colectomy with ileorectostomy or colectomy with ileoanal pouch, Kock pouch, or ileostomy for UC or planned bowel surgery; had a current diagnosis of indeterminate colitis, ulcerative proctitis only, or with a current diagnosis and/or have a history of Crohn's disease; had other TNF immune-modulated disease; OR had a significant history of renal, neurologic, psychiatric, endocrinologic, metabolic, immunologic, cardiovascular, or hepatic disease that in the opinion of the investigator would adversely affect his/her participating in this study. Also, we excluded from the study pregnant or breast-feeding female patients and patients currently participating in another prospective study including controlled clinical trials.

Eligible patients were approached to participate in the study after a decision to change the patient's therapy for adalimumab was already made by the treating physician. To participate in the study and to disclose personal health information, all patients were required to sign a patient authorization form (or written informed consent), which was approved by an Independent Ethics Committee/Institutional Review Board (ClinicalTrials.gov Identifier: NCT02506179). The study was conducted between July 2015 and December 2019 in 23 Canadian sites, with approximately half of the sites being community based and the other half academic based.

Assessments

Patients were followed for 52 wk post initiation of adalimumab treatment (baseline). The assessments were performed during patients' routine care visits schedule, coinciding approximately to 8 and 52 wk after baseline, in accordance with the Canadian approved label (product monograph) and as *per* regional requirements. The completers population was defined as patients who received at least one dose of treatment, and at least one follow-up appointment and did not terminate the study early or discontinue.

During these visits, the patients' medical history and changes in medical conditions, previous and concomitant medications, and disease severity and activity [clinical response defined as simple clinical colitis activity index (SCCAI)[44] decrease from baseline of ≥ 2, clinical remission defined as SCCAI

score ≤ 2, endoscopic evaluation (MES), assessment of rectal bleeding (Mayo Rectal bleeding Subscore), and the physician's global assessment (PGA)] were assessed.

Also, patients were required to fill, on paper at the physician's office, eight PRO questionnaires for evaluating: The presence and severity of depression (PHQ-9 using a 0-27 scale)[10], the entire spectrum of limitations in functioning in patients (IBD-DI questionnaire evaluating 4 domains of body functions, activity and participation, body structures, and environmental factors)[41], HRQoL (EQ-5D-5L questionnaire comprising mobility, self-care, usual activities, pain/discomfort, and anxiety/depression using a 0-1 scale)[45], SIBDQ questionnaire assessing the social, emotional, bowel, and systemic domains on a 1-7 scale[46], fatigue (FACIT-F questionnaire having a fatigue subscale score with a range from 0 to 52)[47], sleep related outcomes [Medical Outcomes Study Sleep scale (MOS Sleep) 12-item questionnaire including sleep disturbance, sleep awakening short of breath or with headache, sleep adequacy, somnolence, and quantity of sleep/optimal sleep][48], work related outcomes [WPAI: UC V2.0[49] presenting percentages of absenteeism (work time missed), presenteeism (impairment while working), an overall work impairment (overall productivity loss, accounting for both absenteeism and presenteeism), and activity impairment (impairment in activities outside work)], and Valuation of Lost Productivity (VOLP) questionnaire[50], assessing the impact of health conditions on lost productivity in monetary units. The order by which the PRO questionnaires were filled was varied to limit the potential of missing data that would systemically be found for a particular instrument.

Safety assessments included serious adverse events (AEs), any non-serious event of malignancy in patients 30 years of age and younger[51], unusual failure in efficacy, and AEs leading to discontinuation. These were coded using Medical Dictionary for Regulatory Activities version 17.1.

Study size and statistical methods

The sample size was calculated assuming a proportion of 15% of patients would improve their PHQ-9 score compared with baseline and change severity category. Using an alpha of 0.05 with a lower CI of 6%, a sample size of 72 patients would be needed. To account for a potential 25% attrition over the course of one year, the sample size was increased to 100 patients. It was anticipated that up to 30% of the 100 moderate-to-severe UC patients newly treated with adalimumab would have prior experience with biologics.

The primary effectiveness endpoint—the proportion of patients with a change in depressive symptoms using the PHQ-9 score from baseline following initiation of adalimumab and after 1 year of treatment—was calculated, and the 95%CIs were estimated. Changes in PHQ-9 scores from baseline were tested by paired sample *t*-test. Least-square mean (LS mean) of the changes were also estimated by the mixed effect repeated measures models where baseline values were included as a covariate. Changes in severity categories were tested by Bowker's test (*kxk* table where $k > 2$) or McNemar's test (2 × 2 table).

To understand the independent effect of clinical effectiveness on the probability of improving in PHQ-9 at week 52, a logistic regression analysis was conducted to examine the effect of clinical response and clinical remission adjusting for the baseline PHQ-9 score and other potential prognostic factors. A similar analysis was conducted to assess the association between clinical effectiveness on changes of PHQ-9 scores from baseline. LS mean of the changes associated with clinical response and clinical remission was estimated by the mixed effect repeated measures models using all follow-up visits.

For secondary outcomes, the IBD-DI, EQ-5D-5L, SIBDQ, FACIT-F, and MOS Sleep, scores at baseline, week 8, and week 52 were summarized, and changes in scores from baseline were tested by paired sample *t*-tests. LS mean of the changes were also estimated by the mixed effect repeated measures models where the baseline value was included as a covariate. Productivity outcomes (WPAI and VOLP) at baseline, week 52, and changes in outcome from baseline were summarized. The 95%CIs for the changes were estimated by bootstrapped percentile CIs based on samples of 10000.

The sensitivity to change for the IBD-DI was evaluated using the effective size (ES) and the standardized response mean (SRM). For both statistics, values of 0.020, 0.50, and 0.80 or greater were used to represent small, moderate, and large, respectively. The association between the change in PROs (EQ-5D-5L, SIBDQ, FACIT-F, and MOS Sleep) and clinical response/remission (effectiveness) were assessed using a mixed model for repeated measures using observations from all follow-up visits with the baseline value included in the model as a covariate. All models with repeated measures included a random intercept with the effectiveness variable (fixed, forced-in), visit (fixed, forced-in), baseline value of the PRO measure (fixed, forced-in) and other covariates. Cross-sectional regression models included an intercept with the effectiveness variable (forced-in), baseline value of the PRO measure (fixed) and other covariates. Least squares means, *P* value and 2-sided 95%CI of the difference between the two groups defined by the clinical effectiveness were determined. Additional details on the statistical analysis used to determine the correlation between effectiveness (clinical response and remission) rates and PRO measures are provided in the Supplementary material section.

Missing data were imputed only for the sensitivity analysis of the primary outcome. For missing responses on PRO questionnaire items, missing data were handled *per* the imputation solutions provided in the coding of the PRO instruments. To assess the impact of missing data on the primary endpoint estimate, the sensitivity analysis was performed using two imputation methods: Non-responder imputation (NRI), defined as patients who did not provide week 52 effectiveness data or

dropped out of the study prior to week 52 were considered as no improvement; and last observation carried forward (LOCF) defined as the last effectiveness assessment prior to week 52 was used for those missing week 52 assessment.

All calculations and analyses were performed using SAS version 9.4 (Cary, NC: SAS Institute Inc.) under the Windows 10 Enterprise operating system at the Centre for Health Evaluation and Outcome Sciences, in Vancouver, Canada.

RESULTS

Patients

One hundred patients from 23 Canadian sites were included in the study (Figure 1). Respectively, 94, 48, and 98 patients were included in the effectiveness population [intent-to-treat (ITT) population], the completers population, and the safety population. Patients in the ITT population had a mean age (SD) of 42.5 (15.3) years and a mean body mass index of 25.4 (4.5) kg/m^2 (Table 1). The majority was White (93.6%) and male (59.6%). The mean age at UC diagnosis was 34.5 (15.3) years, and the mean duration of disease was 7.9 (8.0) years. Forty-eight (48%) patients completed the study.

Impact on psychological distress/depression symptoms

Following routine care treatment with adalimumab, the proportion of patients who improved in psychological distress/depressive symptoms using the PHQ-9 total score at week 52—defined as a change in PHQ-9 total score from baseline, the study primary endpoint—was 61.5% (40/65) (95%CI: 49.7%-73.4%) for the ITT population and 65.9% (29/44) (95%CI: 51.9%-79.9%) for the completers population (Figure 2A). To assess the impact of missing data, the sensitivity analyses conducted on the primary endpoint showed that the proportions of patients who improved in psychological distress/depressive symptoms, using the NRI and LOCF imputation methods, were similar to the proportion obtained using the original non-imputed data analysis, with the ITT population (Supplementary Table 1).

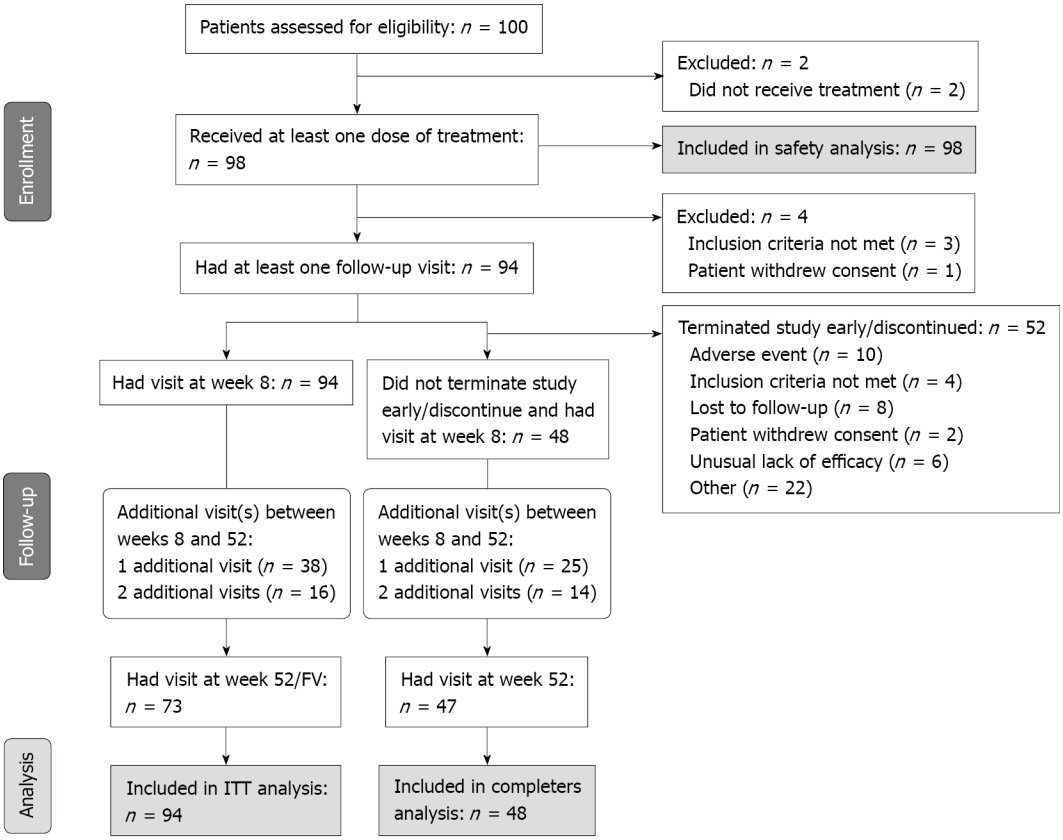
Overall, changes from baseline in the PHQ-9 total score were significant at weeks 8 and 52 (P = 0.010), with changes slightly higher for the completers population [-2.5 (6.1) and -3.4 (6.8) at weeks 8 and 52] than in the ITT population [-2.2 (6.1) -2.4 (7.1)] on a 0-27 scale (Table 2). The proportion of patients with a PHQ-9 total score 10 (yellow flag category, *i.e.*, moderate or more severe depression) was 25.6% (21/82) at week 8, which slightly increased to 29.2% (19/65) at week 52 for the ITT population. These proportions were lower and stable over time (18%-19%) for the completers population. For patients with severe depressive symptoms (red flag category), the proportions improved from 19.1% (18/94) and 16.7% (8/48) at baseline to 12.3% (8/65) and 2.3% (1/44) at week 52 for the ITT population and completers population, respectively.

The PHQ-9 questionnaire items that showed the highest improvement from baseline were 'Poor appetite or overeating' (response 'Not at all' increased by 23.3% from baseline to week 52, and response 'Nearly every day' decreased by 20.3% from baseline to week 52), 'Little interest or pleasure in doing things' (response 'Not at all' increased by 15.3% from baseline to week 52, and response 'Nearly every day' decreased by 12.1% from baseline to week 52), and 'Feeling tired or having little energy' (response 'Not at all' increased by 8.2% from baseline to week 52, and response 'Nearly every day' decreased by 20.3% from baseline to week 52) (Supplementary Table 2).

Clinical endpoints

The proportions of patients who achieved a clinical response (decrease from baseline ≥ 2 in SCCAI score) remained similar throughout the study [64.2% (52/81) at week 8 and 65.7% (44/67) at week 52], and the proportion who achieved clinical remission (SCCAI score ≤ 2) slightly increased [41.5% (34/82) at week 8 and 47.8% (32/67) at week 52] in the ITT population (Figure 2B). For the completers population, these proportions increased during the study for both the clinical response and clinical remission, reaching 85.4% (35/41) and 73.2% (30/41), respectively, at week 52 (Supplementary Table 3).

Similarly, the proportions of patients who achieved endoscopic healing remained constant between weeks 8 and 52 [42.9% (6/14) had a Mayo endoscopic score of 0 or 1 and 11.5% (3/26), had a fecal calprotectin concentration < 50 μg/g] in the ITT population (Figure 2C), whereas in the completers population, the proportions increased over time [71.4% (5/7) and 80.0% (8/10), measured with the Mayo endoscopic score and 7.7% (1/13) and 11.8% (2/17) measured with the fecal calprotectin concentration, at weeks 8 and 52, respectively] (Supplementary Table 3).



No major changes were observed over time in the extracolonic feature, with the majority of patients not having arthritis at both baseline and follow-up visit [81.5% (66/81) at week 8 and 82.1% (55/67) at week 52] (Figure 2D). The proportion of patients who had arthritis at baseline and none at follow-up was 8.6% (7/81) at week 8 and 9.0% (6/67) at week 52. Similar proportions were observed in the completers population (Supplementary Table 3).

Figure 1 UCanADA study flow diagram. The intent-to-treat population was defined as patients who received at least one dose of treatment and had at least one follow-up appointment. The completers population was defined as patients who received at least one dose of treatment, and at least one follow-up appointment and did not terminate the study early or discontinue. The safety population was defined as patients who received at least one dose of treatment. FV: Final visit; ITT: Intent-to-treat.

The proportion of patients who were PGA responders, defined as a decrease from baseline of ≥ 1 point, varied from 66.7% (50/75) to 61.5% (40/65) for the ITT population (Figure 2E) and from 73.2% (30/41) to 83.7% (36/43) for the completers population, from week 8 to week 52, respectively (Supplementary Table 3). While at baseline the majority of patients had moderate disease [73.9% (68/92)], at week 8 the highest proportion of patients had mild disease [35.5% (27/76)], and at week 52, 50.0% (33/66) of patients were assessed as normal (Figure 2E). The proportion of patients assessed with severe disease remained comparable between week 8 [5.3% (4/76)] and week 52 [6.1% (4/66)]. Similar results were reported for the completers population (Supplementary Table 3).

A proportion of 5.5% (4/73) of patients reported complications including hospitalization and surgery at week 52 in the ITT population (Supplementary Table 4), and none were reported among the completers population (Supplementary Table 3). The proportion of patients with current steroid use

P value		0.280	0.681		0.610	0.542
PHQ-9: Yellow flag category, *n* (%)						
	36 (38.3)	21 (25.6)	19 (29.2)	17 (35.4)	8 (18.6)	8 (18.2)
P value		0.028	0.083		0.021	0.059
PHQ-9: Red flag category, *n* (%)						
Yes	18 (19.1)	7 (8.5)	8 (12.3)	8 (16.7)	4 (9.3)	1 (2.3)
P value		0.013	0.134		0.180	0.034

The yellow flag category was defined as the proportion of patients with a Patient Health Questionnaire–9 total score ≥ 10, and the red flag category was defined as patients with severe depressive symptoms. ITT: Intent-to-treat; Max: Maximum; Min: Minimum; PHQ-9: Patient Health Questionnaire–9 items.

decreased between week 8 and week 52 from 29.4% (25/85) to 19.2% (14/73) in the ITT population and from 22.2% (10/45) to 12.8% (6/47) in the completers population.

Improvement in IBD-DI

The mean change from baseline in IBD-DI increased from -10.7 (17.21) at week 8 to -13.8 (22.24) at week 52 ($P < 0.001$), with proportions of patients who improved disability increasing from 72.6% (53/73) to 74.1% (40/54) over time in the ITT population (Figure 2F). Results from the completers population were slightly higher [mean change from baseline = -14.69 (17.99) and -20.09 (17.74) and improved disability = 81.4% (35/43) and 88.9% (32/36) at weeks 8 and 52, respectively] (Supplementary Table 5).

The IBD-DI was moderately sensitive to change for the ITT population, varying from -0.61 to -0.77 for ES and had a SRM of -0.62 (Supplementary Table 6). For the completers population, the IBD-DI was greatly sensitive to change. The ES varied from -0.75 to 1.08 and the SRM varied from -0.82 to -1.13

Correlations between PHQ-9 and clinical outcomes

A correlation analysis showed that at week 52 an improvement in PHQ-9 total score was associated with the baseline PHQ-9 score, with a higher baseline score predicting a greater improvement on the PHQ-9 (Table 3). No associations were detected between an improvement in PHQ-9 and clinical response; however, an association was measured with clinical remission in the ITT analysis (OR: 7.94; 95%CI: 1.42-44.41; $P = 0.018$), though this was not statistically significant in the completer analysis.

Table 3 Association between clinical response/remission and improvement in Patient Health Questionnaire–9 items total score at week 52/final visit–intent-to-treat and completers populations

Analysis population	Parameter	Model coefficient (SE)	Est. odds ratio (95%CI)	*P* value
Clinical response				
ITT	Baseline PHQ-9 total score	0.17 (0.06)	1.19 (1.05-1.34)	0.005
	Clinical response at week 52: Yes versus No	0.30 (0.65)	1.35 (0.38-4.84)	0.648
	UC duration (years)	0.11 (0.05)	1.11 (1.00-1.24)	0.051
Completers	Baseline PHQ-9 total score	0.20 (0.10)	1.22 (1.00-1.48)	0.049
	Clinical response at week 52: Yes versus No	-1.29 (1.29)	0.28 (0.02-3.43)	0.317
	UC duration (years)	0.14 (0.08)	1.15 (0.98-1.35)	0.079
Clinical remission				
ITT	Baseline PHQ-9 total score	0.28 (0.09)	1.33 (1.11-1.59)	0.002
	Clinical remission at week 52: Yes versus No	2.07 (0.88)	7.94 (1.42-44.41)	0.018
	UC duration (years)	0.11 (0.06)	1.11 (1.00-1.24)	0.054
Completers	Baseline PHQ-9 total score	0.22 (0.11)	1.24 (1.00-1.53)	0.045
	Clinical remission at week 52: Yes versus No	1.39 (1.07)	4.00 (0.50-32.37)	0.193
	UC duration (years)	0.14 (0.08)	1.15 (0.98-1.36)	0.095

Clinical response based on simple clinical colitis activity index (SCCAI): decrease from baseline of ≥ 2; Clinical remission: SCCAI ≤ 2; CI: Confidence interval; ITT: Intent-to-treat; PHQ-9: Patient Health Questionnaire–9 Items; SE: Standard error.

A regression analysis between the PHQ-9 total score and clinical response/remission at week 52 showed an association at week 52 using the ITT population ($P < 0.001$), but not in the completer population ($P \geq 0.098$) (Supplementary Table 7).

Impact on other PROs and correlation with clinical outcomes

For the other PRO tools used to assess the impact of the adalimumab treatment, changes from baseline at weeks 8 and 52 were significant for the EQ-5D-5L utility score, SIBDQ total score, FACIT-F total score, MOS Sleep Problems Index I and Sleep Problems Index II ($P = 0.049$) measured in the ITT population (Table 4) and the completers population (Supplementary Tables 8 and 9). A regression analysis showed that changes in the PRO measures between baseline and week 52 were all significantly associated with clinical outcomes ($P < 0.001$), except for the MOS Sleep measures ($P \geq 0.064$) (Supplementary Table 10).

The SIBDQ items of social function and bowel symptoms improved the most from baseline [mean change at week 52, 1.09 (2.11) and 0.93 (1.66), respectively on a 1-7 scale] ($P < 0.001$) (Table 4). Observing the FACIT-F measures, patients reported gaining more over time from the physical fatigue [3.86 (7.11)] than from the functional fatigue [2.58 (6.36)], emotional fatigue [2.06 (5.26)], and social impact of fatigue [1.32 (4.60)], at week 52 ($P = 0.024$). For the MOS Sleep subscales, only the sleep adequacy subscale significantly improved over time, with a mean change from baseline of 11.69 (5.26) at week 52 ($P < 0.001$).

All the WPAI scores improved from baseline, and the ones that improved the most were activity impairment [-16.9% (29.8) at week 8 and -16.7% (33.6) at week 52], *i.e.*, activities performed outside of work, and overall work impairment [-16.2% (30.2) at week 8 and -14.5% (34.4) at week 52], which combines absenteeism and presenteeism at work (Table 4). Similar results were reported for the completers (Supplementary Table 11).

For the VOLP, the most important changes were reported at week 52 and were related to paid work [paid work productivity loss in the past x months = -42.2 (115.7) hours and any paid work productivity loss in the past x months = -17% (-16.7%)] and lost productivity [any costs of lost productivity in the past x month = -15% (11.6%) hours and total costs of lost productivity in the past x months ($) = -1998 (-7299.7) $]. Study completers reported slightly higher results (Supplementary Table 11).

Safety

The safety profile was consistent with the known safety profile of adalimumab. During the study, 18 (18.4%) patients experienced at least one AE (Table 5). The AEs reported by more than 1% of patients

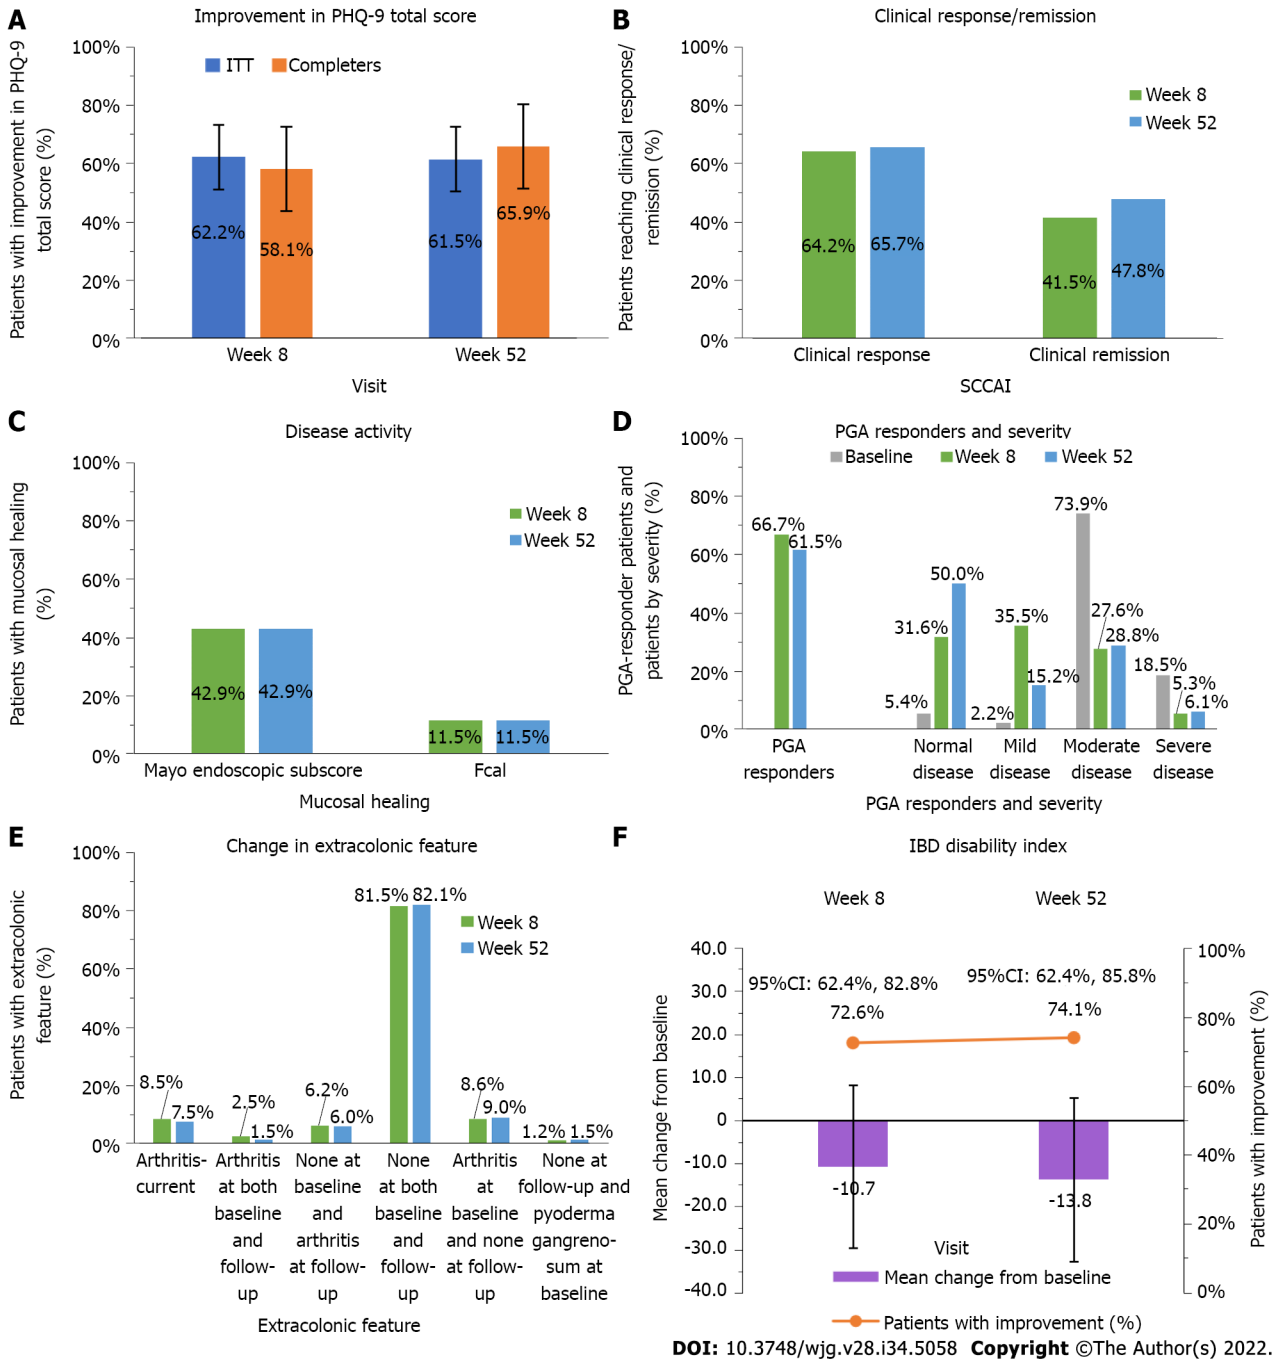
Resulting in hospitalization		6 (6.1%)
Resulting in study drug discontinuation		15 (15.3%)
Malignancy in patients ≤ 30 yr	0	0
Death	0	0

Percentages of patients were calculated based on the total number of patients. Percentages of events were based on the total number of events.
AE: Adverse event.



were: Colitis ulcerative [6 (6.1%) patients], drug ineffective [6 (6.1%) patients], haematochezia [2 (2.0%) patients], and arthralgia [2 (2.0%) patients]. Each of the severe AEs was experienced by only one (1.0%) patient, which included one event each of anal fissure, colitis, dysphagia, and mouth ulceration. One patient experienced two events of severe oesophagitis.

Two (2.0%) patients experienced serious treatment-related AEs that were assessed by the investigator to be reasonably possibly related to adalimumab: 1 (1.0%) patient experienced two events of severe oesophagitis that led to hospitalization and prolongation of hospitalization, and one event of severe aggravated colitis that led to hospitalization; 1 (1.0%) patient experienced severe injection site pain. There was one report of cutaneous basal cell cancer in a 63-year-old male. Monitored as *per* protocol safety variable, there were no reports of malignancy in patients 30 years of age and younger. No death was reported during the study, and no new signal or unexpected trend was identified for the patient population.

DISCUSSION

To fill an information gap on Canadian real-world data on the effectiveness of adalimumab on PRO measures in moderate-to-severe UC patients, and consistent with the FDA guidelines on the use of PRO measures to support labelling claims[20], the UCanADA study enrolled 100 patients from 23 centres using as a primary endpoint the change from baseline in depressive symptoms at week 52, measured by the PHQ-9 questionnaire.

The PHQ-9 measures in study UCanADA showed that over 60% of the study population improved in psychological distress/depression symptoms during the real-world adalimumab treatment, with most gains observed at week 52 in the completers population (65.9%). Significant changes from baseline were observed at week 8, which were maintained at week 52 and were slightly higher for the completers population (P = 0.010). Despite this improvement, these scores may be interpreted as a remaining mild depression in patients[10] and not necessarily a clinically meaningful change[52-54], which indicates a potential relevance to offer psychological support to this population[7,55]. In the present observational

Figure 2 Effect of a real-world adalimumab treatment on effectiveness and patient-reported outcomes in moderate-to-severe ulcerative colitis patients. A: Proportion of patients who improved in Patient Health Questionnaire–9 items total score at week 52 in the intent-to-treat and completers populations (%), improvement defined as change from baseline, bars show 95% confidence intervals; B: Proportion of patients achieving clinical response/remission at weeks 8 and 52 (%), measured by the simple clinical colitis activity index (SCCAI) ≤ 2; C: Proportion of patients with endoscopic healing at weeks 8 and 52 (%), healing measured as a Mayo endoscopic subscore of 0 or 1 or a fecal calprotectin concentration < 50 μg/g; D: Proportion of patients with extracolonic feature at weeks 8 and 52 (%), measured by the SCCAI; E: Proportion of physician's global assessment responders and severity at weeks 8 and 52 (%), responders defined as with a decrease from baseline of ≥ 1 point; F: inflammatory bowel disease index mean change from baseline and proportion of patients who improved (%). Bars represent standard deviations. PRO: Patient-reported outcome; UC: Ulcerative colitis; PHQ-9: Patient Health Questionnaire–9; IBD: Inflammatory bowel disease; SCCAI: Simple clinical colitis activity index; ITT: Intent-to-treat; PGA: Physician's global assessment.

study, while patients who had a preliminary failure to biologics were excluded, patients with secondary failures were included, which may have led to the inclusion of patients with greater psychological burden than biologic-naïve patients.

Our results show a significant change from baseline in PHQ-9 score earlier during treatment than those of a recently reported cohort of 1804 UC outpatients, who were included regardless of treatment assignment or disease activity[26]. However, a similar decrease in PHQ-9 score was measured in UC patients at least 30 d after being initiated on an anti-TNF therapy (including infliximab, adalimumab, or

certolizumab) and/or immunomodulator therapy (methotrexate or azathioprine)[29].

At week 52, clinical response and clinical remission were achieved respectively by 65.7% and 47.8% of the ITT population, and 85.4% and 73.2% of the completers population. These results are comparable to those from the InspirADA study at week 8, in which 463 moderate-to-severe UC patients from 92 international sites were treated with adalimumab following usual clinical practice[40].

To our knowledge, UCanADA is the first study reporting associations between PHQ-9 scores and clinical response/remission in UC patients in a real-world setting. A regression analysis showed that in the ITT population, the odds of improving depressive symptoms for those achieving a clinical remission at week 52 was 7.94 higher compared to those not achieving a clinical remission (OR: 7.94; 95%CI: 1.42-44.41; $P = 0.018$).

These results–as well as the significant associations measured between the PHQ-9 total score and clinical response/remission at week 52 ($P < 0.001$) and between clinical response/remission and IBD-DI, EQ-5D-5L, SIBDQ total score, and FACIT-F fatigue subscale ($P = 0.002$)–are consistent with the other findings showing a relationship between disease activity and HRQoL[34,35,56]. In a 6-mo study including 199 UC patients, a consistent and almost linear relationship was demonstrated between SCCAI values and the EQ-5D-5L index values (correlation: ρ: -0.53; $P < 0.001$)[34].

Other studies conducted in UC patients reported correlations between disease activity indexes and HRQoL measures. Aniwan *et al*[35] reported a good correlation between the SIBDQ and the combination of self-rated rectal bleeding and stool frequency using the 6-point partial Mayo score (ClinPRO2) and MES, from a study on 90 UC patients ($r = -0.70$; $P < 0.01$). Assessed on 110 UC patients, a significant correlation has been reported between SIBDQ and SCCAI and MES alone ($r = −0.79$ and $r = −0.58$, respectively)[56]. Consistent with our findings, these support an association between clinical remission and improved HRQoL.

To the PHQ-9 item 'Feeling tired or having little energy' between baseline and week 52, the proportion of patients feeling it 'Nearly every day' decreased by 20%, and those feeling it 'Not at all' increased by 8%. These results are in line with the significant decrease in fatigue shown in the FACIT-F total score and fatigue subscale ($P = 0.006$).

As fatigue has been reported to be strongly associated with sleep disturbances in IBD patients[18], not surprisingly our scores from the MOS sleep problems indexes I and II also significantly improved during the study, as well as sleep adequacy and sleep quantity subscores ($P = 0.042$ at week 52). Using the NIH PROMIS questionnaire in 160 patients with IBD using either and anti-TNF or vedolizumab, Stevens *et al*[57] reported significant and meaningful improvement in sleep quality by week 6 ($P = 0.009$), which was paralleled by a significant reduction in depression ($P < 0.05$), as measured in the UCanADA study population. These results reinforce the need to assess sleep disorders a part of an algorithmic approach for the systemic workup of fatigue[18].

Also related to fatigue, in a study including 1185 IBD patients (462 with UC), Williet *et al*[58] reported a strong correlation between FACIT-F score and IBD-DI measure ($r = -0.78$) as well as overall work impairment ($r = -0.70$). Similar trends were observed in UCanADA, *i.e.*, a significant improvement in fatigue (FACIT-F total score; $P < 0.001$) mirrored by a significant improvement in IBD-DI measures ($P < 0.001$) as well as a meaningful improvement in overall work impairment during the study. Our IBD-DI measures are similar to those reported from other UC populations[43]. In a meta-analysis including 3167 IBD patients, Lo *et al*[43] reported a significant lower disease disability rates in patients on biological treatment than those on corticosteroids ($P < 0.01$).

At week 8 and week 52, there was a gain between 15% and 17% in work impairment, overall work impairment, and activity impairment in the UCanADA study population. These represent less gains than those reported from the InspirADA population at week 26; however, they were twice as high as the minimal clinically important difference of 7% in WPAI outcome[59].

Limitations of the research methods used in this study are related to, but may not have been limited to, the observational nature of the study with regards to missing data, which has been alleviated with the use of sensitivity analyses for the primary endpoint. This study consisted of a small cohort of patients, and only 48 (48%) patients completed the study. However, the results between the ITT population and completers population were fairly consistent. The PRO questionnaires being self-administered provide subjective data as opposed to objective data. The collection of secondary PROs data may be subject to a recall bias.

CONCLUSION

At week 52 in a real-world setting, adalimumab was effective in reducing depressive symptoms in patients with UC, with more than 60% of the patients achieving an improvement the PHQ-9 with a mean improvement of 2.4 points. A broad range of PROs including HRQoL and work productivity also significantly improved during the study. The safety profile was consistent with the known safety profile of adalimumab, and no new signal or unexpected trend was identified for the patient population.

ARTICLE HIGHLIGHTS

Research background

The efficacy and safety of adalimumab have been demonstrated in pivotal trials, but there remained a need to assess more holistically how the clinical results translate into concrete improvements in key aspects of the daily lives of ulcerative colitis (UC) patients, such as symptoms, health-related quality of life (HRQoL), and disability.

Research motivation

Although some patient-reported outcomes (PROs) from existing studies may have items capturing some of these aspects, limited data was available for adalimumab in UC, specifically on psychological distress/depression, disability, fatigue, and pain or sleep quality in real-life setting.

Research objectives

The overarching goal for the UCanADA study was to assess the real-life effectiveness of adalimumab on PRO measures, while taking the opportunity to use the inflammatory bowel disease disability index to assess the impact of adalimumab on key components of patients' functioning when affected with moderate-to-severe UC.

Research methods

UCanADA was a single arm, prospective, 1-year multicenter Canadian post-marketing observational study in which multiple PRO questionnaires were completed—with psychologic distress/depression symptoms as the primary endpoint—by patients with moderate-to-severe UC. Assessments were performed during patients' routine care visit schedule, which was at the initiation of adalimumab (baseline), after induction (approximately 8 wk), and 52 wk after baseline. Additional optional assessments between weeks 8 and 52 were collected at least once but no more than two times during this period. Serious safety events and per-protocol adverse events were collected.

Research results

One hundred patients were included in this final analysis, with 94 (94%) patients included in the efficacy population (identified as the intent-to-treat (ITT) population), 48 (48%) patients included in the completers' population, and 98 (98%) patients included in the safety population. The primary endpoint–the proportion of patients who achieved a change from baseline, defined as an improvement in total severity score relative to baseline, in the Patient Health Questionnaire–9 items (PHQ-9) measure at week 52–was 61.5% [40/65 patients; 95% confidence interval (CI): 49.7%-73.4%] for the ITT population and 65.9% (29/44 patients; 95%CI: 51.9%-79.9%) for completers. The safety profile was consistent with the known safety profile of adalimumab, and no new signal or unexpected trend was identified for the patient population.

Research conclusions

At week 52, adalimumab, used in a real-life study, was effective in reducing depressive symptoms in patients with UC, with more than 60% of the patients achieving an improvement the PHQ-9 with a mean improvement of 2.4 points. Thus, the treatment with adalimumab contributed to reducing the depressive symptoms frequently experienced in patients with UC as well as improving a broad range of PROs such as HRQoL and work productivity, as assessed with PRO instruments. The safety profile was consistent with the known safety profile of adalimumab, and no new signal or unexpected trend was identified for the patient population.

Research perspectives

Improvements in PHQ-9 were associated with clinical remission. Beyond the PHQ-9, significant improvements in several PROs were observed suggesting an improvement in HRQoL and work productivity as well. The population in the study, as well as the inclusion and exclusion criteria, was representative of the target population. In addition, coinciding the study visits with the patient's routine care visit schedule helped increase generalizability of the PRO instruments by decreasing the impact on real life.

ACKNOWLEDGEMENTS

AbbVie and the authors thank all study investigators (Dr. Kenneth Atkinson, Columbia Gastroenterology Management Ltd.; Dr. Guy Aumais, CHUM-Hôpital Maisonneuve-Rosemont; Dr. Rahman Bacchus, Dr. Rahman Bacchus Medicine Corporation; Dr. Andrew Bellini, Bellini Medicine Professional Corporation; Dr. Edmond-Jean Bernard, Le Centre des Maladies Inflammatoires et Intestinales de

Montréal (CMIIM); Dr. Ian Bookman, Kensington Cancer Screening Clinic; Dr. Raymond Bourdages, CHAU - Hôpital Hotel-Dieu de Levis; Dr. Brian Bressler, Gastrointestinal Research Institute (GIRI); Dr. Sharyle Fowler, Royal University Hospital; Dr. Alexandre Gougeon, Centre Hospitalier de l'Université Laval (CHUL); Dr. Daniel Green, Oshawa Clinic; Dr. Vivian Huang, Zeidler Ledcor Centre; Dr. Mark MacMillan, Dr. Everett Chalmers Regional Hospital; Dr. Remo Panaccione, University of Calgary Gastrointestinal Research Group; Dr. Denis Petrunia, Discovery Clinical Services; Dr. Ranjit Singh, PerCuro Clinical Research Ltd.; Dr. Richmond Sy, Ottawa Hospital - General Campus; Dr. Audrey Weber, CHUM – Hôpital St-Luc; and Dr. Chadwick Williams, Dr. Chadwick Ian Williams Professional) for their contribution and the patients for their participation in this study. Thank you also to Daphne Guh, MSc., from the Centre for Health Evaluation and Outcome Sciences, and Nick Bansback, Ph.D. from University of British Columbia, for the statistical analyses. Medical writing support was provided by Judy Chiu, MPH, from the Centre for Health Evaluation and Outcome Sciences, and Nathalie Ross, PhD, MWC, from McDougall Scientific Ltd. All of these contributors were funded by AbbVie, Inc. AbbVie sponsored the study and medical writing support for this manuscript; contributed to the design; participated in the collection, analysis, and interpretation of data as well as in writing, reviewing, and approving the final version of this manuscript. No honoraria or payments were made for authorship.

FOOTNOTES

Author contributions: Bessissow T was involved in study design, coordinating the data collection, interpretation of the results, and review and revision of the manuscript; Ruel J, Nguyen GC, and Tarabain O were involved in coordinating the data collection, interpretation of the results, and review and revision of the manuscript; Foucault N and McHugh K were involved in study design, interpretation of the results, and review and revision of the manuscript.

Institutional review board statement: All sites had the study reviewed and approved by an ethics committee. While CEC Advarra IRB Services (Aurora, Ontario, Canada) reviewed and approved for some sites, other sites were approved through local/multi centres ethics committees (Dr. Everett Chalmers Regional Hospital, MUHC-Royal Victoria Hospital, CHUM-Hôpital Maisonneuve-Rosemont, CHAU-Hôpital Hôtel-Dieu de Levis, Royal University Hospital, Centre Hospitalier de l'Université de Sherbrooke, CHUM-Hôpital St-Luc, Zeidler Ledcor Centre, Ottawa Hospital-General Campus, Mount Sinai Hospital, London Health Sciences Centre, Centre Hospitalier de l'Université Laval (CHUL), University of Calgary Gastrointestinal Research Group).

Informed consent statement: All patients were required to sign a patient authorization form (or written informed consent) to participate in the study, and to disclose personal health information.

Conflict-of-interest statement: The authors have either received research support from, served as consultant, speakers bureau, scientific officer, participants of steering committees and advisory boards, and/or received honoraria from the following sponsors: T.B.: AbbVie, Janssen, Takeda, Merck, Pfizer, Roche, Bristol Myers Squibb, Gilead, Sandoz, Ferring, Alimentiv Inc. (formerly Robarts Clinical Trials); J.R.: AbbVie, Janssen, Takeda, Pfizer, Sandoz, Ferring, Alimentiv Inc. (formerly Robarts Clinical Trials); G.N.: AbbVie and Takeda; O.T.: AbbVie; N.F. and K.M.: are employees of AbbVie and may own AbbVie stock; L.P.B.: Dr. Peyrin-Biroulet reports personal fees from Galapagos, AbbVie, Janssen, Genentech, Ferring, Tillots, Celltrion, Takeda, Pfizer, Index Pharmaceuticals, Sandoz, Celgene, Biogen, Samsung Bioepis, Inotrem, Allergan, MSD, Roche, Arena, Gilead, Amgen, BMS, Vifor, Norgine, Mylan, Lilly, Fresenius Kabi, OSE Immunotherapeutics, Enthera, Theravance, Pandion Therapeutics, Gossamer Bio, Viatris, Thermo Fisher. Grants from AbbVie, MSD, Takeda, Fresenius Kabi. Stock options: CTMA.

Data sharing statement: AbbVie is committed to responsible data sharing regarding the clinical trials we sponsor. This includes access to anonymized, individual and trial-level data (analysis data sets), as well as other information (*e.g.*, protocols and Clinical Study Reports), as long as the trials are not part of an ongoing or planned regulatory submission. This includes requests for clinical trial data for unlicensed products and indications. This clinical trial data can be requested by any qualified researchers who engage in rigorous, independent scientific research, and will be provided following review and approval of a research proposal and Statistical Analysis Plan (SAP) and execution of a Data Sharing Agreement (DSA). Data requests can be submitted at any time and the data will be accessible for 12 mo, with possible extensions considered. For more information on the process, or to submit a request, visit the following link: https://www.abbvie.com/our-science/clinical-trials/clinical-trials-data-and-information-sharing/data-and-information-sharing-with-qualified-researchers.html.

STROBE statement: The authors have read the STROBE Statement—checklist of items, and the manuscript was prepared and revised according to the STROBE Statement—checklist of items.

Open-Access: This article is an open-access article that was selected by an in-house editor and fully peer-reviewed by external reviewers. It is distributed in accordance with the Creative Commons Attribution NonCommercial (CC BY-NC 4.0) license, which permits others to distribute, remix, adapt, build upon this work non-commercially, and license

their derivative works on different terms, provided the original work is properly cited and the use is non-commercial. See: https://creativecommons.org/Licenses/by-nc/4.0/

Abstract

BACKGROUND

Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors of the gastrointestinal tract. As most of them harbor a *KIT* mutation (75%), selective kinase inhibitors are the therapeutic option and show a sustained objective response among patients with metastatic or unresectable GISTs. A well-known higher risk of neoplasm has been described among renal transplant recipients (RTRs). Nevertheless, only few cases of GIST onset among transplant patients have been reported in the literature.

CASE SUMMARY

Here, we describe 2 cases of gastric GIST occurring during the follow-up of RTRs. We also review the existing literature concerning GIST occurrence in transplant patients. In total and in association with our 2 cases, 16 patients have been reported. The median age was 59.5 years and 69% were male. With a median tumor size of 45 mm, no patient displayed metastatic dissemination at diagnosis.

Time from transplantation to diagnosis was highly variable between 5 mo and 21 years. Histopathological data mostly revealed high risk of progression (43%). Death increased to 29% during follow-up. Surgical treatment was systematically performed when the tumor was operable (94%). The use of adjuvant therapy was uncommon (19%).

CONCLUSION
GISTs represent rare but potentially severe malignant complication among transplant patients.

Key Words: Gastrointestinal stromal tumors; Imatinib mesylate; Transplantation; Kidney transplantation; Proto-oncogene protein c-KIT; Case report

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are the most common mesenchymal tumors of the gastrointestinal (GI) tract[1]. GISTs arise from interstitial cells of Cajal (ICC), which are specialized mesenchymal cells located within the muscle of the GI tract. ICC play a critical role in regulating smooth muscle function and GI tract motility[2]. GISTs are mainly located in the stomach (55%) or the small bowel (30%). About 10% to 47% of patients have metastatic disease at diagnosis[3-5]. About 95% of GISTs display positive staining for the receptor tyrosine kinase KIT (or CD117), 75% of these tumors harbor a *KIT* gene mutation and 10% a platelet-derived growth factor receptor A (*PDGFRA*) gene mutation[6]. Among KIT-negative GISTs, immunohistochemical expression of discovered on GIST-1 (DOG-1) was found in 76% of the cases[7]. Consequently, selective tyrosine kinase inhibitors targeting KIT receptor have been used. The first one, imatinib mesylate (Gleevec®; Novartis, Basel, Switzerland), has shown a sustained objective response in a phase III trial among patients with metastatic or unresectable GISTs in immunocompetent patients[8].

In renal transplant recipients (RTRs), an increased risk of cancer has been reported especially for non-melanoma skin cancer, virus-associated cancer and lymphoproliferative disorders[9]. Currently, malignancy represents a major cause of mortality among RTRs[10]. Nonetheless, only few cases of GIST have been reported among transplant patients. Overall, 8 cases of GIST[11-17] and 2 cases of extra GIST (EGIST)[14,18] have previously been reported in RTRs and respectively 3 cases[19-21] and 1 case[22] in liver transplant recipients.

We report 2 cases of GIST occurring in RTRs and provide a review of the existing literature concerning GIST occurrence in transplant patients.

CASE PRESENTATION

Chief complaints

Case 1: A 60-year-old Caucasian man without any symptoms.

Case 2: A 56-year-old Caucasian man presented with upper GI hemorrhage.

History of present illness

Case 1: Hepatic magnetic resonance imaging (MRI) was performed to explore abnormal hepatic tests.

MRI revealed a 32 mm spherical tumor of the lesser curvature of the stomach.

Case 2: The upper GI hemorrhage led to gastric endoscopy, which revealed a spherical gastric tumor in the fundus.

History of past illness

Case 1: He had end-stage renal disease with a kidney biopsy compatible with nephronophthisis despite negative screening for mutation in hepatocyte nuclear factor 1 beta (*HNF1B*) gene. Hemodialysis was initiated in 2016. In October 2019, he received a kidney transplant from a deceased donor. The initial immunosuppressive therapy combined basiliximab, steroids, tacrolimus, and everolimus. Renal function at hospital discharge was 94 μmol/L, (normal range 53 μmol/L to 97 μmol/L). Initial maintenance immunosuppressive therapy associated steroids, tacrolimus, and everolimus. Due to relapsing lymphocele, everolimus was switched to mycophenolate mofetil (MMF). Moreover, a pre-existing mild cytolysis and cholestasis worsened after transplantation leading to the discontinuation of cotrimoxazole and MMF, which were replaced by atovaquone and belatacept (NULOJIX®; Bristol-Myers Squibb, New York, NY, United States), respectively.

Case 2: The patient developed end-stage renal disease of unknown origin. He received a kidney transplantation from a deceased donor. Due to preformed donor specific antibodies (anti-Cw15, mean fluorescence intensity of 6130) on the day of transplantation, induction immunosuppressive therapy combined basiliximab, steroids, MMF, cyclosporine, and intravenous immunoglobulins. At 10 d after surgery, a kidney biopsy was performed due to delayed graft function. It revealed acute tubular necrosis associated with possible acute humoral rejection (g1 cpt0 v0 i0 t0 according to Banff's classification[23,24], C4d immunostaining was negative). A treatment with high dose steroids, five plasma exchanges and rituximab[25] was initiated allowing improvement of renal function with a nadir in serum creatinine level of 170 μmol/L. Maintenance immunosuppressive therapy included steroids, cyclosporine, and MMF.

Personal and family history

Case 1: His other past medical history consisted in nonalcoholic steatohepatitis, Hashimoto's thyroiditis, and hypertension.

Case 2: The patient had no significant personal or family history.

Physical examination

Case 1: On admission, physical examination was unremarkable.

Case 2: Physical examination was unremarkable except for hematemesis.

Laboratory examinations

Case 1: The patient had mild cytolysis and cholestasis without any other biological abnormality.

Case 2: No abnormal blood test was noticed on admission.

Imaging examinations

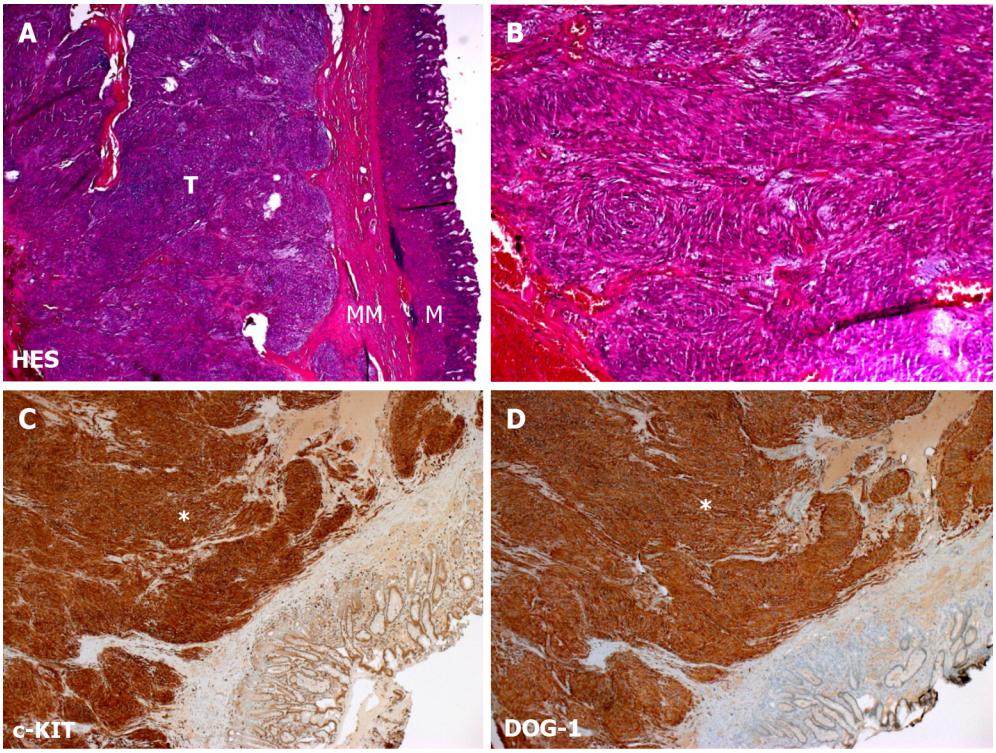
Case 1: Body computed tomography (CT) scan confirmed the absence of metastatic dissemination.

Case 2: Body CT scan was consistent with local tumor without metastatic localizations.

Initial diagnosis

Case 1: Upper GI endoscopy found a 3 cm submucosal tumor of the lesser curvature of the stomach. Tumor biopsies were performed using endoscopic ultrasound guidance. Cytological examination revealed spindle-shaped cells that showed positive staining for c-KIT and DOG-1 in immunohistochemistry, confirming the diagnosis of GIST (Figure 1).

Case 2: The gastric endoscopy revealed a spherical gastric tumor in the fundus with a typical macroscopic aspect of GIST.



Initial treatment

Case 1: Partial gastrectomy was performed without complication.

Case 2: Partial gastrectomy was performed.

Course of illness in the hospital

Case 1: No complication associated with the GIST of its treatment was noticed.

Figure 1 Histopathological features of case 1 gastrointestinal stromal tumor. A: Hematoxylin and eosin staining showing exophytic development of a tumor from the mucosa musculus (magnification, 2.5 ×); B: Hematoxylin and eosin staining showing spindle cell morphology composed of relatively uniform cells arranged in short fascicles (magnification, 20 ×); C: Immunohistochemistry showing strong positive staining for the protooncogene c-KIT (white asterisk; magnification, 5 ×); D: Immunohistochemistry showing strong positive staining for discovered on gastrointestinal stromal tumor protein 1 (white asterisk; magnification, 5 ×). M: Mucosa; MM: Mucosa musculus; T: Tumor.

Case 2: The patient was rapidly discharged after partial gastrectomy without complication.

FINAL DIAGNOSIS

Case 1

Histopathology revealed a 27 mm stromal tumor strongly positive for KIT and moderately positive for DOG-1 with a mitotic count of 2 mitosis for 5 mm^2. The tumor harbored an exon 11 (p. Val559Ala c.1676T>C) *KIT* mutation[23].

Case 2

Histopathology report described a 51 mm GIST strongly positive for KIT harboring a mitotic count of 10 mitosis for 5 mm^2. Of note, an exon 18 D842V *PDGFRA* mutation was identified.

TREATMENT

Case 1

Regarding the very low risk of progression, no adjuvant therapy was initiated.

Case 2

No adjuvant treatment was initiated at the time of diagnosis.

Table 1 Characteristics of 16 transplanted patients with gastrointestinal stromal tumors

	Overall number	
Male sex, *n* (%)	16	11 (69)
Age (yr), median (min; max)	16	59.5 (23; 74)
Type of organ transplantation, *n* (%)	16	
Kidney		12 (75)
Liver		4 (25)
Location of primitive tumor, *n* (%)	16	
Stomach		9 (56)
Small bowel		3 (19)
Colon		1 (6)
Other: pelvis, perineum, mesentery		3 (19)
Time from transplantation to diagnosis (mo), median (min; max)	16	32 (5; 252)
Metastatic dissemination at diagnosis, *n* (%)	16	0 (0)
Tumor size (mm), median (min; max)	15	45 (10; 230)
Risk of progression according to Joensuu's criteria, *n* (%)	14	
Very low		2 (14)
Low		4 (29)
Intermediate		2 (14)
High		6 (43)
Surgical treatment, *n* (%)	16	15 (94)
Adjuvant treatment, *n* (%)	16	3 (19)
Modification of immunosuppression, *n* (%)	11	9 (82)
Death during follow-up, *n* (%)	14	4 (29)

OUTCOME AND FOLLOW-UP

Case 1

The patient remains in remission at the 1-year follow-up.

Case 2

Two years later, a follow-up MRI revealed hepatic vascular nodules compatible with metastatic lesions. Treatment with imatinib mesylate was initiated. In the absence of a tumor response, imatinib was discontinued 4 mo later and sunitinib (SUTENT©; Bayer, Germany), an anti-angiogenic multikinase inhibitor (anti vascular endothelial growth factor-1, -2, -3, PDGFR-α,-β, c-KIT, fms-like tyrosine kinase 3, and RET) was introduced. Five months later, the onset of thrombopenia, neutropenia, and hepatic cytolysis led to replacement of sunitinib with regorafenib (STIVARGA©; Bayer Pharma AG, Germany), another multikinase inhibitor. Due to side effects and tumor progression, regorafenib was discontinued and dasatinib (SPRYCEL©; Bristol-Myers Squibb, New York, NY, United States) was introduced. Disease progression finally led to stopping all therapies in April 2019. Selective transarterial embolization was performed complicated with artery dissection of the kidney transplant requiring stent implantation. The patient was finally admitted with a clinical presentation of hydrops concomitant with acute renal injury and peritoneal carcinosis. The patient eventually died due to disease progression.

DISCUSSION

GISTs represent an uncommon malignant complication of immunosuppression state in solid organ transplantation. We describe 2 cases of typical GIST occurring early in the course of kidney transplantation. The first patient developed an isolated gastric GIST 5 mo after transplantation and the second 4 years after. Both were nonmetastatic at diagnosis although the second patient developed

Table 2 Clinical features and immunosuppression regimen of 16 transplant patients with gastrointestinal stromal tumor

Ref.	Age (yr)/sex	Transplanted organ	Time from transplantation to diagnosis	Location of primitive GIST	Metastasis at diagnosis	Evolution/delay	Immunosuppression before diagnosis	Immunosuppression after diagnosis
Agaimy and Wünsch [11]	59/F	Kidney	40 mo	Stomach	No	Relapse 68 mo	Not described	Not described

multiple hepatic metastasis 2 years after complete tumor resection. Of note, the mutation of *PDGFRA* D842V in the second case was associated with resistance to imatinib mesylate.

We looked for previously reported cases of GIST in the literature during the course of transplantation. We searched PubMed and Web of Science databases using the following Medical Subject Headings words: "Gastrointestinal stromal tumors" AND "Kidney transplantation" or "Gastrointestinal stromal tumors" AND "Transplantation." Using these terms, we found 8 and 31 articles, respectively. Only 12 articles were analyzed. From 2007 to 2020, 14 cases of GIST have been reported in transplant recipients [11-22]. We excluded reports of GIST occurring among nontransplant or bone marrow transplant patients. We also excluded article types different than case reports or case series.

Table 1 summarizes the main features of these patients including the 2 cases described in the present manuscript. Tables 2 and 3 give details on the 14 cases reported. In our literature review, the typical patient profile was a male patient with a median age of 59.5-years-old, who developed large nonmetastatic gastric tumors (median size, 45 mm). The delay between transplantation and diagnosis was highly

Table 3 Histopathological features, treatments, and outcome of 16 transplant patients with gastrointestinal stromal tumor

Ref.	Size (mm)	Mitotic count	Fletcher's criteria	Joensuu's criteria	Mutation identified	Resection	Initial adjuvant treatment	Second line treatment	Outcome

CsA: Cyclosporine.

variable, ranging between 5 mo and 21 years. Histopathological data mostly revealed high risk of progression (42.8%) and death occurred in 29% of the cases during follow-up. Surgical treatment was systematically performed if the tumor features were suitable (94%). The use of adjuvant therapy was uncommon (19%).

Several prognostic classifications have been used to evaluate the risk of recurrence of GIST after surgery. In 2002, Fletcher *et al*[26] claimed size of the tumor and mitotic count, Miettinen and Lasota[27] in 2006 added tumor location and Joensuu *et al*[28] in 2012 adjoined rupture of the tumoral capsule and male gender. Heinrich *et al*[29] demonstrated that *PDGFRA* and *c-KIT* were mutually exclusive proto-oncogenic mutations with similar biologicals consequences, even if associated with different prognostics. Molecular predictors of response to imatinib have been widely studied. Underlying *KIT* or *PDGFRA* mutations are the strongest predictors of imatinib sensitivity[30]. Mutations directly located in the *PDGFRA* binding site of imatinib or inducing variations in tridimensional conformation of the tyrosine kinase receptor and subsequently hiding the binding site, may explain inefficacy of therapy. For instance, *KIT* exon 9 mutation is less sensitive to imatinib and *PDFGRA* exon 18 D842V mutations is associated with imatinib resistance. Nevertheless, these mutations have been correlated with opposite

courses of the disease, indolent for *PDFGRA* exon 18 D842V mutation but aggressive for *KIT* exon 9 mutation[31]. These data should highlight the importance of molecular biomarkers to evaluate prognosis of GIST or EGIST at diagnosis.

Guidelines for the diagnosis, treatment, and follow-up of GIST have recently been published[32]. Management of local or locoregional disease should always aim for complete resection whenever possible. Otherwise, neoadjuvant treatment with imatinib for 6 to 12 mo should be used in case of sensitive mutation with an overall response rate of 50%[30]. Moreover, high-risk patients, as previously described, should receive adjuvant imatinib for a duration of 3 years[33]. Imatinib remains the first-line therapy for metastatic GIST. Several other targeted therapies such as sunitinib or regorafenib have emerged as second- or third-line treatment, and more recently avapritinib and ripretinib. Several biomarkers, such as *KIT* or *PDGFRA* mutations, are used as predictive factors for tumoral response to refine therapeutic strategies[32]. Data are missing concerning the level of tyrosine kinase inhibitors' efficacy in transplanted patients.

Data about the management of immunosuppressive therapy after the diagnosis of GIST are scarce. As both imatinib mesylate and cyclosporin are extensively metabolized by cytochrome P450 3A4, interaction occurrence has been documented[12]. Reduction in the dosage of cyclosporin should be performed if this treatment is maintained. Mammalian target of rapamycin inhibitors (mTORis) have shown antiproliferative properties among transplant patients. Schöffski *et al*[34] highlighted the potential efficacy of association of everolimus and imatinib in imatinib-resistant GIST in a phase II trial. Cheung *et al*[14] reported a case of complete tumoral response with sirolimus in a transplant patient with imatinib-resistant GIST. Among the patients described in Tables 1 and 2, mTORis have been initiated or switched in 4 of them. Three of them were alive and relapse-free at last follow-up and the last patient died from pneumonia 2 years after GIST diagnosis.

This study had several limitations. First, the retrospective analysis of GIST cases impairs the reliability of the data. Very few cases of GIST occurring after solid organ transplantation have been described in the last 15 years reducing the significance of this literature review. Moreover, it was unclear if GIST was a *de novo* feature in our first patient because of the short delay (5 mo) between transplantation and tumor discovery. Unfortunately, the latest available CT scan was performed 7 years before the transplantation. However, some previous cases reported GIST onset within the 1st year following transplantation[14,18-22].

CONCLUSION

To conclude, GISTs represent rare but potentially severe malignant complication among transplant patients. Further analysis of prognosis value of new biomarkers should improve therapeutic strategies.

Abstract

BACKGROUND

Gastrointestinal (GI) lipomas are benign submucosal tumors of mature adipocytes that arise mainly in the colon and stomach, sometimes in the ileum and jejunum, and rarely in the duodenum. Patients with symptomatic lipomas require endoscopic or surgical treatment. Spontaneous expulsion of lipomas after biopsy is a rare condition that has limited case reports.

CASE SUMMARY

A 56-year-old man presented to our hospital with intermittent postprandial epigastric fullness. Esophagogastroduodenoscopy (EGD) revealed a 10-mm soft yellowish submucosal lesion with the "pillow sign," located in the second portion of duodenum. Endoscopic ultrasonography (EUS) using a 12-MHz catheter probe showed a hyperechoic, homogenous, and round solid lesion (OLYMPUS EUS EU-ME2, UM-DP12-25R, 12-MHz radial miniprobe, Olympus Corporation, Tokyo, Japan). Deep biopsy was performed using the bite-on-bite technique with forceps. Histological examination was compatible with submucosal lipoma. The lesion spontaneously expelled 12 d after the biopsy. Follow-up EUS performed after 2 mo confirmed this condition.

CONCLUSION

Deep biopsy could lead to spontaneous GI lipoma expulsion. This might be the first step in lipoma diagnosis and treatment.

Key Words: Lipoma; Duodenal neoplasms; Spontaneous expulsion; Endoscopic biopsy;

Core Tip: Gastrointestinal lipomas are benign tumors consisting of mature adipocytes. Symptomatic patients may require endoscopic or surgical treatment. Here, we report a case of duodenal papillary lipoma, which was spontaneously expelled 12 d after a bite-on-bite deep biopsy with forceps. The spontaneous expulsion of the lipoma shows the possibility of performing a deep biopsy as a fenestration in the first step as a diagnostic and therapeutic procedure.

INTRODUCTION

Gastrointestinal (GI) lipomas are benign submucosal tumors of mature adipocytes that are commonly found incidentally on endoscopy and imaging. They arise throughout the GI tract, mainly in the colon (65%-75%), followed by the ileum and jejunum (25%)[1]. The duodenum is a rare site of GI lipomas, with only 4% of lipomas affected, mostly in the second portion of the duodenum[1]. Lipomas are rarely symptomatic and have no malignant potential. However, they occasionally result in hemorrhage, abdominal pain, intestinal intussusception, or obstructive jaundice, which are related to the characteristics of the lipoma, such as its size and location[1,2]. Symptomatic duodenal lipomas require treatment. They can be excised endoscopically or surgically. This report presents a case of duodenal lipoma diagnosed by endoscopic ultrasonography (EUS) that was spontaneously expelled 12 d after a bite-on-bite deep biopsy with forceps.

CASE PRESENTATION

Chief complaints

A 56-year-old Chinese man presented to our gastroenterology department with intermittent postprandial epigastric fullness for half a year.

History of present illness

The patient had early satiety and mild reflux, especially after greasy meals, without abdominal pain, melena, fever, or jaundice. The symptoms were moderate and paroxysmal, which affected his appetite. No weight loss was reported during the past half a year. There was no history of abdominal surgery.

History of past illness

The patient's past medical history was non-contributory.

Personal and family history

The patient has none family history.

Physical examination

On physical examination, the patient's vital signs were stable with a 37.2 °C body temperature on admission. The subject's height was 170 cm and weight was 80 kg, with body mass index of 27.68 kg/m^2. No obvious abnormalities were observed upon pulmonary and cardiac examination. There was no tenderness, mass, unusual bowel sounds, or Murphy's sign upon abdominal examination. No jaundice or superficial lymphadenopathy was observed.

Laboratory examinations

The analyses of complete blood count, blood biochemistry, and serum tumor marker levels were within the normal range.

Imaging examinations

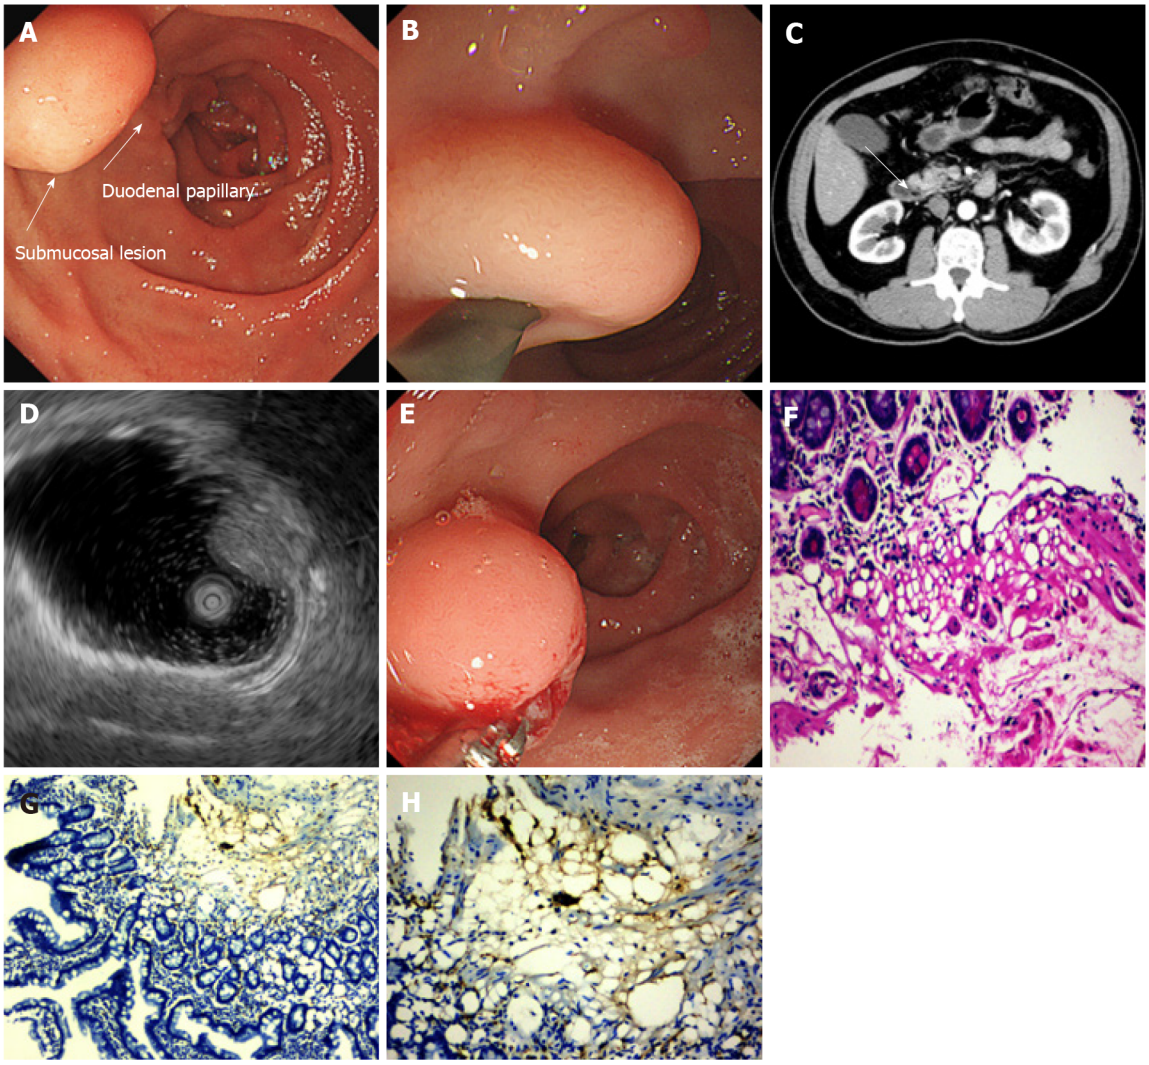
Esophagogastroduodenoscopy (EGD) revealed a 10-mm soft yellowish submucosal lesion with the "pillow sign," located in the second portion of the duodenum, directly upon the duodenal papilla (Figures 1A and B). Contrast-enhanced computed tomography (CT) revealed a suspicious low-density lesion in the periampullary region without enhancement (Figure 1C). Further EUS (OLYMPUS EUS EU-ME2, UM-DP12-25R, 12-MHz radial miniprobe, Olympus Corporation, Tokyo, Japan) revealed a hyperechoic, homogenous, round solid lesion arising from the submucosal layer, accompanied by echo attenuation (Figure 1D).

FINAL DIAGNOSIS

Deep biopsy was performed *via* the bite-on-bite technique using forceps (Micro-Tech Co. Ltd., Nanjing, China) (Figure 1E). Microscopic examination showed a small amount of roundish adipocytes in the submucosa layer, expressing S-100. Tiny lipid droplets were observed in cell cytoplasm. The glands of epithelium were neatly arranged on top. The small fragments of biopsy compatible with a submucosal lipoma. (Figures 1F-H). Based on the classic endoscopic signs, EUS characteristics and histology of the lesion, a diagnosis of duodenal lipoma was made. No bleeding, perforation, or any other complications were observed the patient.

TREATMENT

During endoscopy, the patient underwent neither resection nor hemostatic procedures after the biopsy. Prokinetics and proton pump inhibitor were prescribed to relieve the symptoms. Considering the size and location of the lipoma, we suggested that the patient remain under observation. However, the patient was extremely anxious about the lesion and insisted on its removal; thus, endoscopic resection and prophylactic pancreatic duct stenting were attempted.



OUTCOME AND FOLLOW-UP

The patient reported milder symptoms and fewer episodes after prescription. However, he insisted on resection. On endoscopic resection, which was 12 d after the biopsy, the lipoma had disappeared, with only a red scar and inflammatory mucosa residue in situ of the lesion (Figures 2A and B). Two months after the first EUS, a follow-up EUS was performed, showing that macroscopically the site displayed signs of inflammation and scarring. And the former lesion no longer existed in the surrounding duodenal wall in EUS (Figures 2C-E). After endoscopy, mild symptoms occasionally occurred during the follow-up period, without medications.

DISCUSSION

Duodenal lipoma is a rare benign tumor of the GI tract accounting for 4% of GI lipomas, most of which occur in the second portion of the duodenum[1,2]. Duodenal lipoma can be symptomatic or asymptomatic, depending on the size and location. Moreover, 80% of symptomatic duodenal lipomas have a diameter of > 2 cm, mainly manifesting as intestinal obstruction, hemorrhage, and jaundice[2,3]. The tumor in our case was a submucosal lipoma, which accounts for > 90% of intestinal lipomas, with the others arising from the intermuscular tissue and subserosa[4]. Imaging of lipomas is well recognized. CT shows well-defined border tumors in a uniform low density with fat attenuation of -120 HU to -60 HU, while magnetic resonance imaging shows high-intensity lesion with on T1-weighted, iso-signal intensity on T2-weighted, and low intensity on fat-suppressed T2-weighted imaging[5,6]. The classic endoscopic signs as "pillow sign," "tenting sign," and "naked fat sign" indicate the possibility of lipomas. The typical EUS finding for submucosal lipomas is a homogeneous hyperechoic mass originating from the submucosal layer, with echo attenuation behind and/or inside the rear area[7]. In our case, the duodenal lipoma was present in the second portion of the duodenum, immediately upon the duodenal papilla, with classic imaging on EGD, CT, and EUS, with pathologically confirmation.

Symptomatic lipomas require treatment, including removal *via* endoscopy or surgical excision. There are four techniques for endoscopic excision: Dissection-based resection, endoscopic mucosal resection (EMR), loop-assisted resection, and unroofing[8] (Figure 3). Dissection-based resection defines as endoscopic procedure mainly using dissection-based techniques, such as ESD. Loop-assisted resection is the procedure performed with loop for haemostatic or removal reasons. Because of the poor conduction of electric current in the adipose tissue, endoscopists must apply a higher electrical output during

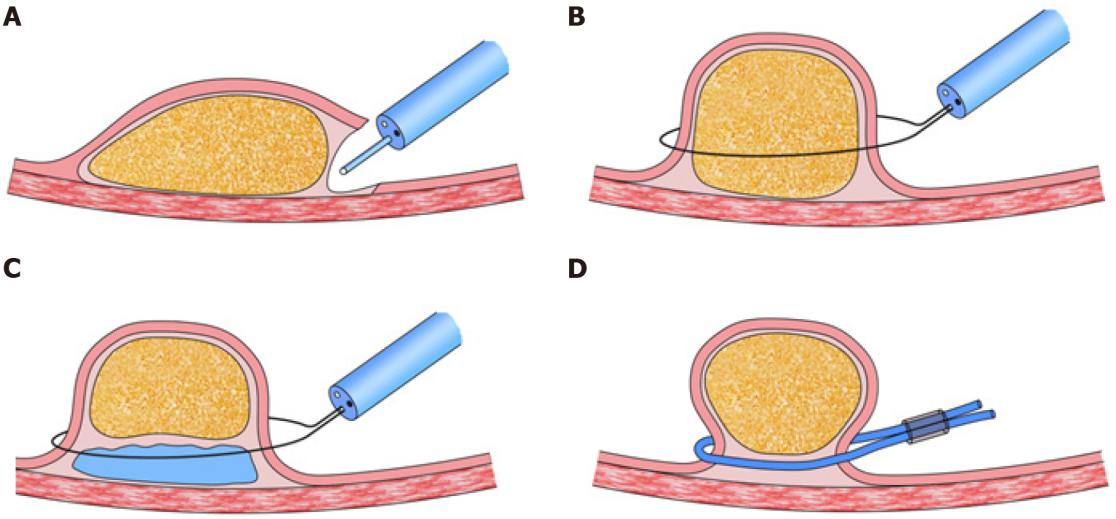
Figure 1 Imaging findings at the time of diagnosis. A and B: Esophagogastroduodenoscopy revealed a 10-mm soft yellowish submucosal lesion with the "pillow sign," located in the second portion of duodenum, immediately upon the duodenal papillary; C: Abdominal contrast-enhanced computed tomography shows a suspicious low-density lesion in the periampullary region without enhancement (white arrow); D: Endoscopic ultrasonography with a 12-MHz catheter probe showed a hyperechoic, homogenous, and round solid lesion with echo attenuation, arising from the submucosal layer; E: Deep biopsy *via* bite-on-bite technique with forceps was performed; F-H: Microscopic examination showed a small amount of roundish adipocyte in the submucosa layer, expressing S-100. Tiny lipid droplets were observed in cell cytoplasm. The glands of epithelium were neatly arranged on top (F: Hematoxylin and eosin staining, × 200; G: Immunohistochemical S-100 stain, × 100; H: IHC S-100 stain, × 200).



resection, which increases the possibility of complications, such as hemorrhage and perforation, especially for giant lipomas. The unroofing technique, which cuts off the upper half of the lesion, with the remaining adipose tissue extruded from the open surface, was first applied by Mimura *et al*[9]. Its efficacy and safety have been approved by several authors in case reports[10-14]. Bronswijk *et al*[8] collected 24 studies (77 lesions included) of endoscopic treatment for colon lipomas, and a systematic review indicated that endoscopic resolution rates were 60%, 100%, 93.6%, and 93.1% for unroofing, dissection-based resection, EMR, and loop-assisted resection, respectively. The former two techniques reported no adverse events, whereas the latter two showed complication rates of 12.9%-13.8%. Yamamoto *et al*[15] proposed a two-step hybrid technique that combined endoscopic unroofing with EMR for giant lipomas.

Spontaneous disappearance or expulsion of lipomas is an extremely rare manifestation that had limited case reports. There have been some cases of spontaneous expulsion per rectum of submucosal lipomas without any intervention. With a certain volume, these submucosal lipomas cause intussusception, which might lead to ischemia, necrosis, and breakage, and the lipomas were spontaneously expelled[4,16-20]. In our case, the lipoma was spontaneously expelled after deep biopsy *via* the bite-on-bite technique with forceps, which we suspected was the result of fat extravasation from the biopsy site as fenestration over time. There were a few cases of spontaneous expulsion after biopsy of GI lipoma[21-24]. Kurahara *et al*[21] first reported a gastric lipoma that was expelled after biopsy. Ishiyama *et al*[22] reported the expulsion of a colonic lipoma after biopsy. We speculated that, in these cases, three

Figure 3 Techniques for endoscopic excision of gastrointestinal lipomas[14]. A: Dissection-based resection technique; B: Unroofing technique; C: Endoscopic mucosal resection; D: Loop-assisted resection technique.

conditions need to be met for the lipoma to disappear: (1) The overlying mucosa and tumor capsule must be damaged by either acquired opening, such as unroofing and deep biopsy, or spontaneous opening, such as ischemia and ulceration; (2) The lipoma should arise from the submucosal layer; and (3) The extravasation rate, which depends on the tumor volume and size of the fenestration, should be faster than the mucosal healing rate. In this case, the special anatomical position might have facilitated pancreatic lipase and bile digestion of the lipoma to speed up the discharge process.

The treatment techniques and cases of spontaneous expulsion lipomas indicate that we might conduct a deep biopsy based on bite-on-bite techniques or more intense "tunneled biopsy" as fenestration routinely when a lipoma is diagnosed with typical EUS and EGD. Such biopsies could aid in further diagnosis in pathology and reduce the size or even remove the lesion as a treatment, particularly in cases where the lesion is relatively large or located in the small intestine[25]. A simple deep biopsy

during diagnosis might decrease the complications caused by the lesion itself or by the next step of endoscopic or surgical resection. Larger studies are necessary to make conclusion on the efficacy of fenestration on lipoma and algorithm of treatment.

CONCLUSION

In this case, we present the spontaneous expulsion of a duodenal lipoma 12 d after a bite-on-bite deep biopsy. Treatments for benign and slow-growing tumors include endoscopic dissection-based resection, EMR, loop-assisted resection, endoscopic unroofing, and surgical resection. The expulsion of lipoma after biopsy enlightens us the possibility of taking a deep biopsy as a fenestration in the first step as the diagnostic and therapeutic procedure.

ACKNOWLEDGEMENTS

Yi-Miao Zhu would extend her sincere gratitude to Yuan Chen for his careful review of the pathology, valuable suggestions, and inspiring advice of the case. Special thanks should go to her beloved husband for his continuous support and encouragement.

ABOUT COVER

Editorial Board of *World Journal of Gastroenterology*, Yoichi Matsuo, MD, PhD, Professor, Department of Gastroenterological Surgery, Nagoya City University Graduate School of Medical Sciences, Kawasumi 1, Mizuho-cho, Mizuho-ku, Nagoya 4678601, Japan. matsuo@med.nagoya-cu.ac.jp

AIMS AND SCOPE

The primary aim of *World Journal of Gastroenterology* (*WJG*, *World J Gastroenterol*) is to provide scholars and readers from various fields of gastroenterology and hepatology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online. *WJG* mainly publishes articles reporting research results and findings obtained in the field of gastroenterology and hepatology and covering a wide range of topics including gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, gastrointestinal oncology, and pediatric gastroenterology.

INDEXING/ABSTRACTING

The *WJG* is now abstracted and indexed in Science Citation Index Expanded (SCIE, also known as SciSearch®), Current Contents/Clinical Medicine, Journal Citation Reports, Index Medicus, MEDLINE, PubMed, PubMed Central, Scopus, Reference Citation Analysis, China National Knowledge Infrastructure, China Science and Technology Journal Database, and Superstar Journals Database. The 2022 edition of Journal Citation Reports® cites the 2021 impact factor (IF) for *WJG* as 5.374; IF without journal self cites: 5.187; 5-year IF: 5.715; Journal Citation Indicator: 0.84; Ranking: 31 among 93 journals in gastroenterology and hepatology; and Quartile category: Q2. The *WJG*'s CiteScore for 2021 is 8.1 and Scopus CiteScore rank 2021: Gastroenterology is 18/149.

Abstract

Robotic colonoscopes could potentially provide a comfortable, less painful and safer alternative to standard colonoscopy. Recent exciting developments in this field are pushing the boundaries to what is possible in the future. This article provides a comprehensive review of the current work in robotic colonoscopes including self-propelled, steerable and disposable endoscopes that could be alternatives to standard colonoscopy. We discuss the advantages and disadvantages of these systems currently in development and highlight the technical readiness of each system to help the reader understand where and when such systems may be available for routine clinical use and get an idea of where and in which situation they can best be deployed.

Key Words: Robot-enhanced procedures; Colonoscopy; Endoscopy; Capsule endoscopy; Colorectal cancer; Colonic polyp

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: Colorectal cancer is a common cause of cancer related mortality. Detection and removal of precancerous polyps reduces the risk of colorectal cancer. Colonoscopy is the gold standard investigation for colorectal polyps and cancer but can be uncomfortable due to the mechanics of the procedure. Robotics has the potential to reduce the discomfort and improve the procedure for patients, while improving key performance indicators. Robotics can offer a more intuitive endoscopic appearance, using various methods to negotiate the colon to reduce discomfort. Robotics could lead to a more effective, better tolerated, safer, autonomous colonoscopy with minimal operator interaction.

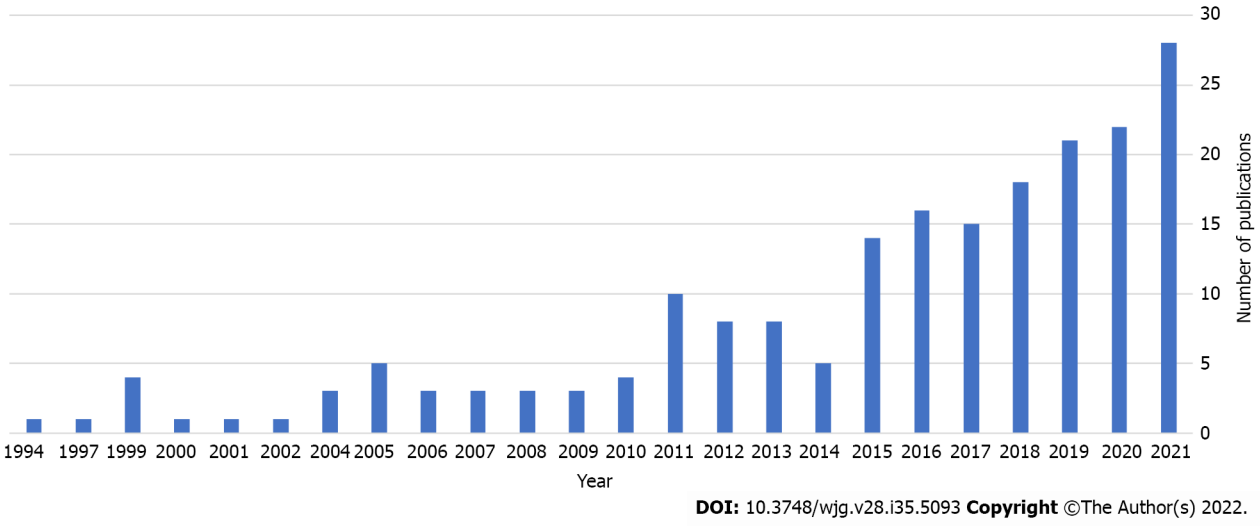
INTRODUCTION

Colorectal cancer incidence

Colorectal cancer (CRC) is the third most diagnosed cancer and the second most common cause of cancer related mortality worldwide[1]. Many countries, particularly those with a high human development index (HDI), continue to see an increasing incidence[2]. Rapid increases in the incidence of CRC can be seen in countries transitioning from medium to high HDI[2]. Although CRC aetiology is heterogeneous, the majority are sporadic, and the increasing incidence has been attributed to the western lifestyle and increasing levels of obesity[3].

The majority of CRCs have a detectable precursor lesion, a colonic polyp, which can be present for many years before cancer develops[4]. Endoscopic resection of colonic polyps has been shown to reduce cancer related mortality by up to 53%[5]. More and more countries are utilising screening programmes to control the increasing incidence of CRC. Screening programmes vary in nature and often utilise faecal testing such as faecal immunochemical testing (FIT). However, colonoscopy remains the gold standard for diagnosing and removing colonic polyps. Colonoscopy is also utilised in many polyp, colitis, and hereditary CRC surveillance programmes[6-9].

Despite the recommendations for colonoscopy as a diagnostic, screening, or surveillance tool, it is often underutilised. Delays in colonoscopy following a positive FIT has been shown to increase the likelihood of finding advanced adenomas, CRC, and advanced CRC[10]. A meta-analysis looking at second evaluation after a positive faecal occult blood test found that only 72.5% underwent a second evaluation in the form of any lower gastrointestinal investigation[11]. Additionally, a recent international survey of FIT screening programmes found that only 79% of those with a positive FIT underwent a colonoscopy[12]. Studies from Lee *et al*[13] and Zorzi *et al*[14] suggest the risk of CRC related mortality is double in those with a positive FIT who refuse colonoscopy than those who undergo a colonoscopy [13,14].



The reason for a lack of follow-up investigation may be the decision of a healthcare worker, for example due to co-morbidity. However, approximately 10% of those with a positive faecal blood test that are not followed up are due to patient refusal to have a colonoscopy[15]. Alternative tests such as computed tomography colonography (CTC) and colon capsule are available, and their merits will be discussed in future sections. Several qualitative studies have been done exploring the barriers and facilitators to colonoscopy. Although the barriers are numerous, complex, and interrelated, previous bad experiences of colonoscopy and fear of pain or discomfort are commonly cited[15-17].

History of colonoscopy

The first descriptions of an endoscope came from Bozzini in 1805 which he called the Lichtleiter (light conductor)[18,19]. Several rigid endoscopes were subsequently invented, but it was over a century before Wolfe and Schindler developed the semi-rigid gastroscope which paved the way for our endoscopes of today[20]. The evolution of the modern endoscope gained speed in the 1950s when Hirschowitz and Curtiss developed the fibreoptic endoscope[21]. A flexible endoscope was developed in Japan to assess of the lower GI tract, the first colonoscope, and by the late 1960s Shinya introduced therapeutics by performing the first polypectomy[21,22]. The charged couple device (CCD) was developed and in the 1980s the videoendoscope was born. Since then, the optics have been the mainstay of research focus and endoscope advancements. We have ever evolving improvements in the optics such as high definition, magnification, and an increasing range of image enhancement virtual chromoendoscopy options. And although the technique by which we perform colonoscopy has been refined, reducing risk and discomfort, we still push and torque a semirigid tube from the distal end to advance around the colon. The introduction of electromagnetic guidance, such as ScopeGuide (ScopeGuide Endoscope Insertion Tube System, Olympus America, Inc., Allentown, PA), allowed further refinement of the technique. However, it was not until the 1990s, with advances in robotics, that the potential for a new way to perform colonoscopy was explored.

Robots in endoscopy

Following Food and Drug Administration (FDA) approval in 2000 of robotic surgical master-slave platforms such as da Vinci and Zeus, there has been an upsurge in interest in robotic endoscopic devices. Figure 1 shows the increasing number of robotic colonoscopy articles on PubMed[23]. Robotic colonoscopy has potential benefits over conventional colonoscopy (CC) for the patient as well as the endoscopist and service provider. Robotics in colonoscopy is not only limited to diagnostic procedures,

DOI: 10.3748/wjg.v28.i35.5093 **Copyright** ©The Author(s) 2022.

Figure 1 PubMed search for "robotic colonoscopy" showing the increasing number of papers over the last 3 decades[23].

the additional dexterity and triangulation offered by many robotic platforms has great potential in therapeutic procedures such as endoscopic submucosal dissection (ESD).

Recent advances in robotics and miniaturisation, as well as the evolving nature of artificial intelligence (AI) in endoscopy, make this the perfect time to explore robotic colonoscopy. The expanding use of surgical robotic platforms should make patients and endoscopists more accepting of these new technologies in endoscopy. The potential for teleoperated endoscopes to facilitate "medical distancing" is also a concept of increasing interest given the current severe acute respiratory syndrome coronavirus 2 global pandemic.

For robotics to be accepted in endoscopy they must not only offer the same role as CC, but more. The ideal robotic colonoscope should fulfil several criteria as listed in Table 1.

POTENTIAL BENEFITS OF ROBOTIC COLONOSCOPY OVER CC

Patients

Much work in robotic colonoscopy is aimed at delivering a less painful and lower risk endoscopic procedure by reducing the forces on the colonic mucosa and tethering structures. The principal method of reducing this discomfort is through altering the actuation method. Many devices have taken inspiration from nature through biomimicry, for example inchworm or snake like movements. Others use external actuation, such as magnets to pull the device through the colon. A lower discomfort procedure also offers the potential for less anaesthetic/sedative use, further lowering the risk of colonoscopy[24]. Miniaturisation, and particularly capsule endoscopy, have the potential to offer a less invasive, less embarrassing, and more convenient option for patients. Some devices may even be provided in a community setting, negating the need to travel to hospital. Although incomplete colonoscopy rates have improved over the last few decades, there remain a number of patients who require a second procedure. Robotics has the potential to reduce the number of failed procedures by improving caecal intubation rates (CIRs).

Endoscopists

Training in both the diagnostic and therapeutic aspects of colonoscopy take considerable time[25,26]. Robotics has the potential to make colonoscopy training easier through more intuitive controls, autonomous features and the increased dexterity offered by many platforms. Less loop formation and lower discomfort rates could translate into improved completion rates. The improvement in manoeuvrability could reduce polyp miss rates and potential post-colonoscopy CRCs. Robotics has the potential to 'democratise' colonoscopy, reducing the variability in polyp detection rates by improving the detection rates of less well performing endoscopists. Many platforms are aiming to improve the ergonomics of colonoscopy in an attempt to reduce fatigue and endoscopy related musculoskeletal injuries[27,28].

Service providers

Our forebearers in surgical robotics have yet to provide any clear answers as to the cost effectiveness of robotic procedures. The initial purchase costs are often high, but the cost benefit thereafter is unclear

Table 1 The features of the ideal robotic colonoscope

No.	Ideal robotic colonoscope features
1	Affordable
2	Acceptable to patients and endoscopists
3	More comfortable than conventional colonoscopy
4	Lower risk than conventional colonoscopy
5	Improved caecal intubation rate compared to conventional colonoscopy
6	Offer at least comparable mucosal visibility with the option of image enhancement (virtual chromoendoscopy)
7	Capable of taking biopsies and therapeutics such as polypectomy
8	Offer integration with artificial intelligence for polyp detection and characterisation
9	Ideally have autonomous features, such as self-navigation
10	Reduce the training time to achieve competence compared to conventional colonoscopy
11	Procedure times should be less than, but must not be significantly longer than, conventional colonoscopy
12	Have sustainability in mind in the manufacturing, reprocessing or disposal of the device

and variable between procedures[29-32]. The Endotics robotic colonoscope, discussed in detail later, claims to offer a cost neutral alternative to standard colonoscopy[33]. Although few robotic colonoscopes are at a technology readiness level (TRL) to perform health economics studies, we will aim to discuss several potential benefits to service providers.

Unsedated procedures offer cost and efficiency saving benefits through utilisation of less anaesthetic and recovery staff, as well as a quicker turnaround within the department. There is an increasing demand on endoscopy services caused by an aging population, increasing environmental and behavioural risk factors, and ever increasing screening and surveillance populations[34]. The addition of the recent pandemic associated service provision issues and enhanced infection control and prevention measures are stretching endoscopy departments to their limit[35]. The ideal robotic colonoscope to ease these pressures would require less staff and be quicker, pain-free, teleoperated, mobile and have therapeutic capabilities. A single use device would negate the cost associated with reprocessing, as well as potentially reducing cross contamination[36]. Improvements in sustainability may also be achieved using single use devices which reduce the need for carbon- and water-heavy reprocessing facilities.

AVAILABLE ALTERNATIVES TO COLONOSCOPY

Alternative procedures to assess the colon are required if a patient refuses or is unfit for a colonoscopy, or in the event of an incomplete colonoscopy. There are a number of alternatives to CC, most commonly CTC and colon capsule endoscopy (CCE). The advantages and limitations of these commonly used alternatives are shown in Table 2.

CTC, until the recent adoption of CCE, was the most commonly used alternative to colonoscopy. CTC has a similar sensitivity to colonoscopy for the detection of large (> 10 mm) polyps and CRC[37,38]. CTC is better tolerated than CC and over half of patients have an additional pathology detected on the scan [37,39]. However, approximately 30% of CTC patients require further investigation, often in the form of a colonoscopy to remove polyps[38]. CTC is significantly less sensitive than colonoscopy for detection of small polyps and flat lesions such as sessile serrated lesions[40].

CCE is better tolerated than CC[41]. A recent meta-analysis showed that when compared with CC, CCE had a sensitivity and specificity of 87% and 88% respectively, for detection of polyps ≥ 6 mm[42]. However, a large retrospective study by Benech *et al*[43], showed that 19% of CCEs had a missed advanced adenoma when they underwent a further procedure[43]. When comparing CTC to CCE, Spada *et al*[44] compared 100 patients with an incomplete colonoscopy and found a relative sensitivity of 2.0 in favour of CCE for identifying polyps ≥ 6 mm[44]. The recently published TOPAZ study also suggested CCE was superior to CTC for the detection of polyps ≥ 6 mm and non-inferior for polyps ≥ 10 mm[45]. However, some inherent biases and flaws in methodology of the TOPAZ study have been pointed out by Burr *et al*[46] which cast some doubt on the validity of these results[46]. A meta-analysis of CTC *vs* CCE in incomplete colonoscopies showed that CCE had superior diagnostic yields for all polyp sizes (37% *vs* 10%), but poorer completion rates (76% *vs* 98%)[47].

Magnetic resonance imaging techniques, magnetic resonance colonography (MRC), have also been evaluated as an alternative to CC. MRC has the benefits of being non-invasive and not carry the radiation risks associated with CTC. However, magnetic resonance imaging scanners can be claustro-

Table 2 Advantages and limitations of conventional colonoscopy alternatives

Procedure	Advantages	Limitations
Conventional colonoscopy	Extensive knowledge base and expertise already available, diagnostic and therapeutic capabilities. Gold standard	Bowel cleansing required, painful for some (sedative and analgesics often required), prolonged training period required, risk of perforation due to forces required
CT colonography [39,41,101]	Lower intensity bowel cleansing, shorter procedure, less discomfort (no sedation or analgesia needed), other intraabdominal pathology can be detected, lower risk of perforation, better patient tolerance	Low dose radiation used, lower sensitivity for small and flat polyps, no therapeutic capability, no direct mucosal visualisation, limited evidence of a benefit in CRC incidence or mortality
Wireless capsule colonoscopy	Minimally invasive, painless, better patient tolerability, low perforation risk	Aggressive bowel cleansing required, lower sensitivity than CC for polyps, no control of the capsule, no therapeutic capability, risk of capsule retention, limited battery life can cut out before complete colon visualisation

CRC: Colorectal cancer; CC: Conventional colonoscopy; CT: Computed tomography.

phobic for some and are very time consuming procedures. A meta-analysis in 2009 found the sensitivity of MRC for the detection of CRC was 100%, but was only 84% for polyps ≥ 10 mm[48]. A study in 30 lynch syndrome patients who underwent tandem MRC then colonoscopy, found that MRC was unable to detect any lesions under 10 mm, including one missed cancer[49]. Another study of MRC in asymptomatic individuals found MRC and colonoscopy had sensitivities of 78.4% and 97.3%, respectively, for polyps ≥ 6 mm[50]. Although some meta-analysis suggest MRC has a good sensitivity for the detection of CRC, other meta-analysis suggest the sensitivity for detection of all lesions could be as low as 75%[51].

CHALLENGES FOR ROBOTIC COLONOSCOPY

As technologies advance, many of the technical challenges to robotic colonoscopy are being resolved. The deformable, slick surface of the colon and it's many and varying orientations and bends make for a challenging environment and a multitude of solutions have been proposed by various research teams.

Locomotion

The first challenge for any robotic device is locomotion. Passive locomotion is adopted by most capsule endoscopes, in which the device passes through the gastrointestinal tract by natural peristalsis. However, the lack of control has the consequence of potentially missing lesions and rules out any therapeutic application.

Actively controlled robotic colonoscopes can be divided into internally and externally actuated devices. Internally actuated devices control propulsion by interacting directly with the surrounding environment by means of wheels, propellers, belts or bio-mimicked animal-like movements. Much inspiration for the locomotion of these devices has been taken from nature with many attempting to copy the movements of animals such as snakes, earthworms, or caterpillars, and some even mimicking the movement of micro cilia. These actuation principles are achieved using electromechanical or pneumatic mechanisms, or a combination of both. External actuation involved controlling the internal device by means of an external mechanism such as magnetic fields and field gradients. With external magnetic actuation comes the challenge of localisation of the endoscope within its environment.

Localisation

Localisation refers to the position and orientation (*i.e.*, pose) of the device. Localisation can be relative or absolute. Relative localisation is a well-developed technology and is implemented in a number of wireless capsule endoscopes (WCE) giving an estimated position with respect to the anatomy. Absolute localisation gives an accurate position and orientation. Several proposed solutions have been investigated in endoscopes including magnetic, ultrasound, radiofrequency and computer-vision technology. Many WCEs use radiofrequency localisation, current capsules have an error in position on average 38 mm and up to 100 mm[52]. Magnetic localisation is gaining increasing academic interest, and can be combined with magnetic actuation. Magnetic localisation can perform a 6 degrees of freedom (DOF) localisation with an average error in position and orientation under 5 mm and 6 mm, respectively[53].

Miniaturisation

Miniaturisation is a challenge for all robotic colonoscopes, but is of particular importance in capsule endoscopy. A capsule endoscope contains several components: External case, optical window, light emitting diode (LED), lens, image sensor, radio frequency transmitter, antenna, and a power source.

Powering a capsule endoscope to allow for the variable colonic transit times requires a battery sufficiently large and often means adjusting the frames *per* seconds, and ultimately sensitivity, to preserve battery life. All this must then fit within a safe size for transit through the GI tract. Most capsule endoscopes are 11 mm in diameter and up to 32 mm in length with a battery life now exceeding 10 h and often containing two cameras[34]. One proposed method to overcome the miniaturisation challenge is external actuation *via* magnetic coupling, reducing the size of the battery in capsules and the need for intricate mechanisms of locomotion. One such commercially available capsule endoscope which already takes advantage of magnetic coupling is the NaviCam (Ankon Technologies, Wuhan, Shanghai, China) for inspection of the upper gastrointestinal tract[54].

Patient tolerance

The goal for most robotic colonoscopes is to improve the patient experience. For most devices this takes the form of reducing discomfort and risk. Capsule endoscopes achieve this by causing no distortion to the GI tract during their passive transit. Actively controlled devices aim to traverse the colon retrograde while reducing distortion and pressure exerted, resulting in less pain. Potentially also reducing the risk of perforation associated with the forces often required to torque and push around the colon in CC. Various actuation methods aim to tackle this problem by rolling, walking, inching, slithering, or pulling with magnets along the colon.

Cost

Not many robotic colonoscopy devices have health economic studies assessing their financial impact. Even the colon capsule, which is now available as an alternative to CC in some health services such as the National Health Service in the United Kingdom, has yet to show any cost effectiveness benefit over CC[55].

Sustainability

Reprocessing presents a massive challenge in robotic colonoscopy due to the intricacy of some devices. Many researchers are pursuing the potential of single use devices. With over 18 million endoscopic procedure *per* year in the United States, endoscopy is the third highest generator of waste in healthcare. Endoscope reprocessing uses up to 100 L of water as well as the electricity, heat, disinfectants and detergents[56]. Single use endoscopes have the potential to avoid this carbon heavy process. Provided the disposal of the device does not incur a higher carbon footprint, single use robotic devices have the potential to present a greener option for colonoscopy.

Autonomy

Perhaps the most notable evidence of robotic autonomy in day-to-day life is in automotive vehicles which can park and even navigate with minimal external input. However, medical robotics is also seeing an evolution in autonomy. Standard colonoscopy is completely under the control of the endoscopist with no autonomy. The introduction of AI for polyp detection has moved endoscopy into the first level of autonomy by visually assisting the endoscopist. Robotic colonoscopes have the potential to push the levels of autonomy much further. Devices capable of autonomously navigating the colon are being researched. However, with such levels of autonomy come challenges such as ethical and legal considerations.

TRL

TRL assessment was introduced by NASA in the 1980 to replace the traditional research and development categories: Basic research, feasibility, development, and demonstration[57]. TRL provides an objective 9 stage assessment of how advanced a technology is towards adoption[58]. When discussing each device, we will attempt to give our objective assessment of the TRL of each device. The score assigned will range from 1 (basic principles of the technology observed and report) to 9 (proof of real-world successful use of the technology) as described in Table 3, and a score will be assigned to each device described alongside the device characteristics in Table 4.

ROBOTIC COLONOSCOPES

For the purpose of this review article a selection of the most advanced platforms will be discussed, dividing them into active flexible platforms, passive devices, robot assisted platforms and robotic platforms with therapeutic applications. A table offering additional detail on the devices, as well as several more devices, is available in Supplementary Table 1.

Table 3 Technology readiness levels as applicable to robotic colonoscopy[57,102,103]

TRL	Definition	Supporting information relevant to robotic colonoscopy
1	Basic principles observed and reported	Published research on the core principals of the technology
2	Technology concept and/or application formulated	Moving from principals to applied research with potential applications speculated
3	Analytical and experimental proof of concept	Active research and development proving the concept within a laboratory setting. Benchtop testing
4	Component validation in laboratory environment	Proof of concept and safety in an *ex-vivo* animal colon
5	Component/system validation in a relevant environment	*In-vivo* animal testing with an aim at providing relevant evidence for human testing or FDA approval
6	High fidelity alpha protype demonstration in a relevant environment	Clinical trials assessing feasibility and safety in small number of humans
7	Beta prototype demonstrated in a relevant environment	Clinical safety and effectiveness trials. Determination of risks and adverse events. Final design validation
8	Completed system and qualified to relevant requirement/standards through testing and demonstration	FDA or equivalent approval
9	Actual system proven through successful operation	Device being marked with post-market studies proving real world operational capability

Adopted from United States Department of Defense Technology Readiness Assessment (TRA) Guidance document, and the supporting evidence required from the United States Department of Defense Technology Readiness Assessment (TRA) Desk book. TRL: Technology readiness level; FDA: Food and Drug Administration.

Table 4 Active flexible colonoscopy platforms with technology readiness level

Device name (manufacturer)	Latest study	Outcomes	TRL
Aer-O-Scope-*GI View Ltd., Ramat Gan, Israel*[21,59-61,63,64]	2016: Human tandem study, 58 CRC screening patients. CIR: 98.2%. CIT: 11 min. 87.5% of polyps detected. No PREMs	CE marked and FDA approved. Balloon propulsion model no longer manufactured	8
ColonoSight-*Stryker GI Ltd., Haifa, Israel*[65,66]	2008: Human study on 178 participants. CIR 90%. CIT: 11.2 min. No PREMs	FDA approved. No longer manufactured	8
Consis medical-*Beer'Sheva, Israel*[21,67]	None available	No regulatory approvals	3
Endoculus-*Department of Mechanical Engineering & Division of Gastroenterology, University of Colorado, United States*[20]	2020: *In-vivo* and *ex-vivo* porcine colon in one. Unable to traverse an *in-vivo* colon, but capable of negotiating an *ex-vivo* porcine colon	No regulatory approvals	4
ENDOO robotic colonoscope-*Endoo Project, Pisa, Italy*[87-89]	2020: *Ex-vivo* porcine colon human simulator study	No regulatory approvals	4
Endotics-*ERA Endoscopy SRL, Peccioli, Italy*[69-74]	2020**:** Learning curve study of 57 participants. CIR and CIT improved to 100% and 22 min following a learning block. PREMs: Mild or no discomfort in most	CE marked and FDA approved. Commercially available in Europe and Japan	8
Invendoscope-*Invendo Medical GmbH, Weinheim, Germany (acquired by Ambu A/S, Copenhagen, Denmark in 2017)*[21,77-79]	2018: Human study on 40 participants using the SC210 model. CIR 95%. CIT 14.2 min. No PREMs on this study, but previous studies reported lower pain scores than CC	CE marked and FDA approved. No longer manufactured	8
Magnetic Flexible Endoscope-*STORM lab, Leeds, United Kingdom & Nashville, TN, United States*[4,53,85,86,104]	2020: *In-vivo* porcine study. Clinical trial due 2022	No regulatory approvals	5

Active flexible colonoscopy platforms

Aer-O-Scope: The Aer-O-Scope (GI View Ltd., Ramat Gan, Israel) is a single use flexible colonoscope that uses a CO_2 propulsion system to self-advance through the colon. With a 200° field of view offered by two cameras it aims to offer better visibility behind folds while reducing discomfort. The device works by inflating two polyurethane balloons (Figure 2), the first balloon is inflated at the rectum to create a seal, a second balloon which pulsates and has a hydrophilic coating to reduce friction is inflated proximal to the first. Using the seal between the balloons, CO_2 is inflated, and the pneumatic force

Figure 2 Aer-O-Scope (GI View Ltd., Ramat Gan, Israel). A: Single use colonoscope scanner; B: Workstation. Citation: Images supplied directly by the manufacturer with email detailing permission to use attached as a text file.

propels the proximal balloon forward. To protect the colon, the system controls the pressure so it does not exceed 60 mbar[59]. The most recent version of the device is equipped with two working channels to allow therapeutics[21]. Tip control is achieved using a hand-held controller. Once in the caecum, the pressures are reversed to propel the proximal balloon back towards the rectum while maintaining colonic distension for visibility.

Safety of this novel propulsion method was first demonstrated in 20 pigs in 2006 were only minor petechiae and no adverse events were noted[60]. That study was quickly followed by a clinical trial in the same year on 12 healthy young adults[61]. In this study 10 out of 12 procedures were completed to the caecum with the other two stopping at the hepatic flexure. In both these cases CC was also unable to progress beyond the hepatic flexure due to redundant colon in one and pain in the other. Caecal intubation occurred in an average of 14 min for the 10 completed. Two subjects requested analgesia, while the other 10 had a non-sedated procedure. Mild localised submucosal petechial lesions, thought to be related to balloon friction, were noted on 4 of the follow-up conventional colonoscopies. No other clinically significant adverse events were reported.

A further prospective, non-randomised clinic trial was published in 2016 on 58 CRC screening patients who underwent tandem colonoscopies with the Aer-O-Scope followed by CC[59]. Caecal intubation was achieved in 98.2% (94.4% in the training cohort and 100% in the study cohort). The Aer-O-Scope detected 87.5% of the polyps found by CC, and 100% of those ≥ 5 mm. Caecal intubation was achieved in a mean of 11 min. No mucosal damage or adverse events were reported. Patients were sedated and no patient related experience measures have been reported on.

A prospective clinical trial using the Aer-O-Scope completed recruitment on clinicaltrial.gov in November 2021 but the results have not yet been published at the time of writing and are likely to be for a newer model of the colonoscope[62]. The Aer-O-Scope is CE marked and received FDA approval in 2016[63]. GI View Ltd no longer produce the self-propelled version of the Aer-O-Scope, instead opting to use the technology on a new version which is a single use robotic colonoscope without the balloon self-propulsion[64].

Following correspondence with GI View Ltd, they felt the advances in colonoscopy technique, with improved CIRs and within shorter times, limited the need for a self-propelled device. Instead, they are choosing to concentrate on a single use colonoscope with a larger lens aimed at improved polyp detection, while maintaining similar controls to reduce the need for new training.

ColonoSight: ColonoSight (Stryker GI Ltd., Haifa, Israel) is a self-advancing system composed of a reusable colonoscope (EndoSight) covered by a single use plastic sleeve (ColonoSleeve). The Colono-Sleeve is a multi-lumen sheath that is inflated with air and progressively unfolds to propel the device through the colonic lumen. The IntraPull force that insufflates the air for propulsion is controlled using a foot pedal. The other controls resemble those of a standard colonoscope using a wheel and pully angulation control system. Push, pull and torque can also be used, similar to standard colonoscopy. On

reaching the caecum, air insufflation is directed toward the tip, insufflating and reversing the pressure. A CCD camera with an LED is used to capture image, eliminating the need for fibre optics. The device contains a working channel for therapeutic tools. The outer surface, tip and channels of the endoscope are single use, therefore negating the need for reprocessing of the reusable EndoSight component[65].

Shike *et al*[65] describe that the operation and safety of the instrument was first tested on animals (12 pigs and 7 sheep) with a mean progression into the colon of 80 cm. *In-vitro* dye and culture studies as well as *in-vivo* culture testing confirmed the integrity of the disposable sleeve to protect against bacterial transfer. A clinical trial published in 2008 included 178 participants achieved a 90% CIR in a mean caecal intubation time (CIT) of 11.2 min. The CIR in the final 50 participants was 94%, suggesting a possible learning curve effect. 40 participants underwent polypectomy, with biopsies and argon plasma coagulation was also performed. No immediate complications were noted, and no complications were reported at a two week follow-up telephone call. Participants received intravenous sedation and no patient experience measures are reported on. Physicians reported the IntraPull helped progress the device[65]. The ColonoSight Model 510B received FDA approval in 2004[66]. Stryker GI Ltd acquired Sightline Technologies Ltd, the original manufacturer, in 2006 and the device is no longer manufactured. The reason for discontinuation is not clear, but Stryker GI Ltd have focused on laparoscopic endoscopic equipment rather than colonoscopes, so they may not have had the infrastructure to market a new colonoscope or they may have chosen to integrate the technology into laparoscopic equipment.

Consis medical: Consis medical (Beer'Sheva, Israel) have developed a semi-disposable, single use colonoscope that self-propels along the colon by means of an inverted sleeve pressurised with water. The head of the device can be removed and sterilised at the end of the procedure, with the sleeve cartridge being disposable[67]. The reusable head contains a camera, light source, steering system and water/air nozzle. Human colon simulation and animal tests were due to take place in 2018 but no published results are yet available[21].

Endoculus: Endoculus (University of Colorado, United States) is a multi-DOF fixed tether single use robotic capsule endoscope. Locomotion is *via* two independently controlled motor drives with micro-pillared treads, offering 2-DOF skid steering. *Via* a fixed tether the Endoculus contains channels for insufflation and irrigation, and a working channel for introduction of endoscopic instruments. The tip of the capsule contains a complementary metal-oxide-semiconductor (CMOS) camera and an adjustable LED. The fixed tether is narrow in diameter and very flexible, however the motorised tip is larger than a standard colonoscope at 6.0 cm × 3.0 cm × 2.3 cm. The research team feel the device could be made smaller with advanced manufacturing techniques[68].

In-vivo testing was carried out in a porcine colon. The device was inserted manually to 10 cm but was then unable to negotiate the sigmoid colon. The research team postulated that this was due to friction from the narrow sigmoid colon in a pig on the non-tread sides of the device. *Ex-vivo* testing on a porcine colon was subsequently conducted on a 40 cm mid colon section. The Endoculus was capable of negotiating the *ex-vivo* colon at speeds up to 40 mm/s both in an insufflated 6 cm diameter colon and also in a collapsed lumen[68].

Endotics: Endotics (ERA Endoscopy SRL, Peccioli, Italy) is an FDA and CE marked biomimicking colonoscope on sale in Europe and Japan[69]. The electropneumatic system uses proximal and distal clamps to attach to the colon wall and in a semi-autonomous process of extension and retraction of the shaft between the clamps it progresses along the colon in an inchworm fashion. Image is captured *via* an integrated CMOS camera lit by an LED light source. The device has a 3 mm working channel, insufflation and suction, and is single use. A 180° steerable head is controlled using a handheld control unit[70].

In-vitro studies reported in 2009 showed the Endotics E-worm system reduced the pressure on sensors around a pig colon by 90% compared to CC. An *in-vivo* animal study showed no complication of the clamping system at follow-up colonoscopy 7 d later[71]. In a pilot tandem study of 40 patients in 2009 the Endotics system only managed to achieve a CIR of 27.5% with mean CIT of 57 minutes, compared to a CIR of 82.5% for CC. The patient experience for the Endotics system was reported to be much better with average pain and discomfort scores of 0.9 and 1.1 out of 10, compared to 6.9 and 6.8 for CC[71].

A second tandem human study on 71 participants was published by Tumino *et al*[72] in 2010 aimed at assessing the Endotics ability to detect polyps. The CIR was 81.6% for the Endotics system and 94.3% for CC, with mean CIT 45.1 (± 18.5) min compared to 23.7 (± 7.2) min, respectively. None of the participants required sedation for the Endotics procedure, with 14/71 asking for sedation during the subsequent CC procedure. The Endotics system showed a sensitivity of 93.3% for the detection of polyps, detecting 14/15 polyps seen on CC. 6/71 (8.4%) of participants reported mild adverse events (nausea, headache, abdominal pain and discomfort) which the authors say, due to the tandem nature of the study, couldn't be distinguished from bowel cleansing or CC related adverse events[72].

A retrospective analysis of 5 years of Endotics examination in a single centre in Italy reported on 102 procedures performed due to incomplete CC. The Endotics system was able to complete a colonoscopy

in 95/102 (93.1%) of these patients. Mean CIT was 51 (± 22.5) min[73]. A learning curve study from Trecca *et al*[74] in 2020 presents two blocks of 27 and 28 participants. The CIR improved from 92.7% to 100% and the CIT from 55 to 22 min between the first and second block. The polyp detection rate and adenoma detection rate was 40% and 26.7%, respectively. The procedure was reported as mild or no distress in most cases with 92.7% willing to have a repeat Endotics procedure[74].

Endotics have performed a health economics study comparing Endotic robotic colonoscopy to standard colonoscopy in the Italian healthcare system and found the robotic colonoscopy to be comparable in price to standard colonoscopy, €441.25 *vs* €426.25, respectively[33].

Invendoscope

The Invendoscope (Invendo Medical GmbH, Weinheim, Germany) has a number of models with several CE and FDA approvals[75,76]. The single use computer-assisted device is propelled through the colon by an inverted sleeve driven by 8 wheels (Figure 3). The wheels grip the inside of the inverted sleeve to move forward and backwards. Control is *via* a handheld joystick. The tip of the colonoscope is robotically assisted and can be defected up to 180°, is equipped with three LEDs and a CMOS vision chip with an 114° field of view. Standard colonoscope functions such as insufflation, suction and irrigation are available, as well as a 3.2 mm working channel.

Animal testing using the SC20 model on the *in-vivo* small bowel of 5 pigs showed the device could be inserted through 3 small bowel loops and there was no mucosal damage found on microscopic pathological examination[77]. In a clinical trial of the SC40 model published in 2008, using two varying length prototypes in 34 participants, CIRs of 79% and 90% were achieved. CITs were 26 min and 20 min. The shorter of the two prototypes had a lower CIR, longer procedure time and more pain and bloating. Five cases had to be excluded due to instrument defects. Two of the failures to achieve caecal intubation were due to pain. Overall, the participants gave a mean acceptance rating of 1.96 (range 1-6). No immediate or delayed complications were reported[77].

A clinical trial on the Invendo SC20 model published by Groth *et al*[78] in 2011 found a CIR of 98.4% in 61 volunteers. Median CIT was 15 min and only 3/61 (4.9%) requested sedation. There were 32 polypectomies and no device-related complications reported. Water instillation was used in half of the cases to aid progression. Endoscope malfunctions were experienced in 2 cases. Post-procedure pain and discomfort scores were 1.6 and 2.3 out of 6, respectively[78].

Invendo Medical GmbH was acquired by Ambu in 2017 and the SC40 inverted sleeve wheel driven prototype has been replaced by the SC200 and then the SC210 which are manually inserted single use devices utilising robotic tip controls[21].

Only a conference abstract could be found on the Invendo SC210 model. In this clinical trial 40 participants underwent colonoscopy with the SC210, CIR was 95% with a median CIT of 14.2 min. Most patients (35/40) received propofol sedation. Twelve patients had polypectomies performed. There were 3 complaints of abdominal pain post-procedure and one self-limiting haemorrhage from the sigmoid colon, but no major complications[79].

The SC210 model no longer has any robotic locomotion, with the only robotics left being tip deflection, making it predominantly a single use colonoscope. Since the acquisition by Ambu, the Invendoscope is no longer on the market. Following correspondence with Ambu, the long scope length (220 cm) required for the self-propelled version made it difficult to control looping. Physicians also reportedly found it difficult to transition to the robotic tip control of the SC210 so Ambu have decided to focus on conventional control mechanisms.

Robotic capsule colonoscope

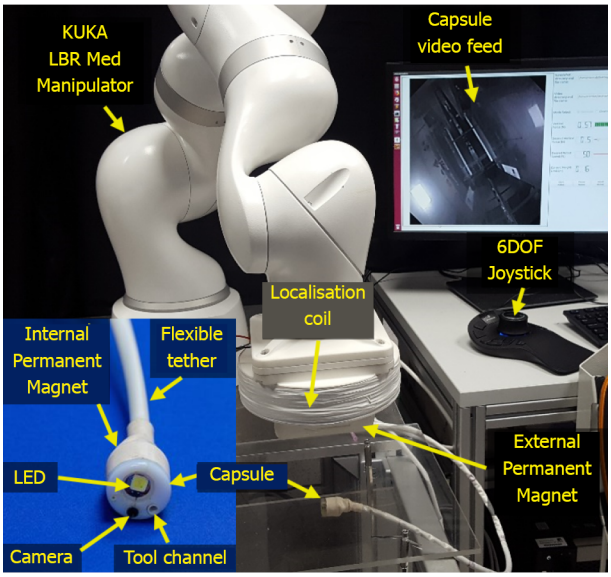
A European FP6 project called "Versatile Endoscopic Capsule for GI TumOr Recognition and therapy" (VECTOR project) was tasked to explore magnetic capsule endoscopy from 2006 to 2011. One of the outputs of the project was a magnetically controlled capsule for colonoscopy. A 13.5 mm × 29.5 mm endoscopic capsule containing 6 LEDs and a CCD camera capable of 550 × 582 pixel resolution and a 120° field of view was designed. The capsule also contained 3 permanent magnets and a triaxial magnetic sensor to monitor the magnetic link. Power and transmission to and from the capsule was achieved *via* a 2 mm cable. The capsule was controlled using an external permanent magnet fixed to a robotic arm end effector which was found to offer more precision than manual control[80]. The robotic arm has 6 DOF and an additional 7th DOF was added at the end effector-magnet connection. The capsule trajectory is controlled by means of controlling the robotic arm and the magnetic attraction between the external and internal magnets pulls the capsule along the colon. The initial version of the device was not able to insufflate the colon, so a Foley catheter had to be passed rectally to insufflate[81].

A benchtop study of the magnetic capsule colonoscope was undertaken, including 11 endoscopist and 11 trainees, who performed the robotic capsule colonoscopy and CC on an *ex-vivo* porcine colon used to simulate a human colon. All 22 participants were able to complete the procedure using both the robotic capsule and conventional colonoscope. Pins inserted in the phantom colon were found with a mean accuracy of 80.9% (± 11.0%) in the robotic capsule procedures and 85.8% (± 9.9%) in the CC procedures[81].

High cecal intubation rates with a new computer-assisted colonoscope: a feasibility study. *Am J Gastroenterol* 2011; 106: 1075-1080. Copyright© The Authors 2020. Published by Creative Commons Attribution-NonCommercial-No Derivative Works 3.0 License.

The next prototype from the same team of researchers, named the Magnetic Air Capsule, included a soft multi-lumen tether to allow insufflation, washing, suctioning, lens cleaning and a working channel for passing therapeutic tools. *Ex-vivo* testing on a porcine colon within a human phantom model was undertaken using 12 participants and all participants were able to complete an 85 cm phantom colonoscopy, with 85% (± 11%) of the beads found. *In-vivo* porcine testing proved the device was capable of traversing an average distance of 800 (± 40) mm in an average of 900 (± 195) seconds[82].

The VECTOR project team were also able to explore several other aspects of robotic colonoscope design. Experiments exploring the human robot interface were conducted and teleoperated (remote control) was found to be more reliable than a human/robot cooperative haptic control using a torque/force sensor[83].



Following on from the VECTOR project, some of the research team have gone on to develop the technologies further in the ENDOO magnetic colonoscope and the magnetic flexible endoscope (MFE).

MFE

The MFE research team (STORM lab, Leeds, United Kingdom and Nashville, TN, United States) has developed the soft tether capsule colonoscope technology further (Figure 4). Advancements in the localisation and real time pose estimation allow closed loop control of the endoscope. Closed loop control allows the user to steer the endoscope based on what they see from the video feed rather than controlling movement of the robotic arm and attempting to translate that into the movement desired of the endoscope tip[53,84]. Further developments have allowed the capsule to levitate in the colon lumen rather than skimming along the mucosal surface. Autonomous navigation and autonomous retroflexion have been demonstrated in porcine studies[4,85]. Laboratory based learning curve studies and task load assessments suggest a quicker learning curve than with CC and a lower perceived workload[86]. *In-vivo* porcine studies have not demonstrated any safety concerns and even novice user were able to navigate the device 85 cm into a pig colon[84]. The platform is currently undergoing final pre-clinical steps in preparation for first-in-human trials.

ENDOO

The ENDOO project (Pisa, Italy) was a European H2020 project between 2015 and 2019 that also designed a magnetically actuated soft tether robot. A permanent magnet in the capsular tip of the endoscope is pulled through the colon using closed loop interaction with an external permanent magnet on an industrial anthropomorphic robotic arm[87,88]. The capsular tip has two 1080p CMOS cameras to allow stereoscopic, 3-dimensional, views. Four LEDs offer white light illumination, and 4 ultraviolet

Figure 4 Magnetic flexible endoscope (STORM lab, Leeds, United Kingdom and Nashville, TN, United States).

LEDs allow narrow band imaging. The 160 cm soft tether carries 4 channels, including a 3.7 mm working channel, providing suction, irrigation, lens cleaning and insufflation. The soft tether also integrates nylon cables to allow variable stiffness of the shaft.

Ex-vivo testing using a porcine colon in a human abdomen simulator compared key functionalities, forces generated, simulated polyp detection and usability when compared to CC in 10 expert endoscopists and 5 trainees. The forces generated by the robotic colonoscope were significantly less than those generated by CC, with cumulative interaction forces of 16.5N for CC and 1.67N for the robotic colonoscope. The robotic colonoscope was able to complete the procedure 67% of the time with a comparable polyp detection rate to CC[89].

PASSIVE COLONOSCOPY

Passive colonoscopes are capsule devices designed to assess the colon with movement through the gastrointestinal tract passively *via* natural peristalsis. There is now a commercially available colon capsule endoscope, the Pillcam™ COLON2 (Given Imaging, Yokneam Illit, Israel). Researchers have also been exploring the addition of further robotics within capsular devices in an attempt to overcome some of their disadvantages. Advances in miniaturisation, image capture and batteries have allowed researchers the space within the small confines of a safe capsule size to add further robotics. A full review of these devices is beyond the scope of this review but have been done in detail by Manfredi[90] and Slawinski *et al*[91].

ROBOT ASSISTED FLEXIBLE ENDOSCOPY PLATFORMS

The previously described robotic platforms aim to provide an alternative to CC. However, some researchers have been developing platforms to assist with some of the challenges of performing CC by adapting the current colonoscope. Adding robotic controls to existing endoscopes could improve the ergonomics and assist with the difficult learning curve associated with colonoscopy.

The Endodrive (ECE Medical Products, Erlangen, Germany) is a platform using a rotating engine and foot pedal to control shaft insertion. Rotation and tip control is still required[92]. Rozeboom *et al*[93] present a robotic-assisted flexible colonoscope that uses an add-on to the handle of the colonoscope that convert the wheel control mechanism into a robotic joystick control. CIR using Rozeboom's device was 68%[93]. Robotic steering and automated lumen centralisation (RS-ALC, Enschede, Netherlands) is another platform which uses joystick control of an add-on to the endoscope handle with the addition of lumen centralisation software. A study of novices and experts on a colon simulation model found that novices had a faster CIT and polyp detection rate with the RS-ALC than CC. The opposite was found of experts, who found CC better[94]. The master–slave endoscopic operation robot (EOR; Kyushu Institute of Technology, Kitakyushu, Japan) which is in its third iteration, added on therapeutic tools. The EOR version 3 uses a rotary motor, rotating handle, torque sensor and mini joystick which allows haptic

feedback and 4 axis movement. An *ex-vivo* colon phantom study using 8 endoscopists performed 48 colonoscopies with a CIR of 100% and CIT of 118.5 (± 89.4) seconds[69].

ROBOTIC FLEXIBLE ENDOSCOPES WITH THERAPEUTIC APPLICATIONS

Advances in the therapeutic capabilities of gastrointestinal endoscopy and the evolution of natural orifice transluminal endoscopy (NOTES) have led researchers to look to robotics to enhance the dexterity offered by our endoscopes. A number of systems have been developed that claim to offer greater triangulation, dexterity and DOF to improve our ability to perform procedures such as ESD, third space endoscopy and NOTES. Examples include Endoluminal Assistant for Surgical Endoscopy (EASE; KARL STORZ/IRCAD, Strasbourg, France) (Figure 5), K-FLEX (EasyEndo Surgical, Daejeon, Korea) and the MASTER (EndoMASTER Pte, Singapore)[95-97]. A detailed review of these devices is beyond the scope of this review article but has been done by Lim[98].

CONCLUSION

Endoscopy is an expanding speciality with colonoscopy demand rising by at least 5% *per* year[99,100]. Yet a significant number of people decline to undergo colonoscopy due to several factors including pain and previous bad experiences[16,17]. Robotics has the potential to provide an alternative to CC. However, the ideal robotic platform must be affordable; versatile and capable of performing precise movements while maintaining patient comfort. The potential for robotics to improve the dexterity of an endoscope in the ever-expanding field of therapeutic endoscopy is also worth consideration and likely to be something we will see in the future. Researchers developing new medical devices must keep sustainability in mind. And with a global pandemic in the forefronts of everyone's minds, the potential for robotics to provide a 'medically distanced' procedure will be appealing to many.

AI has not been covered in this review article but is likely to be integrated in robotic colonoscopes. AI in endoscopy has many facets, including image assistance for lesion detection or characterisation, but also integrates closely with robotics in the form of autonomous movement/navigation. Although for many this seems like science fiction and not yet requiring discussion, the technology is available. The MFE device can autonomously navigate a pig colon.

However, advances in AI and increasingly autonomous tasks introduce a number a challenges. Regulatory, ethical and legal uncertainty is likely to take time to overcome, hindering commercialisation. Integration is therefore likely to be slow, with a gradual increase in the autonomy of devices despite the technology being available for further autonomy.

The technology to allow a completely autonomous colonoscopy, including diagnostics, with an endoscopist only required on a supervisory capacity is not so far away. Autonomous robotic colonoscopy has the potential to increased capacity with fewer operators required to perform more procedures. Endoscopists could potentially be trained much quicker. Robotics has the potential to raise the standard of procedures, democratising colonoscopy, thus reducing post-colonoscopy CRCs, reducing complications and improving the colonoscopy experience for patients.

Some of the devices discussed have reached TRLs of 8 and gained FDA or CE marking, however few have yet been adopted enough to perform post-marketing studies or health economics studies. Although, the Endotics health economics study has shown promising result, health economics studies in other areas of robotic healthcare, such as surgery, have been fraught with conflicting results.

Several of the discussed robotic colonoscopes have been modified, removing some of the robotics and opting to pursue the single use colonoscope market. It is probable that the improvements in endoscopy technique have put off commercialisation for the purpose of improved caecal intubation. However, much of the need for these devices is to improve patient experience, which now seems to be the focus of many research teams. What may seem like more intuitive controls will still be different to the standard endoscope controls experienced endoscopists have grown used to. Resistance to change is going to be a challenge for all new devices.

These technologies are often expensive initially, but the cost should not be confused with the potential cost effectiveness of a test which is more acceptable, with the subsequent reduction in morbidity and mortality. Technological advances are happening at an exponential rate and although none of the device to date have challenged the dominance of CC, it is probable that one will in the very near future.

Abstract

Nonalcoholic fatty liver disease (NAFLD) has emerged as the most common cause of chronic liver disorder worldwide. It represents a spectrum that includes a continuum of different clinical entities ranging from simple steatosis to non-alcoholic steatohepatitis, which can evolve to cirrhosis and in some cases to hepatocellular carcinoma, ultimately leading to liver failure. The pathogenesis of NAFLD and the mechanisms underlying its progression to more pathological stages are not completely understood. Besides genetic factors, evidence indicates that epigenetic mechanisms occurring in response to environmental stimuli also contribute to the disease risk. Noncoding RNAs (ncRNAs), including microRNAs, long noncoding RNAs, and circular RNAs, are one of the epigenetic factors that play key regulatory roles in the development of NAFLD. As the field of ncRNAs is rapidly evolving, the present review aims to explore the current state of knowledge on the roles of these RNA species in the pathogenesis of NAFLD, highlight relevant mechanisms by which some ncRNAs can modulate regulatory networks implicated in NAFLD, and discuss key challenges and future directions facing current research in the hopes of developing ncRNAs as next-generation non-invasive diagnostics and therapies in NAFLD and subsequent progression to hepatocellular carcinoma.

Key Words: MicroRNAs; Nonalcoholic fatty liver disease; Steatohepatitis; Noncoding RNAs; Circular RNAs; Biomarker

Core Tip: Nonalcoholic fatty liver disease (NAFLD) covers a spectrum of hepatic pathologies, ranging from simple steatosis to nonalcoholic steatohepatitis, all of which can evolve to cirrhosis and in some cases to hepatocellular carcinoma. There are now indications that noncoding RNAs (ncRNAs), a component of epigenetic mechanisms, contribute to the pathogenesis of NAFLD and may serve as potential prognostic and diagnostic biomarkers. However, little is known about the role of these RNA species in NAFLD and its progressive forms. This paper discusses the current state of research on the role of most clinically relevant ncRNAs in the pathogenesis of NAFLD.

INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) has emerged as a liver disorder with an increasing prevalence but unclear etiology. The disease covers a wide spectrum of histologic lesions, ranging from simple steatosis to its subtype, nonalcoholic steatohepatitis (NASH), which is characterized by inflammation and hepatocyte injury. Over several years, NASH can progress to more serious disease stages, such as cirrhosis and hepatocellular carcinoma (HCC)[1]. Based on the close association between hepatic steatosis and metabolic dysregulation, international consensus guidelines recommended the renaming of NAFLD to metabolic-associated fatty liver disease[2,3]. The prevalence of NAFLD depends on race and ethnicity. In the United Sates, the estimated prevalence of NAFLD was reported to be about 32%[4]. However, estimates are likely higher in other populations that are currently witnessing the rapid rise in the incidence of type 2 diabetes mellitus (T2DM), obesity, metabolic and insulin resistance syndrome, and dyslipidemia rates[5,6].

NAFLD is sometimes called the "silent killer", because most patients with the condition are typically asymptomatic in the early stages until the liver is severely damaged. The unsuspected disease condition is often found incidentally when liver enzyme levels, such as alanine aminotransferase, are elevated in routine laboratory work-up or hepatic steatosis appears on imaging for reasons other than liver symptoms or signs. Currently, liver biopsy remains the gold standard method for NAFLD diagnosis and degree of liver injury evaluation[7]. Computed tomography scans and ultrasound can also be performed as part of the standard evaluation of NAFLD. However, these methods have a number of limitations, including invasiveness, low sensitivity, sampling variability, and inaccurate diagnosis[8,9]. The American Association for the Study of Liver Diseases has identified uncertainties about these diagnostic tools, which represent a barrier to the effective treatment of patients with NAFLD[10]. Thus, there is increased recognition of the need to develop non-invasive biomarkers that have the ability to identify simple steatosis from NASH patients who are at high risk of progression to cirrhosis and HCC conditions.

Many concepts important to understanding the pathogenesis of NAFLD have arisen. The traditional view of this complex disease suggests that an interplay between genetic and triggering and/or modifying environmental events is the fundamental basis for disease initiation and development[11,12]. Over the last several years, a growing body of functional evidence has pointed towards a central role of epigenetic factors in fatty liver diseases, including NAFLD. Epigenetics was redefined multiple times and Cavalli and Heard described it as "the study of molecules and mechanisms that can perpetuate alternative gene activity states in the context of the same DNA sequence"[13]. Epigenetic machinery could be another layer that orchestrates gene expression and provides a molecular link between genetic and environment effects on NAFLD. Thus, the integration of epigenetic information may represent another opportunity to tackle the complexity of NAFLD and identify new predictive biomarkers and potential therapeutic targets of this disease. Indeed, recent advancements in the emerging field of epigenetics have revealed that epigenetic mechanisms and associated systems may regulate many aspects of the pathogenesis of NAFLD[3,14]. Unlike genetic alterations, epigenetic alterations can be mostly heritable and reversible. Thus, further discoveries in the field could enable the development of epigenetic tools that can be used not only to complement current strategies for early disease diagnosis and optimal individualized patient risk stratification but also to improve therapy.

To date, the most studied epigenetic mechanisms include DNA methylation, histone modifications, and noncoding RNA (ncRNA)-based regulation. While certain epigenetic mechanisms underlying DNA and chromatin modifications in NAFLD were addressed elsewhere[15,16], only relevant studies shedding light on the roles played by ncRNAs' machinery will be reviewed next.

EMERGING ROLE OF NCRNAS IN THE PATHOGENESIS OF NAFLD

For decades, only the portion of the genome that is transcribed into mRNA (approximately 2%) was the central focus of basic science and medical research. The remaining 98% was simply believed non-functional and referred to as "junk DNA" or "dark matter"[17]. Due to advances in high-throughput sequencing technologies enabling more in-depth genomic and transcriptomic analyses, the Encyclopedia of DNA Elements project revealed that up to 80% of the human genome is transcribed, generating a multitude of functional transcripts commonly referred to as ncRNAs[18,19]. The biological significance of these nonprotein coding transcripts is now becoming evident, with many ncRNAs found to have epigenetic activity and substantial roles in regulating diverse cellular processes. Indeed, they can affect gene expression by interacting with the transcriptional apparatus, and regulating chromatin structure and RNA processing mechanisms[20]. There is also proof that interaction and crosstalk between different species of ncRNA groups can create complicated and intertwined networks that can affect gene expression[21]. Regulatory ncRNAs mainly consist of microRNAs (miRNAs) (< 30 nucleotides), long noncoding RNAs (lncRNAs) (≥ 200 nucleotides)[19], and circular RNAs (circRNAs). Due to their stability and easy detection in biological fluids, ncRNAs are continuously investigated as promising diagnostic and therapeutic tools in metabolic diseases. A growing body of literature indicates that ncRNAs are abundantly expressed in the liver and their altered expression patterns are associated with various types of liver diseases including NAFLD[22,23]. Moreover, ncRNAs reveal significant differences in expression according to the severity of NAFLD and histological features[24]. In the next sections, the role of miRNAs, lncRNAs, and circRNAs will be discussed, to better improve our understanding of their appealing potential as biomarkers for early NAFLD/NASH staging and therapeutic targets.

miRNAs in NAFLD

miRNAs are small, highly conserved short single-stranded ncRNAs (approximately 18-22 nucleotides in length) with epigenetic functions able to transcriptionally regulate gene expression of other RNAs notably mRNAs[25]. They are transcribed in the cell nucleus and transported to the cytoplasm, where they are processed into mature miRNAs[26]. With respect to their function, miRNAs primarily regulate gene expression by promoting mRNA degradation or repressing their translation. They serve as master regulators that control the expression of thousands of coding and noncoding genes. Prior research suggests that more than 60% of human coding genes are potential targets of miRNAs[27]. Mounting evidence reveals that dysregulation in miRNAs' expression is associated with molecular processes of various forms of metabolic and liver diseases, including NAFLD conditions[3,28-30]. Indeed, several differentially expressed miRNAs play key roles in the development of NAFLD in animal models and humans[30-33], essentially through the regulation of several pathogenic processes including altered lipid and glucose metabolism, insulin resistance, and inflammation pathways[34,35]. Because miRNAs are stably detected in biofluids and can circulate within microvesicles, exosomes, or apoptotic bodies, or bound to RNA-binding proteins, interest in studying these molecules has increased tremendously. Additionally, considerable research has demonstrated that these RNA species may offer new insights into disease biology, and their easy profiling in the serum has raised enthusiasm about their potential use in clinical practice as biomarkers for early diagnosis and clinical monitoring of NAFLD progression [36,37]. While a plethora of miRNAs are associated with fatty liver diseases, only those shown to be repeatedly involved in different stages of NAFLD will be discussed next.

miR-21

There is evidence that miR-21-mediated regulation may play an important role in the pathogenesis of several types of liver diseases[38]. Dysregulated miR-21 expression has been reported in animal models of steatohepatitis and human NASH. Specifically, the levels of circulating miR-21 and its expression in the liver are heavily elevated in both NAFLD patients and mouse models[39-41]. Likewise, circulating miR-21 Levels are significantly increased in patients suffering from NASH compared to NAFL and healthy controls[42]. Other studies have shown that inhibiting miR-21 can alleviate steatosis by activating peroxisome proliferator-activated receptor alpha (PPARα)[40,43]. In support of these findings, another report indicated that hepatocyte-specific knockout (KO) of miR-21 in mice improved high-fat diet (HFD)-induced steatosis through upregulation of multiple miR-21-targeted pathways governing lipid metabolism[44]. Similarly, miR-21 abrogation along with obeticholic acid treatment significantly reduced NASH in mice[45].

Moreover, miR-21 plays a key role in hepatic lipid metabolism by promoting hepatic lipid accumulation *via* its interaction with several proteins including sterol regulatory element binding protein (SREBP1)[46] and 3-hydroxy-3-methylglutaryl-co-enzyme A reductase (HMGCR)[47]. Additionally, miR-21 can target phosphatase and tensin homolog, which prevents hepatic steatosis[48], and PPARα expression, which induces inflammation and fibrosis progression and activates lipid oxidation in NAFLD[40]. Other investigations have revealed that miR-21 can inactivate the Wnt/β-catenin signaling pathway by targeting low-density lipoprotein (LDL) receptor-related protein 6, thereby aggravating lipid accumulation and inflammation[49]. Mechanistic studies have also demonstrated that miR-21

promotes hepatic insulin resistance and steatosis in diet-induced obese mice through the regulation of several key transcription factors, such as forkhead box protein O1, insulin-induced gene 2, signal transducer and activator of transcription 3, and hepatocyte nuclear factor 4-alpha (HNF4-α)[44]. Together, these studies clearly show that miR-21 plays an essential role in key transitions of NAFLD pathogenesis. Such findings hold the potential to develop miR-21 as a reliable serum biomarker to identify patients "at risk" for NASH.

miR-29a

The miR-29 family of miRNAs consists of miR-29a, miR-29b, and miR-29c members[50], and are mainly expressed in hepatocytes and hepatic stellate cells (HSCs)[51,52]. A body of evidence suggests that miR-29a is significantly associated with diagnostic relevance of NAFLD[31,53], NASH[54] and liver fibrosis [54,55], as well as aggressiveness and prognosis of HCC[31]. López-Riera *et al*[56] identified circulating miR-29a as one of the potential biomarkers that could predict drug-induced NAFLD in humans. Yang *et al*[57] found that serum miR-29a levels were significantly lower in NAFLD patients compared to controls. Furthermore, another study revealed that miR-29a disrupts DNA methyltransferase 3β (DNMT3β) to improve diet-induced NASH in mice. Mattis *et al*[58] used a mouse model to demonstrate that miR-29a protects hepatocytes from steatosis by repressing lipoprotein lipase in hepatocytes. Moreover, miR-29a inhibits glycogen synthase kinase 3 beta to repress sirtuin 1 (SIRT1)-mediated mitochondrial biogenesis and improve methionine–choline-deficient diet-induced NASH in mice[59]. Roderburg *et al*[52] reported that miR-29 family members are downregulated in mouse models of liver fibrosis and in human fibrotic livers. A recent study indicated that miR-29a plays a regulatory role in NAFLD by improving HFD-induced steatohepatitis and liver fibrosis through the suppression of cluster of differentiation 36 (CD36)[31]. Together, these findings highlight the potential of miR-29a-targeted therapy for the treatment of NAFLD and its advanced stages.

miR-33a/miR33b

In humans, the miR-33 family comprises two members, miR-33a and miR-33b (miR-33a/b), which are co-transcribed with the sterol regulatory element-binding protein 2 (SREBP2) and 1 respectively, and their main targets are SREBP and SREBP2 and ATP-binding cassette subfamily A member 1 (ABCA1). miR-33a/b is implicated in fatty liver disease and plays key roles in lipid metabolism and transport by targeting a number of genes involved in cholesterol homeostasis and insulin signaling pathways[60,61]. In mice, there is only one miR-33 isoform, which is an ortholog form of human miR-33a[60].

In addition, expression levels of miR-33 are increased in the liver tissues of patients with NAFLD[62]. Circulating miR-33a is associated with steatosis and inflammation in patients with NAFLD after liver transplantation and can serve as an independent predictor of these pathological conditions[63]. The expression of hepatic miR-33a/miR-144 is increased in NASH patients with morbid obesity[64]. A further study in mice also demonstrated that miR-33 can regulate hepatic lipogenesis signaling and may serve as a potential circulating biomarker of NAFLD[65].

From a therapeutic perspective, several studies have demonstrated that treatment with anti-miR-33 therapeutic agents can significantly reduce plaque burden in mouse models of atherosclerosis and offer promise for treating cardiovascular disease[66-68]. However, a previously published clinical trial indicated that increased expression of miR-33a in the liver is associated with steatohepatitis in morbidly obese humans and metabolic dysfunction[64]. In line with this, long-term therapeutic silencing of miR-33 in mice leads to the development of adverse outcomes, including hypertriglyceridemia and hepatic steatosis[69,70]. miR-33 KO mice exposed to HFD developed marked worsening of obesity and liver steatosis *via* targeting SREBP1[71]. Recently, Price *et al*[61] provided additional evidence that genetic loss of miR-33 results in an increase in food intake and promotes obesity and insulin resistance. Thus, further research is needed to fully understand the role of miR-33a/b in NAFLD, which may provide new insights into the physiopathology of various forms of this disease.

miR-34a

The miR-34 family comprises three members: miR-34a, miR-34b, and miR-34c. miR-34a expression levels are increased both in the liver and serum of patients with NAFLD and NASH compared to healthy controls and are positively correlated with total cholesterol (TC) and triglyceride (TG) levels[72, 73]. miR-34 regulates many transcription factors, such as HNF4-α, SIRT1, and p53, which are involved in lipid metabolism, cholesterol synthesis, and fatty acid b-oxidation[72,74]. In addition, Xu *et al*[73] demonstrated that miR-34a inhibits hepatic very LDL secretion by promoting steatosis through interaction with HNF4-α in patients with NASH and mice fed HFD. miR-34a regulates steatosis by directly targeting PPARα expression in NAFLD[75]. Recently, another study demonstrated that the miR-34a/SIRT1/AMPK pathway is involved in mitochondrial dysfunction in a mouse NASH model[76]. Higher circulating levels of miR-34a have been seen in patients with NAFLD and NASH and mice fed HFD[73,77]. An association of miR-34a and miR-122 with dyslipidemia among patients with NAFLD has also been reported[78], and both miRNAs could be useful biomarkers in children with obesity and NAFLD[79]. Finally, in a meta-analysis study, miR-34a, miR-122, and miR-192 were identified as potential diagnostic markers to segregate NAFL from NASH[32]. Here, miR-34 showed the best

diagnostic accuracy for discriminating NASH *vs* NAFLD.

miR-122

miR-122 is the most abundant and extensively studied hepatic miRNA representing about 70% of the total miRNA in the liver[80]. Current evidence indicates that miR-122 plays an essential role in different aspects of liver function as well as in the epigenetic modulation of several genes linked to chronic hepatic pathology[72,80,81]. miR-122 is involved in the regulation of lipid and cholesterol metabolism. Animal experiments have revealed that inhibition of miR-122 results in a decrease of hepatic fatty acid and cholesterol synthesis rate, reduction in plasma cholesterol levels, enhanced liver fatty acid oxidation, and protection of HFD-fed mice from hepatic steatosis[82,83]. Further investigations have reported that miR-122 targets specific genes of cholesterol biosynthesis, such as *HMGCR*, microsomal TG transfer protein, 3-hydroxy-3-methylglutaryl-coenzyme A (CoA) synthase 1, fatty acid synthase, and acetyl-CoA carboxylase[33,82,83], suggesting a role in the pathogenesis of NAFLD.

Excessive accumulation of TG in the cytoplasm of hepatocytes is a hallmark of NAFLD. Genetic deletion of miR-122 Locus in mice results in TG accumulation in the liver and hepatic steatosis that progresses to NASH, fibrosis, and HCC[81,84], whereas restoration of miR-122a expression reduces disease symptoms and tumorigenesis[84]. Consistent with the results from animal investigations, reduced expression of miR-122 is observed in hepatic tissues of NASH patients compared to that in simple steatosis and healthy controls[72,80]. Interestingly, changes in miRNA expression profiles were observed at various stages of NAFLD, including simple fatty liver, NASH, and liver fibrosis to HCC. In this respect, a study reported that in NAFLD patients, the hepatic miR-122 Levels were lower in patients with mild steatosis compared to those with severe steatosis, while hepatic and serum miR-122 Levels were significantly higher in patients with mild fibrosis than in those with severe fibrosis[74].

Conversely, elevated serum levels of miR-122 have been found in patients with NAFLD patients compared to controls, and these levels are positively correlated with disease severity[85,86]. These data are in line with reports demonstrating that circulating levels of miR-122 are positively associated with fatty liver disease, T2DM, obesity, and atherosclerosis[80,87,88]. Additionally, NASH patients exhibit increased levels of miR-122 in the serum[80] and decreased hepatic expression of this RNA[72]. Although studies have consistently demonstrated that miR-122 expression differs between hepatocytes and blood, mechanisms underlying such an inverse correlation are certainly complex and need further attention. Attempts have been made to explain the observed difference in expression between the two tissues. The elevated levels of circulating miR-122 could be attributed to its secretion *via* liver exosomes. In agreement with this, Gallo *et al*[89] reported that miR-122 is localized in abundance to secreted liver exosomes. However, it must be acknowledged that the dynamic of miRNAs expression, secretion, and transport is complex and the contribution of other tissues such as adipose tissue to the pool of miR-122 Levels must not be ruled out.

miR-155

miR-155 is a multifunctional miRNA known to regulate numerous fundamental processes such as immunity, inflammation, lipid metabolism, and cancer[90,91]. Several studies have reported that miR-155 is one of the biologically most relevant miRNAs in several liver diseases including NAFLD[92,93]. In this respect, a study by Wang *et al*[94] demonstrated that the level of miR-155 is decreased in liver tissue and peripheral blood of NAFLD patients compared with healthy controls. Other studies indicated that miR-155 activity was also decreased in patients with NAFLD, which could be attributed to the adipogenic transcription factors CCAAT/enhancer binding protein (C/EBP)-α, C/EBP-β, PPAR-γ and LXRα[94,95]. On the other hand, miR-155-deficient mice fed a HFD developed increased hepatic steatosis compared to controls[94], while conditionally liver-specific overexpression of miR-155 reduced serum and hepatic levels of TC, TG, and high-density lipoprotein, and alleviated NAFLD[93]. These results suggest that miR-155 has a protective role in NAFLD and its pathological conditions. However, conflicting study results have somewhat dimmed the promise of using this miRNA to prevent NAFLD. For instance, miR-155 KO mice fed a methionine-choline-deficient diet showed a decrease in steatosis along with a reduction in the expression of genes involved in fatty acid metabolism and fibrosis, but not liver injury or inflammation[95]. Upon ingestion of a diet high in fat, high in cholesterol, and high in sucrose, miR-155 KO mice displayed less liver injury, decreased steatosis, and attenuation in fibrosis compared to control mice[96]. The ambiguous miR-155 roles suggest that this transcript may exert pleiotropic functions depending on the etiology and disease context. Another scenario is that miR-155-containing exosomes or miR-155-containing microvesicles released from cells into the surrounding tissue could contribute to the observed differences in results. As an example, adipose tissue-derived miR-155 upregulated by HFD was shown to induce hepatic insulin resistance in murine models[97]. Thus, further studies are warranted to clarify the contradictory results and determine the role of miR-155 in intracellular lipid accumulation and NAFLD development and progression.

miR-192

miR-192 is highly expressed in quiescent HSCs. Overexpression of miR-192 significantly suppresses the activity of these cells by reducing the proliferation and migratory potential of primary mouse HSCs[98].

A previous study found that circulating miR-192 is differentially expressed in NAFLD patients and even identified a miRNA panel (hsa-miR-122-5p, hsa-miR-1290, hsa-miR-27b-3p, and hsa-miR-192-5p) with high diagnostic accuracy for this disease[99]. Another study indicated that serum levels of miR-192-5p were significantly elevated in NAFLD patients and positively associated with hepatic inflammatory activity score and disease progression[100]. Recently, Wang *et al*[101] observed that miR-34a, miR-122, and miR-192 represent suitable biomarkers to distinguish NAFLD and NASH severity. Another study found that in NASH patients levels of miR-192 were elevated in serum, while decreased in the liver[80]. Similar to miR-122, miR-192 was increased in NASH serum compared with steatosis and downregulated in NASH liver, both in human and animal models, suggesting that these miRNAs are released from hepatocytes during pathophysiological states associated with cell membrane impairment[42,100]. A recent meta-analysis identified several miRNAs as potential biomarkers of NAFLD and NASH, including miR-34a, miR-122, and miR-192[32]. Together, these findings suggest that circulating miRNA-192 Levels may represent a potential noninvasive diagnostic biomarker and therapeutic target for the different stages of NAFLD.

miR-375

miR-375 is highly expressed in pancreatic islets and considered to be an essential regulator of glucose homeostasis and insulin secretion[102]. miR-122, miR-192, and miR-375 are significantly upregulated in NAFLD patients compared to controls[80]. miR-375 is involved in the pathogenesis of NAFLD and its inhibition suppresses the production of inflammatory cytokines tumor necrosis factor-alpha as well as interluekin-6, increased the expression of adiponectin, and suppressed lipid accumulation in palmitate (PA)-induced HepG2 cells[103]. These preliminary data suggest that miR-375 as well as the above discussed miRNAs (Table 1) could be promising targets for the prevention and progression of NAFLD.

LncRNAs in NAFLD pathogenesis

LncRNAs are relatively long RNA transcripts (> 200 nucleotides) that lack coding potential[104]. They are regulatory molecules transcribed from intergenic, exonic, or the distal protein-coding regions by RNA polymerase II and capped at the 5′-end and polyadenylated at the 3′-end[104]. Regarding their functions, there are subsets of lncRNAs that act as guides by binding to proteins and directing their localization, providing dynamic scaffolds providing a central platform for the transient assembly of multiple proteins and RNAs[105] and decoys that bind targeted proteins or miRNAs to limit their availability and function by acting as a molecular sink[106]. However, other functions related to these RNA species may arise as research in the field rapidly progresses. Over the last decade, dysregulation of lncRNAs has been linked to the pathophysiology of various human diseases, such as cancer, diabetes, and cardiovascular diseases[107]. In the context of NAFLD, some reports have noted that lncRNA expression patterns are dysregulated, suggesting that these molecules may represent potential drivers of NAFLD biology and have utility as clinical biomarkers. However, the role of lncRNAs in the development and progression of NAFLD still remains relatively unexplored. Herein, we provide a scientific update on lncRNAs relevant to NAFLD and its stages.

H19 LncRNA

The lncRNA H19 (H19) is a transcription product of the *H19* gene and represents one of the first discovered lncRNAs. H19 predominantly acts to affect miRNAs stability in different physiological and pathological conditions[108]. In recent years, H19 has attracted great attention in the research of liver diseases due to its aberrant expression and extensive involvement in several hepatic metabolic processes [109]. In this respect, existing evidence has shown that overexpression of H19 results in hepatic metabolic reprogramming and exacerbates diet-induced fatty liver[110]. In agreement with this, Liu *et al* [111] reported that expression of H19 induces hepatic steatosis by activating both the lipogenic transcription factor MLX interacting protein-like and the mammalian target of rapamycin complex 1 signaling pathways. In animal models, knockdown of H19 inhibited steatosis and alleviated hepatic lipogenesis by directly regulating the miR-130a/PPARγ axis in NAFLD[112]. However, further studies would be useful for determining the precise contribution of H19 to the pathogenesis of NAFLD.

Blnc1

Brown fat lncRNA 1 (Blnc1) is implicated in the regulation of adipocyte differentiation and function [113] and may serve as a regulator of triacylglycerol biosynthesis. Recently, Zhao *et al*[114] reported that hepatic Blnc1 expression was strongly linked to activation of lipogenesis in mouse models of obesity and NAFLD, whereas its liver-specific inactivation abrogated HFD-induced hepatic steatosis and insulin resistance, and protected mice from diet-induced NASH pathogenesis. Conversely, overexpression of Blnc1 in epididymal white fat tissue improved whole body insulin sensitivity, partially attenuated systemic dyslipidemia and glucose metabolism, and markedly protected against diet-induced obesity hepatic steatosis, probably *via* enhancement of mitochondrial biogenesis and function in white fat[115]. Overall, these results suggest that Blnc1 has different regulatory mechanisms and distinct functions in the liver and white adipose tissue.

Table 1 Selected microRNAs shown to be highly involved in the pathogenesis of nonalcoholic fatty liver disease

miRNA	Circulation level	Tissue expression	Main functional and pathophysiological impacts	Ref.
miR-21	↑	↑	Promotes lipogenesis Involved in NASH, fibrosis, and HCC Targets several metabolic and inflammatory signaling pathways related to the pathogenesis of NAFLD	[38-40,42,44]
miR-29a	↑	↓	Highly connected with the diagnostic relevance of NAFLD, NASH, and HCC Modulates oxidative stress and inflammation in the context of NAFLD	[31,53,52,58]
miR-33a/b	↑	↑	Involved in lipid metabolism, glucose homeostasis and hepatic lipogenesis Associated with steatosis and inflammation in patients with NAFLD/NASH	[61-63,65]
miR-34a	↑	↑	Regulates lipoprotein metabolism and promotes liver steatosis Involved in NAFLD/NASH Correlates with the severity of hepatic inflammatory activity Can serve as a biomarker to distinguish NAFLD from NASH patients	[72,73,75]
miR-122	↑	↓	Modulates several genes linked to chronic hepatic pathology and lipid metabolism Promotes hepatic steatosis Serum miR-122 correlates positively with markers of NAFLD severity as well as with NASH	[74,82-84]
miR-155	↑	↑	Regulates key cellular events in NAFLD/NASH Promotes insulin resistance	[96,97]
miR-192	↑	↓	Significantly elevated in NAFLD patients and positively associated with hepatic inflammatory activity score and disease progression Increased in serum from NASH patients compared with steatosis Could be a potential biomarker of NAFLD and NASH	[32,80,100]
miR-375	↑	↑	Involved in the pathogenesis of NAFLD/NASH/fibrosis Key regulator of glucose homeostasis and insulin secretion	[80,102]

HCC: Hepatocellular carcinoma; miRNAs: MicroRNAs; NAFLD: Nonalcoholic fatty liver disease; NASH: Nonalcoholic steatohepatitis.

lncHR1

The lncRNA HCV regulated 1 (lncHR1) was recently identified as a novel human-specific lncRNA that has an effect on lipid metabolism. A study by Li *et al*[116] reported that in an HFD mouse model, overexpression of lncHR1 inhibited fatty acid synthase and lowered oleic acid-induced hepatic cell TG and lipid droplets' accumulation by inhibiting *SREBP1c* gene expression. These findings are relevant to NAFLD since dyslipidemia in patients with NAFLD is atherogenic in nature and it is characterized by increased levels of serum TG. Furthermore, elevated TG levels in the circulation are associated with metabolic syndrome and cardiovascular disease[117].

Metastasis-associated lung adenocarcinoma transcript 1

Metastasis-associated lung adenocarcinoma transcript 1 (MALAT1) is one of the highly conserved lncRNAs shown to play a significant role in many diseases, including cancer, diabetes, and insulin resistance. A previous study showed that excess PA increases MALAT1 expression, activated SREBP1c and induced intracellular lipid accumulation in hepatocytes, whereas inhibition of MALAT1 expression decreased nuclear SREBP1c level and lipid accumulation both *in vitro* and *in vivo*[118]. Further analysis by these authors revealed that the reduction of MALAT1 in the liver improved insulin sensitivity in ob/ob mice. They concluded that MALAT1 may promote hepatic steatosis and insulin resistance by increasing nuclear SREBP1c protein stability in hepatocytes[118]. Furthermore, results from lncRNA profiling in the liver biopsies of NAFLD patients demonstrated the potential of MALAT1 as a regulator of liver inflammation and fibrosis and insulin resistance by targeting the C-X-C motif chemokine ligand 5[119]. Consistent with these observations, another study found that MALAT1 expression was significantly increased in NASH patients compared to NAFLD individuals with simple steatosis and controls[120]. Previous studies have reported that MALAT is overexpressed in both HCC cell lines and clinical tissue samples[121,122], providing additional evidence that this lncRNA could be used as a

biomarker of liver damage and HCC development.

Nuclear enriched abundant transcript 1

Nuclear enriched abundant transcript 1 (NEAT1) is a nuclear lncRNA involved in various liver diseases [123]. It is involved in adipogenesis processes, including lipolysis, lipid uptake, and LDL oxidation. A recent study indicated that the NEAT1 and mTOR signaling pathway proteins were increased in NAFLD *in vitro* and *in vivo* while downregulation of NEAT1 alleviated NAFLD *via* the mTOR/S6K1 signaling pathway in rat model[124]. Additionally, NEAT1 plays an important role in the activation of estrogen receptor alpha to regulate water-glycerol transporter (AQP7)-mediated hepatic steatosis[125]. Chen *et al*[126] found that NEAT1 promotes steatosis by sponging miR-146a-5p, subsequently increasing the expression of Rho-kinase1 (ROCK1) and significantly inducing the AMPK/SREBP pathway. Silencing of NEAT1 alleviated fibrosis and inflammatory responses by regulating the miR-506/GLI3 axis in an NAFLD cellular model[127]. A recent study indicated that NEAT1 and paternally expressed gene 3 were highly expressed in the liver and HSCs from NASH mice and silencing of NEAT1 effectively reduced the fibrotic characteristics of HSCs in the setting of NASH[128]. These results corroborate previous findings by Leti *et al*[119] indicating that NEAT1 is upregulated in the fibrosis of NASH patients compared to controls. Together, these studies highlight the potential value of NEAT1 for aiding in the prognosis and diagnosis of NASH.

Ultra-conserved element

Ultra-conserved element (UC372) is a lncRNA associated with impaired homeostasis of lipid metabolism and may play a role in the pathogenesis of NAFLD. UC372 is upregulated in a murine model of T2DM (db/db mice), HFD-fed mice, and NAFLD patients, indicating a role in liver steatosis and fatty liver[129]. Mechanistically, UC372 may drive hepatic steatosis through binding to pri-miR-195/pri-miR-4668, thus preventing miR-195/miR-4668 from regulating the expression of target genes associated with lipid synthesis and uptake, including acetyl-CoA carboxylase, fatty acid synthase, stearoyl-CoA desaturase 1, and lipid uptake-related genes such as CD36[129]. These preliminary results suggest that UC372 may be a promising target for therapies combating hepatic steatosis.

Maternally expressed gene 3

Maternally expressed gene 3 (MEG3), also known as gene trap locus 2, is another lncRNA that plays a regulatory role in the carcinogenesis and progression of several types of cancer. MEG3 is also suspected to be involved in the pathogenesis of NAFLD. In this respect, an early study reported that expression of hepatic MEG3 was consistently decreased in the chemokine (C-C motif) ligand 4 (CCl4)-induced mouse progressive liver fibrosis model compared to normal tissues, and HSCs may be one of the main sources of the MEG3 Levels present in CCl4-treated livers[130]. The same study revealed that MEG3 was also downregulated in human liver fibrotic tissues compared with control liver tissues. In line with this these studies, Huang *et al*[131] showed that the downregulation of MEG3 in *in vitro* and *in vivo* models of NAFLD is negatively correlated with lipogenesis-related genes, and that overexpression of MEG3 alleviates lipid overaccumulation in HepG2 cells. The downregulation of MEG3 in two models of NAFLD (free fatty acid-challenged primary hepatocytes and HFD-induced mouse) was also indicated in a more recent study by Zou *et al*[132].

In contradiction with these results, hepatic MEG3 Levels are significantly increased in liver fibrosis and NASH cirrhosis in human patients[133]. Similarly, MEG3 was shown to be one of the most differentially expressed lncRNAs in the vascular endothelium in diet-induced obese mice, and its expression was elevated in human nonalcoholic fatty livers and NASH livers, whereas its knockdown potentiated obesity-induced insulin resistance and impaired glucose homeostasis[134]. These conflicting results underline the complexity of MEG regulation, and further studies are required to clarify the biological significance of MEG3 and its potential role MEG3 either as a biomarker or a therapeutic target for NAFLD.

Highly upregulated in liver cancer

The lncRNA highly upregulated in liver cancer (HULC) was the first identified lncRNA specifically overexpressed in HCC. HULC, a functionally important lncRNA, promotes HCC growth, metastasis and drug resistance[135]. HULC expression was found to be increased in the liver tissue of NAFLD rats [136]. Inhibition of this lncRNA improves hepatic fibrosis and lipid deposition and decreases hepatocyte apoptosis in rats with NAFLD *via* inhibition of the mitogen-activated protein kinase signaling pathway in liver tissue[136]. Interestingly, the antidiabetic drug metformin was also reported to decrease HULC by inhibiting the expression of specificity protein 1 transcription factor in liver cancer cells[137]. Indeed, metformin was shown to improve insulin resistance and hyperinsulinemia and increase insulin sensitivity. This drug is now recommended and has proven to be effective for the treatment of NAFLD [138]. Collectively, these findings suggest that HULC could be a promising target for NAFLD diagnosis, staging, and therapy.

Homeobox transcript antisense intergenic RNA

Homeobox (HOX) transcript antisense intergenic RNA (HOTAIR) is a lncRNA that resides on a boundary of the HOXC locus on chromosome 12q13.13. HOTAIR is increased in different forms of cancers and involved in diverse cellular functions. In NAFLD, free fatty acid treatment promotes TG accumulation in HepG2 cells, significantly induces HOTAIR expression and inhibits phosphatase and tensin homolog expression[139]. A recent study reported that HOTAIR was activated in NAFLD, and HOTAIR knockdown significantly inhibited the development of NAFLD *via* mediation of miR-130b-3p/ROCK1/AMPK axis, further suggesting a target for NAFLD[140]. HOTAIR shows several oncogenic functions in HCC and its expression levels are increased in liver fibrosis, which causes acceleration of carcinogenesis in hepatitis B virus-infected patients[141]. Other investigations have reported that HOTAIR can serve as a competing endogenous RNA to sponge miR-29b and then repress DNMT3b, which contributes to hepatic fibrosis[141].

Fatty liver-related lncRNA 2

The lncRNA fatty liver-related lncRNA 2 (FLRL2) is located in the intronic region of the aryl hydrocarbon receptor nuclear translocator-like (*Arntl*) gene, and *Arntl* is predicted as a cis target of FLRL2. FLRL2 was identified as a potential key molecule in the pathogenesis of NAFLD. This nuclear-localized lncRNA is downregulated in the NAFLD mouse model, suggesting a role in the pathogenesis of this disease[142]. Further mechanistic studies have demonstrated that overexpression of FLRL2 alleviates NAFLD through activation of the Arntl-SIRTA pathway, inhibits lipogenesis, and reduces hepatic steatosis in HFD mice[143]. These results render FLRL2 another promising therapeutic candidate for the treatment of NAFLD and its complications. Finally, the above-discussed lncRNAs with their potential functions in NAFLD are also summarized in Table 2.

circRNAs in NAFLD

As their name implies, circRNAs are single-stranded covalently closed RNA species formed through back-splicing. Distinct characteristics of circRNAs, such as high stability, evolutionary conservation among species, exonuclease resistance, and existence in body fluids endow this class of RNAs with numerous potential functions ranging from miRNA and protein sponges to gene transcriptional regulators and protein/peptide translators. Moreover, circRNAs are dysregulated in numerous pathological conditions and may potentially serve as novel diagnostic biomarkers and therapeutic targets.

Although there is increasing evidence linking circRNAs to the pathogenesis of metabolic diseases, studies centered on the investigation of circRNAs in NAFLD were only recently conducted[144-146]. Data from recent literature suggest that circRNAs are involved in several fundamental processes governing the onset and progression of NAFLD and display aberrant expression[147]. For instance, a circRNA_0046367 was decreased in HFD-induced hepatic steatosis[148]. Subsequently, the authors of this study demonstrated that normalization of circRNA_0046367 Levels prevents lipid peroxidation and mitochondrial dysfunction in steatosis through miR-34a sponging and PPARα downregulation. In a further analysis, the same research laboratory identified an additional circRNA: circRNA_0046366, whose expression was also diminished during free fatty acid-induced hepatocellular steatosis in high fat-treated HepG2 cells[149]. In HepG2 cells with hepatic steatosis induced by high-fat stimulation, circRNA_021412 was associated with hepatic steatosis *via* the circRNA_021412/miR-1972/LPIN1axis [150]. circRNA microarrays analysis in an HFD mouse model revealed that circScd1 expression was significantly decreased in NAFLD tissues compared to that in controls. Consistent with this, knockdown of circScd1 promoted hepatosteatosis through the regulation of the Janus kinase 2 and signal transducer and activator of transcription 5 signaling pathway[151]. In an *in vitro* model of NAFLD, Hsa_circ_0048179 was shown to attenuate free fatty acid-induced steatosis *via* Hsa_circ_0048179/miR-188-3p/glutathione peroxidase 4 signaling[152]. circRNA profiling in a NASH mouse model identified circRNA_29981 as the circRNA most significantly differentially expressed in this setting[153].

More recently, Jin *et al*[147] indicated that the circRNA_002581-miR-122-CPEB1 axis aggravates NASH partially through autophagy suppression, while silencing of circRNA_002581 significantly attenuated lipid droplet accumulation, eliminated liver damage in both mouse and cellular models of NASH. Chen *et al*[154] indicated that silencing of circ_0071410 alleviates hepatic stellate activation, a key step of liver cirrhosis. HSCs are the primary cell type responsible for liver fibrosis. In the CCl4-induced mouse model of liver fibrosis, mmu_circ_34116 was able to inhibit HSCs activation[155]. In a mouse model of NAFLD, Chen *et al*[156] found that circ_0057558 can promote NAFLD by regulating ROCK1/AMPK signaling through targeting miR-206. Interestingly, a novel mitochondrial genome-encoded circRNA termed mitochondrial steatohepatitis-associated circRNA ATP5B regulator (SCAR) was identified recently[157]. The latter study found SCAR to be significantly downregulated in liver fibroblasts from patients with NASH. Additionally, the overexpression of SCAR inhibited mitochondrial reactive oxygen species output and fibroblast activation *via* shutting down mitochondrial permeability transition pore. More importantly, *in vivo* targeting of SCAR alleviated HFD-induced cirrhosis and insulin resistance implying that circRNA SCAR may serve as a therapeutic target for NASH[157].

Table 2 Relevant dysregulated long noncoding RNAs associated with alterations in liver metabolism and nonalcoholic fatty liver disease

lncRNA	Expression	Main functional and pathophysiological effects	Ref.
MALAT1	↑	Promotes cell proliferation, migration, and invasion in several different human cancers including HCC Promotes hepatic steatosis and insulin resistance Hepatic MALAT1 levels are higher in NASH patients with fibrosis Promotes NAFLD progression and increase with the severity of the disease	[119-122]
NEAT1	↑	Promotes adipogenesis, lipogenesis, and lipid absorption Modulates fibrosis and inflammatory responses Silencing NEAT1 alleviated fibrosis and inflammatory in a NAFLD cellular model	[124,126,127]
MEG3	↓	Involved in lipid metabolism and glucose homeostasis Correlates with steatosis and inflammation (NASH) in patients with NAFLD	[131-134]
HULC	↑	Promotes HCC growth and metastasis Promotes NAFLD development Metformin decreases HULC expression	[135,136]
HOTAIR	↑	Activates lipid accumulation in hepatocytes and promotes hepatic steatosis development Expression profile is significantly increased in oleic acid-induced steatosis and during the development of HFD-induced NAFLD Accelerates liver fibrosis and carcinogenesis	[139-141]
FLRL2	↓	Decreases endoplasmic reticulum stress and liver inflammation Alleviates NAFLD and steatosis in mouse model	[143]

FLR2: Fatty liver-related lncRNA 2; H19: H19 imprinted maternally expressed transcript; HCC: Hepatocellular carcinoma; HFD: High-fat diet; HOTAIR: HOX transcript antisense RNA; MALAT1: Metastasis-associated lung adenocarcinoma transcript 1; lncRNAs: Long noncoding RNAs; MEG3: Maternally expressed 3; NAFLD: Nonalcoholic fatty liver disease; NASH: Nonalcoholic steatohepatitis; NEAT1: Nuclear paraspeckle assembly transcript 1; HULC: Hepatocellular carcinoma upregulated long noncoding RNA.

Together, these findings suggest that certain circRNAs, including those summarized in Table 3, are likely to contribute to NAFLD phenotype, which makes them attractive targets for the development of diagnostic and interventional pharmacology. However, circRNA data are still lacking functional evidence and their underlying mechanisms are still awaiting elucidation. Nevertheless, further carefully designed prospective studies to emphasize and validate the potential use of circRNAs as NAFLD biomarkers are expected to yield new insights into the pathogenesis of this disease state.

CONCLUSION

The findings from the above research clearly indicate that alterations in miRNA, circRNA and lncRNA expression play critical roles in cellular physiology and many diseases, including NAFLD and cancer. Thus, these ncRNA subsets are promising non-invasive biomarkers for the diagnosis and stratification of patients with NAFLD and could inform future personalized treatments designed for this condition. Even though the concept is promising and optimism is high, there is a consensus that research in the field still has limitations and technical challenges. (1) Sustained research efforts in the ncRNAs field have aimed to develop biomarkers to support the diagnostic process in patients with NAFLD. Unfortunately, most of the studies were carried out in subjects who already display patterns of worsening symptoms and are seeking medical care. To overcome this challenge, an alternative option would be to investigate the status of ncRNAs in the general population, which may assess the risk and capture early stages of disease initiation and evolution. This strategy could help achieve early diagnosis in individuals at risk for NAFLD but yet asymptomatic, and determine whether the overserved aberration in ncRNA

Table 3 Relevant dysregulated circular RNAs associated with alterations in liver metabolism and nonalcoholic fatty liver disease

circRNA	Expression level	Main functional and pathophysiological effects	Ref.
circRNA_0046367	↑	Inhibits hepatic steatosis by preventing hepatotoxicity of lipid peroxidation	[148]
circRNA_0046366	↑	Inhibits hepatic steatosis through miR-34a/PPARα	[149]
circRNA_021412	↑	Associated with hepatic steatosis	[150]
circScd1	↓	Affects steatosis on NAFLD *via* JAK2/STAT5 signaling pathways	[151]
hsa_circ_0048179	↓	Attenuates free fatty acid-induceded steatosis by sponging of miR-188-3p *in vitro*	[152]
mmu_circRNA_29981	↑	Regulatory role in NASH mousee model	[153]
Circ_0057558	↑	Involved in lipogenesis	[156]
		Promotes nonalcoholic fatty liver disease by sponging miR-206	
SCAR	↓	Correlates with steatosis-to-NASH progression	[157]
		In vivo, targeting circRNA SCAR alleviates HFD-induced cirrhosis and insulin resistance	

circRNAs: Circular RNAs; HCC: Hepatocellular carcinoma; HFD: High-fat diet; JAK2: Janus Kinase 2; NAFLD: Nonalcoholic fatty liver disease; NASH: Nonalcoholic steatohepatitis; PPARα: Peroxisome proliferator-activated receptor α; STAT5: Signal transducer and activator of transcription 5.

expression is the trigger or it is just a consequence of other causes such as those associated with lipid metabolism disorder, inflammation and immune system; (2) The role of ncRNAs as mediators of cell and organ crosstalk as well as their impact on different signaling pathways involved in NAFLD pathogenesis are not fully understood. It is now recognized that some ncRNAs are present in the extracellular environment and may be involved in pathophysiological condition. They may act to affect their targets either in an autocrine or paracrine fashion. Hence, special attention should be drawn to further research addressing the role of ncRNAs and their carriers (extracellular vesicles) in mediating potential inter-organ crosstalk in NAFLD condition, and the dynamic interaction of ncRNAs with metabolism cell signaling pathways. While these strategies may seem difficult to carry out and complete, they can be a starting point for increasing our knowledge on the role of circulating ncRNAs in organ crosstalk and may represent an opportunity to better understand how they affect metabolic homeostasis to drive the onset and progression of NAFLD and related pathological conditions; and (3) From a clinical perspective, approaches based on an individual ncRNA targeting or overexpression are what researchers are shooting for. However, each ncRNA has highly redundant roles and multiple functions. Indeed, a previous study revealed that a miRNA can affect a phenotype not only through a simple regulatory process, but *via* multiple targets redundantly and often incoherently, and such a complex regulation is difficult to assemble and control[158]. Indeed, it is becoming evident that it is difficult to diagnose a multifactorial disease such as NAFLD using a single ncRNA. Attempts were conducted to use a combination of serum circulating ncRNAs. Understanding the ncRNA-ncRNA crosstalk and their intricate interplay with different genetic and other epigenetic regulators including DNA methylation, chromatin remodeling, and components of the transcriptional and posttranscriptional machineries to regulate gene networks involved in NAFLD could certainly expand our knowledge on the molecular mechanisms driving this disease. This approach can also lead to a breakdown into NAFLD subtypes which would add resolution and inform about the regulation of molecular processes involved in each stage of the disease by specific ncRNAs.

To sum up, this review highlights the evidence for potential subsets of ncRNAs that are associated with NAFLD and its pathological conditions. The findings from various human and animal studies clearly suggest that dysregulation in ncRNA profiles are critical factors in the initiation and progression of fatty liver diseases, including NAFLD. This may be an appealing argument to further explore the mystery of these RNA molecules and consider their clinical application as biomarkers/therapeutics in the prevention and treatment of NAFLD and its progressive forms.

Abstract

Non-alcoholic steatohepatitis (NASH) is defined as hepatic steatosis, inflammation, and hepatocyte injury with or without fibrosis. It has emerged as the second leading indication for liver transplantation with a rising death rate in the non-transplantable population. While there are many drugs in evaluation, currently no approved therapies are on the market for this condition. Given this importance, the Food and Drug Administration has provided formal guidance regarding drug development for stopping or reversing NASH or NASH associated fibrosis. The complex pathogenesis of NASH and its bidirectional relationship with metabolic syndrome has highlighted multiple drugs of interest that address metabolic, inflammatory, and fibrotic factors. A few promising liver specific targets include farnesoid X receptor agonists and peroxisome proliferator-activated receptor agonists. Previously studied drug classes such as glucagon-like peptide-1 analogs or sodium/glucose transport protein 2 inhibitors have also demonstrated ability to improve hepatic steatosis. Here we discuss current rationale, scientific work, and preliminary data in combining multiple drugs for the purposes of a multimodal attack on the pathogenesis of NASH. We highlight multiple Phase 2 and Phase 3 studies that demonstrate the potential to achieve a response rate higher than previously assessed monotherapies for this condition. Ultimately, one of these combination strategies may rise above in its safety and efficacy to become a part of a standardized approach to NASH.

Key Words: Non-alcoholic steatohepatitis; Fatty liver; Combination treatment; Drug therapy; Pharmacologic treatment; Clinical trials

©**The Author(s) 2022.** Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: Multimodal combination approaches targeting two or more molecular pathways contributing to steatohepatitis and liver fibrosis are needed to augment efficacy of novel investigational drug regimens to achieve non-alcoholic steatohepatitis (NASH) resolution and NASH fibrosis improvement.

INTRODUCTION

Non-alcoholic steatohepatitis (NASH) is defined as the presence of ≥ 5% hepatic steatosis and inflammation with hepatocyte injury with or without fibrosis. Non-alcoholic fatty liver disease (NAFLD) represents a spectrum of pathology encompassing hepatic steatosis, steatohepatitis (NASH), and liver fibrosis, and poses a significant challenge to the medical community as there are currently no Food and Drug Administration (FDA) approved therapies available on the market. The definition of NAFLD includes the lack of secondary causes of hepatic steatosis such as alcohol consumption, steatogenic medication or hereditary liver disease. With NAFLD-associated death rates on the rise and NASH emerging as the second most common indication for liver transplantation, there has been heightened urgency to target various disease pathways in NASH development with the hopes of controlling the global impact of this disease[1,2]. With this rising importance, the FDA has published formal guidance regarding drug development aimed at stopping or reversing NASH and NASH fibrosis. The current drug development pipeline contains many mono-therapeutic options which address a wide range of metabolic, inflammatory, and fibrosis target pathways associated with NASH pathogenesis.

The pathophysiology of NASH is based on a bidirectional relationship between type 2 diabetes mellitus (T2DM), hypertension, obesity and dyslipidemia–or metabolic syndrome. This relationship contributes to excess free fatty acids generated from lipolysis and de novo lipogenesis in the liver, which creates lipotoxic species which induce oxidative stress, inflammasome activation, and fibrinogenesis[3] . Liver specific targets aimed at decreasing histologic inflammation or fibrosis such as farnesoid X receptor (FXR) agonists or peroxisome proliferator-activated receptor (PPAR) agonists are currently being evaluated for the treatment of NASH. These are in addition to drug classes such as glucagon-like peptide-1 (GLP-1) agonists and sodium/glucose transport protein 2 inhibitors that were initially approved for treatment of diabetes but have demonstrated the ability to decrease liver fat content[4,5]. While individually these agents have shown promise in early trials, there has been growing interest in pursuing a multimodal combination approach targeting two or more molecular targets/pathways responsible for NASH and NASH-associated liver fibrosis, particularly in context of modest effects of single agent strategies on histologic endpoints, with fewer than 50% of patients achieving either NASH resolution of fibrosis improvement of one stage or greater[6]. Therefore, this mini review will succinctly summarize the current efforts to examine combination strategies of drugs which may further augment therapeutic response in patients with NASH.

FDA APPROVAL PATHWAY

The FDA generally has two pathways for drug approval. The traditional pathway focuses on clinical benefit endpoints (*i.e.*, morbidity and mortality) and requires long term data. A brief review is provided in Figure 1. The accelerated approval pathway is intended to expedite the process for serious medical conditions with unmet needs. This pathway relies on short term surrogate markers that would reliably predict long term clinical outcomes to support drug approval. To inform clinical trial design for investigational drugs under evaluation for NASH, industry guidance was issued by the FDA in 2018 with a focus on patients with non-cirrhotic NASH with stage 2-3 liver fibrosis[7]. Although histologic endpoints were reinforced as required for assessment of surrogate endpoints for NASH and liver fibrosis, the agency encouraged the development and validation of noninvasive biomarkers in clinical trials to accelerate drug development. NASH was defined as a NAFLD activity score (NAS) greater than or equal to 4 with at least 1 point each in inflammation and ballooning degeneration, plus a NASH Clinical Research Network fibrosis score greater than stage 1 fibrosis but less than stage 4 for enrollment in these trials. Lastly, the primary regulatory endpoints required to support accelerated approval include: (1) NASH resolution on histology (NAS less than 4 with individual components scores of 0 for

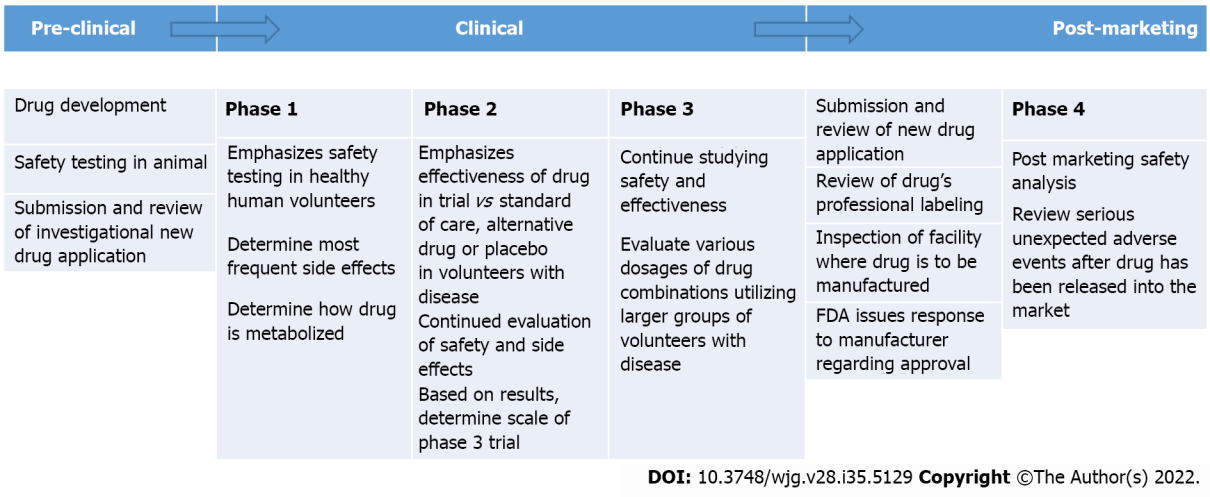

Figure 1 Flow diagram of standard Food and Drug Administration drug approval process.

ballooning degeneration and 0-1 for inflammation) without worsening fibrosis; (2) Improvement in liver fibrosis greater than or equal to one stage without worsening NASH; or (3) NASH resolution and improvement in fibrosis by one stage or greater. Clinical benefit for these drugs was defined as superiority to placebo in delayed disease progression measured by a composite endpoint including progression to cirrhosis, hepatic decompensation, change in MELD score, liver transplantation, or all-cause mortality.

DRUGS IN DEVELOPMENT–PHASE 2

Key phase 2 trials for NASH therapeutics are summarized in Table 1. In brief, one major class being pursued is fibroblast growth factor 21 (FGF21) agonists such as pegbelfermin. FGF21 is endogenously produced by the liver and has a pleiotropic effect on metabolism that may benefit patients with NASH. Endogenous FGF21 concentrations are elevated as much as 10-fold in patients with obesity, NAFLD or NASH, leading to the hypothesis that these may represent an FGF21-resistant state which may benefit from exogenous stimulation to improve insulin sensitivity and lipid metabolism[8] . GLP-1 is an incretin hormone made by intestinal cells post prandially for which receptors are predominantly in the pancreas, adipose tissue and brain. It regulates plasma glucose by stimulating glucose release and inhibiting glucagon secretion. GLP-1 agonists have previously shown to improve hepatic steatosis, decrease liver inflammation, and ameliorate insulin resistance in murine models of fatty liver disease. Semaglutide and liraglutide have shown promising results with statistically significant NASH improvement or resolution compared to placebo[9,10]. Norursodeoxycholic acid is an orally administered side chain-shortened homologue of ursodeoxycholic acid that undergoes hepatic enrichment with hepatoprotective, anti-inflammatory, and antifibrotic activity. It has shown significant reduction of serum alanine aminotransferase (ALT) within 12 wk of treatment when compared with placebo, encouraging further investigation[11]. Aldafermin is an analogue of fibroblast growth factor 19 (FGF19) which regulates bile acid metabolism and fat storage in the liver. FGF19 levels are lower in patients with NAFLD and insulin resistance. Activation of the FGF19 pathway has been shown to improve insulin sensitivity and liver steatosis. In a 24-wk placebo-controlled trial, the aldafermin group experienced a significant reduction in absolute liver fat content compared with placebo (P = 0.002) and fibrosis improvement of at least 1 stage (38% *vs* 18%, P = 0.10)[12]. The currently ongoing phase 2b ALPINE 4 study is designed to assess the efficacy, safety and tolerability of this agent (NCT04210245).

FXR agonists, which bind to the transcription factor FXR to help regulate bile acid metabolism are in multiple phases of clinical trial investigation. The FXR agonist tropifexor has demonstrated a robust and dose-dependent decrease in ALT, hepatic fat fractionation, and body weight with good safety and tolerability after 12 wk of treatment in a phase 2 trial[13]. The PPARα, β/δ and γ, play a central role in the regulation of glucose and lipid metabolism and of the inflammatory and fibrogenic pathways which contribute to NASH pathogenesis. Lanifibranor (IVA337), a pan-PPAR agonist, combines pharmacological effects that could improve fatty acid oxidation, dyslipidemia, and insulin sensitivity, and has demonstrated anti-inflammatory, antifibrotic and hepatoprotective effects in preclinical models and phase 1/2 trials. TVB-2640 is an orally bioavailable, first-in-class fatty acid synthase (FASN) inhibitor. FASN is a key enzyme in the de novo lipogenesis pathway that is responsible for the synthesis of excess fat and activation of fibrogenic and inflammatory mechanisms in the liver of patients with NASH. TVB-2640 demonstrated significant improvement in several NASH endpoints in the FASCINATE-1 trial as

Table 1 Phase 2 trials in non-alcoholic steatohepatitis

Trial name/NCT number	Manufacturer	Drugs	Mechanism of action	Enrollment (targeted)	Study arms	Duration	Primary or relevant end point(s)	Results/SE
NCT03976401	Akero Therapeutics	AKR-001	FGF 21 receptor agonist	80	(1) AKR-001 50 mg QD; and (2) Placebo	112	Change in liver fat fraction measured by MRI-PDFF	Ongoing
NCT04541186	89bio	BIO89-100	FGF 21 receptor agonist	90	(1) BIO89-100 (QW or every 2 wk); and (2) Placebo	112	Change in various lab parameters TG, LDL, HDL, fasting glucose. Change in liver fat fraction measured by MRI-PDFF	Ongoing
NCT02097277	Bristol-Myers Squibb	Pegbelfermin (BMS-986036)	FGF 21 receptor agonist	120	(1) Pegbelfermin 1 mg QD; (2) Pegbelfermin 5 mg QD; (3) Pegbelfermin 20 mg QD; (4) Pegbelfermin 20 mg weekly; and (5) Placebo	84	Safety, tolerability, and change in HbA1c. Change in insulin sensitivity, lipids, adiponectin, and disease progression biomarkers	No significant effects of pegbelfermin versus placebo on HbA1c. Pegbelfermin 20 mg/d significantly improved high-density lipoprotein cholesterol and triglycerides. Most frequent adverse events were injection-site bruising and diarrhea
NCT01237119	Novo Nordisk	Liraglutide	GLP-1analogue	52	(1) Liraglutide 1.8 mg SC QD; and (2) Placebo	336	Resolution of NASH without worsening fibrosis	39% who received liraglutide and underwent end-of-treatment liver biopsy had resolution of definite non-alcoholic steatohepatitis compared with 9% in placebo (P = 0 019). Side efffects diarrhea and loss of appetite
NCT02970942	Novo Nordisk	Semaglutide	GLP-1 analogue	320	(1) Semaglutide 0.1 mg SC QD; (2) Semaglutide 0.2 mg SC QD; (3) Semaglutide 0.4 mg SC QD; and (4) Placebo	504	Resolution of NASH without worsening fibrosis. Improvement in fibrosis, LFTs, A1c level	NASH resolution was achieved in 40% in the 0.1-mg group, 36% in the 0.2-mg group, 59% in the 0.4-mg group, and 17% in the placebo group (P < 0.001 for semaglutide 0.4 mg *vs* placebo). Side effects including nausea, constipation, and vomiting which was higher in the 0.4-mg group
2013-004605-38	Dr Falk Pharma GmbH	Norursodeoxycholic acid	homologue of ursodeoxycholic acid, undergoes hepatic enrichment with hepatoprotective, anti-inflammatory, and antifibrotic activity	198	(1) 500 mg norursodeoxycholic acid QD; (2) 1500 mg norursodeoxycholic acid QD; and (3) Placebo	112	Change in ALT levels	Dose-dependent reduction in ALT with norursodeoxycholic acid versus placebo, with a significant effect in the 1500 mg group (P < 0.0001). Side effects included headache, gastrointestinal disorders, and infections
COHORT 4/NCT02443116	NGM Biopharmaceuticals	Aldafermin	Analog of fibroblast growth factor 19, inhibits bile acid synthesis and regulates metabolic homeostasis	78	(1) aldafermin 1 mg QD; and (2) Placebo	168	Improvement in liver fibrosis of greater or equal to one stage with no worsening of NASH	Aldafermin group with higher rate of liver fat content reduction compared to placebo (7.7% *vs* 2.7%, P = 0.02). Aldafermin produced significantly greater decrease in bile acids, liver enzymes. Fibrosis improvement without worsening NASH higher in aldafermin group (38% *vs* 18%, P = 0.10). NASH resolution without worsening fibrosis higher in aldafermin group (24% *vs* 9%, P = 0.20). Side effects include diarrhea, headache, abdominal distation and peripheral edema

ALPINE 4/NCT04210245	NGM Biopharmaceuticals	Aldafermin	Analog of fibroblast growth factor 19, inhibits bile acid synthesis and regulates metabolic homeostasis	72	(1) Aldafermin 0.3 mg QD; (2) Aldafermin 1 mg QD; (3) Aldafermin 3 mg; and (4) Placebo	168	Improvement in liver fibrosis of greater or equal to one stage with no worsening of NASH	Ongoing
FLIGHT-FXR/NCT02855164	Novartis Pharmaceutical	Tropifexor	FXR agonist	152	(1) TXR 140 g QD; (2) TXR 200gr QD; and (3) Placebo	84	Changes in liver fat fraction, liver enzymes, body weight	End point achieved in TXR 800 mg *vs* 1200 mg *vs* Placebo (51% *vs* 55% *vs* 34%, $P = 0.001$). Side effects include mild pruritus and increase in LDL
NATIVE/NCT03008070	Inventiva	Lanifibranor	PPAR agonist	247	(1) Lanifibranor 800 mg QD; (2) Lanifibranor 1200 mg QD; and (3) Placebo	168	Responder analysis based on the improvement of the SAF activity score	L800 mg *vs* 1200 mg *vs* Placebo (51% *vs* 55% *vs* 34%) $P = 0.0015$. SE weight gain, peripheral edema
FASCINATE-1/NCT03938246	Sagimet Biosciences Inc	TVB-2640	FASN inhibitor	99	(1) TVB2640 25 mg QD; (2) TVB2640 50 mg; and (3) Placebo	84	Change in hepatic fat fraction from baseline in subjects with NASH by proton-density fat fraction by magnetic resonance imaging	Dose-dependent relative changes in liver fat by MRI-PDFF were -28.2% with 50 mg ($P < 0.005$ *vs* placebo), -9.6% with 25 mg, and +4.5% with placebo. 30% relative reduction in liver fat at week 12 were 61% ($P < 0.001$ *vs* placebo)
NCT02856555	Gilead Sciences	Firsocostat	Acetyl-coenzyme A carboxylase Inhibitor	126	(1) Firsocostat 20 mg QD; (2) Firsocostat 5 mg QD; and (3) Placebo	84	Safety and tolerability. Secondary end point efficacy (NASH improvement without fibrosis)	Decrease of at least 30% from baseline in MRI-PDFF occurred in 48% of patients with 20 mg ($P = 0.004$), 23% given 5 mg ($P = 0.43$), and 15% given placebo. SE cause, abdominal pain, diarrhea
VOYAG/LBP20	Viking therapeutics	VK2809	Thyroid beta receptor agonist, selectively cleaved in hepatic tissue	45	(1) VK2809 5 mg QD; (2) VK2809 10 mg QOD; (3) VK280910 mg QD; and (4) Placebo	84	Safety, tolerability and efficacy in reducing liver fat content and LDL	< Liver fat content was 8.7% for 5 mg QD ($P = 0.0014$) *vs* 8.9% 10 mg QOD ($P = 0.013$) *vs* 10.6% for 10 mg QD ($P = 0.0030$), *vs* 1.1% for placebo. 70% in VK2809 therapy showed a ≥ 50%. Reduction in MRI-PDFF ($P = 0.014$)
NCT02912260	Madrigal Pharmaceuticals	Resmetirom (MGL-3196)	Selective thyroid hormone receptor-β agonist	125	(1) Resmetirom 80 mg QD; and (2) Placebo	252	Change in liver fat fraction measured by MRI-PDFF	80 mg *vs* placebo reduction of hepatic fat at week 12 (-32.9% *vs* -10.4%; $P < 0.0001$) and week 36 (-37.3% *vs* -8.5%; $P < 0.0001$)
NCT02784444	Cirius Therapeutics	MSDC-0602K	Insulin sensitizer designed to preferentially target the mitochondrial pyruvate carrier with direct binding to the transcriptional factor PPARγ	392	(1) MSDC-0602K 62.5 mg QD; (2) MSDC-0602K 125 mg QD; (3) MSDC-0602K 250 mg QD; and (4) Placebo	364	Hepatic histological and activity score improvement in either ballooning or lobular inflammationNo increase in fibrosis stage at 12 mo	Primary end point placebo 29.7%, *vs* 62.5 mg 29.8%, *vs* 125 mg 32.9% *vs* 250 mg 39.5% (95%CI: 0.44–1.81) (95%CI: 0.60–2.48), (95%CI: 0.83–3.27)

FGF: Fibroblast growth factor; MRI-PDFF: Magnetic resonance imaging with proton density fat fraction; GLP-1: Glucagon-like peptide-1; FXR: Farnesoid X receptor; PPAR: Peroxisome proliferator-activated receptor; FASN: Fatty acid synthase.

summarized in Table 1[14]. Firsocostat (GS-0976) is an inhibitor of ACC (acetyl-coenzyme A carboxylase) which catalyzes de novo lipogenesis in the liver. In a randomized placebo-controlled trial, firsocostat 20 mg decreased hepatic steatosis and surrogate markers of fibrosis[15]. VK2809 is a small

molecule prodrug of a potent thyroid beta receptor agonist which has demonstrated favorable effects on lipid metabolism and biomarkers of hepatic steatosis and steatohepatitis in a phase 2 trial, supporting its potential role in patients with NASH[16]. MSDC-0602K is a novel insulin sensitizer designed to preferentially target the mitochondrial pyruvate carrier while minimizing direct binding to the transcriptional factor PPARγ. MSDC-0602K did not demonstrate statistically significant effects on primary and secondary histologic endpoints in a phase 2 trial, but favorable effects on liver cell injury and glucose metabolism support further investigation for in patients with type 2 diabetes[17].

DRUGS IN DEVELOPMENT–PHASE 3

Novel investigational agents which have completed are undergoing evaluation in phase 3 trials are summarized in Table 2. Obeticholic acid, an FXR agonist, has been shown to improve the histological features of NASH, with fibrosis improvement in 23% of patients treated with Obeticholic acid compared with 12% in placebo group[18]. Elafibranor, a PPAR agonist, improves liver enzymes, lipids, glucose levels, and markers of systemic inflammation and is being tested in a phase 3 study (NCT02704403)[19]. Aramchol inhibits steroyl-CoA desaturase 1, a key enzyme in hepatic lipogenesis that converts saturated fatty acids into monounsaturated fatty acid. In the phase 2b ARREST trial, aramchol demonstrated liver fat reduction, biochemical improvement, NASH resolution and fibrosis reduction in a dose response pattern[20]. It has since been included in an ongoing phase 3 trial to test its safety and efficacy (NCT04104321). Cenicriviroc is an oral, dual antagonist of C-C motif chemokine receptor (CCR) types 2 and 5. It has shown anti-inflammatory and anti-fibrotic properties, which are mediated by CCR types 2 and 5 (CCR2/CCR5) blockade. In a randomized double-blind phase 2b study of 289 subjects, cenicriviroc was associated with a statistically significant improvement in NASH fibrosis of one stage or greater *vs* placebo (20% *vs* 10%; $P = 0.02$)[21]. A phase 3 randomized, double-blind, placebo-controlled trial (AURORA) is currently ongoing with evaluation of 2000 adults with NASH who are treated with cenicriviroc or placebo for 52 wk[22]. Resmetirom is a liver-directed, orally active, selective thyroid hormone receptor-β agonist designed to improve NASH by increasing hepatic fat metabolism and reducing lipotoxicity. In a phase 2b study, resmetirom treated patients showed a relative reduction of hepatic fat compared with placebo with statistically significant NASH resolution *vs* placebo[23], and is currently under evaluation in a phase 3 registration trial (NCT03900429). GR-MD-02 (belapectin), is an inhibitor of galectin 3 that reduces liver fibrosis and portal hypertension. In a phase 2 trial, belapectin was safe but not associated with significant reduction in hepatic venous pressure gradient (HVPG) or fibrosis. However, in a subgroup analysis of patients without esophageal varices, 2 mg/kg belapectin reduced HVPG and development of varices, suggesting a possible benefit in patients with NASH cirrhosis without esophageal varices[24] . In the phase 3 NAVIGATE trial, the safety and efficacy of belapectin is under evaluation with primary clinical endpoints of development of varices and event-free survival (NCT04365868).

COMBINATION THERAPEUTICS

The rationale of combining two or more strategies for NASH therapy aims to augment rates of NASH resolution and NASH fibrosis improvement. By targeting the development of steatohepatitis, liver fibrosis as well as controlling metabolic syndrome, we may achieve response rates higher than 32% as seen currently *via* trials of drugs as monotherapy[6]. Table 3 is a collection of studies currently underway, and some completed, that evaluate multidrug regimens for the treatment of NASH. FXR agonists, which regulate bile acid metabolism, are one major class of drugs incorporated in many of these trials. Obeticholic acid, a promising drug in this class, has demonstrated the dose-dependent ability to improve liver fibrosis and steatohepatitis in NASH patients with stage F2/F3 fibrosis based on initial and secondary analysis of the REGENERATE trials[18,25]. Cilofexor, another FXR agonist, has been tested in combination with firsocostat, an ACC inhibitor and selonsertib, an ASK1 inhibitor, in the phase 2b ATLAS study that demonstrated improvements in liver enzymes, fibrosis, NAS score on histology and improvements in liver elastography in the cilofexor/firsocostat group compared to placebo[26]. Ongoing studies with tropifexor include combinations with cenicriviroc and LYS0006 with early results still pending and waiting to be reviewed.

By now it is well known that features of metabolic syndrome increase the risk of developing NAFLD. Type 2 diabetes, specifically, is a risk factor for NASH and its presence increases the risk of progression of NASH fibrosis[27,28]. Therefore, some of the ongoing trials in combination therapy for NASH include semaglutide, pioglitazone or licogliflozin; from drug classes that traditionally have been utilized for the management of T2DM. In one randomized, placebo controlled trial in patients with biopsy proven NASH, a GLP-1 analog, liraglutide, was associated with greater improvement in steatohepatitis and lower progression of fibrosis[9]. A proof-of-concept trial is currently underway including semaglutide along with cilofexor and firsocostat. Licogliflozin, which has shown benefit in lowering liver fat content, is being studied as part of a combination trial with tropifexor in the ELIVATE trial.

Table 2 Phase 3 trials in non-alcoholic steatohepatitis

Trial name/NCT number	Manufacturer	Drugs	Mechanism of action	Enrollment (targeted)	Study arms	Duration (weeks)	Primary or relevant end point(s)	Results
REGENERATE/NCT02548351	Intercept Pharmaceuticals	Obeticholic acid	Farnesoid X receptor agonist	2480	(1) Obeticholic acid 10 mg QD; (2) Obeticholic acid 25 mg QD; and (3) Placebo	72-378	Fibrosis improvement (≥ 1 stage) with no worsening of NASH, or NASH resolution with no worsening of fibrosis	Fibrosis improvement endpoint-(12%) placebo, (18%) obeticholic acid 10 mg, (23%) obeticholic acid group 25 mg. Safety most common adverse event was pruritus
RESOLVE-IT/NCT02704403	Genfit	Elafibranor	PPAR agonist	2157	(1) Elafibranor 120 mg QD; and (2) Placebo	72-216	Change in fibrosis. Change in histologic score of NASH	ongoing
ARMOR/NCT0410432	Galmed pharma-ceuticals	Aramchol	SCD-1 inhibitor	247	(1) Aramchol 600 mg QD; (2) Aramchol 400 mg qd; and (3) Placebo	364	(1) Evaluate the safety and efficacy as measured with % change in the liver triglycerides concen-tration; and (2) Safety	Ongoing
AURORA/NCT03028740	Tobira Therapeutics	Cenicriviroc	Dual antagonist of CCR types 2 and 5	2000	(1) Cenicriviroc 150 mg; and (2) Placebo	364	(1) Proportion of subjects with ≥ 1-stage improvement in liver fibrosis and no worsening of steatohepatitis at month 12 relative to screening; and (2) Safety	Ongoing
MAESTRO-NASH/ NCT03900429	Madrigal Pharmaceuticals	Resmetirom	Selective thyroid hormone receptor-β agonist	2000	(1) resmetirom 80 mg QD; (2) resmetirom 100 mg QD; and (3) Placebo	364	NASH resolution, with at least a 2-point reduction in NAS (NASH Activity Score-biopsy), and with no worsening of fibrosis. Secondary end p. (1) Liver fibrosis improvement of at least one stage, with no worsening of NASH; and (2) Lowering of LDL-cholesterol	Ongoing
NAVIGATE/NCT04365868	Galectin Therapeutics	GR-MD-02 (belapectin)	Inhibitor of galectin 3	1010	(1) Belapectin 2 mg/kg intravenously (IV) every other week; (2) Belapectin 4 mg/kg intravenously (IV) every other week; and (3) Placebo	504	Development of new esophageal varices at 78 weeks in the belapectin group Cumulative incidence rate of decompensations and event-free survival by time to first cirrhosis related clinical event	Ongoing

PPAR: Peroxisome proliferator-activated receptor; SCD-1: Steroyl-CoA desaturase 1; CCR: C-C motif chemokine receptor

Numerous trials have already established the benefit of pioglitazone in improving inflammation and fibrosis in patients with biopsy proven NASH and therefore it is included as recommended management for a select group of patients according to the most recent American Association for the Study of Liver Diseases guidelines on NAFLD[29].

Aside from the ability to decrease inflammation and fibrosis in NASH, allowing treatment with lower doses of various drugs in combination or improvement the side effect profile are two alternate motives for pursuing combination therapy. In Wister rat models for NASH, one group was able to demonstrate a synergistic therapeutic effect on inflammation and oxidative stress from combining elafibranor and obeticholic acid at lower doses than with each drug in monotherapy[30]. FXR agonists have been shown to increase low density lipoprotein (LDL) cholesterol concentrations. In the CONTROL study, the

Table 3 Multidrug regimens for the treatment of non-alcoholic steatohepatitis

Trial name/NCT number	Phase	Manufacturer	Drugs	Mechanism of action	Enrollment (targeted)	Study arms	Duration (weeks)	Primary or relevant end point(s)
NCT02781584 (Proof of Concept)	1	Gilead Sciences	Selonsertib, firsocostat, cilofexor, fenofibrate, icosapent ethyl	(1) Selonsertib-selective ASK1 inhibitor; (2) Firsocostat-ACC inhibitor; (3) Cilofexor-FXR agonist; (4) Fenofibrate-PPAR agonist; and (5) Icosapent ethyl-under investigation	220	(1) Selonsertib; (2) Firsocostat; (3) Cilofexor; (4) Selonsertib + cilofexor; (5) Selonsertib + firsocostat; (6) Firsocostat + cilofexor; (7) Firsocostat (cirrhotic patients); (8) Cilofexor (cirrhotic patients); (9) Selonsertib + firsocostat + cilofexor; (10) Firsocostat + fenofibrate 48 mg; (11) Firsocostat + fenofibrate 145 mg; and (12) Icosapent ethyl + firsocostat + cilofexor	12	(1) Adverse events; (2) Serious adverse events; and (3) Lab abnormalities
ATLAS/NCT03449446	2	Gilead Sciences	Selonsertib, firsocostat, cilofexor	(1) Selonsertib-selective ASK1 inhibitor; (2) Firsocostat-ACC inhibitor; and (3) Cilofexor-FXR agonist	395	(1) Selonsertib + firsocostat + placebo; (2) Selonsertib + cilofexor + placebo; (3) Firsocostat + cilofexor + placebo; (4) Selonsertib + placebo + placebo; (5) Firsocostat + placebo + placebo; (6) Cilofexor + placebo + placebo; and (7) 3 placebos	48	(1) Adverse events; (2) Lab abnormalities; and (3) Improvement of ≥ 1-stage in fibrosis without worsening of NASH
NCT03987074	2	Gilead Sciences, Novo Nordisk	Cilofexor, semaglutide, firsocostat	(1) Semaglutide-GLP-1 agonist; (2) Firsocostat-ACC inhibitor; and (3) Cilofexor-FXR agonist	109	(1) Semaglutide; (2) Firsocostat + semaglutide; (3) Semaglutide + cilofexor 30 mg; (4) Semaglutide + cilofexor 100 mg; and (5) Semaglutide + firsocostat + cilofexor	24	(1) Adverse events; (2) Serious adverse events; and (3) Lab abnormalities
ELIVATE/NCT04065841	2	Novartis	Tropifexor, licogli-flozin	(1) Tropifexor-FXR agonist; and (2) Licogliflozin-SGLT1/2 inhibitor	380	(1) Tropifexor + licogliflozin; (2) Tropifexor + placebo; (3) Licogliflozin + placebo; and (4) 2 placebos	48	(1) Improvement of ≥ 1-stage in fibrosis without worsening of NASH; and (2) Resolution of NASH without worsening fibrosis
NCT03776175	2A	Pfizer	PF-05221304, PF-06865571	(1) PF-05221304-ACC inhibitor; and (2) PF-06865571 - DGAT 2 inhibitor	99	(1) ACC inhibitor + placebo; (2) DGAT2 inhibitor + placebo; (3) ACC inhibitor + DGAT2 inhibitor; and (4) 2 placebos	6	Improvement in fat fraction
TANDEM/NCT03517540	2	Novartis, Allergan	Tropifexor, cenicriviroc	(1) Tropifexor-FXR agonist; and (2) Cenicriviroc-CCR2/CCR5 inhibitor	193	(1) Tropifexor; (2) Cenicriviroc; (3) Tropifexor dose 1 + cenicriviroc; and (4) Tropifexor dose 2 + cenicriviroc	48	(1) improvement in fibrosis; and (2) Resolution of steato-hepatitis
CONTROL/NCT02633956	2	Intercept Pharmaceuticals	Obeticholic acid, atorvastatin	(1) Obeticholic acid-FXR agonist; and (2) Atorvastatin-HMG-CoA reductase inhibitor	84	(1) Obeticholic acid 5 mg/10 mg/25 mg + atorvastatin 10 mg/20 mg; and (2) Placebo + atorvastatin 10 mg/20 mg	16	(1) Change in LDL concen-tration; (2) Change in LDL particle size; and (3) Change in LDL particle concentration
NCT04235205	2	Albireo Pharma	Elobixibat, cholestyramine	(1) Elobixibat-IBAT inhibitor; and (2) Cholestyramine-bile acid binding resin	100	(1) Elobixibat + cholestyramine; (2) Elobixibat + placebo; (3) Placebo + cholestyramine; and (4) 2 placebos	16	(1) Change in liver fat fraction measured by MRI-PDFF; and (2) Change in fibrosis measured by MRE
PUVENAFLD/NCT04198805	2	DSM Nutritional Products	Vitamin E, omega-3 fatty acid	(1) Vitamin E-scavenging reactive oxidation species; and (2) Omega 3 FA-competing with omega 6 for cycloox-genase and lipoxygenase-mediated	200	(1) Vitamin E + placebo; (2) Omega-3 fatty acid + placebo; (3) Omega 3-fatty acid + vitamin E; and (4) 2 placebos	24	(1) Change in liver fat fraction measured by MRI-PDFF; (2) Change in liver enzymes; and (3) FIB-4 scores

				inflammatory eicosanoid production, forming anti-inflammatory compounds				
NEXSCOT/NCT04147195	2	Novartis	LYS006, tropifexor	(1) Tropifexor-FXR agonist; and (2) LYS006-leukotriene A4 hydrolase inhibitor	250	(1) LYS006; and (2) LYS006 + tropifexor	21	(1) Change in ELF score; and (2) Change in liver fat fraction measured by MRI-PDFF
NCT02466516	2	Gilead Sciences	Selonsertib, simtuzumab	(1) Selonsertib-selective ASK1 inhibitor; and (2) Simtuzumab-lysyl oxidase-like 2 inhibitor	72	(1) Selonsertib 6 mg; (2) Selonsertib 18 mg; (3) Selonsertib 6 mg + simtuzumab; (4) Selonsertib 18 mg + simtuzumab; and (5) Simtuzumab	24	(1) Adverse events; (2) Serious adverse events; (3) Lab abnormalities; and (4) Number of participants who prematurely discontinued study due to adverse events
NCT01703260	2	AstraZeneca	Roflumilast, pioglitazone	(1) Roflumilast-phosphodiesterase 4 inhibitor; and (2) Pioglitazone-PPAR agonist	16	(1) Roflumilast + pioglitazone; (2) Roflumilast + placebo; and (3) Pioglitazone + placebo	20	(1) Change in liver enzymes; and (2) Change in liver fat fraction measured by MRI-PDFF

ASK1: Apoptosis signal-regulating kinase-1; ACC: Acetyl-coenzyme A carboxylase; FXR: Farnesoid X receptor; PPAR: Peroxisome proliferator-activated receptor; GLP-1: Glucagon-like peptide-1; SGLT: Sodium/glucose transport protein; DGAT: Diacylglycerol acyltransferase; CCR: C-C motif chemokine receptor; IBAT: Ileal bile acid transporter.

authors were able to lower the LDL concentration below baseline with the addition of atorvastatin[31]. In a separate phase 2, proof-of-concept trial, fenofibrate was tested in combination with the ACC inhibitor, firsocostat, to help lower triglyceride levels[32].

CONCLUSION

In this concise review, we have discussed numerous possible therapeutic options for cessation or reversal of NASH and associated fibrosis. It is clear that NASH and particularly NASH fibrosis or cirrhosis is a leading topic garnering much interest in the study of liver diseases today, which would be appropriate considering the clinical impact. Although some of the above targets may seem promising, there are still a few concerns regarding study of this particular topic. Firstly, it is evident by reviewing the endpoints of each of the studies listed above that there is much heterogeneity. This is partly because the gold standard of liver biopsy to prove effectiveness in this endeavor is cumbersome, costly, and generally not favored by patients. The use of surrogates for liver fibrosis and resolution including markers of turnover, inflammation, or non-invasive assessments of liver scarring have not universally been agreed upon in the use of clinical trials. Secondly, for those studies that have utilized liver biopsies are part of their endpoint assessment, there can be considerable inter-observer variability in interpretation of liver biopsy specimens, assuming they are of adequate quality. Additionally, it is apparent that many of the study developers use magnetic resonance imaging with proton density fat fraction for assessment of liver fat content while there are additional tools such as the controlled attenuation parameter of transient elastography systems which might be more acceptable as a point of

care test. Lastly, endoscopic and surgical bariatrics represent an emerging area of therapeutic development for the management of obesity in context of NASH. In one prospective study of 180 patients, bariatric surgery was associated with NASH resolution in 84% of patients with improvement in fibrosis in 70% of patients at the 5 year mark after surgery[33]. Separately, in a 6 mo multi-center study of 85 patients with T2DM undergoing duodenal mucosal resurfacing, not only did their A1c improve, but so did their ALT levels and FIB-4 scores hinting at the possible insulin sensitizing, lipid lowering, anti-inflammatory and antioxidant effects of this procedure[34]. In conclusion, more effective treatments for NASH are urgently needed, and combination pharmacotherapy represents among the most promising approaches in develpoment.

Abstract

BACKGROUND

Pancreatic ductal cancer (PDAC) has high malignancy and poor prognosis. Long noncoding RNAs (lncRNAs) are associated with high levels of malignancy, including PDAC. However, the biological and clinical significance of negative regulator of antiviral response (NRAV) in PDAC is unclear.

AIM

To study the regulatory role of lncRNA NRAV in PDAC.

METHODS

GEPIA analyzed lncRNA NRAV and miRNA (miR-299-3p) expression levels in PDAC tissues and measured them in PDAC cells by quantitative measurements in real time. The specific role of NRAV and miR-299-3p in cell proliferation and transfer potential was evaluated by cell formation analysis, Cell Counting Kit-8 and Transwell analysis. The relationship between NRAV and miR-299-3p was studied by predictive bioinformatics, RNA immunoassay, and fluorescence enzyme analysis. *In vivo* experiments included transplantation of simulated tumor cells under naked mice.

RESULTS

The expression level of lncRNA NRAV was higher in both tumor tissues and cell lines of PDAC and was negatively associated with the clinical survival of PDAC

patients. Functionally, overexpression of NRAV promoted cell proliferation and metastasis of PDAC cells, while knockdown of NRAV reversed these effects. Finally, NRAV was performed as a molecular sponge of miR-299-3p. Moreover, overexpression of miR-299-3p could reverse the promoting effects of NRAV on cell proliferation and metastasis of PDAC cells.

CONCLUSION

NRAV facilitates progression of PDAC as a molecular sponge of miR-299-3p and may be a potential molecular marker for diagnosis and treatment of PDAC.

Key Words: Long noncoding RNA; Negative regulator of antiviral response; miR-299-3p; Proliferation; Migration; Invasion; Pancreatic cancer

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: In the present research, the expression level of long noncoding RNA negative regulator of antiviral response (NRAV) in pancreatic ductal adenocarcinoma (PDAC) was detected, and the clinicopathological relationship between NRAV and PDAC was demonstrated. Moreover, cell and animal tests were conducted to assess the concrete roles of NRAV in the progression of PDAC. Finally, the existence of potential specific molecular mechanisms that can provide new ideas for finding new molecular markers for the diagnosis and treatment of PDAC is demonstrated.

INTRODUCTION

As an extremely malignant tumor, pancreatic ductal adenocarcinoma (PDAC) has shown a rapidly increasing incidence rate in recent years worldwide[1]. According to the latest cancer report in 2021, there are 495773 new cases reported globally every year and about 466003 people die of PDAC annually [2]. Due to insufficient means of early diagnosis and effective treatment, the 5-year survival rate of PDAC patients is only about 8% and will drop to about 3% in patients with advanced PDAC[1]. Therefore, it is urgent to establish a comprehensive pathological mechanism of PDAC and explore a more effective PDAC diagnosis and treatment center.

Long noncoding RNAs (lncRNAs) are new ncRNAs that are composed of > 200 nucleotides, accounting for the largest proportion of the entire human gene transcriptome[3,4]. lncRNAs mainly regulate gene expression in a variety of ways, including chromatin remodeling and transcriptional and post-transcriptional processing, and participate in regulating a variety of biological processes[5,6]. Recently, a large number of researches showed that lncRNAs are dysregulated in most tumors and function as key regulators in the process of tumor growth, metastasis, drug tolerance, and angiogenesis [7,8]. The lncRNA negative regulator of antiviral response (NRAV) is a newly identified lncRNA and is mainly related to immunity[9]. Xu *et al*[10] found that NRAV is highly expressed in the cell system of hepatocytes and regulates the course of hepatocellular carcinoma. However, the statements and specific role of NRAV in PDAC are still unclear.

lncRNAs play an important regulatory role in the occurrence and development of various cancers and may be considered a potential molecular marker. Many studies have shown that RNA plays its biological function of competing with endogenous RNAs[11,12]. Hsa-miR-299-3p plays an important role in the development of many cancers. Many studies describe the regulation of the relationship between miR-299-3p and lncRNAs[13,14]. Many experts conducted in-depth research on the regulation of the relationship between the two and stated that miR-299-3p increased the volume and cellular system and prevented proliferation and metastasis of pancreatic cancer cells with exposure to Notch1 [15]. The relationship between NRAV and miR-299-3p in PDAC has not yet been investigated.

In this study, we tested the expression of NRAV in PDAC and studied its function, and found that NRAV and PDAC have obvious overlaps. The results of functional experiments showed that the level of NRAV expression was directly associated with cell proliferation and metastasis and was closely related to the growth of tumors in naked mice. In addition, we found that NRAV, as a molecular sponge of miR-299-3p, contributes to PDAC progression. Therefore, the results of this study may provide new insights into the role of NRAV in PDAC. It can be a biomarker for the diagnosis and treatment of PDAC.

MATERIALS AND METHODS

Cell lines

PDAC cell lines (PANC-1, AsPC-1, Mia Paca-2 and BxPC-3) and human immortalized normal pancreatic duct epithelial (HPDE) cells were obtained from the American Type Culture Collection (Manassas, VA, United States). The cell lines were cultured at an appropriate concentration in a specific environment in a moistened cell incubator with a CO_2 concentration of 5% at 37 °C. Percentage of 10 fetal serum and 1% penicillin–streptomycin were added to the culture medium, including RPMI-1640 and Dulbecco's modified Eagle's medium.

RNA isolation and quantitative real-time polymerase chain reaction

Total cellular RNA was extracted from cultured cells using Trizol reagent (Invitrogen, Carlsbad, CA, United States). For lncRNA, FastKing gDNA Dispeeling RT Supermix (TIANGEN, China) was selected for reverse transclncRNAn. The specific cDNAs of miRNAs were obtained with a specific kit (miDETECT A Track RT Reagent Kit; RiboBio, China). The quantitative real-time polymerase chain reaction (qRT-PCR) system wasABI 7300 PCR (Foster City, CA, United States). *U6* and *ACTB* were respectively deemed as standardized internal controls of miRNA and lncRNA. The specific sequences of the primers were designed as follows. For NRAV, 5′-GGAGTTGATGCCTCCGAACA-3′ (forward) and 5′-ATGACCGGAGCTGAAAGGTG-3′ (reverse); for β-actin, 5′-TCCCTGGAGAAGAGCTACGA-3′ (forward) and 5′-AGCACTGTGTTGGCGTACAG-3′ (reverse); for miR-299-3p, 5′-ACACTCCAGCTGG-GTATGTGGGATGGTAAAC-3′ (forward) and 5′-GTGCAGGGTCCGAGGT-3′ (reverse); and for U6, 5′-CTCGCTTCGGCAGCACA-3′ (forward) and 5′-AACGCTTCACGAATTTGCGT-3′ (reverse). The relative expression level of each gene was calculated with the $2^{-\Delta\Delta}$Ct method.

Cell transfection

Lipofectamine 2000 kit (Invitrogen) was used to conduct cell transfection. Short hairpin RNAs (shRNAs) targeting NRAV were designed by Genepharma (Shanghai, China). The specific sequences targeting NRAV were designed as follows: For sh-NRAV #1, 5′-CACCTCATCCACAAGTAGGAC-3′; for sh-NRAV #2, 5′-TTGGAGCCAAGGACTGTACTG-3′; and negative control: 5′-TTCTCCGAACGT-GTCACGT-3′. NRAV overexpression plasmid and shRNAs against NRAV were inserted into the pcDNA3.1 vector and pGpU6/GFP/Neo vector, respectively. The miR-299-3p mimic was purchased from RiboBio. qRT-PCR was performed to examine the transfection efficiency.

Cell Counting Kit-8 assay

A 96-well plate was selected, and 2000 tumor cells were cultured in each well. The cells were transfected with different vectors and allowed to stand for 48 h. Cell Counting Kit-8 (CCK-8) solution (10 μL; Mashiki, Japan) was added to each well, and incubated for 2 h. A microplate reader (Winooski, VT, United States) was used to check cell viability.

Colony formation assay

The specific PDAC cells transfected with different plasmids were inoculated into six-well plates and incubated at 37°C for 10 d. Tumor cells were fixed for 20 min in methanol after being washed with phosphate-buffered saline in triplicate. Cell colonies were stained and counted.

Transwell assay

In migration and invasion assays, PDAC cells were added to resuspension after setting a concentration of 10^5 mL in a serum-free environment. Two hundred microliters of cell suspension was added to the upper layer of each Transwell chamber and 600 μL of complete media containing 10% fetal serum was added to the lower layer. To set up the invasion analysis phase, the Matrigel layer (BD Biosciences, United States) was first applied to the chamber membrane, and the cell suspension was placed on top of the transition chamber. A 24-h incubation was followed and the invasive cells were finally fixed and monitored and compared in five random fields.

Tumor xenograft experiments

All animal studies were approved by the Ethics Committee for Animal Studies at Shanghai 10th People's Hospital. Specific PANC-1 cells (2×10^6, 200/L) were transplanted subcutaneously to the right side of naked male mice aged 4 wk. The condition of the mice was monitored daily and the size of the tumor was measured every 5 d. Tumor volume was calculated according to tumor length and length formula volume = length through × wide^2/2. Twenty days after inoculation, mice were killed and the entire tumor removed and weighed.

Immunohistochemical analysis

Mouse tumors were removed for immunohistochemical staining to visualize Ki-67 expression. Paraffin-embedded sections were prepared and wax removed in 100% xylene, followed by rehydration with

various gradients of ethanol and distilled water. The fabric is dyed with a protractor for 1 h at room temperature and removed during washing with distilled water. Tissue sections were incubated for 20 min with secondary antibodies bound to horseradish peroxidase. To facilitate visualization, 3,3'-diaminobenzidine tetrahydrochloride Ki-67 was selected for positive staining.

Nuclear/cytoplasmic fractionation assay

The PARIS Kit (Life Technologies, United States) was used to isolate RNA from the nucleus and cytoplasm. qRT-PCR assays were conducted as described above.

RNA immunoprecipitation assay

RNA immunoprecipitation (RIP) assays were performed by EZ-Magna RNA Immunosuppression Kit (Millipore, United States). The cells were collected and resuspended in an immunodeposition buffer and kept on ice for 30 min. The cell suspension was incubated with a separate RIP buffer containing magnetic beads. Proteinase K was added to the bead state after buffering for further digestion of proteins. All RNA was extracted with Trizol and measured with qRT-PCR.

Dual-luciferase activity assay

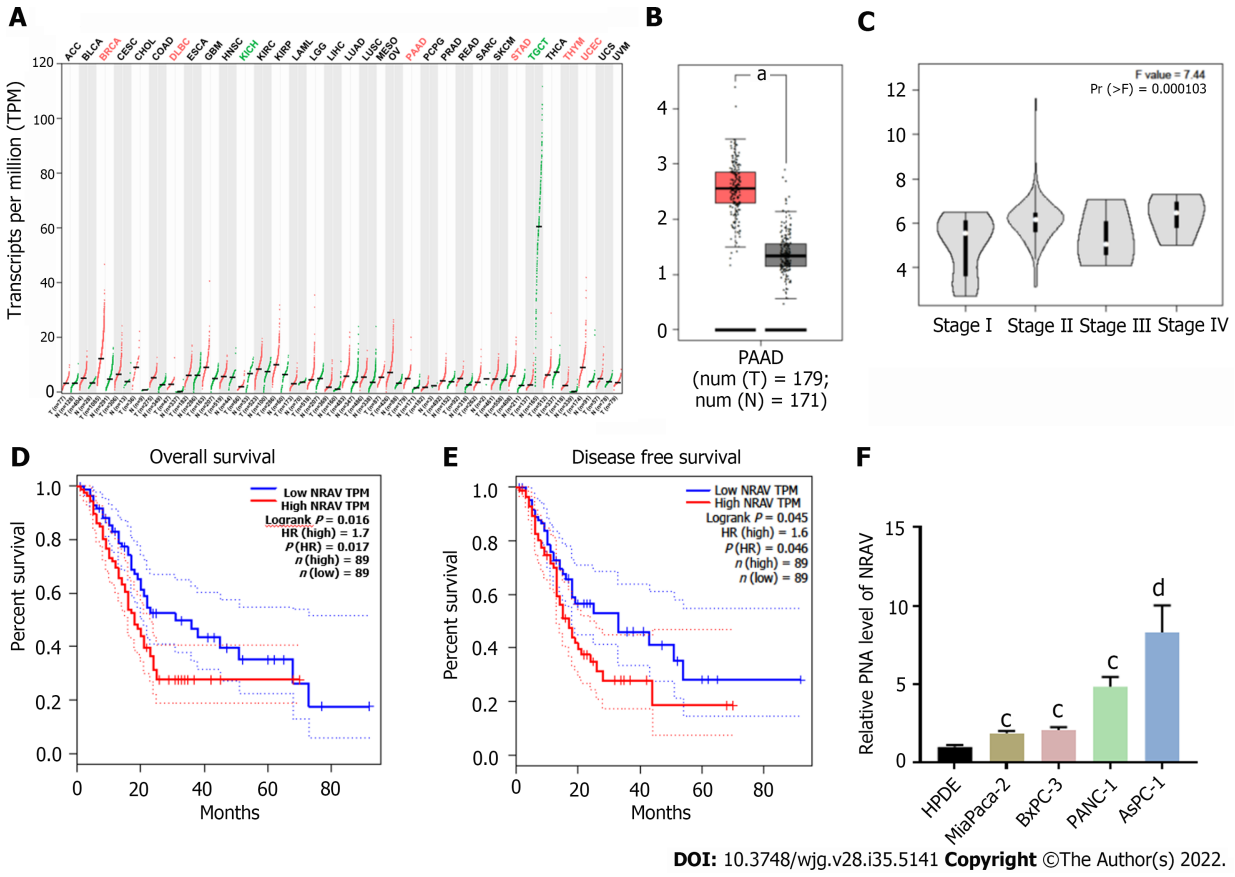
According to a special combination of software for network prediction starbes 3.0 and NRAV miR-299-3p (http://starbase.sysu.edu.cn/ b). Other matters according to the V2 specification (enzyme, China), it is a rapid mutation reagent for NRAV, and supplementary DNA and mutant miR-299-3p are added to psicheck2 (US Promega) (NRAV wild and music) satellite. Paycheck-2 and miR-229-3p plasmid samples or miR-229-3p negative control were transferred to PDAC cells. After 48 h, the fluorescent enzyme activity of each well was examined by the Promega reporting system. The relative activity of luciferase is used for normalization.

Statistical analysis

Statistical analysis was performed using GraphPad Prisma 8.2 (LA Jolla, CA, United States) and SPSS 22.0 (IBM, Armonk, NY, United States). Student *t* test was used to compare the differences between the two groups and calculate the *P* value. $P < 0.05$ was statistically significant.

RESULTS

NRAV was significantly upregulated in PDAC and predicted poor prognosis



We used GEPIA to determine NRAV expression levels as an online bioinformatics tool for gene expression analysis based on the cancer genome database (TCGA)[16]. NRAV expression of PDAC in tissues was significantly higher than that in nonmedical tissues (Figure 1A and B). The survival curve showed that the total life cycle ($P = 0.034$; Figure 1D) and disease-free life cycle ($P = 0.046$; Figure 1E) of PDAC patients were decreasing. The data of the TCGA database showed that the level of emotional expression was negatively correlated with the level of clinical pathology (Figure 1C). The level of NRAV expression in HPDE cells and four PDAC systems was tested. NRAV in the PDAC cell system was significantly higher than that in HPDE cells (Figure 1F). Based on these data, we believe that NRAV may be a potential carcinogen related to lncRNA.

Knockdown of NRAV inhibited proliferation, migration and invasion of PDAC cells

We studied the biological role of NRAV in the PDAC cell system. We used heterogeneous RNA transplantation to reduce NRAV expression in PANC-1 and AsPC-1 cells. qRT-PCR showed a significant decrease in expression after NRAV (Figure 2A). After showing the results of CCK-8 tests and colony formation, there was a significant reduction after removal of signs of proliferation and abscision of PANC-1 and AsPC-1 cells (Figure 2B and C). We performed Transwell analysis to test whether NRAV affected metastasis and damage to police cells. Similarly, after the removal of PANC-1 and AsPC-1 cells, migration and invasion rates slowed significantly (Figure 2D and E). Knockdown of NRAV inhibited proliferation, migration and invasion of PDAC cells.

Overexpression of NRAV promoted PDAC cell proliferation, migration and invasion

High expression of NRAV in BXPC-3 and Mia PaCa-2 cells used to display exogenous particles confirmed the effectiveness of the expression (Figure 3A). The CCK-8 test and the product reduction test showed that NRAV overexpression significantly supported proliferation and formation of PDAC cells (Figure 3B and C). Transwell analysis found that NRAV overexpression significantly increased displacement and invasion of Mia PaCa-2 and BXPC-3 cells (Figure 3D and E). Overall, the results showed that NRAV promotes proliferation, metastasis and invasion of PDAC cells.

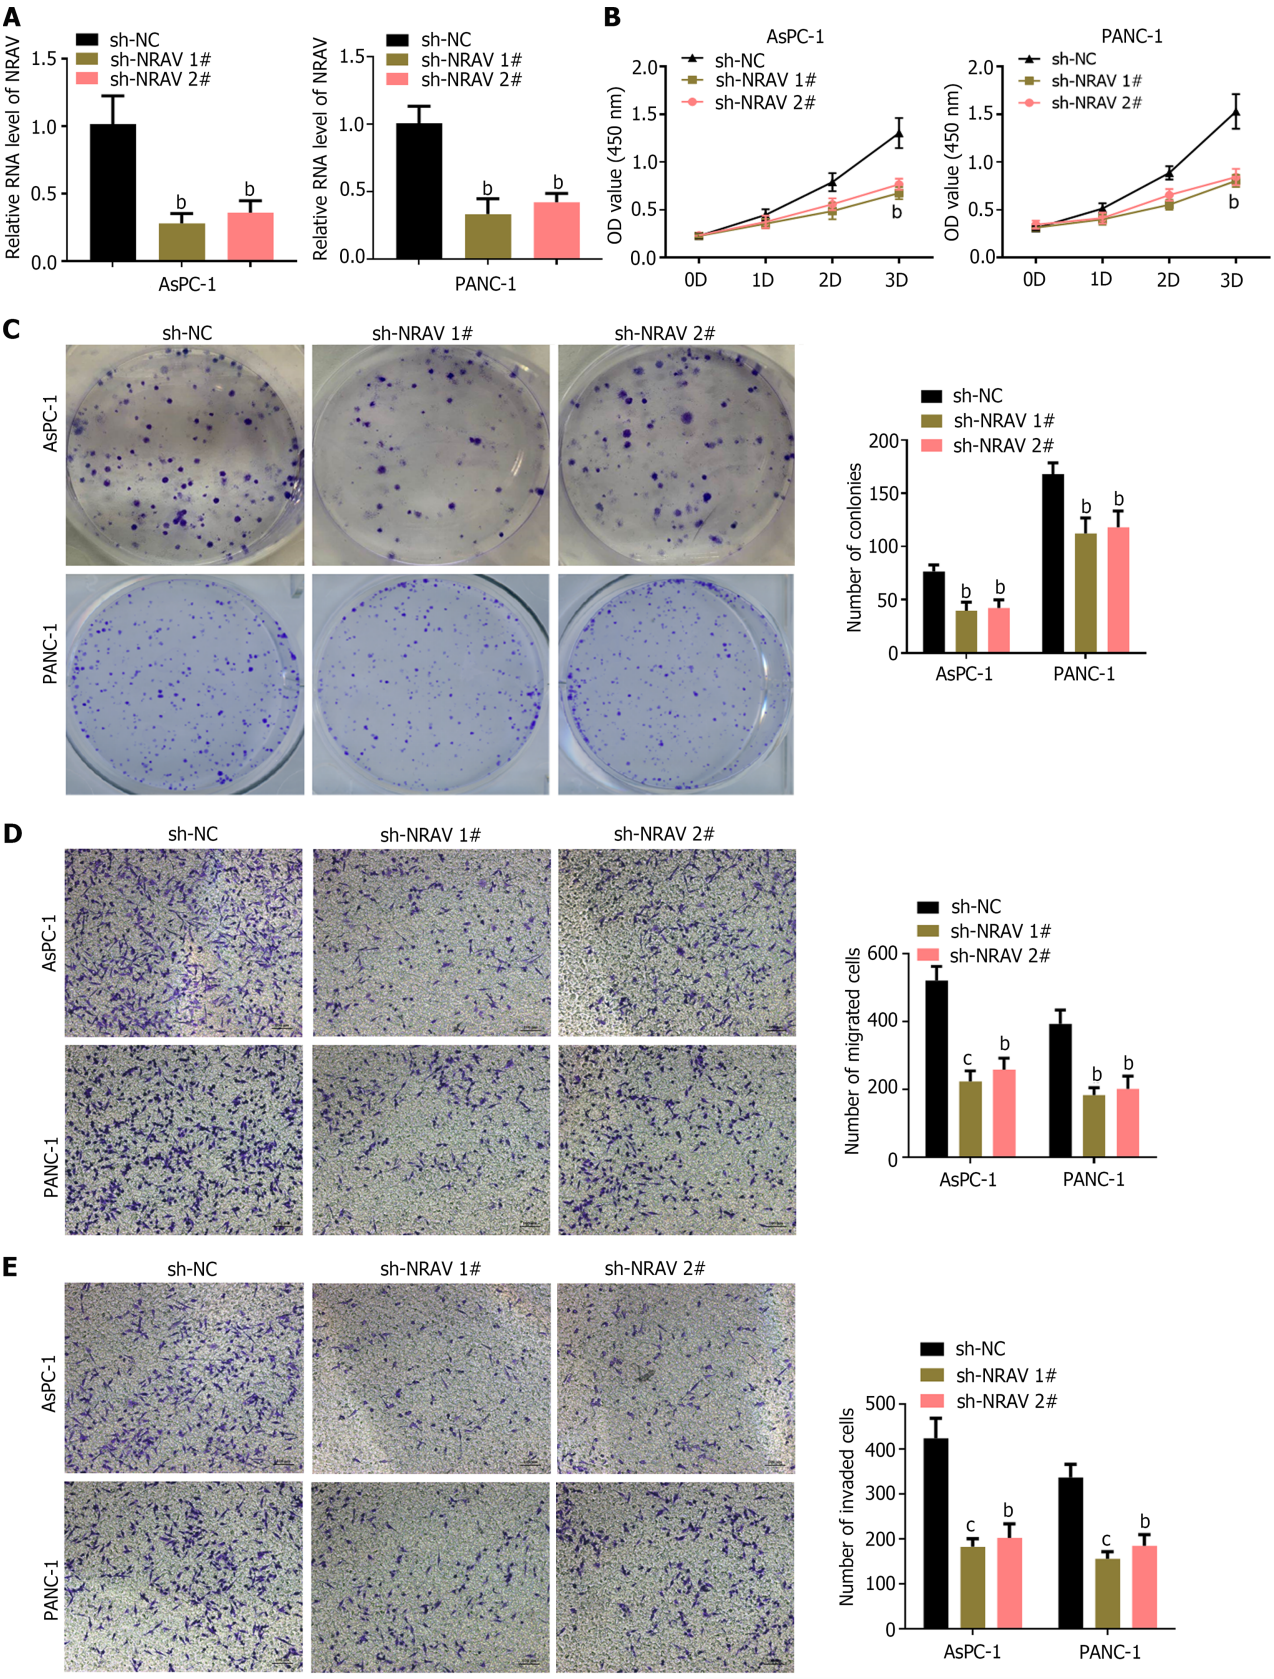
A: The negative regulator of antiviral response (NRAV) expression profile across all tumor samples and paired normal tissues; B: The NRAV expression of pancreatic adenocarcinoma in tissues was significantly higher than that in normal pancreas tissues; C: Expression of NRAV in patients divided by cancer stages using expression data from The Cancer Genome Atlas (TCGA) database; D: Overall survival analyzed by GEPIA based on the TCGA database; E: Disease-free survival analyzed by GEPIA based on the TCGA database; F: Quantitative real-time polymerase chain reaction analysis measured NRAV expression level in four pancreatic cancer and normal cell lines. $^{c}P < 0.001$; $^{d}P < 0.0001$. PAAD: Pancreatic adenocarcinoma; TPM: Transcripts per million; NRAV: Negative regulator of antiviral response; HR: Hazard ratio.

NRAV ablation inhibited tumor growth in vivo

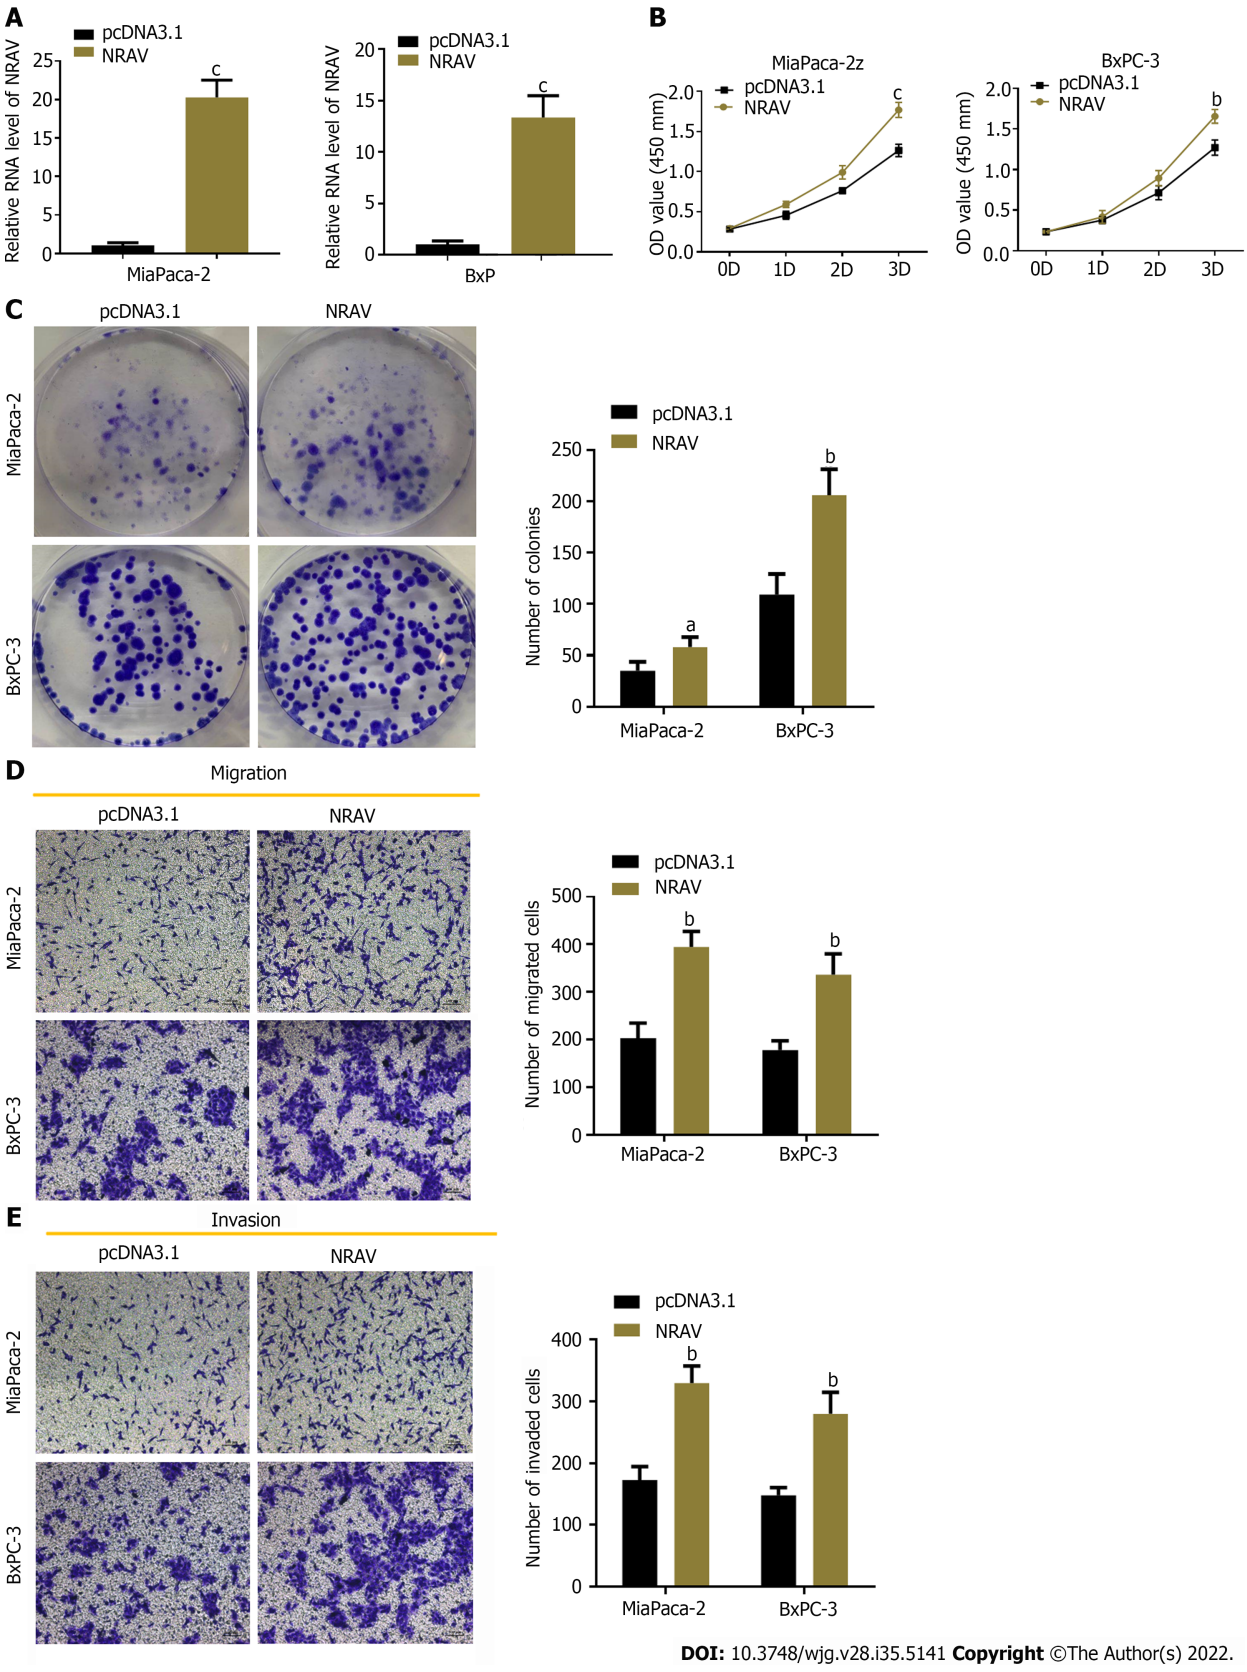


To further investigate whether NRAV supports tumor growth *in vivo*, PANC-1 cells were injected into naked mice treated with sh-NRAV and internal control cells. The tumor volume of the NRAV genotype was significantly lower than the negative control volume (Figure 4A and B). Similarly, the mass of the tumor in the NRAV group (Figure 4C) was significantly reduced compared to the control group. Ki-67 was analyzed for lignin content and immunochemical staining. Reduction of NRAV led to a significant reduction of Ki-67 and inhibition of tumor growth (Figure 4D and E). Overall, these findings suggest that NRAV does not inhibit tumor growth *in vivo*.

NRAV acted as a molecular sponge for miR-299-3p in PDAC

To study how NRAV plays a catalytic role in PDAC, we used the nuclear/cell separation method to determine the location of NRAV in PDAC. Spleen qi was mainly located in cells (Figure 5A), and it can exert its biological function as a competitive endogenous RNA[17,18]. We used starbase V3.0 (http://starbase.sysu.edu.cn/) Interactive Bio information Analysis Software to identify potential miRNAs that may interact with genes. miR-299-3p was selected as the tempered target due to potential point complementarity (Figure 5B). Rip analysis confirms this point[19]. As shown in Overexpression in PDAC cells resulted in significant enrichment of miR-299-3p on ago2 (Figure 5C). The miR-299-3p simulator significantly reduced the fluorescence activity of the wild-type NRAV group, while this change did not occur in the modified NRAV group (Figure 5D). qRT-PCR showed that expression of miR-299-3p in PDAC cells was significantly enhanced after removing the traits (Figure 5E). Spearman's analysis showed that expression of NRAV and miR-299-3p in PDAC tissue was opposite (Figure 5F). Therefore, these results suggest that temper may play the role of molecular sponge miR-299-3p.

miR-299-3p reversed the effect of NRAV on PDAC cells



To validate whether NRAV affected proliferation and metastasis of PDAC cells through sponging miR-299-3p, specific miR-299-3p mimic or mimic NC vector was cotransfected into PDAC cells after overex-

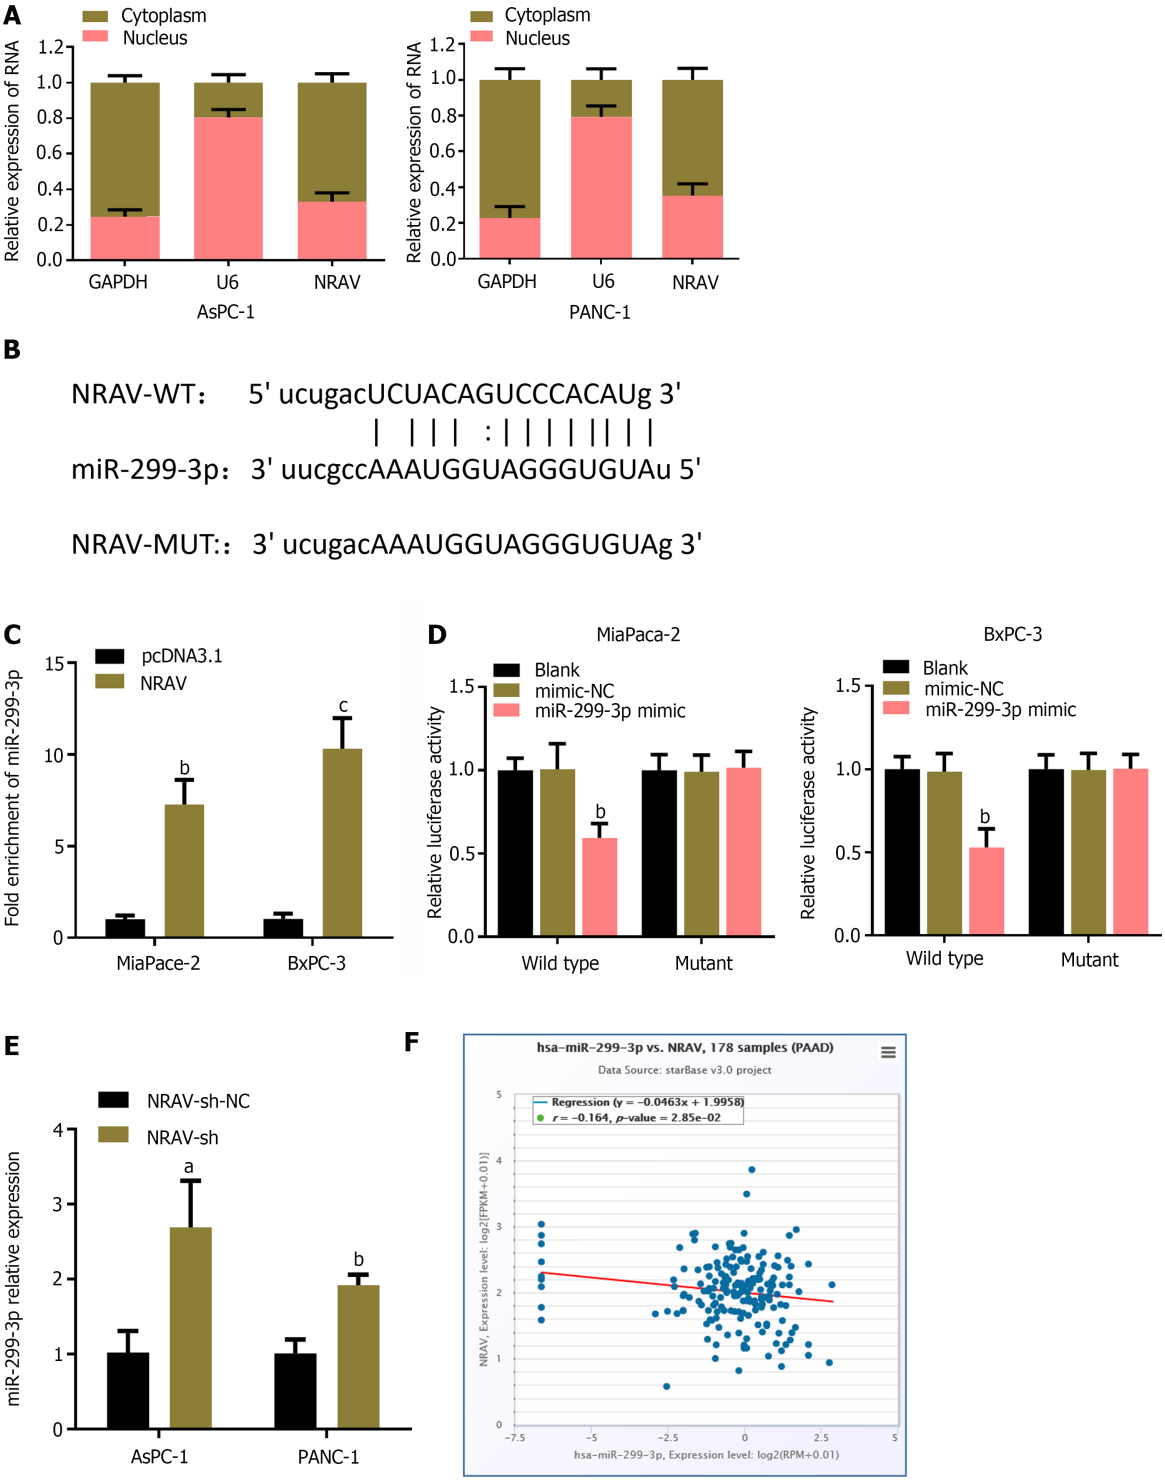
pression of NRAV. Subsequently, we evaluated the cell proliferation, migration and invasion of PDAC cells. miR-299-3p mimic reversed the dramatic promotion by overexpression of NRAV on proliferation (Figure 6A and B). Similarly, miR-299-3p mimic inhibited the promoting effects of NRAV overexpression on migration and invasion of PDAC cells (Figure 6C and D). These results indicated that miR-299-3p mediated the promoting effects of NRAV on PDAC cell proliferation, migration and invasion.



DISCUSSION

An increasing number of studies have shown that lncRNAs play an important role in the development of various malignant tumors. Recent studies have shown that large amounts of lncRNAs are abnormally expressed in PDAC and participate in the tumor process[20,21]. Guo *et al*[22] found that under hypoxia, lncRNAs extract of PDAC *UCA1* cells increased to promote angiogenesis. We used the TCGA database to identify NRAV in PDAC. We confirmed that the code of good conduct is a key element related to the program of action, and that significant progress has been made in the program of action. In addition, in PDAC patients, high levels of NRAV expression inhibit overall and disease-free survival. It is worth noting that NRAV may participate in PDAC progression.

The specific role of NRAV in oncology is not clear due to increased immunization. Recent studies have shown that NRAV expression is significantly increased in liver cancer and myeloma and can play a key role in the development of these two tumors[10,23]. To verify the biological function of NRAV in PDAC, function loss and acquisition studies were carried out. The results of *in vitro* experiments showed that temper has a major contribution to the migration, invasion and reproduction of PDAC cells. In addition, ablation temperament significantly reduced the tumor of the nude mouse model overall, these results show that the NRAV plays an important role in promoting cancer and can be used as a new biometric index for diagnosis and prediction of diseases caused by PDAC.

To further study the potential mechanism of NRAV, nuclear/cell division experiments were carried out in PDAC, and NRAV was mainly in the cytoplasm. Further analysis of the rip report analysis showed that NRAV may play the role of miR-299-3p molecular sponge (Figure 7). In addition, the stimulation effect of NRAV on malignant tumors in PDAC cells was also proved in the rescue experiment. The role of NRAV in promoting progression of PDAC mainly depends on miR-299-3p.

At the beginning of the study, it was emphasized that the significant increase in lncRNA was negatively correlated with overall and disease-free survival in PDAC patients. In addition, it also plays a carcinogenic role by promoting the proliferation and metastasis of cells in the sponge world. Our research shows that NRAV/miR-299-3p play a key role in PDAC and can be used as potential

biomarkers for PDAC diagnosis and treatment.

However, because no samples from patients with pancreatic cancer were collected, there was a lack of correlation analysis between temperament expression and PDAC clinicopathological features. In addition, it is also of great significance to study the significance of NRAV and miR-299-3p in PDAC organization.

Figure 7 Negative regulator of antiviral response plays the role of miR-299-3p molecular sponge to promote the progress of pancreatic ductal cancer.

CONCLUSION

NRAV can act as a molecular sponge of miR-299-3p and significantly promote the proliferation and metastasis of PDAC cells.

ARTICLE HIGHLIGHTS

Research background

Pancreatic ductal adenocarcinoma (PDAC) has high malignancy and poor prognosis. Long noncoding RNAs (lnRNAs) are recognized as crucial factors and associated with progression of PDAC. However, the specific biological role and practical clinical significance of lnRNAs and negative regulator of antiviral response (NRAV) in PDAC remain unclear.

Research motivation

Early and timely diagnosis and treatment of PDAC are still scarce. Therefore, it is a matter of urgency to comprehensively understand the pathogenesis of PDAC and explore more effective targets for its diagnosis and treatment.

Research objectives

To study the role of NRAV in the growth and metastasis of PDAC.

Research methods

Real-time polymerase chain reaction detected expression of NRAV and miR-299-3p in PDAC cells. The temperament correction and miR-299-3p in the process of cell proliferation, metastasis and invasion were verified by Cell Counting Kit-8, precipitation test, and Transwell assay. RNA and fluorescent enzyme immunoprecipitation test to test the interaction between NRAV and miR-299-3p. Verify the interaction between NRAV and miR-299-3p.

Research results

According to our data, NRAV in PDAC was significantly increased, which is related to the negative survival rate of PDAC patients. NRAV overexpression was conducive to the proliferation and metastasis of PDAC cells, and NRAV knockout reversed these effects. Finally, in terms of mechanism, NRAV acts as a miR-299-3p molecular sponge. Overexpression of miR-299-3p significantly changed the role of NRAV in the proliferation, metastasis and invasion of PDAC cells.

Research conclusions

NRAV promotes proliferation and metastasis of PDAC by playing the molecule sponge function of miR-299-3p.

Research perspectives

NRAV facilitated the progression of PDAC, which provides a potential biological marker for diagnosis and therapeutic target for PDAC.

Abstract

BACKGROUND

Colorectal cancer (CRC) is a common malignant tumor. Alcohol consumption is positively correlated with CRC malignant metastasis; however, the mechanism is unclear. The interaction between laminin-γ2 (LAMC2) and integrin-β1 (ITGB1) plays a role in premetastatic niche signaling, which may induce epithelial mesenchymal transformation (EMT) and lead to metastasis.

AIM

To investigate the effects of alcohol on CRC metastasis from the molecular mechanism of the premetastatic niche.

METHODS

The interaction between LAMC2 and ITGB1 was measured by Duolink assay, and the expression levels of LAMC2, ITGB1 and focal adhesion kinase (FAK), snail, fibronectin, N-cadherin and special AT-rich sequence binding protein 1 (SATB1) were measured by quantitative real-time polymerase chain reaction, immunohistochemistry and western blotting. Interleukin-1β (IL-1β), tumor necrosis factor-α (TNF-α) and IL-6 levels were measured *via* enzyme-linked immunosorbent assay, histopathological assessment *via* hematoxylin eosin staining, and determination of

aberrant crypt foci *via* methylene blue.

RESULTS

The lymph node metastasis rate was higher in the alcohol group than non-alcohol group. There was a significant increase in interaction signals between LAMC2 and ITGB1, and an increase in phosphorylate-FAK/FAK, snail, fibronectin, N-cadherin and SATB1, whereas E-cadherin was reduced in the alcohol group compared to the non-alcohol group in both animal and clinical samples. Serum IL-1β, TNF-α and IL-6 were higher in alcohol group than in non-alcohol group. Alcohol may promote CRC metastasis by influencing the molecular mechanism of the premetastatic niche.

CONCLUSION

Our study suggests that alcohol promotes EMT-mediated premetastatic niche formation of CRC by activating the early interaction between LAMC2 and ITGB1 and lead to CRC metastasis.

Key Words: Alcohol; Colorectal cancer; Premetastatic niche; Epithelial mesenchymal transformation; Metastasis

INTRODUCTION

Colorectal cancer (CRC) is the third most commonly diagnosed malignancy worldwide[1]. A majority of colorectal cancers are associated with the environmental factors such as lifestyle changes including diet, obesity, smoking and alcohol consumption[2,3]. It is reported that long-term alcohol consumption is associated with an increased risk of CRC metastasis[3]. In the presence of concomitant metastasis, the maximum survival rates after surgical intervention do not exceed 20%[4,5]. Therefore, the relationship between alcohol consumption and CRC metastasis should be investigated. However, the mechanism that the alcohol promotes CRC metastasis has not been clearly explained[6,7].

Accumulating evidence suggests that metastasis develops from disseminated cancer cells that can remain dormant, and the dissemination may occur during the early stage of tumor evolution[7,8]. The microenvironment around the early disseminated cancer cells, also known as the premetastatic niche[9,10], may play an important role during the proliferation and migration of disseminated cancer cells in the early stage of tumors[11-13]. The extracellular matrix (ECM) is an important part of the premetastatic niche[14-17].

As an important component of the ECM, laminins are important for adhesion, differentiation, migration, and resistance to apoptosis of various cells, including cancer cells[18-21]. Reports have indicated that laminins are involved in the formation of the premetastatic niche[22,23]. Laminin-γ2 (LAMC2), a subunit of laminin-332, has been reported to be an important component in the survival dependent environment of epithelial cells in CRC and plays a key role in the regulation of tumor cell motility in premetastatic niche formation[24-27]. The interaction between LAMC2 and integrin-β1 (ITGB1) may stimulate the formation of premetastatic focal contacts by activating the premetastatic niche signaling, which promotes the migration of cancer cells[28]. Focal adhesion kinase (FAK) is a premetastatic focal contact involved in LAMC2 and β1 integrin signal transduction[29]. Signaling cascades triggered by integrin-laminin interactions in cells phosphorylate FAK, which induced epithelial mesenchymal transformation (EMT). EMT is a key initiating step during the metastasis and invasion of cancer[30,31] and involved in the formation of the premetastatic niche[32,33].

Alcohol consumption may influence the ECM remodeling and thus induce EMT, which may be closely related to the premetastatic niche[34]. Therefore, we explore its effect on CRC metastasis from the view of the premetastatic niche.

MATERIALS AND METHODS

Antibodies and reagents

The following antibodies were used: LAMC2 monoclonal antibody (YT5379, Immunoway, United States), ITGB1 monoclonal antibody (sc-9970, Santa Cruz, United States), glyceraldehyde-3-phosphate dehydrogenase (GAPDH) monoclonal antibody (ab125247, ABCAM, United Kingdom), phosphorylate-FAK (p-FAK)-Y397 (AP0302, ABclonal, Wuhan, China), FAK monoclonal antibody (A11131, ABclonal, Wuhan, China), snail monoclonal antibody (ab53519, ABCAM, United Kingdom), E-cadherin polyclonal antibody (ab1416, ABCAM, United Kingdom), N-cadherin polyclonal antibody (22018-1-AP, Proteintech, United States), fibronectin polyclonal antibody (A16678, ABclonal, Wuhan, China) and special AT-rich sequence binding protein 1 (SATB1) polyclonal antibody (A5800, ABclonal, Wuhan, China). Secondary antibodies were ab288151 and ab150113 (ABCAM, United Kingdom). Polyvinylidene difluoride membranes with a pore size of 0.45 mm (Millipore, United States) were used. RNAEX reagent (Accurate Biotechnology, Beijing, China), Evo M-MLV RT Premix (Accurate Biotechnology, Beijing, China), SYBR Green Premix Pro Taq HS qPCR Kit (Accurate Biotechnology, China). Interleukin-6 (IL-6), IL-1β and tumor necrosis factor-α (TNF-α) enzyme-linked immunosorbent assay (ELISA) kits (Enzyme-linked Biotechnology Co., LTD, Shanghai, China) were used. Duolink proximity ligation assay (PLA) kits (DUO92012, Merck, United States), Duolink PLA Rabbit PLUS (DUO92002, Merck, United States), and PLA Mouse MINUS (DUO92004, Merck, United States) proximity probes were purchased from Sigma-Aldrich. All above the mentioned antibodies can be used in both in rats and in humans.

Patients and clinical data

A total of 63 patients (26-86 years old) at The First Affiliated Hospital of Guangzhou University of Chinese Medicine (Guangzhou, China) from July 2019 to February 2020 was enrolled in this study. The baseline characteristics were collected, and data on alcohol consumption were collected at baseline using a direct interview method[35]. Participants were asked to answer whether they drank alcoholic beverages ("Yes", "Yes, but not now", or "No" were the answer options to the question, "Have you ever drunk alcohol?"), and for "ever drinkers", consumption frequency and average quantity of one serving over the past year by beverage type was recorded. CRC patients who never drank alcohol were added into the non-alcohol group, and CRC patients who drank alcohol over 3 times a week for more than 5 years were added into the alcohol group. And patients with smoking, family history, blood lipids, obesity, and chronic diseases were excluded. The present study was approved by the Ethics Committee of First Affiliated Hospital of Guangzhou University of Chinese Medicine [No. Y (2019) 172] and carried out in accordance with the "Helsinki Declaration". All CRC patients have sighed informed consent. Patients who received neoadjuvant chemotherapy or radiotherapy or had a history of malignancy were excluded. Clinicopathological data including pathological report, sex, age, macroscopic classification, tumor location, tumor size, tumor differentiation, lymphatic infiltration and invasion depth were collected *via* medical record. The American Joint Council on Cancer tumor, node and metastasis (TNM) staging system is used for the clinical staging of tumors[36].

Animals, induction of CRC and treatments

A total of 32 male Wistar rats, 7 wk old and weighing 200 ± 20 g, were obtained from the Experimental Animal Center of Southern Medical University [Certificate of quality: SCXK (Yue) 2016-0041]. All rats were housed in cages (25 cm × 30 cm × 30 cm, four rats per cage) under specified-pathogens free conditions at 25°C, 40%-60% relative humidity, and a 12-h light/dark cycle in the experimental animal center of Guangzhou University of Chinese Medicine. All rats had ad libitum access to standard rodent chow and filtered water and were acclimatized for 1 wk prior to the initiation of the experiment. The use of laboratory animals was checked by the "Institutional Animal Ethical Committee" and all procedures were approved by the Ethics Committee of Guangzhou University of Chinese Medicine, and performed according to the "Principles of Laboratory Animal Care" as well as specific national laws where applicable. All experimental protocols and handling of the animals followed the guide for the care and use of laboratory animals[37].

A total of 32 rats were randomly divided into two groups: the non-alcohol group and the alcohol group, with 16 rats in each group. Non-alcohol group: The rats were fed water (10 mL/kg b.wt.) every day and from the 6th week on, the rats were administered a subcutaneous injection of 1,2-dimethylhydrazine hydrochloride (DMH) at a dose of 30, 35, 25 or 20 mg/kg b.wt. once a week for 12 wk in order to induce CRC. Alcohol group (DMH + ethanol): The rats were fed 30% ethanol (10 mL/kg b.wt.) every day, and from the 6th week on, they were administered a subcutaneous injection of DMH at a dose of 30, 35, 25 or 20 mg/kg b.wt. once a week for 12 wk in order to induce CRC. The details of the specific modeling method of each group were shown in Figure 1. The blood samples were collected through the posterior orbital venous plexus. And the rats were sacrificed by cervical dislocation, then the colons were removed and used in further experiments.

Hematoxylin and eosin staining and histological evaluation

All specimens were fixed in 4% paraformaldehyde solution for 24 h and embedded in paraffin and

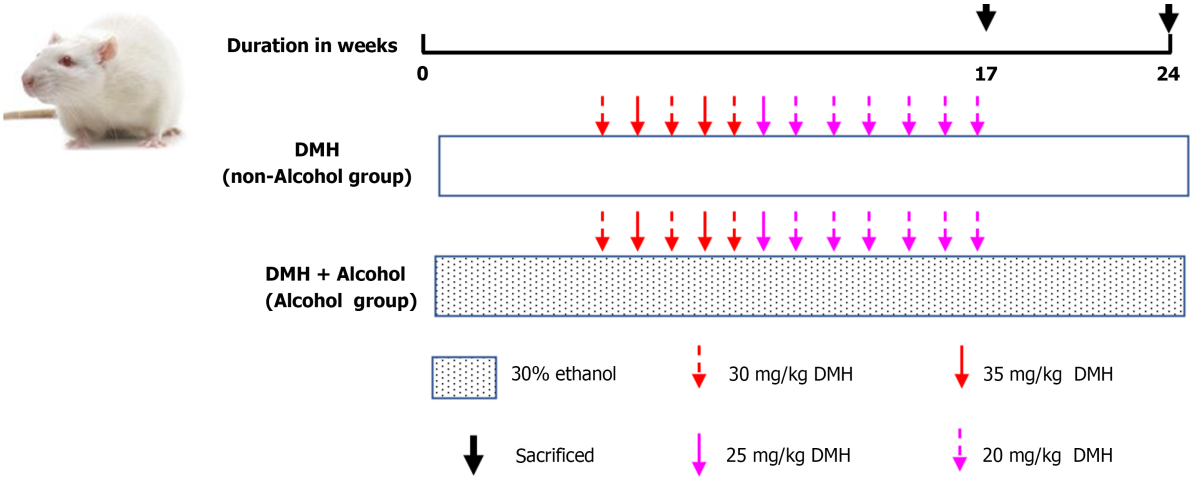

Figure 1 Schematic diagram of animal experimental modeling. DMH: 1,2-Dimethylhydrazine hydrochloride.

processed by standard histological processing techniques. Tissue sections (4-μm thick) were obtained from each sample. The hematoxylin and eosin results were observed under a light microscope at 40× magnifications (Olympus, BX51) to observe the colonic histology differences by the method of Martin B [38].

Determination of aberrant crypt foci

Aberrant crypt foci (ACF) were determined according to the method described by Bird *et al*[39]. Then, the formalin-fixed colon was stained with 0.2% methylene blue for 3 min and observed under light microscope. The diagnosis of colonic pathology and ACF was performed by two pathologists. The number of ACF was counted as described by Sivaranjani *et al*[40].

Cytokines detection by ELISA

Serum samples of rats were collected, and the inflammatory factors (TNF-α, IL-6 and IL-1β) were determined using ELISA kits according to the manufacturers' instructions. The optical density of the colorimetric reaction was measured at 450 nm with a flat microplate reader.

Western blotting

For western blotting, 50 μg of extracted protein was fractionated on a 10% SDS-PAGE gel and then transferred to a polyvinylidene fluoride membrane with a 0.45-mm pore size (Millipore, MA, United States). The membrane was blocked in 5% milk for 3 h at room temperature and probed with antibodies against acetylated LAMC2 (1:1000), integrinβ1 (1:1000), p-FAK (1:1000), FAK (1:1000), snail (1:1000), E-cadherin (1:1000), fibronectin (1:1000) and N-cadherin (1:1000) at 4°C overnight. Horseradish peroxide-conjugated goat anti-rabbit and rabbit anti-mouse was used as the secondary antibodies. FAK and GAPDH (1:8000) were used as loading controls. Band intensity was visualized by ChemiDoc TMXRS+ (Bio-Rad, United States).

Immunohistochemical staining

The immunohistochemical (IHC) was performed by the method described in previous studies[41,42], all colonic tissue were fixed with 4% paraformaldehyde and paraffin embedded, then thin 4μm sections were obtained and deparaffinized in xylene and rehydrated through decreasing grades of alcohol. The sections were placed in a 95°C antigen retrieval solution for 15 min. After cooling the retrieval solutions for 20 min at room temperature, the slides were treated with hydrogen peroxide (H_2O_2) for 10 min to block endogenous peroxidase activity. Then, slides were incubated with primary antibodies against ITGB1 (dilution 1:100), LAMC2 (dilution 1:500), p-FAK (dilution 1:500), snail (dilution 1:500), E-cadherin (dilution 1:100), N-cadherin (dilution 1:800), fibronectin (dilution 1:200), and SATB1 (dilution 1:200) overnight at 4°C. The next day, biotin-conjugated secondary antibody and streptavidin-biotin peroxidase were applied each for 20 min. 3,3'-Diaminobenzidine tetrahydrochloride was used as the substrate, and nuclear contrast was performed using hematoxylin counterstaining. The negative controls for IHC are performed with PBS instead of primary antibody. The results were observed under a light microscope at 40× magnifications (Olympus, BX51). For quantitative analyses, the IHC images were analyzed by Image-Pro Plus 6.0 to calculate the average optical density (AOD), and the following equation: AOD = integrated optical density/area.

Duolink PLA

The Duolink PLA in situ was used in this study to detect the interaction between LAMC2 and ITGB1 in tissue samples, and it was performed as previously described by Bai *et al*[43]. Briefly, after washing, permeabilizing, and blocking as histological analysis, colon sections were incubated with primary antibodies against LAMC2 (1:200) and ITGB1 (1:400) overnight at 4°C. Then the slides were incubated with Duolink PLA Rabbit MINUS and PLA Mouse PLUS proximity probes for 1 h at 37°C. Ligation and amplification were conducted using the Duolink in situ detection reagent kit according to the protocol. Images were captured under the light microscope (Olympus, BX51).

RNA extraction and quantitative real-time polymerase chain reaction

The total RNA was extracted from tissues using RNAEX reagent (Accurate Biotechnology, China). It

was reverse transcribed into cDNA by using Evo M-MLV RT premix (Accurate Biotechnology, China) and quantitative real-time polymerase chain reaction (RT-PCR) system (TaKaRa, Japan). Then a SYBR Green Premix Pro Taq HS qPCR Kit (Accurate Biotechnology, China) was used for PCR. The PCR liquid volume was 20 μL. Quantitative PCR was performed using an RT-PCR system (BioRad, Singapore). At 95°C, 40 cycles were amplified after 90 s of initial denaturation, 10 s desaturation at 95°C, and 34 s of extension at 60°C. GAPDH was used as the reference gene for calculation. And the primer sequences are shown in Table 1.

Statistical analysis

The data were described using the mean (standard deviation), median (range), or frequency (percentage). An independent-samples *t* test or the Mann-Whitney U test was applied for the comparison between two groups (non-alcohol group and alcohol group). The associations between the clinical parameters and immunohistochemical results were analyzed using the χ^2 test. Statistical analyses were conducted using SPSS version 25.0 for Windows (SPSS, Inc.). Statistical analysis was performed: $^{b}P < 0.01$; $^{a}P < 0.05$; $^{ns}P > 0.05$.

RESULTS

Alcohol consumption promoted malignant progression in CRC rats

The total number of ACFs detected in the alcohol group was 70.33 ± 5.16 and 51.6 ± 4.5 in the non-alcohol group (Figure 2E and F), which implied that alcohol consumption may significantly increase considerably raise the risk of precancerous lesions of colorectal cancer ($P < 0.05$). Furthermore, CRC rats in alcohol group had more tumors and larger tumor size was observed in the alcohol group than those in the non-alcohol group (Figure 2A and B). Histopathological analysis revealed that at 17th week, 62.5% of rats in the non-alcohol group showed atypical hyperplasia, and the other 37.5% showed normal colonic tissues. Atypical hyperplasia was seen in 75% of the rats in the alcohol group; however, 25% of the rats in the alcohol group had many heteroepithelial cells in the colonic epithelium and one or more large nucleoli in the pleomorphic cystic nucleus, indicating a carcinoma adenoma. At the 24th week, 25%

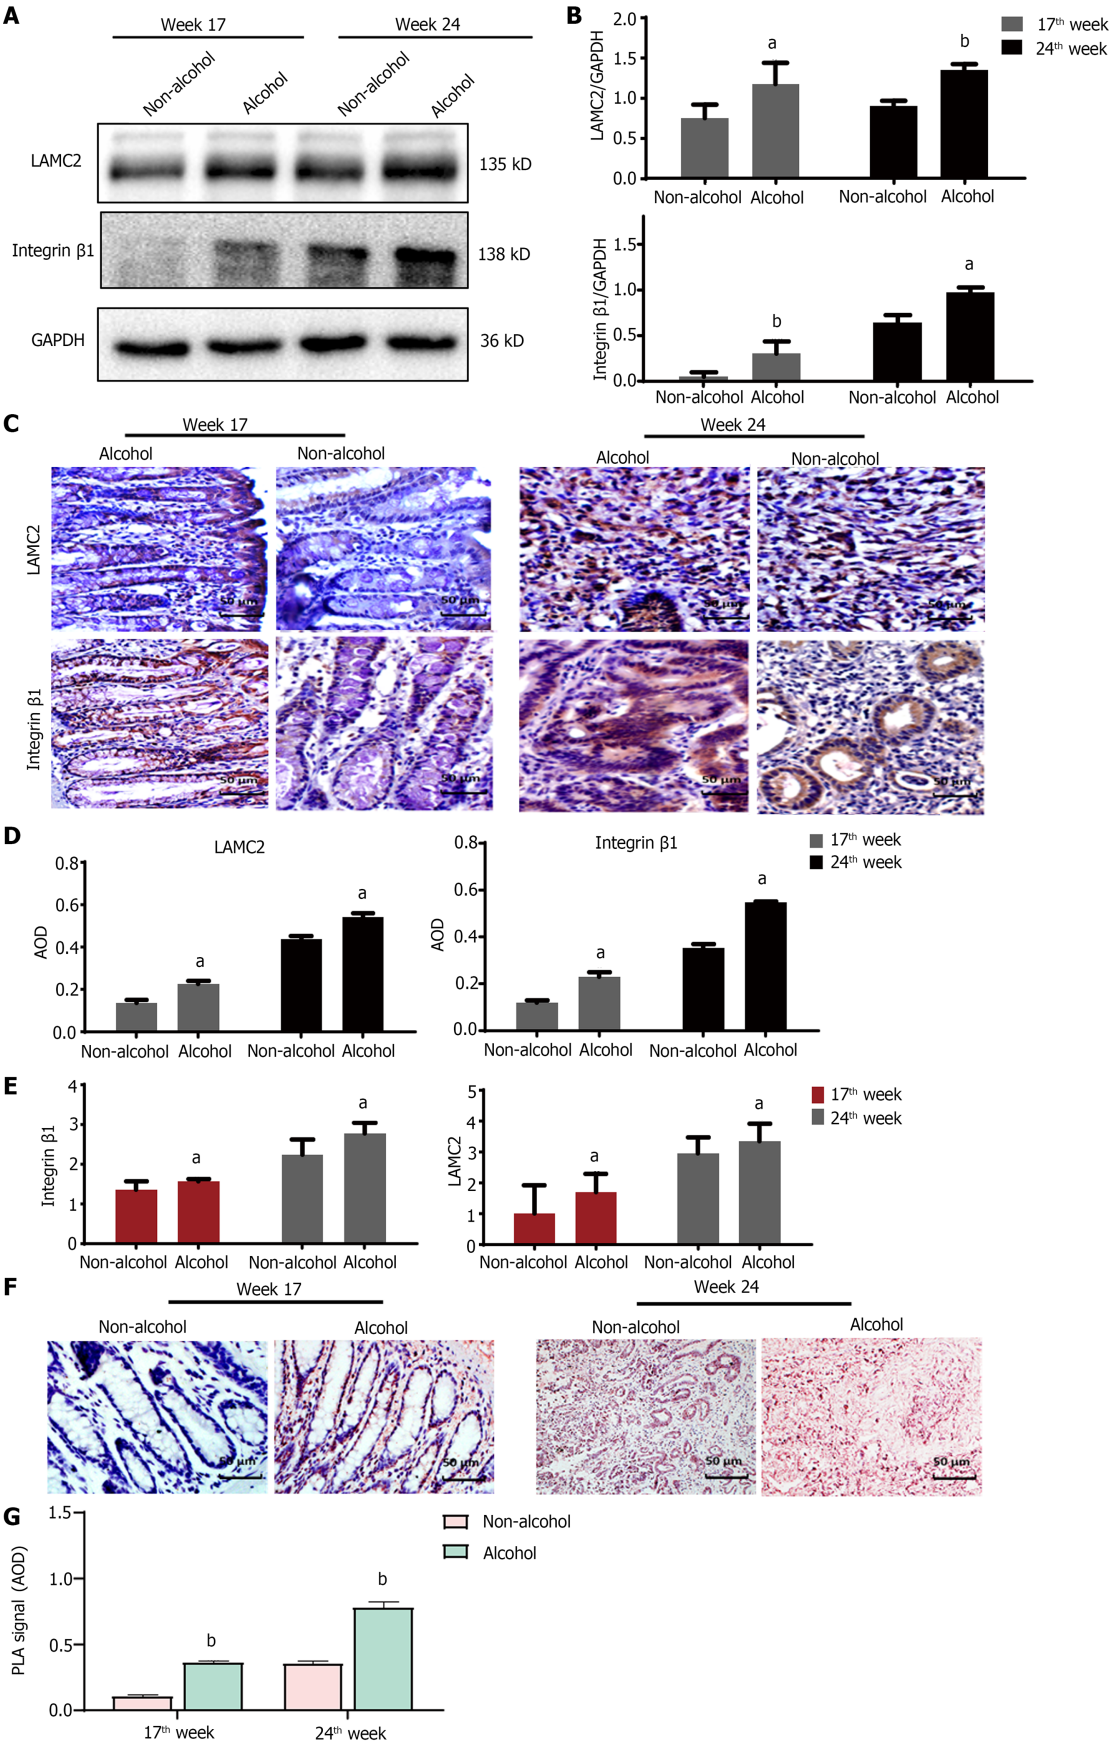

Figure 3 Alcohol consumption regulates the expression and interaction of integrin-β1 and laminin-γ2 in animal samples. The bars represent the mean ± SD (n = 8). A and B: Quantification of the protein levels of integrin-β1 (ITGB1) and laminin-γ2 (LAMC2) detected by western blotting in animal samples; C and D: Quantification of the protein levels of ITGB1 and LAMC2 by immunohistochemical (IHC) in animal samples; E: Quantification of the mRNA levels of ITGB1 and LAMC2 by quantitative real-time polymerase chain reaction in clinical samples; F: Statistical analysis of IHC was performed by counting the average optical density

(AOD). In Duolink proximity ligation assay (PLA), the brown dot particles observed under the microscope represent the interactions between LAMC2 and ITGB1; G: The statistical analysis of PLA positive signals was performed by counting the AOD under a light microscope. Compared with the non-alcohol group: $^{b}P < 0.01$, $^{a}P < 0.05$. ITGB1: Integrin-β1; LAMC2: Laminin-γ2; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; PLA: Proximity ligation assay; IHC: Immunohistochemical staining; AOD: Average optical density.

of rats in the alcohol group showed intramucosal carcinoma (mucosal carcinoma), which was characterized by less mucus secretion of colonic epithelial cells, compact and irregular arrangement of glandular ducts, and clear invasion of cancer cells into lamina propria in colons. The other 75% of rats in the alcohol group had invasive mucosal infiltrating carcinoma (infiltrating carcinoma), which manifested as abnormal tubular or mucinous structures invading through the muscularis mucosa or deep intestinal wall. In total, 75% and 25% of rats in the non-alcohol group showed mucosal carcinoma and infiltrating carcinoma, respectively. We found no lymphatic metastasis in the non-alcohol group, while cancer cell infiltration was found in the lymph nodes of the alcohol group and the lymph node metastasis rate was 37.5% (Figure 2C and D; Table 2). The abovementioned results indicated that alcohol consumption promoted CRC metastasis.

Alcohol consumption increased the expression of LAMC2, ITGB1 and FAK in CRC rats

The protein levels of LAMC2 and ITGB1 measured by western blotting (Figure 3A and B) and IHC (Figure 3C and D). The result showed that at both of 17th week and 24th week, the protein levels of LAMC2 and ITGB1 in the alcohol group were higher than those in the non-alcohol group ($P < 0.05$). Furthermore, the mRNA levels of LAMC2 and ITGB1 in alcohol group were higher than those in non-alcohol group at both of 17th week and 24th week ($P < 0.05$; Figure 3E). In addition, the protein level of FAK in the alcohol group was higher than that in the non-alcohol group at the 17th and 24th weeks (Figures 4 and 5, $P < 0.05$). However, there was no significant difference in the mRNA level of FAK between the alcohol and non-alcohol group at both of the 17th and 24th week ($P > 0.05$; Figure 6A).

Alcohol consumption enhanced the early interaction between LAMC2 and ITGB1 in CRC rats

Duolink PLA were used to detect the interaction between ITGB1 and LAMC2, and the red spots represent the interactions between LAMC2 and ITGB1. The results revealed that (Figure 3F and G) at 17th week, more early interacting signals between LAMC2 and ITGB1 were found in the alcohol group than that in non-alcohol group. At week 24, the results were consistent with that of week 17. The present study suggested that alcohol consumption may enhance the early interaction between LAMC2 and ITGB1 in CRC rats.

Alcohol consumption increased the expression of the CRC metastasis marker SATB1 in CRC rats

High expression level of SATB1 significantly influenced the malignant phenotypic characteristics of CRC. As shown in Figures 4 and 5, the results of IHC and western blotting indicated that at 17th week, the protein level of SATB1 in the alcohol group was higher than that in non-alcohol group, and the results of qRT-PCR (Figure 6A) showed that the mRNA level of SATB1 was higher than that in non-alcohol group.

Alcohol consumption regulates the protein and mRNA levels of EMT-associated markers in CRC rats

EMT is one of the key events that occur during the formation of premetastatic niche[44]. The results of western blotting (Figure 4A) and IHC (Figure 5) suggested that at the 17th week, long-term alcohol consumption resulted in an increase in the proteins involved in triggering the EMT process including p-FAK, N-cadherin, fibronectin and snail; however, there was a decrease in E-cadherin in the alcohol group. At week 24, the results were similar to those of week 17. In addition, the mRNA levels of FAK, E-cadherin, N-cadherin, fibronectin and snail were measured by qRT-PCR, and the results were consistent with those of protein levels (Figure 6A). The abovementioned results indicated that alcohol consumption may abnormally change the expression levels of EMT biomarkers in CRC rats in early stage.

Alcohol consumption increased the expression of proinflammatory factors associated with premetastatic niche in CRC rats

The results of ELISA (Figure 6B) showed that IL-1β, IL-6 and TNF-α levels in the alcohol group were higher than those in the non-alcohol group at week 17. The results at week 24 were consistent with those at week 17, indicating that the concentrations of IL-1β, IL-6, and TNF-α were higher in the alcohol group than in the non-alcohol group during precancerous lesions, which may be one of the reasons for lymph node metastasis in CRC patients in the alcohol group.

The obtained results showed that in early stages of CRC, the contents of IL-6, IL-1β and TNF-α in the alcohol group were higher than those in the non-alcohol group. This might be one of the explanations for the higher metastatic rate in the alcohol group.

Baseline characteristics of CRC patients

A total of 63 patients with a preliminary diagnosis of colorectal cancer participated in the trial. According to the baseline characteristics and data on alcohol consumption of 63 CRC patients, 29 CRC patients who had been drinking alcohol over 3 times each week for more than 5 years were classified in alcohol group, while the remaining 34 CRC patients who have never drunk alcohol before were classified in non-alcohol group. As shown in Table 3, there are significant differences in clinical stage and tumor metastasis ($P < 0.05$) between alcohol group and non-alcohol group. There were no significant differences in sex, age, degree of differentiation or T stage ($P > 0.05$). The experimental

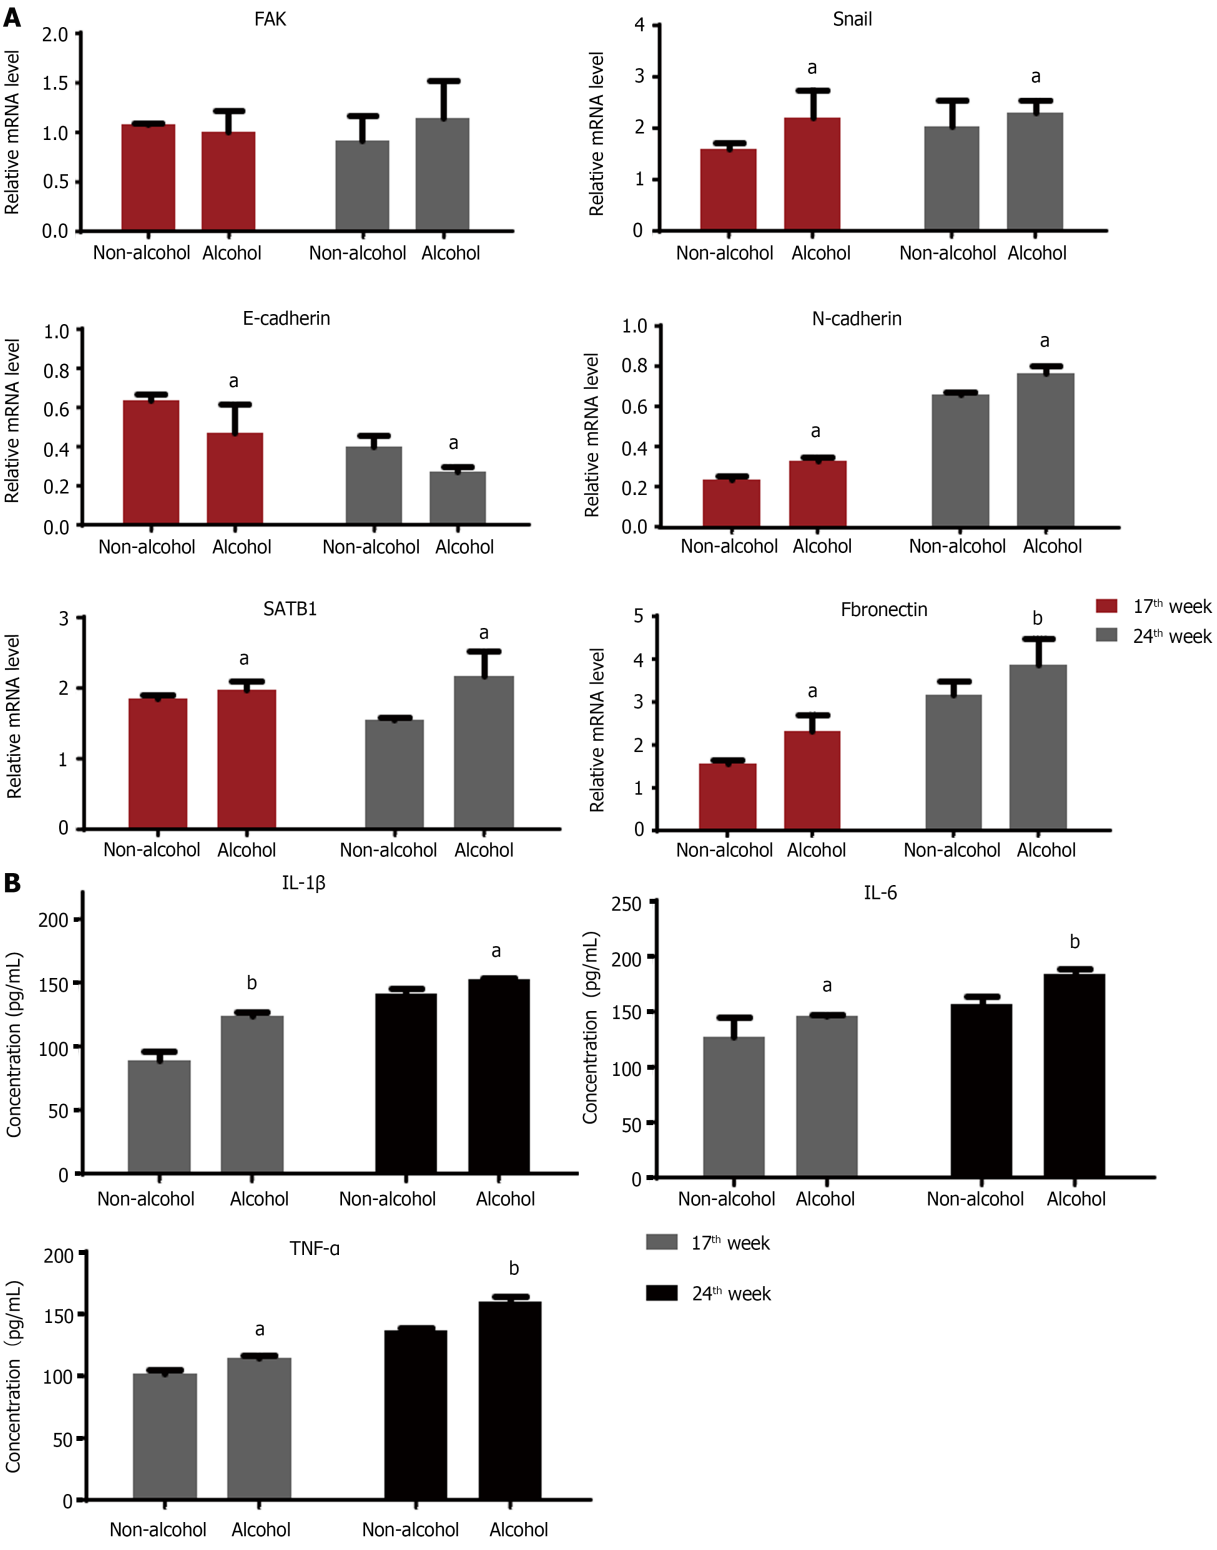

Figure 6 Alcohol consumption regulated the mRNA expression of epithelial mesenchymal transformation-related markers and proinflammatory factors in colorectal cancer rats. The bars represent the mean ± SD (n = 8). A: Quantification of the mRNA levels of snail, focal adhesion kinase, fibronectin, N-cadherin, E-cadherin and special AT-rich sequence binding protein 1 in each group analyzed by quantitative real-time polymerase chain reaction; B: Tumor necrosis factor-α, interleukin-6 (IL-6) and IL-1β levels in each group. Compared with the non-alcohol group: $^{b}P < 0.01$, $^{a}P < 0.05$. SATB1: Special AT-rich sequence binding protein 1; FAK: Focal adhesion kinase; IL-1β: Interleukin-1β; IL-6: Interleukin-6; TNF-α: Tumor necrosis factor-α.

results were consistent with the results of animal experiments. The degree of tumor deterioration in CRC patients in the alcohol group was significantly higher than that in non-alcohol group.

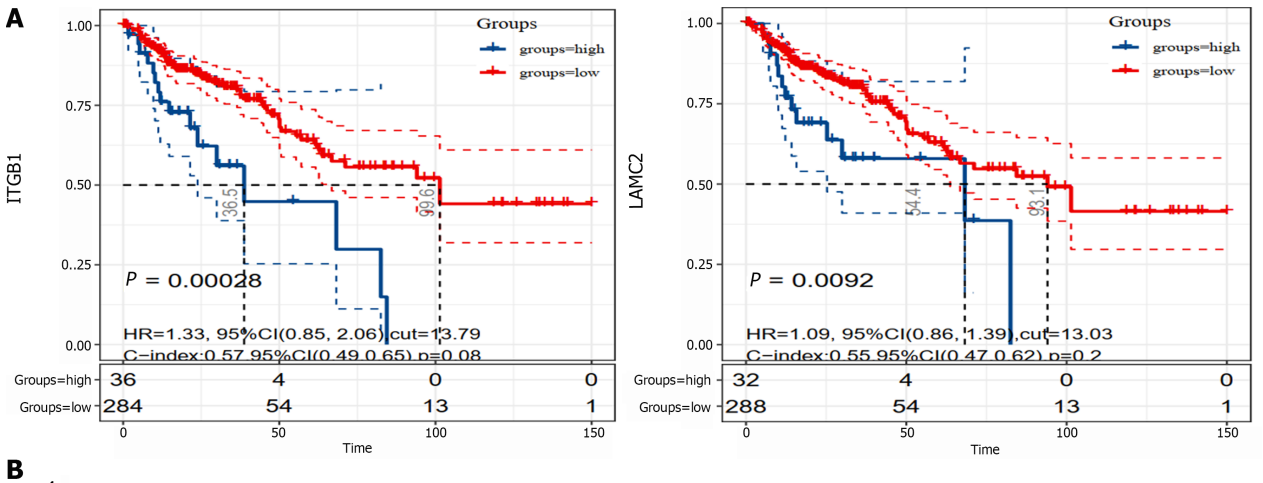
Alcohol consumption increased the expression and interaction of LAMC2 and ITGB1 in CRC patients

The expression of LAMC2 and ITGB1 in clinical samples determined by IHC (shown in Figure 7C and D). In cancer tissues, the mRNA and protein levels of LAMC2 and ITGB1 in alcohol group were significantly higher than those in non-alcohol group (Figure 7B). In addition, according to the survival analysis of 392 CRC patient samples from the GSE39582 dataset, we explored the prognostic significance of LAMC2 and ITGB1. As shown in Figure 7A, the overexpression of LAMC2 and ITGB1 was closely related to poor CRC prognosis. The abovementioned results were consistent with the results of animal experiments. Alcohol consumption may increase the expression levels and the interaction of LAMC2 and ITGB1 in CRC patients.

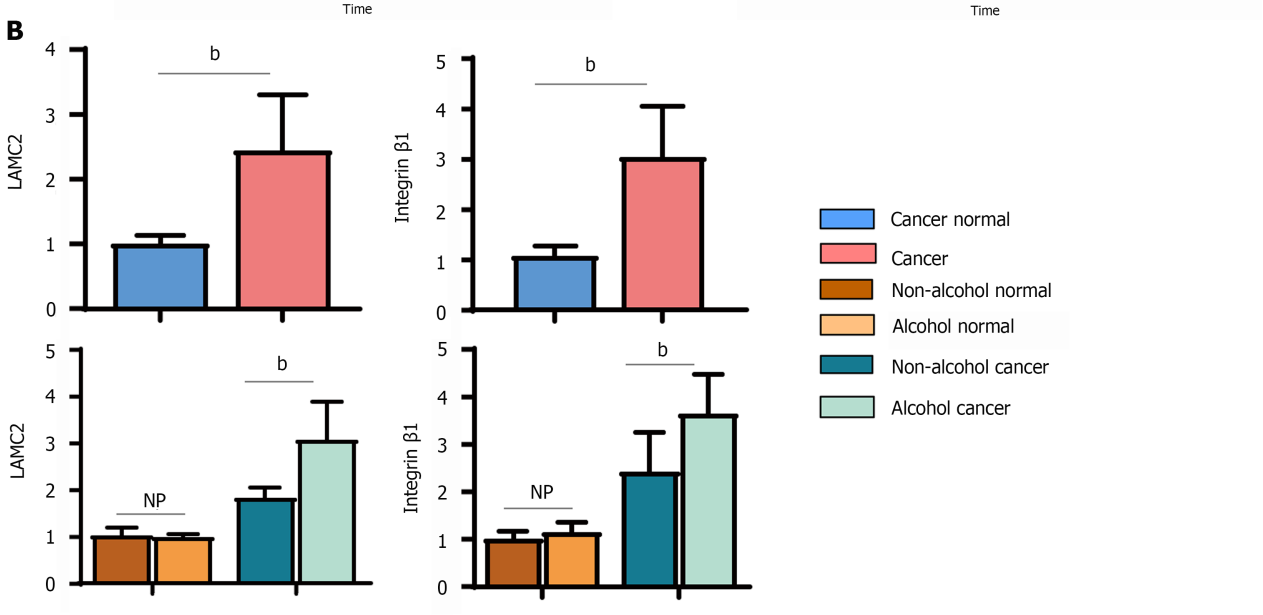
The interactions of LAMC2-ITGB1 are pivotal in CRC progression. Animal experiments revealed that more interactions between LAMC2 and ITGB1 were found in the alcohol group than in the non-alcohol group in the early stage of CRC. And it has been validated in clinical samples. According to the results of duolink PLA (Figure 7E and F), more interacting signals between LAMC2 and ITGB1 were found in alcohol group than those in non-alcohol group.

Alcohol consumption influenced the protein and mRNA expression of EMT-associated markers in CRC patients

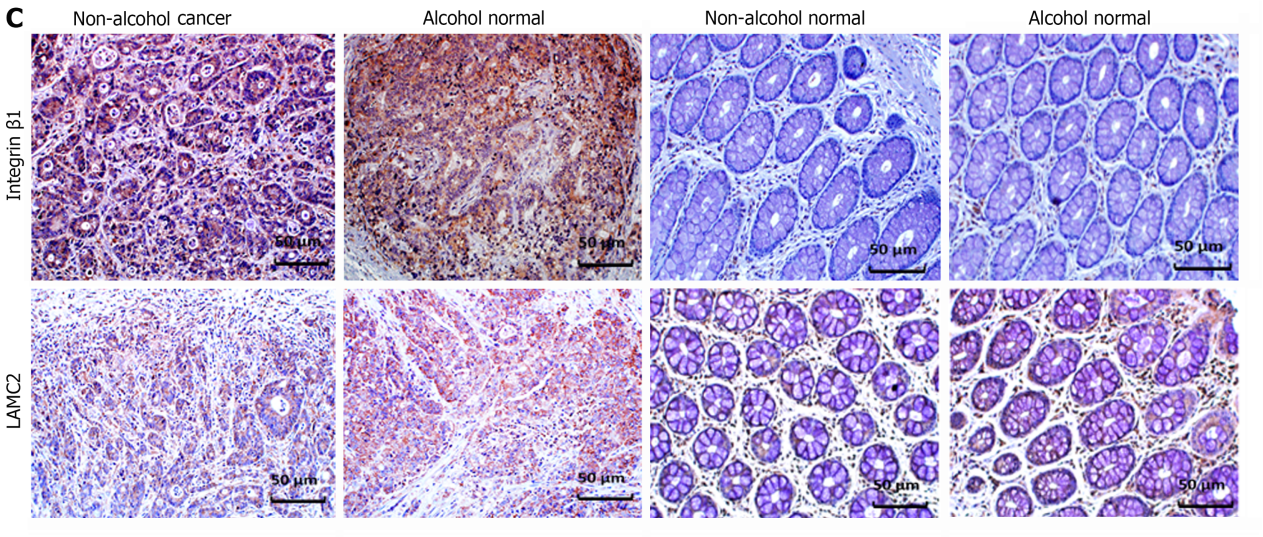
In the animal experiment, we found that alcohol may abnormally change the expression levels of EMT-associated biomarkers in CRC rats in the early stage. To verify the clinical implications of this finding, the levels of EMT biomarkers were detected in clinical samples. The results of IHC (Figure 8A and B) showed that there were significant differences in EMT-associated biomarkers ($P < 0.01$) in cancer tissues between the alcohol and non-alcohol group. In cancer tissues, the protein levels of p-FAK, N-cadherin, fibronectin and snail were significantly higher in alcohol group was significantly higher than that in non-alcohol group; however, the expression of E-cadherin in alcohol group was significantly lower in alcohol group than that in non-alcohol group. The qRT-PCR results (Figure 8C) also showed that the mRNA levels of N-cadherin, fibronectin and snail in the cancer tissues of alcohol group was higher than that in non-alcohol group. The abovementioned findings were consistent with the results of animal experiments. The abnormal expression of EMT biomarkers in CRC patients was different from that in alcohol group, and the abnormal expression of LAMC2 and ITGB1 was more severe in alcohol group.



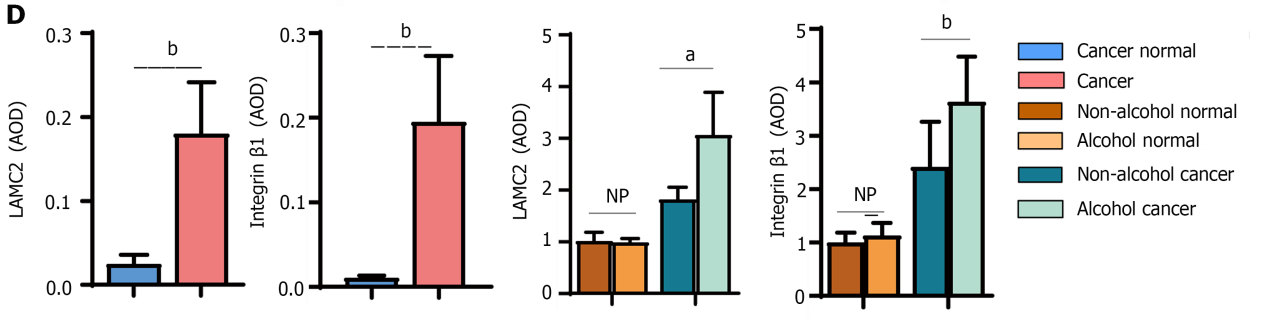
Alcohol consumption increased the expression of the CRC metastasis marker SATB1 in CRC patients



In animal experiments, alcohol consumption was found to increase the expression of SATB1 in CRC rats. IHC and qRT-PCR were used to evaluate the protein and mRNA levels of SATB1 in clinical samples (Figure 8A-C). The obtained results showed that protein and mRNA levels of SATB1 in cancer tissues were significantly higher in alcohol group than that in non-Alcohol group. Our results indicate that the expression of SATB1 is higher in alcohol group than those in non-Alcohol group, which is consistent with the higher metastasis rate of CRC patients who drink alcohol as described by TNM staging. The above results suggest that alcohol consumption may up-regulate the expression of SATB1, thereby induce the early EMT event and leads to malignant metastasis of the tumor[45].



DISCUSSION



Metastasis is the prominent cause of death in CRC[7]. Chronic alcohol intake has been extensively reported to enhance CRC metastasis; nevertheless, the specific mechanism remains unknown. In the present study, the results of TNM stage, pathological grade and other clinicopathological parameters suggested that the tumor deterioration rate of patients in alcohol group was higher than that in non-alcohol group, and the results were consistent with previous reports[6,7]. The present study demonstrated that the metastasis rate in alcohol group was higher than that in non-alcohol group. Similar to the clinical results, in animal experiments, the number of ACFs in the alcohol group was significantly higher than that in the non-alcohol group, and the pathological evaluation results were similar to the ACF screening results, suggesting that the alcohol group had a higher risk of precolonic lesions in CRC rats. And the number and size of tumors in the alcohol group were higher than those in the non-alcohol group. Lymph node metastasis was found in 37.5% of patients in the alcohol group, while no metastasis was found in the non-alcohol group. The present study indicated a higher risk of precancerous lesions and malignant metastasis of CRC were found in alcohol group compared with the non-alcohol group. Thus, we hypothesized that alcohol may promote the metastasis of CRC, however, the molecular mechanism is still unclear.

A key step in the formation of metastasis is the extravasation of circulating tumor cells to distant organs and their adaptation to the new environment[46,47]. Thus, the interaction between disseminated cancer cells and the microenvironment of the premetastatic niche is necessary for metastasis[10]. Primary tumor cells regulate the metastasis by secreting a variety of molecules that promote the mobilization and recruitment of various cells to the premetastatic niche and alter ECM protein expression and ECM properties in secondary organs[25,48]. The ECM constitutes a scaffold that

supports the attachment and thus reactivation of survival signaling in cancer cells[16]. And the remodeling of ECM is essential during formation of premetastatic niche, which may support cancer cell attachment, metabolism and migration of recruited cells[17,18]. Laminin, as an important component of the ECM and the main structural component of basement membrane, is involved in the formation of pre-metastasis niche[49]. Among them, LAMC2 is an important component of the survival-dependent environment of colorectal cancer epithelial cells and plays a key role in the regulation of tumor cell motility by premetastatic niche formation[50]. LAMC2 plays a role in premetastatic niche signaling by stimulating the formation of premetastatic local contacts and promoting the migration of cancer cells through its interaction with ITGB1[51]. It has been reported that the interaction of ITGB1 and LAMC2 may promote the tumor budding of CRC cells, which leads to malignant metastasis of CRC, and the focal adhesion formed by the interaction of LAMC2 and ITGB1 plays an important role in the prognosis of CRC. This adhesion is not only the basis of cancer cell survival but is also closely related to the migration and metastasis of cancer cells[52]. FAK is involved in LAMC2 and ITGB1 signal transduction, and the overexpression of FAK was found to play a key regulatory role in ITGB1-mediated signal transduction. As the phosphorylated FAK is activated, it transmits signals to the transcription factor snail, thereby inducing EMT[32,33]. The interaction of LAMC2 and ITGB1 and the overexpression of FAK were seen as markers of premetastatic niche formation, which may lead to malignant metastasis of CRC[52]. According to the results of our study, more interacting signals between LAMC2 and ITGB1, and higher level of FAK were found in the alcohol group than those in the non-alcohol group at early stage. In addition, the higher ratio of p-FAK/FAK in the alcohol group in the early stage indicates a higher degree of FAK activation, which may induce early EMT events and promote CRC metastasis.

CRC metastasis depends on EMT, during EMT, epithelial cells lose the connectivity and top-to-base polarity, resulting in a mesenchymal phenotype capability of migration and invasion[32]. There is evidence that some cancer cells may acquire the ability to spread and metastasize before they are fully malignant, which suggests that EMT may be an early event involving in the metastasis[53]. In addition, SATB1 has been found to be associated with early EMT events and can be used as a marker of CRC metastasis[54]. SATB1 was found to be a driver of the malignant phenotype in CRC, and its expression was shown to be positively associated with invasion depth, poor degree of differentiation and advanced TNM stage of CRC. And SATB1 organizes chromatin into spatial rings that provide the necessary "docking sites" for further binding of transcription factors and chromatin modifying enzymes[45]. SATB1 was found to regulate entire genes, even those located on distant chromosomes[55]. The results of the animal experiment suggested that the expression of SATB1 was significantly higher in the alcohol group than that in the non-alcohol group during precancerous lesions, which may predict the early EMT events.

In addition, there is an increasing evidence that proinflammatory cytokines play an important role in the formation of premetastatic niches. Previous studies have shown that the high expression of IL-6 and IL-1β may activate ITGB1[56,57] to stimulate the adhesion of bone marrow cells to endothelial cells, thereby promote the formation of premetastatic niche, and inducing EMT to promote metastasis[58]. Pal *et al*[55] found that TNF-α induces EMT in human HCT116 cells and promotes colorectal cancer invasion and metastasis. According to our study, the levels of the proinflammatory cytokines IL-1β, TNF-α and IL-6 in CRC rats in the alcohol group were significantly increased at the early stage of precancerous lesions, which may serve as paracrine signals to enhance the proliferation and invasion of early disseminated cancer cells. It may help cancer cells change their phenotypes through EMT to enhance metastasis.

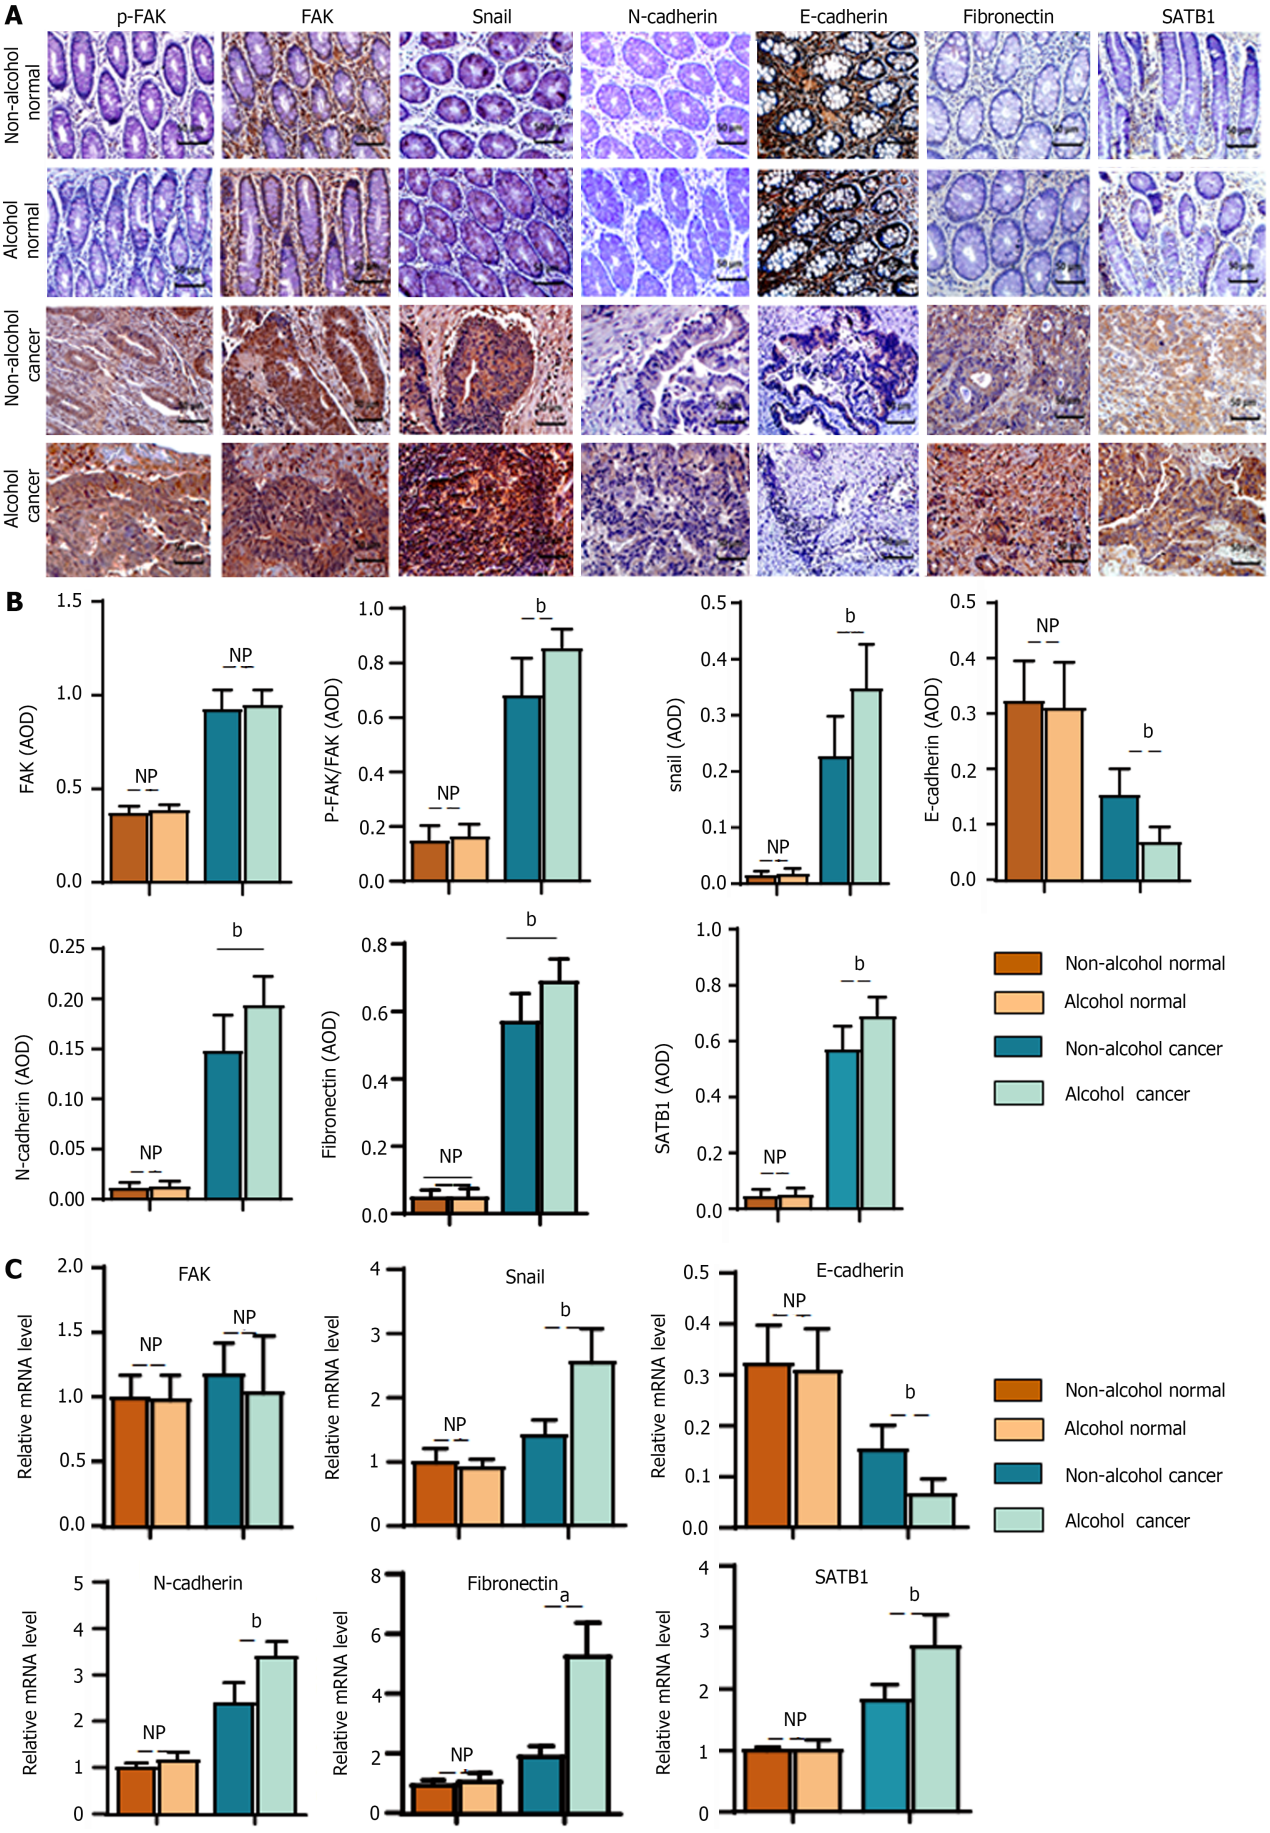

Figure 8 Alcohol consumption influenced the protein and mRNA levels of epithelial mesenchymal transformation -associated markers in

colorectal cancer patients. The bars represent the mean ± SD (n = 8). A: Representative immunohistochemical images of phosphorylate-focal adhesion kinase (p-FAK), FAK, snail, fibronectin, E-cadherin, N-cadherin and special AT-rich sequence binding protein 1 (SATB1) in different groups in clinical samples (× 400); B: Quantification of the protein levels of FAK, p-FAK/FAK, snail, fibronectin, E-cadherin, N-cadherin and SATB1 by counting the average optical density in clinical samples; C: Quantification of the mRNA levels of FAK, snail, fibronectin, E-cadherin, N-cadherin and SATB1 by quantitative real-time polymerase chain reaction in clinical samples. Compared with the non-alcohol group: $^{b}P < 0.01$, $^{a}P < 0.05$. SATB1: Special AT-rich sequence binding protein 1; FAK: Focal adhesion kinase; p-FAK: Phosphorylate focal adhesion kinase; AOD: Average optical density. NP: No statistical difference.

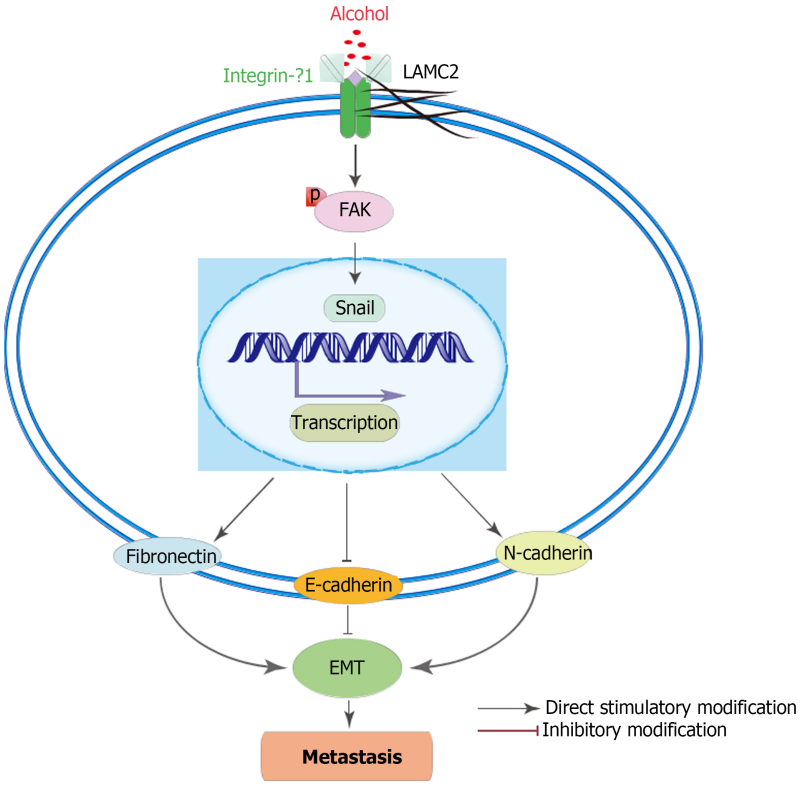

Figure 9 Schematic diagram of the possible signaling pathway regulated by alcohol. EMT: Epithelial mesenchymal transformation; LAMC2: Laminin-γ2; ITGB1: Integrin-β1; FAK: Focal adhesion kinase; p-FAK: Phosphorylate focal adhesion kinase.

The EMT event is also a key event involving in the formation of the premetastatic niche[32,33], which is almost featuring the loss of E-cadherin expression and overexpression of snail, N-cadherin and fibronectin[56,59]. The results of animal experiments suggested that long-term alcohol consumption (shown in Figure 9), as a risk factor of CRC, may further activate p-FAK by enhancing the interaction between LAMC2 and ITGB1 and forming a premetastatic niche, thus upregulating the expression of snail in precancerous lesions. Thus, the expression levels of N-cadherin and fibronectin were increased and the expression level of E-cadherin was downregulated, leading to the mesenchymal phenotype of cancer cells and colorectal cancer metastasis. This may be one of the reasons for the higher metastasis rate of CRC rats in the alcohol group. We found the similar results in clinical samples. The main limitation of the clinical study is the relatively small sample size. Larger-scale functional studies are required to improve our understanding of the effects of alcohol on the premetastatic niche in CRC. However, the obtained results provide some interesting suggestions for future studies with an increased sample size. Based on the abovementioned results, the present study demonstrated that alcohol may promote the formation of premetastatic niche *via* enhancing the EMT event mediated by the LAMC2-ITGB1 interaction, leading to the high incidence of CRC metastasis in the alcohol group.

CONCLUSION

In summary, the present study attempted to examine the nonspecific effect of alcohol on the premetastatic niche of colorectal cancer. Our study suggests that alcohol has an effect on the colorectal carcinogenesis paradigm and may accelerate the malignant metastasis of CRC. The molecular mechanism may involve the effect of alcohol on the early EMT-mediated premetastatic niche of colorectal cancer induced by LAMC2 and ITGB1 interactions.

ACKNOWLEDGMENT

We are very grateful to all the staff of Guangzhou University of Chinese Medicine and The First Affiliated Hospital of Guangxi University of Chinese Medicine for their help in the study.

ARTICLE HIGHLIGHTS

Research background

Colorectal cancer (CRC) is a common malignant tumor.

Research motivation

Alcohol consumption is positively correlated with CRC malignant metastasis; however, the mechanism is unclear.

Research objectives

To investigate the effects of alcohol on CRC metastasis

Research methods

The interaction between laminin-γ2 (LAMC2) and integrin-β1 (ITGB1) was measured by Duolink assay, and the expression levels of LAMC2, ITGB1 and focal adhesion kinase, snail, fibronectin, N-cadherin and special AT-rich sequence binding protein 1 were measured by quantitative real-time polymerase chain reaction, immunohistochemistry and western blotting. Interleukin-1β (IL-1β), tumor necrosis factor-α and IL-6 levels were measured *via* enzyme-linked immunosorbent assay, histopathological assessment *via* hematoxylin eosin staining, and determination of aberrant crypt foci *via* methylene blue.

Research results

Alcohol may promote CRC metastasis by influencing the molecular mechanism of the premetastatic niche.

Research conclusions

Our study suggests that alcohol promotes epithelial mesenchymal transformation-mediated premetastatic niche formation of CRC by activating the early interaction between LAMC2 and ITGB1 and lead to CRC metastasis.

Research perspectives

To explore the effect of alcohol on colorectal cancer metastasis.

Abstract

BACKGROUND

Hepatic hydrothorax (HH) is an uncommon and difficult-to-manage complication of cirrhosis with limited treatment options.

AIM

To define the clinical outcomes of patients presenting with HH managed with current standards-of-care and to identify factors associated with mortality.

METHODS

Cirrhotic patients with HH presenting to 3 tertiary centres from 2010 to 2018 were retrospectively identified. HH was defined as pleural effusion in the absence of cardiopulmonary disease. The primary outcomes were overall and transplant-free survival at 12-mo after the index admission. Cox proportional hazards analysis was used to determine factors associated with the primary outcomes.

RESULTS

Overall, 84 patients were included (mean age, 58 years) with a mean model for end-stage liver disease score of 29. Management with diuretics alone achieved long-term resolution of HH in only 12% patients. At least one thoracocentesis was performed in 73.8% patients, transjugular intrahepatic portosystemic shunt insertion in 11.9% patients and 33% patients received liver transplantation within 12-mo of index admission. Overall patient survival and transplant-free survival at 12 mo were 68% and 41% respectively. At multivariable analysis, current smoking

[hazard ratio (HR) = 8.65, 95% confidence interval (CI): 3.43-21.9, $P < 0.001$) and acute kidney injury (AKI) (HR = 2.91, 95%CI: 1.21-6.97, $P = 0.017$) were associated with a significantly increased risk of mortality.

CONCLUSION

Cirrhotic patients with HH are a challenging population with a poor 12-mo survival despite current treatments. Current smoking and episodes of AKI are potential modifiable factors affecting survival. HH is often refractory of diuretic therapy and transplant assessment should be considered in all cases.

Key Words: Cirrhosis; Portal hypertension; Hepatic hydrothorax; Ascites; Liver transplantation

Core Tip: The development of hepatic hydrothorax (HH) in cirrhotic patients continues to be associated with a very poor prognosis despite current standards-of-care. In one of the largest series to investigate the natural history of patients with hepatic hydrothoraces, a 45-d overall survival rate of 80% and 12-mo transplant-free survival of 41% was observed after index hospitalisation with HH. At multivariate analysis, current smoking and development of acute kidney injury were both independently associated with mortality, and represent important modifiable risk factors.

INTRODUCTION

Hepatic hydrothorax (HH) is an uncommon but serious complication occurring in patients with decompensated cirrhosis. HH is defined as the accumulation of more than 500 mL of transudative pleural fluid in a patient with cirrhosis and portal hypertension, where primary cardiopulmonary or malignant aetiologies have been excluded[1]. HH has been reported to occur in 5% to 11% of patients with cirrhosis, with more than 90% of cases occurring in Child-Pugh B or C disease[1,2]. HH is thought to arise from direct passage of fluid from the peritoneal cavity to the pleural cavity through diaphragmatic fenestrations[1]. Nuclear medicine studies, using labelled albumin have confirmed unidirectional passage of fluid from the abdominal to the pleural cavity[3], thus supporting a diaphragmatic defect process.

Clinically significant HH develops when accumulation of ascites in the pleural cavity exceeds the absorptive capacity of the pleura and patients typically present with shortness of breath, cough, hypoxia or chest discomfort[1,3]. Most cases occur in patients with appreciable ascites, however ascites may not be a prominent finding in up to 42%[1]. HH is most often unilateral and right-sided (59%-80%), however, there are increasing reports of left-sided (12%-17%) or bilateral (8%-24%) involvement[1,4]. Similar to the development of spontaneous bacterial peritonitis (SBP) in patients with ascites, patients with HH may develop spontaneous infections within the pleural fluid, which are termed spontaneous bacterial empyema (SBEM)[3].

The clinical management of HH remains complex and challenging. Treatment priorities in cirrhotic patients presenting with a pleural effusion include confirming a diagnosis of HH and excluding alternative pathology, relieving symptoms, preventing pulmonary complications and managing the underlying ascites. Diagnostic or therapeutic thoracocentesis is typically performed to confirm the presence of transudative fluid and to exclude SBEM or alternative pathology[5]. Recently developed American Association for the Study of Liver Disease (AASLD) guidelines state that first-line management should include sodium restriction and diuresis[6]. It is recognised, however, that 20%-30% of patients with cirrhosis and HH will develop persistent or recurrent pleural effusion despite these measures[6]. Refractory HH represents a particularly challenging management issue and patients are often considered for repeat therapeutic thoracocentesis and transjugular intrahepatic portosystemic shunt (TIPS) placement. Liver transplantation (LT) is the definitive treatment for HH, and post-transplant outcomes are comparable to outcomes for alternative indications[6].

Currently, there remains a paucity of literature examining the natural history and prognostic significance of HH. No randomised controlled trials have been performed in this population and clinical guidelines were only published for the first time in 2020[6]. Previous small studies have indicated the development of HH is associated with significant morbidity and extremely poor survival in the absence of LT[2,7,8]. The aims of this study were to: (1) Evaluate the probability of survival in a cohort of patients with liver cirrhosis presenting with HH and to examine factors associated with mortality; and (2) Provide a descriptive analysis of the treatments and complications associated with HH treatment during hospitalisation.

MATERIALS AND METHODS

Study design and setting

We conducted a multi-centre retrospective cohort study of patients with cirrhosis and HH presenting to three Australian metropolitan tertiary hospitals, one of which was a liver transplant centre, over a 9-year period from 2010 to 2018. Across all study sites, patients with decompensated cirrhosis were admitted under a specialist gastroenterology or liver transplant unit. Individual patient management was at the discretion of the attending gastroenterologist.

Ethics approval

The Human Research Ethics Committee at Monash Health and Austin Health approved the study as a quality assurance activity and the committee provided a waiver for informed consent (RES-19-0000-343Q).

Study participants

International Classification of Diseases (10th revision) codes for cirrhosis and chronic liver disease (K74, K74.6), HH (J 94.8) and pleural effusion (J90, J91) were used to retrospectively identify eligible patients with cirrhosis and HH[9]. The study eligibility criteria were: (1) Adult patients ≥ 18 years; (2) A confirmed diagnosis of cirrhosis, either biopsy-proven or based on clinical complications of cirrhosis; (3) Confirmed diagnosis of pleural effusion, based on imaging (plain X-ray or computed tomography); (4) Evidence of portal hypertension, as established by the presence of oesophageal varices, ascites and/or thrombocytopenia; and (5) Exclusion of cardiopulmonary or malignant pathology as a cause for the pleural fluid collection. Eligible patients were excluded if they had previously undergone LT. Included patients were followed for 12-mo from the date of the index admission.

Outcomes

The primary outcomes were 12-mo overall and transplant-free patient survival following index hospital admission with HH. Patients were followed-up from the date of first hospital admission with HH to an endpoint of death, LT or end of the study period. We report the 12-mo overall survival using the endpoint of death, censored for LT; and the 12-mo transplant-free survival using a composite endpoint of death and LT. The secondary outcomes included the incidence of specific treatments of HH and associated complications and to determine patient-specific prognostic factors associated with mortality.

HH definition and treatment protocols

HH was defined as the presence of a pleural effusion occurring in a patient with liver cirrhosis where no alternative aetiology was identified. Each patient was reviewed by a specialist hepatologist to ensure that the aetiology of pleural effusion was secondary to HH. Patients were excluded if the pleural effusion was felt to be due to primary infection, cardiopulmonary or malignant pathology.

Paracentesis was performed following radiological marking and thoracocentesis was performed by an interventional radiologist or the unit treating doctor with ultrasound guidance. In all cases, baseline observations were recorded, and the procedure was performed using sterile technique. Intravenous albumin (100 mL of 20% concentrated human albumin) was administered after every 2 liters of ascites or pleural fluid drained as per institutional protocol. Clinical observations were performed every 30 min for the duration of the procedure. Pleural and ascitic fluid was sent for analysis at the discretion of the physician performing the procedure according to indication and specimen viability. Where available, serum-pleural ascites gradient (SPAG) or serum-ascites albumin gradient values were obtained. SPAG greater than 11 g/L is consistent with a transudate[2], and was used to confirm portal hypertensive pathophysiology. SBEM was defined as pleural fluid with polymorphonuclear count of > 500 cells/mm^3 or > 250 cells/mm^3 with a positive culture, where parapneumonic effusion had been excluded[3]. Thoracocentesis without significant fluid drainage (diagnostic aspiration) was not considered in this analysis. TIPS insertion was available at all study centres and was performed by interventional radiology.

Treatment modalities pertaining to HH were categorized as: (1) Medical therapy with diuretics, and/or thoracocentesis; (2) TIPS; and (3) LT. All patients were risk stratified using the model for end-

stage liver disease (MELD) score which was calculated at the time of presentation for each admission. An in-hospital complication was defined as the occurrence of one or more of the following: Infection, procedural complication (hematoma, pneumothorax, death), acute kidney injury (AKI, defined as at least 1.5-1.9 times baseline or ≥ 26.5 mmol/L increase from baseline[10]), and new-onset acute hepatic encephalopathy which was not present on admission.

Data sources

For each patient, baseline demographic data, aetiology of liver disease, comorbidities, medication use, radiology results and laboratory results were extracted from electronic medical records. For patients with recurrent hospital admissions due to HH during the study period, data was collected for each presentation. Death was determined through hospital medical records and confirmed with a patient's Local Medical Officer if required.

Statistical analysis

mean ± SD was used to describe normally distributed continuous data, and median and interquartile range (IQR) for data that was significantly skewed. χ^2 analysis was used to examine the association between categorical variables. For the primary outcome, we used the Cox proportional hazards regression survival model to analyze the time of onset of HH to death. The time at risk begins at the first admission for HH (the index admission, t_0) and patients were censored at the time of LT or study conclusion (365 d after t_0). For transplant-free survival analysis, we omitted censoring LT and treated the transplant date as an outcome event. For each readmission, further clinical data was collected for analysis. The model incorporates enduring baseline variables (age, sex, comorbidities, smoking, alcohol intake, aetiology of cirrhosis) as well as a number of time-varying covariates (MELD score, AKI, encephalopathy, treatment-related complications, functional status, and TIPS).

From the univariable analyses, we included variables with a $P < 0.20$ into the multivariable model. Through backward elimination steps, we retained covariates with a $P < 0.05$ and checked the general model fit using partial Cox-Snell residuals. We used fractional polynomials to assist parameterization of continuous variables. The proportional hazards assumption was tested by examining the Schoenfeld residuals. The DFBETA estimates were used to detect influential observations. To validate our findings, we conducted bootstrapping of the Cox regression analysis with 1000 replications to generate bootstrapped confidence intervals (CIs). All analyses were conducted with STATA 16.1 (StataCorp, TX, United States), and a $P < 0.05$ was considered statistically significant.

RESULTS

Patient characteristics

A total of 246 patients with cirrhosis presenting to hospital with a pleural effusion were identified during the study period, of which 162 were excluded as the pleural effusion did not meet the criteria for HH. The final analysis included 84 patients who had a total of 167 hospital admissions over the study period. The baseline characteristics of the patients are summarized in Table 1. The mean age was 58.3 years, with only 11% patients over the age of 70, and there was a slight predominance of males. All patients had established liver cirrhosis and clinical evidence of portal hypertension. The median MELD score at time of hospital admission was 29 (IQR: 25-33). A diagnosis of hepatocellular carcinoma was present in 27.4% patients.

Across all hospital admissions, 59% of patients were treated with lactulose (13% variation within patients between admissions), 27% of patients were treated with rifaximin (average 12% variation within patients between admissions), and 56% of patients were receiving prophylaxis for SBP (average 12% variation within patients between admissions). Prior to hospital presentation with HH, 93% patients were prescribed diuretic therapy, with median furosemide and spironolactone doses of 40 mg and 100 mg per day respectively and 70% of these patients were receiving dual diuretic treatment.

HH clinical features and management

The clinical features and management of HH are summarized in Table 2. The majority of the hydrothoraces were unilateral on the right side. Of the 167 episodes of HH, 20 (12.0%) were managed solely with increased diuretics. Concurrent treatment with diuretics and ascitic fluid drainage was commonly performed, with abdominal paracentesis performed during 47 (28.1%) presentations, where the median volume of fluid drained was 5 litres. The proportion of patients requiring thoracocentesis, abdominal paracentesis and the complications rates were similar for readmissions compared to the index admission. However, the dose of diuretics used was higher on readmissions than during the index admission.

Thoracocentesis and complications: In total, 115 thoracocentesis procedures were performed in 62 (73.8%) patients with a median of 3 litres drained per procedure. Thoracocentesis was performed in 53 of 84 (63%) patients during the index admission. A further 62 thoracocentesis procedures were

performed in 33 of 43 patients who required one or more readmissions. On average, the probability of receiving another thoracocentesis was 77% during each readmission episode. Sufficient laboratory data to perform pleural/ascitic fluid analysis was available in 31% of procedures. Of these, SBEM was detected in 10 (8.7%) thoracocentesis procedures.

Blood products, including pooled platelets, fresh frozen plasma, cryoprecipitate, were administered in 29% of patients prior to or following thoracocentesis. Sixteen patients received an indwelling intercostal catheter for ongoing drainage rather than simple thoracocentesis in the setting of acute instability (*n* = 4) or refractory disease (*n* = 12). A pneumothorax complicated 17 (15%) thoracocentesis procedures, of which 7 were managed conservatively, 9 required an intercostal catheter insertion, and 1 patient died. Bleeding complications from thoracocentesis were uncommon and we could not determine if blood product infusions (platelets, fresh frozen plasma, cryoprecipitate, or prothrombin complex

NYHA: New York Heart Association; TIPS: Transjugular intrahepatic portosystemic shunt.

concentrate) reduced procedural complications or affected patient survival.

Other complications: One or more non-pleural complications were recorded in 80 (48%) of HH admissions. The most frequent complications were AKI in 58 (35%) patients, followed by infection in 31 (19%) and new-onset hepatic encephalopathy in 21 (13%). The incidence of these complications was similar for the index admission and readmissions.

TIPS insertion: Ten (12%) patients received a TIPS insertion, with 2 patients receiving TIPS insertion during the index admission, and 8 patients on a readmission. Significantly more females than males received a TIPS (21% *vs* 4%, $P = 0.038$), but age and MELD score did not differ between patients who received TIPS and those who did not. No patient who received a TIPS proceeded to LT within 12 mo of

the index admission.

LT: Forty-seven patients (56%) were referred for liver transplant assessment and 28 patients (33%) were successfully transplanted in the 12-mo following their index admission. The median time to transplantation from the index admission was 105 d (IQR: 55-200 d). The effect of LT on survival could not be estimated as there were no deaths amongst the transplanted patients within the study period.

Hospital length of stay and readmissions

The median hospital length of stay was 8 d (IQR: 4-17) for the index admission and 6 d (IQR: 4-14) for subsequent hospital readmissions. Within 12-mo of the index admission, 22 (26%) patients had 1 readmission, 9 (11%) had 2 readmissions, and 12 (14%) had ≥ 3 readmissions. In the 43 patients who required readmission, the median time interval between the index admission and the first readmission was 32 d (IQR: 12-74 d). The primary reasons for hospital readmissions were recurrent hydrothorax in 24 (38%) patients and decompensated cirrhosis in 26 (41%). There was strong evidence for an association between the New York Health Association (NYHA) functional class of dyspnoea and total number of readmissions (χ^2 = 46.2, P < 0.001) but the strength of the association was weak (Kendall's tau-b = 0.11). Intensive care unit (ICU) admission was required in 13 (15%) patients during the index admission, and 10 (12%) of 83 readmission episodes.

Mortality

There were 23 deaths (27.4% of the cohort) within 12-mo of the index admission. The total time-at-risk was 17850 patient-days with a mortality rate of 1.3 deaths per 1000 patient-days. The Kaplan-Meier survivor functions for overall and transplant-free patient survival are shown in Figure 1. Most deaths occurred early after the index admission, with 30-d overall survival of 87% (95%CI: 78%-93%), 45-d survival of 80% (95%CI: 70%-87%), and 12-mo survival of 68% (95%CI: 56%-78%). For transplant-free survival, the 30-d survival was 85% (95%CI: 75%-91%), 45-d survival of 76% (95%CI: 66%-84%), and 12-mo survival of 41% (95%CI: 30%-51%). Most deaths were due to complications of end-stage liver disease and multiorgan failure (75%) or hepatocellular carcinoma (10%), but a small number were due to cardiovascular events (15%). We noted that the mortality rate for current smokers was 5.58 per 1000 patient-days, compared to non-smokers of 0.86 per 1000 patient-days, giving a mortality rate ratio for current smokers of 6.5 (95%CI: 2.5-16.1, P < 0.001).

Univariable and multivariable Cox regression analysis

The results of univariable analyses are summarised in Table 3. Factors consistently associated with an increased hazard of death were current smoking, episodes of AKI, higher MELD score, and hepatic encephalopathy. In addition, when analysing transplant-free survival, diabetes and TIPS insertion were associated with a lower hazard for death or LT while incident pneumothoraces were associated with greater hazard.

The results of the multivariable analyses are summarised in Table 4. When examining the overall patient survival model, we decided not to include hepatic encephalopathy in the multivariable model as there were only 4 cases of severe encephalopathy on admission which were associated with an increased risk of death. In the transplant-free survival model, age, diabetes, TIPS and incident pneumothoraces were not statistically significant after adjusting for MELD, smoking, AKI, and hepatic encephalopathy. There were no significant statistical interactions between variables in the final models, and the models were a reasonable fit for the data when assessed by partial Cox-Snell residuals.

Due to the cohort size, we conducted bootstrapped analysis to validate our findings (Table 4). The significance of current smoking and AKI remained robust. In the overall survival model, a current smoker had 8.7 times the hazard of death of a non-smoker or ex-smoker; and one or more episodes of AKI was associated with a 2.9-fold increase in the hazard of death, after allowing for age and MELD score. In the transplant-free survival model, a current smoker had 3.1 times the hazard of death of a non-smoker or ex-smoker; and AKI was associated with a 2.2-fold increase in the hazard of death; after allowing for MELD and hepatic encephalopathy. These findings are represented in Figure 2.

Other analysis

To compare with the traditional Cox model, we also performed a competing risks regression analysis (Fine-Gray subdistribution proportional hazards) using the same covariates, with the assumption that all patients were on the active liver transplant waiting list. In this analysis, the effect of smoking and AKI on survival remained significant, and our conclusions remained unchanged. The subhazard ratio (SHR) of smoking on mortality was 6.26 (95%CI: 2.75-14.3), P < 0.001. The SHR of AKI on mortality was 2.60 (95%CI: 1.25-5.36), P = 0.01. The clear effect of smoking can be illustrated by examining the cumulative incidence function for active smokers compared to non-smokers (see Supplementary Figure 1).

Table 3 Univariable Cox regression on patient survival to 12 mo

Enduring variables	Overall[1], 12-mo survival	Transplant-free, 12-mo survival

DISCUSSION

HH remains an uncommon but extremely challenging complication in patients with liver cirrhosis. This study represents one of the largest series to analyse the natural history and outcomes of patients with HH and to our knowledge, is the first study to examine factors associated with survival in this population. We demonstrated that development of HH was associated with poor prognosis despite current therapeutic modalities, with a 45-d overall survival of 80% and 12-mo transplant-free survival of 41%. HH is a refractory disease, and the use of diuretics in isolation was rarely effective in this cohort, with 52% of patients experiencing recurrence of HH and rehospitalisation. At multivariable analysis, smoking status and the presence of AKI confer significant additional mortality risk.

Table 4 Multivariable Cox regression on patient survival to 12 mo

Model and variables	AHR (95%CI)	*P* value	Bootstrap CI	*P* value
Overall survival[1]				
Age, per 5-yr increase	1.30 (1.01-1.67)	0.043	0.91-1.85	0.15
MELD score, per 5 points	1.53 (1.06-1.67)	0.025	0.89-2.66	0.13
Current smoking	8.65 (3.43-21.9)	< 0.001	2.54-29.5	0.001
Acute kidney injury	2.91 (1.21-6.97)	0.017	1.04-8.12	0.042
Transplant-free survival

Figure 1 Kaplan-Meier survival curves. Kaplan-Meier survival curves showing transplant-free survival at 12 mo, with liver transplantation and death treated as composite endpoints, and overall patient survival at 12 mo, with patients censored at the time of liver transplantation (ticks on survival curve).

Hospitalisation with symptomatic HH is an uncommon presentation, with 84 patients recruited over a 9-year period to 3 metropolitan tertiary hospitals. The majority of patients presented with a right-sided pleural effusion and concurrent ascites, which is consistent with previous series[1,2,4]. The median MELD score of 29 in our cohort highlights that HH typically occurs in patients with advanced cirrhosis who often have other decompensating events such as hepatic encephalopathy. The median MELD score in our study was higher than that reported in other smaller studies[2,4,11], which may reflect use of data from a LT centre.

Patient management in this study aligns with recent AASLD guidelines, which recommend diuresis as the first-line therapy[6]. Most patients in our study were receiving diuretic therapy at the time of hospital presentation, with 70% receiving 2 diuretic agents, however the median doses of furosemide and spironolactone was well below the recommended maximum doses of 160 mg and 400 mg daily respectively[1]. Nonetheless, only 12% patients achieved long-term resolution of HH with diuretic therapy alone. An important limiting factor in relation to diuretic therapy is the propensity for AKI in patients with advanced cirrhosis. AKI was recorded in nearly one-third of presentations, and this was associated with a significantly higher risk of mortality. This suggests that diuretic therapy should be titrated cautiously in patients with HH with close monitoring of renal function.

There remains no consensus on universal diagnostic thoracocentesis in hospitalised patients with HH. In practice, whilst HH may be suspected on the basis of imaging and clinical presentation, thoracocentesis is useful to confirm transudative fluid and exclude other causes of a pleural effusion. We demonstrated that thoracocentesis in the HH population was associated with a significant higher risk of

Figure 2 Multivariate survival analysis. A: Multivariable Cox regression of overall patient survival (censored for transplantation), showing survival estimates for patients with hepatic hydrothorax by smoking and acute kidney injury status, with age and model for end-stage liver disease (MELD) scores held at the mean values; B: Bootstrapped pointwise confidence intervals for survival functions by active smoking status, in the absence of acute kidney injury and with age and MELD held at the means, demonstrating a robust association between active smoking and mortality in patients with hepatic hydrothorax. AKI: Acute kidney injury.

pneumothorax of 15% compared to the standard pneumothorax risk of 6% in non-cirrhotic populations, despite being performed under ultrasound guidance[12]. Shojaee *et al*[13] reported that repeat thoracocentesis in cirrhotic patients was associated with a higher rate of major complications compared to thoracocentesis for other aetiologies (8% *vs* 0%). In addition, Xiol *et al*[5], observed a pneumothorax rate of 25% in cirrhotic patients undergoing serial therapeutic thoracocentesis. Our analysis suggested that pneumothorax complications were associated with lower transplant-free survival [hazard ratio (HR) = 2.78; 95%CI: 1.39-5.56], however this was not significant in multivariable analysis. Other series have also suggested that HH requiring thoracocentesis independently confers significant morbidity and increased mortality[7,14]. Given the greater complications associated with thoracocentesis in cirrhotic patients, it was concerning that 74.7% of patients who were readmitted underwent repeat thoracocentesis. Further study is needed to elucidate the cause of the high complication rate and strategies to mitigate this risk. For example, it remains unclear if abdominal paracentesis effectively prevents HH recurrence[1].

In relation to other treatment modalities, indwelling intercostal catheter drains are thought to carry substantial risk and are not recommended by current guidelines, with some studies observing complication rates of 80%-90%[11,15]. In our cohort, an indwelling intercostal catheter was placed in 19% of patients, most commonly due to respiratory compromise and rapid re-accumulation of pleural fluid. In contrast, consideration of TIPS insertion is recommended by AASLD guidelines, based on evidence of a 70%-80% response rate in patients with refractory HH[3,6,16-18]. The outcomes following TIPS insertion may be comparable to those for management of refractory ascites and although a survival benefit in HH has not been established[19], the study by Badillo and Rockey[2] suggests a trend toward improved survival in patients proceeding to TIPS. Only 10 (17.9%) of the 56 patients in our cohort who were deemed not suitable for LT received TIPS insertion. No overall survival benefit from TIPS insertion was demonstrated, but transplant-free survival was higher (HR = 0.13; 95%CI: 0.02-0.96), as no patient who had TIPS insertion underwent LT.

Multiple studies have demonstrated that development of HH is associated with a poor prognosis[2,20,21], but mortality is difficult to compare due to heterogeneity between studies[2,4,11,15,21,22]. Our 12-mo transplant-free survival of 41%, however, is comparable to the 12-mo mortality of 57% reported by Badillo and Rockey[2]. In multivariable analysis, increasing age and MELD score, hepatic encephalopathy, development of AKI and active smoking were important factors independently associated with mortality. Given that the majority of deaths in our cohort were observed within 45-d of hospital admission and were most frequently due to complications of end-stage liver disease, we would advocate that in all patients presenting with HH, the appropriateness of transplantation should be considered with early referral for suitable candidates. Indeed, no deaths were recorded in patients who received LT, highlighting the successful outcomes of transplantation in patients with HH.

The strong association between smoking and poor outcomes has not previously been reported in patients with HH. Our study echoes a growing body of literature demonstrating an association between cigarette smoking and poorer outcomes in patients with liver disease[23,24]. Current smokers with cirrhosis have up to a 3.6 times higher mortality risk and cigarette smoking has been linked with progression of fibrosis in non-alcoholic fatty liver disease[24], hepatitis C and primary biliary cholangitis and is associated with an increased incidence of hepatocellular carcinoma[23]. Cigarette smoking represents an important modifiable risk factor that should be actively addressed in all patients with cirrhosis but appears critical in the HH population.

Study strengths and limitations

This is one of the largest, multicentre studies to investigate the prognostic significance of HH requiring hospitalisation in cirrhotic patients. Study inclusion criteria were broad and pragmatic, and represent generalisable real-world data. The Victorian Liver Transplant Centre was established in 1988 and currently performs over 100 transplants annually. The cohort had comprehensive assessments by gastroenterology specialists to confirm HH, which also assured treatment consistent with current standard-of-care practice guidelines. We used multivariable analysis to allow for confounders of mortality, and were able to identify smoking as a novel factor associated with significantly lower 12-mo survival in patients with HH. This study was able to elucidate the less well-described challenges in HH patients, such as need for ICU admission, hospital readmissions, and blood product requirement.

This study is limited by its retrospective design, with the inherent risks of missing information or extraction of inaccurate records. Complete pleural fluid analysis was only available in 31% of patients, which limited our ability to detect complications such as SBEM. SBEM has been associated in other studies with high short-term mortality (20% to 38%)[1]. SBEM was detected in 8.7% of thoracocentesis procedures in our study, which is almost certainly an underrepresentation of the true rate and lower than a study by Xiol *et al*[5], which found SBEM was present in 13% of patients with HH on presentation. Reasons for the low rate of complete pleural fluid analysis included the large number of hospital settings in which thoracocentesis was performed (including the emergency department, ICU, gastroenterology ward, radiology department or other acute hospital wards) with associated heterogeneity in process, incorrect requests for fluid analysis, incorrect tube collection to facilitate fluid analysis, clotting of fluid which precluded analysis, emergency procedures due to patient distress or instability and thoracocentesis performed prior to a diagnosis of HH being made. This reflects the real-world nature of the study and pleural fluid analysis rates were similar across all study sites. As such, we were not able to determine if specific pleural fluid findings were associated with refractory symptoms, rehospitalisation, or poor survival. In addition, factors associated with treatment failure or rehospitalisation such as compliance with diuretics were difficult to discern. The observational nature of the study also limits any causality inferences and eliminates the ability to ensure standardisation, which is particularly relevant to thoracocentesis technique. We could not exclude the possibility that some patients may have been admitted to a non-study hospital, although in practice this would be uncommon, and thus readmissions and complications may be underestimated.

In order to assess if TIPS may have provided clinical benefit apart from survival, we examined the readmissions, thoracocentesis, or ascitic drainage procedures in patients who received TIPS. Four patients had a single readmission post-TIPS, of which 3 occurred < 30 d and one at 6 mo post-TIPS. Thoracocentesis was performed in 3 of 4 of these readmitted patients, and ascitic drainage in 1 of 4 of these readmitted patients. Due to these low frequencies and different timing of TIPS, we cannot provide a meaningful statistical comparison with patients who did not have TIPS.

CONCLUSION

The development of HH is associated with poor transplant-free survival despite current standards-of-care and should prompt consideration of the appropriateness of LT in all patients. HH is often refractory to both conservative and invasive management and patients frequently require repeat hospitalisations. Active smoking and AKI may be important modifiable risk factors to reduce mortality in cirrhotic patients with HH.

ARTICLE HIGHLIGHTS

Research background

Hepatic hydrothorax (HH) is an important complication of cirrhosis, however management is often challenging and the natural history is poorly understood.

Research motivation

HH is a significant complication of cirrhosis, with a paucity of literature studying natural history and factors affecting survival.

Research objectives

This study sought to: (1) Evaluate factors associated with survival in a cohort of patients hospitalised with HH; and (2) Provide descriptive analysis of treatments, complications and outcomes following HH hospitalisation.

Research methods

Cirrhotic patients with HH presenting to three tertiary centres from 2010 to 2018 were retrospectively identified. Patients were followed-up from the date of first hospital admission with HH to an endpoint of death, liver transplantation (LT) or end of the study period. The primary outcomes were overall and transplant free survival at 12 mo after the index admission. The secondary outcomes included the incidence of specific treatments of HH and associated complications and to determine patient-specific prognostic factors associated with mortality.

Research results

Only 12% of patients achieved long-term resolution of HH with diuretic therapy alone. 74% of patients required thoracocentesis, with 15% of procedures being complicated by pneumothorax. 12-mo transplant free survival was 41%. 45-d overall survival was 80%.

Research conclusions

The development of HH is associated with poor transplant-free survival despite current standards-of-care and should prompt consideration of the appropriateness of LT in all patients. HH is often refractory to both conservative and invasive management and patients frequently require repeat hospitalisations. Active smoking and acute kidney injury may be important modifiable risk factors to reduce mortality in cirrhotic patients with HH.

Research perspectives

This study represents one of the largest series examining survival in persons hospitalised with HH, and importantly has identified modifiable risk factors that may alter the natural history in this challenging patient population.

Abstract

BACKGROUND

The microbes and metabolomics of microbiota dysbiosis in the gut in the different phases of hepatitis B virus (HBV) infection are not fully understood.

AIM

To investigate the specific gut microbiota and metabolites of the immune-tolerant (IT) and immune-active (IA) phases of chronic hepatitis B (CHB).

METHODS

Clinical fecal samples from healthy individuals and patients in the IT and IA phases of HBV infection were collected. Next, non-target metabolomics, bioinformatics, and 16S rDNA sequencing analyses were performed.

RESULTS

A total of 293 different metabolites in 14 phyla, 22 classes, 29 orders, 51 families, and 190 genera were identified. The four phyla of *Firmicutes*, *Bacteroidetes*, *Actinobacteria*, and *Proteobacteria* were the most abundant, accounting for 99.72%, 99.79%, and 99.55% in the healthy controls, IT-phase patients, and IA-phase patients, respectively. We further identified 16 genera with different richness in the IT phase and IA phase of HBV infection. Of the 134 named metabolites, 57 were upregulated and 77 were downregulated. A total of 101 different metabolic functions were predicted in this study, with 6 metabolic pathways having the highest enrichments, namely carbohydrate metabolism (14.85%), amino acid

metabolism (12.87%), lipid metabolism (11.88%), metabolism of cofactors and vitamins (11.88%), xenobiotic biodegradation (9.9%), and metabolism of terpenoids and polyketides (7.92%).

CONCLUSION

These findings provide observational evidence of compositional alterations of the gut microbiome and some related metabolites in patients with IT-phase or IA-phase HBV infection. Further studies should investigate whether microbiota modulation can facilitate the progression of CHB and the cause-effect relationship between the gut microbiota and CHB.

Key Words: Microbes; Metabolomics; Gut microbiota; Immune-tolerant phase; Hepatitis B virus

INTRODUCTION

As a disease of public health significance, hepatitis B often leads to liver cirrhosis or hepatocellular carcinoma (HCC). Currently, there are few effective treatments and strategies for eliminating hepatitis B virus (HBV) infection. The immune-tolerant (IT) phase is the first stage of HBV infection, and recent studies suggest that HBV-infected patients in this phase suffer from a high risk of HCC and death[1-3]. However, anti-HBV treatment is not generally recommended at this stage. The IT status of patients largely determines the patients' outcomes. Thus, the identification of factors that affect the consequences of HBV infection is crucial for eliminating this disease.

Recent studies indicate that the gut microbiota is involved in chronic hepatitis B (CHB) as well as other liver diseases[4-6]. Some commensal bacteria regulate the host metabolic pathways by improving food-derived energy or modulating the host-derived compounds that alter metabolism[7-9]. In addition, there are various gut microbiota in patients with CHB, hepatitis B-related liver cirrhosis, or HCC[10-12]. To date, information about the gut microbiota in patients at the initial phase of HBV infection remains largely unknown. We believe that studies on the gut microbiota of HBV-infected patients in the IT phase would help to elucidate the underlying mechanism of HBV IT as it will provide valuable information about the immune environment for HBV and its long-term existence.

Most studies on the microbiome have been cross-sectional with samples collected at a single time point, and only some studies have been performed with samples from different stages of HBV infection [12-15]; moreover, few comparisons of HBV-infected patients and healthy individuals have been carried out in these studies. CHB patients may develop recurrent active hepatitis, while the IT phase may change into the immune-active (IA) phase at a later stage in patients[16], which can lead to a substantial change in the composition of the gut microbiota. Therefore, understanding how the gut microbiota change from the IT phase to the IA phase will be important for the development of potential microbiome-targeting therapeutic drugs to combat HBV infection. Furthermore, this dynamic variation in gut microbiota in HBV-infected patients may help us to identify unique bacterial taxa that would contribute to postponing disease progression.

The present study focused on the dynamic profiles of the gut microbiota in IT-phase patients and IA-phase HBV-infected patients without liver fibrosis by 16S rDNA sequencing and analysis. We aimed to identify changes of bacteria involved in the transition from the IT phase to the IA phase in HBV-infected patients and to illustrate the regulation of both microbiota and metabolites. The results will provide a new perspective for the noninvasive diagnosis and treatment of IT-phase HBV-infected patients.

MATERIALS AND METHODS

Recruitment of participants

HBV-infected patients in the IT phase or the IA phase were recruited from The First Affiliated Hospital of Fujian Medical University from January 2018 to December 2020. All HBV-infected patients were at least 18-years-old, hepatitis B surface antigen positive for ≥ 6 mo, and hepatitis B virus e-antigen positive; moreover, the IT patients had a normal alanine aminotransferase level (< 40 IU/L), HBV DNA > 1 million IU/mL, and no fibrosis found by FibroScan analysis[17]. The IA patients had an HBV DNA serum concentration of > 20000 IU/mL as well as elevated alanine aminotransferase and/or aspartate aminotransferase levels[17]. However, patients who suffered from other non-HBV diseases/infections were excluded from the study. Samples from healthy volunteers were blindly collected, and participants who had received antiviral therapy, immunotherapy, probiotics, or antibiotics within 8 wk before enrollment were excluded. Verbal informed consent was provided by all participants. The experimental protocol and participant enrollment procedure were approved by the Ethics Review Committee of the university and were conducted according to the Declaration of Helsinki guidelines.

Clinical measurements

Liver stiffness measurements were conducted using a FibroScan instrument. Measurements with more than ten successful acquisitions were obtained (with a rate > 60% and an interquartile range < 30%). In addition, the alanine aminotransferase, aspartate aminotransferase, glutamyl transpeptidase, total bilirubin, albumin, globulin, and alpha-fetoprotein levels were measured. HBV serological testing was performed with the Architect platform (Abbott Laboratories, Chicago, IL, United States). HBV DNA was tested by a quantitative PCR assay (PG Company, Shenzhen, China).

Sampling, DNA extraction, and PCR

Fecal samples were obtained from all participants, filtered with a 2-mm sieve to remove interferents, and then stored at -80 °C for the following experiments. Total bacterial DNA extraction was performed with a PowerSoil DNA Isolation Kit (MoBio Laboratories, Carlsbad, CA, United States), and the purity and quality of the genomic DNA were checked by electrophoresis on 0.8% agarose gels. The V3-4 hypervariable region of bacterial 16S rDNA was amplified by previously reported conserved primers: 338F (5′-ACTCCTACGGGAGGCAGCAG-3′) and 806R (5′-GGACTACHVGGGTWTCTAAT-3′)[18]. For each sample, the 10-digit barcode sequence was added to the 5′-end of the forward and reverse primers (provided by Allwegene Company, Beijing, China). The PCR was carried out on a Mastercycler Gradient (Eppendorf, Germany) using a reaction volume of 25 μL, containing 12.5 μL of KAPA 2G Robust Hot Start Ready Mix, 1 μL of forward primer (5 μmol/L), 1 μL of reverse primer (5 μmol/L), 5 μL of DNA (total template quantity of 30 ng), and 5.5 μL of H_2O. The cycling parameters were 95 °C for 5 min, followed by 28 cycles of 95 °C for 45 s, 55 °C for 50 s, and 72 °C for 45 s, with a final extension at 72 °C for 10 min.

Three PCR products per sample were pooled to mitigate reaction-level PCR biases. The PCR products were purified using a QIAquick Gel Extraction Kit (QIAGEN, Germany), quantified using real-time PCR, and sequenced at Allwegene Company, Beijing, China. Deep sequencing was done with the Miseq platform at the Allwegene Company (Beijing, China). The raw data were first screened, and sequences were removed from consideration if they were shorter than 200 bp, had a low quality score (≤ 20), contained ambiguous bases, or did not exactly match the primer sequences and barcode tags. Qualified reads were separated using the sample-specific barcode sequences and trimmed with Illumina Analysis Pipeline Version 2.6. Thereafter, the dataset after cleaning was analyzed using the Quantitative Insights into Microbial Ecology (QIIME) platform.

All sequences were clustered into operational taxonomic units (OTUs) at a similarity level of 97%[19] to generate rarefaction curves. The Ribosomal Database Project classifier tool was used to analyze different taxonomic groups[20]. The Venn diagram was built by the R package program. Shared taxa presented in all groups were defined as the core microbiota. Clustering analysis and principal component analysis were performed by using the R package, as described previously[21]. The evolution distances were analyzed with the unweighted pair group method and an arithmetic mean clustering tree[22]. Heatmaps of the top 20 OTUs were generated using Mothur, as described in a previous study [23].

Metabolic pathway and non-target metabolomics

Phylogenetic Investigation of Communities by Reconstruction of Unobserved States (PICRUSt) analysis based on the 16S rDNA was performed. The OTU table derived from QIIME was compared using the Kyoto Encyclopedia of Genes and Genomes and MetaboAnalyst (http://www.metaboanalyst.ca/) databases, and the metabolic function of the gut microbiota was predicted based on the findings. The abundances of functional genes were visualized as heatmaps by the R package.

For metabolite extraction, a 10-μL aliquot of each sample was mixed with 990 μL of the extraction solvent (acetonitrile/methanol/water, 2:2:1), and the mixture was vortexed for 30 s, incubated at -20 °C for 1 h, and then centrifuged at 12000 rpm and 4 °C for 15 min. Finally, the supernatant was diluted 10

times for ultra-high-performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS) analysis[24]. UHPLC separation was performed on an Agilent 1290 Infinity II series UHPLC system (Agilent Technologies). Mobile phase A included both 10 mmol/L ammonium formate and 10 mmol/L ammonia, while mobile phase B was acetonitrile. The temperatures for the column and the autosampler were set at 35 °C and 4 °C, respectively[25].

Statistical analysis

One-way analysis of variance was performed to compare continuous variables between two groups. The Wilcoxon signed rank test, Kruskal–Wallis test, χ^2 test, or Student's t test was used to compare categorical variables between groups. All statistical analyses were calculated either in the R package (version 3.6.1) or SPSS (version 26.0). P values less than 0.05 were considered as significant differences.

RESULTS

Overview of gut microbial community shift in patients

To differentiate the characteristics of the gut microbiota in IT-phase HBV-infected patients, IA-phase HBV-infected patients, and healthy individuals, 16S rDNA gene sequencing was performed on the stool samples from 14 IT-phase HBV-infected patients, 10 IA-phase HBV-infected patients, and 13 healthy donors (Table 1). A total of 1521813, 411189, and 1109236 sequences were acquired for the IT, IA, and healthy groups, respectively, after excluding low-quality reads. A total of 19556 clean tags were obtained, of which 824 OTUs were matched. After applying strict trimming criteria to exclude low-quality clean tags, the numbers of OTUs for healthy individuals, IT-phase patients, and IA-phase patients were 633, 662, and 489, respectively, as shown in Table 2. A total of 95, 132, and 27 OTUs existed independently in the healthy controls, IT-phase patients, and IA-phase patients, respectively (Figure 1). There were no significant differences in the Chao1, Shannon, and Simpson indices among the IT, IA, and healthy groups (all P values > 0.05, Table 2). The bacterial communities in the healthy individuals were relatively more heterogeneous than those found in the IT- or IA-phase patients. The IT and IA patients could be separated from the healthy individuals by non-metric multidimensional scaling and principal component analysis (Figure 2A and B). Partial least squares discriminant analysis showed structural differences in the gut bacterial community structure among the groups, indicating that the classification model was effective (Figure 2C).

Predominant bacteria at different levels

To show the abundance of bacteria of all fecal samples, 14 phyla, 22 classes, 29 orders, 51 families, and 190 genera were identified, and the dominant gut microbiota are shown in Supplementary Table 1 and Figure 3. The four phyla of *Firmicutes*, *Bacteroidetes*, *Actinobacteria*, and *Proteobacteria* were the most abundant, accounting for 99.72%, 99.79%, and 99.55% in the healthy controls, IT-phase patients, and IA-phase patients, respectively. In detail, the highest relative abundance of *Actinobacteria*, which reached 7.32%, was found in the healthy group. Meanwhile, compared with the healthy control and the IA-phase patients, the IT patients had the highest abundance of *Bacteroidetes* (33.27%). The IT-phase patients had less *Firmicutes* (61.00%) and *Actinobacteria* (2.71%) than the IA-phase patients. *Clostridiales*, *Bacteroidales*, *Selenomonadales*, *Bifidobacteriales*, *Coriobacteriales*, *Erysipelotrichales*, *Lactobacillales*, and *Enterobacteriales* were the most abundant bacteria at the order level in all three groups.

For the genus level, an abundance of *Bacteroides* (16.19%), *Prevotella 9* (9.04%), and *Megamonas* (7.66%) was found in the IT-phase patients. However, *Blautia* (19.20%) and *Faecalibacterium* (12.68%) were enriched in the IA-phase patients. Interestingly, the healthy groups had more *Eubacterium rectale* (6.69%), *Eubacterium hallii* (4.03%), *Bifidobacterium* (3.87%), and *Dorea* (3.23%). In addition, *Faecalibacterium* and *Blautia* accounted for a high proportion in the IA-phase patients; these bacteria are involved in butyrate short-chain fatty acid metabolism and inhibit inflammation.

Linear discriminant analysis effect size analysis to identify specific microbial taxa related to IT and IA patients

Linear discriminant analysis (LDA) effect size modeling was applied to identify specific bacterial taxa associated with different stages of CHB (Figure 2D and E). There were markedly significant differences in the community compositions in CHB patients compared with the healthy individuals. There were 12 and 6 significantly different taxa in the IT- and IA-phase patients, respectively. The five most enriched genera in the IT-phase patients were *Senegalimassilia* (LDA score = 4.38, $P < 0.05$), *Prevotella 2* (LDA score = 4.24, $P < 0.01$), *Alloprevotella* (LDA score = 4.09, $P < 0.05$), *Sutterella* (LDA score = 3.67, $P < 0.001$), and *Haemophilus* (LDA score = 3.58, $P < 0.05$). The four most enriched genera in the IA-phase patients included *Blautia* (LDA score = 4.78, $P < 0.01$), *Faecalibacterium* (LDA score = 4.51, $P < 0.05$), *Clostridium innocuum* group (LDA score = 4.23, $P < 0.01$), and *Faecalitalea* (LDA score = 3.76, $P < 0.05$) (Supplementary Table 2). These significantly different gut microbial taxa can be used as potential noninvasive biomarkers for the diagnosis of different immune phases of infection in CHB.

Table 1 Basic information and clinical characteristics of healthy individuals, immune-tolerant phase hepatitis B virus infection patients, and immune-active phase hepatitis B virus infection patients

Characteristic	H, *n* = 13	IT, *n* = 14	IA, *n* = 10	*P* value

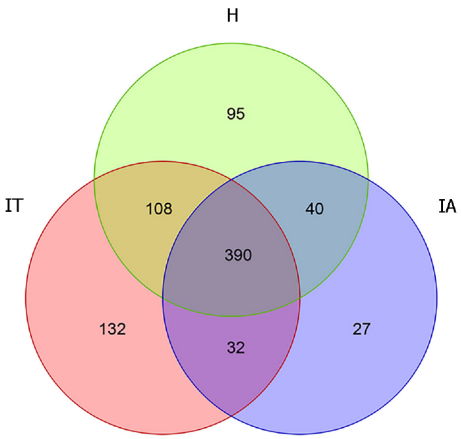
Table 2 Species richness indices in the fecal samples



Group	Healthy controls, *n* = 14	IT phase HBV infection, *n* = 13	IA phase HBV infection, *n* = 10	*P* value
OTUs	633	662	489	
α-diversity indexes, median				
Chao1	264.310	233.825	227.000	0.924
Shannon	5.020	4.720	4.705	1.739
Simpson	0.940	0.885	0.915	1.666

IT: Immune-tolerant; IA: Immune-active; HBV: Hepatitis B virus; OTUs: Operational taxonomic units.

Furthermore, the Wilcoxon and Kruskal-Wallis rank sum tests showed the abundance at different taxonomic levels with $P < 0.05$ and FDR $q < 0.1$ (Supplementary Table 3). The top 20 gut microbiota at the genus level consisted of *Bacteroides*, *Prevotella 9*, *Megamonas*, *Blautia*, *Faecalibacterium*, *Roseburia*, *Fusicatenibacter*, *Anaerostipes*, *Prevotella 2*, *Ruminococcus 2*, *Phascolarctobacterium*, *Alloprevotella*, *Bifidobacterium*, *Subdoligranulum*, *Dialister*, *Eubacterium rectale*, *Eubacterium eligens*, *Dorea*, *Eubacterium hallii*, and *Streptococcus*. Moreover, the shared species between the significantly different gut microbiota and the top 20 gut microbiota were *Blautia*, *Faecalibacterium*, *Fusicatenibacter*, *Prevotella 2*, *Alloprevotella*, and *Eubacterium hallii* group, which might be highly associated with the outcomes of CHB in different phases. The differences found in this study revealed the dysbiosis involved in the development of CHB and the aberrant ecological networks of microbial communities during infection.

Longitudinal analysis of patients in the IT phase of HBV infection

Longitudinal follow-up analysis showed that 3 patients progressed from the IT phase to the IA phase and required medical treatments. The change in the microbiota of these 3 patients during treatment was studied. The abundance of *Firmicutes* and *Actinobacteria* increased, while the abundance of *Bacteroidetes* and *Proteobacteria* decreased at the phylum level (Figure 4A). Moreover, *Bacteroides*, *Alistipes*, and *Bilophila* were mostly abundant in the IT phase, while *Actinomyces*, *Adlercreutzia*, and *Streptococcus* were more abundant in the IA phase (Figure 4B and C). A decreased ratio of *Bacteroidetes* to *Firmicutes* was observed, which might be involved in inflammatory disorders in the IA phase.

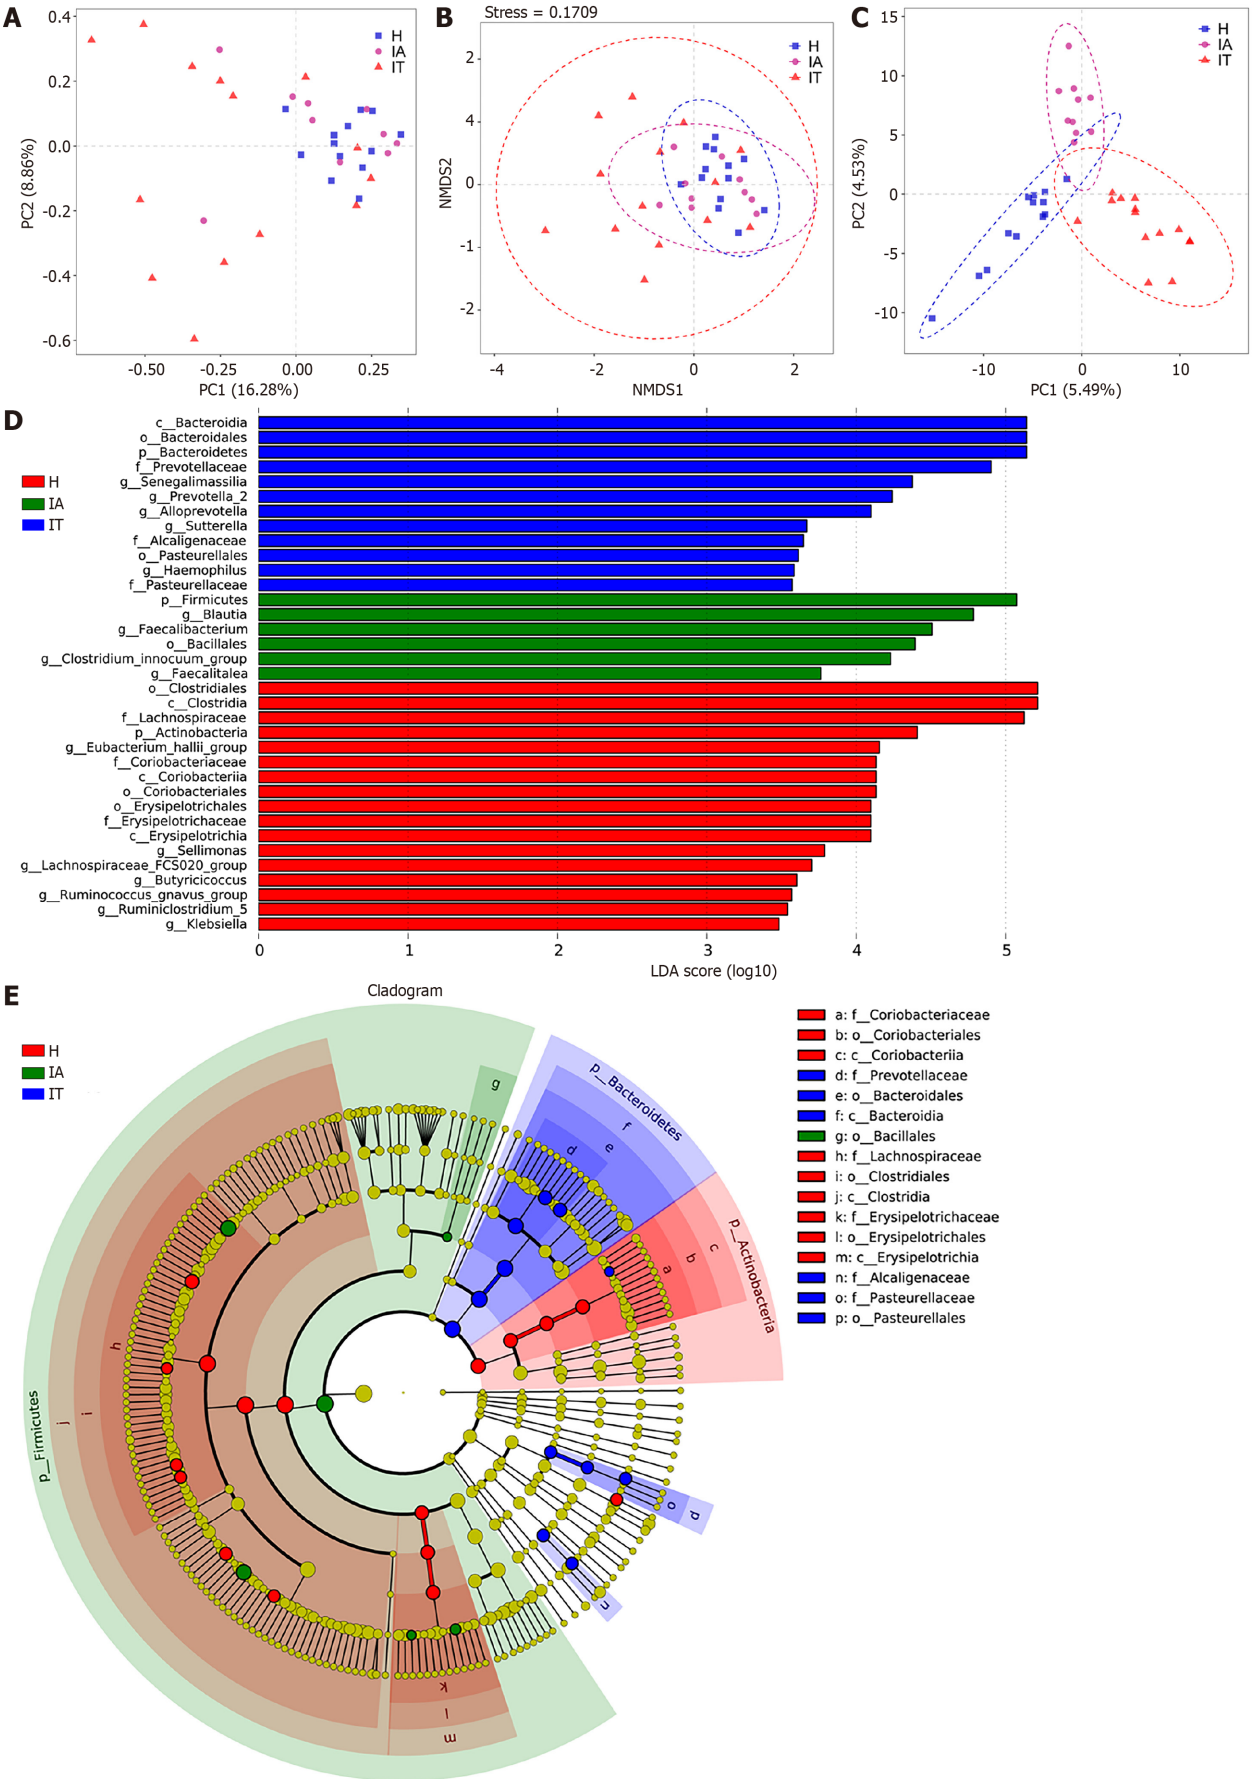
Microbial functional dysbiosis in IT and IA patients and co-occurrence network analysis

To identify the bacterial functional alteration in IT and IA patients, we analyzed the functional potential of gut microbiota with PICRUSt analysis. A total of 101 different metabolic functions were predicted in this study, with 6 metabolic pathways having the highest enrichments, namely carbohydrate metabolism (14.85%), amino acid metabolism (12.87%), lipid metabolism (11.88%), metabolism of cofactors and vitamins (11.88%), xenobiotic biodegradation (9.90%), and metabolism of terpenoids and polyketides (7.92%). In addition, the functional roles of the bacteria were highly related to infectious diseases, including bacterial infection (50.00%) and parasitic infection (33.33%) as well as cardiovascular disease (10.00%) and neurodegenerative disease (10.00%) (Supplementary Table 4). The parasitic infectious disease-related gene subgroups (P = 0.03) in the IA-phase patients were highly enriched (Figure 5). The cell motility-related genes were highly enriched in the IA-phase patients (Figure 5A), while the transport and catabolism-related genes (P = 0.03) were significantly enriched in the IT-phase patients. However, signal transduction-related genes were significantly enriched in the healthy controls (P < 0.01) (Figure 5B). The replication repair-related genes and digestive system-related genes in the IT-phase patients were more abundant than in the other groups, but the difference between the three groups was not statistically significant (Figure 5C and E). Moreover, the digestive system disease-related gene subset (P = 0.02) was highly enriched in the IT-phase patients (Figure 5D). Genes that are related to the amino acid metabolism glycosyl biosynthesis cofactors and vitamin metabolism were more enriched in the IT-phase patients than in the healthy controls (P < 0.01) (Figure 5F). These observed results suggested that changes in the bacterial composition can significantly alter gene function, which may contribute to the development of CHB.

As shown in the co-occurrence network analysis using Cytoscape software (Supplementary Figure 1), five genera (Dorea, Bifidobacterium, Bacteroides, Blautia, and Romboutsia) were highly positively correlated. Dorea and Bifidobacterium exhibited the highest degree of linkage, while Dorea and Bacteroides had the least degree of linkage.

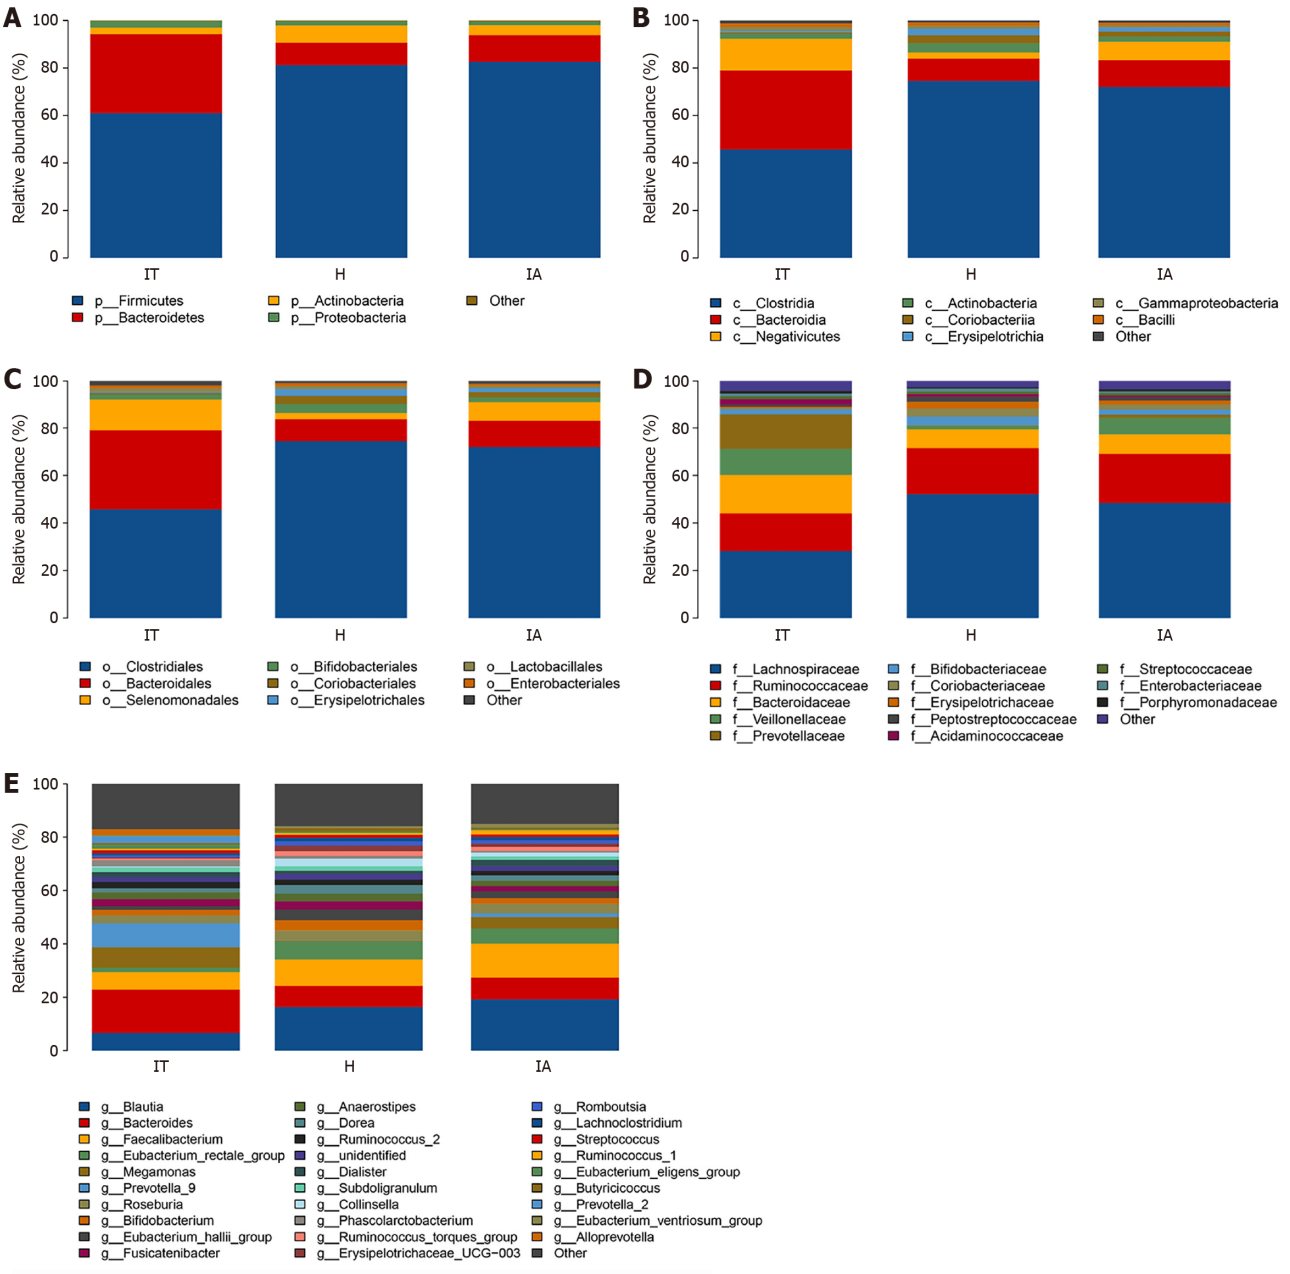


Non-target metabolomics analysis

A total of 293 substantially different metabolites were identified, among which 134 metabolites had an MS2.name provided by the mass spectrometry qualitative matching analysis. A total of 57 metabolites were upregulated, while 77 were downregulated. The different metabolites are shown in Supplementary Table 5.

DISCUSSION

To date, there are limited studies showing the role of dysbiosis of the gut microbiota in HBV-infected patients during the different immune phases of infection. This study revealed the profiles of the gut microbiota during HBV infection from the IT phase to the IA phase. The results suggested that the diversity, composition, and functionality of the microbiota changed from the IT phase to the IA phase and were related to the progression of CHB.



In our study, analysis of α-diversity using the Chao1, Shannon, and Simpson diversity indices showed no significant differences among the three groups. Nevertheless, one study has reported that the α-diversity is increased in cirrhosis patients compared to healthy controls and positively correlated to the Child-Pugh score[26]. In our study, a decreased ratio of *Bacteroidetes* to *Firmicutes* was observed as

patients progressed from the IT phase to the IA phase, while another study has demonstrated that the ratio of *Bacteroidetes* to *Firmicutes* increased in patients with HBV-related cirrhosis compared to that of healthy individuals[27]. These results in different studies indicate that the results may vary greatly depending on the grouping. In addition, our results suggest that the composition of the gut microbiota had changed in the early stages of HBV infection. Furthermore, metabolic changes at different stages of HBV infection were also observed by PICRUSt analysis. Consistent with another study[27], these results suggest that changes in the composition of the gut microbiota can significantly alter gene function,

which may have a potential role in HBV-infected patients.

When compared to the healthy controls, there was a correlation between some gut microbiota in patients at the IT and IA phases. Notably, the IT group presented a high relative abundance of *Senegalimassilia*, *Prevotella 2*, *Alloprevotella*, *Sutterella*, and *Haemophilus*; while the IA group showed a high relative abundance of *Blautia*, *Faecalibacterium*, *Clostridium innocuum* group, and *Faecalitalea*. Some *Prevotella* strains have been reported as potentially clinically important pathobionts in human diseases by increasing the levels of interleukin (IL)-23, IL-1, IL-8, IL-6, and C-C motif chemokine ligand 20[28]. In addition, *Alloprevotella* is enriched in fecal samples from patients with chronic kidney disease[29].

IT: Immune-tolerant; IA: Immune-active; H: Healthy.

Moreover, the gut microbiota in prediabetic individuals was found to be aberrant, with decreased *Clostridium* and increased *Sutterella* levels[30]. Furthermore, *Sutterella* has the capacity to degrade IgA, causing failure of therapeutics treating ulcerative colitis[31]. These findings reveal that *Prevotella 2*, *Alloprevotella*, and *Sutterella* are involved in chronic human diseases. Our results also indicate that *Prevotella 2*, *Alloprevotella*, and *Sutterella* are specifically related to HBV infection in the IT phase, suggesting their role of mediating viral escape from the host immune response.

Blautia, *Faecalibacterium*, *Clostridium innocuum* group, and *Faecalitalea* were identified as signature gut microbiota related to HBV infection in the IA phase. Notably, an elevated abundance of *Blautia* has been shown to alleviate the severity of lethal acute graft-versus-host disease[32]. In addition, Benítez-Páez *et al*[33] proposed that *Blautia luti* and *Blautia wexlerae* might help to reduce the inflammation that is linked to obesity-related complications. Moreover, *Blautia* is positively associated with the pathophysiology of type 2 diabetes[34]. Furthermore, *Faecalibacterium prausnitzii*, belonging to *Faecalibacterium*, is a major constituent of the gut microbiota in healthy individuals. This bacterium, which has anti-inflammatory activity, is decreased in patients with inflammatory bowel diseases such as Crohn's disease. Interestingly, *Blautia* and *Faecalibacterium* have been shown to be beneficial in a healthy gut[35]; these bacteria enhance the production of butyrate succinate and lactate, thus providing energy and reducing inflammation[36].

Additionally, a recent finding indicated that in patients with early HBV-related HCC, genera belonging to butyrate-producing bacterial families, including *Ruminococcus*, *Oscillibacter*, *Faecalibacterium* , *Clostridium IV*, and *Coprococcus* decreased, while the lipopolysaccharide-producing bacteria *Klebsiella* and *Haemophilus* increased compared to the levels in cirrhosis patients[37]. Herein, the proportions of *Blautia*, *Faecalibacterium*, and *Clostridium innocuum* group were higher in the IA-phase patients than in the controls, indicating that enrichment of these three signature microbial taxa might be a sign of severe inflammation or exacerbation of disease. Notably, these beneficial gut microbiota might help to clear viral infection in the IA phase, while some gut microbiota in the IT phase might help the virus to escape from host immune responses. Taken together, these findings highlight an important role for the composition of the gut microbiota in the progression of HBV infection, which has significant clinical implications.

Based on the composition and structure of the gut microbiota, the metabolic function of the microflora was further analyzed through PICRUSt. In this study, the genes involved in glycan biosynthesis and metabolism as well as cofactor and vitamin metabolism were more enriched in the IT-phase patients than in the healthy controls. One explanation for this finding is that *Senegalimassilia*, *Prevotella 2*, *Alloprevotella*, *Sutterella*, and *Haemophilus* are enriched in the IT phase and consume glycan as their energy source; the genes found in these bacteria are related to cofactor and vitamin metabolism. In contrast, terpenoid and polyketide metabolism-related genes were more abundant in the IA phase, suggesting that *Senegalimassilia*, *Prevotella 2*, *Alloprevotella*, *Sutterella*, and *Haemophilus* participate in the metabolism of terpenoids and polyketides. These results may indicate that the gut microbiota and metabolites contribute to the abnormal metabolism status in CHB.

Previous research has shown that the gut microbiota composition is closely related to the occurrence of various chronic liver diseases[38-40]. Our current study demonstrated that potential links exist between certain bacteria and different pathological mechanisms during CHB progression from the IT phase to the IA phase.

Studies using mouse models have uncovered that the gut microbiota have a vital role in overcoming the IT phase of viral infection at different ages[41] and that gut microbiota lead to Kupffer cell-mediated T cell suppression, which is associated with HBV persistence[42]. In addition, fecal microbiota transplantation therapy has been shown to improve the clearance rate of HBV antigens in CHB patients after long-term therapy[43]. Our study demonstrated that the gut microbiota composition changed at different phases of HBV infection. Changes in the gut microbiota composition could be a biological factor for the progression of CHB. We believe that the gut microbiome of CHB patients may provide a useful prognostic marker for disease progression, outcome prediction, and treatment and that further microbiome-based study may provide new insights into the pathogenesis of CHB, the etiology of its progression, and novel therapeutic strategies such as the use of probiotics or fecal microbiota transplantation.

Although this study uncovered some insightful findings, some limitations remain. First, all patients enrolled in this study were from different families. Having different genetic backgrounds and dietary habits might affect the gut microbiota composition. In addition, the healthy donors should have had a similar age to the patients; however, the controls were not age-matched to the patients in this study. Second, only 3 patients were followed up from the IT phase to the IA phase. A larger longitudinal sample size will strengthen the results. Third, a real-world cross-sectional study would be beneficial to understand the impact of the microbiota on the progression of liver disease. Fourth, the methods we used have some limitations. Although transcriptomics also contributes to gene expression, the findings could be further confirmed if we used metagenomic sequencing rather than 16S rDNA gene sequencing. Metagenomic sequencing not only sequences the 16S rDNA genes, but it also sequences the whole genome of each bacterium. Thus, only by doing metagenomic sequencing, one can get the complete picture. Fifth, the functional studies of the gut microbiota are based on statistical predictions; therefore, further studies using germ-free animal models and related functional studies are required to investigate

the specific roles of the gut microbiota in CHB. Furthermore, the IT phase is an important phase that needs more attention.

CONCLUSION

These findings provide observational evidence of compositional alterations of the gut microbiome and some related metabolites in patients with IT-phase or IA-phase HBV infection. Further studies should investigate whether microbiota modulation can facilitate the progression of CHB and the cause-effect relationship between the gut microbiota and CHB.

ARTICLE HIGHLIGHTS

Research background

Chronic hepatitis B virus (HBV) infection (CHB) represents a public health problem that may progress to cirrhosis and hepatocellular carcinoma (HCC). HBV-infected individuals in immune tolerance (IT) are generally not recommended for anti-HBV treatment, owing to the absence of curative treatment and the evidence of a low risk of progressive liver injury in the IT patients. However, recent studies indicated hepatocarcinogenesis may occur in IT-phase patients; the body's IT status is a key factor affecting the outcome of the disease. Therefore, finding out the factors that affect the prognosis of HBV infection is of paramount significance for the rapid elimination of virus and the reduction of CHB.

Research motivation

The bacterial diversity level and composition varied between CHB, hepatitis B-related liver cirrhosis, and HCC. Gut microbiota of healthy controls is more consistent, whereas those of CHB, hepatitis B-related liver cirrhosis and HCC varied substantially. As the first phase of HBV progression, IT phase provides a favorable immune environment for HBV invasion and long-term existence, then transitions to immune clearance in the third decade. Therefore, in-depth study of the disease status and changes in the body during the IT phase is conducive to the development of new antiviral treatment methods to break the IT of the body and improve the antiviral efficacy and thus improve the long-term prognosis.

Research objectives

This study aimed to find some potential bacteria, linking different pathological mechanisms of IT phase HBV infection and some related metabolites to the IT phase of CHB infection.

Research methods

Clinical fecal samples from healthy individuals and patients in the IT and IA phases of HBV infection were collected. Next, non-target metabolomics, bioinformatics, and 16S rDNA sequencing analyses were performed.

Research results

A total of 293 different metabolites in 14 phyla, 22 classes, 29 orders, 51 families, and 190 genera were identified. The four phyla of *Firmicutes*, *Bacteroidetes*, *Actinobacteria*, and *Proteobacteria* were the most abundant, accounting for 99.72%, 99.79%, and 99.55% in the healthy controls, IT-phase patients, and IA-phase patients, respectively. We further identified 16 genera with different richness in the IT phase and IA phase of HBV infection. Of the 134 named metabolites, 57 were upregulated and 77 were downregulated. A total of 101 different metabolic functions were predicted in this study, with 6 metabolic pathways having the highest enrichments, namely carbohydrate metabolism (14.85%), amino acid metabolism (12.87%), lipid metabolism (11.88%), metabolism of cofactors and vitamins (11.88%), xenobiotic biodegradation (9.9%), and metabolism of terpenoids and polyketides (7.92%).

Research conclusions

The composition of the gut microbiota changed in the early stages of HBV infection, and changes in the composition of the gut microbiota can significantly alter gene function, which may have a potential role in HBV-infected patients.

Research perspectives

It is relatively difficult to fully understand the causal relationship between gut microbiota and HBV-induced chronic liver disease at different stages in this real-world cross-sectional study. Nevertheless, it should be noted that germ-free animals are good models to study the effect of gut microbiota on human diseases. In a future study, it is imperative to use germ-free animal models and additional biofunctional assays to reveal the cause-effect relationship between gut microbiota and chronic HBV infection.

Abstract

BACKGROUND

Acute pancreatitis (AP) is an inflammatory disorder of the pancreas with an unpredictable course of illness. A major challenge of AP is the early identification of patients at high-risk for organ failure and death. However, scoring systems are complicated and time consuming, and the predictive values for the clinical course are vague.

AIM

To determine whether the dynamic changes in presepsin levels can be used to evaluate the severity of disease and outcome of AP.

METHODS

In this multicentric cohort study, 133 patients with AP were included. Clinical severity was dynamically evaluated using the 2012 revised Atlanta Classification. Blood presepsin levels were measured at days 1, 3, 5 and 7 after admission by chemiluminescent enzyme immunoassay.

RESULTS

The median concentration of presepsin increased and the clearance rate of presepsin decreased with disease severity and organ failure in AP patients. The presepsin levels on days 3, 5 and 7 were independent predictors of moderately severe and severe AP with time-specific area under the curve (AUC) values of 0.827, 0.848 and 0.867, respectively. The presepsin levels positively correlated with bedside index of severity in AP, Ranson, acute physiology and chronic health evaluation II, computed tomography severity index and Marshall scores. Presepsin levels on days 3, 5 and 7 were independent predictors of 28-d mortality of

AP patients with AUC values of 0.781, 0.846 and 0.843, respectively.

CONCLUSION
Blood presepsin levels within 7 d of admission were associated with and may be useful to dynamically predict the severity of disease course and 28-d mortality in AP patients.

Key Words: Presepsin; Acute pancreatitis; Severity; Mortality; Disease severity

Core Tip: Acute pancreatitis has diverse clinical manifestations with an unpredictable clinical course. A major challenge of acute pancreatitis is the early identification of patients at high-risk for organ failure and death. Scoring systems are complicated and time consuming with limited predictive value for the clinical course. In this study, we investigated the association between the dynamic levels of blood presepsin, a new infection biomarker, and the changes of severity in the early course of acute pancreatitis. We found the predictive value of presepsin for 28-d mortality was similar to the bedside index of severity in acute pancreatitis, Ranson and acute physiology and chronic health evaluation II scores.

INTRODUCTION

Acute pancreatitis (AP) is an inflammatory disorder of the pancreas that can lead to systemic inflammatory response syndrome, organ failure and sepsis. AP is one of the most common causes of abdominal emergencies and is associated with mortality rates up to 35%[1,2]. Gallstones and alcohol consumption are the most frequent causes of AP. Irrespective of the etiology, AP has diverse clinical manifestations with an unpredictable clinical course. Various clinical scoring systems such as the bedside index of severity in acute pancreatitis (BISAP) score, Ranson criteria, computed tomography severity index (CTSI) and acute physiology and chronic health evaluation (APACHE) II scores have been developed to predict the illness severity at admission[3]. However, accurate prediction of the clinical course remains difficult[4]. A major challenge of AP is the early identification of patients at high risk for organ failure and death. Moreover, some of these scoring systems are complicated and time consuming with limited predictive value for the clinical course. Therefore, it is necessary to develop simple and convenient biomarkers to dynamically predict the severity of AP in its early course.

Presepsin is a subtype of soluble CD14 formed by a 13 kDa fragment and is an emerging biomarker of infection[5]. CD14 is a glycoprotein receptor for lipopolysaccharide. After lipopolysaccharide binds to CD14, presepsin is released into the blood and cleared by the kidney[6]. Presepsin has been confirmed to predict illness severity[7], number of organs experiencing dysfunction[8] and septic 90-d death rates [9,10]. This study aimed to assess the predictive value of blood presepsin levels for the severity of disease course and outcomes in patients with AP.

MATERIALS AND METHODS

Study population

This prospective, multicentric, and observational cohort study was conducted at the Emergency Departments of Beijing Friendship Hospital and Beijing Chaoyang Hospital affiliated with Capital Medical University. This study was approved by the Beijing Friendship Hospital Ethics Committee (Approval No. 2017-P2-103-02). Written informed consent was obtained from patients or their relatives. Patients diagnosed with AP as per the 2012 revised Atlanta Classification[11] were screened within 24 h of admission and followed up for 28 d. Patients were classified into one of three groups (mild, moderately severe and severe AP) based on the hospital course. Patients with mild AP had neither local complications nor organ failure. Patients with moderately severe AP had transient (< 48 h) organ failure or local complications or both, whereas patients with severe AP had persistent (> 48 h) organ failure. Organ failure was defined as a Marshall score > 2[11]. Patients were subsequently divided into one of

two groups [mild and non-mild (moderately severe and severe) AP] based on their presentation during the first, third, 5th and 7th day of admission. Pregnant women and patients younger than 18 years of age were excluded. All patients received standardized treatment according to the 2012 revised Atlanta Classification[11].

Data collection

The collected data included age, sex, comorbidities, etiologies, scoring, pancreatic imaging and interventions. Abdominal ultrasonography at admission and abdominal computed tomography scans 72 h after symptom onset were performed. The BISAP score, Ranson score, CTSI, APACHE II score, Marshall score and severity of AP were determined at 1, 3, 5 and 7 d post-admission. BISAP and APACHE II scores were evaluated within 24 h. The Ranson score was calculated within 48 h. Levels of the conventional inflammatory biomarkers procalcitonin and C-reactive protein were obtained from the clinical laboratory data. AP patients were classified into survival and non-survival groups based on their 28-d survival.

Determination of blood presepsin concentration

Venous blood samples were collected in tubes containing heparin at days 1, 3, 5 and 7 after admission and stored at 4 °C for analysis within 24 h. Presepsin concentration in the blood was measured using a chemiluminescent enzyme immunoassay[12] with a compact automated immunoanalyzer (PATHFAST; Mitsubishi Chemical Medience Corporation, Tokyo, Japan). The lower and upper detection limits of presepsin concentrations were 20 pg/mL and 200000 pg/mL, respectively.

Statistical analysis

All analyses were performed using SPSS version 25.0 (SPSS, Chicago, IL, United States). With a two-sided $\alpha = 0.05$, a $\beta = 0.2$ and 70% of patients with mild pancreatitis[13], it was determined that 106 patients were required for enrollment, 74 with mild pancreatitis and 32 with non-mild pancreatitis. This study enrolled 137 patients to account for 20% of patients lost to follow-up. The clearance ratio of presepsin was calculated using the following formula: the presepsin level on day 1 minus the presepsin level on days 3, 5 or 7, divided by the presepsin level on day 1 and multiplied by 100%. Data with normal distribution were expressed as mean ± SD and were analyzed by Student's *t* test or variance analysis. Data with non-normal distribution were expressed as the median with quartiles and were analyzed by the Mann-Whitney *U* or Kruskal-Wallis tests. The χ^2 test or Fisher's exact test was used for comparison of frequencies. A receiver operating characteristic (ROC) curve was constructed to assess the predictive value of presepsin for moderate/severe AP and 28-d mortality. Prognostic parameters including sensitivity, specificity, positive predictive value and negative predictive value were calculated based on ROC curve analysis. The areas under the ROC curves (AUCs) were compared by MedCalc version 11.4 (MedCalc Software, Ostend, Belgium). The correlation was analyzed by Spearman rank correlation. Binary logistic regression analyses were used to determine the independent predictors for disease severity and 28-d mortality of AP patients. Cox proportional hazards regression model was used to estimate the independent contribution of presepsin for the prediction of 28-d mortality. All statistical tests were two-tailed, and a P value < 0.05 was considered statistically significant.

RESULTS

Patient characteristics

A total of 137 patients were screened in the emergency departments of the two hospitals from January 2018 to September 2019. Of these, 4 patients were excluded from analysis: 1 patient was diagnosed with pancreatic cancer, and 3 patients were lost to follow-up. Thus, 133 patients were enrolled and classified throughout the course of the disease as mild AP (n = 95 patients), moderately severe AP (n = 21 patients) and severe AP (n = 17 patients) according to the Atlanta 2012 classification. Patient characteristics are described in Table 1. The median age of patients was 65 years. There were 86 males and 47 females. The etiologies of AP included gallstones (63.2%), hypertriglyceridemia (9.0%), post-endoscopic retrograde cholangiopancreatography (11.3%), idiopathic (13.5%) and alcohol (3.0%). The BISAP, Ranson, CTSI and APACHE II scores increased with the severity of disease (all P < 0.01). The incidence of organ failure, mortality and the cost of hospitalization increased with the severity of disease (all P < 0.001).

The role of serial blood presepsin concentration in predicting severity of AP

Compared to patients with mild or moderately severe AP, the presepsin concentration at days 3 and 5 were significantly higher in patients with severe AP (Figure 1A). Compared with the mild group, the presepsin concentration in the moderately severe group at days 5 and 7 and in the severe group at day 7 were significantly higher (Figure 1A). The median clearance rate of presepsin on days 3 and 5 in moderately severe and severe patients were reduced compared to patients in the mild group (Figure 1B).

Data are presented as mean ± SD, *n* (%), or median (25^{th}-75^{th} percentile). CHF: Chronic heart failure; COPD: Chronic obstructive pulmonary disease; BISAP: Bedside index of severity in acute pancreatitis; CTSI: Computed tomography severity index; APACHE: Acute physiology and chronic health evaluation; CRRT: Continuous renal replacement therapy; ERCP: Endoscopic retrograde cholangiopancreatography.

Moreover, presepsin concentration remained significantly higher in the non-mild group compared to the mild group at days 3, 5 and 7 (Figure 1C). The concentrations of presepsin through the 7 d increased progressively with the number of organs failing as defined by the Marshall score (Figure 1D).

Independent predictors of severity of AP

Compared to the mild group, the proportion of patients with biliary etiology in the non-mild group was significantly less (69.4% *vs* 45.7%; $P = 0.013$) and those with idiopathic AP was significantly higher (6.1% *vs* 34.3%; $P < 0.001$). The median presepsin concentration on day 1 in patients with biliary AP was higher compared to those with other etiologies [1154.00 (728.75-2108.50) *vs* 749.00 (474.00-1174.00); $P = 0.001$]. The presepsin concentration on day 1 and etiology were independent predictive factors for non-mild AP on day 1 (Table 2). The presepsin concentrations on days 3, 5 and 7, but not etiology, were

Table 2 Independent factors for time-specific prediction of non-mild (moderately severe and severe) acute pancreatitis

Variable	β	Standard error	Wald statistic	Degrees of freedom	*P* value	Odds ratio	95%CI	
							Lower limit	Upper limit
Non-mild AP day 1								
Etiology	0.456	0.133	11.707	1	0.001	1.578	1.215	2.050
Presepsin day 1	0.000	0.000	5.872	1	0.015	1.001	1.000	1.001
Non-mild AP day 3

AP: Acute pancreatitis.

independent predictive factors for non-mild AP on days 3, 5 and 7, respectively (Table 2). Presepsin concentration showed time-specific AUCs of 0.827, 0.848 and 0.867 on days 3, 5 and 7, respectively, in predicting moderately severe and severe AP (Table 3).

Correlation of presepsin concentration with scoring systems and other biomarkers

The Spearman correlation analysis revealed that the presepsin levels through day 7 in AP patients positively correlated with BISAP and Ranson scores (all $P < 0.05$, Figure 2). Positive correlations were also observed between the presepsin concentration on days 5 and 7 with the APACHE II scores. Presepsin levels at days 3, 5 and 7 also positively correlated with CTSI and Marshall scores (all $P < 0.05$, Figure 2). There was a positive correlation between presepsin and procalcitonin levels on days 1 and 3 and between presepsin and C-reactive protein levels on days 3 and 7 (Table 4).

Dynamic changes in presepsin concentrations and clearance rates in survivors and non-survivors

Presepsin levels decreased persistently through the first 7 d after admission in survivors but tended to decrease on day 3 and then increase on day 5 in non-survivors. The presepsin concentration in non-survivors on days 3, 5 and 7 were significantly higher when compared with survivors (Figure 3A). Moreover, the median clearance rate of presepsin on day 3 in the survivors was higher than that in the non-survivors (Figure 3B; $P < 0.01$).

Presepsin concentration for predicting 28-d mortality in patients with AP

The clinical characteristics between survival and non-survival groups are presented in Table 5. The binary logistic regression analysis showed that the presepsin levels on days 3, 5 and 7 and the BISAP, Ranson and APACHE II scores were independent predictors of 28-d mortality in patients with AP (Table 6). The AUC of presepsin for predicting 28-d mortality in AP patients was 0.781 on day 3, 0.846 on day 5 and 0.843 on day 7, which were slightly lower compared to APACHE II (0.955; all $P > 0.05$) and Ranson (0.900; all $P > 0.05$) scores but similar to BISAP (0.811; all $P > 0.05$) scores (Figure 4). The optimal prognostic cutoff values for predicting 28-d mortality on days 3, 5 and 7 were 681.5 pg/mL, 613 pg/mL and 770 pg/mL of presepsin, respectively.

Using the cutoff values determined by ROC curves, the Cox proportional hazards regression model was adjusted for age, sex and etiology to analyze the 28-d survival curves of patients (Figure 5). The hazard ratio (HR) of presepsin at day 3 was 9.475 (95%CI: 1.133-79.226; $P = 0.038$), the HR of presepsin at day 5 was 11.191 (95%CI: 1.297-96.518; $P = 0.028$), and the HR of presepsin at day 7 was 16.495 (95%CI: 2.759-98.615; $P = 0.002$).

Table 3 Time-specific area under the receiver operating characteristic curve of presepsin for prediction of moderately severe and severe acute pancreatitis

Time point	Cutoff (pg/mL)	Sensitivity	Specificity	PPV	NPV	AUROC (95%CI)	*P* value
Day 3	657.5	92.9%	71.4%	76.5%	90.9%	0.827 (0.730-0.923)	< 0.001
Day 5	593.5	84.6%	80.4%	81.2%	83.9%	0.848 (0.751-0.945)	< 0.001
Day 7	601.5	72.7%	89.8%	87.7%	76.7%	0.867 (0.756-0.977)	< 0.001

AUROC: Area under the receiver operating characteristic curve; NPV: Negative predictive value; PPV: Positive predictive value.

Table 4 Correlation between presepsin and procalcitonin or C-reactive protein levels

Variables	Procalcitonin	C-reactive protein
Presepsin day 1	$r = 0.464$	$r = 0.179$
	$P < 0.001$	$P = 0.080$
Presepsin day 3	$r = 0.318$	$r = 0.254$

DISCUSSION

The current findings demonstrated that blood presepsin levels correlated with the severity of AP, and the clearance rate of presepsin was lower in patients with moderately severe or severe AP compared to patients with mild AP. Furthermore, the presepsin levels on days 1, 3, 5 and 7 during the hospital stay independently predicted the severity of AP. High levels of presepsin through the first 7 d after admission were associated with organ failure. It was also found that presepsin positively correlated with the BISAP, Ranson, CTSI, APACHE II, and Marshall scores as well as conventional biomarkers such as procalcitonin and C-reactive protein. Dynamic changes in the concentration of presepsin can be used for ongoing risk stratification of disease course and prediction of 28-d mortality in AP patients. Both presepsin and the clearance rate of presepsin on day 3 may be used as early biomarkers to predict the severity and prognosis of AP.

Recently, the blood presepsin concentration has been shown to be an early biomarker of various infections[14,15] as well as a valuable biomarker for diagnosing the occurrence[16], severity[17] or prognosis[7] of sepsis. Presepsin levels were shown to have good diagnostic and prognostic value for bacterial community-acquired pneumonia (CAP) and intensive care unit (ICU) mortality[18]. Similarly, our previous study showed that presepsin could predict acute respiratory distress syndrome, severe CAP, and 28-d mortality[19]. Recently, Yao *et al*[20] found that presepsin has a better predictive ability than existing biomarkers for bacterial infection following major hepato-biliary-pancreatic surgery. The study of Hiraki *et al*[21] showed that a higher concentration of presepsin in the drainage fluid was an independent predictive marker for clinically relevant postoperative pancreatic fistula after pancreaticoduodenectomy.

For noninfectious diseases, presepsin correlates with the disease activity of autoimmune diseases, such as systemic lupus erythematosus[22]. Higher presepsin levels are associated with renal and liver dysfunction[10]. Presepsin is a 13 kDa peptide that may be cleared by the kidney[6]. Presepsin levels have been shown to increase as the glomerular filtration rate (GFR) decreases and are markedly high in patients with chronic renal failure or receiving hemodialysis[23]. Presepsin concentrations correlate with serum creatinine and GFR levels in patients with chronic kidney disease[24]. Recently, presepsin was found to be a predictor of acute kidney injury and initiation of renal replacement therapy in sepsis patients[25]. Masson *et al*[10] found that presepsin levels are significantly higher in septic patients with shock than those without shock. A gender- and age-matched study on patients with severe AP and healthy volunteers showed that presepsin was an independent predictor of local complications, organ failure and in-hospital mortality[26].

In this study, we observed the dynamic changes of plasma presepsin levels and clearance rate of presepsin with time in patients with mild, moderate and severe AP and found that the presepsin

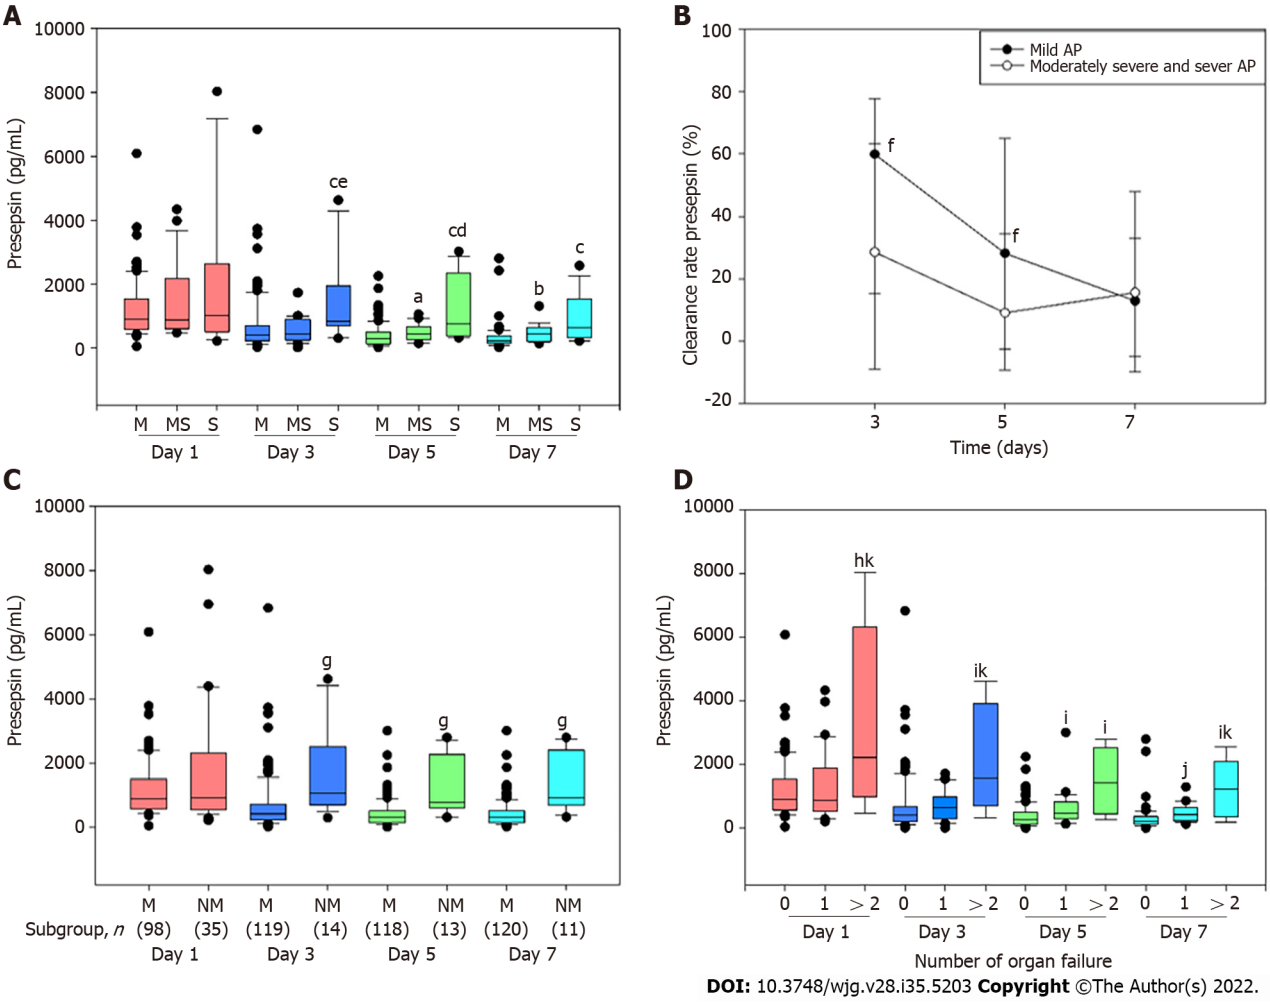
Data are presented as *n* (%), or median (25^{th}-75^{th} percentile). CHF: Chronic heart failure; COPD: Chronic obstructive pulmonary disease; ERCP: Endoscopic retrograde cholangiopancreatography; BISAP: Bedside index of severity in acute pancreatitis; CTSI: Computed tomography severity index; APACHE: Acute physiology and chronic health evaluation; CRRT: Continuous renal replacement therapy.



concentrations on days 3, 5 and 7 (but not day 1) increased with the severity of AP. A high presepsin value and low clearance rate of presepsin at day 3 were found to be more valuable in early identification of mild or moderate *vs* severe compared to mild *vs* moderate disease. Inconsistently, the concentrations of presepsin on day 1 through 7 increased significantly with the number of organs experiencing failure.

In most high-income countries, gallstones (45%) and alcohol abuse (20%) are the most frequent causes of AP[27]. In the current study, gallstones (63.2%), but not alcohol (3.0%), was the most common etiology of AP, which is consistent with the conclusion of an 8-year Chinese study by Zhu *et al*[28]. Upon multivariate analysis, after adjusting for the confounding factor of etiology, it was found that presepsin levels were independent predictors for the severity of AP on days 1, 3, 5 and 7. In this study, the proportion of patients with biliary etiology were significantly less, and those with idiopathic AP were significantly higher in the moderately severe or severe AP group compared to the mild AP group. It was shown that the presepsin values on day 1, but not on days 3, 5 or 7, were higher in patients with biliary AP than in other etiologies, which is in line with the procalcitonin values of the study of Modrau

Table 6 Independent factors for the prediction of 28-d mortality in patients with acute pancreatitis

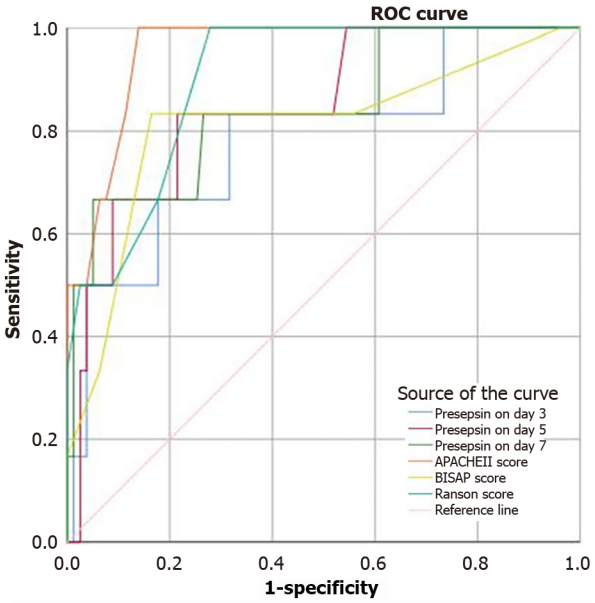

Figure 2 Correlation between presepsin and bedside index of severity in acute pancreatitis, Ranson, acute physiology and chronic health evaluation-II, computed tomography severity index and Marshall scores. BISAP: Bedside index of severity in acute pancreatitis; APACHE: Acute physiology and chronic health evaluation; CTSI: Computed tomography severity index.

Procalcitonin is a sensitive biomarker for the detection of pancreatic infection, and C-reactive protein levels ≥ 150 mg/L at day 3 is a prognostic indicator for severe AP[13]. The current study illustrated that presepsin levels were positively correlated with procalcitonin levels on days 1 and 3 and with C-reactive protein levels on days 3 and 7. There was a positive correlation between the presepsin levels and Marshall scores (including respiratory function, cardiovascular system, renal dysfunction) on days 3, 5 and 7. Meanwhile, the current study found a significant positive correlation between the presepsin levels and other AP scores, such as BISAP, Ranson and APACHE II. In this study, increased presepsin levels were found to be an accurate predictor of disease severity. For the prediction of moderately

severe or severe AP, the AUCs of presepsin on days 3, 5 and 7 were 0.827, 0.848 and 0.867, respectively, with high sensitivity and specificity.

The dynamic changes in presepsin were different in survivors and non-survivors of this study. In survivors, presepsin levels showed a decreasing trend over time but in non-survivors presepsin levels first decreased and then increased. Similar trends in presepsin levels have been reported in patients with severe sepsis[31]. In addition, clearance rates of presepsin in non-survivors were lower than that of survivors in the early stage of AP (day 3). Potential explanations involve a reduced clearance of presepsin due to reduced kidney function[22-24] and circulatory dysfunction[10]. The most common organ systems to fail in non-survivors were circulatory [71.4% (5/7 patients)], respiratory [85.7% (6/7 patients)] and renal [42.8% (3/7 patients)] systems. Studies have showed that higher presepsin levels were associated with ICU death and mortality in sepsis[7], CAP[18], cardiac arrest patients after return of spontaneous circulation[32] and severe AP[25]. Interestingly, the presepsin levels on days 3, 5,and 7 were found to independently predict 28-d mortality in AP.

This study has certain limitations. First, the patient population was heterogeneous. Second, the study did not compare presepsin with other biomarkers. Third, the relevance of presepsin during the latter course of AP was not studied. Fourth, the association between presepsin levels and hepatorenal

Figure 5 Cox regression survival curves. A: Acute pancreatitis (AP) patients with presepsin levels higher than 681.5 pg/mL on day 3 had a lower probability of survival at 28 d compared to patients with lower levels; B and C: Similarly, AP patients with presepsin levels on day 5 (B) and day 7 (C) higher than 613 pg/mL and 770 pg/mL, respectively, had a lower probability of survival at 28 d than patients with lower levels. AP: acute pancreatitis.

function was not evaluated. Future multicentric studies with larger cohorts that consider these factors should be conducted to validate the findings of this study.

CONCLUSION

This cohort study found that blood presepsin levels in the first 7 d after admission could accurately predict the severity of disease course and 28-d mortality in patients with AP and may be a promising prognostic marker.

ARTICLE HIGHLIGHTS

Research background

Acute pancreatitis (AP) is one of the most common causes of abdominal emergencies and is associated with sepsis, organ failure and high mortality rates (up to 35%). AP has diverse clinical manifestations with an unpredictable clinical course. It is necessary to predict the severity of AP rapidly and accurately.

Research motivation

A major challenge in AP is the early identification of patients at high-risk for organ failure and death. However, scoring systems are complicated and time consuming with limited predictive value for the clinical course. Biomarkers are promising for the dynamic prediction of disease severity.

Research objectives

To determine whether the dynamic levels of an emerging biomarker, presepsin, can be used to evaluate the severity of disease course and outcome of AP.

Research methods

In this prospective and multicentric cohort study, 133 patients with AP were included from January 2018 to September 2019. Clinical severity (mild, moderately severe and severe AP) was dynamically evaluated using the 2012 revised Atlanta Classification. Blood presepsin levels were measured at days 1, 3, 5 and 7 after admission by chemiluminescent enzyme immunoassay. The patients were followed up for 28 d.

Research results

The median concentration of presepsin increased, and the clearance rate of presepsin decreased with disease severity and organ failure in AP patients. The presepsin levels on days 3, 5 and 7 were independent predictors of moderately severe and severe AP with time-specific area under the curve (AUC) values of 0.827, 0.848 and 0.867, respectively. The presepsin levels positively correlated with bedside index of severity in acute pancreatitis, Ranson, acute physiology and chronic health evaluation-II, computed tomography severity index and Marshall scores and conventional biomarkers such as procalcitonin and C-reactive protein. Presepsin levels on days 3, 5 and 7 were independent predictors of 28-d mortality of AP patients with AUC values of 0.781, 0.846 and 0.843, respectively.

Research conclusions

The blood presepsin levels within 7 d of admission were associated with and may be useful to dynamically predict the severity of disease course and 28-d mortality in AP patients. Both presepsin and clearance rate of presepsin on day 3 may be used as early biomarkers to predict the severity and prognosis of AP.

Research perspectives

Prospective cohort studies report the predictive value of presepsin in the severity of AP. Future research should focus on the guiding significance of presepsin in the treatment of AP, such as antibiotic use.

ACKNOWLEDGEMENTS

We thank Drs. Jian-Dong Zhang, Jie Yang, Shuai Xia, Mei-Ying Zhang, Si-Jia Wang and Zheng Wang for collecting cases. We also thank Dr. Shan-Shan Wu for statistical analyses. We also gratefully acknowledge all health care workers on the front line and all patients involved in the study.

Abstract

BACKGROUND

Chronic hepatitis B virus (HBV) and hepatitis C virus (HCV) infections are known risk factors for liver disease, cirrhosis and hepatocellular carcinoma (HCC). There is substantial global variation in HBV and HCV prevalence resulting in variations in cirrhosis and HCC. We previously reported high prevalence of HBV and HCV infections in Somali immigrants seen at an academic medical center in Minnesota.

AIM

To determine the prevalence of chronic viral hepatitis in Somali immigrants in Minnesota through a community-based screening program.

METHODS

We conducted a prospective community-based participatory research study in the Somali community in Minnesota in partnership with community advisory boards, community clinics and local mosques between November 2010 and December 2015 (data was analyzed in 2020). Serum was tested for hepatitis B surface antigen, hepatitis B core antibody, hepatitis B surface antibody and anti-HCV antibody.

RESULTS

Of 779 participants, 15.4% tested positive for chronic HBV infection, 50.2% for prior exposure to HBV and 7.6% for chronic HCV infection. Calculated age-adjusted frequencies in males and females for chronic HBV were 12.5% and 11.6%; for prior exposure to HBV were 44.8% and 41.3%; and for chronic HCV were 6.7% and 5.7%, respectively. Seven participants developed incident HCC during follow up.

CONCLUSION

Chronic HBV and HCV are major risk factors for liver disease and HCC among Somali immigrants, with prevalence of both infections substantially higher than in the general United States population. Community-based screening is essential for identifying and providing health education and linkage to care for diagnosed patients.

Key Words: Viral hepatitis; Liver disease; Community engagement; African; Immigrant health

Core Tip: This prospective community-based study evaluated the prevalence of chronic hepatitis B and C among the immigrant Somali community. Through community partnerships we were able to demonstrate a framework that can be used with other immigrant and/or minority communities at-risk for infectious diseases such as hepatitis B and C.

INTRODUCTION

Globally, liver cancer ranks 6th in cancer incidence and 4th in cancer mortality[1]. For many years, chronic hepatitis C virus (HCV) infection has been the most common risk factor for hepatocellular carcinoma (HCC) in the United States[2-6]. There is a high prevalence of chronic viral hepatitis in Asia and sub-Saharan Africa[7-11]. Partly due to immigration from high-prevalence countries in Africa and Asia,

hepatitis B virus (HBV) infection remains an important risk factor in the United States[12-15]. Consequently, HCC disproportionately affects individuals of African and Asian ancestry and Hispanic ethnicity[16,17]. Africa has the youngest median [interquartile range (IQR); range] age at HCC diagnosis worldwide [45 (35-57; 8-95)], increasing the burden of years of life lost from chronic viral hepatitis.

Minnesota's foreign-born population constitutes approximately 9% of the state population[18]. From 2008 to 2017, the Minnesota Department of Health reported an age-adjusted incidence rate of liver cancer of 22.4 per 100000 person-years among Black Minnesotans, a 4.3-fold higher rate than the rate of 5.2 per 100000 person-years among white, non-Hispanic Minnesotans[19]. A substantial proportion of Minnesota's Black population are recent African immigrants[18,20-22]. However, due to a general lack of awareness of viral hepatitis, Minnesota's most recent immigrants from Somalia have limited appreciation of their risk from chronic viral hepatitis and its associated complications[23].

To date, few studies have focused on chronic HBV and HCV infection and their sequelae among recent African immigrants to the United States. There is no population-based study of the rates of HBV and HCV infections among Somalis[20,24-28]. We previously conducted a clinic/hospital-based retrospective study of the rates of HBV and/or HCV infections in Somalis seen at Mayo Clinic from July 1996 to October 2009[29]. We found higher frequencies of chronic HBV (13.6%), prior exposure to HBV (55.5%), and chronic HCV (9.1%) in Somali Americans compared to 1.2%, 10.9%, and 2.2% respectively in non-Somali residents of Olmsted County (of whom 90% have European ancestry). Of 30 Somali HCC patients seen, 22 of 29 with available results (76%) were anti-HCV positive, while 5 of 28 with available results (18%) were hepatitis B surface antigen (HBsAg) positive. These results showed high rates of chronic HBV and HCV and revealed that HCV was a primary risk factor for HCC in Somalis[29]. Since clinic/hospital-based studies may overestimate true community disease prevalence, we tested for HBV and HCV in community-resident Somalis through a community-wide screening program.

MATERIALS AND METHODS

Study design

We performed a cross-sectional, community-wide screening study of Somali immigrant adults. Between November 2010 and December 2015, we used a community-based engagement research framework to offer free HBV and HCV screening to Somali immigrant adults living in Minnesota. Eligible individuals who self-identified as: (1) Of Somali descent; (2) ≥ 18 years of age; and (3) Resident in Minnesota received free HBV and HCV serological screening. Screening was provided for both foreign-born and United States-born participants. Study recruitment was carried out in the community. We partnered with three community-based health clinics with large Somali clienteles and faith-based establishments and charter schools, to which participants could come for enrollment and blood draws. In partnership with the Somali Health Advisory Committee (SHAC), a community advisory board based in Rochester and Minneapolis/St Paul, the research team provided educational seminars on viral hepatitis screening and liver disease. In addition, members of SHAC facilitated recruitment through word-of-mouth, advertisements, educational sessions and booths at various community events and health fairs in cities across Minnesota.

Study population

Individuals of Somali heritage who were at least 18 years of age were recruited to participate in the study. Participants provided written informed consent. At the completion of the study, participants received a $20 gift check (remuneration) mailed to their home address. Screening occurred at: (1) The Mayo Clinic Clinical Research and Trials Unit; (2) Community-based clinics; (3) A community-based health center; (4) Religious establishments (*i.e.* mosques); (5) Charter schools; or (6) At various community health-fairs. The study team consented and screened 779 participants aged 18 years to 91 years, of whom 49.9% (389) were male.

Ethical approval

The Mayo Clinic Institutional Review Board approved the study and study related materials including flyers and weekly community outreach program documentation. Study team members conducted outreach field recruitment to inform potential participants about the study in both English and Somali.

Serological tests

Blood samples were processed, stored at -80 °C, and tested for HBsAg, hepatitis B core antibody (HBcAb), hepatitis B surface antibody (HBsAb) and anti-HCV at the Mayo Clinic Department of Laboratory Medicine and Pathology. Participants were administered surveys either in English or in Somali, assessing their age, sex, country of birth, cultural practices and immigration patterns. The screening results were organized into 5 groups depending on the serological test results (Table 1). The first 4 groups defined the hepatitis B infection status, while the fifth reported hepatitis C antibody status. The chronic HBV infected group was defined as those who tested HBsAg positive, HBsAb

Table 1 Antibody and antigen biomarkers for hepatitis B and hepatitis C infections

	Chronic HBV	Resolved HBV	HBV vaccinated	HBV Susceptible	Chronic HCV
HBsAg	Pos	Neg	Neg	Neg	Pos/neg
HBcAb	Pos	Pos	Neg	Neg	Pos/neg
HBsAb	Neg	Pos/indeter/neg	Pos	Neg/indeter	Pos/neg
Anti-HCV	Neg/pos	Neg/pos	Neg/pos	Neg/pos	Pos

HBcAb: Hepatitis B core antibody; HBsAg: Hepatitis B surface antigen; HBsAb: Hepatitis B surface antibody; HBV: Hepatitis B virus; HCV: Hepatitis C virus; Indeter: Indeterminate; Neg: Negative; Pos: Positive.

negative, and HBcAb positive, regardless of anti-HCV status. The resolved HBV group, immune due to exposure to the live virus, was defined as participants who tested HBsAg negative, HBsAb positive and HBcAb positive, regardless of anti-HCV status. Combining the chronic HBV-infected group with the resolved HBV group gives the total number of persons exposed to live HBV infection. The vaccinated group was defined as those who tested HBsAg negative, HBsAb positive, and HBcAb negative, regardless of anti-HCV status. The HBV susceptible group was defined as those who tested HBsAg negative, HBsAb negative and HBcAb negative, regardless of anti-HCV status. Lastly, the chronic HCV infected group was defined as anyone who tested anti-HCV positive, regardless of HBsAg, HBcAb, or HBsAb status. We have previously shown that 93% of anti-HCV antibody-positive individuals in the Somali community also had measurable HCV RNA; thus, the rate of false positive anti-HCV antibody testing in this population is low[29]. Referrals for follow-up testing, health education, counseling, vaccination and treatment were provided to participants depending on their results.

Statistical methods

Descriptive statistics were computed to describe the study population. JMP (v.10; SAS Institute Inc., Cary, NC) was used for statistical analyses. Adjusted frequencies for viral hepatitis infection statuses were standardized using the 2010 United States Census and were stratified based on age and sex[30].

RESULTS

Characteristics of the study population

The study team consented and screened 779 participants aged 18 years to 91 years, of whom 49.9% (389) were male. This number represents 2.3% or 1 in 43 of the estimated 33208 Somalis aged 18 years to 84 years resident in Minnesota between 2013 and 2017[31]. The age distribution of the participants and the primary summary of rates are presented in Table 2.

Proportion of patients with HBV and HCV infections

The crude rates for each age and sex group are shown in Table 2, along with the age-adjusted rate for each group. Of the 779 Somali participants screened, 120 (15.4%) had chronic HBV (HBsAg+, HBcAb+, HBsAb-), and 271 (34.8%) were immune due to prior HBV infection (HBcAb+, HBsAg-, HBsAb+). In addition, a small subset of the patients had HBV and HCV co-infection (n = 5). The crude rates showed that, as is typical for HBV infection in Africa, many participants tested positive for chronic HBV infection by the age of 20. However, the converse was true for HCV, with most positive individuals being over 50 years. The age-adjusted rates for persons with chronic HBV were 12.5% and 11.6% for males and females, respectively. The age-adjusted rates for persons with resolved HBV, characteristic of prior exposure to HBV infection with spontaneous clearance, were 32.3% and 29.7% for males and females, respectively. For prior HBV exposure resulting in either chronic infection or spontaneous clearance, which measures all previous exposure to infectious HBV, the age-adjusted rates were 44.8% for males and 41.3% for females. Lastly, the age-adjusted positive rates for anti-HCV, the marker for HCV infection, were 6.7% for males and 5.7% for females. Of the 59 anti-HCV positive participants, 29 (49.2%) had follow-up testing for HCV RNA, and 28 (96.6%) of the 29 tested positive. This was consistent with the results of our previous retrospective study, in which 93% of anti-HCV-positive Somalis were HCV RNA positive. The most common HCV genotype was 4 (43%) followed by genotype 3 (14%).

Proportion of patients vaccinated or susceptible to HBV infections

Of the 779 Somali participants, 388 (49.8%) had not previously been exposed to HBV. Of these, 195 (25.0% of the total) tested positive for HBsAb only, consistent with immunity due to HBV vaccination. The remaining 193 (24.8%) tested negative for all HBV markers, indicating susceptibility to HBV

Table 2 Frequency of hepatitis B virus- and hepatitis C virus-positive test results in Community Recruited Minnesota Somali Residents

HBcAb: Hepatitis B core antibody; HBsAg: Hepatitis B surface antigen; HBV: Hepatitis B virus; HCV: Hepatitis C virus.

(Table 3). Remarkably, of the 518 participants from this high prevalence community under age 50, 146 (28.2%) were unvaccinated and susceptible to HBV.

Age and sex group characteristics of HBV and HCV infections

Both age- and sex-specific rates showed differences. The highest proportion of HBsAg in Somalis was observed in females > 70 years of age (34.5%); in males, the highest proportion was in the 51-year-old to 60-year-old age group (24.0%) (Figure 1A). For HBcAb, the highest proportion of positivity for males was in the 61- year-old to 70-year-old age group (57.1%) and for females in the > 70-year-old group (41.4%) (Figure 1B). For anti-HCV, the highest proportion for males was > 70 years of age (39.5%), while the highest proportion for females was in the 61-year-old to 70-year-old age group (25.0%) (Figure 1C).

Follow-up and referral

After completing the serological tests, participants received screening results *via* telephone calls. Participants with positive HBsAg or anti-HCV were referred to their local medical care facility (University of Minnesota Gastroenterology Hepatology and Nutrition or Mayo Clinic Division of Gastroenterology and Hepatology) for subsequent management, surveillance and/or treatment. Participants who were HBsAg negative and anti-HBs negative were referred to their local primary care clinic (Gargar Clinic and Urgent Care or Axis Medical Center) to complete the HBV vaccination series.

Characteristics of participants who developed HCC

After serological tests confirmed positive HBV and/or HCV infection or susceptibility to HBV infection, patients were linked to care for treatment or monitoring of their viral hepatitis, as appropriate, or for HBV vaccination. They were encouraged to notify the study staff if they were diagnosed with advanced liver disease or HCC. Seven individuals were identified by review of the medical records or patient self-report to have HCC in follow-up after testing. Their ages ranged from 43 years to 83 years (mean 69.8 years; IQR 65.8, 76.8). Four were male (57%), and three (43%) were female. The most common etiology was HCV infection (n = 4; 57%); one patient had HBV infection (14%), one had non-alcoholic fatty liver disease without cirrhosis, and one had no known risk factor for HCC. Three of the 4 HCV HCC patients had cirrhosis (Table 4).

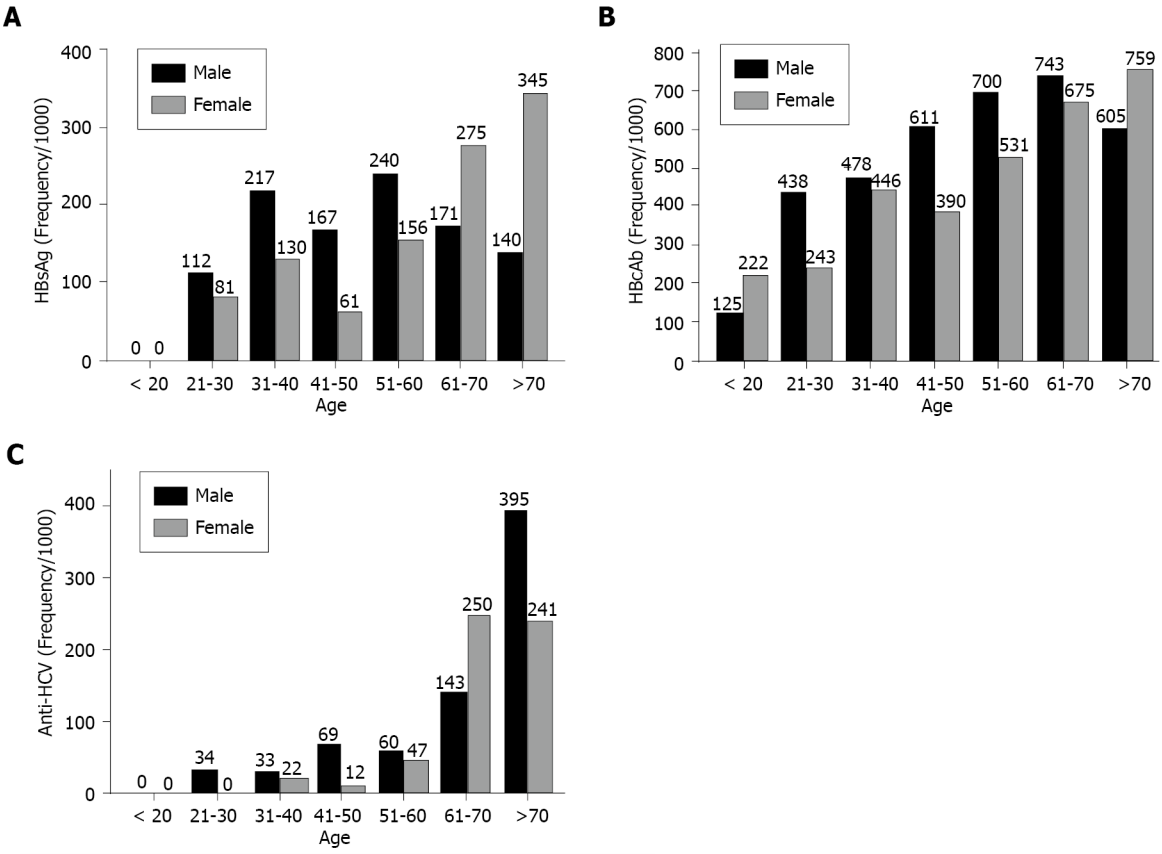
Due to the number of participants lost to follow-up, we do not have complete follow-up of the entire cohort of participants over the period and, therefore, were unable to calculate the exact incidence of HCC in the participants of this screening study. However, comparison to our previous retrospective hospital/clinic-based study, in which we found 30 Somali patients with HCC (2.5%) out of a total of 1218 patients tested for any chronic hepatitis markers, shows a lower incidence of 7 HCC cases (0.9%) of the 779 adults tested in this community-recruited cohort. This is not surprising, since the hospital/clinic-based cohort almost certainly had a selection bias for viral hepatitis or more severe chronic liver disease.

Table 3 Rates of hepatitis B virus vaccination and susceptibility in Community Recruited Minnesota Somali Residents

Age group (yr)	HBV vaccinated		HBV susceptible	
	HBV vaccinated[1]/total males, *n*	HBV vaccinated[1]/total females, *n*	HBV susceptible[2]/total males, *n*	HBV susceptible[2]/total females, *n*
≤ 20	4/8	4/9	3/8	3/9
21-30	27/89	37/74	23/89	19/74
31-40	22/92	23/92	26/92	28/92
41-50	15/72	19/82	13/72	31/82
51-60	8/50	13/64	7/50	17/64
61-70	4/35	5/40	5/35	8/40
> 70	10/43	4/29	7/43	3/29
Total	90/389	105/390	84/389	109/390
Age-adjusted frequency (per 1000 population)	299	305	253	282

[1]Vaccinated: Hepatitis B surface antigen negative; anti-HBc negative; anti-HBs positive.
[2]Susceptible: Hepatitis B surface antigen negative; anti-HBc negative; anti-HBc negative.
HBV: Hepatitis B virus.

Table 4 Characteristics of 7 Somali participants who developed hepatocellular carcinoma



Patient no.	Age	Sex	Etiology	HCV genotype	Cirrhosis	MELD Score	Metastatic HCC	Portal hypertension	Fibrosis staging
1	69	Male	NAFLD	-	No	8	No	No	NR
2	65	Female	HCV	3	Yes	7	No	Yes	NR
3	76	Female	Unknown	-	No	7	No	No	NR
4	75	Male	HCV	4	No	7	Yes	No	2 to 3/4
5	77	Male	HCV	UTG	Yes	11	No	No	4
6	43	Male	HBV	-	No	7	Yes	No	NR
7	83	Female	HCV	UTG	Yes	6	No	No	3 to 4

UTG: Unable to genotype; NR: Not reported; NAFLD: Non-alcoholic fatty liver disease; HCV: Hepatitis C virus; HBV: Hepatitis B virus; MELD: Model for end-stage liver disease; HCC: Hepatocellular carcinoma.

The observed incidence of 7 HCCs in the cohort of 779 adults prospectively tested in this study, albeit with incomplete follow-up over a median of approximately 8 years, is estimated to be 112 per 100000 person-years or 0.11% per year risk of HCC in the entire cohort. This is almost certainly an overestimate as some of the cases may have had unrecognized HCC at the time of initial testing.

DISCUSSION

The primary goal of our study was to examine the prevalence of HBV and HCV viral infections in the immigrant Somali community residing in Minnesota. As a secondary goal, we also ascertained any cases of HCC that developed in study participants by voluntary notification and review of available medical records. This study is the first of its kind to report the results of community-wide screening for HBV and HCV in this immigrant population. We found that 15.4% of participants had chronic HBV infection compared to the estimated United States general population prevalence of 0.4%[32]. HCV prevalence was 7.6%, also significantly higher than the general United States population prevalence of HCV which is less than 2%[33]. In comparison to our previously published results, this prospective study determined that chronic HBV rates are higher than the frequency reported in the 2012 clinic/hospital-based retrospective study[29].

Figure 1 Frequency in Somali Patients Screening. A: Hepatitis B virus (HBV)-positive test results; B: Prior exposure of HBV test results; C: Hepatitis C virus-positive test results. HBcAb: Hepatitis B core antibody; HBsAg: Hepatitis B surface antigen; HCV: Hepatitis C virus.

Somalis in Minnesota are younger than the general population with a median age of 25 years compared to the general population median age of 37 years[34]. Therefore, surveillance for viral hepatitis is important for this community. Given the high prevalence of HBV and HCV infections in Somalia noted in prior studies, a significant number of Somali immigrants are likely to have chronic hepatitis and are at risk for HCC. Yang *et al*[35] reported that African-born individuals diagnosed with HCC in the United States, particularly those of West African ancestry, are diagnosed at a younger age. Most of these individuals have chronic HBV infection, which was acquired in the first few years of life, and it is recommended that HCC surveillance of this group begin at the age of 20 years[5]. The Somali immigrant community may be different; in addition to high rates of chronic HBV infection, there is also a high prevalence of chronic HCV infection, most likely acquired during adulthood. A multi-center, multi-national, retrospective observational cohort study that investigated the current clinical presentation of Africans with HCC showed that in Egypt, where chronic HCV is the major etiology of HCC, the median age of HCC onset was 58 years, compared to 46 years in eight other African countries with a predominance of HBV-induced HCC[6].

While the high level of chronic HBV infection in the immigrant Somali population suggests an elevated risk of maternal-to-child transmission and horizontal transmission of HBV between family members at an early age, it is important to note that about a third of all the individuals we screened had evidence of prior exposure to HBV infection that they had cleared spontaneously. This phenomenon occurs most commonly in adults exposed to HBV infection and suggests substantial transmission of HBV among adolescents and adults in the community. Risk factors associated with these infections need to be identified and addressed. Individuals from areas affected by conflict and displacement are at a greater risk of contracting infectious agents, such as viral hepatitis infections[36]. For instance, Khan *et al* [37] reported that internally displaced individuals have high levels of HBV and HCV infections. This may reflect the lack of basic health infrastructure and services in refugee camps and displaced communities.

Shire *et al*[29] showed an increased frequency of HBV and HCV among Somali patients seen in the hospital/clinic setting, which could potentially have been due to selection bias. However, our community-based screening study of Somali immigrants in Minnesota confirms high rates of chronic HBV and HCV infection rates among this population. The best outcomes for communities with high prevalence of chronic HBV and HCV infections have been shown in Japan and Taiwan, which have

comprehensive programs for screening all adults for chronic viral hepatitis and enrolling those at risk into surveillance programs for HCC. These programs have resulted in ≥ 70% of HCCs being detected at early stages when they are eligible for curative treatment. Consequently, the 5-year survival rate of patients diagnosed with HCC in these countries ranges from 50%-70%, substantially higher than the currently estimated rate of 15% in the United States[38]. Whether HCC surveillance decreases liver disease mortality is still controversial, but almost all international guidelines now recommend surveillance for HCC among high-risk patients using liver ultrasound performed every 6 mo with or without measurement of the serum alpha-fetoprotein[39-45]. There are active efforts underway to develop more sensitive and effective biomarker and imaging technologies for HCC surveillance. We are performing additional studies to assess the stage at diagnosis of HCC in the immigrant Somali community and discern any barriers or disparities in care related to chronic liver disease and HCC.

Furthermore, the observed incidence of 7 HCCs in the cohort of 779 adults prospectively tested in this study is estimated to be 112 per 100000 person-years or 0.11% per year risk of HCC in the entire cohort. This is almost certainly an overestimate as some of the cases may have had unrecognized HCC at the time of initial testing. By comparison, for the time period between 2012 and 2016, the age-standardized rates of liver cancer incidence in Minnesota were 5.7 per 100000 for Non-Hispanic Whites and 24.7 per 100000 for Blacks[46]. Since the total number of Somali adults aged 18-84 in Minnesota, estimated at 33208, represents approximately 23% of the 146020 adults of African descent aged 18-84 who are resident in Minnesota, the Somali immigrant community likely contributes substantially to the overall incidence of HCC in Minnesota[47,48].

The results of this study suggest a need to develop strategies to improve awareness of chronic hepatitis[49], increase screening for chronic HBV and HCV infections in the immigrant Somali community in the United States and promote hepatitis B vaccination in unvaccinated children and adults. These strategies could help prevent chronic liver disease and HCC, increase access to currently available treatments that suppress HBV viral load or cure HCV and substantially reduce the burden of hepatobiliary malignancies observed in Minnesota's non-Hispanic Black population[50-52]. Ahmed Mohammed *et al*[53] reported that visits to gastrointestinal/hepatologist specialists were linked to increased HCC surveillance in Minnesota residents, as compared to primary care practitioner visits. Given the limitations in access to specialist care, efforts to encourage HBV and HCV testing of immigrant Somalis in the primary care setting could improve the early diagnosis of chronic viral hepatitis and appropriate linkage to care.

Limitations

There are several limitations to this study. The first limitation is selection bias and this is due to the nature of the study design. However, through the use of community advisory boards, community-based organizations and clinics, we are confident that our data can be generalizable to the larger Somali community of Minnesota. Second, loss to follow-up was another limitation associated with this study, especially for those individuals who have developed liver cancer and associated co-morbidities. On the contrary, there are several strengths associated with this study. First, the implementation of community-engagement through health education and listening sessions have ensured participants are informed of the goals of the study in a culturally sensitive and responsive framework. Second, building strong partnerships with community-based organizations, charter schools and clinics were instrumental in the success of recruitment and dissemination of information.

CONCLUSION

Chronic HBV and HCV infections are prevalent among Somali immigrants in Minnesota and associated with high rates of HCC. Partnering with community stakeholders helped to improve recruitment rates and to spread awareness of the need for viral hepatitis screening. Community-wide screening is an effective way to identify and provide health education and linkage to care for individuals with or at risk for viral hepatitis. It is important to develop and implement culturally and linguistically acceptable viral hepatitis awareness programs in partnership with communities, in order to promote preventative vaccination, treatment of viral hepatitis and reduction of cancer risk.

ARTICLE HIGHLIGHTS

Research background

Somali immigrants come from regions of the world where viral hepatitis is endemic. Since the start of the Somali civil war in 1991, limited data is available on the impact of viral hepatitis in the community, especially those individuals in the diaspora.

Research motivation

The impetus of this project was communal outcry about community members succumbing to liver disease. In partnership with the community, our research team worked to assess the burden of viral hepatitis in Minnesota. Addressing this pressing communal matter, we were able to connect those who tested positive for hepatitis infections and/or were not vaccinated for hepatitis B virus (HBV) with the needed healthcare.

Research objectives

Our objective was to determine the prevalence of viral hepatitis infections within the community. This is significant because it laid the foundation to start conducting studies on host-viral interactions and the unique development of liver disease among this population. This is relevant to clinical practice because we can use this information to tailor screening practices and treatments for individuals from endemic regions which are historically under studied.

Research methods

In partnership with the community stakeholders, we conducted a prospective study using community-based participatory research from 2010 to 2015. We screened for viral hepatitis infections and reported the results back to the study participant. This is the first study of its kind to screen community based Somali immigrants in Minnesota at a large scale.

Research results

Viral hepatitis infections are a major under recognized disease within the Somali immigrant population. Age-adjusted prevalence rates are high and call for prioritizing responses from health agencies. This data will be used to lobby public health institutions to help address the unique needs of the Minnesota Somali population and for healthcare providers to implement programs to screen community members for both HBV and hepatitis C virus. Furthermore, the follow-up after the patients have enrolled into the study was quite difficult. We should consider effective methods to follow-up patients to assess the potential for development of liver disease sequelae.

Research conclusions

Although there were limitations to the study, we have learned that chronic viral hepatitis infection in the Somali community is high. Effective screening programs need to be implemented in order to prevent suffering and needless death. The use of community-based participatory research was a success and was the first of its kind with this community regarding a disease considered taboo. We will continue this partnership and expand research within this population historically under reported in clinical research.

Research perspectives

We will continue maintaining the partnership and will continue to understand the unique host-viral interactions. We have studies on immunoprofiling as well as examining the influence of the viral genome on liver disease progression. These studies will be used to improve the health of persons from this region of the world.

ACKNOWLEDGEMENTS

The authors would like to thank the study participants and their family members. In addition, the authors would like to thank the community partners who provided their community facilities to recruit, enroll, accrue and disseminate findings (*i.e.* Gargar Urgent Care and Clinic, Axis Medical Center, Masjed Abu Huraira, Masjed Al-Nur, Masjed Abubakr Al-Seddiq, and Mankato Mosque) and the Somali Health Advisory Committee, who ensured that we provided a culturally relevant and responsive manner in our efforts. In addition, the authors would like to thank Dr. Yu Wang, Dr. Chen-Chao Ma, the Mayo Clinic Clinical Trials and Research Unit and Lea Dacy for technical support.

Abstract

It was reported that the urotensin II (U-II) level in inflammatory bowel disease (IBD) patients are significantly higher than in controls. To provide future guidance for the management of cardiovascular risk factors in IBD patients, the sample size of the current study appears to be limited, and more clinical samples to compare U-II levels in IBD patients and controls are needed. This will clarify the possible roles of inflammation factors and related signaling pathways (like EPK1/2, NF-κB and Rho/ROCK) in the pathophysiology of IBD. Therefore, large multicenter studies should be done to confirm the findings and underlying mechanisms in the future.

Key Words: Inflammatory bowel disease; Urotensin II; Inflammatory factors; High sensitivity C reactive peptide

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: An observational report showed that the level of urotensin II (U-II) in inflammatory bowel disease (IBD) patients was significantly increased compared with that in controls. The authors also reported that blood U-II level was positively correlated with high-sensitivity C-reactive protein, and severe endoscopic features of the disease. This study provides us with a new role of U-II in IBD, which warrants larger, multicenter clinical and basic studies to determine the mechanisms by which U-II triggers inflammatory responses and activates signaling pathways (EPK1/2, NF-κB and Rho/ROCK).

TO THE EDITOR

We read the observational study reported by Alicic *et al*[1], who have convincingly shown the role of elevated urotensin II (U-II) level in patients with inflammatory bowel disease (IBD). IBD comprising Crohn's disease (CD) and ulcerative colitis (UC) is a multifactorial condition of relapsing chronic inflammation in the gastrointestinal tract with an unpredictable course[2]. In addition, extraintestinal manifestations of IBD cardiovascular risk factors occur frequently and contribute to morbidity and reduced quality of life[3-5].

U-II is a peptide ligand that acts as a potent vasoconstrictor, which was originally discovered four decades ago. The vasoconstriction activity of U-II is 10-fold more potent than that of endothelin-1[6]. Most studies of U-II have been conducted to understand its role in the development of cardiovascular diseases[7]. A growing number of scholars have recognized the links of U-II levels with malignant lesions associated with the liver, pancreas and gut[8]. Whether U-II participates in the initiation and progress of IBD has always intrigued contemporary gastroenterologists. This observational study reported the potential relationship of U-II and IBD, which provides the field with new knowledge and attracted our attention.

Alicic *et al*[1] compared the blood level of U-II in IBD patients and healthy controls, and investigated the association of U-II levels with the anthropometric, clinical and biochemical parameters. The study included 50 adult patients with prediagnosed IBD (24 with UC and 26 with CD) and 50 healthy, age- and gender-matched controls. IBD patients had significantly higher U-II level than control subjects had. Significant positive correlations between serum U-II level and high-sensitivity C-reactive protein (hsCRP) level, UC Endoscopic Index of Severity and Simple Endoscopic Score for CD were observed. Whether these clinical data imply the involvement of U-II in the inflammatory responses and disease outcomes of IBD patients remains to be confirmed.

The action of U-II is mediated by U-II receptor (UTR). UTR is also called GPR14, which is a G-protein-linked receptor[9]. Both U-II and UTR can be found in various cells of the cardiovascular, pulmonary and central nervous systems, kidneys, and other metabolic organs and tissues. The biding of U-II as a ligand activates UTR, which mobilizes calcium in the cytoplasm, induces proliferation of smooth myocytes, and triggers inflammation[10,11]. As expected, the level of inflammatory factor hsCRP in IBD patients is significantly higher than that in healthy controls.

The study by Alicic *et al*[1] is the first clinical study to investigate blood UII level in both UC and CD patients. However, limitations can be seen, which could bolster the authors' conclusions if resolved: (1) This single center study only had 50 subjects each in the IBD and control groups. If more institutions were included in a multicenter investigation and more patients were recruited, the conclusions would become more convincing and relevant. Therefore, large multicenter studies are anticipated in the future; and (2) the results showed that elevation of blood U-II level was associated with disease development and progression, and attributed to the inflammation mediated by hsCRP. However, the levels of other inflammatory factors were not measured (*e.g.*, interleukin-6, interleukin-8, and tumor necrosis factor-α). Their level and involvement in the elevated U-II concentration and inflammatory responses in those patients should be clarified. Regarding the mechanisms, it is possible that U-II as a ligand activates pathways that stimulate the release of inflammatory effectors, such as the cytokines listed above. These cytokines may potently activate signaling pathways consisting of EPK1/2, NF-κB and Rho/ROCK, which regulate a variety of downstream inflammatory responses[12-14]. Whether those cytokines and U-II act against each other or in concert to form a system influencing the host inflammation status remains to be answered. In the future, gastroenterologists should investigate how U-II interacts with other inflammatory mediators, and how U-II modifies those signaling pathways to potentiate IBD severity in various *in vivo* and *in vitro* systems. In so doing, more results could be collected and analyzed, which are needed to form theoretical and practical evidence to guide prevention and treatment of cardiovascular complications in IBD. Additionally, antagonists to the UTR activation system could also be developed, which may counteract any detrimental effects due to increased level of U-II in patients with IBD.

Abstract

End-stage liver disease is frequently caused by hepatitis B virus (HBV) and alcohol consumption. Notably, the mechanism by which alcohol affects the course of HBV-associated liver disease is unknown, and additional research is needed in this area. A reduced immunological response, oxidative stress, endoplasmic reticulum stress, Golgi apparatus stress, and enhanced HBV replication are a few potential causes.

Key Words: Hepatitis B virus; Alcohol; Hepatocarcinoma; Immunity; Liver disease

©The Author(s) 2022. Published by Baishideng Publishing Group Inc. All rights reserved.

Core Tip: In this letter to the editor, we comment on and discuss the combined effects of alcohol consumption and hepatitis B virus (HBV) infection in the progression of liver diseases. In the worst evolution of end-stage liver pathologies, a concordant clinical relationship between alcohol consumption and HBV infection starts to be revealed. There are many potential causes, but some might include increased viral replication, oxidative stress on cellular organelles, and weakened immune responses. Understanding these precepts will open new avenues in managing and treating these patients.

TO THE EDITOR

We have read with great attention and special interest the review by Ganesan and collaborators entitled "Role of alcohol in the pathogenesis of hepatitis B virus (HBV) infection"[1]. The authors examine the potential mechanisms by which alcohol results in an increased risk of HBV-associated liver disease. HBV infection combined with alcohol usage accelerates the progression of liver damage[2,3], primarily hepatocellular carcinoma, the fifth most common type of cancer. The mechanisms behind these adverse effects of alcohol in HBV-positive patients are unknown. Chronic alcohol consumption changes the architecture of the liver and reduces its functional capability.

The effects of alcohol metabolism on protein function, DNA, immune system changes, and oxidative stress impact both hepatocytes and other liver cells. Because the liver is the central location for the replication of hepatotropic viruses (HCV and HBV), ethanol metabolism is linked to viral hepatitis[4,5].

Regarding the immune system, the early stages of viral infections result in the generation of interferon (IFN) type 1 and the activation of natural killer (NK) cells. IFN type 1 and other antiviral cytokines, which HBV induces, are not particularly efficient. According to various investigations of persistent HBV infection, NK cells exhibit varying alterations in quantity, phenotype, and/or function. HBV-infected hepatocytes are cleared more quickly when activated NK cells are present. However, when chronic infection progresses, the tolerogenic actions of liver ligands and cytokines can inhibit both NK and T cells, limiting their antiviral activity[6,7]. According to reports, alcohol has an impact on NK cell antiviral activity during acute HBV infection[8].

The large, medium, and small forms of HBsAg, as well as the hepatitis B virus core antigen (HBcAg) and hepatitis B e antigen (HBeAg), can all be targeted by polyclonal antibodies produced by B cells in chronic HBV-infected patients[9]. During acute HBV infection, distinct antibodies are produced against the HBV surface antigen and the HBV core antigen. Anti-HBc is a marker for current or past infection, whereas anti-HBs signifies sickness remission[10]. Alcohol may reduce the number of B cells, decreasing HBV antibodies by weakening B cell immunological responses[11].

The B cell response to acute HBV infection is less well understood, but HBV-specific CD4+ and CD8+ T cell-mediated responses usually become detectable as HBV replication increases exponentially[12,13]. Numerous studies have demonstrated a substantial correlation and link between acute hepatitis, CD4+ T cell response, and viral shedding[14-16].

Cytotoxic T lymphocytes (CTLs) that express particular T cell receptors are in charge of eliminating HBV-infected hepatocytes in HBV infection. CTL activation may be diminished, which thus prevents clearance of HBV-infected hepatocytes when the viral peptide/MHC class I complex display in HBV-infected hepatocytes is compromised[17]. The body's capacity to eliminate HBV may be diminished due to ethanol consumption, allowing the virus to persist and eventually produce end-stage liver disorders such as cirrhosis and hepatocellular carcinoma.

The immune response in the liver is meticulously regulated by signals from the commensal microbiota in the gut. Additionally, drinking alcohol causes the close connections between intestinal epithelial cells to weaken, allowing germs to enter the bloodstream and cause an infection[18-20].

However, hepatic metabolism of ethanol may increase the production of reactive oxygen species (ROS), principally hydrogen peroxide and superoxide anion[21].

Recent studies have shown that the ethanol metabolite acetaldehyde can suppress proteasome activity, which is essential for producing antigenic peptides for MHC class I-restricted antigen presentation and can also cause lipid peroxidation, the formation of protein adducts with 4-hydroxynonenal and malonaldehydes (oxidative stress markers). This reduces the HBV-MHC peptide class I complex exposure to CTL identification and restricts the removal of infected cells[1], which causes HBV persistence and ensuing end-stage liver disease. HBV and alcohol addiction stresses the endoplasmic reticulum (ER), and these two stresses may have additive or synergistic effects. Alcohol has been shown to synergistically cause ER stress when other substances, the environment, or a viral illness are present [22]. The increase in HBV DNA, HbsAg, and HBx protein caused by alcohol may be the mechanism by which alcohol induces ER stress in HBV infection. A strained Golgi apparatus frequently matches a stressed ER.

Further study in this area is required since the interaction of alcohol misuse and HBV infection can be harmful. Future research should examine how alcohol metabolism affects innate IFN responses and IFN-stimulated gene activation throughout the pathogenesis of HBV infection, as well as if IFN therapy might be an effective treatment option for alcoholics with HBV infection.

Additionally, there is a significant gap between the role of alcohol in controlling B cell function and its contribution to the pathogenesis of HBV, necessitating further research in this area. To fully comprehend the processes of alcohol-induced impairment and investigate the effects of ethanol on MHC class II presentation, which is mainly catalyzed by effector cells, additional studies examining the relationship between alcohol and HBV adaptive immune response are required.

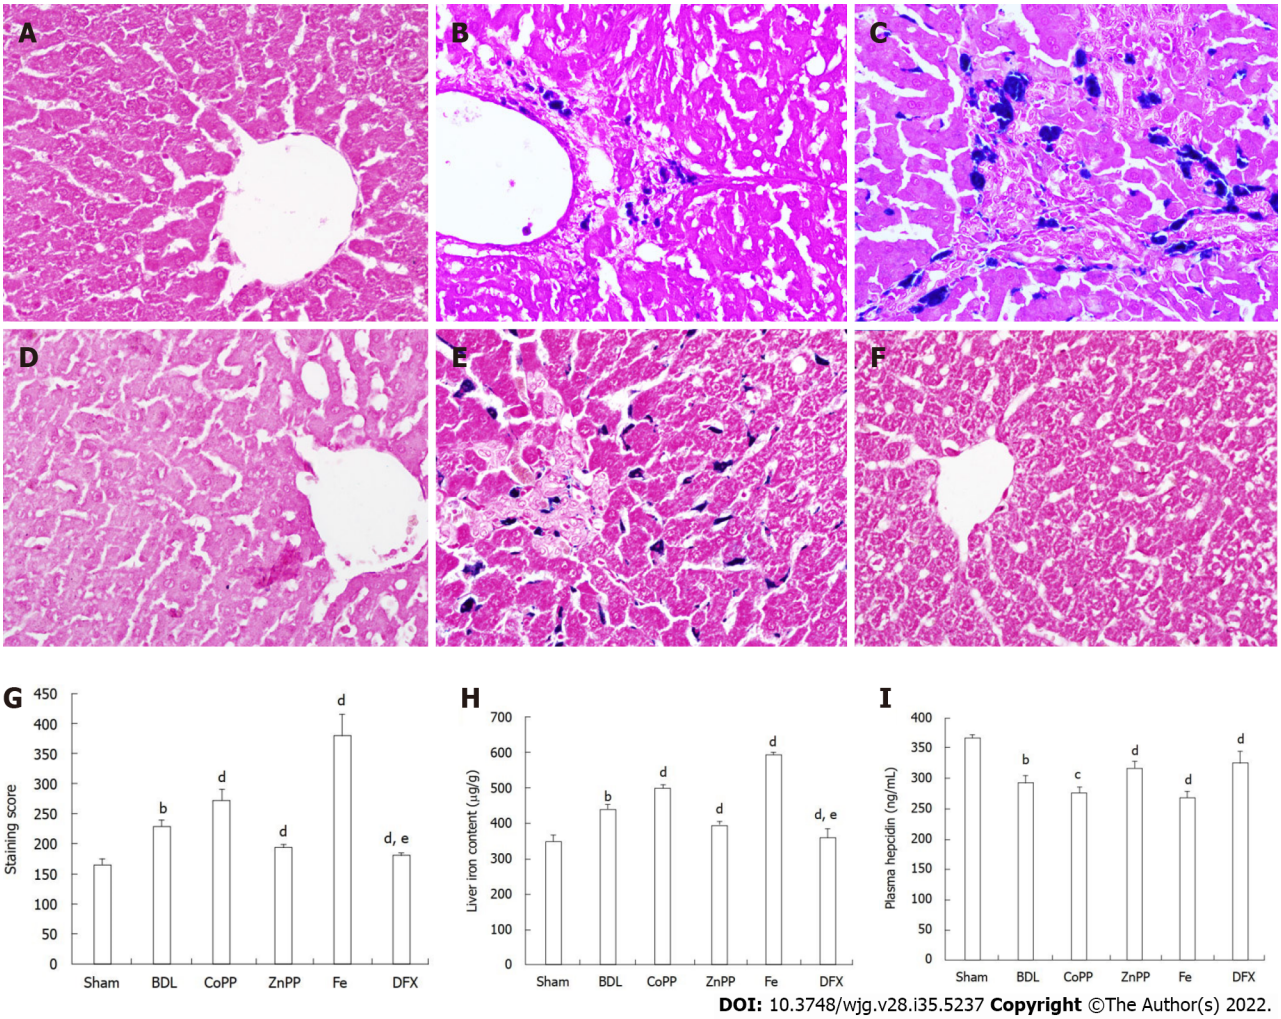
Abstract



We found a mistake in Figure 6. Panels A (Sham group) and F (DFX group) (180 degrees rotated) is same images. We have replaced the incorrect images (Panels F) with the correct Figure. This error does not change the meaning of the picture or the conclusion of the manuscript. We apologize for our unintentional mistakes, which caused great inconvenience.

Key Words: Heme oxygenase-1; Hepcidin; Iron accumulation; Oxidative stress; Portal vein pressure; Carboxyhemoglobin; Bile duct ligation

Figure 1 erl's Prussian blue staining, levels of hepcidin, serum and liver iron. A: No iron accumulated in the Sham group; B: A small amount of iron mainly accumulated on Kupffer cells in the bile duct ligation (BDL) group; C: Much more iron accumulation was found in interlobular and macrophagocytes in the cobalt protoporphyrin (CoPP) group; D and F: Almost no iron accumulation was detected in the zinc protoporphyrin (ZnPP) group and deferoxamine (DFX) group; E: Massive iron accumulation was observed in the Fe group; G and H: There were no differences in the hepatic and serum iron content of these six groups; I: Plasma hepcidin also was measured by enzyme-linked immuno sorbent assay (magnification × 400). Values are expressed as mean ± SE (n = 6). $^{b}P < 0.01$ *vs* Sham group; $^{c}P < 0.05$, $^{d}P < 0.01$ *vs* BDL group; $^{e}P < 0.05$ *vs* ZnPP group.

TO THE EDITOR

We found a mistake in Figure 6. Panels A (Sham group) and F (DFX group) (180 degrees rotated) is same images. We have replaced the incorrect images (Panels F) with the correct Figure 1. We only revised the incorrect figure, and the Manuscript NO: 75978 don't need to revise[1].

FOOTNOTES

Author contributions: Wang QM and Du JL performed the experiments, analyzed the data and wrote the manuscript; Duan ZJ and Wang QM designed the experiments; Wang QM performed the experiments, analyzed the data and wrote the manuscript; Duan ZJ and Guo SB revised the manuscript.

Conflict-of-interest statement: We declare that we have no conflict of interest.

ABOUT COVER

Editorial Board of *World Journal of Gastroenterology*, Akihiro Tamori, MD, PhD, Professor, Department of Hepatology, Osaka City University Graduate School of Medicine, Osaka 5458585, Japan. tamori-a@omu.ac.jp

AIMS AND SCOPE

The primary aim of *World Journal of Gastroenterology* (*WJG*, *World J Gastroenterol*) is to provide scholars and readers from various fields of gastroenterology and hepatology with a platform to publish high-quality basic and clinical research articles and communicate their research findings online. *WJG* mainly publishes articles reporting research results and findings obtained in the field of gastroenterology and hepatology and covering a wide range of topics including gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, gastrointestinal oncology, and pediatric gastroenterology.
